While those who believed it was not necessary to establish separate institutions to train teachers and that adequate provision could be afforded for such work in existing institutions had won a victory in the State of New York, the question was not permanently settled. The training of teachers was being considered in a broad, comprehensive manner by thoughtful educators, by State supervisory school officers, by governors and by State legislatures. The strong presentation of the subject by Walter R. Johnson of Germantown, Pa., published in 1825 and of Rev. Thomas H. Gallaudet in the same year had made a deep impression upon those who were specifically interested in the solution of the problem. Dr. Philip Lindsley in his inaugural address as president of Cumberland College, Nashville, Tenn., in 1825, stated that the teacher needed training for his work as much as a lawyer or doctor and urged the establishment of teachers' seminaries and in 1826 he appeared before the legislature of that State and advocated the establishment of such seminaries. In the same year Gov. DeWitt Clinton in his message to the legislature of New York also advocated the establishment of a seminary for teachers. In 1826 State Superintendent Spencer in a special report to the senate of New York also urged the plan of teachers' seminaries. Governor Lincoln of Massachusetts in his messages of 1826 and 1827 to the legislature of that State urged the importance of making provision for the training of teachers. The American Institute of Instruction petitioned the legislature of Massachusetts upon the same subject in 1827. Dr. George Junkin, president of Lafayette College, and Rev. Chauncey Colton, president of Bristol College, in 1833 urged upon the legislature of Pennsylvania the establishment of courses in colleges for the training of teachers and that the common schools in the town should be used as practice departments. In December 1829, 57 citizens of Rochester, N. Y., called a public meeting in that city to consider the educational needs of the times. This committee prepared a report which was adopted by the meeting and among the recommendations was one for a State seminary to train teachers. A comprehensive plan was proposed for the administration of the seminary and for the course of study. This plan proposed "a farm of 100 to 200 acres, under the direction of an intelligent but *practical* farmer, a garden and a nursery under the direction of a practical gardener and nurseryman and a mechanics' shop with a general assortment of tools, such as the miscellaneous business of the farm and garden may require." In 1836 a public meeting of citizens in Philadelphia recommended the establishment of a teachers' seminary as an independent institution containing a three years' course of study and a model school. In the same year State Superintendent Burrowes of Pennsylvania recommended an appropriation of $10,000 for the establishment of two institutions — one in the eastern part of the State and the other in the western part, for the training of teachers. In 1829 the 'Annals of Education' edited by Woodbridge published a translation from a German periodical giving an account of the Prussian seminaries for the training of teachers. Articles on and translations of Cousin's 'Report on Public Instruction in Germany' appeared between 1830 and 1835. These were published extensively by the newspapers in all parts of the country. It was out of all these discussions and proposals that the normal school idea developed in America. There were two men in Massachusetts who rendered a vital service in the successful effort to establish a normal school. These men were Mr. Charles Brooks and Mr. James G. Carter. Mr. Brooks made a careful study of the Prussian system of normal schools and in a Thanksgiving sermon in 1835 at Hingham he explained that system. He prepared three lectures on the subject which he delivered in various parts of the State. He issued a circular inviting citizens of Plymouth County to meet him to consider the subject. This invitation included every board of selectmen, every school committee and every clergyman in the county. A large audience greeted him at the courthouse. The address so impressed Ichabod Morton that he offered to contribute $1,000 for the establishment of a normal school at Plymouth. Mr. Brooks traveled over 2,000 miles, delivering addresses in the State, and contributed a continuous series of articles on the subject to the newspapers. The house of representatives invited him to address that body, and, in January 1837, he addressed that house twice. He also addressed the legislatures of Vermont, New Hampshire, Maine and New Jersey, and many cities and villages in other States. Mr. Carter, who has often been called the "Father of Normal Schools," had given a comprehensive outline of his plan for training teachers in the articles which he wrote for the Boston *Patriot* in 1824–25. He specified three essential elements in the work of a normal school. These were: (1) the development of sound scholarship; (2) a course of study upon the science and art of education; (3) a model or practice school. Nearly a century later these three points are the vital features of the normal schools of America. The people of the town of Lancaster, Mass., offered to aid him in the establishment of a school in Lancaster, but later put obstacles in his way and the project failed. In 1835 Mr. Carter was elected to the legislature, and in 1836 he was made chairman of the committee on education. He urged the legislature to establish a seminary to train teachers, but failed in his efforts. He drew the bill providing for a State Board of Education, which became a law in 1837, and in 1838 his generalship and addresses brought about the enactment of the Normal School Law. Horace Mann, who was president of the Massachusetts senate, was chosen the first secretary of the State Board of Education in 1837. Mr. Mann was a strong advocate of the establishment of State normal schools. He obtained a promise from Edmund Dwight to provide $10,000 for the establishment of institutions to train teachers if the State would appropriate an additional $10,000. Mr. Mann communicated this proposition to the legislature 12 March 1838, and on 22 March a joint committee which had considered the subject reported a resolution appropriating $10,000 to the State Board of Education for the training of teachers, but conditioned on an additional $10,000 being paid to said board to aid in the enterprise. Governor Edward Everett gave executive approval to the resolution 19 April. The State Board was not restricted in the type of institution which it should establish. The action of the legislature gave that body the right to exercise its discretion. The State Board decided to establish three normal schools. The first of these institutions was opened at Lexington on 3 July 1839, with three pupils. The school was later removed to Framingham, and of course has the distinction of being the first normal school established in America. The second school was established at Barre in the same year, but was later removed to Westfield. Mr. Cyrus Pierce was the first principal of the Lexington school. The wisdom, the energy and the diplomacy of Horace Mann and of Principal Pierce made possible the success of this initial effort to establish a normal school in the United States. The third school was established at Bridgewater in 1840. The real battle ground for the establishment of normal schools was in Massachusetts and New York. Although those who favored the organization of training classes in New York had won a temporary victory, the campaign for a separate institution devoted solely to the training of teachers was continued in that State. The work accomplished in these training classes had not proved satisfactory. State Superintendent Spencer in 1840 appointed Dr. Alonzo Potter of Union College, later Bishop Potter of Philadelphia, and Hon. D. H. Little, a committee to examine these classes. The report of Dr. Potter was adverse to the training classes and recommended the establishment of a normal school. Superintendent Spencer had long been an advocate of training teachers in the academies and did not, therefore, agree with the report of Dr. Potter. Spencer was succeeded in office by Col. Samuel Young, a warm advocate of the normal school idea. Young was supported by Governor Seward and Governor Bouck. He made speeches throughout the State in favor of organizing a normal school and called a State meeting of deputy superintendents, similar to county superintendents, at Utica in 1842. This was a notable meeting. Gen. John A. Dix, who later became Secretary of War, Secretary of State and governor of New York; Hon. John C. Spencer, Secretary of War; Horace Mann, secretary of the Massachusetts State Board of Education; Dr. George B. Emerson of Boston, and Rev. William Gallaudet of Connecticut, attended this meeting. These distinguished guests from New England came upon invitation to express their views upon the normal school idea. The convention endorsed indirectly the plan to organize a normal school. Hon. C. T. Hulburd, chairman of the assembly committee on common schools, submitted an exhaustive report to the legislature of 1844 favoring the establishment of a normal school. A measure authorizing the establishment of such a school at Albany was passed by the legislature in 1844 appropriating $10,000 annually for a period of five years. The establishment of these schools in Massachusetts and in New York did not prevent their enemies from opposing the continuation or development of such schools. Governor Dix of New York who had been friendly to the academies for many years was decidedly hostile to such schools in his message of 1874, and Governor Robinson in his messages of 1877 and 1879 made a direct attack upon normal schools and stated that they were "wholly useless." In the same year the legislature authorized an investigation of such schools. In 1840 the house of representatives of Massachusetts directed the committee on education to consider the expedience of abolishing the State Board of Education and the State normal schools. A majority of that committee prepared a report recommending that both should be abolished and presented a bill to carry out such recommendation. The measure failed to pass. It is in the face of such determined opposition as above outlined that the normal schools have arisen in America. The success of these first institutions in Massachusetts and of the Albany school made it possible to develop the system of normal schools now in existence in the United States. Others were gradually established. The New Britain school was organized in 1849, the Ypsilanti in 1852 and about 70 others previous to 1875. At the present time there are 237 public State normal schools, and before the war the number of students in attendance upon such institutions preparing to become teachers was nearly 100,000. There are also 45 private normal schools attended by nearly 6,000 pupils.

These schools are supported by State appropriations. In some States they are wholly under the supervision of the State educational authorities. In others they are only partially under such supervision and in some the State exercises practically no supervision or control whatever. The age of admission is generally 16 years. The courses of study are generally either two years or four years, depending upon the qualifications of the students when they enter. In some schools, as those of New York, the requirements for admission are graduation from a four-years' approved high school course. In such normal schools the course is two years and is devoted to professional work. In many schools a student is admitted from the elementary schools and for such students the course is generally four years. When normal schools were first organized, their courses of study included much academic instruction. The development of high schools throughout the country has resulted in decreasing the academic work in normal schools and in increasing the professional work. The present tendency is to lengthen the courses so as to cover three or four years. In New York the Board of Regents have recently authorized three-year courses in all the normal schools of that State. In many of these schools special courses such as kindergarten, drawing, music, manual training, home making, rural school and other courses are given. Practice departments or model schools are maintained in all the normal schools and in many cases the normal schools use the public schools for practice departments. These schools generally train teachers for the elementary schools, although some prepare teachers for secondary schools also. Some of the normal schools give extension courses on Saturdays and during vacation periods and some take their students into the rural schools for practice work and for demonstration.

The State College for Teachers at Albany prepares teachers for secondary schools only. The courses cover a period of four years, and the admission requirements are the completion of a four-years' approved high school course. The work in this institution is of collegiate grade and degrees are conferred upon those who complete prescribed courses. There are 800 students in this institution preparing to teach in the high schools of the State.

The Education Law in New York has required since 1895 that all teachers employed in the cities and in the villages having a population of 5,000 or more shall have graduated from a four-years' high school course and thereafter from a two-years' professional course. (Chapter 1031, Laws of 1895). In many cities of the other States a similar requirement is prescribed. Normal schools are unable to meet the demand for teachers and many cities have organized city training or city normal schools. These schools generally maintain entrance requirements and courses of study equivalent to those of the normal schools. These schools prepare teachers for the kindergarten and the elementary schools. New York maintains three of these schools, Philadelphia, two, and a school of this type is maintained in Albany, Buffalo, Rochester, Syracuse, Schenectady, Yonkers, Boston, Pittsburgh, Cincinnati and in most of the large cities of the country.

Within the last 25 years there has been a demand in all parts of the country for better trained teachers in the rural schools. About one-third of the teachers employed in these schools have had no training whatever. This demand has resulted in the establishment of agencies of various types in about one-half of the States for training teachers for rural schools. In New York the training classes maintained in high schools have supplied these teachers for years. Missouri, Vermont and several other States have organized similar classes in their high schools for training rural school teachers. In Michigan, county normal training classes have been organized, but these do not differ materially from the training classes in these other States. Wisconsin has organized not only this type of training class in her high schools, but she has also organized county training schools. These county training schools are in no way connected with other schools, but are generally maintained in separate buildings and have an independent organization. The requirements for admission to these classes vary. In New York it is high school graduation. In most States it is the completion of two years' high school work. In other States the last year of the high school course is devoted to teacher training. In other States students are admitted from the elementary schools. The course of study usually covers one year and the age of admission is from 16 to 17 years. Many of the State normal schools maintain special courses for rural teachers.

Several efforts were made to establish chairs of pedagogy or colleges of education in the universities which would take rank with the department of law, medicine or engineering. New York University established a chair of the philosophy of education for educating teachers of common schools in 1832. Thomas H. Gallaudet occupied this chair from 1832 to 1834. It seems to have been abandoned at that time. Brown University established a similar course in 1850, but discontinued it in 1855. Horace Mann included as an elective study in the regular course of Antioch College, Ohio, in 1853 the theory and practice of teaching. From 1853 to 1873 Iowa University offered courses for teachers and in 1878 opened its college of normal instruction.

On the recommendation of President Angell, Michigan University established in 1879 a "chair of the science and art of teaching" for the following purposes: "To fit university students for the higher positions in the public school service; to promote educational science; to teach the history of education and of educational doctrine; to secure to teaching the rights, prerogatives and advantages of a profession; to give a more perfect unity to the State educational system by bringing the secondary schools into closer relation with the university." A plan was proposed for giving instruction in the science and art of teaching in Columbia University in 1858, but was not carried out at that time. In 1880 the college opened certain courses for training teachers and in 1888 Teachers' College was founded and in 1889 chartered. Doctor Nicholas Murray Butler, now president of Columbia University, was the first head of this new institution and as president of Columbia is now president of Teachers' College. This college is one of the notable institutions of the world. It trains teachers, supervisors, directors and superintendents for all the higher technical and professional positions in the teaching and supervisory staffs of the city and State school systems of the country. Several thousand students are annually enrolled in this institution. All the leading universities of the country now maintain departments of education or colleges which are rapidly taking rank with the departments or colleges of law, medicine and engineering and are meeting the demand for specialists which the developing public educational systems of the country require.

Summer schools have become a strong and influential factor in the training of teachers. Harvard University was one of the pioneer institutions in America to give summer courses. Harvard has given such courses for 48 years. Martha's Vineyard Summer Institute, organized at Cottage City, Mass., in 1878 by Col. Homer Sprague, has been one of the notable institutions of this type. It was closed in 1905. In 1879 the Sunday School Assembly at Chautauqua, N. Y., organized a summer course of psychology and pedagogy which soon became an important centre for teachers. The courses for teachers was increased and the summer sessions now held at Chautauqua give several courses for teachers. After these and some other institutions had been successful in holding summer sessions the work was rapidly taken up by normal schools, colleges and universities, and the most of these important institutions in the country now hold summer sessions. About 800 summer schools were held in 1919 and the attendance upon these was approximately 300,000. The enrolment at Columbia University exceeded 10,000.

Teachers' institutes were established in this country about the same time that normal schools were organized. In 1837 Mr. Stephen R. Sweet opened a temporary school «for qualifying teachers for the winter schools» at Watertown, N. Y. Mr. Sweet contemplated holding a similar school in the late winter or early spring for the purpose of «qualifying teachers for summer schools.» These schools were in session for eight weeks. In 1842 Mr. Sweet opened one of these temporary schools in the Kingsboro Academy, New York, and he called the school the «Kingsboro Temporary Normal School.» The work which he did in this temporary school is quite similar to that which was later done in teachers' institutes. The schools organized by Mr. Sweet became known very generally as temporary schools for training teachers, or temporary normal schools. It is quite probable that Mr. Sweet obtained his idea of this temporary school from the work which was being done to train teachers in the training classes which had been organized in academies in New York.

In 1839 and 1840 Dr. Henry Barnard of Connecticut held a convention of teachers at Hartford. The purpose of these conventions was to improve the scholarship of those who were to teach and to discuss methods of presentation of subjects in the classroom. The work which was done in these conventions was also quite similar to that which was later done in teachers' institutes.

The term «teachers' institute,» however, was first used in New York in 1843. This undoubtedly was the first institute organized in America. It was held at Ithaca and was organized by J. S. Denman, the county superintendent of Tompkins County. The fame of this institute became known and others were organized in different parts of the State. Within three years teachers' institutes were organized in Massachusetts, Ohio, Rhode Island, Indiana, Michigan, New Hampshire and Vermont. It is probable that New York and Pennsylvania organized a more thorough system of institutes than was organized in other States. Institutes were abolished in New York State in 1912, and teachers' conferences under the direction of district superintendents were substituted therefor. The law defining the power of a district superintendent in connection with these conferences is as follows:

"To assemble all the teachers of his district by towns or otherwise for the purpose of conferences on courses of study, for reports of and advice and counsel in relation to discipline, school management, and other school work, and for promoting the general good of all the schools of the district."

Institutes are held in many States. In Pennsylvania and Ohio they form an important feature of the teacher training process. They are organized and managed generally by the superintendent of the supervisory district, county or city. Schools are closed for the period of the institute, which is generally two days in the cities and one week in the rural districts. Appropriations are made in some instances by the State and in others by the county to meet expenses. Fees are also paid by teachers. Attendance is usually compulsory. The method of instruction is generally the lecture system. These lectures are upon subject matter, school discipline, school organization, school management, methods of instruction and popular and inspirational themes. In some instances they depart from the primary purposes of an institute which is to improve the teaching force and take the form of community centres. In such cases they have become mass meetings instead of classrooms for instruction.

In 1895 the Paulist Fathers in New York organized an institute for the general improvement of the teachers in Catholic schools. It is called the National Catholic Teachers' Institute, and under the general management of this organization provision is made for the maintenance of local institutes in various parts of the country for the benefit of the teaching orders connected with Catholic schools.

Teachers' reading circles have exerted a strong influence in developing a professional spirit among the teaching fraternity. The first circle was probably organized in Ohio in 1883 upon the suggestion of Mrs. D. L. Williams, a teacher in that State. The circle was formulated somewhat upon the plan of the Chautauqua literary course. Many of the other States of the Central West and West have organized such circles. These circles are under the management of the State Teachers' Association or the State Education Department. In some States the circle is under the joint management of such authority. A definite course of reading is prescribed, textbooks suggested and examinations prescribed. Many States give some credit in their plan of certification to those who have done successful work in the circle. In 1915 the National Rural Teachers' Reading Circle was organized under the direction of the Bureau of Education at Washington.

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State of New York.

TEACHERS' COLLEGE, a school for the training of teachers, affiliated with Columbia University. For several years the college has maintained courses for teachers in the New York schools, and since 1897 has made these courses an integral part of the regular college courses. The continual increase in the number of teachers taking these courses led to the organization of an extension department in 1903 which includes the entire university system. The university accepts courses in education as part of the requirement for the degrees of A.B., A.M. and Ph.D. The college diploma is conferred upon students who have successfully completed some one of the general courses, and a departmental diploma upon those who have fitted themselves for particular branches of school work. Under-graduate students of Columbia and Barnard colleges may obtain the diploma of Teachers' College when they receive the degree of bachelor of arts.

These are the undergraduate courses: Secondary course leading to the degree of A.B., and the college diploma; general course leading to the college diploma in elementary teaching; general course leading to the college diploma in kindergarten teaching. Then there are several courses leading to the college diploma in art, domestic art, domestic science and manual training. Candidates for the first of these courses must be either college graduates or candidates for the degree of A.B., in Columbia University. There is a combined course of study prescribed for the degree of A.B., in Columbia University and the diploma of Teachers' College.

TEACHERS' EMPLOYMENT AGENCIES. Teachers' employment agencies are of two classes, viz.: (1) Those that carry on the work in a commercial way and collect fees from teachers for the service rendered in obtaining positions; (2) those managed by institutions of learning, as colleges and normal schools, that obtain positions for their own students or graduates without payment other than general tuition fees. Commercial agencies have existed since 1855 but did not become a prominent factor in the employment of teachers prior to 1880. At the present time there are agencies in most of the prominent cities of the country, some doing a local business, others being national in the scope of their activity. The methods employed by all commercial agencies are quite similar. A teacher enrolls by paying the required fee; making a written statement of his age, education, experience and general qualifications, and giving references. The agency on receipt of the statement writes to the references for further data. When a call for a teacher is received by the agency, two or three of the enrolled teachers best qualified for the place are asked to make application, and the strongest candidate is usually recommended by the agency. If the agency's candidate is elected to the position he usually pays the agency a fee of 5 per cent of the first year's salary. A well-managed agency becomes an important factor in placing teachers in the positions for which they are best qualified. Probably the most valuable service rendered by agencies, however, is the proper placing of teachers with special and unusual qualifications.

HORATIO M. POLLOCK.

TEACHERS' INSTITUTES. See TEACHERS, PROFESSIONAL TRAINING OF.

TEACHING METHODS AND SYSTEMS. Teaching, or the imparting of knowledge by the means of lessons or example, has been a matter of study, of discussion, of acceptance or rejection of methods and plans through the entire history of educational science. Talleyrand said that methods are the masters of teachers — "les methodes sont les maitres des maitres." The present trend of educational workers is to make method an aid to instruction. Two general basic schemes for the acquisition of knowledge have long prevailed. The inductive lesson is used in early childhood where associations are made into classes, groups or families of things which are alike in use, structure and appearances. The child easily gains a *percept* of a chair when shown a piece of simple furniture with four legs, a seat and a back. He may find in process of time that various articles appear in its construction, wood, grass, wire, cloth and different shapes have been evolved — low, broad, deep — but from his early percept he is able to classify all as chairs. On the other hand, a thing he cannot understand, he cannot use, he cannot classify, is useless to him. "When a general idea or principle, which applies to several concrete or individual instances so as to explain or give them meaning, is obtained through the study of concrete or individual instances, the process of thought is inductive." Deduction is the opposite of induction; instead of forming one's own conclusions from a series of facts, the student here employs those principles already reached out of his own experience or that established by others. The teacher employs the deductive method when he asks pupils to answer questions, to solve problems, to master situations by referring to rules, laws and axioms; the child uses it when he reduces a fraction to its lowest terms; by applying the rule that a fraction may be reduced to its lowest terms by dividing both numerator and denominator by their common factors until no common factor remains. In the process of deduction, rules which apply may not always readily appear. Different ones may be tried, schemes searched out, tried, rejected — "guiding principles must sometimes be sought long and earnestly before they are found."

The specific methods of the class period divide themselves into three fundamentals, testing, drilling, teaching. Testing the pupils' knowledge provides the instructor a starting point, showing the achievement of the class and its progress, and giving opportunity for classification and adjustment. Skilful tests, oral or written, help the teacher to individualize pupils' needs in such a way as to enable her not only to offer definite instruction to the individual but class instruction as well. Careful observation and a record of mistakes show the direction and nature of the pupils' errors. This test of knowledge lends itself admirably to schemes for review in that proper emphasis may be placed on the needs of the section.

Drilling in the use of the tools of the trade is as essential to the student as it is to the laborer. "Habit," James tells us, "is the result of oft-repeated action in the same line." There are certain fundamentals in educational procedure which must be acquired in such a way as to be habitual. The formation of letters in writing, the acquisition of the multiplication table, the ability to recognize easily a noun or a verb, the familiarity with the paradigms and conjugations of a foreign language, ready application of axioms and laws, all results from oft-repeated action in the same line. They are reached by drill — constant, steady, repeated drill. Instruction without drill leads to chaos, loss of time, inefficiency, educational disaster. Drill should be constant. The multiplication table should be repeated so often that reaction is instant. Methods employed may be flash cards, group recital, simple problems, etc. Drill should be accurate. James again points out that to break an undesirable habit it was necessary never to lapse into it. This implies correct copy, clearly presented and easy of imitation, given under such environment as will lead to skill.

Progress in the career of the student is made by the addition of new knowledge. Knowledge may be imparted by teaching students new facts, varying in method from brief comment to the formal lecture. Comments and explanations are part of most recitations; the danger lies in the fact that the teacher consumes too much time and loses sight of the fact that one large way for a child to learn is to tell what he knows to someone else. The teacher using this method should never lose sight of the fact that children learn to write by writing — to do by doing, to acquire ability in expression and understanding of fact by relating their experience to someone else. New knowledge may be obtained by notetaking, from dictation, from jotting down of facts, from individual research. New knowledge is acquired by illustration and object teaching, by dramatization in literature, by the use of apparatus in physical science, by pictures and maps in history and geographical science, by stimulation of thought in mathematics.

The question and answer method is employed largely in aiding students to formulate their knowledge, to aid them in their expression, to ripen their judgment, and to form correct conclusions. This method is being introduced with the greatest success in language teaching, where spaking practice is essential if the pupil is to acquire anything more than a mere bowing acquaintance with the language under study. Questions and answers are planned so that the teacher speaks very little and the pupils a great deal. The question should be correct in form, definite in meaning, framed in simple terms within the comprehension and adapted to the knowledge of the pupil, stimulating to the thought, addressed to the class and framed so as to draw forth a complete expression. The question and answer method should lead naturally into the topical method which encourages pupils in freedom of expression and gives opportunity as strength comes to discuss topics and make reports on assigned subjects calling for mastery of the subject and independence of thought. This develops skill in organization of ideas, provides powers of expression and furnishes practice in alertness, systematic thinking, and establishes confidence in one's self. This method can be successfully used in the development of all new topics where the new matter is to be connected to the old in the mind of the learner. It may be a half-formed conversation between teacher and class, directed by the teacher and commanding such full and free expression as will fulfil the mastery and development of the topic.

Lesson plans carefully considered and clearly formulated are of great practical value. In the daily plan the teacher considers the subject matter of the review and advance lesson and the class procedure. The daily plan finds its place in the term scheme and the term scheme is a unit of the syllabus for the year. This daily planning prevents a haphazard course and provides for regular orderly progress. A well-organized plan involves a definite aim, bringing to its aid the proper method, which economizes time and effort.

Results obtained by supervised study have become so successful that a brief survey of this method should arouse the interest of school men in such a way as to lead to its wide adoption. By means of it the teacher is enabled to present the subject matter in such a clear, concise way that every pupil is afforded an adequate opportunity to understand and to master the various daily problems of the subject. It is an elaborate and complete assignment of the next lesson, made so clear that the details present themselves so plainly and logically that all have a maximum opportunity to learn the lesson. It has the advantage of giving aid when aid is most needed, of economizing time and effort and forming correct habits of attack and application of principles. With the modern trend of social conditions in the city, crowded part time and frequent abundant attraction, some method and supervision should reach into the home to grip parent and student alike. Frequent reports of progress should go to parents; specific direction given in study; students held to the definite performance of certain tasks and an effort made to train in such economy of time and effort as to make school work a delight; this can be accomplished by carefully scheduled program at home and at school.

JOHN MANVILLE SAYLES,
Professor of Education, State College for Teachers, Albany, N. Y.

TEACHING OF THE TWELVE APOSTLES, a part of the Apostolic Constitutions (q.v.) enunciating principles of Christian faith and practice. It was first (1873) discovered by Bryennius, metropolitan of Nicomedia, in a manuscript of the 11th century and was published in 1875; since which it has been the occasion of much discussion. Consult Harnack, 'Texte und Untersuchungen zur Altchristlichen Literatur' (1886); Schaff, 'The Teaching of the Twelve Apostles' (1885).

TEAK, a large, verbenaceous forest tree (*Tectona grandis*), native to southern Asia and to the Malayan Islands, which furnishes the valuable lumber known as teak. The heartwood is golden-brown when first cut, but when aged darkens to the tint of black walnut. It is very durable, examples in house-timbers having already survived for hundreds of years, is straight in grain and easily worked. It takes a high polish and if properly seasoned will not warp or split. Teak is used for house-building, furniture and wood-carving and is one of the most valuable woods for shipbuilding, especially for decking and for backing the metal plates of iron-clads, since it contains a resinous oil, which prevents it from corroding iron; it is also in demand for car-wheels, gun-carriages, railway ties and engineering works. Although the natural supply of teak, throughout its range was great, as it occurred in mixed forests, most luxuriantly in Burma and adjacent regions, it was rapidly disappearing on account of the unceasing demand and lack of replanting. Great Britain has checked this waste by efficient protection and forest-administration in its Indian and Burmese dominions. The timber is mostly consumed in India. The tree is not usually found in pure forests, but mixed with bamboo, which it overtops and which seems necessary for its growth. It requires a light soil with good sub-drainage. The leaves, which are nearly 10 inches long and resemble those of the tobacco, are somewhat drooping and coriaceous and appear as soon as the rainy season opens. They yield a red dye. Teak trees may easily be distinguished for some time during the rains, by their broad terminal panicles of flowers, which are small, white and fragrant, on slender branchlets. The seeds are oily, in a hard nut covered with a felt of matted hairs and further enclosed in an enlarged membranous calyx. These feathery panicles render the tree again conspicuous during the dry season, when it is leafless. The seeds are plentiful and would soon restore the forests, were it not for the forest-fires, raging just about the time when the nuts are falling. Many of the seeds, however, are washed down by the first heavy rains of the monsoon, into the valleys, where the trees are principally found. Although many logs of teak have cracks or hollows running up through the centre from the butt, that are probably caused by the fires, the market value of the teak, which is greater than that of any other wood except mahogany, depends upon the regular cylindrical shape of the log. This should be without knots or other irregularities and great care is taken in the plantations to rid the trees of creepers which, by their clinging habit, distort the trunks. Teak trees may reach a height of from 100 to 150 feet and a circumference of from 20 to 25 feet; to attain the latter girth, a tree grown under natural conditions must have lived at least 100 years. In the plantations growth is quicker. To get these great logs out of the Burmese forests to the coast it is necessary to raft them down the rivers, but, since green teak will not float and if felled to dry on the ground, the result is uneven seasoning and the lumber still does not float readily, the old Burmese method of drying the wood when standing is still the best available. This is done by girding, a broad annual strip of bark and sapwood is taken off, completely encircling the trunk and the cuts striking down quite into the heart wood. The supply of sap of the upper portion of the trees is of course entirely cut off and the tree dies above the girdle. It stands in that condition for two or three years, according to its size, seasoning evenly and completely, being exposed to the weather on all sides. The logs will then float easily and are sent down the water-ways, sometimes one by one, until they reach a river large enough for them to be formed into a raft. When they reach the lumber yards, elephants are often employed to move the teak about and stack up the logs.

TEAL, a small fresh-water wild duck of the genus *Querquedula*, *Nettion*, or some closely related genus, many species of which occur in various parts of the world. The three North American species are the blue-winged (*Q. discors*), the cinnamon (*Q. cyanoptera*) and the green-winged (*Nettion carolinensis*). The first and last are of common occurrence all over the Continent and breed in suitable places throughout the northern United States and Canada. The males are noted for their brilliance of plumage, as compared with the sober dress of the little females; hence almost any small and gaudy duck is likely to be called a teal in the books of unscientific sportsmen and travelers.

TEARS. See EYE.

TEARS OF SAINT LAWRENCE. See SHOOTING STARS.

TEASDALE, Sara (MRS E. B. FILSINGER), American poetess: b. Saint Louis, Mo., 8 Aug. 1884. She received her education at private schools in Saint Louis and spent several years in European travel. Her published works, marked by a charming lyric quality and a fine rythmic feeling, include 'Sonnets to Duse and Other Poems' (1907); 'Helen of Troy and Other Poems' (1911); 'River to the Sea' (1915); 'Love Songs' (1917).

TEASEL, any member of the genus *Dipsacus*, botanically not far removed from the campanulus. They are tall, rough, hairy or prickly herbs, the most important species being the fuller's teasel (*D. fullonum*), a stout biennial, with sessile, lanceolate to pinnatifid leaves, which are opposite and often connate. The pale lilac, tubular flowers are gathered into dense, terminal, oblong heads, subtended by an involucre and many-bracted. The flowers open, a few at a time, in horizontal zones. Both bracts and involucre are rigid and tipped with spines, the latter being hooked and remaining in fruit. They are then brown and thickly set, radiating from every side of the head, become cylindrical and are very suitable for raising the nap upon woolen cloths or "teazing" them. The heads are fixed for this purpose around the circumference of a broad wheel or on flat cards. The teasel is cultivated and is suspected to be only a variety of the wild *D. sylvestris*, which differs chiefly in the spines of the bracts, which are straight.

TECHE (tĕsh) **BAYOU**, in the southern part of Louisiana, a small tide-water channel, west of Grand Lake, which flows generally south by east into Atchafalaya Bay. It was once the outlet or the main channel, by which the Red River discharged its waters into the Gulf of Mexico. The land through which the Bayou Teche now flows has been formed from the sediment brought down by the rivers and by the overflows. It contains some of the richest soils of the State. On it are raised large quantities of cotton, sugarcane and rice. The Teche is navigable to Saint Martinsville, about 100 miles, and above that point for small boats, when there is high water.

TECHNICAL EDUCATION. See EDUCATION, TECHNICAL.

TECHNOLOGY, Schools of. Schools of technology in the United States are of comparatively recent date. The earliest was the Rensselaer Polytechnic Institute of Troy, N. Y. (q.v.), founded in 1824; then followed the Massachusetts Institute of Technology, Boston, Mass., 1861; the Worcester Polytechnic Institute, Worcester, Mass., 1868; Lehigh University, 1866; Stevens Institute of Technology, 1871, and the Case School of Applied Science, in 1880 (qq.v.). From that time on the number increased rapidly and in 1900 there were 43 institutions in the United States classed as schools of the technology by the Commissioner of Education. Among these are privately-endowed institutions, like the Stevens Institute of Technology; State institutions, like the Sibley College of Cornell University; scientific departments of older universities and schools partly industrial, like the Pratt and the Armour institutes.

Technical schools in Germany have long been graded as (1) elementary industrial schools; (2) secondary industrial schools; (3) higher polytechnic institutes. The tendency in the United States is along the same lines, providing all needed forms of education, including more or less technical training, in connection with universities, colleges and schools already existing. Many of the State colleges are affording in one institution the whole range of pure and applied science. The requirements for entrance to most of the technical schools of the United States are algebra, plane geometry, English literature, the history of the United States, French and a knowledge of the common English branches. Some schools require solid geometry, plane trigonometry, elementary physics and chemistry and some require Latin in addition to the above. The general courses of study pursued are civil engineering, mechanical engineering, electrical engineering, railway engineering, mining engineering, chemical engineering, sanitary engineering, architecture, pharmacy and chemistry. The length of each course is usually four years. Marine engineering forms an additional course in the University of Maine, University of Michigan, Cornell, Columbia and New York universities. Naval architecture is offered as a course in the Massachusetts Institute of Technology, in Columbia, New York and Cornell universities and in the University of Michigan, etc. Schools of forestry are connected with Yale, Michigan, Cornell and Syracuse universities; with the University of Nebraska and the Ohio State University. Horticulture is taught in Harvard University. Ohio State University, Iowa State College, University of Nebraska, etc. Domestic art, domestic science and the fine arts, in addition to steam and machine design and applied electricity are given prominence in Pratt Institute, Brooklyn, N. Y. At the Armour Institute, Chicago Ill., typewriting, music and domestic art are added to the usual engineering courses. The universities and colleges of the United States have so universally added technological courses to their systems of instruction that it is no longer possible to separate the technological schools. The United States Commissioner of Education has ceased to classify them separately and only a few are known as distinctly polytechnic institutions.

Schools of Agriculture and Mechanic Arts.— The pioneers of technical education in the United States were privately endowed schools of technology, but technical education received its greatest impulse by the «Land Grant Act» and «Morrill Bill» of Congress from the year 1862 to 1890. (See COLLEGES, LAND GRANTS). Under these acts the Federal government has given more than 13,000,000 acres of public lands for the establishment and maintenance of colleges of agriculture and mechanic arts. The name has not always been retained as acts of State legislatures and private benefactions and other causes have led to a change or to an affiliation with State institutions. But as a result, at least one such institution has been established and is now in operation in each State and Territory of the United States, except Alaska. The International Typographical Union has established a large school of typography at Indianapolis and the International Printing Pressmen and Assistant's Union, a school of presswork, near Rogersville, Tenn. Other trade unions are initiating the method and in this way many very important trade schools are developing. Of the institutions that have been organized under these acts, 51 are colleges of agriculture and mechanic arts, having in 1917 over 5,000 instructors; 54,931 white men students; 14,460 white women students, and 4,405 colored men and 6,208 colored women students. Separate institutions for colored students have been established in most southern States. The courses of study pursued in these schools are agriculture, all the branches of engineering, textile engineering (in North Carolina and Mississippi); forestry (in Michigan), and horticulture (in Washington and Virginia). Clemson Agricultural College, in South Carolina, has a full equipment of cotton machinery for illustrating the manufacture of yarn and woven fabrics. Requirements for entrance differ very greatly in different States. (For detailed information regarding technical education in the United States, see EDUCATION, ENGINEERING; MANUAL TRAINING; TECHNICAL EDUCATION; TRADE SCHOOLS). Consult also 'Annual Report of the United States Commissioner of Education'; 'Report of the United States Commissioner of Labor on Trade and Technical Education'; 'Annual Reports of the Society of Mechanical Engineers.'

TECTONIC GEOLOGY. See GEOLOGY — *Structural Geology.*

TECUMSEH, tĕ-kŭm'sē, Shawnee chief: b. near Springfield, Ohio, about 1768; d. 5 Oct.

1813. About 1805 he formed the design of uniting the tribes of western Indians against the whites. He claimed that the land-treaties between individual tribes and the settlers were void, inasmuch as the land was the common property of all the tribes and could be alienated only by unanimous assent. British agents fanned the dissatisfaction, which was likewise increased by the ejectment of Indians by speculators. Gen. W. H. Harrison (q.v.) warned him to discontinue his scheme and held a parley with him without result near Vincennes, Ind. He was aided in his plans by a brother, Tenskwatawa, who was reverenced by the Indians as a prophet. Tenskwatawa directed the attack at Tippecanoe (q.v.) 4 Nov. 1811, though he remained on a hill during its progress. Tecumseh was not present. He incited the Creeks in their futile revolt, joined the British, was made a brigadier-general, led 2,000 Indians at the siege of Fort Meigs, commanded the right wing at the Thames and was killed there. He possessed great qualities of leadership. Consult Drake, 'Life of Tecumseh.'

TECUMSEH, Mich., village in Lenawee County, on the Raisin River and on the Lake Shore and Michigan Southern and the Chicago, Jackson and Missouri railroads, about 35 miles northwest of Toledo and nine miles northeast of Adrian. It is in an agricultural region noted for its fruit, especially peaches. The chief manufactures are flour, furniture, wagons, carriages, brick, tile, paper, lumber, foundry and machine-shop products and dairy products. It has a high school, graded schools and a public library. The two State banks have a combined capital of $70,000. Pop. about 2,332.

TECUMSEH, Neb., city, county-seat of Johnson County, on the Big Nemaha River and on the Burlington and Missouri River Railroad, about 45 miles southeast of Lincoln and 60 miles south of Omaha. It is in a rich agricultural region. It is the commercial centre of a large portion of the county; the chief shipments are grain, livestock, vegetables and fruit. The city has eight churches, a high school, four public school buildings and a public library. There are two banks, a national and a State, with a combined capital of $100,000. Pop. 1,748.

TEES, tēz, a river in northern England, which rises east of Cross Fell forming along its entire course the boundary between Durham and the North Riding of Yorkshire, passes by Barnard Castle, becomes navigable between Dalton and Yarm, and, after flowing a distance of 70 miles, empties into the North Sea at Middleborough, forming the Tees Bay.

TEETH, hard structures developed in the mouth and adjacent parts of vertebrated animals and concerned in the obtaining and mastication of food and secondarily in a variety of other functions. "They present," says Owen, "many varieties as to number, size, form, structure, position and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding or grinding the food. In some species they are modified to serve as formidable weapons of offense and defense; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal and are, therefore, highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals." For further information as to the development of the varied forms of teeth in relation to use, see KINETOGENESIS.

Teeth are a production of skin, and homologous with the scales of fishes, and various other hardenings of the surface; in some of the fishes and lower invertebrates there is an insensible gradation from one to the other. In one large class, the birds (q.v.), they are now wholly absent, their functions being performed by the horny covering of the jaws (bill) or by the gizzard, or both; but in the earliest extinct birds they were present in both jaws and had a close resemblance to those of reptiles. Turtles, also, and many amphibians are toothless; and in some of the inferior mammals teeth are present only as embryonic rudiments, which disappear before or soon after birth. Many small, sharp hardened structures in the worms, echinoderms, mollusks, insects and other invertebrate animals, which are more or less concerned in biting, are popularly spoken of as teeth, but, strictly speaking, should be otherwise designated. In general the present article will treat of the teeth as found in the mouth of man and the higher vertebrates, where they arise from the gum or covering of the jaw-bones, each rooted in a socket or sockets of its own formed by the alveolar processes of the maxillary bone.

Structure of Teeth.— A tooth begins, early in embryonic life, by the development from the mucous membrane of the gum of a group of modified epithelial cells which dip down into the substance of the gum and form an organ, the germ of the tooth, which will furnish the enamel needed. Below that there next develops a mass of special tissue which takes the shape of the future tooth. In due time it begins to calcify upon the surface, and this process proceeds, downward and inward, until all of the substance of the papilla has been changed into solid dentine except a central cavity which remains filled with growing tissue (pulp), supplied with blood and nerves. This dentine is the principal constituent of the greater number of teeth, and is seen to best advantage in the massive ivory of the tusks of the elephant and walrus, and consists of an organic basis richly impregnated with mineral (chiefly phosphate of lime) disposed in the form of minute tubes, each open at its inner end and occupied by a fibril of living nutritive tissue connected with the pulp. In the ordinary case these dentinal tubes radiate from the pulp cavity in a slightly wavy course to the outer surface. "The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli also receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient though languid vitality of the system. The delicate nerve branches on the pulp's surface convey sensations of impressions affecting the dentine — every one has experienced the acute sensations when decay has affected the dentine or when mechanical or chemical stimuli have «set the teeth on edge.» When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by «vascular canals» into the substance of the tissue. Such dentine is called vaso-dentine and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. When the cellular basis is arranged in concentric layers around the vascular canals, and contains «radiated cells,» like those of bone, this is termed osteo-dentine, and resembles true bone very closely.

While this dentine is developing the tissue around the tooth-germ is forming a capsule or wall called the tooth-sac, the inner layer of which ossifies, forming a bony coat, the crusta petrosa or cement, on the external surface of the tooth. It is often found only as a thin layer on the surface of the root, which develops downward as the tooth grows, forcing the tooth upward, through and above the gum; but sometimes, as in the molar teeth of the horse, elephant and mastodon, it is a structure which plays a very important part covering and filling in the interstices between the folds of the enamel. It is much like true bone in its constitution. Meanwhile the epithelial cells of the superficial layer of the skin over the tooth-germ are depositing upon the dentine of the upper part of the tooth, which is to be exposed, an extremely hard bluish white, translucent, protective layer, composed of about 96 per cent of mineral matter, called the enamel, and destined to resist the wear to which teeth are subjected in their work. It is the hardest organic substance known.

Teeth are of various forms, but reducible to two types, of which the simpler and more primitive is represented on a large scale by the tusk (incisor) of the elephant or beaver, in which the pulp retains its conical form and activity, or is «persistent,» and continues to supply dentine at the base of the tooth, which thus grows throughout life to compensate for its wearing away at the tip. These teeth are said to be «rootless.» The other type, exemplified in man, is called «rooted,» and in this case, after the «crown,» or exposed part of the tooth has been fully formed, the pulp within the «neck,» or that part just beneath the surface of the gum, begins to fill with dentine, and to form a downward growing pointed mass, the «root» or «fang,» which at last is solid except for a narrow central canal in which the contracted remainder of the pulp persists, largely supplied with nervous filaments from the pair of cranial nerves. Various intermediate conditions between these two types exist.

In form teeth vary from a simple spine-like or conical shape, to many chisel-like or massive and complicated forms, all of which are determined in the germ, and before the tooth makes its appearance above the gum or is «cut,» which in mammals never normally occurs before birth. This appearance in some, as the seals, may take place all at once; but in most cases occurs at intervals, the front teeth usually showing before the back ones, which sometimes are not cut (for example, the «wisdom teeth» in man) until several years later. In man and higher mammals two sets of teeth are developed: the early, *milk*, or *deciduous* teeth, and the permanent set. Such forms are, therefore, named *diphyodont;* while those in which one set only is developed are named *monophyodont.* When more than one set occurs those of the second are developed in precisely the same place and manner as the first, except as to certain details of the enamel germs. The milk or temporary teeth are gradually displaced from below by the upward growth of the permanent teeth, the fangs of the milk teeth being absorbed, and the latter falling out as their successors are more fully developed. This arrangement is adaptive to the growth of the animal's jaws, among other advantages. The milk set in man consists of 20 teeth; and numbers four incisors, two canines, and four premolars or bicuspids in each jaw. The permanent set includes, in addition to the foregoing teeth, six true molars in each jaw — the latter being thus unrepresented in the milk set. The milk-teeth begin to appear about the sixth month of life, and continue to be developed till about the end of the second year. The permanent teeth begin to appear about the sixth year of life, the first being the front molar of each side, while the last molars or wisdom-teeth are not usually developed until adult life has been attained. Man has thus 32 teeth in his permanent set — 16 in each jaw.

The incisors or front teeth are single-fanged, and have chisel-shaped crowns, suitable for biting. To the incisors succeeds on each side the single canine tooth, which has also a single root and a more pointed crown. This is a piercing, holding or tearing instrument, most highly developed in the dog (*canis*) and other beasts of prey. The fourth and fifth teeth, premolars or bicuspids, derive their latter name from the presence of two pointed cusps or tubercles on their crowns. The fourth tooth, or first premolar, shows a tendency to become double-fanged, while the fifth, or second premolar, is double rooted, and the crowns of both are broad. The molars — three on each side of each jaw — have the broadest crowns of all, and possess each two or three fangs, each growing from a separate pulp and rooted in its own socket. The sixth upper molar is the largest tooth of the whole set. These massive teeth crush or grind the food, and vary greatly in the character of the surface of the crown according to the nature of the food. Thus in the insectivorous mammals, as the shrews, the crowns are covered with numerous sharp edges and points which, working against one another, like shears, as the lower and upper molars are closed together in chewing, cut up the hard shells of insects into little pieces fit for swallowing and digestion. Such a type of crown is called *secodont.* Another type, the *bunodont,* is seen in the molars of omnivorous animals, such as man, monkeys, pigs, etc., where the surface of the crown is broad, flattened, and elevated into rounded tubercles. In the herbivores the crown is crossed by parallel ridges, which are greatly varied and complicated, up to the huge molars ot the elephant family; in these cases the ridges are formed by partition-like infoldings of the enamel and the interspaces are filled with cement. When such a tooth wears away at the surface, the different density of the layers of the substances of which it is composed — enamel, cement and dentine — causes them to wear unequally, the hard enamel ridges projecting beyond the others and thus, as Flower says, "giving rise to a grinding surface of great mechanical advantage." The patterns of these ridges are characteristic of species; and by the changes of pattern which occur as they wear down, the age of the animal may often be closely estimated, a fact constantly utilized in the case of horses. This infolding of the enamel reached its highest complication in the curious "labyrinthodont" teeth of the ancient stegocephalian reptiles.

The dentition of any animal is expressed by a *dental formula*. That of man runs thus:

$$\text{I.}\frac{2-2}{2-2}:\text{C}\frac{1-1}{1-1}:\text{P.M}\frac{2-2}{2-2}:\text{M}\frac{3-3}{3-3}=32.$$

This means that the incisors (I.) number two on each side of each jaw — the numbers *above* the horizontal line corresponding to the teeth in the upper jaw, those below the line indicating those of the lower jaw; while the further subdivision of the teeth above and below the line is meant to indicate the numbers in each side of each jaw respectively. The other signs and numbers, therefore, read that the canines (C.), premolars (P.M.) and molars (M.) number two, four and six in each jaw; making a total of 32 teeth. Similarly the dental formula of a ruminant (q.v.) such as the sheep would run thus:

$$\text{I.}\frac{0-0}{3-3}:\text{C}\frac{0-0}{1-1}:\text{P.M}\frac{3-3}{3-3}:\text{M}\frac{3-3}{3-3}=32.$$

It is presumed by this notation that each tooth has its strict homologue, in all kinds of mammals at least; and if any are missing their character or name may be accurately defined. This theory encounters difficulties, for example, in comparing the dentition of marsupials with the higher mammals; but it serves conveniently in the description of ordinary animals.

Among the lower vertebrates teeth appear in great variety, as to number, form and functional modification. Those of fishes and fish-eating animals as the dolphins, are simple sharp-curved cones, useful in seizing and holding their slippery prey, which is usually swallowed whole. In fishes and most reptiles the teeth are usually attached by ligaments, and shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives. In sharks the teeth are placed in a common groove, and row after row may be developed in fishes as the front and older teeth are worn away or destroyed. Fishes and amphibians may have teeth in two rows in each jaw, and also on the back part of the mouth and on the skull or even on the tongue, gillarches (*Perch*), pharyngeal bones, sides of the mouth and in other situations. The lower vertebrates have the teeth fastened in various ways to the jaws, and not implanted in sockets as in man. In reptiles, as a general rule, the base of the tooth is anchylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth germs being apparently unlimited in this class. The teeth of crocodiles grow successively, a new one arising inside the pulp-cavity of the old one and displacing it. In many lizards teeth become anchylosed to the summit of the jaw (acrodont dentition), or to the outer side of the bone (pleurodont). Reptilian teeth sometimes undergo great modifications, as in the hinged poison-fangs of vipers and rattlesnakes (qq.v.). Extraordinary modifications among mammals are seen in the horny pseudo-teeth of the duck-bill; the entire absence of teeth of some edentates; the transitory teeth of the baleen whales succeeded by whalebone; the "horn" of the narwhal, the tusks of the elephant, walrus, wild boar, etc., each in relation to peculiar habits.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a physiological argument for the mixed diet which general custom has decided to be most natural to our species.

Diseases of the Teeth.— Decay (caries) is by far the most common of the diseases which affect the teeth, and consist in a gradual and progressive disintegration of the tooth substance. Among the chief predisposing causes are hereditary defects of quality; imperfect calcification; pits and grooves in the enamel; overcrowding of the teeth, facilitating the retention of particles of food between them; constitutional disorders affecting the digestive organs and debilitating causes generally. Dental caries consists in the decalcification of the teeth by lactic acid generated in the mouth by fermentation due to micro-organisms. Decay is rarely met with on smooth surfaces exposed to the friction of food and the direct washings of the saliva. It usually begins in some pit or groove in the enamel or between the teeth, such points forming a lodgment for the development of the organisms. Once the enamel has been penetrated the decay proceeds more rapidly, spreading laterally beneath the as yet healthy enamel and toward the pulp. The more dense the structure of the tooth the more directly does the decay penetrate in the direction of the pulp, though its process is not so rapid and its tendency to spread is less. Caries is most common in early life, by far the greater number of cavities making their appearance between the ages of 6 and 18. The treatment of caries can only be undertaken by the dentist, and varies with the extent and character of the disease.

Periostitis and Alveolar Abscess.— Periostitis is an inflammation of the membrane (periosteum) which covers the roots of the teeth and lines their sockets. By far the most common cause is the presence of a dead nerve, the poisonous products of which cause violent inflammation at the end of the root. When acute periostitis has fairly set in, it and its usual accompaniment, alveolar abscess, are perhaps the most painful affections to which the teeth are subject.

Alveolar abscess may be defined as a suppuration around the root or roots of a tooth. Its causes are those of periostitis which precedes it, the continuous and throbbing nature of the pain indicating the formation of matter (pus) within the surrounding bone. The face, with the glands about the neck, swell, and the glands exhibit tenderness on touch. The pent-up pus forces its way through the bone to reach the surface of the gum at the point of least resistance, which is most often opposite the end of the root or roots (this is popularly known as a «gum boil»). With the escape of pus there is a marked abatement in the intensity of the pain, which generally disappears in a few hours and the swelling in a few days.

Impaction and Difficult Eruption.— It is not uncommon to find certain of the temporary teeth firmly set in the adult jaw, and occupying the place of the permanent ones. In such cases the permanent tooth is usually present in the body of the jaw, but it has been retarded in eruption by being too deeply embedded in the bone. Impaction may also be due to abnormal direction of growth. Such teeth may appear late in life after all the others are lost, and the bone overlying them has been absorbed and so exposed them. When these cases do occur they are responsible for the popular but incorrect idea of a third set of teeth. An impacted tooth seldom gives rise to any trouble, unless it be an upper or lower wisdom, particularly the latter. The cutting of these teeth is sometimes accompanied by distressing symptoms, which may be protracted for months or years, unless they are removed by extraction of the tooth. This condition is usually due to imperfect development of the jaw. The tooth usually takes its natural vertical direction, but, being wedged in between the tooth in front and the ascending portion of the jaw behind, only a small portion of the crown is visible. The overlying gum is apt to be bruised by the occlusion of the opposing tooth in the upper jaw; inflammation is thereupon set up, and being maintained by biting may extend to the surrounding parts. Swallowing becomes painful and the motion of the jaws restricted. When it is evident that there is insufficient accommodation in the jaw for the erupting tooth it should be removed.

Inflammation of the gums, though not a disease of the teeth proper, is one of the most common causes of the premature loss. It may arise from constitutional causes — chronic dyspepsia, rheumatism or gout — or from the administration of such drugs as mercury or iodide of potassium. Most often, however, it results from the presence of tartar about the necks of the teeth, and lack of thorough cleansing. When due to constitutional causes, their appropriate remedies are called for; but when due to the presence of tartar, this deposit should be carefully removed.

Toothache.— Other diseases of the teeth are less commonly suffered, and more obscure. The advice of a dentist should be sought on suspicion that the teeth are in any respect out of order. An aching tooth is a symptom of disease which requires instant attention. When due to caries with or without simple exposure of the pulp, the attack is brought on by taking hot or cold, sweet or acid fluids, and is seldom of long duration. To afford relief in such cases as these, gently wash out the cavity with a solution of carbonate of soda; then, drying it carefully with a piece of cotton-wool, take a very small pellet of wool dipped in eucalyptus oil and place it in the bottom of the cavity; over this place a piece of cotton wool large enough to fill the cavity and saturated with the following solution: one dram of mastic in one and one-half ounces of eau de Cologne. This should be changed daily. When the pain is caused by the forming of an alveolar abscess the tooth will be found insensitive to change of temperature but very susceptible to pressure. The patient now becomes feverish, and the pain, which is at first of a dull heavy character, becomes more intense, throbbing, and continues, till pus has been formed and discharged through the gum. Provided the tooth is likely to prove useful and the patient cannot consult a dentist, the gum should be carefully painted with tincture of iodine, or the old-fashioned plan of placing a roasted fig over the root may be resorted to; at the same time it is well to give an aperient such as Epsom salts, followed by a full dose of quinine — six to eight grains for an adult. Great relief follows this treatment, which is, of course, only temporary. If an abscess shows signs of pointing on the gums it may with advantage be lanced. Poultices should never be applied to the face, for heat tends to draw the pus outward. Abscesses in connection with the lower wisdoms often assume a very serious character unless cut short by extraction of the tooth.

Hygienic Care of the Teeth.— Many of the diseases of the teeth and gums might be prevented or greatly retarded by proper attention to the cleansing of these organs. The implements best fitted for this purpose comprise the quill toothpick, waxed silk thread and brushes, with suitable powders. The toothpick ought to be used after every meal, but it should be supplemented by the use, between the teeth, of floss silk, which will remove deposits accumulating where contiguous teeth touch. The brush is used to remove all deposits solid and mucous, and it gives the teeth a bright and polished appearance; its mechanical friction, too, stimulates the gums to more healthful action. An excellent tooth powder is composed of precipitated chalk, two ounces; light magnesia, two ounces; oil of cinnamon, eight drops; thymol crystals, four grains; otto of roses, 10 drops. The teeth should be brushed twice daily, in the morning and in the evening. The manner of using the brush is more important than many people suppose. The general method is to brush horizontally, but a moment's reflection will show that this leaves untouched the very situations most in need of cleansing. The brush, used properly, should be pressed against the teeth and the handle rotated so as to make the bristles sweep vertically between and over them; this coupled with an up-and-down motion will thoroughly cleanse the interspaces; the inner surfaces of the back teeth are best cleaned in a like manner, while the corresponding parts of the upper and lower incisors are effectually reached by a vertical drawing movement. The brush should be of medium texture, and the bristles of unequal length, and not too closely placed. A hard-and-fast rule cannot, of course, be laid down for every one to follow, but in the majority of cases it is advisable to use the powder in the morning and a mouth wash with the brush in the evening. For the latter purpose the following is good (especially where a tendency to inflammation exists) — tannic acid, four grains; rose water, one ounce; tincture of pyrethrum, one-half dram; oil of cinnamon, 10 drops. Over-brushing must be guarded against as carefully as under-brushing, lest the gums and the necks of the teeth be injured. During an illness these precautions are doubly necessary as the corrosive effects of many medicines are then added to the evil results of a weakened vitality. The use of a glass tube in taking medicine that contains mineral acids and iron is usually supposed to be a sufficient precaution against the action of such drugs on the teeth, but this is quite erroneous; the only sure preventive being a weak solution of ordinary baking soda, with which the mouth should be rinsed after every dose. The choice of a tooth powder should be left to the dentist, for many dentifrices which, no doubt, whiten the teeth, do so by the action of some agent which is as deadly to the tooth substance as to the impurities it is meant to remove. Charcoal (so much used) is quite unsuitable because of its gritty nature. As far as the ordinary individual is concerned, the use of brush and toothpick is the limit up to which one can take of one's own teeth, so that a thorough examination of the mouth once or twice a year by a trustworthy professional man is necessary to check the diseases of the teeth before they have gone so far as to be irreparable. Especially should this be attended to in children. It is almost impossible to overrate the importance of following, at least in the main if not in detail, the hints given above, for when we consider that the teeth are placed at the very gateway of life, it is not surprising that their neglect should be answerable for many of the disorders of the system. Surely precaution is better than cure. See also DENTISTRY.

TEFFT, Benjamin Franklin, American Methodist Episcopal clergyman, college president and diplomat: b. Floyd, N. Y., 20 Aug. 1813; d. Brewer, Me., 16 Sept. 1885. He was graduated at the Wesleyan University in 1835 and in 1839 entered the Methodist Episcopal ministry. He held pastorates at Bangor and at Boston and in 1843–46 he was professor of Greek and Hebrew at Asbury, Ind. (now De Pauw), University. He edited the *Ladies' Repository* in 1846–52; was president of Genesee College, Lima, N. Y., in 1851–54, also editing the *Northern New Yorker* in 1852–54; and held pastorates at Bangor in 1858–61. He was appointed United States Consul at Stockholm and acting Minister to Sweden in 1861; and in 1864 was made commissioner of immigration from northern Europe for the State of Maine. In 1873–78 he edited the *Northern Border* at Bangor. Author of 'Prison Life' (1847); 'Hungary and Kossuth' (1852); 'Webster and His Masterpieces' (2 vols., 1854); 'Methodism Successful' (1860); 'Evolution and Christianity' (1895), etc.

TEGEA, Arcadia, city of ancient Greece whose site was near the modern Tripolitza. It was situated on the southern portion of a plateau nearly enclosed by mountains, the northern half being occupied by Mantineia. It was a highly fertile region, but was subject to floods because of an insufficiency of outlets through its mountain barriers and together with Mantineia was dependent upon underground drainage conduits. This common dependency was a cause of frequent wars with Mantineia, while Tegea's natural position controlling the chief roads leading from Laconia to Argus and the Isthmus made her for long a bulwark between Arcadia and Sparta and caused many wars with the Spartans. Sparta, however, subdued Tegea about 550 B.C. and forced the city to join the Spartan League but did not otherwise deprive it of its independence. Later it joined the Arcadian and Argive League against Sparta, but after a decisive defeat about 468–467 B.C. it again became Sparta's ally. It was a member of the Arcadian Confederacy after the battle of Leuctra in 371 B.C. and later belonged to the Ætolian League. It remained a place of importance after the Roman conquest of Greece, but in 400 A.D. it was destroyed by Alaric. The excavation of its ruins was begun in 1879. Its most important building was the temple Athena Alea, rebuilt by the sculptor Scopas in 395 B.C. It was a combination of Doric, Ionic and Corinthian architecture 72 by 154 feet; the sculptures also were by Scopas and represented the slaying of the Calydonian bear and the combat of Telephus and Achilles. While these are in fragments they were evidently in the best manner of Scopas. Consult Curtius, E., 'Peloponnesos' (1851); Mendel, G., 'Bulletin de correspondence hellénique' (Vol. XXV, 1901); Gardener, E. A., 'Fragments of Greek Sculpture' (1915).

TEGERNSEE, Germany, village and mountain lake resort in the province of Upper Bavaria, on Lake Tegernsee, 32 miles southeast of Munich, 2,390 feet above sea-level. It has a castle which originally was a monastery founded in 719; a parish church of the 15th century; and an ophthalmic hospital founded by Duke Charles Theodore of Bavaria. It is much frequented as a summer resort, the lake and the fine mountain scenery offering many attractions. Pop. about 1,900.

TEGNÉR, těng-nār′, **Esaias,** Swedish poet: b. Kirkerud, Wermland, 1782; d. Wexiö, Småland, 1846. He was graduated at the University of Lund in 1803, became (1812) professor of Greek literature and member of the Swedish Academy, was ordained priest and in 1824 was appointed bishop of Wexiö. As a poet he struck out a new path in Swedish literature. His first attempts did not meet with much acceptance, but at length he came to be regarded as the greatest poet of Sweden. His poetry is characterized by inexhaustible wit, rich, fancy and lively feeling. His most notable work and the direct cause of his promotion to the bishopric was 'Frithjof's Saga,' a species of epic, repeatedly translated into English. Its great value lies in its accurate reproduction of the legends that are included. He also wrote the national song 'The Gotha Lion' and 'The Children of the Lord's Supper,' translated by Longfellow. His works were collected and published by Böttiger, his biographer (1847–50; jubilee ed. 1882–85). The later years of his life were spent in a retreat for the insane and on a paralytic couch. (See FRITHJOF'S SAGA). Consult Boyesen, H. H., 'Essays on Scandinavian Literature' (New York 1895); Erdmann, 'Esaias Tegnér' (Stockholm 1896).

TEGUCIGALPA, tä-goo-sē-gäl'pä, Honduras, the capital of the republic since 1880 and of the department of the same name, situated on the Choluteca River, 60 miles northeast of the Gulf of Fonseca. It is one of the old Aztec cities and lies on a plateau 3,250 feet high. An imposing bridge connects it with the suburb of Comayagua. The government maintains a central institute with subsidized colleges and five normal schools. Its cathedral is the finest building in the country and there are besides five other churches, a university and other less pretentious public buildings. Gold and silver mines are worked in the neighborhood, which is also a fertile agricultural district. Pop. 28,950.

TEGUEXIN, tĕ-gĕk'sĭn, a lizard. See TEJU.

TEHERAN, tĕh-ĕ-rän', Persia, (1) Capital of a province of the same name, at the northeast and about 66 miles south of the Caspian Sea. It lies on an elevated plain, with the lofty ranges of Elburz and Demavend rising at the north and east, 20,000 feet being the elevation reached by the latter volcanic peak. The old fortifications were demolished and others were completed in 1874. A fine promenade was made on the site of the old walls and the new fortifications are much more extensive, enclosing an area of about 10 miles. The principal streets extend from the 12 gates to the central bazaar, which displays a great variety of domestic and foreign goods. The ark is the principal feature and is the name given to the citadel and its enclosures, chief of which is the handsome palace of the shah, with its extensive grounds and fountains. There are various schools, including a Koran school and a college conducted by European professors. Besides numerous mosques, the buildings of the British legation and of other legations are worthy of notice and the suburbs lying at the foot of the Elburz hills, contain many charming villas resorted to by the wealthier class in warm weather. The ruins of Rei, in the vicinity, are among the most remarkable of Persia. Water supplied to the town by 30 subterranean canals, is brought from the northern slopes and in 1866 a tramway was constructed to Shah Abdul Azim, a place of pilgrimage south of Teherán and others were built connecting various sections of the town. Gas was first used in 1892 to light the city. Harûn-el-Raschid was born in the vicinity. The manufactures include carpets, silks, cotton goods and ironware. In 1913 the police service of Teherán was turned over to the control of Swedish officials, the Swedes having largely officered the Persian army. Pop. (est.) 280,000. (2) The province of Teherán comprises six districts, containing much fine agricultural land and numerous villages, two of which are held in fief by the British and Russian governments respectively. There are fine coal fields in Kasran and streams abounding in fish. Veramin District is watered by the Jájrúd River. The chief products are fruit and grain, wheat, barley and rice. A railway, passing through Mesopotamia, connects the Mediterranean with the Black Sea and the Gulf of Persia. It furnishes an all-rail route from Calcutta to the British Channel and shortens the distance from Teherán to Constantinople by two weeks.

TEHUANTEPEC, tä-wän-tä-pĕk', **City of,** situated in the state of Oaxaca, Mexico, 18 miles from the Pacific Ocean, is the centre of a fertile and productive country in which coffee, sugar and other tropical products are largely grown. It has a considerable trade in cattle which are raised on adjacent lands. The city is an important station of the new inter-oceanic railway. Pop. about 18,000, including a large number of persons of Indian extraction.

TEHUANTEPEC, Isthmus of, comprises that section of the Republic of Mexico within the states of Vera Cruz and Oaxaca where the Gulf of Mexico and the Pacific Ocean approach nearest one another, the distance from the mouth of the Coatzacoalcos River, on the east, to the port of Salina Cruz, on the west, being 143½ miles. This point is one of the rare instances where a depression exists in that vast chain of mountains which extends from north to south along the western shores of both American continents. At Tarifa, the lowest point of the summit level, the altitude is but 754 feet above the sea. Cortes, searching for a safe harbor for his ships, discovered the Coatzacoalcos River, wide and deep where it empties into the Gulf, and pronounced it the finest in Mexico. Informed of the narrow strip separating the two oceans, the conqueror was evidently impressed and at once grasped the idea of inter-oceanic communication at this point. With prophetic insight and influenced by the enormous advantages which were certain to result to the isthmus by the construction of a ship canal, Cortes located a vast land grant, presented by his sovereign, in close proximity, and chose for a title "Marquis of Tehuantepec." His successors caused superficial surveys of the route to be made and were convinced that no serious obstacles prevented building a ship canal and, considering the diminutive proportions of vessels at that period, the enterprise was well within the engineering capacity of the 16th century. It was proposed to employ native slave labor in its construction. Political and strategic considerations prevented the Spanish government from ever encouraging the enterprise. When Mexico became independent it was too much engaged in restoring order to give attention to internal improvements and it was not until 1842 that a concession for opening a line of communication by canal or railway, or both, was granted to Don Jose de Garay, a citizen of that country. Accurate surveys were made and a practicable route selected, but, for lack of financial encouragement, the concession was afterward surrendered. Until 1852 capitalists of the United States betrayed no special interest in the enterprise, but when the permanent development of California and Oregon was assured, the importance of more rapid communication between the East and West was quickly realized. In that year the Barnard and Williams expedition was dispatched to the isthmus to survey a route for an inter-oceanic railway. These explorers made very careful surveys of the entire route and pronounced the enterprise perfectly feasible, but were subsequently ordered out of the country, the introduction of American capital not being encouraged by the Mexican government, so soon after the war between the two countries. In 1871 the expedition under Commodore Shufeldt was dispatched to the isthmus by the United States government to make a final survey and finally determine whether a ship canal could be built over the route or not. The result of the survey was a decision that a ship canal, capacious enough for modern vessels, was not practicable owing to insufficient water supply for the upper levels. This expedition also reported adversely to the lagoons, which indent the western coast and were considered the natural location for a terminal harbor, on account of certain unfavorable physical conditions there existing. A new location for a terminal was chosen at Salina Cruz, a few miles westward of the mouth of Tehuantepec River, where greater depth of water was afforded, as well as more complete shelter from the prevailing winds.

Henceforward all projects for building a ship canal over the Isthmus of Tehuantepec were abandoned, but the Mexican government readily granted concession after concession to parties, mostly Americans, to construct railways; but owing to powerful influences every attempt was frustrated and the liberal grants suffered to lapse or were withdrawn.

The Eads Ship Railway.— In 1883 James B. Eads, a distinguished engineer, conceived a plan for the construction of a railway over the isthmus by which vessels of the largest dimensions could be transported by rail at a speed of 10 miles an hour. The details contemplated the deepening of the Coatzacoalcos River for a distance of 20 miles to the town of Minatitlan, which was to be the eastern terminus. The western terminus was to be at Salina Cruz. At these points giant pontoon docks were to be located and three lines of railway of standard gauge connected the two points. As a vessel sailed into the pontoons it rested upon a railway carriage, secured from all strain by ingeniously contrived supports. Raised to the level of the tracks the carriage was connected to three powerful locomotives and with its load carried across the isthmus and deposited into the sea at the other terminal. The length of the railway was to be 165 miles, with a very substantial roadbed and with not greater than 20-mile curves. Where abrupt curves existed, they were to be avoided by turntables at five different points. Vessels in transit were thus always in a straight line. The plan after being subjected to much criticism was at last endorsed by the highest engineering authority in the world and would probably have been built but for the death of its projector in 1887. Its cost was estimated at $75,000,000. Mexico granted 1,000,000 acres of public land in its aid. Thus for three and a half centuries every plan conceived for the attainment of communication over the isthmus having failed, Mexico determined upon the construction of the railway as a national work and spent $20,000,000. Finally about 1907 the railway was opened to a length of 192 miles, but the impending opening of the Panama Canal greatly reduced its importance.

TEIXEIRA DE MATTOS, tā-shā'rä dä mät'tōs, **Alexander Louis**, English journalist and translator: b. Amsterdam, Holland, 9 April 1865. He settled in England in 1874, was educated at Beaumont College, Old Windsor, and entered journalism. He has been engaged as correspondent and as associate editor on various periodicals and has published translations of Melati van Java's 'Resident's Daughter' Zola's 'Curée'; 'Memoirs of Chateaubriand' and of the plays: Zola's 'Thérèse'; Josine Holland's 'Leida'; 'The Cradle' (from the Flemish) and some of Maeterlinck's tales.

TEJU, or **TEGUEXIN**, a large lizard (*Tupinambis teguexin*), inhabiting tropical America. The upper parts are deep-black, mottled with green and yellow; the sides show two rows of white spots; and the under parts are yellow, marked with black stripes. A full-grown specimen may be three feet in length, mostly tail. These lizards frequent forests and plantations, are carnivorous and their strength and speed enable them to catch a great variety of animals, including barnyard chickens and eggs. They are consequently hunted, not only as pests, but because they are themselves good to eat. They dwell in burrows, lay hard-shelled eggs in the ground and defend themselves by vigorous lashing of the tail. Their general resemblance to the Egyptian *Varanus* gives them the borrowed name «salvator» in some places. This lizard represents an American family, the *Tejidæ*, with long forked tongues largely covered with scale-like papillæ. The teeth are solid and implanted almost on the edge of the jaw and are therefore intermediate between acrodont and pleurodont. The body is covered with small scales (osteoderms are absent) or the skin may be simply granular above; the under surface is covered with larger scales, generally arranged in transverse rows. «This large family,» says Gadow, «which comprises nearly 40 genera with more than 100 species, exhibits great diversity of form. Some are inhabitants of forests and are arboreal, while others are strictly terrestrial, preferring hot and sandy plains, or they dwell below the surface and are transformed into almost limbless and blindworm-shaped creatures.» Representatives of the family are spread from Texas and Utah to the borders of Patagonia.

TEKELI, tĕk'ĕ-lĭ, or **TOKOLY**, tė'kėl-yĭ, **Emmerich**, Count of, Hungarian noble: b. about the middle of the 17th century; d. Nicomedia, Asia Minor, 1705. His father had headed an insurrectionary movement against Austria and he himself was chosen by the Hungarians in 1678 their commander-in-chief. He broke into Upper Hungary, captured several fortresses and towns, devastated Moravia and penetrated into Upper Austria. The emperor consented to redress several grievances at the Diet of Oedenburg (1681); but the insurgents were not satisfied and refused to lay down their arms. Tekeli now put himself under the protection of the Sultan Mohammed IV, by whom he was declared king of Hungary. A war between the emperor and the Porte ensued in which the Turks advanced (1683) as far as Vienna, but were totally defeated before that city by John Sobieski, king of Poland (12 Sept. 1683). The count continued the war, but without success. He fell under the suspicion of the

Turks, who sent him a prisoner to Adrianople (1685). Meanwhile his wife was besieged by the Austrians in the castle of Munkács, where she held out for three years, until she was compelled by famine to surrender (January 1688). The Turks discovered the groundlessness of their suspicions of Tekeli and he once more received the support of the sultan, who designated him prince of Transylvania. He penetrated into that country and routed the imperial general (1690); but in the same year he was compelled by Louis, margrave of Baden, to retire. He continued in all the struggles between Austria and Turkey till 1697, when the Peace of Carlovitz was concluded, in which Turkey renounced the cause of the Hungarians. Tekeli then retired to the dominions of the sultan, who conferred upon him several estates, with the title of prince of Widdin.

TEL EL AMARNA. See Tell el Amarna.

TEL EL KEBIR. See Tell el Kebir.

TELAUTOGRAPH, an instrument for the instantaneous transmission of a facsimile copy of writing or pen drawing. Telautograph was the name given by Elisha Gray, who invented the apparatus to his particular form, but it has been extended to cover varieties of machines having the same purpose. In Gray's apparatus the transmitting pen is connected by silk cords to mechanism by means of which the motions of the pen cause a pulsatory current to pass into two telegraph wires. These pulsatory currents produce rapid pulsatory motion of the armature of a system of electro-magnets by means of which the receiving pen is caused to follow the motions of the transmitter. Another electro-magnetic arrangement lifts the receiving pen off of the paper at the end of each line, while still another moves the paper forward to receive the next line from the pen. As commonly used a pencil is employed instead of a pen for transmitting and a continuous roll of paper is provided at both the transmitter and receiver. The writer or sender of the message pulls a little lever to shift his paper and the motion is conveyed electrically to the paper roll at the receiver. The receiving pen is a capillary glass tube at the junction of two light metal arms. This glass fountain pencil repeats automatically all the movements of the sending pencil, so that either words, pictures or signs are accurately duplicated. This apparatus can be used on the same wires as a telephone without disturbing the use of the latter, does not require an operator at the receiving end, and interception of the message by wire tapping is impossible.

In a modified form of telautograph known as the telechirograph, invented by Gruhn, a radically different receiving apparatus is used. The transmitted currents influence two electro-magnets which in turn cause a small concave mirror to move; a light ray from a small incandescent lamp falls upon the mirror whence it is reflected to a sheet of sensitized paper. The mirror is attached by means of cement to a small iron plate in the form of a triangle, one corner of which rests upon a set screw upon which the mirror can oscillate. Beneath the two other corners extend two armatures subjected to the attraction of the electro-magnets. These armatures undergo oscillations corresponding to the component movements of the transmitting pencil; they are carried by flat springs, and the oscillations are given to the iron plate and, of course, to the mirror fastened to it. Before the message can be delivered the receiving sheet must be developed; the apparatus for this is simple: when the message is completed a small electric motor operated by an independent battery in the receiving room is set in motion; this motor works a train of wheels or rollers which draw the portion of the film written upon by the light ray through a developing bath and out again through a pair of rubber drying rolls. The completed message is delivered in less than 35 seconds after the transmitting operator has placed his pencil in its rest.

TELECHIROGRAPH. See Telautograph.

TELEDU, a badger (*Mydaus meliceps*) of Java, which is skunk-like in its habits, and in the copious and far-reaching vileness of the secretion in its anal glands.

TELEGONY, the inheritance by offspring of the characteristics of some previous mate of one or both parents. That such inheritances existed was long the belief of breeders of live-stock, who spoke of the phenomenon as «throwing back.» Until about 1890 scientific men generally lent their support to this theory, although Weismann long ago expressed serious doubts. About 1895 Ewart began a series of careful experiments at Penicuik, near Edinburgh, Scotland, and certain others were undertaken in Germany and Brazil, the outcome of which was to show that the phenomena noticed were evidences of atavism, or reversion or variation, and that no such a thing as telegony existed. See Heredity.

TELEGRAPH BATTALIONS. The general duty of signal troops is to collect and transmit information, to assist in providing security for troops, to assist in directing fire attack during combat, to provide means for ready verbal and written communication between distant commanders and troop leaders, to facilitate the transmission of verbal and written messages and orders, to insure the secrecy of such messages when necessary by means of codes and ciphers, to exercise supervision over the character of matter transmitted by means under its control, and when circumstances make it neccessary, to fight in order to accomplish any of these objects.

The work of signal troops assigned to lines of information in war varies with the nature of the lines which they control, viz. (1) The maintenance and operation of electrical lines of information from the capital of the nation to the headquarters of the armies in the field. (2) The construction, maintenance and operation of the radio stations and central permanent telegraph and telephone lines connecting the headquarters of each army in the field with its various divisions and other units, and the necessary camp telephone and telegraph lines within these armies. These lines are included in the zone of the advance.

The signal organizations assigned to both these classes of duties are called *Telegraph Battalions*. In the first class they are distributed along the lines and at stations as required for construction, maintenance and operation without being supplied with the special technical equipment and transportation required in the field. They operate the telegraph cable and radio offices and the telephone systems with substantially the same apparatus used in times of peace. These lines extend from the seat of government through the zone of the line of communications up to army headquarters. For maintenance, repair and extension the material and equipment supplied is the same as in commercial practice.

In the second class of work signal troops must instal and operate lines under quite different conditions. The poles and wire must be light and the instruments of special design for a service unlike that encountered in commercial practice. For administrative purposes the telegraph battalions employed in this class of work are organized into companies, and these in turn into sections, each equipped with supplies and transportation for installation of a complete telegraph or telephone system in the mobile units with which they serve. The telegraph battalion prescribed in the tables of organization consists of two companies. Each company has six sections — three telegraph and three telephone. A telegraph section is equipped to instal 20 miles of wire on lances with three telegraph offices. The equipment is carried in one wagon of the escort type and one lance truck. The 10 men of the section furnish the linemen, operators and messengers necessary for the construction, maintenance and operation of 20 miles of line. The telegraph equipment and personnel of the company is sufficient for 60 miles of line and that of the battalion for 120 miles. A telephone section is supplied with material for the installation of a telephone system of 20 telephones connected with a field switchboard and 20 miles of insulated wire laid on the ground or supported on lance poles. The equipment is carried in two telephone wagons of the escort type and the lance truck. Twenty-one men make up the switchboard operators, linemen and messengers needed. The equipment of the telegraph battalion is necessarily bulky and heavy and its mobility in general is limited to that of the supply train.

TELEGRAPHONE, a recording telephone, the invention of Valdemar Poulsen, of Copenhagen. He devised a magnet of sufficient delicacy to limit the magnetizing of a metal plate to the direct point of contact, no matter how minute that point might be. His magnet, in tracing its course over a steel disc, magnetizes only the molecules of the steel with which it comes into direct contact. Thus localized and defined, electro-magnetism becomes controllable. The result was a mechanism that recorded the sounds given into a telephone receiver, on discs that could be mailed like letters, and reproduced by the recipient. This interesting machine failed of commercial success. Consult *Scientific American* Sup. (Vol. LXIII, No. 1625, 23 Feb. 1907).

TELEGRAPHY. The word telegraph is derived from the Greek, *tele*, «afar off,» and *graph*, «to write.» In the modern practice of telegraphy, however, the term has a wider meaning and is used to signify any means by which intelligence is transmitted to a distance by signs or sounds. In this sense the word would also include the transmission of speech electrically to a distance, but inasmuch as that highly important art possesses its own appellation (telephony) such a use of the word is unnecessary.

From remotest times methods of communicating intelligence to a distance have been employed for purposes of war and defense. The Greeks were perhaps the first to adopt systematic methods of telegraphing, and a description of a telegraph system that was employed 300 B.C. is to be found in the writings of the Greek General Polybius.

Polybius Telegraph.— The operation of this system was as follows: At each station there were two walls about seven feet in length and about six feet in height, separated by a space of three feet. At night one or more torches, as desired, but not exceeding five in all, were placed on top of the walls, and certain combinations of the torches represented the letters of the Greek alphabet. A tablet showing the combinations of torches for the various letters was provided at each station. For instance, two torches on the right-hand wall and three on the left wall would represent the letter H. Five torches on the right wall and four on the left, Y, and so on. When it was desired to signal a station, two torches were set on a wall, which signal was answered by a similar arrangement of torches at the other station. The operator then proceeded to spell out his message by placing the torches in the required combinations, one letter at a time. The tablet mentioned was divided into five vertical and five horizontal rows of squares, each letter of the alphabet being allotted a certain square, beginning at the upper left-hand corner with A, and running horizontally across the tablet. Any letter could thus be found by giving the number of vertical and horizontal rows at the intersection of which was the square allotted to that letter. For instance, the letter Y would be at the intersection of the fourth horizontal and the fifth vertical rows. The code thus formed, in a more or less modified form, is in use to-day by the military departments of various countries as a means of telegraphing maps of a locality.

Fire and Smoke Signals.— The use of fires by night and smoke by day has long been practised by even the most uncivilized races, as a means of communicating intelligence to a distance. In numerous places in this country there still remain evidences of this practice by the aborigines, in the shape of mounds on hill tops and other points of advantage, on which the accumulated ashes of beacon fires of bygone years may be found beneath the roots of trees of gigantic size. In the country between Chillicothe and Columbus, Ohio, for instance, may be traced over 20 such mounds, so related to one another that if all the trees were removed fire signals might be transmitted from one end of the valley to the other in a few minutes. To this day the Indians of North America practise this method of signaling the approach of enemies in their territory; and up to within a comparatively short time beacon fires were the most favored methods of signaling the approach of an enemy in Great Britain and other parts of Europe.

Semaphore Systems.— It was not until the end of the 18th century that any comprehensive plan of signaling was employed in Europe or in this country. The plan then introduced was that known as the Chappé semaphore system of signaling. This semaphore resembled the semaphore so common on all railways to-day, consisting of an upright post, on the top of which movable arms or blades are pivoted, but in the Chappé semaphore the arms were arranged quite differently from those of the ordinary railroad device. Thus the crossarm on the top of the post was 14 feet in length, and at each end of this arm a shorter arm was pivoted at right angles to the longer arm. By a system of ropes and pulleys these arms could be manipulated by the operator and placed in many different positions, certain positions of the arms representing given letters of the alphabet. Hence by appropriately placing the arms, the manipulator could spell out words and messages which an operator at a distant station could read and, if necessary, retransmit to another station further on. These semaphores were placed on substantial stone towers at distances apart ranging from six to 10 miles, and their use spread rapidly throughout Europe. In France, Germany and Russia especially the system was widely used. For example, a string of 220 semaphore towers, extending from the Prussian frontier to Petrograd, via Warsaw, a distance of over 1,200 miles, and employing over 1,300 operators was erected at great expense. In Prussia also a line of semaphore stations from Berlin to Treves, via Potsdam, Magdeburg, Cologne and Coblenz, was established in 1832, at a cost of 170,000 thalers. In France there was a semaphore line from Paris to Toulon, 475 miles apart, and requiring 120 stations.

The transmission of signals by semaphore systems was necessarily slow (about one signal per minute), inasmuch as each signal was verified by the receiving station before another was transmitted. The time taken in transmitting a signal or letter from Paris to Toulon was, however, comparatively speedy, namely, 10 to 12 minutes.

Semaphore signaling is still usefully employed in some countries for communicating from ship to shore, between coast-guard stations, at rifle ranges, etc. One plan of this kind consists in the use of two small flags, one held in each hand. The flags are about 18 inches square, the staff is about three feet in length. The letters of the alphabet are represented by the positions in which the flags or the arms are held. With the aid of a telescope, signals may be transmitted by this method to a distance of three miles in fair weather. Messages may also be read by the use of the arms alone, employing the same alphabet, in which case this is termed the human semaphore.

Electric Telegraph Systems.—Although up to 1852 a number of visual systems of telegraphy, such as the semaphore system, were, as stated, in quite extensive use, electricity had been utilized experimentally long prior to that date for purposes of telegraphy but its growth in this direction was slow and the scepticism with which its commercial utility was at first regarded is evidenced by the extensive establishment of semaphore stations, just mentioned, long after the possibility of electric telegraphy had been more or less clearly indicated.

In 1774, Lesage of Geneva constructed an electric telegraph system which employed in its operation 24 line wires, one for each letter of the alphabet. At the terminal of each wire pith balls were suitably suspended, and, taking advantage of the well-known repellant effect that follows the similar electrification of such light substances, Lesage, by the use of frictional electricity applied to the wires, transmitted intelligible signals over them. In 1815 Francis Ronalds of England improved on this arrangement. A revolving dial, operated by clock-work, was employed at each end of a wire. The dials rotated synchronously. A notch was cut in each dial, behind which the letters of the alphabet were placed in a circle, so that as the dial revolved one letter at a time was seen through the notch. Pith balls were electrically connected at each end of the wire. At a given signal the dials were set in rotation and as the notch arrived at a desired letter the pith balls were actuated electrically. The letter was noted and in that way messages were transmitted. In 1774 Volta had discovered that electricity could be generated by means of the "voltaic" battery, and availing of the current from such a battery efforts were made, with more or less success, between the years 1806 and 1830, to utilize the electrolytic property of an electric current to decompose chemical solutions at the distant end of a wire to indicate telegraph signals. These experiments were the precursors of others more successful in the line of electrochemical telegraph systems of later years, and to which further reference will be made herein.

Needle Telegraph Systems.—Availing of Oersted's discovery that a pivoted magnetic needle is deflected from its normal position, parallel to a wire, when an electric current passes in that wire needle telegraph systems came into existence and were extensively employed in Europe at one time and are yet in use there. For this purpose a magnetic needle is pivoted in the centre of a coil of wire, and a pointer suitably attached to the needle, swings in front of a dial. The needle and with it the pointer can be deflected to the right or left by changing the direction of the current through the coil. Certain deflections of the needle to the right or left, or combinations of deflections to the right and left represent the letters of the alphabet, and these deflections are produced by sending over the wire current pulsations in positive or negative direction, or alterations of both, as required by the letter to be transmitted. For instance, if the Morse alphabet were used, a motion to the right would represent a dot; one to the left a dash. The alterations of polarity are transmitted by a "drop-handle" or a "tapper." The tapper is similar to the double-sending key used in submarine telegraphy. (See Fig. 15). A needle system employing two needles has also been used. This required two wires, but gives a higher rate of speed — about 15 to 20 words per minute. The operator reads incoming signals by observing the movements of the needle or needles.

Bright's Bell.—A modification of the needle telegraph is that known as "Bright's Bell," in which two bells of different tone are struck by a hammer, one tone representing, for instance, a dot; the other, a dash. In other instances, the needle of the needle system is caused to strike metal tubes of different tones, one tone indicating a deflection in one direction, the other tone a deflection in the opposite direction. These have been termed acoustic telegraphs.

Electric Chemical Telegraphs.— See *Automatic Telegraph Systems* in this article.

Morse Electro-Magnetic Telegraph.— In 1824 Sturgeon of England discovered that when a current of electricity is caused to flow in an insulated coil of wire, surrounding a bar of soft iron (that is, well-annealed iron), the bar takes on magnetic properties, and when the current ceases to flow in the coil the iron at once loses its magnetism. Employing these electromagnetic phenomena, Morse, in 1837, invented the telegraph system which bears his name, and which to-day is in extensive use in one form or another in every part of the world. It was then known that when a piece of soft iron is placed near a magnet there is a mutual magnetic attraction which tends to draw them together. This fact is also availed of in the Morse telegraph system as will be shown in the case of the Morse relay and sounder.

To obtain the flow of current in the coil of wire required to magnetize the iron bar, the circuit must be complete, and a source of electromotive force must be provided.

An electric «circuit» may be represented, as in Fig. 1, by a line or wire, *W;* battery, *B,* the

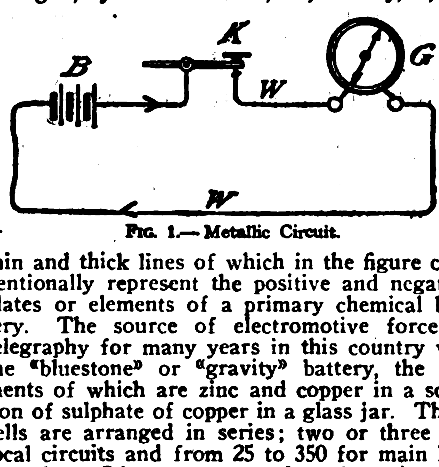

Fig. 1.— Metallic Circuit.

thin and thick lines of which in the figure conventionally represent the positive and negative plates or elements of a primary chemical battery. The source of electromotive force in telegraphy for many years in this country was the «bluestone» or «gravity» battery, the elements of which are zinc and copper in a solution of sulphate of copper in a glass jar. These cells are arranged in series; two or three for local circuits and from 25 to 350 for main line batteries. Of recent years these batteries and the bichromate primary batteries employed in Europe, have given way largely to storage batteries and dynamo machines as a source of electromotive force.

When dynamos are employed they are in some cases designed to develop about 70 volts each. Several of these machines are connected in series so that by tapping the machines at different points an electromotive force of 70, 140, 210 volts, etc., may be obtained. In other cases dynamos developing 70, 140, 300 volts, respectively, are employed. Two sets of such machines are provided, one set to furnish positive polarity, the other negative polarity, inasmuch as it is essential in the practice of telegraphy to utilize currents of opposite direction or polarity; instances of which will be noted in connection with the descriptions of duplex and quadruplex telegraphy in this article.

Reverting to Fig. 1, *G* is a galvanometer, an instrument to indicate the presence of an electric current in a circuit, and which is constructed on the principle of the indicating needle of needle telegraph systems previously mentioned. The direction of the current in the circuit is assumed to be from the positive pole of the battery *B* to the galvanometer *G,* and back to the negative pole of the battery. The key *K* affords a ready means of «opening» and «closing,» or of «making» and «breaking» the circuit. When the key is closed, or down, the circuit is complete and current flows; when the key is «open» or up, the circuit is open or broken, and no current flows therein. An ordinary telegraph circuit without instruments is indicated in Fig. 2. This is termed a ground

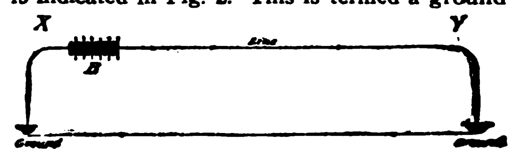

Fig. 2.— Ground Return Circuit.

return circuit. A circuit like that indicated in Fig. 1 is termed a «round» or metallic circuit. In the case of a ground return circuit the earth acts virtually as though it were a wire of inappreciable electrical resistance, completing the circuit from end to end.

In the Morse telegraph system signals are transmitted electrically from one station to another by the opening and closing of the circuit, or wire, by means of the key, for short and long intervals, which acts operate the Morse relay and sounder or register, and cause them to produce sounds or printed characters corresponding to dots and dashes of what is known as the Morse telegraph alphabet.

In Fig. 3 is shown theoretically the essential apparatus of a Morse telegraph equipment at two terminal stations, *X, Y. B* is the battery; *K* is the Morse key. *S* is an iron core or bar, arranged in the shape of a horseshoe, around which a coil of fine wire is wound. *A* is a small piece of iron, termed the «armature,» which is mounted on a

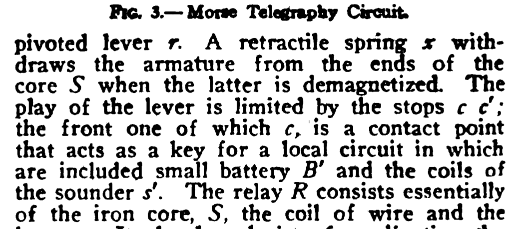

Fig. 3.— Morse Telegraphy Circuit.

pivoted lever *r.* A retractile spring *x* withdraws the armature from the ends of the core *S* when the latter is demagnetized. The play of the lever is limited by the stops *c c';* the front one of which *c,* is a contact point that acts as a key for a local circuit in which are included small battery *B'* and the coils of the sounder *s'.* The relay *R* consists essentially of the iron core, *S,* the coil of wire and the lever *r.* It also has devices for adjusting the position of the armature relative to the ends of the core, and screw posts for facilitating the connections of the wires leading into and out of the instrument. (See Fig. 5).

The object in using the sounder s' in Morse telegraphy is to obtain louder sound than is practicable with the Morse relay. The magnetism developed in a given electro-magnet, such as a relay or sounder, increases with the strength of current, also with the number of convolutions of wire in the coils, within certain limits. In fact, up to the point of magnetic saturation of the iron, the resulting magnetism is directly proportional to the product of the current strength in amperes by the number of convolutions, or turns, of wire; which product is termed the «ampere turns.» Saturation is, however, seldom or never reached in the magnets used in telegraphy. Again, with a given electromotive force the current strength is inversely proportional to the resistance of the circuit, and as the resistance of a wire of given diameter increases directly with its length, the longer the wire, the weaker will be the current. It is found that to produce the clear, loud click of the ordinary Morse sounder, about .25 ampere is required, while a main line relay will operate freely with .040 ampere (40 milliamperes). To operate a sounder placed in a main line having 1,200 ohms resistance would require an electromotive force of about 300 volts. It is, therefore, more economical and in other ways better to employ a lower electromotive force, about 60 volts in this case, and a relay having many turns of finer wire than the sounder (about No. 30 B & S gauge) and a light armature, not designed to produce a large volume of sound, which relay by means of its armature lever and a «logical» battery is then caused to operate a sounder as indicated in Fig. 1.

The sounder is constructed on the same principles as the relay, but the wire with which it is wound is larger, about No. 24 B & S gauge, and its armature and lever are heavier. Since the lever r of the relay controls the local circuit of the sounder it follows that as the main line is closed and opened, thereby closing and opening the relay, the local circuit will be similarly closed and opened, by which actions the electromagnet of the sounder will be correspondingly alternately magnetized and demagnetized, and the armature lever will be attracted by the magnetism and withdrawn by its retractile spring. The motions of the sounder thus produced cause the long and short sounds which are translated into letters of the alphabet by an expert operator. When a Morse register or ink recorder is used in place of the sounder these dots and dashes are embossed or printed on strips of paper from which the message may then be transcribed by any one familiar with the dot and dash code. Plainly many more relays may be placed in the main circuit than are shown in Fig. 3. It is not uncommon in this country to have 30 or 40 relays in one Morse telegraph line, and with but two main batteries, one at each end. When any one of the keys of a Morse telegraph circuit is open none of the remaining keys can close the circuit, and when any one key is operated all the relays on the same wire will be operated concurrently, by reason of the opening and closing of the circuit by that key. Any attempt to operate two keys at once on this circuit results in the clashing of signals. Such circuits are termed «single» or «simplex,» inasmuch as but one message at a time can be sent over them. This fact distinguishes simplex from multiplex circuits over which two or more messages can be transmitted simultaneously, instances of which will be given herein.

The arrangement of Morse circuits just described is termed the «closed circuit» method of operation, from the fact that the circuit is normally closed with current on the line. In Europe the Morse circuits have generally been operated on what is termed the «open circuit» plan, which consists in so arranging the apparatus that the battery shall only be placed to the line when a message is to be transmitted; at other times the battery is disconnected from the line. For this purpose a key with front and back contacts is used, similar to K in Fig. 12; battery being placed as there shown, and the receiving instrument being placed in the circuit of the back contact at x in that figure. In the open circuit method battery is necessary at every station.

Telegraph Alphabets.— The American Morse code or alphabet which is in general use on overland Morse telegraph lines in the United States and Canada is composed of dots and dashes and of combinations of dots, dashes and spaces. Letters made up partly of spaces are termed «spaced» letters. The letters C and R are instances of spaced letters. (See illustration below). Dots, dashes and spaces are formed by the length of time during which the key or other transmitting instrument may be held closed or open; the

time of making a dot being taken as one, or one "time unit." In length or duration a dash is theoretically equal to three time units. The space between the elements of a non-spaced letter is equal to one time unit; the space between letters of a word is equal to three time units; the space between words, to five time units; the interval in spaced letters is equal to three time units. The object of the framers of this alphabet in utilizing spaces in some of the letters was to minimize the length of the letters and thus practically to increase the speed of transmission by this alphabet. It was found, however, in automatic telegraphy that the use of spaced letters increased the liability to errors, and hence an alphabet, known as the Continental or Universal Code, was adopted in Europe in which spaced letters are not used. This alphabet is now employed universally in Morse telegraphy outside of the United States and Canada. The American Morse and Continental Morse alphabets or codes are given on preceding page.

Morse Telegraph Apparatus Manual Transmitting Keys —As previously intimated, the characters of the Morse alphabet are formed by the manipulation of a suitable key. The key originally employed by Morse was a cumbersome piece of apparatus. The key now employed in the United States could not well be made lighter. Its construction will readily be grasped by reference to Fig. 4. A steel

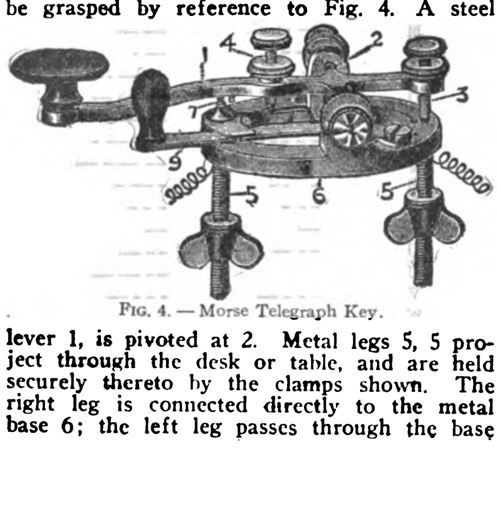

FIG. 4. — Morse Telegraph Key.

lever 1, is pivoted at 2. Metal legs 5, 5 project through the desk or table, and are held securely thereto by the clamps shown. The right leg is connected directly to the metal base 6; the left leg passes through the base and is insulated therefrom by a hard-rubber bushing. On its top there is a cone-shaped cap, termed the anvil, carrying a small platinum contact point, 7. A small strip of metal extends out from the cap. At a point on its under side, directly above the contact 7, the lever 1 is provided with a platinum contact 8, termed the hammer. A curved strip of metal 9, the "circuit closer," is pivoted on the base 6. When the circuit closer is pushed under the strip projecting from the cap 7, it closes the circuit, regardless of the opening between the anvil and the hammer. The lever 1 and the circuit closer 9 are supplied with hard-rubber finger tips, or knobs, by which they may be handled freely without danger of shocks. A spring adjustable by a set screw 4, normally lifts the lever 1 from the anvil. When the operator is about to "send," the circuit closer must be first pushed out from 7 so that the lever when operated may open and close the circuit; for it will be seen that when the hammer is brought into contact with the anvil the circuit is closed at that point. Platinum is employed at all important contacts because of its durability and freedom from oxidation due to the sparking which usually occurs when electric circuits are broken. The manually operated Morse keys employed in Great Britain and Europe are practically similar to that shown here, but they are larger and heavier.

Morse Telegraph Relay.— The electro-magnet which Morse first employed in telegraphy weighed over 300 pounds. In 1844, however, the weight of this instrument had been reduced to 185 pounds. Within 15 years from that time many improvements had been made in the instrument and it then weighed but little more than the modern main-line relay (typified in Fig. 5), about three pounds. As late as 1867 relays were wound to 1,100 ohms; the present standard resistance of this instrument is about 150 ohms. In the case of what are termed "low resistance" relays the coils are wound to 37.5 ohms. These relays are utilized in a number of instances where many relays are employed on one circuit, as on railway telegraph lines and the total reduction of resistance brought about by their use is found to effect a very beneficial result in the operation of the circuits in wet and foggy weather. The obvious explanation of this result is that, since the electric current seeks the path of least resistance, the lower the resistance of the wire circuit the less will be the tendency of the current to escape by the "leaks" to ground, where foliage, trees, etc., touch the wire.

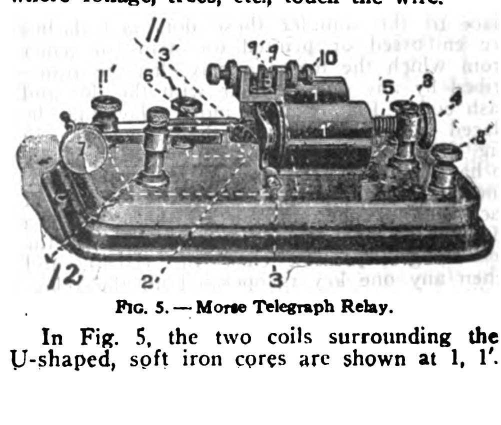

FIG. 5. — Morse Telegraph Relay.

In Fig. 5, the two coils surrounding the U-shaped, soft iron cores are shown at 1, 1'.

These coils are covered by hard rubber sleeves. The armature 2 in this type of relay is a part of the iron lever 9'. These relays are adjusted in two ways; either by drawing the cores away from the armature by means of the screw 4, or by means of the retractile spring 6 attached to the armature, the tension of which is variable by the winding device 7. This winding screw is movable toward or from the relay coils by aid of the post 12 through which the supporting piece of 7 passes. The main line wires are connected to the screw posts 8, 8', from which small wires lead to the coil 1, 1'. The local, or sounder, circuit wires are brought to screw posts 11', 11, from which posts wires lead to the armature lever 2, and to the front contact 10. The object of the relay being to repeat or relay the signals passing on the main line to the sounder, the play of the armature lever (which latter is pivoted at 3, 3'), should not be large. This play is regulated by the front stop screw, that is, the stop next the coils, and by the back stop screw, which is insulated.

Telegraph Sounder.— Many different styles of sounders are in use. A well-known form is illustrated in Fig. 6. In this *B, B* are the

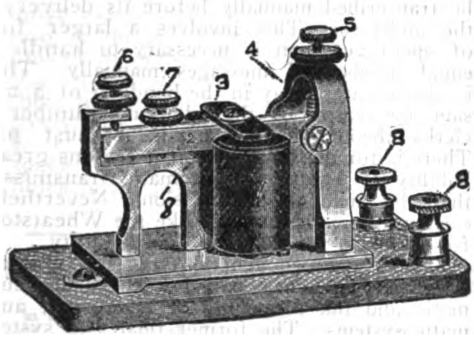

Fig. 6. — Morse Telegraph Sounder.

binding posts; 1 represents the electromagnets; 2 the lever, pivoted on the support 4; a spring adjustable by the screw 5 gives the left end of the lever a tendency to rest on the upper stop 6. Magnetism in the cores draws the armature down, and with it, the lever, until the stop 7 meets the metal support 8. The base is designed to give resonant effects. When used on primary battery circuits these sounders are wound to 4 ohms: when employed on dynamo circuits they are often wound to 20 and 40 ohms.

Telegraph Transmitters.— With the object of obtaining a simple and speedier method of transmitting the characters of his alphabet than the manually operated key method, Morse devised several mechanical arrangements. One of these consisted of a plate of ebonite or wood on the surface of which were placed in a vertical row short and long strips of metal, corresponding to the letters of his alphabet. These strips were all metallically connected under the plate by a wire which led to the battery, relay and ground. The line wire was connected by an insulated wire to a metal stylus. This stylus was held in the hand of the operator and in transmitting a message he would run the point of the stylus over the metal strips representing the given letters, thereby closing and opening the circuit, in a manner corresponding to the manual transmission of the letter. Another somewhat similar device, also due to Morse, consisted of a metal cylinder on the surface of which the characters of the Morse alphabet were arranged in a practically similar way. A keyboard was arranged over this cylinder and the depression of a key brought a metal brush into contact with the cylinder. At the same time the cylinder was caused to make a partial revolution. The characters on the cylinder being connected to the line, and the brush to the earth, the foregoing described actions resulted in the transmission of Morse characters. These transmitters did not go into wide use at that time, but within the past four or five years a keyboard transmitter, termed the "Yetman" transmitter, which is a much improved form of the Morse cylinder transmitter, has been largely adopted by telegraph operators in this country. The employment of this device was no doubt encouraged by the recent employment by operators of the typewriters as a means of transcribing received messages, which gave the receiving operator an advantage over the sending operator who could only send from 30 to 40 words per minute at best speed. By means of the keyboard transmitter a speed of transmission approaching the speed of transcription by the typewriter is obtained. This use of the typewriter was accompanied by a new arrangement of the sounder, which is now placed in a box, or resonator, mounted on an adjustable rod that brings the sounder in close proximity to the ear of the operator.

Lightning Arresters.— Lightning discharges tend to follow telegraph wires into cables across rivers, and into the telegraph offices, causing damage to the cables and instruments. Damage is sometimes caused also by the contact of telegraph wires with electric light and power wires. To prevent as far as possible damage from these causes, lightning arresters and fuses are placed at points just outside of cables and at points where the wires enter offices. A combination lightning arrester and

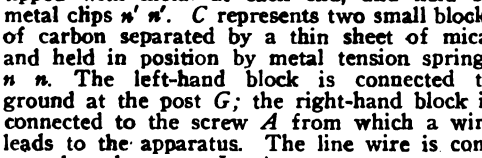

Fig. 7. — Lightning Arrester and Fuse Wire.

fuse wire is shown in Fig. 7. *F* is a small fuse wire carried on a strip of mica *m* which is tipped with metal at each end, and held by metal clips *n' n'*. *C* represents two small blocks of carbon separated by a thin sheet of mica, and held in position by metal tension springs *n n*. The left-hand block is connected to ground at the post *G;* the right-hand block is connected to the screw *A* from which a wire leads to the apparatus. The line wire is connected to the screw *L*. A strong current passing through the fine wire *F* will fuse it; a lightning discharge will jump to ground by way of the carbon blocks; in either case protecting the cable or instruments.

Automatic Telegraph Repeaters.— The function of a Morse automatic repeater is to take, as it were, the message from one wire and "relay" it to another wire without the intervention of an operator. Some of the reasons that render repeaters necessary are, first, that the resistance of the wire increases directly with its length, which tends to a diminution of current strength; second, the escape of current from the line wire at points where it makes contact with trees is greater on a wire of high resistance than one of low resistance (see RELAYS); third, the speed of signaling decreases as the electrostatic capacity is increased and this capacity increases with the length of the wire. Hence it is found desirable in practice to limit the direct length of a telegraph circuit to a maximum of about 500 miles in this country.

The apparatus and circuits of an automatic telegraph repeater at an intermediate station are outlined theoretically in Fig. 8. This is

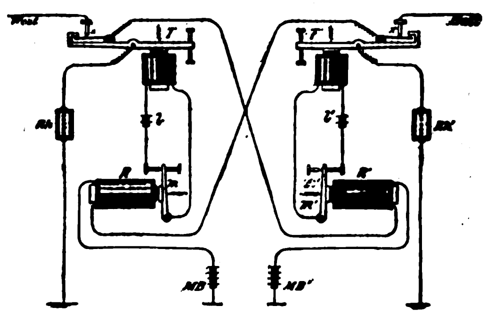

FIG. 8.—The Toye Repeater.

known as the "Toye" repeater, which was at one time much in use, and is chosen for illustration because of its comparative simplicity. It may be noticed that relay *R* controls the "continuity preserving" transmitter *T* by means of its armature lever *m*, and local battery *b*; while relay *R′* controls *T′* by means of lever *m′* and battery *b′*. Also that transmitter *T* controls the western main circuit at *x*; while *T′* controls the eastern circuit at *x′*. In practice *T′* is the "opposite" transmitter to relay *R*, and *T* is the "opposite" transmitter to *R′*. In the operation of an automatic repeater the desideratum is automatically to keep the "opposite" transmitter passive while its circuit is being repeated into, in shop phrase. The operation of the Toye repeater is as follows: Assume that the East is sending to the West. When the eastern operator opens his key, thereby opening the eastern circuit, relay *R* opens, as in the figure. This opens transmitter *T*, and in consequence the western circuit is opened at *x*. At the instant, however, that the western circuit is opened at *x*, the circuit which includes the relay *R′* and main battery *MB′* is closed via the lever of *T*, through a resistance *Rh* equal to that of the eastern circuit. As this transposition or substitution of circuits maintains the current passing through relay *R′* at the same strength as before the change of circuits was made that relay, and, consequently, the transmitter *T′* remains closed. In this way the "opposite" transmitter is automatically kept passive. When the eastern operator again closes his key, relay *R*, and in turn *T*, are likewise closed, resulting in the closing of the western circuit at *x*. When the West sends to the East the described actions are reversed.

Among the other automatic repeaters now in use may be mentioned, the Milliken, the Neilson, the Weiny, the Maver-Gardanier, the Atkinson, the Ghegan and the Varley.

Automatic Telegraph Systems.—Automatic telegraphy consists of arrangements of apparatus whereby Morse characters are transmitted at a rate of speed ranging from 80 to 2,000 or 3,000 words per minute. As the rate of speed by hand transmission of Morse characters is from, say, 15 to 40 words per minute, it is obvious that by the use of a rapid automatic system many more messages may be transmitted over one wire in a given time than by the manual method; and since the cost of construction and maintenance of the wires is a large portion of the expense of a telegraph equipment, if everything else were equal, the advantage would be largely in favor of the automatic systems. But, as frequently happens, everything else is not equal. In the first place, every message sent by an automatic Morse system has to be manually prepared for transmission by the automatic machinery, and every message received must be transcribed manually before its delivery to the addressee. This involves a larger force of operatives than is necessary to handle an equal number of messages manually. There is also greater delay in the handling of a message by reason of the additional number of clerks through whose hands it must pass. There is for the same and other reasons greater liability to errors by automatic transmission than by manual transmission. Nevertheless certain automatic systems, like the Wheatstone, for instance, are found of much utility.

There are two general types of automatic telegraph systems, namely, chemical automatic and ink recording, or embossing, automatic systems. The former relates to systems in which electrochemical action produces the records of the signals, the latter to systems in which, as the term implies, the signals are recorded by ink recorders.

Chemical Automatic Telegraphs.—At one time in Europe and in the United States chemical automatic telegraph systems were largely employed in commercial telegraphy, but at the present time its use is confined almost exclusively to recording signals in police, fire alarm and similar systems. (See ELECTRIC SIGNALING). The message for transmission by chemical telegraphy is usually prepared by perforating, in a paper strip, holes corresponding to the characters of the Morse alphabet. This strip is then drawn over a metal roller on which rests a steel needle or brush; the needles and the roller being made a part of the circuit in which there is a primary battery or other suitable source of electromotive force. As the paper is drawn along, the needle, or brush, drops into the holes in the paper, making contact with the roller and completing the circuit. In this way current pulsations corresponding in duration to dots and dashes are sent over the wire. At the receiving station there is a practically similar arrangement, except that the perforated paper is not used, but, instead, a strip of paper that has been immersed in a chemical solution is drawn over a roller.

Wheatstone Automatic Telegraph — This is an ink recording system. Its apparatus consists of a *perforating machine* by which messages are prepared for transmission; a *transmitter* which utilizes the perforated paper to transmit messages thus prepared, and a *receiver* which, being actuated by the electrical pulsations set up by the transmitter, records them in ink, on stiff paper tape, as dots and dashes. The *perforator* consists of small hollow cylinders with keen edges, in close proximity to which the paper to be perforated is caused to pass. Three discs, connected with these cylinders and representing the dot, dash and space, are depressed by the stroke of a mallet in the hands of an operator, with the result that holes of a certain order are punched in the paper. Thus when the dot disc is depressed, three vertical holes are cut; when the dash disc is depressed two vertical and two horizontal holes are cut, and when the space disc is depressed one central hole is cut, virtually as shown at the left of Fig. 9. The *transmitter* in its operation takes the place of the operator's hand and formulates dots and dashes with an accuracy superior to and at a speed 10 to 15 times greater than the most expert operator can attain. That portion of the transmitter apparatus actually employed in transmitting signals is outlined in Fig. 9. *L' L* are vertical rods attached at their lower ends to crank-levers *A' A*, respectively. By means of adjusting screws *F, F, L'* is set to the left of *L* a distance equal to the space between any two horizontal central holes in the paper. The crank-levers are provided with horizontal connecting rods *H, H'*, the right ends of which pass through holes in a centrally pivoted lever *M* and through supporting sleeves *x x*. *H, H'* are provided with collets *C, C'* which at certain times alternately engage with ends *P' D* of lever *M* and push them over. The springs *s s'* give the rods *L L'* a constant tendency upward, but their upward motion is checked by the pins *R' R* on the rocking beam *V*, which by suitable mechanism within the box on which the apparatus is supported is given a rocking motion. When the right end of the beam moves upward the spring *s'* causes rod *L* to follow pin *R*, and at the same time the connecting rod *H* pushes the strip *P'* on *M* against the upper contact 2 on a metal strip *N*; while concurrently the end *D* of *M* is brought into contact with the lower contact 3 on a metal strip *P*. The positive pole of a battery *B* is brought to strip *P*, the negative pole to strip *N*. The "ground" is connected with the lower

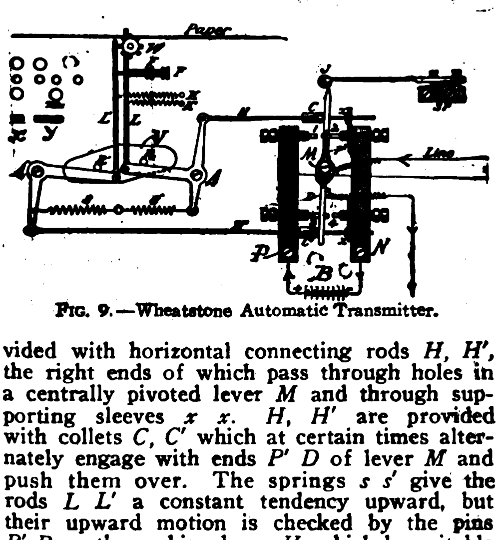

FIG. 9.—Wheatstone Automatic Transmitter.

end *D* of *M*; the line wire to the upper end *P'*; *D* and *P'* being insulated from one another. The lever *M* is really a pole-changing key and the rods and levers simply displace the operator's fingers, causing that key to reverse the poles of the battery. In the present position of *M* in the figure the negative pole of the battery is placed to the line. The perforated paper is shown by a single line and the rod *L* has passed through a hole in the paper. A revolving star-wheel *W* meshes with the central rows of holes in the paper and draws it along at a uniform rate of speed. Assuming there is another hole in the paper immediately opposite that one through which *L* has just passed, when the lever *L'* moves upward it will pass through that hole, the paper having been moved forward by the star-wheel just enough to bring the hole opposite *L'*. At the same time, by the downward motion of *L* the collet *C* has been withdrawn, giving collet *C'* on *H'* free scope to push *D* against its right contact, 4, and *P'* against the contact 1 which it will be seen reverses the polarity of the battery to line. If a succession of dot holes were punched on the paper, a succession of short positive and negative currents would pass over the line. When, however, a set of diagonal holes, as at *Y* in Fig. 9, is punched on the paper, the result is different, for at the first upward movement of *L* it will pass through the hole, pushing end *P'* of *M* to the right, but at the following upward movement of *L'* it meets the paper at a point opposite the hole through which *L* had just passed and its further upward motion is arrested. Hence *M* is not pushed over and the battery is not reversed. At the next upward movement of *L* its motion is similarly arrested and the polarity of the battery is still unchanged, until at the next upward movement of *L'* it comes opposite and passes through the hole *M*, causing the collet *C'* to push *D* against contact 4, thereby reversing the poles of the battery to line. This delay in the reversal of the battery is sufficient to make an appreciable difference in the length of the signal recorded, and constitutes a dash. The effect of these different actions is that, depending on the position of the perforations in the paper strip, dots and dashes are transmitted by the pole-changer *M*.

The Wheatstone automatic receiver, or ink recorder, consists of a polarized relay (see *Polar Duplex* in this article), the armature lever of which is extended at a right angle at its upper end, and this extension at certain times is caused to impinge against a light rod pivoted at one end. On the end of this rod is a small circular disc, the lower portion of whose periphery is immersed in an ink well; an upper portion of its periphery is placed very near the stiff paper tape previously mentioned. The axle of this disc is given a slight tension away from the paper. When, however, a current of positive polarity, designed to record a dot or dash on the paper, actuates the polarized relay, its extended armature lever presses against the axle of the disc causing it to deposit a mark on the moving paper tape. A negative current causes the withdrawal of the disc from the paper. The positive current in this system is termed a "marking" current; the negative current a "spacing" current, when it is operated by the «double current» or reversal of polarity method; to which further reference will be made in connection with *Duplex Telegraphy*, also in this article. The circular disc is kept in rotation by simple clockwork mechanism and thus constantly renews its supply of ink. The paper strip is drawn forward at a desired rate by rollers operated by mechanism within the box.

The Wheatstone automatic telegraph may be worked duplex by using a differentially wound relay and the other necessary apparatus of a duplex system. When worked as a duplex it gives a wire of moderate length, in which there are no very long submarine or underground cables, a capacity of from 200 to 350 words in each direction. On a 1,000-mile duplex circuit, such as from New York to Chicago, with one repeater station at Buffalo, a speed of about 125 words per minute in each direction is now obtainable.

Writing Telegraph Systems.— Writing or automatic telegraph systems transmit and record facsimiles of letters or characters while they are being formed by the stylus or pen in the hand of the operator. The first to produce a writing telegraph system was probably Mr. A. E. Cowper, of England, who employed in the operation of his system the principle of the parallelogram of forces, whereby by compounding the movements of a point in two directions, the one at an angle to the other, the actual movement of the point is the resultant of the two movements. The Telautograph (q.v.) also operates on this principle. In the Cowper system the receiving pen depends for its movements upon variations of the magnetism of two electromagnets placed at right angles to one another, which variations produce changes in their magnetic fields, to which changes an armature carrying the receiving pen is free to respond. The magnets are placed in separate circuits. The variations in the magnetic strength of the magnets are caused by variations of the current strength in their circuits, which variations are brought about by means of a pencil which when moved by the operator in the act of writing is caused to switch resistance coils in and out of the respective circuits.

Duplex Telegraphy.— This consists in the sending of two messages over one wire in opposite directions at the same time. Since on an ordinary Morse telegraph circuit it is not possible to send more than one message at a time over a wire, it is essential, in order to make duplex telegraphy possible, that the signals transmitted from the sending station shall not interfere with the signals to be received at that station. The receiving instruments must, therefore, be so constructed or so placed that while ready to respond to all signals from the distant station they shall not respond to signals from the near or home station. These requirements are met in two ways in practice; one method being known as the «differential,» the other as the «bridge» method. The differential plan is used almost exclusively on land line duplex telegraphy; the bridge plan is utilized exclusively on long submarine cable telegraphy. The «differential» plan avails of the fact that if a soft iron bar or core, *B* Fig. 10, be wound with two coils of wire — oppositely wound as shown — a current from a battery *b* will flow in opposite directions around

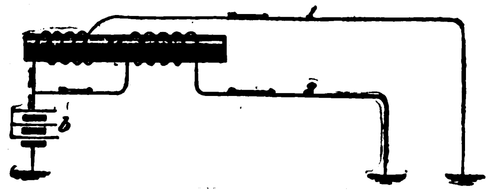

FIG. 10.—Theory of Differential Method.

the iron bar, and as each current tends to set up opposite magnetic poles in the iron, one current will neutralize the other and no magnetic effects will be produced in the core. If, however, another battery or source of electromotive force should be placed in the circuit of wire 1 at its distant or right-hand end, a greater amount of current will flow in coil 1 than in coil 2, and in consequence the core will be magnetized to a degree depending on the difference in the strength of currents flowing in the respective coils; hence the term differential, and a relay wound in this way is termed a differential relay. The theory of the «bridge» plan is outlined in Fig. 11. The battery, and

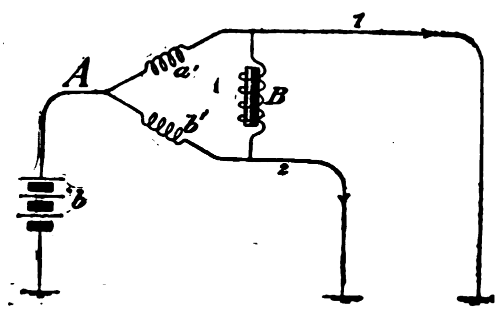

FIG. 11.—Theory of Bridge Duplex.

wires 1 and 2 remain as before, but the iron bar *B* is now connected between them and is wound with but one coil. *a′*, *b′* are coils of resistance, termed the arms of the «bridge» (Wheatstone bridge). Assuming the resistance of wires *a′*, *b′* and wires 1 and 2 to be equal, the electric pressure due to battery *b*, at the terminals of the bridge wire, will be equal and opposite, and hence no current will flow in the bridge wire.

There are two systems of duplex telegraphy in use in this country and elsewhere, namely, the «Stearns» duplex and the «Polar» duplex, and these combined comprise the Edison «Quadruplex,» described later.

The Stearns Duplex.— The Stearns duplex is operated by increment and decrement of current on the line, virtually as the single Morse system is operated, namely, by sending a current over the line to actuate the distant relay, which attracts its armature; and by removing the current from the line, whereupon the armature is withdrawn by its retractile spring. The near or home battery is prevented from affecting the near relay by winding the relays differentially. The theory of the Stearns duplex is shown in Fig. 12, which represents the apparatus at two stations, *A* and *B*. The relays *M, M'*, are wound with two coils in opposite directions around the cores; one of the coils of each relay being connected to the main line and the other to a rheostat, or resistance coils, *R, R'*. *K* and *K'* are transmitting keys. When key *K* is closed it puts a positive electromotive force to the line; when key *K'* is closed it puts a negative electromotive force to the line. When the keys are «open» the line wire is placed to ground. Since the battery current will divide between the two coils of the relay in proportion to the resistance of the circuits attached to each coil, a means must be provided to make those circuits of equal resistance, otherwise unequal currents will flow through the coils and the relays will be operated by the home battery. It is the function of the rheostats *R* to provide a resistance equal to that of the main line and the main line coil 1, of the distant relay, so that there will be a «balance.» In the figure, key *K* being closed and key *K'* open, a current flows as indicated by the arrows from *A* to *B*. As equal currents are flowing in opposite directions around the core of relay *M* its armature is not attracted. On the other hand, as there is a direct path for the current at *B* to earth, via the back contact of key *K'*, no current from *A* will flow through coil 2 of relay *M'*. Consequently, the core of *M'* is magnetized

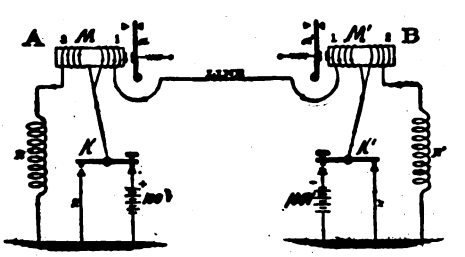

FIG. 12.—Theory of Stearns Duplex.

and attracts its armature *a'* as shown. If now key *K'* should be closed this would add 100 volts negative polarity to the main line circuit, making 200 volts on the main line, while it would place only 100 volts to the artificial line coil at *B*. Hence double the amount of current will flow in the line coils 1, of each relay, that flows through the artificial line coils 1 and 2. Thus the armature *a'* of *M'* is now attracted and armature *a* of *M* continues to be attracted.

The Polar Duplex.— This system also employs differential wound relays, transmitting keys and main and artificial lines similar to those of the Stearns duplex and for the same purposes, but the type of transmitting keys and relays is different in the two systems.

The relay employed in this system is termed a polarized relay (*E, E'*, Fig. 13) and is based on the fact that unlike magnetic poles attract one another, and that like poles repel one another. Then if one pole of a bar permanent magnet *a*, say its north pole *N*, be so pivoted that it may move freely toward the south pole *s* of an electromagnet *E*, it will follow that by changing the direction of the current flowing in the coils of the electromagnet, the permanent magnet *a* will oscillate between the poles in response to the changes of polarity in the electromagnet. If the permanent magnet *a*, which is virtually the armature of a polarized relay, be given control of a local circuit containing a sounder *D* and battery *b*, it may be caused to record signals in a manner practically similar to that in which the Stearns'

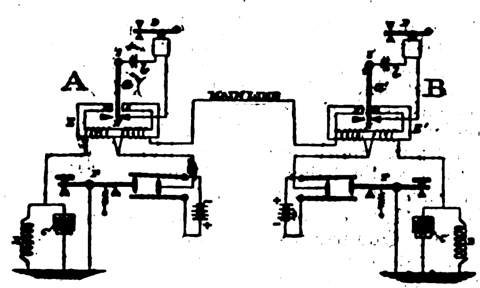

FIG. 13.—Theory of Polar Duplex.

relay records them. It is only necessary to provide a pole-changing key *F F'* to reverse the direction of the current flowing in the line, to bring about this result. Fig. 13 represents in theory the circuits and apparatus of a differential polar duplex; the apparatus and arrangement of circuits at the terminal stations *A* and *B* being indicated. When the «pole-changer» *F* is «closed» as at *A*, a positive pole of a battery is placed to the line and the direction of the current is as indicated by the arrows. When the key *F'* at *B* is closed, a negative pole of a battery is placed to the line. In these positions of the keys the direction of the currents in the main and artificial lines is as shown by the arrows, and the relays at both ends of the line are recording a signal, the sounders being attracted. This is due to the fact that an excess of current is flowing in the line coils of each relay in a direction to produce magnetic poles in the cores of the relays as marked. If now, for instance, the key *F'* at *B* should be opened the effect would be to place a positive pole of the battery to the line. The effect of this is that each end of the main line is placed at equal and like potentials, and hence no current flows over the main line or in the main line coils of the relays. A positive current from the battery at *A* with a strength of say 1 will still flow through artificial line coil at *A*, but in a direction which will reverse the previous polarity of the core; consequently the armature *a* of the relay is attracted to the left side and the local circuit of sounder *D* is opened. An examination of the conditions will show in every case that when the pole-changer at either end is opened or closed, the local circuits controlled by the armature of the distant relays will also be «opened» or «closed.» From which it follows that dots and dashes may be transmitted from both ends of the line simultaneously by a proper manipulation of the pole changers.

The instrument *C C'* shown at *A* and *B* is an electrical condenser. It performs a very useful function in duplex and quadruplex telegraphy as follows. The artificial line coils R R which are used to "balance" with are usually composed of spools of fine German silver wire, wound double, or non-inductively, so that they may not possess any perceptible magnetic effect or inductance. These coils have no static capacity. The main line it is known does possess static capacity. Hence at the moment of charging and discharging the line there is a momentary inrush and outrush of current into and from the line greater than that due to the ohmic resistance of the line. This would produce a momentary inequality in the current in the coils of the relays unless equal capacity were given to the artificial line. This is done by adding the condensers C C' to the artificial line. These condensers are adjustable and by means of metal plugs more or less capacity may be added until a static balance is obtained. The rheostats are also adjustable in order that the resistance balance may be readily obtained.

The Quadruplex (Edison).— The Stearns duplex depends for its operation upon the increase or decrease of the strength of current on the line, regardless of the direction (polarity) of the current, whilst the polar duplex depends upon changes in the direction of the current regardless of current strength. In the operation of the Edison quadruplex system both of these principles are combined on one wire; the instruments used being the transmitting key (transmitter) and Morse relay (the neutral relay) of the Stearns duplex, and the pole-changer and polarized relay of the polar duplex.

The relays are wound differentially for the purpose stated previously and rheostats, condensers, etc., are employed, as in the duplex systems described. In the Stearns duplex, when the transmitter is open there is no electromotive force to the line, the wire in that case being placed directly to ground. Since the polar duplex depends for its operation upon the reversal of polarity, provision is made for this requirement in the quadruplex by so arranging the connections of the transmitter K that when the latter is "open" a small portion, 1, of battery B is left in the circuit to be operated by the pole-changer PC. When K is closed, the full battery B is reversed by the

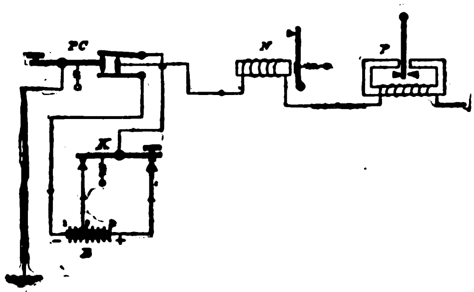

Fig. 14.—Theory of Edison Quadruplex.

pole-changer. On the other hand, when the small portion 1 of battery B is to the line, and only a weak current is traversing the line, the adjustment of the retractile spring is such that the armature a is withdrawn from the core; while, when the key K is closed, and the full strength of battery passes to line, the armature is attracted. Both stations are similarly equipped. Thus an operator may manipulate key K and the consequent increase and decrease in the current strength will operate the distant neutral relay N. But the operation of key K will not practically affect the distant polarized relay P, inasmuch as that key does not alter the direction of current on the line. On the other hand the pole-changer PC will operate the distant polarized relay, but will not operate the distant neutral relay. Thus two messages may be sent in opposite directions at once over a quadruplex circuit; this system, therefore, giving the equivalent of four wires from one. The three wires thus gained are termed "phantom" wires.

Many details of apparatus required in practice are, for lack of space, omitted here, but complete details of these systems are given in the author's 'American Telegraphy and Encyclopedia of the Telegraph,' from which work a number of the diagrams used in this article are reproduced with the consent of the publishers.

Submarine Cable Telegraphy.— The speed of signaling through an electrical conductor is inversely proportional to the product of its electrostatic capacity and the resistance. The capacity and resistance of a conductor increases directly with its length. The capacity also varies with the material comprising the insulating medium (see Electric Condenser). The high electrostatic capacity and the great length of submarine cables conduce to slow signaling. When a long cable is connected with a source of electromotive force the charge is communicated to the distant end almost immediately, but the amount of charge at first arriving is extremely small and the charge or current rises slowly thereafter to its maximum. The discharge is approximately as gradual as the charge. Hence a desideratum in submarine telegraphy is a receiving instrument that will respond to a very feeble current, for the weaker the current required the shorter will be the time of charging and discharging the cable, and the more rapid will be the rate of signaling. The first most successful receiving instrument devised for this work was the Thomson mirror galvanometer (see Galvanometer). The light from a lamp is thrown upon the mirror and the light is reflected back upon a screen. The mirror is carried on a suspension system including several very small magnetic needles, which are in the centre of a coil of fine wire, the coil being in the circuit of the cable. Minute pulsations of current cause the needles to be deflected to the right or left according to the direction of the currents. This causes the spot of light on the screen to be deflected to the right or left. A deflection to the right constitutes a dash, one to the left a dot. The direction of the deflections is regulated by a special form of key (K, Fig. 15) at the sending end (a tapper) by means of which positive and negative currents may be transmitted. The mirror receiver gives no record of the message, the signals being written down by the operator as they are received.

A later invention, the Siphon recorder, also due to Sir Wm. Thomson (Lord Kelvin) overcomes this objection. This instrument, outlined in Fig. 15, consists of a coil of fine copper wire, A, which is suspended between the poles of a powerful magnet, M, in such a manner that when a current passes through the coil it, like the needles in the mirror galvanometer, tends to place itself at right angles to the lines of force of the magnetic field. When no current is flowing in the coil, two small weights, w, suspended from the lower end of the coil, hold it in the plane of the magnetic lines of force of the magnet. A siphon C consisting of a very small glass tube is attached to the coil

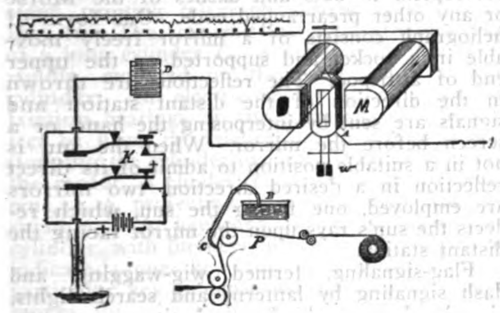

FIG. 15.—Theory of Submarine Cable Telegraphy.

by a fine wire. The lower and bent end of the siphon is placed directly over the centre, or imaginary zero, of a paper ribbon P. The double pole-changing key K sets up momentary pulsations of positive and negative currents through the coil the movements of which cause the lower end of the siphon to move to one side or other of the zero line of the paper. The upper end of the siphon dips in an ink-well B and, by an ingenious electrical arrangement, not shown in the figure, the ink is caused to spurt out at the lower end of the siphon upon the paper strip as a succession of very fine dots. Thus it is not needful that the siphon should touch the paper and in this way friction is avoided. A specimen of the signals as recorded by the siphon recorder is shown at the top of the figure.

For reasons not well known the earth's electric potential varies at different parts of the earth. Hence there is usually a difference of potential between the terminals of a long cable. This would tend to produce a current in a sensitive receiving instrument, which would deflect it to the detriment of signaling. To avoid this difficulty a condenser p is placed between the cable and the earth. This, so to speak, breaks the continuity of the circuit for slow changes of potential. When the condenser is once charged with the earth's potential, current ceases to flow into the cable and the receiving instrument comes to zero. The changes in the earth's potential occur comparatively slowly — from maximum positive to negative in perhaps five minutes. Consequently these changes are scarcely perceptible on the receiving instrument. The quick changes of potential due to the transmitter, however, produce currents of charge and discharge that operate that instrument.

Long submarine cables are usually duplexed, the «bridge» method of preventing the effect of the home transmitting key upon the home receiving instruments, being employed. An artificial cable consisting of strips of tin foil arranged to give resistance and capacity equal to the actual cable is employed instead of the rheostats and condenser used for the artificial line in overland duplex telegraphy.

Signals are now usually transmitted over long submarine cables by automatic transmitters somewhat similar to the Wheatstone transmitter; the messages being perforated in advance on a strip of paper. A speed of about 40 words per minute in each direction is reached on some of the newer Atlantic cables.

Simultaneous Telegraphy and Telephony. — This is sometimes erroneously termed «composite telegraphy.» The art relates to telegraphing and telephoning over one wire at the one time.

When a telephone receiver is inserted in an ordinary telegraph circuit the operation of the Morse keys deflects the diaphragm abruptly and produces loud noises in the telephone which render the reception of speech nearly impossible. Van Rysselberghe, of Belgium, discovered that if the rise and fall of the telegraph currents were made gradual no disturbing sounds would be heard in the telephone. To bring about this result he introduced into the telegraph circuit a combination of electromagnets and condensers, which by retarding the rise and prolonging the fall of the telegraph currents merely inflect the diaphragm of the telephone, but do not produce any sound thereby. When this result is obtained the telephone currents may then be superposed upon the telegraph currents without impairing the efficiency of the telegraph signals. Simultaneous telegraphy and telephony is now in successful use in the United States on a large scale; two telegraph circuits being operated as one telephone metallic (two wire) circuit, on circuits up to 400 miles in length.

Synchronous Multiplex Telegraphy.— It is known that 500 pulsations of electricity per second can be transmitted on an overhead wire of moderate length. A telegraph operator at his best speed is not capable of transmitting more than an average of 10 dots per second. Hence it was thought that if means were devised whereby a number of operators should consecutively be given exclusive control of a wire for brief intervals of time the same wire might be utilized to transmit four, six or more messages at practically the same time. In order that this might be done satisfactorily it was evident that the corresponding transmitting and receiving instruments at the near and distant stations should be placed in connection with the wire at identical instants. This entailed the construction of devices for obtaining exact synchronism; hence the name of the system.

The apparatus for obtaining synchronism and for apportioning the wire among a number of operators consists of a revolving wheel at each end of the telegraph line, the wheels revolving as nearly as possible at a uniform rate. Each wheel is driven by an electric motor whose motion is controlled by a vibrating reed at each station, which reeds are attuned to the same rate of vibration, as closely as possible. This wheel is supported on a vertical shaft. Below it is a stationary circular disc made up chiefly of a large number of metal segments (84) radiating from near the centre of the disc, and insulated from one another by suitable material. The shaft supporting the wheel passes through the centre of the disc. The shaft carries by a suitable projection a brush or trailer, which, as the wheel revolves, is swept over the segments in rapid succession. As the trailer makes three revolutions per second it comes in contact with each segment three times per second. If it is desired to transmit six messages at once, 72 segments are set apart for the purpose, and each of six desks at each end of the wire are allotted 12 segments. That is, starting from any given point on the disc, the first segment will be given to desk No. 1; the second segment to desk No. 2, and so on to the sixth segment, where two segments are skipped, being reserved for synchronizing purposes. A second series of six segments is then connected to desks Nos. 1, 2, 3, and so on around the disc. The line wire is connected to the shaft or trailer of the revolving wheel at each station, and, consequently, as the trailers make three revolutions per second, each desk of the six is placed in contact with the line, and with its corresponding desk at the distant station, 36 times per second. As an operator cannot make a dot in less than the one-twelfth of a second it follows that in that time the trailer will have given him contact with the line thrice. Hence each one of six operators may transmit messages as though he had entire control of the line. As each character received at any one desk is formed of a number of pulsations an arrangement of relays with a contact on the «back-stop» is employed which delivers the signals virtually unbroken at the receiving end. Synchronism is maintained by means of the two segments referred to which send «correcting» impulses that retard or accelerate the speed of the wheel that carries the trailer.

Dial Telegraphs.— Variously known as dial, A, B, C, and pointer telegraph system; due to Breguet, Kramer, Frischen, Wheatstone and Siemens-Halske. These systems employ a dial carrying on an outer circle the letters of the alphabet and on an inner circle figures and punctuation marks. A pointer operated by suitable mechanism within a case moves like the minute hand of a clock around the dial in response to pulsations of electricity from a sending instrument. The sending instrument has a similar dial and is equipped with a key which is movable around the face of the dial. As the key is thus moved it opens or closes a circuit, or it causes the movement of a magnet before coils of wire within the case, that transmits pulsations of electricity over the line, which in turn actuate, by means of an electromagnet, an escape wheel that moves the pointer as stated. The operator moves the transmitting key uniformly around the dial. As he does so the pointer on the receiving instrument moves a corresponding distance. When the key arrives at a desired letter the operator pauses. The receiving operator or attendant notes the letter; the sender moves his key to the next desired letter, and so on, in this manner spelling out his message. This system is slow, but it possesses the advantage of requiring little or no skill on the part of the user for its operation. Hence, especially before the days of the telephone, it was in favor as a means of communication between police and fire headquarters, on railroads, etc. As elsewhere stated telegraphs of this order are still in use in other countries.

Military and Naval Telegraph.— Heliography is quite extensively employed by the army and navy of this and other countries. The distance covered between any two stations is about 25 miles. Signals are transmitted by reflections of the rays of the sun, the duration of the reflections being made to correspond to dots and dashes of the Morse or any other prearranged code. One form of heliograph consists of a mirror freely movable in a socket and supported on the upper end of a tripod. The reflections are thrown in the direction of the distant station and signals are sent by interposing the hand or a screen before the mirror. When the sun is not in a suitable position to admit of its direct reflection in a desired direction, two mirrors are employed, one facing the sun, which reflects the sun's rays upon the mirror facing the distant station.

Flag-signaling, termed wig-wagging and flash signaling by lanterns and search lights, also by horns, whistles and sirens are employed by the various armies and navies of the world. Also Morse telegraphy and wireless telegraphy (q.v.). Torches at night take the place of the flag in signaling. In flag and torch signaling, as well as in heliography and lantern signaling the Continental Morse alphabet is now used. Arbitrary characters of this general type have long been used in needle telegraph systems in which a deflection to the left is represented by the figure «1»; a deflection to the right by the figure «3.» Thus A would be represented by «33» in one such alphabet, or two deflections to the right.

In wigwagging or torch signaling the flagman faces exactly toward the distant station; staff is vertical in front of centre of body, but at height of waist. When the Morse alphabet is employed, a dot is represented by a motion of flag or torch to right; the dash, a motion to the left; the space by a «front» motion. See SEMAPHORE.

Printing Telegraphy, Stock Tickers.— Printing telegraphy relates to those telegraph systems in which telegrams are printed as received on strips or sheets of paper. Generally speaking, printing telegraph systems of the stock ticker type depend for their operation upon the synchronous rotation of a wheel or cylinder at a receiving station with a typewheel at a receiving station. If, for example, two wheels of equal size having on their peripheries type letters of the alphabet are placed side by side and are caused to rotate, it is obvious that if they start with a similar letter at a given point, each wheel will continue to present a similar letter at the given point as long as the wheels rotate at equal speeds. It is, however, a difficult matter to obtain a continuous synchronous rotation of two or more such wheels or cylinders, especially when they are revolving at a high rate of speed, unless their movements are under control of some master wheel or transmitter. Consequently, in electrical printing telegraphy, controlling devices of this nature are employed. For instance, in the well-known «ticker» systems, the type-wheels of the tickers in the various offices are placed under control of a transmitter which maintains them in synchronism by a «step-by-step» movement, so called. In certain other printing telegraph systems, such as the Hughes, largely used in Europe, the uniform rotation of the transmitting and receiving wheels is maintained by a nearly synchronous rotation of the motors at each end of the circuit, and, in addition, by a «correcting» device applied to the type-wheel. See *Synchronous Multiplex Telegraph* in this article.

A theoretical diagram of a simple «step-by-step» printing telegraph system is shown in Fig. 16. The transmitting apparatus consists of a long cylinder *T*. A metal segmental *W* is rigidly mounted on the same shaft as the cylinder. An electric motor is mounted by friction bearings on the same shaft. The object of using the friction bearings is to permit stopping the cylinder instantly, without stopping the motor. Cylinder *T* carries a set of blunt pins, *p*, *p*, projecting in a spiral row from its surface. A keyboard is placed above the cylinder, with the keys directly over the pins as indicated; one key for each pin. When a particular key is depressed, its spur, or catch, moves into the path of a corresponding pin,

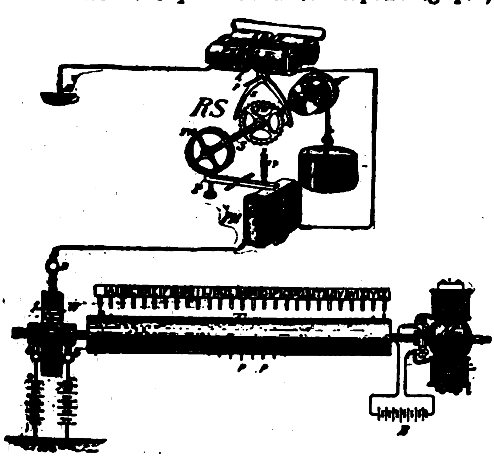

FIG. 16.—Theory of "Ticker" Telegraph.

thereby instantly arresting the cylinder. The wheel *W* is insulated in two parts or segments as indicated by the zig-zag line *i*. As the wheel rotates, portions of the respective segments (*s*, *s'*) alternately pass under brush *B*, with the result that momentary currents pass alternately from positive and negative batteries *b*, *b'*, giving the equivalent of an alternating current on the line.

The receiving apparatus or «ticker» proper, *RS*, consists of a polarized relay *PR* (see section *Polar Duplex*); an electromagnet, termed the «press» magnet *PM*; a typewheel *TW*, and an escape-wheel *EW*. A drum *D* by its weight *F* tends to rotate the shaft *S* on which *TW* and *EW* are mounted. The escape E is connected rigidly with an armature *A* of *PR*, and is pivoted at *P*. Relays *PM* and *PR* are in the same circuit, as shown. The line pulsations are of sufficient strength to oscillate rapidly the armature of the polarized relay, in consequence of which the escapement *E* allows the escape wheel and type-wheel to revolve rapidly. Owing to the greater inertia of the press magnet lever it does not respond to these rapid pulsations of current. When, however, the cylinder *T* is brought to rest, the steady current operates *PM* and its lever is sharply attracted and prints a letter.

Assuming that the wheel *W* sends out 32 electrical pulsations in one revolution these pulsations will cause one revolution of the type-wheel. Thus, if the transmitter be set in motion with brush *B* resting on the segment that is in line with, say, the pin under key *A;* while the letter *A* on the type-wheel is opposite the platen *P* on the end of the lever of the press-magnet, it follows that for every revolution, or part of a revolution, of the cylinder just enough pulsations will be transmitted to cause the type-wheel to present a letter opposite the platen corresponding to the key depressed. If the transmitter and type-wheel do not start with corresponding letters in the required position misprints follow. This is obviated by devices which bring the apparatus to a «unison» point after a few revolutions of the cylinder. The speed of rotation of this apparatus is about 120 revolutions per minute.

The apparatus shown prints letters only. When figures are to be printed, a figure wheel is placed on the shaft, side by side with the letter wheel, and a «shifting» device is employed which shifts the letter or figure wheel under the printing platen when a letter or figure is to be printed. Usually two wires are employed in the latter case, one to operate the «shift» apparatus.

In printing telegraph systems of the kind just mentioned, considerable loss of time ensues from the fact that frequently it is necessary to rotate the type-wheel the greater part of a revolution in order to print one letter. Thus, if the letter A follows B in a given word, it will require 31 pulsations of current to print A, assuming that there are 32 letters and punctuation marks on the type-wheel. If R follows C, 15 pulsations will be necessary. This conduces to a low rate of speed, perhaps an average of 30 to 40 words per minute; the message being printed on a paper strip.

Hughes' Printing Telegraph.—An understanding of the operation of this system may be gathered in a general way from the immediately preceding remarks. It is not, however, a step-by-step system, but depends for its operation on the synchronous rotation of two wheels, one at each end. When a key of the keyboard is depressed at the sending station it catches a pin on a rotating wheel, or *chariot*, but does not stop the wheel. The pin so caught, however, at that instant causes the transmission of an electric current over the line. This pulsation in turn instantly operates an electromagnet at the receiving end which trips a device that throws the paper strip against the letter on a type-wheel which at that moment is in the printing position, and, assuming the transmitting and receiving apparatus to be in synchronism, a letter corresponding to the key depressed will be printed at the receiving station. The synchronous rotation of the wheels is obtained primarily by means of a pendulum at each station which is adjusted and arranged to ensure a proximate rate of rotation to the respective wheels, but as the pendulums alone cannot be depended upon to maintain proper synchronism, a cam arrangement is provided which, every time a letter is printed, moves into a receptacle on the edge of the printing wheel and corrects the synchronism of the wheel, putting the wheel slightly forward or backward, as may be necessary. Pulsations of current are thus only transmitted over the line when a letter is to be printed.

Buckingham Page Printer.— To avoid the loss of time due to the rotation of a single type-wheel with many characters the Buckingham printer (in one of its forms) employs four very small octagonal type-wheels mounted side by side on one shaft. On the periphery of each wheel eight letters and other characters are placed, 32 in all. The shaft on which these type-wheels are mounted is so arranged that by an ingenious disposition of five electro-mechanically operated levers, it may be given both a lateral and a rotary motion such that any one of the 32 characters on the type-wheels may be placed before a given point for printing, by five pulsations of current. The selection and printing of any letter or punctuation mark are brought about by a cycle of six pulsations of current in all — that is, three alternations of

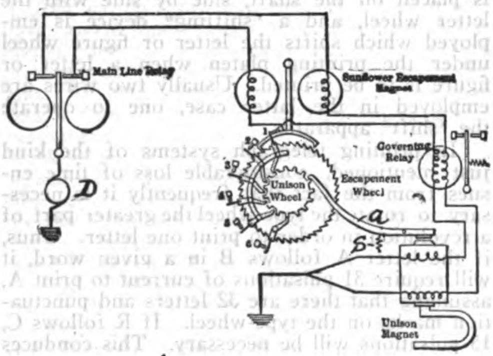

FIG. 17.—Buckingham Printing Telegraph.

polarity. These pulsations are of varying length, akin in this respect to the Morse alphabet. For example, the letter A will be selected by a dash, short space, dot, short space, dot; B by a dot, long space, dash, long space, dot, dots and dashes being made by positive currents, spaces by negative currents, as in the Wheatstone automatic telegraph (q.v.). The combinations of dots, dashes and spaces representing the different letters comprise what is known as the Buckingham alphabet. For the actual printing of a character the sixth pulse, corresponding to the space between letters and words in the Morse and Wheatstone systems, is utilized. This is always a negative pulsation. In the preparation of messages for transmission, and in the actual transmission of messages this system is almost identical with the Wheatstone automatic telegraph, and if the Wheatstone receiver were employed the messages would be recorded as dots, dashes and spaces.

The transmission of the six pulses of alternating polarity for each letter of the Buckingham alphabet operates a polarized relay in the main line at the receiving station, which relay by its armature controls two local circuits, in which are a governing relay, a unison magnet and an escapement magnet, the latter imparting, by means of an escapement, a step-by-step motion to a "sunflower," or distributor, of peculiar construction, to such purpose that, with the co-operation of the governing relay, and depending on the duration of the received pulses and the order of their arrival, one or more selecting relays are operated, and these, in turn, cause the operation of the type-moving levers which bring a desired letter on the type-wheel to the printing position. Hence the Buckingham printer is a positive or "step-by-step" system in which an escape-wheel, and with it the sunflower, is caused by a cycle of six pulses of current, one or more of which are prolonged, to undergo a cycle of six steps for each letter or character selected and printed. Consult author's ‹American Telegraphy and Encyclopedia of the Telegraph› for details of this system).

The Barclay Page Printer.— This system is a modification of the Buckingham page printer just briefly described. The operation of the Barclay printer up to the selecting relays is virtually similar to that of the Buckingham. At this point, in the Barclay arrangement the selecting relays, instead of operating the type-wheel shaft, are caused to select a given one of 30 or 32 electromagnets, each of which controls or operates a certain type of a typewriter which prints the letter; the message being printed by the typewriter in the ordinary way, by the aid of electrical devices. Messages may be transmitted by this system by means of a keyboard manipulated by an operator, or by means of perforated paper.

Murray Page Printer.— This printer is being used on the lines of the British Post-office. The messages to be transmitted are prepared somewhat as in the case of the method utilized in the Wheatstone automatic system. The perforated paper sends certain combinations of electrical pulsations for any given letter over a main line and these pulsations in turn operate apparatus at the receiving station which perforates a paper strip in a manner corresponding to the letters transmitted. This paper is then caused to pass before a set of metal strips which in their operation, and depending on the combination of perforations in the paper, select a certain letter of a typewriter, the message being thereby printed in page form. This system depends on synchronous movements of the transmitting and receiving apparatus, which is maintained by the action of the received pulsations upon apparatus in a local circuit at the receiving station. The speed of this system is about 103 words per minute. Consult Trans. Am. Inst. El. Engrs., 1901.

Baudot Multiple Printer.— This system is in successful operation on many of the telegraph lines of the French government. For its multiplex feature it employs devices practically similar to those described herein relative to Synchronous Multiplex Telegraphy. A keyboard is used, and letters are transmitted by depressing a given key which sends out the necessary combination of pulsations to reproduce a given letter at the receiving end, where by suitable selecting relays the given letter is selected and printed. The rate of signaling by this system is about 120 words per minute on one circuit. Consult Thomas' 'Traité de Telegraphique Electrique'; also *Electrical Review*, New York, 12 April 1899.

The Multiplex Printing Telegraph System. — In this country and in Great Britain a successful printing telegraph system based largely on the Baudot and Murray systems has been recently developed and by means of which eight and 12 messages are sent on one wire simultaneously at a rate of 40 and 30 words respectively, per minute.

A brief description of this system may be essayed here. In one respect it resembles the synchronous multiplex system previously described herein.

Thus it employs a number of insulated segments arranged circularly at each end of the circuit and over which a revolving brush or trailer is caused to pass. Instead of attaching a Morse key and relay to alternate segments of the circular disc, however, each of five consecutive segments of such a disc are connected at the transmitting end with a key, each key controlling a source of electromotive force, while at the receiving end of the circuit each of five corresponding consecutive segments of a segmental disc or ring is connected with a relay. There are four series of such consecutively connected keys and relays on the segmental discs. One or more of each series of keys may be depressed to form a certain combination of electric impulses representing a given letter, which impulses are transmitted by the trailer over the circuit and in turn these impulses operate a corresponding series of relays at the receiving station. These relays by their armature operate mechanism whereby a desired given letter is selected and printed in page form. As there are four series of keys and relays attached to the segmental discs it will be clear that four letters of four different given words or messages may be transmitted at every revolution of the trailer around the disc. The rate of transmission of words will then depend on the speed of rotation of the trailers, and this in turn is largely controlled by the mechanical and electrical limitations of the apparatus and line. In the Baudot system a keyboard is used to transmit a prearranged combination of electric impulses to form a letter. In the multiplex printing telegraph system under consideration the messages are transmitted by perforated paper strips, operating a transmitter, somewhat as described herein in the case of the Wheatstone automatic system. In the multiplex printer the paper is perforated by a keyboard perforator manipulated by an operator at a speed slightly greater than that of the automatic transmitter of the printer, and the paper there prepared is fed directly from the perforating machine into the said transmitter. By the foregoing arrangement four "channels" are provided on one wire and as the wire is duplexed in the manner described herein in connection with the Morse duplex system the equivalent of eight channels is obtained on one wire. As each channel may be operated at the rate of 40 words per minute a total of 320 words per minute is thus obtainable in practice on long circuits, the messages being printed in Roman letters on regular telegraph blanks in page form. Means are provided for the maintenance of exact synchronism between the transmitting and receiving trailers over their respective segmental discs — analogously as in the synchronous multiplex Morse system, but greater refinement of apparatus and operation is necessary in the multiplex printer. Obviously this must be so from the fact that in the multiplex printer means are provided for operating the typewriter carriage, printing the letters, etc.

The code or alphabet employed in this multiplex printing telegraph system is virtually similar to the Baudot alphabet. It is known as a five equal unit alphabet, that is, five impulses of positive or negative current are combined to form a given letter. Thus the letter *A* is assigned two positive and three negative impulses, *B* one positive, two negative and two positive units. Each current impulse in the Baudot code is of equal length and by different combinations of the five impulses it is possible to form 31 letters or characters. In the Morse code the dots and dashes representing letters and figures are of varying lengths, and hence a letter of the Morse code may consist of from 1 to 12 units. The average number of units in a letter of the continental Morse code is practically nine units per letter. It has been calculated that this disparity in the two codes results in an advantage for the Baudot alphabet in practice of about 65 per cent over the Continental Morse alphabet in the rate of transmission over circuits of equal length.

This multiplex printer rendered most efficient service in France under the direction of the United States Signal Corps.

Miscellaneous Telegraph Systems.— In addition to the telegraph systems referred to herein, many others have been in actual operation during the past century, either experimentally or commercially, among which may be mentioned the electrostatic systems of Lomond, Reusse, Reizen, Don Silva, Betancourt, Cavallo; Ronald's synchronous system; the electrolytic systems of Soemmering and Coxe; the chemical facsimile systems of Caselli, Bakewell, Denison and Bonelli's chemical printer; the chemical dot and dash systems of Bain, Morse, Anderson, Delany, Dyar; the electromagnetic systems of Alexander, Gauss and Weber, Steinheil, Schweiger; the needle systems of Wheatstone and Cooke, Davy; the dial systems of Siemens, Breguet, Kramer; the printers of House, Hughes, Phelps; the Meyer multiplex; the Mercadier multiplex and the Alteneck mechanical automatic system.

Telegraph Systems in Practical Operation.— Wherever the electric telegraph is employed the Morse system is the one most generally utilized. In some countries such as the United States and Canada, Sweden, Portugal, Switzerland, Egypt, Bulgaria, New Zealand, India, Australia and South America, the Morse system is used almost exclusively. In Great Britain, Italy, Russia, France, China, Japan, the Morse and the Wheatstone automatic, which is simply a fast Morse system, are largely employed. In Austria, Belgium, Great Britain, Hungary, Sweden, Russia, France, the Hughes printer is in extensive use. In France the Baudot printer is utilized; also in Italy, Holland and Switzerland to a limited extent. In Great Britain, about 750 Morse ink recorders; 925 Bright's

Bell; 5,000 A B C telegraph, 30 Delany multiplex and 4,700 single needle apparatus are in operation. All told there are approximately 70,000 Morse sets in operation in the United States and Canada, and 45,000 in all other parts of the world. There are in Europe about 1,700 Hughes apparatus, and in Europe and elsewhere about 530 Wheatstone automatic sets in operation. Needle systems; A B C and Bell apparatus are quite largely used in Europe on the railroad and commercial telegraph lines. A page printing telegraph system, termed Morkrum Printer, is also in extensive use in the United States.

It may be remarked that there is a desire on the part of the telegraphing public in all countries to receive telegrams in type and in page form, and as far as practicable the various telegraph administrations are endeavoring to comply therewith. In the United States, as already intimated, the Morse operators in numerous instances transcribe messages by the typewriter as received. In Great Britain the Murray page printer has been adopted by the government, and in Europe generally, where messages are received on paper strips as by the Hughes and Baudot systems, the strips are pasted on blanks in page form, for delivery.

Speed of Different Systems.— The average speed of transmission by the Morse manual telegraph may be placed at about 20 to 25 words per minute, although skilful operators attain a speed of 45 and 50 words per minute. The speed by the Wheatstone system on short lines is about 500 to 600 words per minute. By the Hughes an average of about 30 words per minute in one direction is obtained. This system may be duplexed, giving 50 words per minute on one wire. By the Baudot system, operating as a quadruplex, 120 words per minute; as a sextuplex, 180 words per minute. By the Buckingham and the Barclay systems a speed of 80 words per minute, in each direction, may be obtained on circuits from New York to Chicago, with repeaters midway. By the Murray printer, about 80 to 100 words per minute in each direction may be obtained.

Mileage of Telegraph Lines, Wires and Submarine Cables.— In the United States the total amount of pole lines is about 238,000 miles, on which about 1,270,000 miles of copper and iron wire are erected. In Canada there are about 35,000 miles of lines and 84,500 miles of wire. In both cases the various railroad companies also operate a considerable amount of telegraph line (about 250,000 miles of wire) for the movement of trains, etc. In all other parts of the world there are approximately 435,000 miles of telegraph pole line and 1,450,000 miles of wire, exclusive of about 48,000 miles of pole lines and 216,000 miles of wire controlled by railroads. The average size of the copper wire used on telegraph pole lines is No. 12 or 14 B. & S. gauge; that of iron wire, No. 6 or 8. The nature and size of the poles varies in different countries. Cedar is largely used in the United States and Canada; fir in Europe. Poles 30 to 40 feet long and set five feet in the earth are used. Thirty to 40 poles to the mile has been common practice, but the tendency in this country is toward the use of 45, 50 and more poles per mile to obtain greater security against sleet and wind storms. Iron telegraph poles are used in some countries.

The amount of submarine cables in all parts of the world is about 200,000 miles. Of this amount about 27,500 miles are owned and controlled by governments; the remainder is owned and operated by private companies. In all there are about 1,000 submarine cables of varying length in different parts of the globe.

While, as stated, the telegraph systems of the United States and Canada are mainly operated by private companies, the governments of both of these countries have constructed and laid for their own purposes many miles of overhead lines and submarine cables. Thus the United States government has constructed its own telegraph lines and cables in Alaska and the Philippines. The Alaskan lines extend from Seattle, Wash., to Nomé, Alaska, a distance of 3,625 miles, including 1,439 miles of land lines, 2,079 miles of submarine cable and a wireless circuits of 107 miles in length. The government handles private commercial messages on these lines at a regular fixed charge. The Canadian government owns and operates about 3,900 miles of land lines and cables. The bulletins giving the movements of fish in the waters of the Gulf of Saint Lawrence and other shore lines, together with messages relating to weather, quarantine and signal service, are transmitted free of charge.

Administration of the Telegraph.— The administration of the telegraph is to-day in the hands of the government in all parts of the world. The actual management of the telegraph systems of the various countries of the world is, of course, in the hands of the proper authorities of those countries, but, in general, the disposition of all matters that relate to the regulation of international telegraph traffic, such, for instance, as the maximum number of letters that shall constitute a word, the alphabet to be used, etc., is reposed in the hands of the International Bureau of Telegraph Administrations, Berne, Switzerland. In fact, however, even the United States and Canada incidentally come under the control of this bureau in so far as relates to the intercommunication of telegrams with countries under the jurisdiction of the bureau. Thus if the bureau decides that the maximum number of letters in a word for telegraph purposes shall be 10, the countries mentioned must perforce comply with that regulation as regards telegrams that may be destined for or that may emanate from territory wholly within the jurisdiction of the international bureau.

William Maver, Jr.,
Author of ‹American Telegraphy and Encyclopedia of the Telegraph.›

TELEGRAPHY, Submarine Sound, a system of communication between steamships at sea by sound telegraph through water. In 1901 A. J. Mundy tested an experimental boat in Boston Harbor, based on experiments in the conductivity of sound through liquids by Prof. Elisha Gray. Experiments by J. B. Millet proved remarkably successful. Signals were exchanged between lightship bell and a ship seven miles distant at sea. Sound travels faster through water or liquids than air, and this is taken advantage of in a practical way. In the ship at sea are two sound receivers, one upon each side in the hold, located approximately 20 feet below the surface of the water. The lightship has the sounding bell hung through a well in the centre of the ship, about 25 feet below the bottom. It also has a receiving apparatus. Near the lighthouse on shore is a buoy from which depends a bell, with a pipe leading to the shore to a compressed-air reservoir in the lighthouse. The bell is suspended by a main chain, while a second operating chain is attached at its lower end to the bell crank of the hammer, and the upper end to a pneumatic piston, which is operated by compressed air either from the anchored lightship or the lighthouse, as the case may be, or it may be operated by a direct upward pull by manual power if desired. It has been ascertained that the receiver for collecting the sound vibrations need not be located on the outside of the vessel, but operates as well when clamped on the inside against the inner surface of the outer hull, especially in iron ships. The sound vibration from the bell passing through the water is communicated to the side of the ship's hull, and that in turn to the liquid or water in the receiver; which is a cup-shaped metal cylinder having the open end clamped against the side of the hull. Inserted in the top of the receiver is an electric transmitter, something on the order of a telephone transmitter, from which wires are run to the pilot-house of the ship. As the sound travels through the water in every direction from its source, it is found that the impulse will be stronger and louder on the side of the ship nearest to the source. By this means the direction of the sounding bell is ascertained, for by listening to the telephone receiver attached to the starboard side water receiver, and then switching over to the port side and listening to that telephone receiver, the ear detects at once which is the louder sound of the two. This was determined experimentally by turning the ship around in a large circle. In foggy weather, signals of this kind are readily heard, regardless of which way the wind is blowing. The usefulness of the system in safeguarding ships against collisions at sea at night or in a fog is evident. Simon Lake, inventor of the Lake submarine boat, has experimented with under-water telephony with considerable success and applied it to his undersea craft.

TELEGRAPHY, Wireless. During the past 20 years attempts have been made, with more or less success, to avail of electromagnetic induction for signaling to a distance without wires, by means of what have been termed induction telegraph systems. Such systems employ in their operation the well-known principle that when an electric current is rising or falling in one wire it will develop by induction a current in a neighboring parallel wire. Phelps and Edison have employed this principle in signaling to and from moving trains. These systems were in operation for a time on several railroads in this country, but were eventually abandoned for lack of patronage. Preece also, in Great Britain, devised and had in operation a wireless induction telegraph system. In the Preece system a wire several miles in length is strung on poles along the coast of the mainland, a parallel wire being erected on poles along the shore of an island. These wires are placed in the earth, or «grounded,» at their respective terminals. By employing a battery, an induction coil and a Morse telegraph key in one of the wires, and a telephone receiver in the other, it is feasible to transmit signals by induction (possibly assisted by conduction through the water), without connecting wires, across an intervening space of two to four miles. In the operation of these induction telegraph systems from 50 to 300 electromagnetic pulsations or waves per second are utilized.

Notable as the results obtained by induction telegraph systems were considered at one time, they have been completely overshadowed by those systems in which electric waves or oscillations of a much higher order, namely, from many thousands to several millions per second, are utilized, and to which systems the term «wireless telegraphy» is now generally applied. The term «radio telegraphy» is, however, also much used.

The growth of present-day electric wireless telegraphy has been comparatively slow and the discovery and development of the art can scarcely be placed to the credit of any one mind. In 1864 Clerk-Maxwell demonstrated mathematically the electromagnetic theory of light, which in effect is that electromagnetic manifestations are due to undulations of the all-pervading ether, of a nature more or less similar to the undulations of the ether which produce the manifestations of light, and that, in so far as they differ, it is mainly a difference as to the number of oscillations per second, the undulations that produce the sensation of light occurring, for instance, at the rate of from four hundred million of millions per second, to seven hundred million of millions per second; while, as just intimated, the electric undulations may not exceed a few millions per second.

After the announcement of the electromagnetic theory of light, which involved the existence of electric waves in free space, many scientists endeavored to demonstrate experimentally the truth of the theory. This honor fell to Prof. H. Hertz in 1887. It had been shown by Professor Henry in 1842 and by Sir William Thomson (Lord Kelvin) in 1853 that when a Leyden jar or other highly insulated condenser is discharged, the previous charge is not dissipated in one rush, but gradually, in a series of oscillations.

It is well known that in an electric circuit containing coils of wire the current is perceptibly retarded in rising and falling, which fact is due to a property termed inductance, which all conductors possess. On the contrary, when a wire possesses electro-static capacity the current is assisted in rising and accelerated in falling. The property of inductance is usually likened to inertia, while capacity is likened to elasticity, in mechanics. The shortest electric wave thus far produced is about .15 inch in length. This is still much longer than the longest light-wave and 60 or 70 times longer than the longest dark heat wave yet measured. In the electric circuits employed in wireless telegraphy the resistance is small. In fact, if the resistance be too great the discharge will not be oscillatory. The time of an oscillation period is expressed by the formula

$T = 2\pi\sqrt{KL}$; where T is the time in seconds, π is ratio of circumference to diameter (3.1416), K is capacity in farads, and L the inductance in henrys; resistance R being neglected.

In proceeding with his experiments, Hertz reasoned that, analogously as light-waves affect the eye when they fall upon it, so should electric waves in the ether affect a suitable «eye» or detector when they fall upon it. The apparatus employed by Hertz to show the existence of electric waves in the ether of free space consisted of an electric oscillator for setting up electric waves in the ether, and an electric resonator to detect the waves. The circuit in which electric oscillations are set up emit electric waves in the ether. The Hertz oscillator and detector are shown in Fig. 1. The generator of the oscillations consists of an induction coil *I*, the terminals of its secondary wire being connected to small metal balls *b, b*, to which short metal cylinders, or wings, *w w* are attached. The balls are separated by a small air space, or spark-gap *s*, across which sparks jump when the coil is in operation. The vibrations of the interrupter *a* set up pulsations of current, due to battery *B*, in the primary circuit of the induction coil, which pulsations, by magnetic induction, cause alternations of greatly enhanced electromotive force in the secondary circuit. When the electric pressure rises to a point sufficient to break down the resistance of the air space between the balls *b, b*, oscillations surge back and forth in the oscillating circuit *w, b, s, b, w*, the rate of which oscillations will vary with the electrical dimensions of the circuit, namely, inductance, capacity and resistance. The rate at which the interrupter of an induction coil vibrates may vary from 50 or less to hundreds of vibrations per second. The oscillations of the electric oscillator may be many millions per second. It is evident, therefore, that the induction coil, or other alternating current generator, merely serves to strike the blow, so to speak, that sets up the rapid electric oscillations in the oscillating circuit, analogously as when we wish to keep a tuning-fork in vibration we must strike it at intervals. As a detector, Hertz employed a copper wire of circular shape, but broken at one point. On the ends of this wire he placed small metal knobs, *d*, the distance between which could be regulated by a micrometer screw. This wire was supported on an insulating stand in a darkened room and small sparks could be seen passing between the knobs *d* when oscillations were established in the oscillating circuit *w, b, s, b, w*. The results of this experiment were held to demonstrate the existence of electric waves in the ether, as predicted by Maxwell.

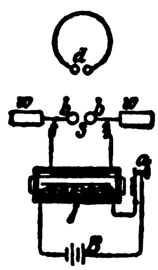

FIG. 1.—Oscillator and Detector.

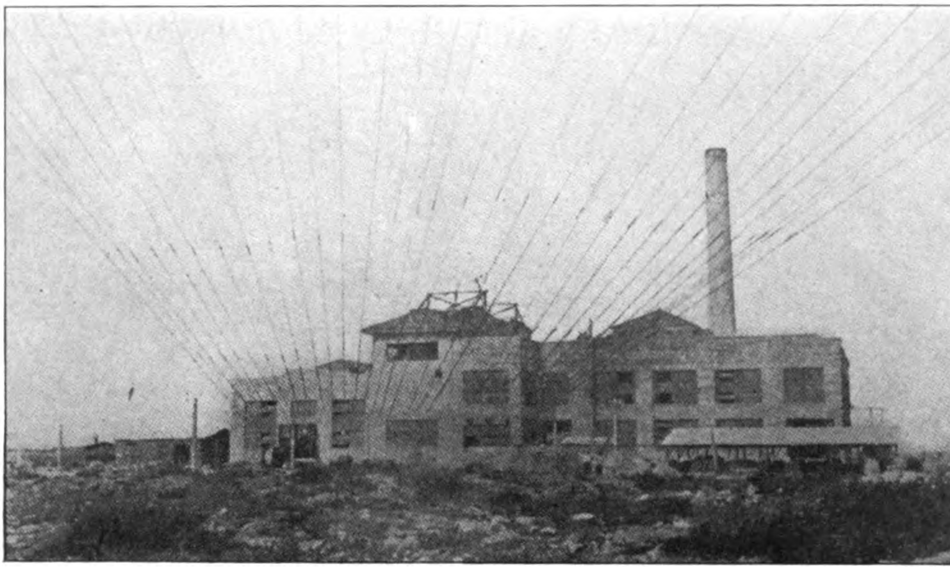
The distance at which electric waves are detected by the Hertz devices is very limited, perhaps not more than 10 or 12 feet at most. These devices, however, demonstrated the possibility of signaling to a distance by electric waves. Not long after the announcement of Hertz's experiments, Dr. Branly discovered that metal filings, when thrown together loosely and made part of an electric circuit, have normally a high resistance, but under the influence of electric oscillations they lose this resistance and become good conductors of an electric current. It is assumed in explanation of this effect that the electromotive forces that accompany the electric oscillations in the circuit cause the filings, by electrostatic attraction, to cohere, thereby making a better electrical contact with one another, thus reducing the resistance of the circuit; hence the application of the term «coherer» to this type of electric wave detector. It was also found that when the filings had cohered they retained their electrical conductivity until they were jarred, or otherwise mechanically disturbed.

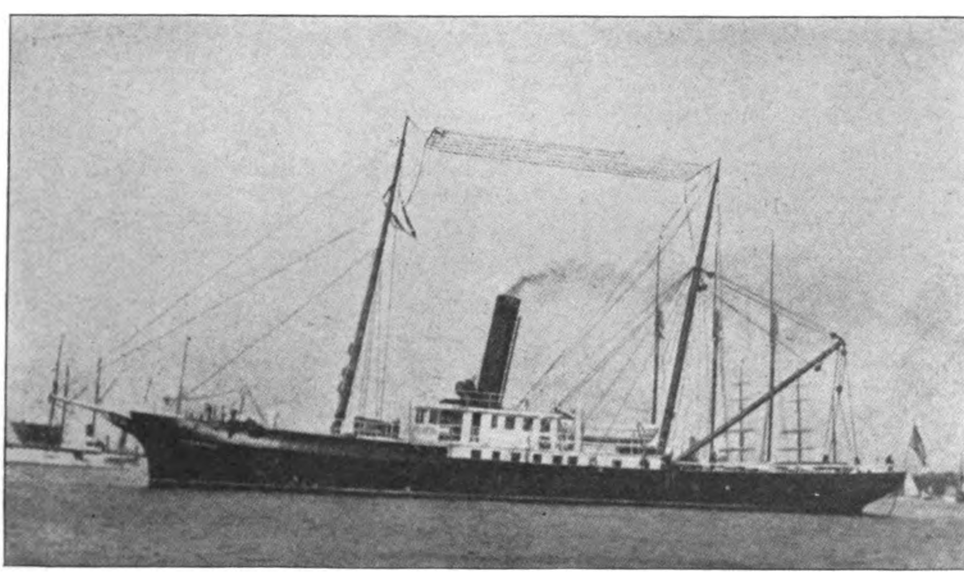
In 1894 Dr. O. Lodge (now Sir O. Lodge), in a lecture before the Royal Society, London, showed that the filings coherer could be used to transmit signals telegraphically by placing them in a glass tube and making them part of an electric circuit in which were a battery and a telegraph receiver. In this experiment when the induction coil was operated at a distance of some yards from the coherer the latter was actuated. In order that the filings should not remain cohered after the oscillations had ceased, the hammer of a bell operated by clock-work was caused to strike or tap the glass tube as long as the electric oscillations continued. An electric bell has generally been employed in the later use of the filings coherer. In 1895–96 Popoff and others utilized the filings coherer as a means of detecting atmospheric electricity, employing for this purpose a vertical wire extending many feet into the air, the coherer being placed between the lower end of the vertical wire and the earth.

Theories of Electric Wave Propagation.— Obviously substances opaque to light obstruct the passage of the luminiferous ether waves. Analogously it was thought in the early days of electric wireless telegraphy, that the curvature of the earth or sea between points several hundred miles apart would prove a barrier to electric waves traveling, like light-waves, in straight lines, inasmuch as it would not be practicable to obtain masts, or other means of support for vertical wires, of sufficient height to overlook the barrier. Later experiments showed that with wires only 200 feet high signals could be transmitted to points between which there was a wall of earth or water 15 or 20 miles in height, due to the curvature of the earth. A number of theories have been advanced in explanation of this fact. For example, that the waves are propagated around the earth by diffraction or reflection, but these theories are not generally held to be tenable. A theory that meets with most acceptance at present is that the electric waves are propagated as sliding waves over the surface of the earth or sea.

Brief allusion may be made to the supposed action that takes place in and around the Hertz oscillator in the production of free electric waves in the ether. The Hertz oscillator corresponds to a condenser with widely separated plates. In the act of electrically charging the arms or rods of the oscillator, lines of force or strain spring out all around the rods in the dielectric, that is, the air surrounding the rods. To fix ideas these lines of force may be likened



Typical power plant of a Marconi long-distance station, showing aerial wires leading into the building



The Yankee Salvage Association's tug Forward, which sends ashore the press reports to the vicinity of New York Harbor

to highly elastic hoops, partially flattened out, and with their ends resting on the rods. One end of the lines of force is assumed to be positive, the other negative. These hoops or lines resist straightening out and their resistance to the strain increases the further they are straightened out, until their back pressure equals the charging force. According to Maxwell's theory of displacement currents in dielectrics, during the process of applying this strain a displacement current flows in the circuit, and when the counter pressure of the lines equals that of the charging force the displacement current ceases to flow. At this time the rods of the oscillating circuit have acquired the potential of the charging electromotive force. When the external electromotive force reaches a point where it breaks down the resistance of the air gap, the energy stored in the dielectric is returned to the circuit and a current flows across the gap and the strain in the dielectric is thereby relieved, concurrently (Poynting) with which the ends of the lines of strain contract, one end sliding down the rod, the other gliding up the rod toward the air gap. The extreme outside portion of the lines also tend to contract, but as such portions of the lines move more slowly than the ends, the latter meet, and as they cannot pass one another, the lines are snapped or whipped off, perhaps like rings of smoke from the smoke-stack of a locomotive, forming closed electric lines of force which are radiated into space. Coincidentally also with, and as a result of, the collapse of the electric lines of force, magnetic lines of force are set up concentric with the Hertz rods and at right angles to the electric lines of force. When the magnetic lines of force reach their maximum the electric lines of strain will have vanished. Immediately, however, the magnetic lines of force now begin to collapse and are detached, their collapse setting up new electric lines of strain. These processes are repeated until the oscillations cease, to be renewed when the rods are again charged and the spark gap again breaks down. The detached lines of force thus jointly constitute electric radiation, or free electric waves which are propagated as ever-expanding electromagnetic waves in free space. Any portion of these waves on reaching a receiving vertical wire excite therein the electric oscillations which affect the coherer or other detector.

Theory shows that the grounded vertical wire may be considered to be equal to one-half of a Hertz oscillator (Fig. 1). The other half being the ground itself. On this assumption the earth is a perfect conductor — therefore a reflector of high frequency electric waves — and the vertical wire may be supposed to have a reflected counterpart below it, virtually like the image seen under a pencil standing vertically on the surface of a mirror lying horizontally on a table. This is in accordance with what is termed the image theory, advanced by Delaricci and Blondel. The electric oscillations in such a system may then correspond to those in the Hertz oscillator, a complete oscillation consisting in a wave from the spark-gap to the top of the antenna back to the spark-gap, thence to the foot of the reflected or imaginary wire and back to the spark-gap, which constitutes a wave length four times that of the vertical wire proper.

Marconi's Early Experiments and Work. — The Lodge experiments in 1894 were followed by those of G. Marconi of Italy in 1895. In these experiments Marconi employed an induction coil, a Morse telegraph key, batteries and vertical wire, for the transmission of signals, and for the reception of signals, a filings coherer, a telegraph relay, batteries and vertical wire. The general arrangement of Marconi's simplest apparatus is outlined in Figs 2 and 3. In Fig 2, *I* is the induction coil, *a* is its interrupter, *p* is the primary wire, *s* is the secondary wire of induction coil, *B* is a storage battery of about five cells. *K* is the Morse key; *b b'* are the spark balls. The vertical wire *A* at its lower end is connected to ball *b*; the other ball *b'* is connected with a wire leading to the earth. Balls *b b'* of the oscillator are thus in series with the vertical wire. The terminals *w w'* of the secondary wire are also connected respectively to *b* and *b'*. The receiving apparatus is

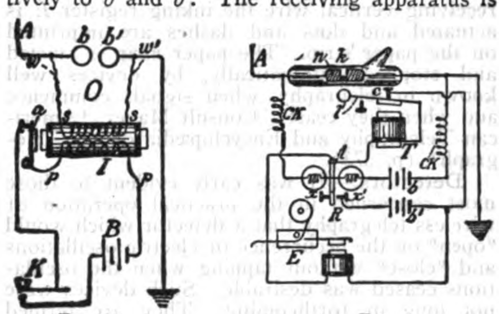


FIG. 2. FIG. 3.

Marconi Earlier Experiments.

outlined in Fig. 3. The Marconi filings coherer is shown at *k*. It consists of a glass tube, suitably upheld, about 1.57 inches long and .1 inch inside diameter. The filings, a mixture of 90 per cent nickel and 10 per cent silver filings, are inserted in a small space between two plugs *n*, which fit snugly into the tube which is exhausted of air. Small wires extend from these plugs to the outside of the tube. One of these wires is connected with the vertical wire *A*, the other with a wire leading to the earth. Hence the coherer is in series with the vertical wire. The relay *R* is in a shunt circuit with a single cell of battery *b* and the coherer, as shown. The armature lever *l* of this relay controls the local circuits of the electric bell *T* and an ink recording register *E*, which are operated by local battery *b'* of four or six cells.

The actual transmission of messages is effected by means of key *K*, Fig. 2. Each time the key is closed the vibrator *a* starts into operation with the result that electric oscillations are set up in the vertical wire and a train of electric waves is radiated therefrom in the ether. Thus by opening and closing the key for a shorter or longer time the train of waves is broken up into signals corresponding to dots and dashes which are received as such at the receiving station. The operation at the receiving station is practically as follows: Normally the armature lever *l* of the tapper *T* is given a tension which holds it against the contact *c*. Normally, also, the armature lever *l* of relay *R* is on its back stop *x*. Hence at this time the local circuit of battery *b'* is open. When then the electric waves set up by the oscillator arrive and electric oscillations are thereby excited in the vertical wire at the receiving station, the resistance of the coherer drops sufficiently to allow the battery *b* to energize the relay *R* and its lever *l* moves over to contact *x'*, closing thereby the circuit of battery *b'*, whereupon the electromagnet of tapper *T* attracts its armature *l'*, which act opens its own circuit at contact point *c*. At once the armature of *T* flies back on its contact point, at the same time striking the tube, decohering the filings and demagnetizing relay *R*, whose armature lever returns to its back stop *x*. Immediately, however, the filings again cohere (assuming that the oscillations continue), with the result that *R* is again magnetized, the actions just described being repeated many times in a second. Hence, while the oscillations are being received the tapper keeps up a buzz or hum, which stops when the oscillations cease. Likewise, while the oscillations continue in the receiving vertical wire the inking register *E* is actuated and dots and dashes are imprinted on the paper strip. The paper strip is started and stopped automatically, by devices well known in telegraphy, when signals commence and when they cease. Consult Maver, 'American Telegraphy and Encyclopædia of the Telegraph' (p. 373).

Detectors.— It was early evident to those most concerned in the practical operation of wireless telegraphy that a detector which would «open» on the occurrence of electric oscillations and «close» without tapping when the oscillations ceased was desirable. Such devices were not long in forthcoming. They are termed detectors.

One of the first detectors used in wireless telegraphy is due to Castelli. Detectors have also been devised by Marconi, DeForest, Fessenden and others. The Castelli detector is outlined in Fig. 4. It consists of a glass tube

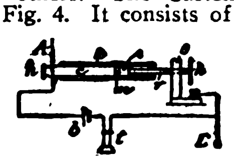

FIG. 4. — Castelli Detector.

K, 1.7 inches in length, a carbon rod *c*, a plug of iron *i* within the tube, and a small drop of mercury *m*, placed between *c* and *i*. The rod *c* and plug *i* are adjustable within the tube by the screws *h*, *h*. *A* is the vertical wire which is made a part of the coherer circuit. A telephone receiver *t* and a small battery *b* are placed in a shunt circuit around the detector. Normally, the imperfect contact between the mercury and the carbon causes a high resistance in the detector, but when electric oscillations occur in the circuit the mercury and the carbon cohere and the resistance falls. The consequent variations of current in the shunt circuit produce sounds in the telephone receiver of long and short duration corresponding to the dashes and dots transmitted. This detector was used extensively in the Italian navy and was used by Marconi in some of his trans-Atlantic experiments.

Among other detectors are the carborundum, due to General Dunwoody of Washington, D. C.; the DeForest Audion, and the Silicon detector of Mr. G. W. Pickard of Amesbury, Mass. The Dunwoody detector consists of a small crystal of carborundum clamped at its edges between two metal electrodes or terminals. It is placed in circuit with a small battery and a telephone receiver. Its operation appears to depend on the development of heat, due to the local battery, at the minute points of contact, which heat reduces the resistance of the carborundum. Incoming oscillations affect this resistance and thus produce sounds in the telephone. The sensitiveness of this detector is somewhat greater than the filings coherer. It possesses the advantage for shipboard use that jarring does not disturb its operation.

The Silicon Detector.— Detectors of this type are now termed crystal detectors. This detector employs in its operation the principal of the thermo-electric couple. (See THERMO-ELECTRICITY). The electrodes or thermo-electric couple employed by Mr. Pickard in this receiver are pure silicon and a metallic element of low resistance under a certain mechanical pressure. This couple is placed in the receiving oscillation circuit in which is also placed a telephone receiver, but no battery. According to the inventor the received oscillations are converted into heat at the thermo-electric couple, the amount of heat developed being in accordance with the C^2R law, the energy of which is converted into direct electric currents which are heard in the telephone receiver as sounds. Tests by Pickard of a number of the best known electric wave detectors show the amount of energy required to give a just audible dot (or sound) in the telephone receiver to be as follows: Electrolytic detector, .000364 to .000400 Erg.; Magnetic detector, .000400 to .000410 Erg.; Silicon detector, .000430 to .000450 Erg.; Carborundum detector, .009000 to .014000 Erg.

Vacuum Tube Detectors.— The most useful detector of wireless telegraph and telephone signals to-day is the vacuum tube detector. It has been known for a number of years that the air or gas surrounding an incandescent wire or filament is ionized due to electrons escaping from the incandescent body. The Edison «effect» discovered in the last century was due to this fact, but the correct explanation was not forthcoming at that time. Thus in Houston's 'Electrical Directory,' published in 1892, the Edison effect is defined as follows: «An electric discharge which occurs between one of the terminals of the incandescent filament of an electric lamp placed near the filament but disconnected therefrom, as soon as a certain difference of potential is reached between the lamp terminals. The effect of the discharge is to produce a current in a circuit connected to one pole of the lamp terminals and the metallic plate, as may be shown by means of a galvonometer.» The vacuum tube detector is based primarily on the Edison effect. Apparatus and circuits to show this effect are outlined in Fig. 5. An electric current from a battery *A* heats the filament or wire *F* to a desired temperature when it is found that the platinum plate *W* adjacent to, but not touching *F*, becomes positively electrified to a few volts, as shown by a galvanometer *G*, this indicating that the intermediate gas is ionized or rendered electrically conducting. In the later use of vacuum tubes for X-ray work, wireless telegraphy and telephony, very high vacuums are used which give a pure electron discharge, with greatly improved results, especially perhaps in X-ray work.

The number of electrons flowing from the filament to the plate in a high vacuum tube

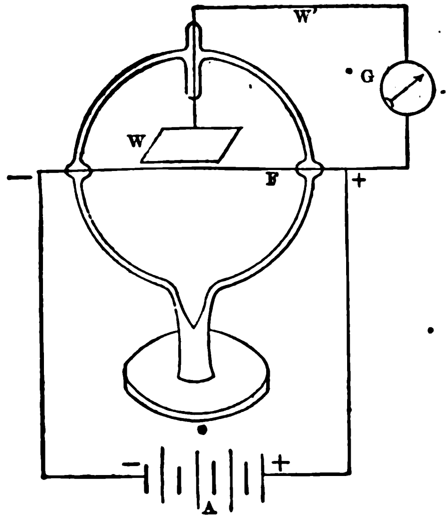

Fig. 5. — Theory of "Edison Effect."

depends on the temperature of the filament and the potential or space charge of the plate. The amount of current in the filament to plate circuit depends on the number of electrons released or emitted from the filament and has been calculated to correspond to 10^{19} electrons per ampere. After a certain increase in the temperature of the filament, which is limited by the strength of its material, and at a certain positive potential of the plate, saturation is reached. The flow of electrons, which are assumed to be negatively electrically charged particles, is apparently from the filament to the plate, which is charged with positive potential, while the current flow is from the plate to the filament.

As already noted the bulbs used in this service require an exceedingly high vacuum for their proper operation. It is also important that the filament and other metallic elements of the tube be free of gas.

Fleming Valve Detector.— Fleming improved upon and utilized the foregoing Edison device by making it a wireless detector known as the Fleming valve or current rectifier, Fig. 6. In the figure *A* is the aerial; *p*, *s* are the

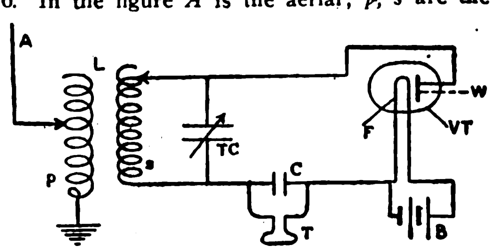

Fig. 6.— Fleming Valve Detector.

primary and secondary coils of the receiving transformer *L*. *TC* is a variable condenser. *VT* is the vacuum tube detector. Plate *W* is part of an oscillation circuit *S*, *C*, *F*, *W*. Filament *F* is brought to incandescence by the battery *B*; this releasing electrons at the filament. Incoming oscillations from the aerial due to arriving Morse signals set up alternations of positive and negative potential on plate *W*. When the plate is charged positively the negative electrons are drawn over from the filament, increasing the potential on *W* which in turn charges the condenser *C* at that instant. When the plate *W* is charged by incoming negative oscillations electrons do not pass from *F*. Hence positive or uni-directional currents only are allowed to pass. Between the positive charges of plate *W*, the condenser *C* discharges through the telephone receiver *T*, thereby reproducing the transmitted dot and dash signals.

The De Forest Audion.— To the Fleming valve de Forest added a metal grid *G* (Fig. 7) between the filament *F* and the plate *P*, making it a three electrode tube *VT*. He also added a potential battery *PB* to plate *P*, which combination produces remarkable results. De Forest termed this device the audion, from the words audible and ion. *A* is an aerial; *p*, *s*, are the primary and secondary coils of the tuning coil or receiving transformer *L*. *TC* is a variable, or adjustable, tuning condenser. *C* is the grid condenser. The grid *G* intercepts the electrons flowing from *F* to *P*, and it is found that a given variation of voltage in the grid produces a greater variation in the plate currents than is effected by a similar variation of potential on the plate *P* with the grid removed. The incoming oscillations from the aerial in the grid-filament circuit are repeated or relayed into the grid-plate circuit more or less amplified. This fact constitutes the audion an amplifier of current and consequently of sounds, and because of this relaying property the audion is also termed an electron relay.

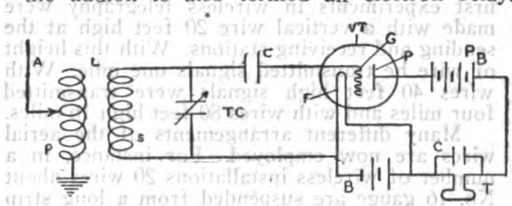

Fig. 7.— De Forest Audion.

Figs. 6 and 7 may be regarded as showing theoretically the ordinary wireless receiving circuits in which the respective detectors indicated are employed.

Another way of regarding the operation of the vacuum tube is to assume that the heated filament sets up a negative electromotive force due to the presence of negative electrons. The potential battery *PB* produces a positive potential at the plate. The conventional explanation then would be that the current flows from the positive potential at the plate to the negative potential at the filament; the battery in this case providing the supply of electrons or, in other words, the current. On this hypothesis a reduction of the negative potential at the filament, the potential at the plate remaining the same, will cause a reduction of current between *F* and *P*. Similarly a reduction in the positive potential at the plate will reduce the current. By obtaining control of the potential of the plate and grid a variation in the output of the tube is obtained. The grid element in the tube provides a means of varying the plate potential, and reversely a variation in the plate potential affects in an opposite sense the potential of the grid.

The three electrode vacuum tube has recently undergone great improvements at the hands of many experimenters, and it is now not only utilized as a detector and amplifier of wireless telegraph and telephone currents, but also as a generator of high frequency electrical oscillations and a modulator of radio waves in Wireless Telephony (q.v.). This tube is also employed as a repeater or relay in long distance wire telephony and indeed it is largely due to the amplifying and relaying properties of this instrument that trans-continental telephony is commercially possible.

There are at least three variations of this tube now in use, termed, respectively: The kenotron, the pliotron and the dynatron. «The kenotron rectifier utilizes the unidirectional property of the current between a hot and cold electrode in vacuum. The pliotron utilizes the space charge property of this current which allows the current to be controlled by the electrostatic effect of a grid. The dynatron utilizes the secondary emission of electrons by a plate upon which the primary electrons fall; it is, as its name indicates, a generator of electric power and feeds energy into any circuit to which it is connected.» For fuller information on this subject the reader is referred to the ‹Proceedings› of the Institute of Radio Engineers, September 1915, and to the bibliography appended thereto. For details relating to and for other examples of circuits in which the three electrode tube is utilized see TELEPHONY, WIRELESS.

The Vertical Wire or Aerial.— Marconi's first experiments in wireless telegraphy were made with a vertical wire 20 feet high at the sending and receiving stations. With this height of wire he transmitted signals one mile. With wires 40 feet high signals were transmitted four miles and with wires 80 feet high 16 miles.

Many different arrangements of the aerial wires are now employed. For instance, in a number of wireless installations 20 wires about No. 16 gauge are suspended from a long strip of wood, which is upheld by insulators supported by a rope between the tops of two masts about 150 or 200 feet high. The wires, two feet apart, drop vertically to a similar wooden strip, where the wires are joined together and led into the instrument room. In other cases the wires are suspended from towers by well-insulated arms and are kept apart by wooden spreaders until near the ground, where the wires are connected and thence are carried into the operating room. In still other cases a single mast is employed, from the top of which a number of wires are suspended. Each wire is attached, at a distance of about 50 feet from the top of the mast, to a guy-rope, which is itself attached to an anchor post in the earth, 40 feet or more from the base of the mast. The guy-rope thus first draws the wires away obliquely from the mast, then at its point of connection with the guy-rope each wire is drawn toward the foot of the mast, where all the wires converge and are thence led into the operating room; the wires forming a >, with the mast as a base and no spreaders are required.

In Fig. 8 are shown various ways in which two or more aerial wires may be employed as antennæ. The wires may be of varying length depending on requirements. In the figure, *a* may represent two wires open or closed at top, *c* indicates a four-wire arrangement; *f* is a cage arrangement of four, six or more wires in which the wires are held apart by hoops; *g* is a box method in which the wires are separated by a wooden frame. The plan shown at *c* is much used. The wires in this case are held apart by wooden spreaders

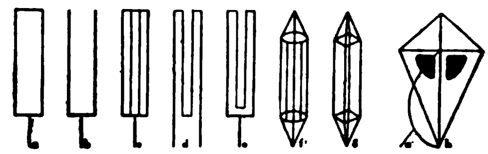

FIG. 8.— Some Forms of Aerials.

at the top and bottom and also at the middle if the wires are very long; *a* represents an Eddy Kite arrangement for supporting an aerial; two or more of these kites may be used in tandem.

Again two high masts or towers 100 and more feet apart are employed, having a number of horizontal wires strung between them at their tops. Vertical wires are attached to the horizontal wires and are dropped to a wooden strip and thence are led into the instrument room. On shipboard horizontal wires are usually strung between the tops of one fore-mast and one aft-mast, from which horizontal wires the vertical wires of the antennæ are conducted to the operating room.

For the very powerful wireless stations much more elaborate antennæ than those described are necessary. For instance, at the Belmar, N. J., station on the Atlantic Coast four iron masts are usually arranged in alignment at right angles to the coast. These masts are 300 feet high and are about one-quarter of a mile apart. Horizontal wires are supported by these masts and vertical wires are connected therewith, which are led into the station.

Kites and captive balloons for supporting the vertical wires have frequently been availed of for temporary use and for military operations. The material of the vertical wire does not appear to affect the results. Iron, copper and aluminum wires have been used. Wire netting has also been employed. The insulation of the vertical wires from the mast is, however, very important. Good earth connection for the vertical wire has been found very essential in practice, especially at the transmitting end. Copper plates 30 feet long and 4 feet wide, embedded two or three feet in damp earth, giving about 2,400 feet of plate surface, are sometimes used for this purpose. When feasible the ground plate is sunk in the sea. On shipboard the «earth» is secured by attaching a wire to bolts on the iron frame of the vessel.

The main object in employing a number of aerial wires or antennæ has been to obtain increased capacity wherein to store electrical energy to be radiated as electric waves, the vertical wires being virtually one plate of a condenser, the earth the other plate and the air the insulating medium. The effective capacity of closely adjacent parallel wires is not, however, proportional to the number of such wires, but is equal, roughly, to the square root of the number of wires. The capacity of a vertical wire .1 inch in diameter and 100 feet in length is .0002 micro-farad (Fleming).

For ordinary service the grounded antenna has been found to operate satisfactorily, but for tuned circuits the direct earth connection possesses some disadvantages. Thus variations in the resistance of the earth connections have introduced difficulties in the way of maintaining exact tuning or syntony. (Described subsequently).

In shipboard practice the aerials *A* are frequently extended in a sort of cage arrangement *C* from the heads of the fore- and aft-masts as outlined in Fig. 9. The cage con-

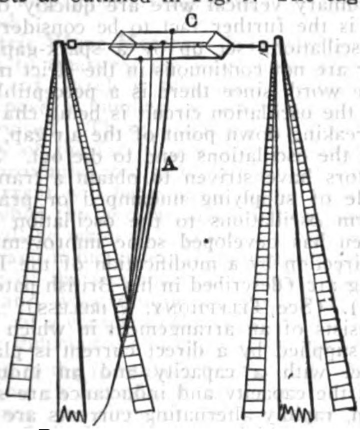

Fig. 9. — Shipboard Aerial Wires.

sists of wires held apart by insulated hoops or spreaders. This cage arrangement is also used in land or shore stations. In this case the cage is about 20 feet in length and consists of six or eight wires. The upper end of the cage is attached in the usual way to the top of the mast or tower; a single wire suspended more or less obliquely connects the cage with the wireless apparatus.

On shipboard when the available masts are low the number of wires must be increased to obtain capacity in the radiating system. A type of aerial much used on ships and at shore stations is that known as the *T* or *L* aerial. An *L* aerial is indicated in Fig. 10, in which between two masts six horizontal wires *W* are supported and from which 6 vertical wires *W'* held apart by wooden spreaders *S* are dropped

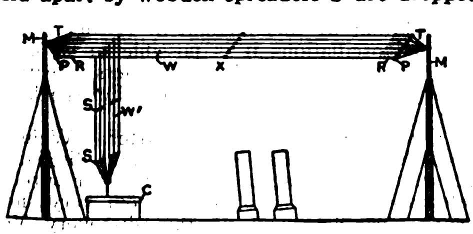

Fig. 10.— Shipboard L Aerial.

to a point near the deck where they converge and after being cabled are led into an operating room *C*. In a *T* aerial the vertical wires are attached to the horizontal wires at *X*. In the *L* arrangement the horizontal wires, which possibly give a directive tendency to the aerial waves, are connected at the far end. The horizontal wires are supported by corrugated insulators *R*, about two feet in length, and are attached to the masthead *M* by suitable tackle *T*, which upholds the spar *P* 15 feet in length and to which the insulators are fastened. The horizontal wires are two and five feet apart.

Condensers.— The condensers used in transmitting circuits for installations up to one or two kilowatts are generally of the Leyden jar-type. Such jars, 16 inches high by 5.25 inches in diameter, have a capacity of .004 micro-farad. For more powerful installations, large plate-glass condensers immersed in oil, contained in insulated tanks, have been used by Marconi, De Forest, Fessenden and others.

Generators of Electric Oscillations.— The need of greater radiating power in long distance wireless transmission than is obtainable from the ordinary induction coil, as well as the unreliability of the interrupters of such coils, when used with large currents, which soon wear out the contact points, has led to the adoption of special types of transformers. Instead of battery power also, alternating current generators are employed as the source of electromotive force for these transformers. The power of the generators may vary from 1 kilowatt to 300 or more kilowatts. The rate of alternations of the transformer depends on the frequency of the generator. The electromotive force in the primary circuit of the transformer may be from 50 to 200 volts, which is greatly increased at the secondary terminals of the transformer; in some cases to 20,000 or 50,000 volts. In the case of the New Brunswick, N. J., transatlantic station a 60-cycle 24,000-volt current in the secondary circuit of the transformers is employed to charge the large glass condensers, which in discharging produce the high frequency oscillations thrown upon the aerial wire.

In addition to the spark gap method of generating high frequency oscillation in wireless telegraphy, as described in the foregoing, by means of induction coils, several other methods are now employed, namely, the Poulsen arc generator, the high frequency machine alternator and the three-electrode vacuum tube oscillator, to which reference will be found in article on (Wireless Telephony (q.v.). Consult Anderson and Elliott, 'Poulsen Arc' (*Electric Work*, 30 Aug. 1919); "Trans-Atlantic Radio Communication" ('Proceedings,' American Institute of Electrical Engineers, 1 Oct. 1919). Marconi has also developed a successful method of obtaining sustained oscillations by means of rapidly rotating metal discs which by suitable arrangements of capacities and inductances set up rapid charges in an oscillation circuit. For a description of this oscillator consult 'Transactions,' Royal Institution (London, March 1908) or Maver, 'Wireless Telegraphy and Telephony' (Part 2, page 9).

Syntony or Tuning.— An important defect of wireless telegraphy in the simple form thus far described consists in the fact that but one message can be sent at one time, for the reason that if it is attempted to send two messages at once in the same vicinity, the signals will clash. Many inventors have striven to overcome this defect, among others Lodge, Marconi and Slaby. The plan followed by these workers has been that of employing a syntonic or tuning method; that is, a method by which the transmitting and receiving circuits are adjusted or attuned to a fundamental rate of electric oscillations, to which rate of oscillations and no other the receiver so attuned will respond. This is done by taking advantage of the fact that the rate of oscillations, or the frequency of an electric circuit is proportional, as already noted, to the inductance, capacity and resistance of the circuit. Hence by varying the capacity or inductance of the tuning circuits any desired rate of oscillation is obtainable. Tuned circuits are termed selective circuits, since by sending out a given rate of waves any desired tuned circuit within signaling distance may be selected as the receiving station.

Tuning also possesses the advantage that the benefits of resonance may be obtained by its use as follows: It is known that a vertical wire grounded directly at its lower end is an excellent radiator of electric waves, but as it possesses very little capacity its oscillations are quickly damped as indicated in Fig. 11 and

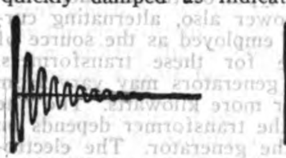

FIG. 11.—Quickly damped Radiator

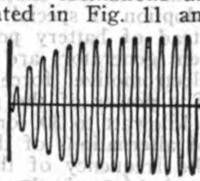

FIG. 12.—Persistent Radiator.

it is only the first few oscillations that are of sufficient strength to affect a receiver. When capacity and inductance are added to a circuit in certain proportions it may be made a persistent vibrator (Fig. 12) and consequently a given amount of electrical energy expended at the transmitter in producing a succession of waves of more uniform amplitude will have a cumulative or resonant effect upon a receiving circuit of equal capacity and inductance, and will eventually cause it to respond to the waves emitted by the transmitter; while an untuned receiving circuit containing a detector as sensitive as the first one, would probably not respond to those particular oscillations. In the case of tuned circuits, this is doubtless because the faintest oscillations, or electromotive forces, excited in the receiving circuit are resonantly amplified by the incoming waves of a selected frequency until they affect the detector.

As a rule, the spark-gap and the receiving apparatus of untuned circuits are connected directly to earth as indicated in Fig. 13, in which *A* is the antenna; *b b* are the spark balls or knobs; *s* is the spark-gap; *S* is the secondary

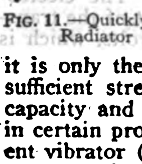

FIG. 13.—Open Circuit.

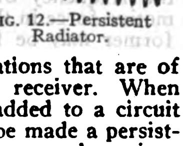

FIG. 14.—Closed Circuit.

and *P* is the primary of an induction coil or transformer. In such an oscillating circuit (*A*, *b*, *b*), the oscillations are quickly damped. In the case of tuned circuits, or where, at least, the effects of resonance are desired, there is provided a closed oscillating circuit which is separated from the vertical wire by a transformer. Such an arrangement is outlined in Fig. 14. The closed circuit in this case consists of the spark-gap, condensers *c c*, and the primary of transformer *T*. In practice the condensers and the inductance coils are made adjustable, so that the capacity and the inductance may be varied at will. Best results are obtained when the oscillating circuit and the vertical wire have equal fundamental oscillation periods; or when the one is a multiple of the other. Oscillating circuits arranged as in Fig 13 are said to be tightly coupled. When arranged as in Fig. 14 they are said to be loosely coupled.

In addition to the fact that the oscillations in an ordinary vertical wire are quickly damped, there is the further fact to be considered that the oscillations set up by a spark-gap transmitter are not continuous in the strict meaning of the word, since there is a perceptible time, while the oscillation circuit is being charged to the breaking down point of the air-gap, during which the oscillations tend to die out. Several inventors have striven to obtain a transmitter capable of supplying undamped or practically uniform oscillations to the oscillation circuit. Poulsen has developed some improvements in this direction by a modification of the Duddell singing arc (described in his British patent No. 21,629). (See TELEPHONY, WIRELESS). Briefly, it consists of an arrangement in which an arc lamp supplied by a direct current is placed in parallel with a capacity and an inductance. When the capacity and inductance are suitably chosen, rapidly alternating currents are set up in this arc which produce a tone — hence the name singing arc. In Poulsen's modification of this arrangement the negative electrode of the arc is carbon, while the positive electrode is copper, the arc being enclosed in a box containing hydrogen gas. The arc is shunted by a capacity and inductance and rapidly alternating currents are continuously set up which are thrown on to the vertical wire in the usual way. With the Duddell arrangement the frequency of oscillation was about 10,000 to 15,000 periods per second — too low for utilization in wireless telegraphy. A much higher frequency is obtained by the Poulsen arrangement which is attributable to the atmosphere of hydrogen. To further the cooling of the electrodes (an essential first noted by Elihu Thomson, in United States Patent No. 500,630), the copper electrode is made in the shape of a hollow ring through which water is passed. Tests have demonstrated that by this method of setting up undamped oscillations it is possible to signal to greater distances with much less electrical energy than is required with the spark-gap method.

Quenched Spark Transmitter.— Wein in 1906 discovered that very powerful discharges possessing advantageous properties for wireless telegraphy could be obtained from very short spark-gaps To avail of this discovery Von Lepel employed as an oscillation generator, a device consisting of a metal box having a partition of two copper plates separated by a very thin sheet of paper provided with a small aperture in its centre. The terminals of the usual charging electromotive force are each connected with one of the plates and the arc is formed at the small aperture between the plates, which arc slowly burns away the paper which must be renewed at intervals. The arc is shunted by the usual inductance and capacity. This arrangement produces very rapid quenching of the spark at the electrodes. Hence the primary oscillation circuit ceases to give out energy after the first blow, so to speak, while the secondary or aerial oscillation circuit continues to oscillate. It has been found in practice that with such rapidly damped primary oscillation circuits in coupled circuits, only one set of oscillations is radiated, whereas in less rapidly damped primary circuits the radiation of more than one set of radiations is not uncommon. Forms of quenched spark transmitters other than the Von Lepel arrangement have also been employed.

Electric Wave Meters.— It is very essential at times to measures the wave lengths or frequencies of wireless telegraph circuits. For this purpose a number of wave meters have been devised. These wave meters are based primarily on the fact that with an exciting current in proximity to a secondary circuit a maximum current will be induced in the secondary circuit when the two circuits are in resonance, which will be when they possess corresponding capacity and inductance. If the capacity and inductance of the secondary are known, the frequency and wave length are deducible. The period T of a complete electric oscillation varies with the inductance and capacity of the circuit, according to the formula $T = 2\pi\sqrt{KL}$ when T is the time in seconds, π is the ratio of circumference to diameter, K is capacity in farads and L the inductance in Henrys — or $T = 6.2832\sqrt{KL}$. Hence it is evident that the frequency n of the oscillations (number per second) will be equal to 1 divided by T; that is, $n = \frac{1}{T}$. The velocity V of propagation of the oscillations or waves being equal to that of light waves, 186,000 miles per second, the wave length then equals velocity divided by frequency $\frac{V}{n}$, or wave length equals,

$$T\ V\ \sqrt{KL} = 2\pi\ V\ \sqrt{KL}.$$

In ordinary practice resonance is indicated by the loudness of received signals in the telephone receiver.

One of the early wave meters, the Donitz, is shown in Fig. 15. A brief description of the device will explain the general principle on which wave meters operate. The Donitz wave meter consists of a coil of wire C, about eight inches in diameter that may be placed in the vicinity of the oscillation circuit to be measured, for instance, coil C' which may be a loop in an aerial circuit. Coil C is in series with a condenser K and another coil of wire c. c is in inductive relation to a smaller secondary wire W in the circuit of which is a small heat wire H, placed in one end of a U-shaped tube T, partly filled with a colored liquid. The capacity K consists of two sets of semi-circular metal plates, one set fixed, the other set movable to or from the fixed plates, the whole being contained in a glass case and immersed in oil. The movable plates are operated by means of a knob N to which is also attached a pointer P, which moves around a graduated scale S. The capacity K of this oscillation circuit varies with the

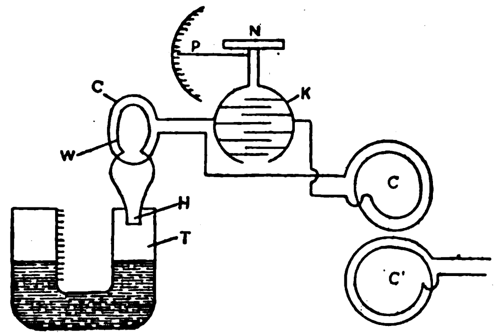

FIG. 15.— Donitz Wave Meter.

adjustment of the condenser plates. This capacity is then adjusted until the circuit is in resonance with the external circuit C', which will be indicated when the liquid in the left arm of the tube T is forced to a maximum height by expansion of the air or gas in the right arm of the tube due to heat wire H. At this time the pointer P will be opposite a given point on the calibrated scale that indicates the wave length or frequency corresponding to the inductance and capacity of the wave meter circuit at that time, which also corresponds with the frequency of the external oscillation circuit C'. Ordinarily the coil C' is placed concentrically within coil C. For more accurate results and to avoid reactance effects from coil C, the coils should be separated about one inch. If removed too far, the adjustment for resonance will not be so accurate. This wave meter is quite compact, the containing box being about one foot square.

Marconi's Tuned Wireless Telegraph System.— One early arrangement of Marconi's tuned or syntonic transmitting and receiving circuits is shown theoretically in Figs. 16 and 17. Fig. 16 represents the transmitting apparatus and circuits. In this A is the vertical wire in which is inserted a coil w, the number of turns of which, in use, may be varied by a sliding contact x. By this means the period of a vertical wire may be adjusted to correspond with that of the closed oscillating circuit p, c, b, b. The

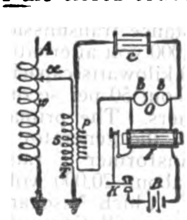

FIG. 16.

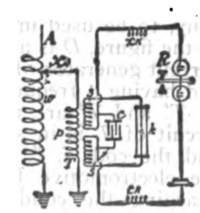

FIG. 17.

Marconi Tuned System.

condenser c, usually Leyden jars, of about .25 micro-farad capacity, may also be adjustable. I is an induction coil. K is a Morse key and B is a storage battery of five or six cells. The receiving apparatus and circuits are illustrated in Fig. 17. As in Fig. 16, A is the vertical wire, attached at its lower end to an inductance coil w. The coils p and s s constitute what is termed a "jigger," or hoister; it is in fact a type of "step up" transformer and is used to increase the efficiency of the apparatus by enhancing the electromotive forces acting upon the coherer; availing of the fact that there is a "node" of electromotive force and a "loop" of current at the foot of the vertical wire — that is, at that point the electrostatic energy is at minimum while electromagnetic energy is at maximum. *K* is the Marconi filings coherer, which is in series with the secondary coil *s s* of the jigger. A small condenser *c* is connected as shown, forming a short path for the oscillatory currents via the coherer, since for momentary currents the condenser is practically a conductor. *ck ck* are small choke coils (really inductance coils), which, being virtually opaque to rapid oscillations of current, direct the oscillatory currents across condenser *c*, thereby precluding any diversion of these currents through the relay *R*. This is a polarized relay of from 1,200 to 10,000 ohms resistance, in the circuit of which is a single cell *b*. The relay is usually inclosed in a cylindrical case to exclude dust. Some of the relays used for this work will respond to a current of $\frac{1}{20000}$ of an ampere. In practice this relay, the jigger, the coherer and tapper are enclosed in a metal sheathed box to prevent the action of external electric waves upon the coherer. For the same reason the local contacts of the relay and tapper are shunted with resistances, not shown in the figure. The Morse key employed is massive, with front and back contacts which are insulated from one another. It is provided with a large vertical ebonite handle to protect the operator against shocks. The use of the coherer for commercial use has been displaced by more modern devices.

The Fleming Long Distance Transmitting Circuit.— In Fig. 18 is shown diagrammatically

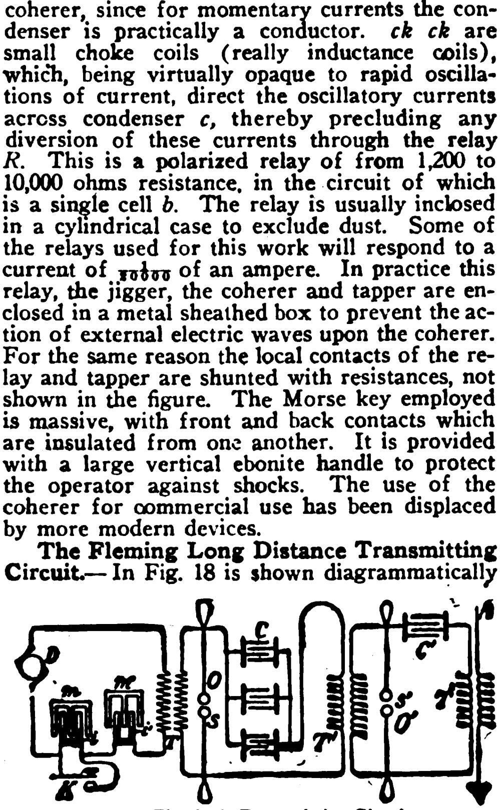

FIG. 18.—Fleming's Transmitting Circuits.

an arrangement, designed by Prof. J. A. Fleming for the Marconi Wireless Telegraph Company, to be used in long distance transmission. In the figure, *D* is a 500 or 1,000 volt alternating current generator of 10 or 20 kilowatts capacity, and having a frequency of about 50 per second. *T*, *T'* and *T''* are transformers. The primary circuit of *T* is in series with the generator *D*, and the coils *i*, *i'*. The transformer *T* raises the electromotive force to about 20,000 volts, charging the condensers *C*, which discharge across spark-gap *S*, setting up oscillations of a high order in the oscillating circuit *O*, *S*, *C*, *T'*. These oscillations are again transformed to higher voltage in the secondary of *T''*, which in turn charges condenser *C'*, and this, in discharging in the oscillating circuit *O'*, *S'*, *C'*, *T''*, still further increases the electromotive force thrown upon the vertical wire or wires *A*. The estimated electromotive force obtained at the vertical wire in this way is about 100,000 volts. These condensers are of glass immersed in oil and the transformers are of special construction to withstand these high pressures and to give the desired capacity and inductance. To avoid directly opening and closing the primary circuit of the transformer *T*, the two choke coils *i*, *i'*, having movable iron cores, *m*, *m'*, are placed in that circuit. The iron core *m'* of *i'* is so adjusted that as much current as may safely be passed through the primary of *T* shall normally flow in the circuit. The core *m* of *i* is inserted to its full length in the coil, and its inductance is sufficient to stop all flow of alternating current in the circuit. This coil may, however, be short-circuited by the key *K*, in dot and dash signaling, at which times the current attains its full value. Hence the circuit is not opened in the usual sense, but to avoid sparking the contact points of key *K* may be immersed in oil.

In Fig. 18a is shown theoretically a type of transmitting apparatus and circuits now employed in ordinary ship and land stations. *G M*

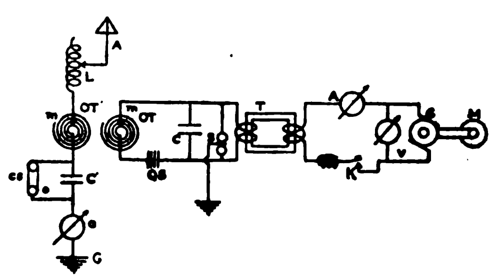

FIG. 18a.— Modern Transmitting Circuit. Land or Shipboard Station.

is a motor-generator controlled by a motor starter not shown. The motor is usually supplied with current at 110 volts pressure. The generator *G* may develop from 110 to 500 or more volts as desired. *QS* is the spark-gap (quenched gap type), *K* is a Morse key in the primary circuit of the transformer *T*. Specially designed keys for this work will open the circuit without excessive sparking with a current of 25 amperes and 110 volts. The voltage in the oscillation circuit *C*, *OT*, *QS*, may be raised to 10,000 volts or more by the transformer *T*. *C* represents a battery of Leyden jars or condensers. The oscillation circuit is connected by loose coupling to the aerial *A*, by means of oscillation transformers *OT*. The oscillation transformers in some cases consist of two independent coils of heavy bar copper wire with widely separated spirals and with one of the coils movable outside of the other for varying the coupling. Clips *m* are also provided whereby more or less of the coils may be connected in the circuit for tuning. *L* is a tuning inductance in the aerial. *C'* is a condenser used for short wave signaling. It may be cut out as in the figure by the switch *CS*. *A* is a hot wire ammeter placed in the aerial to show when oscillations are being thrown upon the aerial and to indicate the strength of current therein. Resonance is indicated between the circuits when the current in *h* is at maximum. *S* is a safety device designed to discharge excess current in the oscillation circuit to ground. A motor starting arrangement for the motor-generator is shown and described in the author's work 'Wireless Telegraphy and Telephony' (page 103).

Wave Motion, Directive Signaling and Direction Finders.— In ordinary wireless telegraph signaling the electric waves are radiated from the antenna in every direction, as, for instance, the light waves from a lamp on a pole are radiated in every direction. Attempts have been made to reflect and direct electric waves as light is reflected, but by means of metallic mirrors. These attempts were not successful owing to the difficulty in meeting the requirement that the diameter of the reflecting mirror must be large in comparison with the length of the electric wave to be radiated, and that the reflector must not be further than a quarter wave length from the oscillator or source of oscillations. This difficulty results from the great length of the electric waves used in wireless telegraphy and telephony. For instance, in the case of oscillations of 100,000 per second, over 9,840 feet. On the contrary the length of light waves is so infinitesimal that the smallest mirrors possible to construct, or even particles of air, are large by comparison with light waves. Some success has been met with in the matter of directive signaling by methods different from the mirror reflection method. Before describing some of these methods it may be not amiss to refer briefly to the theory of wave motion.

Wave undulations or oscillations of simple harmonic form are frequently shown graphically as a sinusoidal curve, or sine wave, derived, for example, from the motion of a point on the surface of a rolling wheel, or from the tracing made by the movement of a pencil point in a rectangular slot, under which a strip of paper is drawn with a uniform motion, the oscillatory movement of the pencil corresponding to a point moving back and forth along the diameter of a circle. In Fig. 19, the vertical lines *m n* may represent such a back and forth

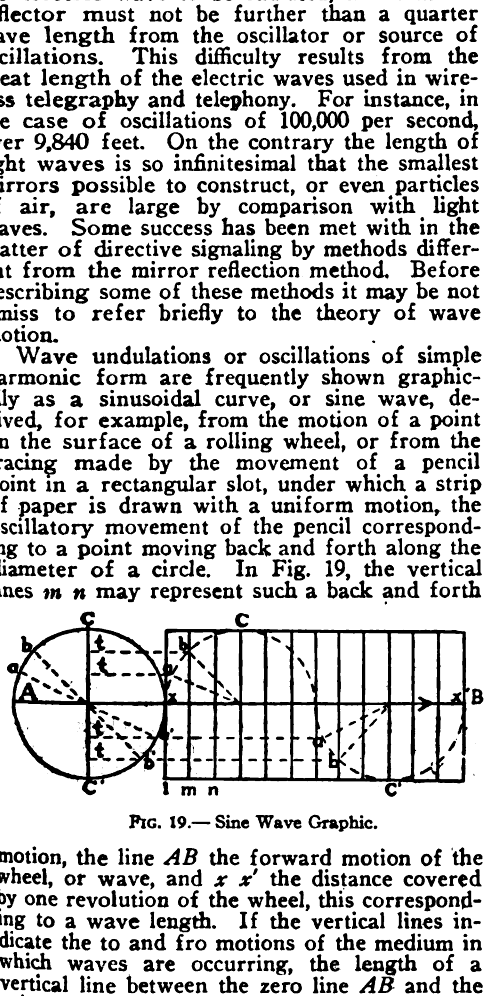

FIG. 19.— Sine Wave Graphic.

motion, the line *AB* the forward motion of the wheel, or wave, and *x x'* the distance covered by one revolution of the wheel, this corresponding to a wave length. If the vertical lines indicate the to and fro motions of the medium in which waves are occurring, the length of a vertical line between the zero line *AB* and the point of intersection of the curve will represent the extent of a motion of a given particle of the wave at a given point and instant. This is graphically shown by the horizontal lines *t* from vertical lines *C C'* in the circle, to points *b a; a' b'* on the curve. When used to represent an alternating current wave these lines indicate the strength of current or the *E.M.F.* at any given point and instant of the cycle. The period of a wave is the time taken by a particle to move from a given point, say, *x*, around the circle to point *x* again; or for the pencil point in the slot to perform one to and fro motion. On the solid horizontal line this as stated would correspond to the distance *x x'*. In wave motion it is understood that the particles of the medium do not move forward with the wave, but merely rise and fall like chips on the surface of a pond as the waves pass under them. As the wave progresses each particle of the medium in turn rises to the crest and drops to the trough of the wave. In an elastic medium it is assumed that the particle is displaced from its zero position by a force or strain which it resists with a counter force termed stress, the stress varying with the extent of the displacement, and tending to restore the particle to zero position. The position of a point or particle at a given instant relative to any fixed position is termed the phase, and the difference of position of a given point or particle relative to another particle during its motion over a circle is termed phase difference. Thus a particle at *b* will pass through point *C* in advance of particle *a*, the direction of motion being as shown by the arrow, and their phase difference when measured as an angle will be equal to the difference of the angles made by their radii with a fixed line *A x*. For example, the difference of phase between a particle at *C* and one at *x* is 90°, or one-quarter wave length; while a particle at *C* and one at *C'* will have a phase difference of 180° or one-half wave length. When two particles pass through the same point at the same time they have no phase difference. Any two particles one wave length apart are said to be in the same phase, and two waves of the same frequency whose corresponding parts are moving in opposite directions with the same velocity are said to have a phase difference of 180°. For present purposes the broken curved line in Fig. 19 may be considered to represent the contour of an electric wave, while that portion of the curve above the line *x x'* may represent an electric positive force or sign; that below the lines a negative force or sign, and the magnitude of the force of the wave at a given point and instant may be represented by the length of the vertical lines between *x x'* and their intersection with the curve. In this view, waves of different or equal phase and magnitude and agreeing or opposing in direction or sign may be caused to assist or neutralize one another, more or less; some instance of which will be given herein, and analogous instances of which may be found in textbooks on light and sound.

Electric Wave Localizer.— A device due to John Stone Stone for determining the direction from which wireless telegraph signals are emanating is shown in Fig. 20, theoretically. In the figure *V V'* represents vertical wires placed on a common axis *a*, and in series with which are coils of wire *x y* respectively. These coils are so wound that when oscillations of equal strength and direction simultaneously pass through them from wires *V V'* the coil *z*, which is in inductive relation to those coils, will not be affected. When the oscillations in coils *x y* are in opposite directions or differ in strength coil *z* will be affected. Coil *z* is in series with detector *d*, condenser *C* and telephone receiver *t*. In order to obtain the maximum effects of the wave energy the wires *V V'* in this arrangement are placed the distance of half a wave length apart, which distance can be ascertained by means of a wave meter. Assuming the length of the arriving waves to be

50 feet, the wires 25 feet apart, and that their plane is in the line of motion of the advancing wave, the wires will receive the waves at a phase difference of 180° or half a wave length. Hence the oscillations in the wires due thereto will be of equal strength, say, 10, as indicated in the figure, but opposite in sign, or direction, in coils *x y*, and the coil *z* will be inductively affected to a maximum extent. If the wires

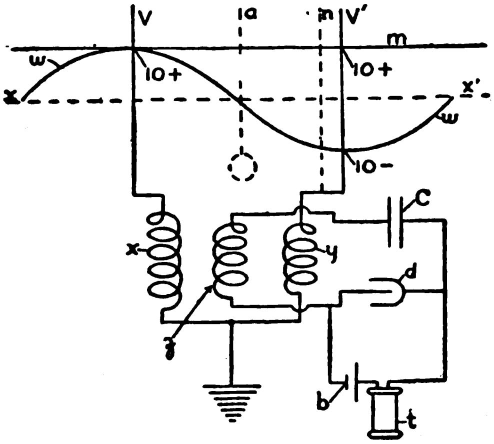

Fig. 20.— Stone Localizer.

are so moved that the distance between them is less than half a wave length the sign in the respective wires may still be opposite, but the strength in each will not be equal. Thus, if wire *V'* is moved to the point indicated by dotted line *n*, the force of the wave at *V* will still be 10+, while at *V'* it will be less than 10— and the oscillation current strength in coil *x* will be greater than that in coil *y*, and detector *d* will be energized. Or keeping the wires half a wave length apart, but rotating them on the axis *a* until this plane is perpendicular to the front of an advancing wave having at a given instant a force of, say, 10+, it will fall on both wires as indicated by line *m* where the force and sign are equal. Oscillations of equal strength and direction will then be set up in the vertical wires, the effect of which on the coil *z* is nil, owing to the differential winding of the coils *x y*. To determine then, the direction of arriving waves it is only necessary to turn the wires *V*, *V'*, on their axis *a* until the combined forces of the oscillations in coils *x y* upon *z* are zero which will be when the plane of the wires is at right angles to the direction of the arriving waves. According to Mr. Stone the apparatus of this device has never been used with a wave length exactly twice the distance between the two aerials or vertical wires *V V'*. The object in having the wave length equal to twice the said distance is that such an arrangement gives maximum intensity of signals, the signals under all conditions being a maximum when the plane of the waves is at right angles to a plane down through the two antennæ; the signals being canceled in the coils *x y* when the plane of the waves is parallel with the plane passing through the vertical wires. Consult U. S. Patent No. 716,135, 1902, covering this device.

Bent Antennæ in Directive Wireless Signaling.— De Forest states that by using a vertical wire to which is attached a pivoted horizontal wire signals are received by means of the detector in the vertical wire, the strength of which signals appear to vary according as the position of the wires approach or depart from a position of parallelism with the direction of travel of the waves. The various arrangements of *T* and *L* antennæ so largely employed for capacity on shipboard and in land stations correspond more or less to the foregoing device but practical experience does not definitely indicate that in ordinary shipboard working the signals are affected favorably or otherwise as regards the directive effect on signaling by such arrangement of the aerial wires.

Marconi has made numerous experiments relative to directive wireless signaling and has found that by placing a large number of wires, arranged as an *L* aerial, or bent antennæ, and with the open end pointing away from the distant station the direction of effective radiation may be largely controlled; also that by using a similar antennæ the reception of signals is much improved. Braun, Artom and others have also experimented with directive wireless telegraph devices, an account of which may be found in textbooks on wireless telegraphy.

Bellini-Tosi Directive Wireless Signal System and Direction Finder.— These inventors began their experiments in France, using a triangular nearly closed aerial circuit capable of rotation on its axis, using a transmitter and receiver somewhat similar to those already described. Like other experimenters Bellini and Tosi found that the strength of received signals was a maximum when the plane of the triangular transmitting circuit was placed in the

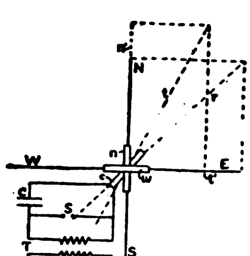

Fig. 21.

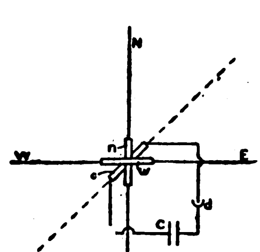

Fig. 22.

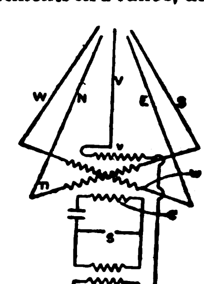

Fig. 23.

Bellini-Tosi Direction Finder. Using Goniometer.

direction of the receiving station, and that upon turning the triangle on its axis directing its plane away from that station the strength of signals gradually weakened and was always zero when the plane was at right angles to that station. To avoid the difficulties involved in the use of movable aerials for directive purposes the inventors devised the plan of using two sets of triangular aerials, placed at right angles to one another, as outlined in Figs. 21, 22, 23 in which *W E* indicate the two upper sides of one triangle and *N S'* similar sides of the other triangle. In connection with this arrangement of aerials a device termed a radio-goniometer *n w C* is utilized in which will be seen a certain resemblance to the Stone localizer previously described. The radio-goniometer consists of two fixed coils *n w* at right angles to one other, and of a central coil *C* movable on a pivot in any direction within the coils *n w*. When used for transmitting, the coil *C*, Figs. 21, 23, is the primary of an oscillation transformer with two secondaries, *n w*. When used for reception of signals, as in Fig. 22, coil *C* becomes the secondary of two primaries *n w*. The fixed coil *n* is connected with aerial wires *N S*; fixed coil *w* with aerials *W E*. When the device is used as a transmitter, if it is desired to transmit signals in the direction of the plane, of say *N S*, the primary coil *C* is turned on its pivot until it is parallel with coil *n*, at which time inductive effects will be inappreciable in coil *w*, but will be a maximum in coil *n*, and the direction of transmission will be *N S*. If the primary coil be placed parallel with coil *w* the direction of radiation will be *W E*. If it is desired to send signals in any direction between *W N* or *E S*, this is effected by placing coil *C* in the desired position in which case each coil *n w* will be acted upon proportionately to its angle with coil *C*, and the direction of radiation will be a resultant due to the combination of the two electromagnetic forces developed by the coils *n w*, virtually according to the law of the parallelogram of forces. In Fig. 21, for instance, with coil as shown, the resultant direction would be as indicated by the dotted lines *r*. The length of the thick lines *N E*, respectively, represent the assumed magnitude of the component forces in the direction indicated by those lines; or if the coil *C* be turned in the direction of dotted or resultant line *t*, the magnitude of the component force due to coil *w* would be reduced by the amount indicated by the intersecting dotted line at *t'*, while the component force due to coil *n* would be indicated by the dotted line *n'*. Reversely when the radio-goniometer is used as a receiver or direction finder, Fig. 22, the incoming wave fronts will fall on the closed aerial oscillation circuits, virtually as stated in connection with Fig. 20. Thus if an arriving wave front is in the plane of *N S*, coil *n* only will be affected and coil *C* is turned bv the operator until maximum current or signals are obtained. If, on the other hand, the wave front is advancing from a direction midway between *N* and *E*, the coils *n w* will be equally affected and the best position for coil *C* will be as indicated by the dotted line *n* in Fig. 21. The foregoing described device derives added importance from the fact that it forms the basis of the now well-known Marconi-Bellini-Tosi Direction Finder. (Consult Weagent, 'Static Eliminator'). This and other direction finders are likely to be of great utility in enabling the navigators of air ships to obtain their bearings when in fogs, etc., etc. For example, assuming that certain land stations are instructed to send out prearranged signals, the navigator by means of a direction finder on his ship can quickly ascertain his direction.

Statics and Atmospheric Interference in Wireless Telegraphy.— Marconi found during his experiments that daylight was inimical to long distance wireless telegraphy. In other words, that signals could be received at a much greater distance at night than in the daytime. It is supposed that this is because ionization of the air is greater in daylight than at night and that the ionized air of the atmosphere absorbs more or less of the long waves employed in trans-oceanic wireless telegraphy. Marconi observed that the effect of ionization of the atmosphere was not noticeable to an injurious degree at distances less than 500 miles.

It has long been known that atmospheric electricity can be drawn from points above the earth's surface by means of a wire upheld in the air. This is due to the fact that the upper layers of the atmosphere are statically charged with electricity to a point of electric potential differing from that at the earth's surface. The grounded aerial wire tends to equalize this difference of potential and currents of electricity discharge through it to earth. The aerial wire used in wireless telegraphy similarly acts as a medium of discharge for atmospheric electricity, and in so doing produces currents of electricity that have been the source of much interference with the operation of wireless telegraphy and telephony. This particular source of external interference can be measurably obviated by disconnecting the wireless aerial from the cable. Lightning storms and snow-storms also set up interference, but they do not constitute a very serious obstacle to the operation of wireless telegraphy. The foregoing and other electrical disturbances encountered in wireless telegraphy, are known under the general names of «statics,» «X's» or «strays,» and certain types of such disturbances have hitherto made the successful operation of trans-oceanic and long distance wireless telegraphy generally, very difficult. The effect of the discharge of atmospheric electricity by way of the aerial wire to earth is termed «hissing.» Other types of static interference are termed respectively «clicks» and «grinders.»

An electrical source of interference due to «strays» or electromagnetic waves, probably caused by variations in the electrical condition of the atmosphere, produces disturbances in the wireless receiving apparatus sufficient to render signals unreadable while the disturbances last. These effects are very pronounced in the tropics and are much less noticeable in winter than in summer or temperate zones.

A number of devices have been used to partially eliminate the effects of statics, the most common being the placing of a small air gap in the aerial wire, across which the static currents pass, thereby diverting them from the receiving apparatus. For short distances this device is of use.

To avoid static effects, Fessenden devised the plan of divided circuits shown in Fig. 24.

A is the aerial. *B B'* are branched circuits from the aerial, coupled differentially, to a detector circuit *C, C, C*. *T* is a head telephone receiver. The assumed operation of this device was that if one of the branch circuits, say *B*, be attuned to arriving signals and the other branch, *B'* be not so attuned, the attuned circuit would respond to arriving signals while the untuned branch would not so respond, and, further, that the static currents, being forced vibrations, would pass through both branches in equal strength and would, therefore, cancel each other in the differented coils. It has been pointed out, however, that the static currents are also responsive to tuning of the branches to different rates of oscillation which prevents the desired cancellation of the static currents in *B B'*, hence the static noises will be heard in the receiver. Consequently, any apparent benefit derived from this arrangement must be due to the loose coupling of the circuits, which diminishes the strength of the static currents.

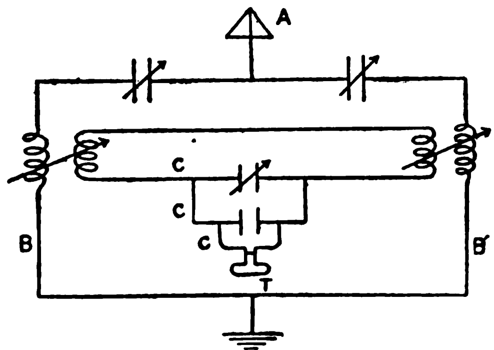

FIG. 24.— Fessenden Interference Preventer.

Dieckman designed a protective shield of wires to be placed over and around the wires of an *L* antenna to cut off the static currents from the aerial and divert them to the earth. This device is expensive since it practically duplicates the regular antennæ, but it largely diverts atmospheric currents from the aerial proper. It does not, however, divert horizontal electromagnetic strays from the antenna.

Weagent Anti-Static Device.— The principle involved in this device is the outcome of Weagent's remarkable discovery that the statics producing the greatest interference in wireless telegraphy are not parallel with the waves due to radiation from wireless telegraph stations, but are vertical in direction. It is beyond the scope of this article to give more than a brief description of the methods which Mr. Weagent has invented to avail of this discovery. For a full description thereof the reader is referred to the Journal of the Institute of Radio Engineers, March 1919.

Granting the accuracy of Mr. Weagent's assumption as to the vertical direction of static currents or waves the direction of their propagation will be at right angles to that of advancing wireless telegraph waves. The problem was then to separate the wireless signal waves from those due to statics in the antenna circuit.

The Weagent arrangement of circuits and apparatus to effect this result is shown theoretically in Fig. 25, the explanation of which will perhaps be simplified by reference to the description of the Stone Direction Finder, and the Bellini-Tosi goniometer, herein. For his purpose Mr. Weagent arranged two loops *L L'* of aerial wires supported on poles, the receiving station being at *X*. The length of each loop is, say, three miles, although the inventor has

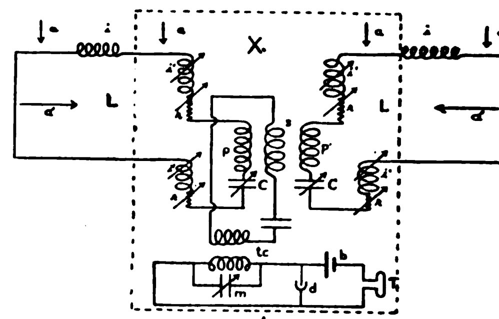

FIG. 25.— Weagent Anti-Static System. Two-Wire Aerials.

experimented with loops of varying lengths less than three miles. The sustaining poles are 30 feet high. The wires of the loops are spaced 15 feet apart on the poles. Each loop is connected at *X* in series with a condenser *C* and one primary coil *p, p'* of a radio goniometer, the secondary coil *s* of which in turn is coupled with the tuning coil *tc* of a wireless receiving circuit containing the usual variable condenser *m*, detector *d*, battery *b* and telephone receiver *T*. Variable inductances *i'* and resistances *r* are placed in the loops *L L'* for adjustment purposes. The coil *s* may be rotated into a desired position.

The vertically moving static waves are indicated by the downward arrows *a a*, the electromagnetic waves due to wireless signals are indicated by the horizontal arrows *a' a'*. Since the static waves cut both of the loops simultaneously the currents set up by them in the primary coils *p p'* of the goniometer (being wound oppositely to each other) are in phase and produce no effect on the secondary coil *s* of that apparatus. But the arriving signaling waves cut the respective loops at different times with the result that the currents set up thereby are not in phase and a preponderating current is produced in one or other of the primary coils of the goniometer, which induces a current in the secondary *s* of those coils that is heard in the detector circuit as in ordinary wireless telegraph operation.

Mr. Weagent in his paper states that to obtain tuning in the loops an inductance coil *i, i* of 30 millihenrys is placed in the upper wire of each loop and best results are obtained when this inductance is placed near the middle, when the tuning is at a maximum. A similar coil placed in the lower wire of a loop effects no change in tuning. Experiments showed that a coil of 30 millihenrys was best for a wave-length of 12,000 meters while a coil of five millihenrys gave best results for a 6,000-meter wave. Both values, however, were satisfactory for either length of wave with loops three miles in length.

While the foregoing device was efficacious in getting rid of the vertical statics termed grinders, it was found, in long-continued tests made by Mr. Weagent with a two-wire aerial system installed at Lakewood, N. J., that the interference due to clicks or horizontal waves could not be altogether eliminated by the two-wire loop arrangement. Mr. Weagent defines the interference termed grinders as that which produces in the telephone receiver a continuous rattle with occasional crashes, and it is more noticeable in warm than in cold seasons. On the other hand clicks, which are widely spaced crashes in the telephone, are more noticeable in cold weather, but they are not so continuous in their action as grinders. For instance, it was found that with the two-wire loop arrangement clicks interfered materially with the reception of signals emanating from such comparatively low power stations as Clifden, Ireland, and the Eiffel tower, and that any plan devised to reduce the effect of the clicks also weakened the signals. On the other hand the clicks were not of sufficient strength unduly to impair signals received from the more powerful stations at Carnarvon, Wales, or Nauen, Germany.

By means of another device due to Mr. Weagent and shown in Fig. 26, it became possible to eliminate the statics due to clicks to the extent that the signals from the weaker European stations were easily readable. Since it was demonstrated by the experiments referred to that the two-loop aerial picked up vertical static waves and horizontal electromagnetic waves, Mr. Weagent conceived the idea of utilizing the two-loop aerial as a tank or receptacle for the static waves that produce grinders and clicks, and then avail of these waves at a given instant to balance out by suitable means the practically similar waves developed in a third aerial that would constitute the receiving circuit proper in the manner now to be described.

In Fig. 26 *SL SL* comprise the two-wire aerial tanks for this purpose. The instruments and circuits at the receiving station are indicated within the dashes. The receiving aerial proper is the long horizontal wire *L L*, which is suspended on the same poles as the tank aerials *SL SL*. The function of *SL SL* as intimated is to accumulate and supply at a desired instant currents due to grinders and clicks which by suitable adjustment of a goniometer *S*, *P*, *P'*, and of the inductance coils *i'*, resistances *r* and condensers *C* shown, are made to neutralize or balance the static and click currents picked up by the receiving aerial *L*, *L*, before reaching the vacuum tube detector circuit *A*. The rotary goniometer coil *S* is coupled to the detector circuit *A* at *a'* and to the receiving aerial *L L* at *a*. Circuit *A* is also coupled to the receiving aerial *L* via *a'* and *a*. This device allows the current signals from distant stations to be received at normal strength and without static or click interference, during all hours of the day.

It is claimed by Mr. Weagent that continued use of his static eliminator has shown beyond question that its performance is not occasional or accidental, but is reliable and consistent. With this system of reception trans-Atlantic radio telegraphy can now be carried on free from interruptions caused by statics of any kind, excepting only that due to local lightning. Further, the barrier in the way of radio telephony is by means of this system also removed, inasmuch as statics have interfered with radio telephony to a much greater extent than with radio telegraphy. Improvements have been lately perfected by means of which radio messages may be successfully received from across the Atlantic Ocean, with apparatus, including the entire equipment, and miniature aerials, so comparatively diminutive that they may be placed on a lecture platform.

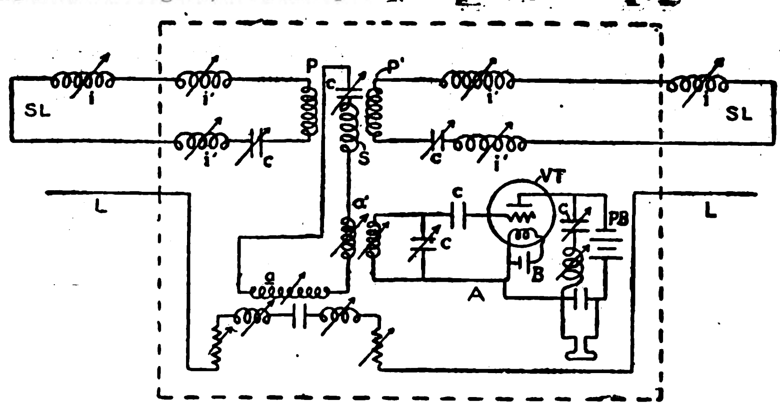

Fig. 26.— Weagent Three-Wire Aerial·Static Eliminator System.

Comments on Trans-Atlantic Wireless Telegraphy.— The Great War interfered materially with the free use of wireless telegraphy and during the term of the war the governments of the various nations of the world exercised complete control of its operation over land and sea. The following remarks concerning the status of trans-Atlantic Wireless telegraphy are drawn from an article in the 'International Cable Register Supplement,' by E. B. Pillsbury.

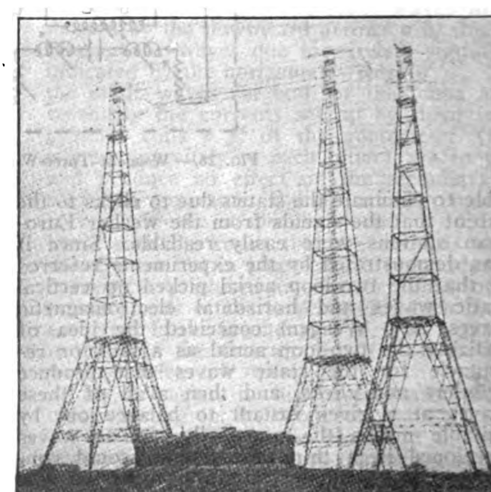
"Regular message traffic has been transmitted between Europe and America by Wireless telegraphy continuously for over eight years by means of a duplex circuit between Clifden, Ireland, and Glace Bay, Cape Breton, that is, messages between those points are transmitted in either direction simultaneously. The transmitting and receiving apparatus are not placed in one station but in separate stations a number of miles apart, connected by land lines, which make it possible to localize the sending and receiving operators in the one room. The receiving instruments are coupled to two distinct aerials, one of which is used for receiving, while the other, known as the balancing aerial, is so arranged that it is practically unaffected by the signals from the distant station from which it is expected to receive. The effect produced by the balancing aerial on the receiving apparatus by the adjacent transmitter is equal and opposite to that produced thereby through the receiving aerial which is tuned to the wave-length of the signals it is desired to receive. The latest type of the Marconi receiving apparatus greatly minimizes the atmosphere interference to which wireless transmission over long distance was particularly exposed in the early days. The signals arriving in Glace Bay from Clifden are as a rule easily read through any ordinary electric atmospheric disturbance. The strengthening of received signals has made possible the employment of recording instruments which not only give a permanent record of the received messages, but are also capable of operation at a much higher rate of speed than would be obtainable by an operator receiving by sound or sight. The method employed for this purpose is to insert into a gramophone the wireless telephone whereby the received dot and dash signals are impressed on the wax cylinder. These signals may thus be recorded at maximum speed and afterward be removed to another gramophone that may be speeded down to the capacity of the receiving operator. A high rate of transmission of signals is attained by the used of a Wheatstone automatic transmitter (see TELEGRAPHY) using perforated paper tape.»

While the war has interrupted the free use of wireless telegraphy and telephony it has at the same time made demands upon the engineers of this country and Europe in the direction of improvements in these arts that have no doubt produced practical results that would not otherwise have been forthcoming in years. This has been remarkably true with regard to the improvements in vacuum-tube apparatus and the results obtained thereby in the service of the United States Signal Corps. For this service alone the production of high quality standardized tubes has been at the rate of over 1,000,000 per annum. For interesting data on this subject consult a lecture given by Maj.-Gen. George O. Squier before the American Institute of Electrical Engineers, 10 Jan. 1919, on «Aeronautics in the United States from the Beginning of the War to the Present Time.»

The Marconi Wireless Telegraph Station at Belmar, N. J.— The building shown in the foreground is the operating-room of the station. It is over 82 feet in length. This station is intended to communicate with the high power station at Carnarvon, Wales. The masts shown are 300 feet in height and extend westward one mile from the shore. The room containing the tuning apparatus is over 80 feet long. The messages received and transmitted from this station are sent to and from the Marconi offices in Broad street, New York, by automatic telegraph apparatus. Similarly, messages are received and transmitted from the Marconi office in London to the high power station at Carnarvon.

Marconi Wireless Station at Belmar, N. J.

Proposed Pan-American Wireless Chain of Stations.— It has recently been announced that the largest wireless station in the world is to be constructed near Buenos Aires, South America. This will be one of a series of wireless stations designed to connect the United States with all the important countries of South America, including Argentina, Brazil, Uruguay, Chile, Peru and Ecuador. Mexico and Cuba are also to be placed in wireless communication



It is understood that the lofty towers from which the aerials will be swung in the South American station will be of the self-supporting type, somewhat similar to the Arlington towers here illustrated.

with these countries. The South American wireless system will connect at New York with trans-Atlantic wireless to Great Britain, Scandinavia and Russia and at San Francisco with the Hawaiian Islands and thence with the Orient. In the United States the system will connect with the 25,000 stations of the Western Union land lines.

The aerials of the proposed station at Buenos Aires will be supported by self-supporting towers corresponding to the towers of the powerful station at Arlington, Va., which are illustrated in the accompanying illustration. Further details of this projected chain of wireless stations will be found in *The Wireless Age* (August 1918).

TELEKI, Samuel, COUNT, African explorer: b. Saromberke, Eastern Transylvania, 1845; d. March 1916. He won a distinguished place on the roll of African explorers by his expedition of 1886–89, during which Lake Rudolf, fourth in size of the great lakes of Equatorial Africa, was for the first time sighted by white men. The existence of a great lake in the unknown area between the Victoria Nyanza and Abyssinia had for some years been rumored, and after the route in this direction had been opened up by Joseph Thomson's journey through Masailand, Count Teleki was the first to take advantage of this open road. He not only made his way to the lake, but traced it to its northern extremity, bringing back valuable observations on the geography, geology and ethnology of the country traversed. He made various subsequent journeys in Africa and the East, but resulting in no further geographical discovery.

TELEMACHUS, tĕ-lĕm'a-kŭs, in the Homeric Trojan War cycle, a son of Ulysses (q.v.) and Penelope. He was still in the cradle when his father went to the Trojan War. When his father had been absent from home about 20 years, Telemachus was urged by Athēna (Minerva), who appeared to him in the guise of Mentor, a friend of Ulysses, to go and seek him; and as the place of his residence and the cause of his long absence were then unknown, he visited the courts of Nestor and Menelaus to obtain information. He afterward returned to Ithaca, where the suitors of his mother, Penelope, had conspired to murder him; but he escaped their treachery. His father had arrived in the island two days before him, and was then in the house of Eumæus, a faithful swineherd. Telemachus is the hero of Fénelon's famous romance 'Les Aventures de Télémaque' from which the word "Mentor" has been adopted into proverbial use. See TÉLÉMAQUE.

TELEMACHUS, a Syrian monk, who, in the time of the Emperor Honorius, about 400 A.D., leaped into the arena of the Coliseum and attempted to separate the gladiators. He lost his life at the hands of the enraged populace, but the occurrence is said to have influenced Honorius to discontinue gladiatorial combats, which he did soon afterward.

TÉLÉMAQUE, a romance by Fénelon. 'Télémaque' is in form a novel, and relates the adventures of Telemachus in search of his father, Ulysses. In its flowery poetic style, however, and in its division into 24 books, it suggests the epic poem rather than the modern novel. It is based upon the Odyssey of Homer, and uses the mythology and introduces many of the characters of that poem. Its intention was primarily didactic. It was one of several works that Fénelon wrote for the instruction of the young Duc de Bourgogne, grandson of Louis XIV, whose tutor he was (1689–95). By his experiences and observation during his wanderings, in various lands and among different peoples, aided especially by the wise comments and interpretations of Minerva, who accompanies him in the form of Mentor, the young Telemachus, future ruler of Ithaca, and through him the future ruler of France, received those lessons on the proper conduct of life and especially on the duties of a king and on sound principles of government, which were calculated to prepare them for the responsibilities of their high stations. It is a striking mark of the honesty and independence of Fénelon that these lessons are singularly liberal and modern, and contain implicitly a sweeping indictment of the government and policies of Louis XIV. 'Télémaque' has often been translated into English. ARTHUR G. CANFIELD.

TELEMETER, any one of various instruments designed to measure the distance of objects more or less remote. It is used by surveyors and engineers, where rapid work is necessary and a fair amount of accuracy required, on the battlefield to determine ranges, etc., where it is usually called a range-finder. One form is a recording apparatus electrically connected with a distant meteorological or other instrument. The surveyor's telemeter is better known as a stadia, and consists of a mounted telescope with horizontal cross-wires, which, when in use, intercept the divisions upon a graduated rod held by an assistant at the distant point. The reading multiplied by the "factor" of the instrument gives the distance.

TELEOCEPHALL, that is, (Gr. τέλεος) complete (Gr. κεφαλ'η) head. A name applied by some authorities to a group of fishes embracing most of the teleosts, or true bony fishes, especially those bearing a full complement of cranial and opercular bones, with the anterior vertebræ separate.

TELEOLOGY (Greek, *telos,* "end" or "purpose") denotes a mode of explanation in accordance with which the world as a whole, or particular forms within it, are regarded as due to the realization of some end or purpose on the part of some intelligence existing either in the world or outside it. Thus we might account for the various arrangements of the physical universe — the distribution of land and water, the movements of the heavenly bodies, the changes of the seasons — by referring them to some end that the governing power of the universe is thereby achieving, as, for example, the preservation and comfort of mankind. Or we might explain the structure of an organism or of any of its parts by reference to the purpose that it serves, as, for example, the presence of fish in the sea through their usefulness to man as food, or the structure of the eye through the actual service that it renders. It is natural to assume that everything has been made for man and to regard all things as existing for his service and convenience, that «even the cork-trees,» as Hegel remarked in satirizing this view, «have been produced in order that we may have stoppers for our bottles.» Teleology does not always adopt this narrowly anthropocentric point of view. But the very essence of its procedure is to postulate the existence of some intelligible ends or purposes in the world, and to read the various natural phenomena by reference to these ends. It is thus explanation in terms of final causality, rather than in terms of efficient causes or mechanism. Teleology seeks to make things intelligible by showing their relation to an end that is being realized; it answers the question «Why?» or, «For what purpose?» Mechanism, or explanation by efficient causes, on the other hand, knows nothing of a purpose. It shows how the result has actually been produced by the operation of natural causes, acting according to invariable laws. It explains by answering the question «How?» It is well known that there has been a constant conflict, throughout the whole history of thought, between teleological and mechanical modes of explanation. Indeed, this may be said to be the supreme question at issue in all philosophy. Is the world and all that it contains merely the natural product of efficient causes acting without any intelligent guidance, or is there some purpose or system of purposes being realized?

The terms in which the conflict between teleology and mechanism are expressed have been modified in recent times, and it is perhaps well to note some fundamental differences between the thought of the present time and the earlier mode of conceiving teleology. The older teleology regarded God (or the gods) as a being outside of the world who in an external way was accomplishing some purpose through it, as the mechanician uses a machine to accomplish his purposes. From the modern point of view, God is identical with the ultimate principle of things. The purpose of the world, if any intelligible purpose exists, is not something superimposed on it from without, but an inner or immanent purpose to which it naturally and everywhere gives expression. The general acceptance of the modern doctrine of evolution, with its natural explanation of organic forms and modifications, at first appeared to overthrow teleology. For it was from the phenomena of organic life that the defenders of the older teleology had drawn their strongest proofs. Living forms and processes did not seem explicable by mechanical process, and here, at particular points, it was supposed one could trace the operation and determining influence of the teleological factor. The Darwinian theory doubtless destroys the possibility of conceiving teleology as a particular influence that occasionally intervenes at special points in the process of the world, superseding and doing the work of efficient causes. But modern thought has come to realize that the end or purpose is not something that operates here or there, at particular points, but as immanent principle is the underlying basis of the world-process as a whole. In other words, there is no conflict between teleology and mechanism — between explantation by means of final and that by means of efficient causes — when the proper sphere and limitations of each are understood, but it is rather true that as mutually complementary conceptions they presuppose each other. Modern teleology admits to the full the rights of mechanical explanation in every field. But it insists that the facts of experience and the nature of our intelligence demand that we shall everywhere go beyond this standpoint and recognize an underlying system of purposes in the world-process. The two modes of explanation are thus on different planes, and opposition between them only arises from failure to recognize this fact. As Lotze says: «The true source of the life of science is to be found in showing how absolutely universal is the extent, and at the same time how completely limited the significance of the mission which mechanism has to fulfil in the structure of the universe.»

Both a mechanical and a teleological view of the world was developed by Greek philosophy, the former by the Atomists, of whom Democritus is chief, the latter mainly by Plato and Aristotle. The influence of the latter thinkers, united with the general spirit of the Christian doctrines, made the teleological the prevailing mode of explanation during the Middle Ages. The pioneers of modern thought,— Galileo, Bacon, Descartes, Gassendi, Hobbes, Spinoza — worked out anew the mechanical theory, making it a powerful instrument of research by basing it on exact mathematical principles. They were strongly opposed to teleology, which they regarded as entirely unable to furnish scientific explanations of natural occurrences. Leibnitz was perhaps the first thinker in modern times who saw that teleology and mechanism can be reconciled by properly distinguishing the planes where each principle has its valid application. For Kant (whose treatment of teleology is very important), mechanism is the only principle that we can confidently apply in science as objectively determining phenomena. Teleology, on the other hand, although a necessary subjective thought when we are dealing with organic phenomena, cannot be affirmed to have objective application. Living things must appear to us as if they were determined by some end, but we can never say that this purpose is actually present outside our minds in the objective phenomena themselves. At the same time, while mechanism is and must remain the sole principle of determination in the phenomenal world, Kant teaches that we are obliged to postulate a world of noumenal or more ultimate reality where teleology, by recognition of a moral purpose in the world, becomes the final determining principle. would do the same for any sound, even that of speech, this experiment revealed to him the possibility of accomplishing the desired results. The next day he gave instructions for the making of his first real telephone, known as the «Gallows» type. (Fig. 4). It consisted of a framework carrying an electro-magnet with its reed armature, the free end of which was attached to the centre of a small drumhead of gold-beater's skin. A mouthpiece was provided

for speaking purposes. With this instrument, speech sounds were transmitted over a short line and heard by means of a second instrument of like character. From this time on, many forms of receivers and transmitters were experimented with until, on 10 March 1876, the first articulate complete sentences were transmitted. Professor Bell was then experimenting with his liquid transmitter. (Fig. 5). This instrument consisted essentially of a diaphragm, capable of being vibrated by the voice, to the centre of which was attached a small conduct-

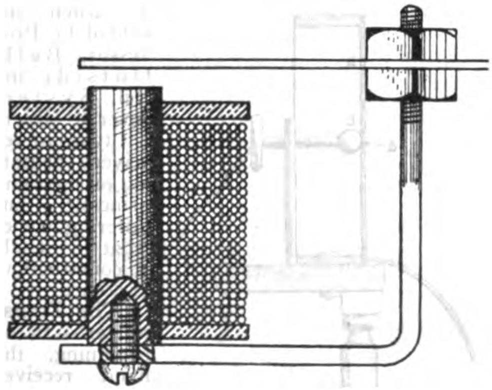

FIG. 6.—Cross-section of Bell's Tuned Harmonic Receiver.

ing rod dipping into acidulated water contained within a small cup. A large flaring mouthpiece was provided and the whole was suitably mounted on a frame and base with connecting terminals. This transmitter was connected in series with a battery and a tuned harmonic receiver. (Fig. 6). Undulating current was produced by the change in resistance of the circuit as more or less of the rod was immersed due to the vibration of the diaphragm. With these instruments, Professor Bell speaking, and Mr. Watson listening, the first complete articulate telephone message was transmitted.

On 9 Oct. 1876 the first reciprocal conversation took place over an outdoor line, two miles long, between Boston and Cambridgeport, Mass. The instruments (Fig. 7) had, as diaphragms,

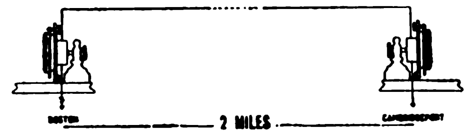

FIG. 7.—Circuit and instruments used by Professor Bell, 9 Oct. 1876. The first time that satisfactory and sustained conversation was carried on by electrical means between persons miles apart.

thin iron discs which responded to the voice vibrations. Close to, but not touching, the centre of the diaphragm was the core of an electro-magnet, the windings of which were connected in series with a battery, the line and a similar instrument at the other end. With these instruments was carried on a sustained conversation which was fully reported in the next morning's papers as the latest startling scientific achievement.

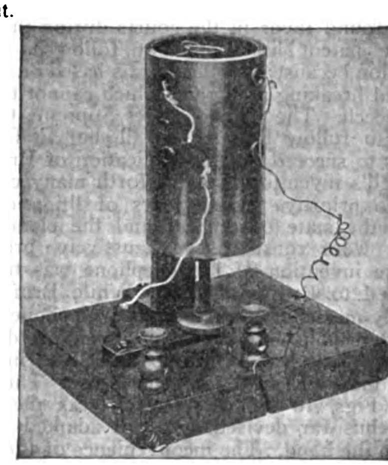

FIG. 8.— Bell's Centennial Iron Box Receiver, 1876.

Professor Bell exhibited his telephone inventions at the Centennial Exposition in Philadelphia in 1876. There he demonstrated, before the judges of the exposition and a large number

of people, his liquid transmitter (Fig. 5); iron box receiver (Fig. 8); single pole membrane telephone (Fig. 9), and other types of instruments. As a result of this exhibition of the telephone its fame spread rapidly.

Work of Early Investigators Preceding Bell.— The idea of applying electricity for the transmission of sound arose as soon as the effects of electric telegraphy were observed. Page, in 1837, discovered that a magnetic bar could emit sounds when rapidly magnetized and demagnetized. Electric vibrators devised by Macaulay, Wagner and Neef and adapted to produce musical sounds by Froment and Petrina in 1847 to 1852, showed that the transmission of sound to a distance was not impossible. Bourseul, in 1854, suggested that if one spoke near a movable disc sufficiently flexible to lose none of the vibrations of the voice, this disc, by alternately making and breaking the current from a battery, might cause another disc, at a distance, to execute the same vibrations simultaneously. Reis, in 1870, invented a musical telephone that, by alternately making and breaking an electric circuit, could transmit musical tones over a wire to a distant point. Reis' work, although urged as an anticipation of Bell, never found favor in the courts during the extensive patent litigation that followed Bell's invention because his scheme was based on making and breaking a current, which cannot transmit speech. The United States Supreme Court said «to follow Reis is to fail, but to follow Bell is to succeed.» The publication of Professor Bell's invention brought forth many claimants to priority. After years of litigation in which the state of the art and the claims of others were considered exhaustively, priority for the invention of the telephone was finally awarded to Professor Bell. While Professor Bell, by means of lectures on the telephone, was arousing public interest in his invention, development work was begun to make the instruments more practical for general use. The box type (Figs. 10 and 11), which was the best form thus far devised, was not adapted to be held in the hand. The inconvenience of the box telephone led to the development of a style of instrument which could be held in the hand readily and used for transmitting or receiving as desired.

The Receiver.— Several forms of receiver (hand telephone) employing wood for the containing case were produced and placed in public use in the early days. Fig. 12 illustrates one of these. This type was subsequently improved in design and hard rubber replaced wood for the handle and ear-piece. (Fig. 13). Thus far the receiver had one pole-piece and coil placed on the end of a permanent magnet. In 1890 the first type of receiver having two pole-pieces and coils was developed. The bi-polar receiver has passed through a long period of evolution, each successive step in the development increasing its talking efficiency or improving the mechanical features of its design. Fig. 14 shows the bi-polar receiver in use at the present time in the Bell System. Two permanent magnets are used. To their poles are welded soft iron pole-pieces which constitute the cores of the electro-magnetic coils. The supporting cup, of non-magnetic material, is welded to the magnets and cores, thus forming a rigid unit which is mounted within a hard rubber case and ear cap. The latter clamps the diaphragm firmly in place close to, but not touching, the pole-pieces. Every part is made of carefully selected material, manufactured to extremely accurate dimensions, and the whole is assembled and tested with the utmost care in order that instruments of the greatest attainable efficiency and mechanical strength may be secured. In all, over 50 different types and styles of receivers have been developed for use in the Bell System. Practically all of these have been abandoned in favor of the latest improved type. While great improvements have been made in the design and efficiency of the telephone receiver, its fundamental electrical principle is the same to-day as when invented by Professor Bell. Outside the Bell System several different types of receivers operating on the same principle, but differing somewhat in details of construction, are used.

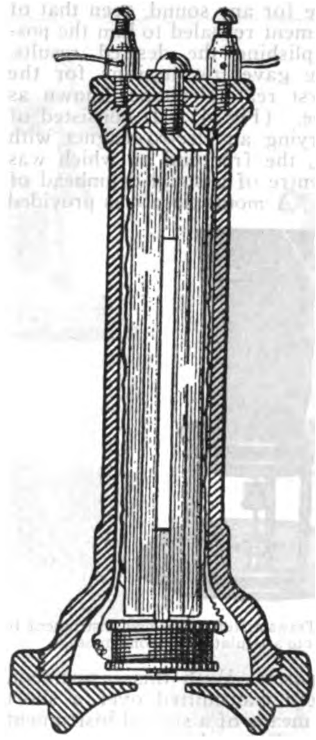

Fig. 13.— Cross-section of improved Hand Telephone, with hard rubber handle and ear-piece.

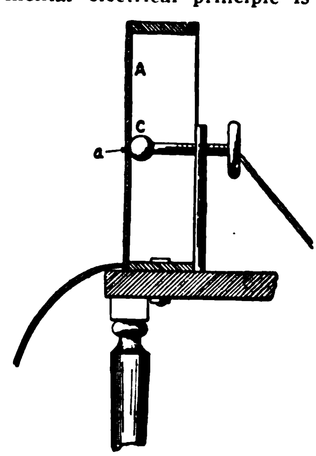

Fig. 16.—Early form of Berliner Transmitter.

The Transmitter.— In the beginning, the hand receiver type of instrument was also used as a transmitter. This was shortly developed into the magneto box transmitter. (Fig. 15). Except for very short lines, this magneto type of transmitter was not sufficiently powerful. The solution of the vitally important problem of improving this part of the telephone system grew out of the invention of the variable contact resistance transmitter.

In 1877 Emile Berliner inverted a transmitter (Fig. 16) having, in contact, two pieces of metal; one stationary, the other capable of being vibrated by the voice. The principle was this: with two bodies in contact and forming part of an electric circuit, if the pressure on the contact be increased, the electrical resistance of the circuit is diminished and more current flows, whereas, if the pressure be diminished the resistance increases and less current flows. In the figure, *A* is a metallic diaphragm capable of being vibrated by the voice. This diaphragm at its centre is in contact with a metal ball *C*. The essential contact is at *a*. Vibration of the diaphragm, as explained above, causes corresponding undulations in the current flowing in a circuit including the contact, a battery, the line and the receiving instrument. In later forms of the Berliner transmitter, carbon contacts were employed instead of metal.

In 1877 Edison invented a transmitter (Fig. 17) in which the current varying element consisted of a small disc of carbon (lamp black) placed between two plates so arranged that the vibration of a diaphragm varied the contact pressure.

In 1878 Francis Blake invented an important improvement in contact or microphone transmitters. He employed a platinum point

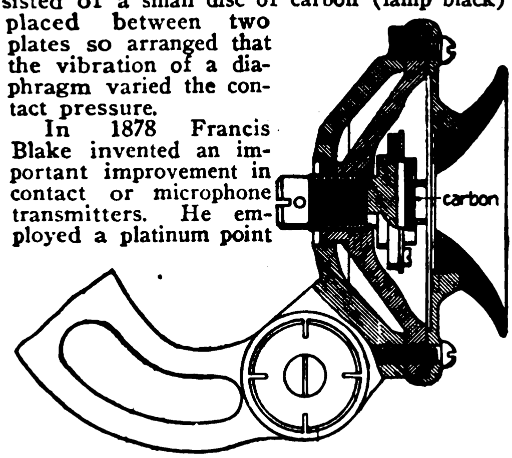

FIG. 17.—Cross-section of Edison Carbon Transmitter. Later type.

bearing against a hard carbon surface. Fig. 18 is a cross-section of a Blake transmitter. The platinum point *K* is borne by a light spring *A*. The hard carbon disc *C*, mounted in a brass cup *W*, is supported by a substantial spring *S*. The platinum and carbon are first brought into light contact with each other after which the platinum point is forced against the diaphragm centre under considerable pressure from spring *S*. The commercial form of this instrument

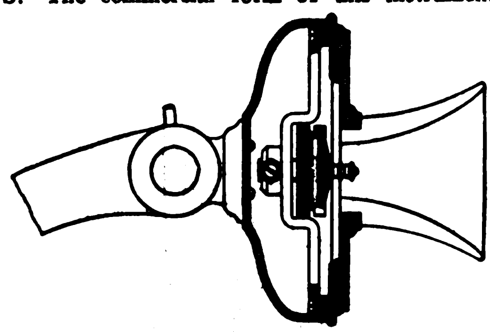

FIG. 21.—Cross-section of modern Solid Back Transmitter.

(Fig. 19) displaced the Berliner and Edison types and was extensively used for a long time as the Bell System standard.

In 1880 an English clergyman, Henry Hunnings, invented a transmitter employing granular carbon to secure a large number of points of microphonic contact. The essential feature was a thin platinum diaphragm in contact with a mass of granular carbon enclosed within a chamber having at the rear a plate of metal or carbon in contact with the granular carbon. In 1885 Bell engineers improved the Hunnings transmitter (Fig. 20) by using a horizontal platinum diaphragm *A* and a gold-plated electrode *C* dipping into the granular carbon. While this transmitter operated well when at its best, after being used for some time the large quantity of granular carbon produced an insensitive condition that seriously affected its efficiency.

To overcome this, A. C. White, in 1890, working in the Bell laboratories, invented the solid back transmitter (Fig. 21) in which the contact element is in the form of a small chamber (termed the "button") containing two carbon disc electrodes; one fixed, the other free to vibrate. These electrodes are separated by a small space partially filled with granular carbon. The fixed electrode is rigidly supported by the solid backing afforded by a stout metal bridge. The movable electrode is firmly attached to the centre of the diaphragm. The function of the granular carbon is the same as in the Hunnings type but the defects of the latter are overcome. This instrument has proved so perfect in its operation and so satisfactory in its general design that it has formed the basis of all the best types of transmitter. A number of modifications from the original design have, however, been made to improve its electrical and mechanical features. Fig. 22 shows the construction of the "button" of the modern common-battery solid back transmitter. Over 70 different types and styles of transmitter have been developed and placed in service by the Bell system. Practically all of them have been displaced by the type just described. Transmitters employed by independent companies operate on the same general principle as the type just

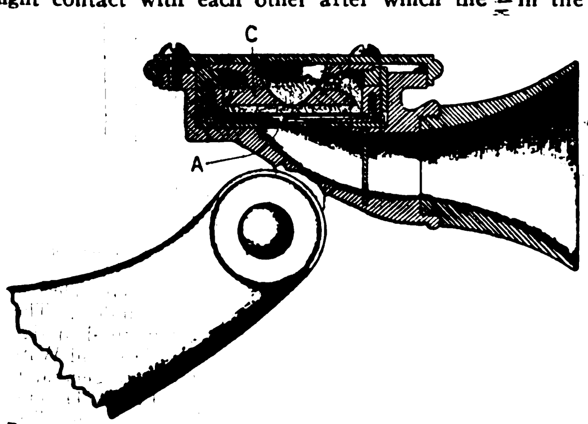

FIG. 20.—Cross-section of early form of Long Distance Transmitter.

described and resemble it in appearance.

The Induction Coil.— Coincidently with the introduction of the variable contact (microphone) transmitter came the application of the induction coil to the telephone. Fig. 23 shows

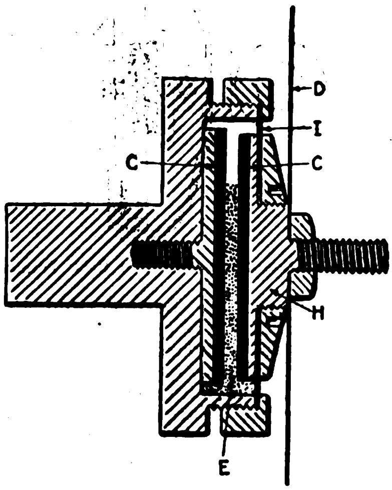

Fig. 22.— Cross-section of Granular Button or Cell for Solid Back Transmitter.

the original telephone circuit and two important steps in the evolution of telephony whereby it became possible to talk over greater distances than formerly. In the simple magneto telephone circuit *A*, the amount of electrical energy transmitted depended on the ability of the telephone, when spoken into, to generate a current independent of any outside source. This current was limited in strength to the small amount obtainable from the vibration of the diaphragm by the voice. *B* in Fig. 23 shows a circuit in which the variable contact transmitters, the receivers, the line and the source of

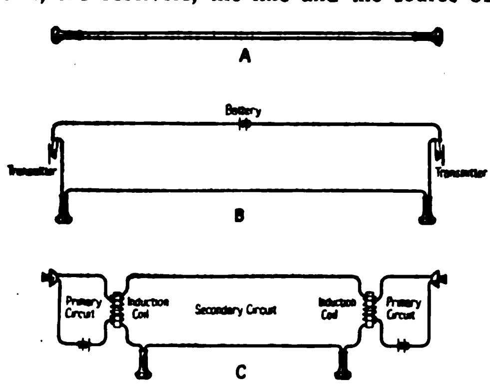

Fig. 23.— Three steps in the evolution of the telephone circuit.

energy (battery) were connected together in series. With this arrangement better results were obtained, the extent of improvement depending on the voltage of the battery, the conductivity of the line and the current changing capabilities of the transmitter. In this circuit the transmitter acted as a valve to vary the energy furnished by the battery. *C* in Fig. 23 shows the use of the induction coil, the latter consisting of a bundle of iron wires surrounded by two separate wire windings. Each transmitter is placed in series with a battery and the primary winding of an induction coil consisting of a few turns of large wire. The secondary winding of the induction coil, consisting of many turns of relatively fine wire, is connected in series with the line and the receivers. Placing the transmitter in a local circuit, independent of the line circuit, permitted the use of a low voltage battery and allowed the variation in resistance produced by the transmitter to be large in comparison with the total resistance of the primary circuit. The induction coil operates as a transformer. The relatively large variable current at low voltage in the primary circuit is transformed into a small current at high voltage in the secondary circuit by reason of the large ratio of the number of turns in the secondary winding to those in the primary winding. The secondary current traverses the line with less loss than would be the case if the current were of lower voltage but larger.

Signalling Systems.— When the box telephone was first employed, the custom was to tap on the diaphragm with a pencil as a method of calling the party at the other end of the line. Later this was superseded by a hand-operated hammer mechanism which gave a vigorous blow on the diaphragm that was transmitted telephonically to the station at the other end of the line (Fig. 11). Tap bells were also em-

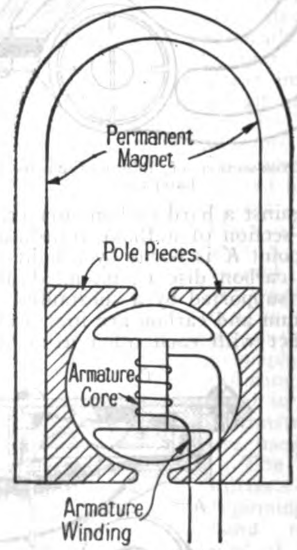

Fig. 26.—Diagram of Magneto Telephone Generator.

ployed for signalling as were ordinary electric vibrating bells and telegraph sounders. The need for a reliable and efficient method of signalling was realized at an early date and Watson developed a ringer and magneto-generator to meet this need. The ringer (Fig. 24) consisted of an electro-magnet having a centrally-pivoted polarized armature carrying the striker which played between two gongs. Polarizing the armature made it responsive to the reversals in polarity of the magnet when alternating current passed through the coils of the latter. To furnish the alternating current, a small magneto-electric generator (Fig. 25) was provided, consisting of a powerful permanent magnet carrying an armature capable of being rotated by a wheel which the calling party turned by means of a crank. Figs. 26 and 27 show, in diagrammatic form, the principles of the latest types of generator and ringer.

Automatic Switchhook.— It was early apparent that some means should be provided for switching, to and from the line, the signalling and talking circuits at the substation whenever it was desired to do so. At first, hand-operated switches were used for this purpose but it was

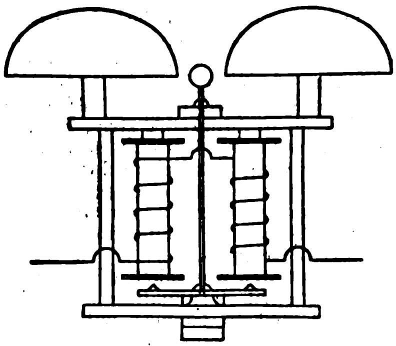

Fig. 27.—Diagram of Magneto Telephone Ringer.

soon found desirable to make the switching operation automatic, as users would frequently leave the hand-operated switch in the wrong position. To attain this end, a lever switch upon which to hang the receiver was invented by H. L. Roosevelt. The switch was operated by the weight of the receiver. Fig. 28 shows an early set arranged to accomplish the desired purpose. The hook-switch, in its downward position, left the circuit free for the incoming signal; in its upward position, which it assumed when the receiver was removed from it, the necessary contacts for talking were closed. Figs. 29 and 30 illustrate the switchhook arrangement for the present telephone. Figs. 31 and 32 show the circuits controlled by the switchhook for a standard magneto and common-battery substation circuit respectively.

Series and Bridging Bells.— In the early days, after the development of the magneto-bell, or "ringer," it was the practice, on party lines, to connect the sets in series, as shown in Fig. 33. To enable the ringer to operate effectively it was necessary to provide it with a large num-

Fig. 30.— Switchhook for Modern Telephone, showing contacts.

ber of turns of wire. As a result these ringers possessed considerable impedance, i.e., they offered substantial obstruction to the telephone

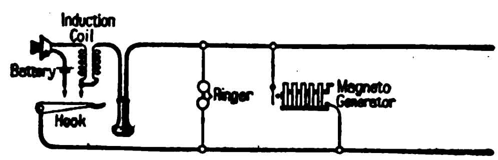

Fig. 31.—Magneto Substation Circuit.

current, seriously affecting the service between any two talking stations. The more ringers in the circuit, the poorer was the talk. To improve

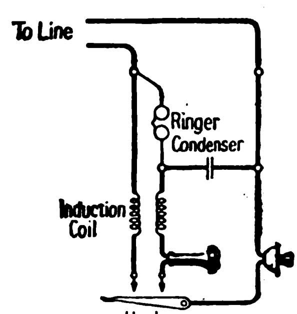

Fig. 32.—Common-Battery Substation Circuit.

this condition, in 1889, John J. Carty, who at that time was known as one of the chief technical experts, and who has since become the rec-

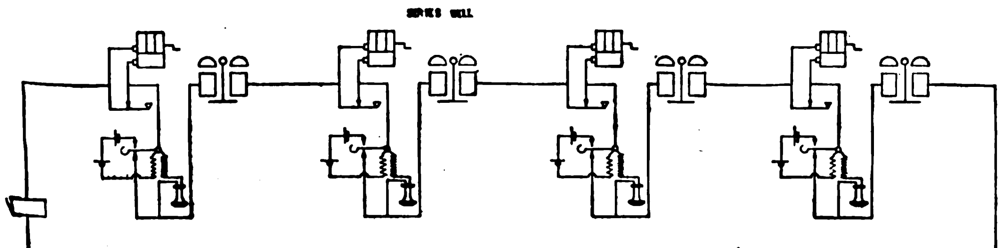

Fig. 33.—Party Line Circuit with Series Bell.

ognized engineering leader in telephony, invented the bridging bell. In this arrangement (Fig. 34) the bell, or "ringer," has a high impedance winding which, while responsive to the relatively low frequency ringing current, does not permit the talking current to pass over the ringer circuit, but does allow it to pass over the line from one station to another. It was this invention which made possible the successful use of party lines.

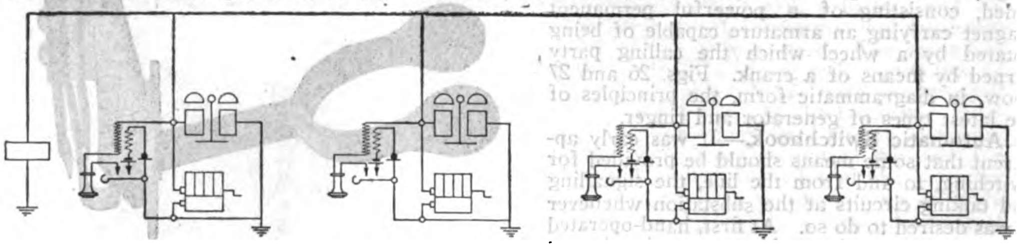

FIG. 34.—Party Line Circuit with Bridging Bell.

Switchboards.— If its use had been restricted to isolated lines only, the telephone would undoubtedly have remained scarcely more than an interesting scientific curiosity. With the development of the instruments themselves, the necessity for connecting one telephone station with another, by means of some switching device, at once became apparent.

The first interconnection of telephone lines by means of a switchboard took place at Boston in 1877. A few burglar-alarm lines were equipped at the station ends with box telephones. At the burglar-alarm office, each line was connected to a small metal block. These blocks were so arranged, in relation to other metal blocks placed closely beside them, that metal plugs could be employed to connect the blocks together in various ways, thus permitting the lines to be interconnected as desired. (Fig. 35).

The first commercial switchboard was installed at New Haven, Conn., in January 1878. (Fig. 36). This small board accommodated only a few lines. It did away with the block and plug method of connection, substituting, for the latter, pivoted strips of metal adapted to be rotated into contact with metallic buttons, all being mounted on a wooden board. Each line was connected through the pivot, with one of the rotatable metal strips. Every other line was connected with a metal button, these buttons being so placed, around the circumference of a circle, that, by rotating the strip, connection could be made with any desired button and line.

Shortly following this, many different types of switchboards were made employing either plugs or button switches in various arrangements for making the connections. Fig. 37 shows one of these types.

An important step was taken when the flexible connecting cord, terminating at each end in a plug, adapted to connect with any line, was adopted as a substitute for the hand switch described above. Fig. 38 shows an early type of board employing connecting cords. In this style of board each subscriber's line was provided with an electromagnetic annunciator the shutter or index of which moved, when a subscriber operated the magneto-generator at his station, thus attracting the operator's attention to the fact that a connection was desired. Each subscriber's line was also connected at the

switchboard to a device known as a «spring-jack.» The insertion of one plug of a connecting cord into the spring-jack associated with the line of the calling subscriber and the plug at the other end of the same cord into the jack of the line of the called subscriber, placed these subscribers in connection so that they could talk with each other. The cords were provided with listening and ringing keys. The former enabled the operator to communicate with the calling subscriber to ascertain the line with which connection was desired. The latter permitted the operator to send alternating current over the called line for the purpose of ringing the called subscriber's bell. An electromagnetic disconnect annunciator in each cord circuit enabled either subscriber, by operating his magneto-generator, to signal to the operator that the conversation had ended.

as the «transfer» board. As the number of lines grew, it gave less satisfactory service and it was seen that, unless something better was developed, the switchboard would be a serious limitation on the growth of the business. The solution was found by multiplying the points of access to each subscriber's line so that a means of access (spring-jack) to each subscriber's line in the office appeared in the face of the switchboard within reach of every operator, thus obviating the necessity for trunking calls between operators in the same office. The switchboard in which this «multiple» principle was first used was known as the «series multiple» board. The invention of the multiple was made by L. B. Firman. A simplified diagram of the wiring of this board is shown in Fig. 39, which also illustrates the construction of the spring-jack. In this arrangement each subscriber's line was carried through the board with branching taps to the ring (outer contact) of the jack associated with the line at each operator's position. The other side of the line was carried through the board in series with the cut-off spring contact of each jack associated with the line. The object of the spring contact was to disconnect the line signal from the line while talking was going on.

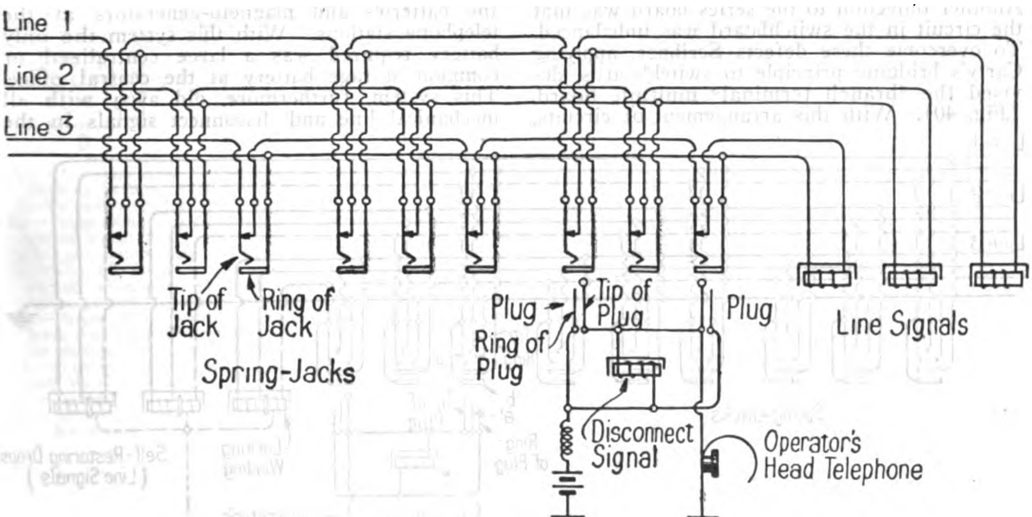

Fig. 39.—Simplified Circuit Diagram of Series Multiple Switchboard. (Operator's telephone shown connected for "busy test").

Switchboards of this general type were used until the number of lines terminating in a telephone central office had grown so large as to exceed the ability of one operator to complete all of the connections. This situation was met by placing two or more switchboards side by side, the operators completing the connections by reaching across, with their flexible cords, from one board to another. As the number of sections of switchboard placed side by side increased still further, the distance to which an operator could reach was exceeded. The next step was to join the sections of switchboard by metal strips or wires. An operator could then connect a calling subscriber with a certain strip and request another operator, more conveniently situated, to connect the called subscriber to the same strip. These strips constituted the first use of the so-called «trunk line» between switchboards. The practice led to much confusion, due to the operators calling out the desired numbers, and resulted in the development of means enabling the operators to communicate along the switchboard by telephoning one another. This type of switchboard was known

As every line appeared at several points, so as to be accessible to every operator, it became necessary to provide some means for indicating to the operator desiring to complete a connection, whether or not the called line was already in use. To accomplish this Charles E. Scribner, for many years chief engineer of the Western Electric Company — the manufacturing department of the Bell Telephone System — invented the click busy test. The circuits were so arranged by him that when one operator had inserted a plug in the jack of any line, an electrical potential was placed on the rings of all of the jacks of that line which were multipled before the operators. Any operator desiring to complete a connection with a line was required to touch the tip of the connecting plug against the ring of the jack with which connection was desired before completely inserting the plug into the jack. If the desired line was already in use, the potential on the ring of its jack would cause the operator to hear a «click» in her head telephone, thus indicating that the line was already in use through a connection established at some other part of the switchboard. These two very important principles — the multiple and the busy test — have persisted, in one form or another, in every large switchboard up to the present time. A serious objection to the series type of board was that dirt or dust, accidentally lodging in the spring jack contacts, would introduce high resistance into the line, or even cause the circuit to become open, thus interfering with or quite preventing conversation over the line. Another objection to the series board was that the circuit in the switchboard was unbalanced. To overcome these defects Scribner, applying Carty's bridging principle to switchboards, devised the «branch terminal» multiple board. (Fig. 40). With this arrangement of circuits, two wire system, the switchboard had to be adapted throughout to the new plan of working. This meant a wholesale displacement of existing grounded line switchboards by boards of the newer metallic circuit type.

For a long time after multiple switchboards came into use, batteries were required at each telephone station to furnish the current for actuating the transmitter, and magneto-generators, operated by turning a crank, were employed for signaling the central office whenever a connection was desired. The generator was also used for signalling «disconnect,» and was not wholly satisfactory for this purpose, as subscribers frequently neglected to give the disconnect signal, making it necessary for operators to «listen in» on connections and ask «Are you through?» The invention and development of the common battery system did away with the batteries and magneto-generators at the telephone stations. With this system the only battery required was a large centralized or common storage battery at the central office. This system, furthermore, did away with all mechanical line and disconnect signals in the

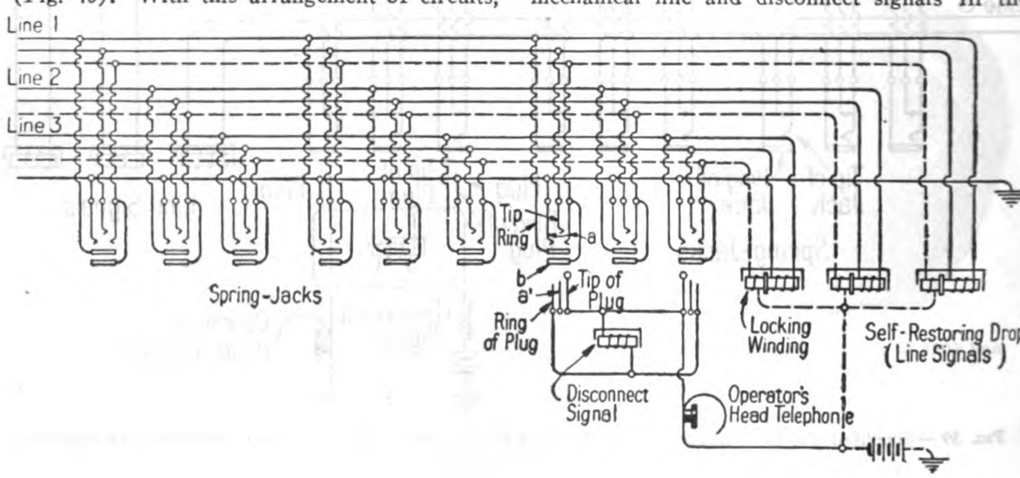

Fig. 40.—Simplified Circuit Diagram of Branch Terminal Multiple Board. (Operator's telephone shown connected for "busy test").

Description of operation: On insertion of plug, springs (*a*) are connected together by collar (*a'*) on plug, causing current to flow from battery, through locking winding of drop, to ground, restoring shutter of drop to original position, and also preventing operation of drop while line is in use. It also places test thimble (*b*) and all other test thimbles on same line at ground potential. Operator on touching such thimbles with tip of plug gets flow of current through her receiver, and is warned that line is in use, by click in her ear. When line is not in use, thimbles are at same potential as tips of plugs, and no click occurs.

bridged multiple taps were provided from each side of the line to springs in the jacks in the multiple before the operators, and the line signals were wound to a high impedance. By doing this, and adding a locking winding to prevent false operation, the need for disconnecting the line signals from the circuit when the line was in use was avoided. A feature added at this time was the «self-restoring» drop (line signal) which provided for the automatic restoring of the annunciator to its original position upon the insertion of a plug in the answering jack of the calling line. Before this time, the annunciators had to be restored by the operators by hand.

The metallic circuit principle (described below) was introduced in switchboards at an early date, for as soon as any of the lines in a telephone office were changed to the metallic, or switchboard by enabling tiny electric lamps, governed by relays, to be substituted for them. This was one of the most important improvements ever made in telephone switchboards. The subscriber, connected with a common battery board, calls the central office by merely removing his receiver from the hook, the motion of the latter causing a lamp associated with his line to light before the operator. Completion of the conversation is indicated to the operator by suitable lamp signals in the cord circuit, when the receiver is replaced upon its hook. The circuits of common battery switchboards are of two types,— the impedance coil type and the repeating coil type. Fig. 41 shows a typical circuit diagram of the latter type, which is the more generally employed. Fig. 42-A shows the front view of a modern common-battery switchboard. The operators sit on chairs in front of the switchboard. Fig. 42-B shows the detail of a single position. Where the telephone message is the unit of service charge, each subscriber's line is provided, at the central

office, with an accurate message registering device, by means of which each completed connection can be recorded.

Trunking Systems.— In large cities it is impracticable to concentrate all subscribers' lines at one central office on account of the distances involved, which affect both the resistance of the lines and their cost, and also on account of the fact that more than one switchboard would generally be required. Where several central offices are required in one city, connections from subscribers whose lines terminate at one office to subscribers whose lines terminate at another office must be completed with the aid of trunk lines connecting the offices. In the early days, an operator, initiating a trunked connection, by applying the busy test, selected an idle trunk line over which she called the operator at the distant office by ringing as though the trunk were a subscriber's line. When, in response to a signal operated by the ringing current, the operator at the distant office answered, the first-mentioned operator transmitted to her the number of the line with which connection was desired and this line was then connected by her to the trunk line.

Trunking was greatly improved by the advent of the reverse call-wire method. With this method the operator at the office where the call originates (known as the «A» operator), by depressing a push button key, of which she has one for each central office in the district, establishes connection with a call circuit permanently connected with the head telephone of the operator at the distant office (known as the «B» operator). The number of the desired line is then transmitted over the call circuit to the «B» operator, who, by visual inspection, selects an idle trunk line and transmits back its number to the «A» operator, who at once connects the calling party with that trunk line, the «B» operator meanwhile establishing connection between the other end of the same trunk line and the line of the called party. The call circuits are used for no other purpose than communication between operators.

Trunk circuits have been designed, and are in general use, which allow the «A» operator to supervise a connection completed in a distant office as readily as would be the case with a connection completed in her own office. The same is true of machine ringing circuits whereby the bell of the called subscriber at the distant office begins to ring automatically as soon as the trunk line plug is inserted in the jack of his line without the «B» operator being required to operate a ringing key.

Toll Boards.— The term «toll connection» is applied to connections between subscribers so far removed telephonically from each other that a special toll charge is made for the connection. On account of the fact that the toll lines between one place and another have to be grouped together for efficient operation and that each toll message has to be carefully timed and a ticket record made of the call, toll connections generally require special switchboard circuits and apparatus at the central office and the service of special operators. In the case of the smaller central offices the toll switchboard is sometimes combined with a portion of the local switchboard. In larger places, to enable adequate toll service to be given, separate large and complicated toll switchboards are ordinarily required. These toll switchboards are usually centralized at one point in the city and are connected by special trunk lines with the local switchboards in the several central offices of the city. In cities of the largest size more than one toll switchboard centre may be required.

Party Lines.— Serving more than one telephone user by means of a single line (party line) enables those having but little use for the telephone to obtain service on a basis which otherwise would be impracticable. The successful operation of the party line depends upon the Carty bridging bell principle already described. The extensive use of party lines to serve farmer's or rural stations, by destroying the isolation of the farmer, has produced a wonderful improvement in his economic and social life by placing him in constant touch with markets and sources of supply, and with the weather bureau, and has provided for his family a means of communication available not only for social purposes, but also ready at all times for summoning help in the event of sickness or danger. On party lines equipped with two stations, and on some equipped with four stations, means have been devised whereby the bell at a given party line station may be rung, the others meanwhile remaining silent.

Private Branch Exchanges.— Important adjuncts to the telephone central office are the private branch exchanges. These consist of switchboards, generally of small size, located in such places as hotels, apartment buildings or large business houses and having connected to them all the subscriber's lines in such establishments. Private branch exchanges are also connected with the nearest telephone central office by a sufficient number of trunk lines to handle the traffic arising from and flowing to them. Calls originating within the establishment where the private branch exchange is located, for parties within the same establishment, are completed by the private branch exchange operator without passing through the telephone central office. The introduction of the common battery system greatly facilitated the operation of private branch exchanges and enabled the necessary talking current to be supplied over trunk lines from the central office. Fig. 43 shows a typical private branch exchange of moderate size. Some of the largest private branch exchange switchboards are comparable in size to central office switchboards serving large communities.

Automatic Systems.— Throughout the development of the manually operated switchboard, the tendency was continually toward increasing the use of automatic labor-saving machinery. In the most modern forms of manually operated boards a complete analysis of all the operations involved shows that a large proportion of them are performed automatically. The term "automatic," or "machine switching," is, however, applied to systems in which the number of operators required at the central office is reduced to a relatively small number, the switching functions otherwise performed by operators being, to a greater or less extent, performed by electro-mechanical appliances. During recent years there has been extensive development of machine switching systems. The apparatus is highly complex and ingeniously devised.

In what is known as the full automatic system, the subscriber puts the automatic mechanism at the central office in motion and directs it so as to obtain the desired connection by suitably operating a movable numerical dial attached to the base of his substation set. Fig. 44 shows a typical set with the dial. The face of the dial is shown in Fig. 44-A.

Briefly the operation is as follows: Assume connection is desired with subscriber's line 753. The calling subscriber places his finger-tip in the hole of the dial, on his set, over figure 7 and turns the movable part of the dial in the direction of the hands of a clock, until his finger reaches the crescent-shaped stop. He then releases the dial which is automatically moved back, in the opposite direction, by a spring. This motion, by making and breaking a current on the line seven times, sets in operation in the central office an electro-mechanical device known as a selector, whose function it is to select some idle trunk line in the 700 group. These trunk lines terminate in other selectors of a similar type. By repeating the dialling operation, this time for figure 5, connection is established with the fifties in the 700 group. By dialling once again, this time for figure 3, the line of the calling subscriber is placed in connection with line 753. The selectors are made in a great variety of forms. In one form the terminals of the trunks and subscribers lines are arranged in panels, one above another, with selector rods moving vertically in front of these panels. In another form the terminals are arranged in layers around an arc, contact being established by a central arm capable of being raised to the proper level and then rotated.

In both forms suitable means are provided for automatically ringing the called subscriber's bell and for indicating to the calling party when the called line is already in use.

In the semi-automatic system the subscriber removes his telephone from the hook and transmits the desired number by telephone to the central office operator, as in the manual system. Thereafter, however, the operator makes use of automatic machinery at the central office to complete the connection, instead of performing the switching operations manually.

In modern telephone engineering the particular factors, surrounding each case where new central office equipment is to be recommended, are carefully studied in order to decide whether a manual, semi-automatic or full automatic system is, in view of all the circumstances, the best. The names of Keith, Lorimer, McQuarrie and Strowger are prominent among those who have contributed to automatic switchboard development.

Telephone Lines. Early Lines Similar to Telegraph Lines.— The first telephone line was a copy of the best telegraph line of the day. It was a single iron wire using the ground for a return circuit. In addition to electrical disturbances, coming from no one knew where, picked up by these early grounded lines, and frequently causing noises in the telephone so loud as to destroy conversation, it was discovered that iron wire was not as good a conductor for the telephone current as it was for the telegraph current. The talking distance, therefore, was limited by the imperfect carrying power of the conductor. It was realized that, if the telephone system was to grow, something better than iron wire would be required. Various metals and alloys were studied and it was found that copper best met the electrical requirements. But copper made into wire according to the then state of the art was too weak in mechanical strength. T. B. Doolittle conceived the idea that if a copper rod could be drawn cold through a series of dies, the resulting wire would acquire a degree of tensile strength much greater than that of the soft, annealed wire which was the only copper wire then known to the trade. He conducted a series of experiments which resulted in the production of commercial hard drawn copper wire having substantially all of the favorable electrical characteristics of soft copper wire, coupled with a tensile strength nearly double that of the soft wire, and fully equal to the strength of ordinary iron wire of the same size.

An experimental line, the first long distance telephone line in the world, was constructed in 1884 between New York and Boston, carrying two hard drawn copper wires 0.104 inches in diameter. The satisfactory conversations conducted over this line demonstrated the commercial feasibility of the new type of wire. In the following year, 1885, another line, built between New York and Philadelphia, was equipped with 24 hard drawn copper wires of various sizes. Careful experiments conducted on this line established the properties and qualities of the new product and the relative efficiencies of different sizes and variations.

Following this development, the use of hard drawn copper wire became the standard for long telephone lines, first in the Bell Telephone System, and later the world over, greatly extending the range of transmission. In 1892, New York was placed in telephonic communication with Chicago. The wire employed for

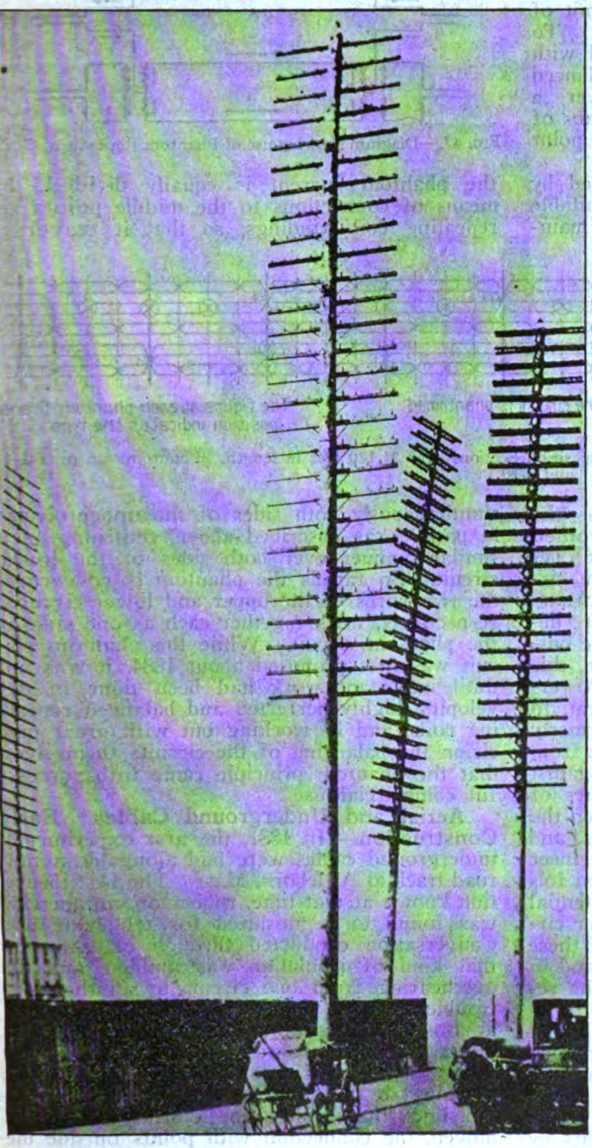

FIG. 45.— Highest Pole Line ever built, on West street, New York City. Poles were 90 feet long and some of them carried as many as 30 crossarms.

this circuit, which first realized the commercial 1,000-mile talk, was of hard drawn copper No. 8 B. W. G. in size (0.165 inches in diameter). The pair of wires required to connect Chicago with New York weighed about 870,000 pounds — a full load for a 22 car freight train.

Before the local service wires in cities had reached such numbers as to necessitate placing them underground they had been strung on poles and roof tops. This was objectionable on account of the corrosion of the iron wires by chimney gases, wires breaking when loaded with sleet, the cost of roof-repairing, the unsightliness of the construction and the lack of room for more wires. It was, however, the only possible way known at that period. The overhead method was soon outgrown. Some streets in the larger cities had become black with wires. Poles had risen to 50 feet in height, then 60, 70 and 80. Finally, the highest of all pole lines was built along West street, New York City, using 90 foot poles of Norway pine, and carrying 30 crossarms and 300 wires. (Fig. 45). This condition of wire crowding was overcome by the development of cables, later described.

Telephone Grounded Circuit. Difficulties.— When the ground was used for the return circuit, not only was the talking distance limited by the confusing effect of all sorts of disturbing currents from the atmosphere and from neighboring telegraph wires, but also, when a second telephone wire was strung alongside of the first, even though perfectly insulated from it, conversation carried on over one of these wires could be heard plainly on the other.

The Balanced Metallic Circuit. Open Wire Lines.— In 1883, it was discovered that the bad effects of these disturbing currents could be greatly lessened by severing the earth connection from the ends of each wire, and substituting a second wire for the return circuit through the earth. The new arrangement was known as the «metallic circuit.» For the reason that the «metallic circuit» principle involved rebuilding practically the entire plant, telephone engineers sought less costly methods of reducing the electrical disturbances.

Between 1885 and 1892, large numbers of so-called anti-induction devices were proposed and investigated. None of them proved sufficiently successful to warrant adoption. Those that killed induction killed transmission as well. A system using a common return wire for a number of telephone circuits was used to a considerable extent. It reduced the disturbances due to ground potentials but was not effective against induced currents. The reconstruction of the telephone plant on the metallic circuits basis was carried out largely between 1890 and 1900.

To aid further in rendering metallic circuits free from induction from power circuits and from crosstalk, the wires were transposed (i.e., interchanged in position on the crossarm) at periodic intervals of space.

The first transposition scheme was worked out in 1886.

Fig. 46 shows a typical transposition diagram for the 10 wires carried on one crossarm of a line. On this diagram the vertical lines represent poles 1,300 feet apart, that is, about every 10th pole. The interchange in position of the wires is indicated by the crossing of the horizontal lines which represent the wires. At the points indicated by small circles, special types of transpositions are placed to admit of phantom circuit working (described below). To ensure quiet circuits, the apparatus used with metallic circuits has to be carefully balanced when arranged for talking. Wherever a ground connection is used, as in some forms of signalling, it has to be placed at a neutral point in the telephone circuit.

Balance in the line circuits is attained by uniformity in the wire used and by suitable arrangements in its installation and maintenance. Any slight imperfection in the balance of the line conductors in phantomed circuits manifests itself by crosstalk between the phantom and its constituent circuits. While the metallic circuit, transposed according to the methods first devised by the Bell engineers, eliminated the outside disturbances that existed at the time, this was not the state of affairs for long. Powerful electric light and power circuits began to spring up and methods which had formerly been successful in protecting the telephone from disturbing currents were not effective against these new high powers. Years and years of work have been devoted to safeguarding the telephone circuit from these disturbances, and each new success which the telephone engineer has accomplished in this direction has been followed by a further advance in high potential and high current on the part of the power circuits. It has been said with truth that if these high power circuits had been discovered and in use before the telephone was invented, the results obtained from the first telephone lines would have been so utterly impracticable that it is hard to think of any one being rash enough to regard the telephone as having any commercial value.

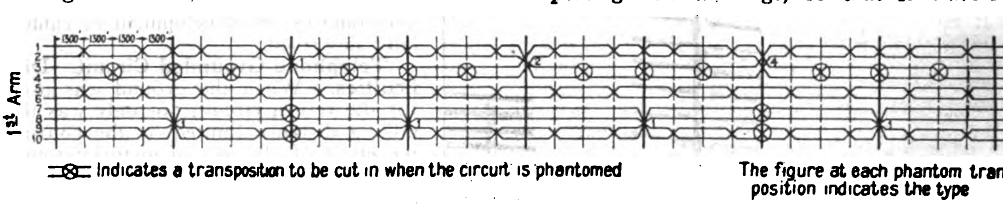

Fig. 46.— Typical Transposition Diagram for Transposition Sections over 21,120 feet in length. Phantoms on pins 1-4 and 7-10.

Phantom Circuits.— It is possible to make a third circuit out of two metallic circuits by connecting them together, with suitable apparatus, in a peculiar way. (Fig. 47). The third circuit is termed a "phantom" circuit. Conversations can go on over a phantom circuit without disturbing, or being disturbed by, simultaneous conversations over the two metallic circuits from which the phantom circuit is formed. The operation of the phantom circuit depends upon the principle that if two currents of exactly the same strength, and similar in all respects as to form, are transmitted simultaneously over the two wires of a circuit, they produce no sound in the telephones associated with that circuit. Fig. 47 shows how

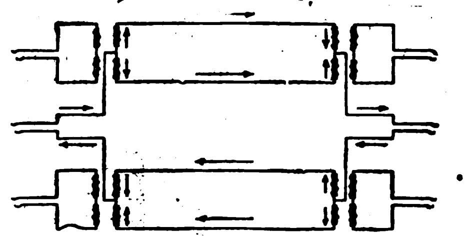

Fig. 47.—Diagram showing use of Phantom Repeating Coils.

the phantom current is equally divided, by means of connections to the middle points of repeating coil windings, so that it traverses simultaneously both sides of the upper circuit in parallel, as described above, returning in a similar manner over both sides of the lower circuit. So far as the phantom is concerned, the two wires of the upper and lower circuits, respectively, work together each as one side of the phantom circuit. While the phantom circuit was first proposed about 1884, it was not until important work had been done in developing highly perfected and balanced repeating coils, and in working out with great precision the balancing of the circuits themselves, that the phantom principle came into successful commercial use.

Aerial and Underground Cables. Early Construction.— In 1881, the first experimental underground cables were laid alongside a railroad track at Attleboro, Mass. The best insulation known at that time, rubber or guttapercha, was found to be unsuited for telephone use. Conversation conducted through cables using that kind of insulation was muffled, and the overhearing from one circuit to another was troublesome. In 1882 several cables were laid at Boston, Mass., the longest of which was about 1,500 feet. It was found that when these cables were used in connection with lines reaching to the suburbs, the voice became so indistinct that, unless the difficulty were removed, the connection with points outside the city would have been almost, if not quite, useless to those whose wires were underground. Type after type of cable was installed only to be withdrawn in a few years and replaced by something better.

The use of rubber insulated cable was followed by the development of a cable in which the individual wires were covered with cotton insulation and drawn into a pipe which was then filled with oil. This oil-filled cable carried the telephone business through half

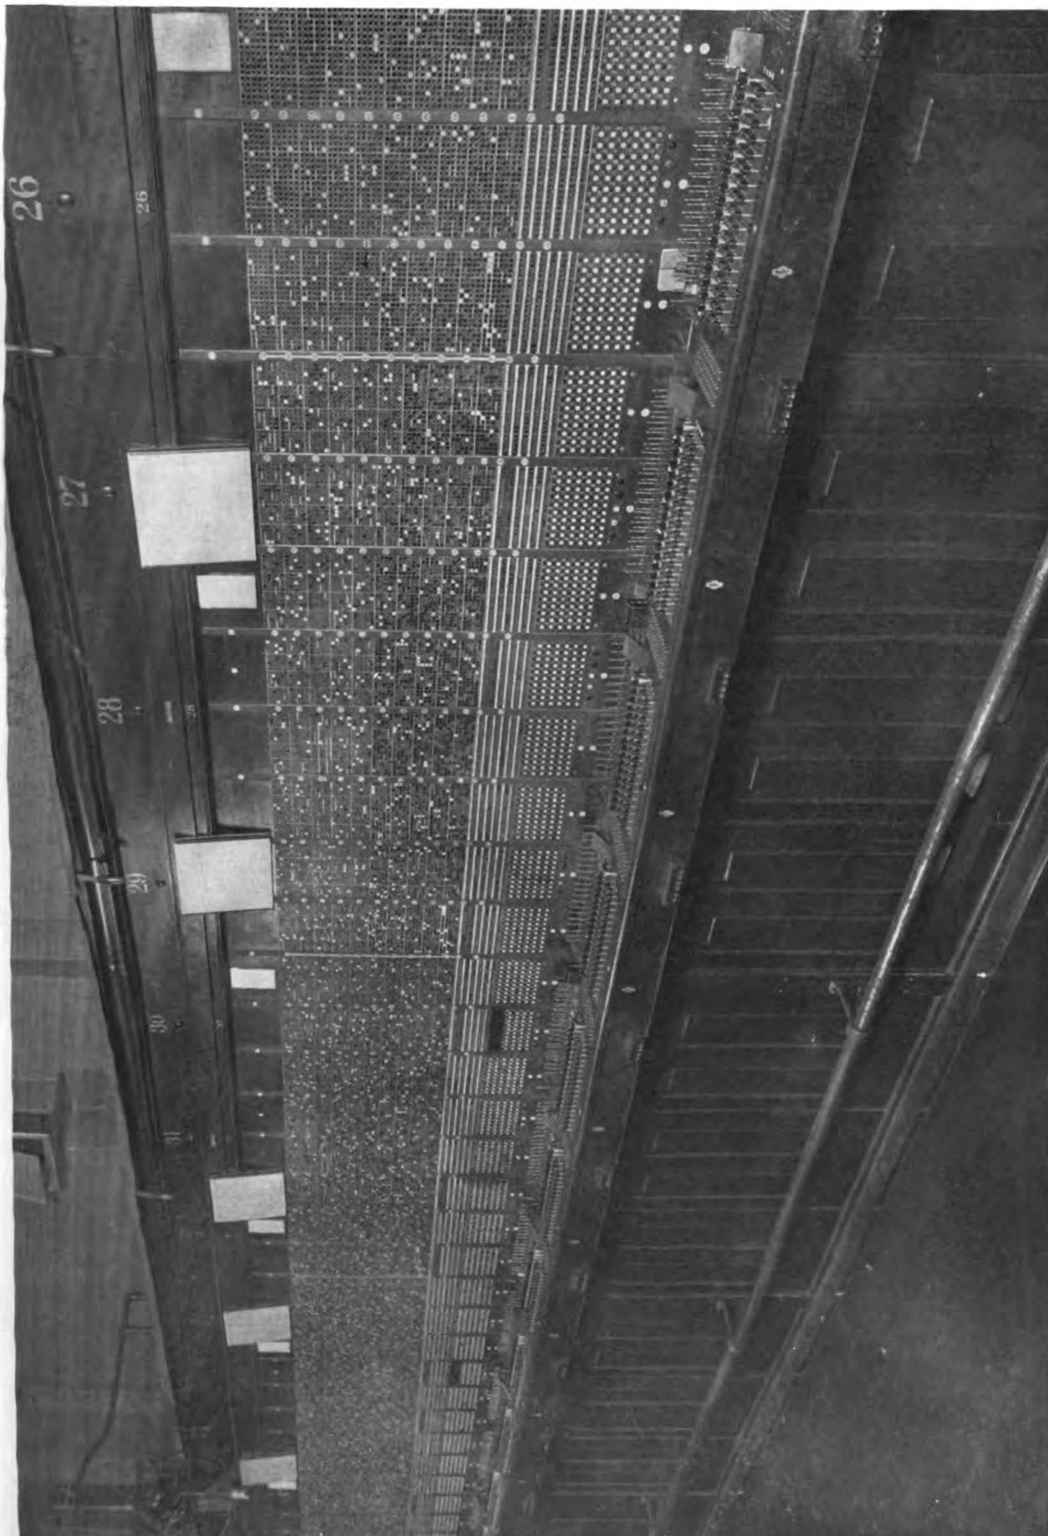

Fig. 42-A — Front View of a Modern Common-Battery "A" Switchboard

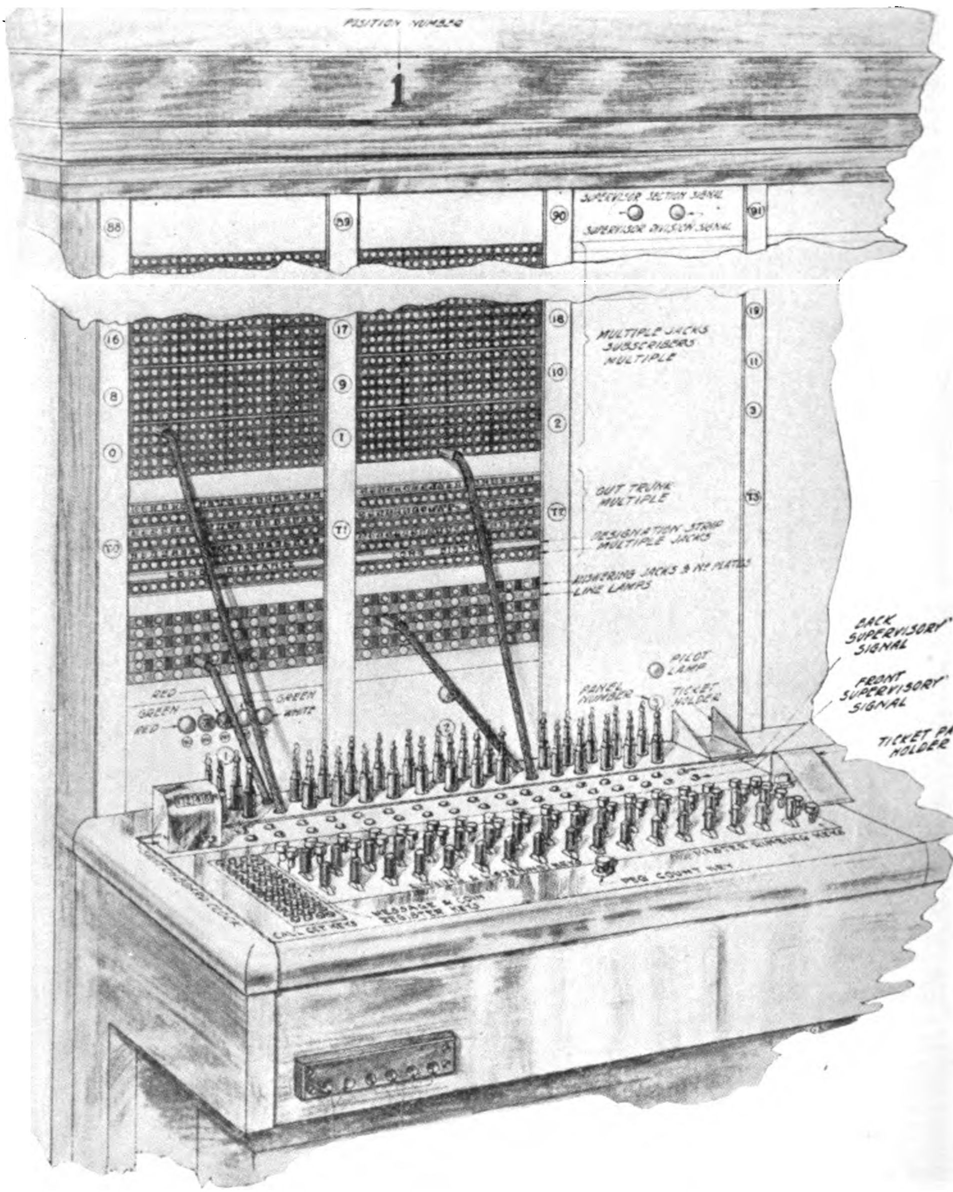

Fig. 42-B — Front View of Single Position of Modern Common-Battery "A" Switchboard

a dozen years but by no means was it the final type.

This was followed by the use of cotton covered wires having the cotton impregnated with a moisture-proof compound, the insulated wires being drawn into lead pipes, each section about 20 feet long. When the cable was laid the sections were connected by means of plumbers' joints. The next development resulted in the use of cable wires insulated with dry cotton, it having been found that cotton baked dry, so as to expel all moisture, was a good insulator if placed in a lead pipe and promptly sealed. This was an important development as cotton had formerly been considered a bad insulator. Moulding hot lead in a continuous sheath around the cable core of twisted wires was found to be an advantage as it meant a tight covering with fewer sleeves and splices and ultimately did away with the use of oil or moisture-proof compounds. By 1887 the introduction of twisted pair construction for conductors in cable began. This type of construction carried out the application of the transposed metallic circuit principle to cables. It obviated interference from overhearing (known in the art as "crosstalk") between circuits in the same cable. This improvement meant the abandonment of the entire existing cable plant and the introduction of the new type, without which the telephone system, as it is known today, would have been an impossibility.

Insulated Dry-Core Paper Cable.— More development work, extending over several years, constantly aiming to reduce the specific inductive capacity of the insulating material, led to experiments with paper twine. This proved too flimsy and methods were devised for putting paper on the wire flat, crumpling it around the wire instead of winding it tightly. This resulted in the production of the best type of insulating material known for telephone cables, namely, dry paper hermetically sealed in a continuous lead sheath. In 1890, "dry-core" cable, the first of the modern type, was laid in Philadelphia. The conductors, wound with loose paper, were really cushioned largely with air, the best insulator known. This was the best talking cable that had ever been made up to that time. The first dry-core paper cables contained 50 pairs of wires No. 18, B. & S. G. in size (0.0403 inches in diameter). By 1891, the use of wires No. 19, B. & S. G. in size (0.0359 inches in diameter) was settled upon. Subsequent progress in cables employing this size of wire has been largely in the direction of increasing the number of pairs of wires that can be placed in a full-sized sheath. This has been accomplished chiefly through improvements in the insulating paper and in the methods of applying the paper to the wires. The progress made is shown in the following table which gives, for cables of No. 19 gauge wires, about 2½ inches in outside diameter, the date when a cable of the given number of pairs was made available for commercial use:

DATE	Number of pairs of No. 19 gauge wires
1892	100 pairs of wires
1895	120 pairs of wires
1896	150 pairs of wires
1898	200 pairs of wires
1903	300 pairs of wires

Fine Wire Cable.— The extraordinary increase in the number of the telephone wires, and the difficulty in many places of obtaining additional space underground led to the development of the so-called "fine wire" type of cable employing wires No. 22, B. & S. G. in size (0.0253 inches in diameter). The progress made in this development is shown in the following table which gives, for cables of No. 22 gauge wires, about 2½ inches in outside diameter, the date when a cable of the given number of pairs was made available for commercial use.

DATE	Number of pairs of No. 22 gauge wires
1900	300 and 400 pairs of wires
1903	600 pairs of wires
1912	900 pairs of wires

During 1914, there was developed a type of underground cable carrying 1,200 pairs (2,400 wires) No. 24 B. & S. G. in size (0.0201) inches in diameter). Fig. 48 shows a cross-section (reduced in size) of this cable. The improvement which it represents may be understood when it is known that to carry the same number of open wires on poles would require 8 huge pole lines of the size shown in Fig. 45. The economies accomplished by these improvements are not limited to the cables themselves, but extend to the underground duct systems whose capacity is multiplied enormously by the increase in the number of wires which each cable may carry.

It was early found that lead alone did not possess the requisite corrosion-resisting and strength properties for underground cable sheaths. Aerial cables, furthermore, are subject to peculiar conditions causing vibration in the cable, and a tendency to crystallization of the sheath if pure lead is employed. For a long period, cable sheaths having the proper qualities were made of lead alloyed with about 3 per cent of tin. Considerable increases in the cost of tin led to experimental investigations of a wide range of other alloys. This resulted in finding, in 1912, a cheaper and at least equally efficient alloy in which the lead was alloyed with a very small amount of antimony.

Early Interurban Cables.— In the earliest interurban cables every effort of the engineers was bent toward improving transmission efficiency by using wires of large size so arranged in cabling as to secure a soft core giving the lowest practicable mutual electrostatic capacity between the wires of a pair. Wires as large as 0.095 inches in diameter were used and cables of this character as long as 25 miles were placed. In European practice, the use of wires even larger than this continued for many years. In the United States, the development was in the direction of using smaller wires provided with means for improving their transmission efficiency so that it not only equaled, but considerably exceeded that obtainable with the larger and more expensive wires. By 1902, the art had so advanced, by the use of Pupin loading coils (described below) and other improvements, that a loaded cable for suburban toll service was successfully installed between New York and Newark. By 1905, a loaded cable 20 miles long had been extended from New York in the direction of Philadelphia, and by 1906, a cable 90 miles long was successfully operated between those two cities, but in the then state of the art, that cable could not be used beyond Philadelphia or New York.

Boston-Washington Underground Cable. — During the year 1913 such advances were made in the art of loading and balancing underground circuits, and such improvements in the use of repeaters (described below) that it became possible to talk satisfactorily by underground wires from Boston to Washington, a distance of about 450 miles, employing a cable (Fig. 49) so designed that the phantom principle could be employed in it. At the present time, there are underground cables along this whole route, furnishing service of the highest reliability between many important cities, the number of cables varying from two to four, depending on the density of the telephone traffic. Loading is used on all the circuits in these cables, and repeaters are applied to a large proportion of the circuits over 60 miles in length. The Boston-Washington telephone cable is several times longer than any other in the world. These developments tended to increase greatly the long-distance traffic and to accomplish enormous savings in the amounts of copper which otherwise would have been required to establish communication between remote points.

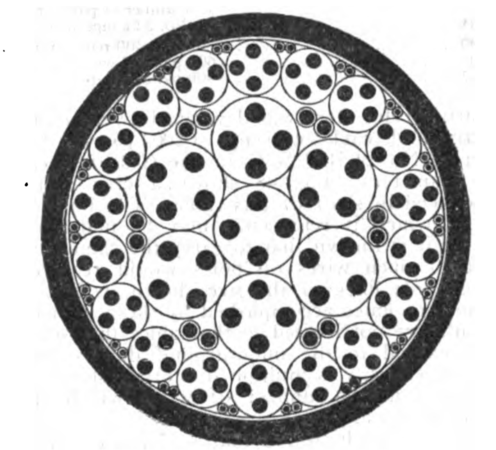

FIG. 49.— Diagrammatic Cross-section of Boston-Washington Underground Cable. (Outside diameter, 2 9-16 inches).

Telephone Transmission Theory.—In telephony, as already described, mechanical vibrations of the transmitter diaphragm set up electrical oscillations. These are transmitted over the circuit and set up corresponding mechanical vibrations of the receiver diaphragm. The following section deals with the electrical characteristics of the telephone circuit and the transmission of telephone currents over it.

To develop the principles of telephone transmission, it is necessary to know the character of the speech waves. For ordinary practical working, satisfactory results are obtained on the basis that speech waves, largely the overtones of the voice, consist of a varying mixture of single frequency tones ranging from about 400 cycles per second (in musical sound, equivalent to G above middle C) to about 2,000 cycles per second (approximately the octave above high C), and that each frequency persists in a constant state for a sufficient length of time to follow the same electrical laws as though it persisted for a long time. This basis is by no means exact, since frequencies outside the above range are of some importance in speech, and speech is so irregular and discontinuous in character that the transient oscillations, which are produced by the rapidly changing speech waves, are in many cases of considerable importance.

A telephone line possesses four «linear constants» on which depend the character of transmission over it. These, with the symbols employed to represent them in the formulæ which follow, are:

Resistance in series with the line. Symbol R.

Inductance in series with the line: Symbol L.

Capacitance shunted across the line: Symbol C.

Conductance shunted across the line: Symbol G.

The differential equation determining the transmission of current over the line with these constants is as follows, «i» standing for the current, «x» for the distance measured along the line and «t» for the time:

$$\frac{d^2i}{dx^2} = \left(LC\frac{d^2}{dt^2} + \left[RC + LG\right]\frac{d}{dt} + RG\right)i$$

For a current of a given frequency $f = \frac{p}{2\pi}$ cycles per second, there may be deduced, from the above equation, the following expression for the current at any point in a long line, when the current at the sending end is $I_0 \sin pt$.

$$i = I_0 e^{-\alpha x} \sin(pt - \beta x)$$

In this expression are used two constants, α and β, known respectively as the «attenuation constant,» and the «wave length constant.» The expressions for these constants are as follows:

$$\alpha = \sqrt{\tfrac{1}{2}\sqrt{(L^2p^2 + R^2)(C^2p^2 + G^2)} + \tfrac{1}{2}(RG - p^2LC)}$$

$$\beta = \sqrt{\tfrac{1}{2}\sqrt{(L^2p^2 + R^2)(C^2p^2 + G^2)} - \tfrac{1}{2}(RG - p^2LC)}$$

The first of these constants determines the rate at which the current diminishes in amplitude as it passes along the line. The second determines the velocity at which electrical phase is propagated along the line. Another important constant of a line is its so-called «characteristic impedance,» which is the ratio of the voltage applied to a line to the current entering the line. In terms of the above noted constants, the expression for it is:

$$Z = \sqrt{\frac{R + jLp}{G + jCp}}$$

Where a line is not electrically long, and is terminated with an impedance differing from the characteristic impedance of the line, then the formula as given for the current at any point along the line must be modified to take account of the «reflection effects» which take place due to this difference in impedance. Such reflection effects may be reduced, in practical cases, by placing a transformer of proper ratio between two lines, or between a line and terminal apparatus of different impedance. An analysis of the above formulæ will show that not only is the energy in the speech waves attenuated as they pass over the line, but that different frequencies of speech are attenuated at different rates, the higher frequencies generally undergoing the higher attenuations. Therefore, not only is the volume of energy received less than that transmitted, but the character, or «quality,» of the speech wave is distorted. In addition to this distortion of speech waves, there is further distortion, due to transient effects, already referred to.

Loaded Lines.—«Loading» is a practical method for increasing the efficiency of long telephone circuits by increasing the inductance of the circuit. The mathematical possibility of doing this had long been realized but no one was able to point out any practical method of increasing the distributed inductance of a telephone circuit without bringing difficulties of one kind or another which were fatal. Vaschy, Heaviside and others either suggested or unsuccessfully tested the insertion of self-induction in coils on actual lines as a means of increasing their transmission efficiency. No practical results followed from their work and no actual progress was made in the matter of using lumped inductance to improve the transmission efficiency of telephone circuits until the year 1900, when the patents of Prof. Michael I. Pupin, dealing with the reducing of attenuation of electrical waves, were issued. Professor Pupin and Dr. George A. Campbell of the Bell Telephone Research Staff, who had also worked on this problem, have published several papers dealing with it. These authors discuss fully the mathematical theory of loading and establish the fact that inductance in coils suitably spaced along a telephone circuit will produce the same effects as uniformly distributed inductance. They also show how to locate these inductance coils suitably. The matter of properly spacing the inductance coils is of vital importance and must be kept in mind because the spacing of the coils is the key to the use of lumped inductance and it was from the failure to establish this fact and give due weight to it that the earlier workers failed.

Fig. 50 shows, in a diagrammatic form, the

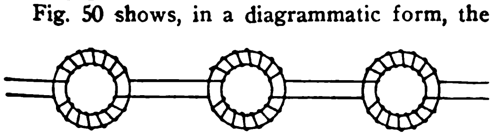

FIG. 50.— Diagram of Loading Coil Windings and method of connecting into line.

manner in which the lumped inductance coils («loading» coils) are connected into the telephone circuit. Figs. 51-A and 51-B show a coil of the type applied to cable circuits. Large numbers of such coils are contained in a single case as shown in Fig. 52. Fig. 53 shows a typical form of loading coil of the kind applied to open wire lines.

The function of these coils is to reduce attenuation losses in the line. They bring in no supply of new energy, but make the line a better conductor for telephone currents. On open wire lines they are placed at intervals of about eight miles. On cable circuits they are placed

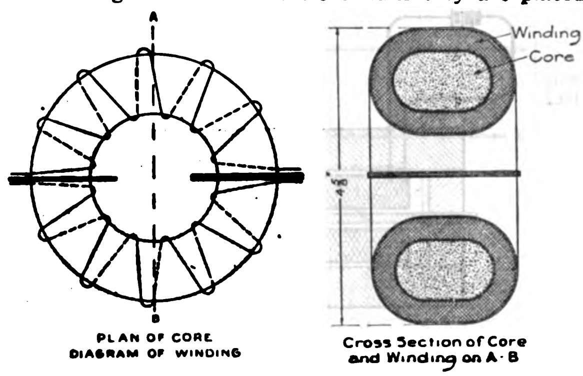

FIG. 51-A.— Diagrams of Cable Loading Coil.

at intervals of from one to two miles depending upon the size of the cable conductor to be loaded and the character of the loading. The use of these coils approximately doubles the range of transmission practicable with open wires of a given size and increases the range of cable transmission three to four-fold. In other words, by means of loading, it became possible to talk over cable circuits three to four times as far as formerly, with equally good transmission results.

The fundamental principles of loading, as disclosed in the patents of Pupin, were in mathematical form. The development work required to embody the theory of loading in practical loading coils has been a task constituting the work of years of a large group of highly trained scientific men on the technical staff of the Bell system. The application of loading has comparatively recently been extended to phantom circuits so that it is now possible to load not only the physical or side circuits composing a phantom circuit, but also the phantom circuit itself. Phantom loading is applicable to suitably constructed cables (called duplex or «quadded» cables) as well as to open wire lines.

Telephone Repeaters.— A highly important method of improving the transmission efficiency of telephone circuits is the insertion into them of devices known as «telephone repeaters,» which increase the amplitudes, or strength, of the telephone currents that pass through them, without changing the effective form of the waves. The energy added by the repeaters is drawn from a battery associated with the repeater itself.

The telephone repeater may be considered as consisting of two parts: (a) the repeater «element,» that is, the amplifying device itself; and (b) the circuits and associated apparatus for connecting the repeater element, or elements, into the line.

The first form of repeater element to come into commercial use was the so-called «mechanical» type consisting, in principle, of a telephone receiver acting directly into a telephone transmitter. A simplified diagram of this repeater is shown in Fig. 54. Currents received from the line flow through the winding of a receiver magnet acting upon a diaphragm carrying one electrode of a transmitter button, thus causing to be put out currents of approximately the same form as the incoming waves, but of greater amplitude.

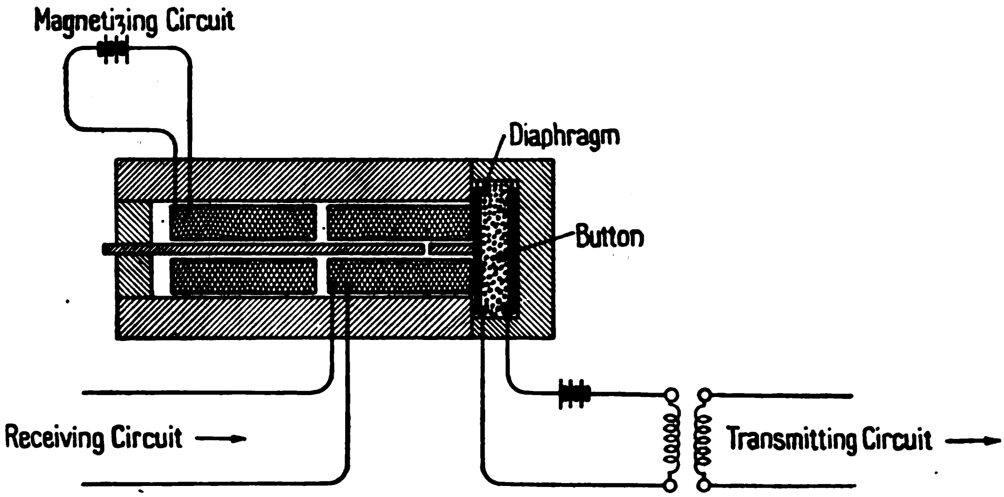

Fig. 54.—Simplified Diagram of Mechanical Type Repeater Element.

The preferred form of telephone repeater element is now the «vacuum tube» type. This was developed by the Bell engineers from a device known as the «audion,» invented by DeForest for other uses. The structure of this type of element is shown in Figs. 55 and 56. It consists of a highly evacuated glass bulb in which are placed three parts, known as filament, grid and plate. Referring to Fig. 56, the filament is composed of materials which, when heated by current from battery *A*, give off electrons actively. Under the action of battery *B*, these electrons pass from the filament to the flat electrode, known as the «plate,» thus constituting an electric current. The grid, so termed from its grid-like structure, is maintained generally at a potential negative to the filament by battery *C*. The incoming voltage sets up variations in potential difference between the grid and filament, and the electrical field thus produced causes corresponding changes in the current between the filament and plate, thus setting up amplified waves of the same form in the transmitting circuit.

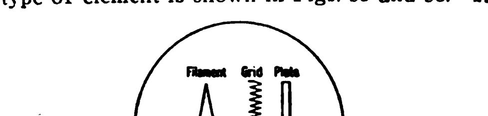

Fig. 56.—Diagram of Vacuum Tube Repeater. (The grid and plate at the left hand side of the filament are omitted for the sake of clearness).

The circuits for connecting the repeater elements into the line to give transmission in both directions are of various types, the two commonest forms being shown in Figs. 57 and 58. The first includes a single repeater element which amplifies the energy for transmission in either direction. The second includes a separate repeater element for transmission in each of the two directions. An important feature in these circuits is the balanced condition which is essential.

The circuit diagrams show certain auxiliary apparatus such as the «balancing network,» a combination of coils and condensers to simulate the actual line for balancing purposes; the «potentiometer,» a device for adjusting potentials; and the «filter,» which serves to blot out certain undesirable current elements.

Referring to Fig. 57, it will be noted that, if the lines in both directions are similar, and have, therefore, similar impedance, the amplified currents, leaving the repeater element, will cause no current to be set up in the receiving circuit of the repeater element. If, however, the circuits are sufficiently dissimilar, the balance is imperfect, and current put out by the repeater element will cause currents in the receiving circuit of the element which will again be amplified, thus setting up a circulating path in which current will flow. If the unbalance is sufficiently great, a steady state of oscillation may be set up that will prevent the use of the circuit. On the other hand, if the unbalance is not so great as to produce steady oscillations there may still be considerable distortion caused by it.

In the case of the second circuit (Fig. 58), similar conditions hold, except that in this case each line is balanced against an artificial line as indicated. If the unbalances at these points are not kept small, sustained oscillations may be set up as in the case of the other circuit, but in this case the circulating currents must flow through the two unbalances in series. If either balance is very good, the other unbalance may be large without unfavorable results.

The balances noted above must be obtained for all of the frequencies important in telephone transmission. The impedance of a circuit, measured at any point, is affected by every part of the circuit, the amount of the effect caused by any part being dependent on the amount of attenuation between the part being considered and the point at which the impedance is being measured. It is, therefore, evident that these balance conditions are affected by every part of a circuit on which the repeaters are used, so that every part of a circuit containing repeaters must be carefully designed with respect to this characteristic. For high grade repeater elements, the improvement obtainable under any particular circumstances is dependent, almost wholly, on line conditions.

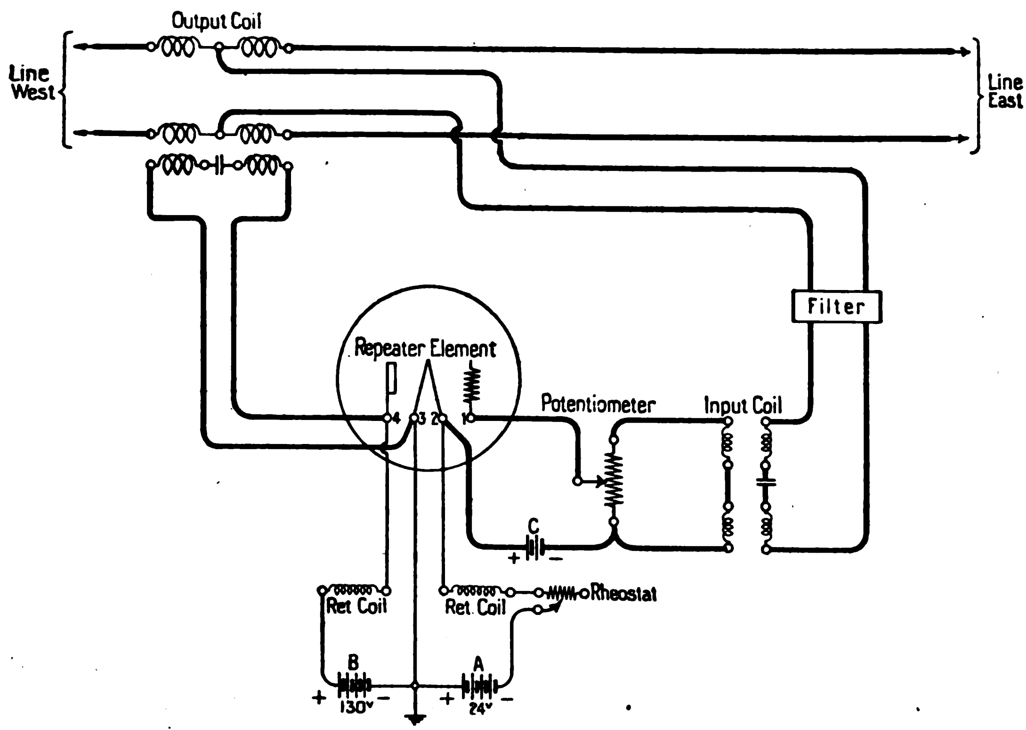

Fig. 57.— Simplified Diagram of Circuit with Single Repeater Element.

Transcontinental Circuits.— The best known circuits on which repeaters are used are those which place the cities along the Atlantic seaboard in telephonic communication with the cities along the Pacific Coast. Without loading and repeaters it would be impossible to talk 1,000 miles with the same grade of transmission that is actually obtained over these circuits 3,000 miles in length.

Further Advances.— By the joint operation of loading and repeaters, coupled with other advances recently made, it is now possible to carry on satisfactory talks over wires in cables more than 1,000 miles in length, where commercial conditions will justify them, employing practically no more copper in each circuit than was used 35 years ago in cables which caused serious interference with transmission when employed in lengths of only a fraction of a mile.

Interference from Other Electrical Systems.— Telephone lines, except those in underground cable, are generally subject to disturbances from lightning, and to the possibility of accidental contact with ordinary electric light and power distribution wires. When these conditions exist, protectors are successfully used on the telephone lines to minimize the hazard to persons and property. It is not practicable to use protectors which will handle the large amounts of energy that would be imposed on telephone lines by high voltage transmission circuits coming in contact with them. Protection from such circuits is obtained by keeping them separated from the telephone circuits wherever practicable and, where adequate separation is not practicable, by building the lines of high strength so as to prevent contact.

Multiplex Telephony.— The only type of multiplex telephone apparatus that has been developed into form suitable for commercial use is known as the carrier current multiplex system with which it has been found commercially practicable to transmit five telephone conversations simultaneously over the same pair of wires. This requires sending over the line five different currents at the same time and providing means, at the end of the line, whereby these currents may be completely separated from each other so that each current, coming from one particular telephone at one end, may go to a particular telephone at the other end, although on the line the five currents have all been mixed together. This is done by combining each ordinary telephone current with a current of definite higher frequency, termed a «carrier current.» The frequency of each of the carrier currents is different from that of the other carrier currents used on the same pair of wires and is adjusted to the separating devices at the distant end of the line. The arrangement is applicable on lines of such length that the installation of the necessary apparatus gives a saving in cost compared with erecting new circuits.

Telephone Systems.—The Bell System consists of nearly 11,000,000 telephone stations scattered all over the United States. Each station is enabled to connect with the nearest central office, of which there are upwards of 5,700, by a pair of wires called the subscriber's line, or «exchange circuit.» Due to party lines and private branch exchanges, about 3,700,000 exchange circuits serve to connect all the stations with the central offices. In places of moderate size there is usually one switchboard, to which all of the subscribers' lines are brought, local connections being completed within that switchboard. Large cities have a number of switchboards, connected together by trunk lines, all of the more important central offices having trunk lines connecting each switchboard with every other important switchboard in the city. To reach the smaller central offices, in outlying sections of a large city, from central offices, particularly those in a distant portion of the city, it is sometimes necessary to make use of two or more trunk lines, connected together by intermediate operators for the purpose of completing such a call. In the business portions of the largest cities where the telephonic density is at the highest, more than one switchboard is sometimes placed in a central office building.

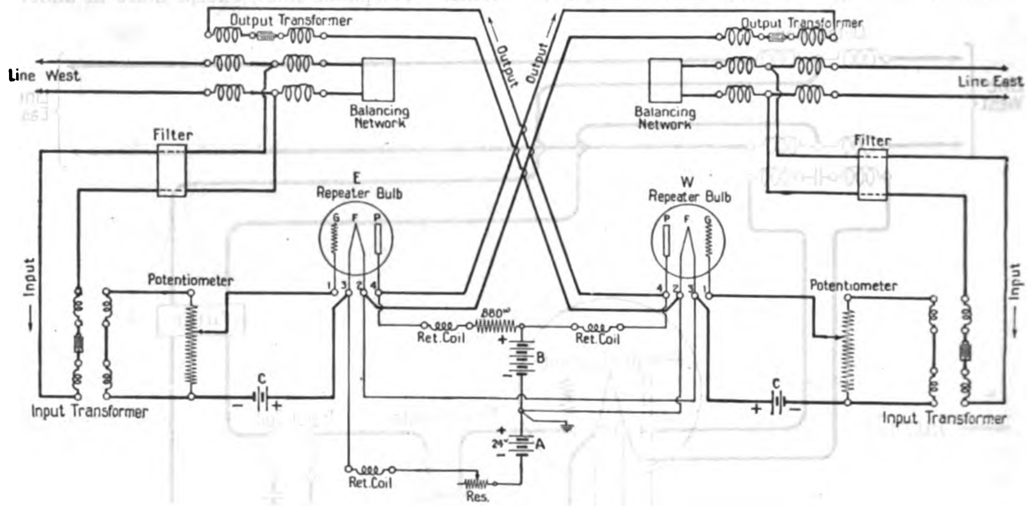

FIG. 58.— Simplified Diagram of Circuit with Two Repeater Elements, each line balanced against an artificial line.

In New York City, the largest exchange system in the world, there are upwards of 800,000 telephone stations, connected by more than 400,000 lines with 87 central offices which are inter-connected by more than 50,000 trunk lines, handling local calls only.

Connections between exchanges in different cities are completed over toll and long distance lines. More than 3,000,000 miles of wire are in use for this purpose. Special trunk lines are usually employed for connecting central offices with toll and long distance switchboards.

STATISTICS — NUMBER OF TELEPHONE STATIONS IN UNITED STATES.

YEAR (1 Jan.)	Bell system			Independent	Total Bell and independent	Population	Stations per 100 population
	Owned stations	Connected stations	Total				
1880	30,872	....	30,872	....	30,872	49,673,000	0 06
1885	147,715	....	147,715	....	147,715	56,069,000	0.26
1890	211,503	....	211,503	....	211,503	62,464,000	0.34
1895	270,381	....	270,381	15,000	285,381	68,988,000	0.41
1900	666,733	10,000	676,733	328,000	1,004,733	75,511,000	1.33
1905	1,838,034	167,213	2,005,247	1,348,000	3,353,247	83,411,000	4.02
1910	3,522,079	1,620,613	5,142,692	1,853,000	6,995,692	91,500,000	7.65
1915	5,584,853	3,064,140	8,648,993	1,397,425	10,046,418	99,590,000	10.09
1919	7,201,757	3,790,568	10,992,325	1,085,312	12,077,637	106,062,000	11.39

About 3,400 trunk lines are used for this purpose in New York City alone.

There are, in the Bell System, about 200,000 employees. It is impossible to describe, in an article of limited length, many matters of importance in the operation of telephone systems, such as traffic and commercial features.

TELEPHONE WIRE MILEAGE OF THE WORLD
(1 Jan. 1914)*

TELEPHONE SYSTEMS, Cost of Installing and Maintaining. See TELEPHONE SYSTEMS, INDEPENDENT.

TELEPHONE SYSTEMS, Independent. Under this designation are placed all those telephones not owned by Bell system companies, such as certain telephones used for military purposes, some of the telephones in those cities where there are two or more exchanges existing and operating side by side, such interior telephones as are used solely for inter-communication in buildings, hotels, factories, etc., and some of the farm or rural telephones.

The original Bell patents expired in 1893 and for 17 years prior thereto the patents granted to the first inventor of the telephone were upheld in the United States and all telephones in commercial use were supplied under license by the predecessors of the American Telephone and Telegraph Company. Upon the expiration of the original Bell patents, numerous manufacturers began to supply telephone instruments and considerable numbers of these came into use especially in the rural districts.

*Transactions of American Institute of Electrical Engineers.

For many years the independent development of the telephone business has been in progress largely in the rural districts where local co-operative and rural independent companies are established. A large proportion of these now have connection contracts with the Bell system. These lines are found in every part of the country, uniting homes, factories and camps by means of party lines, which allow conversation between the different stations of the line as well as from any station to a central exchange.

Up to the present time the independent telephone movement has placed more than 800,000 American farmers, timbermen and miners in touch with their markets, their own communities and towns and cities near them. The movement has been especially active in the Middle and Western States. These telephones are used not only for general purposes of communication, and in numerous ways for securing information regarding market quotations, but also in gaining information of financial value and advantage. The independent telephone business, however, is not limited to the country or isolated districts but has established itself in a number of cases in towns and cities.

In many cases, where two systems have come into existence, side by side, arrangements have been made to consolidate the systems by one interest disposing of its plant to the other. Such consolidations have very generally met with the approval of regulatory bodies and in this way many telephone users have had their range of communication greatly extended.

The growth of the independent systems increased over 250 per cent in the decade beginning about 1902 and ending in 1912. In the year first named there were reported in operation 9,092 independent systems and lines with 1,512,527 miles of wire. The number of telephones operated on these systems was 1,053,866 and the number of messages or conversations per annum was estimated at 1,996,024,493. In the year 1912 the independent systems had increased to 32,157 with 5,115,140 miles of wire and operating 3,642,565 telephone instruments. The estimated number of messages or conversations over these independent systems in the latter year was 4,602,431,409. Of the total number of stations in the Bell system, in 1918 (10,992,325), 3,790,568 were owned by local cooperative and rural independent companies or associations having sublicense or connection contracts with the Bell system. There are in the United States 9,338 independent companies whose telephone systems connect with the Bell system, and about 1,600 independent companies whose telephone systems do not connect with the Bell system. There are also a large number of rural lines and systems which connect with the telephone systems of these companies, over 26,000 of which are connected with the Bell system. There are about 1,000,000 stations owned by independent companies not connected with the Bell system.

The exigencies of war service emphasized the great adaptability of the telephone to many situations and there was an increased call for telephone systems for reporting enemy operations, directing the movements of troops, munitions and supplies, controlling artillery fire and in numerous other ways increasing the effectiveness of the armed forces.

The scientific investigation of electromagnetic waves has resulted in a clear understanding of the generation, propagation and detection of these waves and in the development of wireless telephony. The requirements of successful radio-telephony began with a generator of undamped waves of very high frequency, so that the wave trains when received were above the range of audibility. Wireless telephony owes much to the work of the engineers of the American Telephone and Telegraph Company, who, in the latter part of 1915, succeeded in telephoning by wireless from Washington, D. C., to Paris, and from Washington to Hawaii, the latter a distance of 4,900 miles. The great expense of installations for long-distance work may limit competitive systems, but it is safe to look for the widespread employment of independent short-distance wireless telephone sets.

Armies in the field employ portable wireless sets for insuring communication between scattered commands. Some sets for use in rugged country are arranged to be carried on muleback and are known as pack sets; but the most common wireless sets are those mounted on two wagons, one for the generating equipment and the other for the wireless apparatus proper. The European War gave especial impetus to wireless telephony, especially as applied to air craft. In designing radio apparatus for airships and aeroplanes due consideration must be given to the extremely limited space available on such craft and the limited weight that can be carried. On board airships of the Zeppelin or the flexible types it is possible to employ more powerful apparatus, hence a greater range can be covered.

A typical airship installation consists of a transformer, quenched spark gap, capacity and inductance, aerial wire lowered down from a winch, ammeter, rapid-change switch for different wave-lengths and an alternating current generator driven off one of the engines of the airship. Such a set weighs about 55 pounds without the alternator and has a range between 60 and 120 miles. The aerial wire is over 600 feet long when fully paid out.

TELEPHONE TRANSMITTERS. See TELEPHONE.

TELEPHONES, Electrical. See TELEPHONE.

TELEPHONES, Farm. See TELEPHONE SYSTEMS, INDEPENDENT.

TELEPHONY, Wireless. Prior to the transmission of speech without wires by means of ether waves developed electrically several more or less successful wireless methods of transmitting speech were utilized experimentally; For instance, a device termed the photophone

FIG. 1.—Bell's Photophone

was employed by Bell, the inventor of the telephone, in which light rays were utilized. In this device, Fig. 1, a beam of light is concentrated by means of a lens *l* upon a small concave mirror carried on the exact centre of a diaphragm attached to a mouthpiece *P*. The rays reflected from the mirror are directed upon a receiving apparatus by a double convex mirror l^1 suitably positioned. In the receiving apparatus a small selenium cell is placed in the focus of a parabolic reflector l^2. This cell is made part of an electric circuit consisting of a telephone receiver t and an ordinary dry cell b. Selenium possesses the property of varying its electrical resistance with the variations of light to which it is exposed. Hence when speech is uttered at the mouthpiece the diaphragm vibrates in consonance with the sound waves of the voice. These vibrations cause variations in the light rays reflected from the small mirror, which variations are reproduced at the selenium cell. This in turn causes variations in the resistance and current of the telephone circuit and the speech spoken at the mouthpiece is reproduced in the telephone receiver.

The rate of air vibrations or oscillations due to speech ranges from about 20 to 20,000 per second. As the length of an electric wave or oscillation is equal to the speed of electricity, 186,000 miles per second, divided by the number of oscillations per second, it is evident that the length of electrical oscillations of 20 to 20,000 per second is comparatively great. Hence to attempt to transmit without wires electrical oscillations set up primarily by the voice by means of a telephone transmitter, aerial wires about 15 miles in length would be necessary, which is not feasible.

For reasons that will become obvious it may not be amiss to refer here to the Van Rysselberghe system of Simultaneous Telegraphy and Telephony which for years has been in service on a large scale in this country. This system is briefly described in the article on TELEGRAPHY. Any action of the telegraph signals upon the telephone receiver is prevented by placing induction coils in the circuit which makes the rise and fall of the telegraph currents so gradual that the diaphragm of the telephone receiver is merely deflected and does not produce an appreciable sound. Upon this gradual rise and fall of the telegraph current is superposed the rapid vibrations of the speech waves set up by the telephone transmitter on the same wire. These minute vibrations do not affect the telegraph instruments. Quoting from Maver, W., 'American Telegraphy,' p. 347, "the theory of the operation of simultaneous telegraphy and telephony may be briefly outlined as follows: Assuming, for example only, the strength of the telegraph current to be 2,000 and that of the telephone current to be 1. If, while the diaphragm of the telephone receiver is attracted or in process of gradual attraction by a telegraph current of positive direction, a telephone current of similar direction be transmitted the total current will be suddenly increased to 2,001 and the diaphragm will be given a sudden minute impulse toward its magnet. Should then a negative telephone current follow, the telegraph current remaining as before, the current on the line will be suddenly reduced to 1,999 and the diaphragm by its own tension recedes rapidly from its magnet. In the actual operation of these systems many hundreds of pulsatory currents might be sent during the time taken to transmit one telegraphic signal, and thus, while the diaphragm is being gradually attracted to or is gradually receding from its magnet owing to variations in the telegraph current, at the same time it may be making hundreds of intermediate forward and backward movements of less amplitude, due to the variations of the line currents caused by the telephone transmitter in transmitting speech waves." In present day language the foregoing would be termed a modulation of the telegraph current in accordance with the variations of current due to voice waves.

It was recognized by the early workers in wireless telegraphy and telephony that if it should be found practicable to modify or modulate the high frequency ether waves utilized in wireless telegraph operation, it would be possible to transmit speech without wires to a distance approximating that of wireless telegraphy. A difficulty, however, in availing of high frequency electromagnetic waves for this purpose has been that as ordinarily obtained from the discharges of a condenser at the spark gap in wireless telegraphy such waves are intermittent and their amplitude is not uniform, but is quickly damped, as noted in the article WIRELESS TELEGRAPHY. Thus, in case of an alternating current generator developing a current of, say, 60 cycles, or 120 alterations per second, there will be 120 sparks per second at the gap if at each alternation the oscillation circuit is charged to sparking potential, which is not always the case. Assume that each discharge of the oscillation circuits gives rise to oscillations of a frequency of one million per second in that circuit, with a consequent wave length of 300 meters. The exact number of oscillations and wave length depends on the inductance and capacity of the oscillation circuit. (To conform to the word inductance the capacity of a circuit is now frequently termed capacitance). As the capacitance of the aerial is usually supplied by the aerial wires and is not readily variable, the frequency rate is varied by placing an adjustable inductance in the aerial circuit in the shape of a spiral coil of wire more or less of which may be inserted in or removed from the circuit. The capacity of the aerial is sometimes reduced, for short wave signaling, by placing a condenser (capacity) in the aerial circuit. In electrical diagrams a variable or adjustable condenser or inductance is conventionally indicated by an arrow through the apparatus. In the case in point if the oscillations were maintained throughout the interval between discharges there would be 8,334 oscillations per spark, that is, the quotient of 1,000,000 divided by 120. Since, however, the oscillations in such a circuit die out very rapidly, due to the damping effects mentioned in the article WIRELESS TELEGRAPHY, there are only two or three strong oscillations for each discharge in highly damped circuits and 10, 20 or 30 strong oscillations in less strongly damped circuits. Hence oscillations are only maintained during a brief interval between spark discharges, leaving approximately the one hundred and twentieth of a second between such discharges during which there are no oscillations in the oscillation circuit and at that time no waves are radiated from the aerial. In wireless telegraphy these intermittent or group oscillations after reception by a detector are observable in the telephone head receiver as a continuous tone or buzz which is broken into dots and dashes of the Morse alphabet by a telegraph key. If the attempt were made to superpose vibrations corresponding to voice waves upon these intermittent or broken oscillations, it is evident that portions of the voice waves set up by the transmitter would be lost.

Kennelly has mathematically demonstrated that speech might be transmitted telephonically with harmonics, or overtones, not exceeding 2,000 per second, but Fessenden has found by experiment that for satisfactory speech a frequency of at least 20,000 per second must be employed, otherwise disagreeable noises will be heard in the telephone receiver. Therefore, continuous or sustained oscillations of a fairly high frequency and uniform amplitude are essential upon which to superpose the voice frequencies for successful wireless telephony. To this end fairly successful efforts have been made by different inventors to produce a machine generator, or alternator, capable of delivering an alternating current of very high frequency notably by Fessenden, Goldsmith and Alexanderson. Owing to the mechanical difficulties of construction of such machines it is perhaps a question if they will prove commercially successful in general use. Nevertheless such machines have given and are giving good service in a number of instances. An idea of the difficulties of construction of high frequency alternators will be obtained when it is pointed out that to obtain 100,000 oscillations per second in a 600-pole rotor having a diameter of two feet, a speed of 20,000 revolutions per minute is necessary. Fairly full descriptions of high frequency machine generators will be found in books mentioned in *Bibliography*. Consult paper by Alexanderson, Proceedings American Institute Electrical Engineers (October 1919).

Another method of obtaining sustained electrical oscillations is known as the singing arc, due to Duddell, who discovered that when an arc lamp is in shunt with a capacity and an inductance of given proportions, a musical tone is set up in the arc. Ultimately Duddell obtained frequencies of 40,000 per second from this source. An explanation of this phenomenon is that when the shunt circuit is completed a current flows from the arc circuit into the condenser or capacity circuit which decreases the current flowing in the arc. This increases the electromotive force between the terminals of the arc, causing still more current to flow in the condenser circuit raising its electromotive force above the normal voltage of the arc. Consequently the condenser begins to discharge back into the arc, increasing the current therein and reducing the electromotive force between its terminals, when the reverse process is set up, and in this way continuous oscillations are maintained in the arc and shunt circuits.

When sustained oscillations are comparatively uniform in amplitude and their frequency is above audibility these oscillations are not heard in the telephone receiver. But, while the telephone receiver or at least the human ear will not respond to such high frequencies, if the amplitude or contour of the oscillation waves be modulated by speaking into a microphonic transmitter placed in the oscillation circuit, or in the aerial circuit of a wireless system, a telephone receiver will under proper conditions reproduce the speech spoken at the transmitter, virtually as speech is reproduced by modulating the amplitude of a beam of light, or a telegraph current in the case previously cited. The terms "radio frequency" and "audio frequency" are now commonly used to indicate the inaudible high frequency oscillations and the audible or low frequency oscillations, respectively, in wireless telephony.

The discovery of the oscillating arc paved the way for the use of sustained oscillations of high frequency and by means of modifications of Duddell's device much progress has been made in wireless telegraphy and wireless telephony. Such devices are now sometimes termed arc radio transmitters or arc converters.

An important improvement in the Duddell oscillating arc is that due to Poulsen. In the Poulsen arrangement the positive electrode of the arc is a water-cooled copper cylinder. The negative electrode is carbon. The arc is placed in a strong magnetic field which tends to blow out the arc, after the Elihu Thomson effect. The source of current supply for the arc is a direct current generator supplying from five kilowatts to 100 kilowatts at 500 to 600 volts. The arc converts the energy of the direct current machine into alternating currents of a frequency of say 60,000 per second. The practical efficiency of the arc converter is 33 per cent to 50 per cent of the input. For further interesting details of this arc converter and its utility in Wireless Telegraphy, consult an article in *Electrical World* (30 Aug. 1919, p. 452).

A very important source of sustained high frequency oscillations in wireless telegraphy and telephony of more recent origin is the three electrode high vacuum tube to which more extended reference will be made herein.

A great advantage of sustained oscillations in wireless telephony and wireless telegraphy also is that the property of resonance may be more fully availed of than when more or less intermittent oscillations are employed. It may be noted that in wireless telegraph and wireless telephone operation the receiving apparatus is practically the same. In wireless telegraphy the full effect of the radiated waves from maximum to zero is available, whereas in wireless telephony only a small portion of the emitted wave energy is available, namely, that due to the modulation of the wave energy caused by the action of the telephone transmitter, estimated to be about 5 per cent of the total energy radiated. This, however, in view of the amplifying powers of the high vacuum tube detector is not now of so much importance. See TELEGRAPHY, WIRELESS.

De Forest Wireless Telephone.— In Fig. 2 is outlined an arrangement of the De Forest wireless telephone system employed in 1909 and possibly prior thereto. A singing arc *a* is employed as the source of sustained high frequency oscillations. *C* is a variable condenser, *L* is a transformer or tuning coil, the secondary soil *s* of which is in series with the aerial wire *A*, and a microphone transmitter *M*. *a* is an arc with copper-carbon electrodes, burning in the flame of an alcohol lamp *m*. The arc is supplied with a 220 or 440 volt direct current supplied by a generator indicated at *G*. *K K* are choke coils, or inductances, in the supply circuit, used to shut out the high frequency oscillations of the arc from the generator. The arc a sets up in the circuit a, C, p sustained oscillations that are radiated as electric waves from the aerial wire A. Speech spoken into transmitter M modulates the amplitude of these waves practically in a manner equivalent to the action of the voice currents in the Van Rysselberghe simultaneous system of telegraphy and telephony upon the telegraph currents therein. There is, of course, the difference that in the latter case it is the slow telegraph impulses of current that are modulated by the voice currents, whereas in the case under consideration it is the high frequency radio currents that are modulated by the voice currents. It is now the practice to term the modulated high-frequency waves employed in wireless telephony, and it may be added, in wire telephony also, carrier waves, since they virtually carry the voice waves.

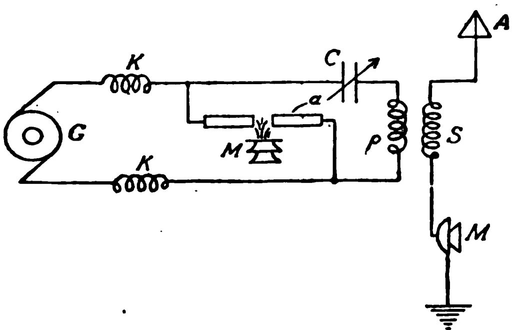

FIG. 2.— De Forest Wireless Telephone Transmitter Circuit.

The receiving circuits of the said De Forest telephone system are shown in Fig. 3. A is the aerial, L is the tuning coil, C is a variable condenser. The detector employed is the De Forest audion. (See TELEGRAPHY, WIRELESS). It comprises a tantalum lamp filament F, a grid G of No. 22 platinum wire and a small platinum plate P, all within an exhausted bulb b, resembling a six-volt incandescent lamp. The filament is lighted or heated by a three-cell storage battery B, the current strength of which is regulated by a variable resistance r. PB is a potential battery of 10 to 30 volts, adjustable as to potential by a potentiometer, not shown. One terminal of the oscillation circuit L, C is connected to the grid, the other terminal to the filament, as in the figure.

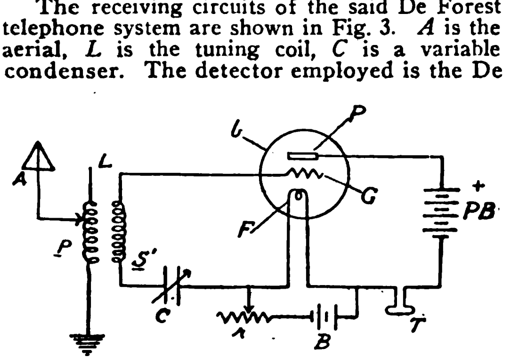

FIG. 3.—De Forest Wireless Telephone Receiver.

When the heating battery and the potential battery are properly adjusted the audion is very sensitive and produces amplified sounds in the telephone receiver. The incoming high frequency, or radio sustained oscillations, as stated, do not perceptibly affect the telephone receiver owing to their regularity, uniformity of amplitude and high frequency, but the modulations of the amplitude of the incoming audio oscillations due to the microphone transmitter, being within the range of the human ear, are heard in the telephone receiver as articulate speech.

Wireless Telephone Transmitters.— The transmitters for this work necessarily require high current strength in the transmitter circuit. This develops heat in the carbon granules of the microphone transmitter, which leads to packing of the carbon. This impairs or stops the transmission of voice waves. The packing can be broken up by tapping the transmitter at suitable intervals, and De Forest provides a special device for this purpose. In other cases a device consisting of a number of tubes leading from a single mouthpiece to a number of transmitters, all acting upon the one circuit, is employed. Fessenden uses a special transmitter for this work, by means of which a current strength of 15 amperes is modulated successfully. For aeroplane service during the war transmitters of special design were found to be necessary if successful results were to be obtained. In this service, besides difficulties due to packing, precautions had to be taken to annul engine, propeller and other external noises. To this end the diaphragm of one type of transmitter is so constructed as not to respond readily to air vibrations below 200 or above 2,000 per second. In another type a perforated plate is interposed between the speaker's mouth and the diaphragm of the transmitter, which device baffles the movement of extraneous sound waves toward the diaphragm while the voice waves spoken directly into the mouthpiece are not impeded. Still another device employed in this service consists in leaving the back of the transmitter open in such a way that exterior noises impinge on the back and front of the diaphragm of the transmitter with equal strength, effecting no result, whereas the voice waves hit the diaphragm in one direction only and thus set up the required variations in the transmitter circuit, even although at such times the pilot or observer cannot hear his own voice.

Three Electrode Vacuum Tube Oscillator.— As previously intimated the De Forest three electrode vacuum tube is now used as a source of high frequency sustained oscillations, and many different arrangements of circuits have been designed to utilize this remarkable feature of these tubes, now in practice frequently designated vacuum tubes or VT's. One such arrangement of circuits to obtain sustained oscillations is shown in simple form in Fig. 4, termed a vacuum tube oscillator. It illustrates the «feed back» or «regenerative» coupling of circuits, perhaps first devised by Armstrong. F is the usual filament, G is the grid, P is the plate of the tube proper. HB is the heating or lighting battery. r, r' are regenerative or feed-back tuning coils. C is a condenser across the filament grid-circuit. Closing the circuit or jarring the tube will cause an initial impulse or oscillation in the grid-plate circuit, including coil r'. This oscillation in turn reacts on the grid-filament and r circuit, which again reacts on the former circuit, thereby producing a feed-back or regenerative oscillating current in the tube that may be termed self-perpetuating. After a brief interval a steady sustained oscillation is produced. The coils r, r' and condenser C are adjusted to oscillate at a desired frequency in the usual way. By means of this tube oscillations from one-half cycle to 20,000,000 per second are now obtainable.

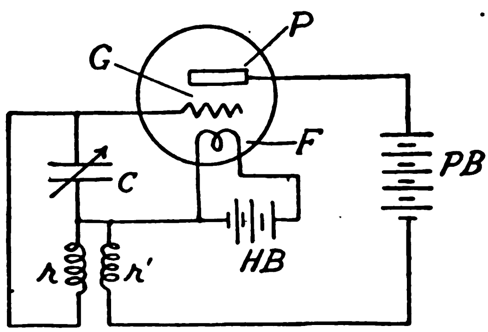

FIG. 4.—Vacuum Tube Oscillator.

It has been noted by another writer in expounding the oscillating feature of these tubes that "in order to set tube circuits into a state of radio frequency oscillation it is necessary that the connections be so made that the grid end of the grid inductance will be alternately negative and positive, as the plate end of the plate inductance is positive and negative. When the grid and plate radio frequency circuits are coupled with the proper phase relation any variation in voltage in either the grid or plate circuits will cause minute disturbance in the oscillation circuits, setting them into oscillation at whatever frequency they may happen to be adjusted to. For example, a slight variation of voltage in the plate circuit by any means whatever will cause its resonant circuit to oscillate at radio frequency, and the resultant current will act upon the grid circuit, setting it into action at the same frequency. The resulting radio frequency fluctuations of the grid potential will act upon the plate at the right time to keep the plate resonance circuit in a state of oscillation, and this state of affairs will continue so long as the proper supply of voltage and filament current is maintained, but not otherwise. The tube is able to generate alternating currents because of its amplifying properties. The energy delivered to the grid circuit in accordance with the actions just outlined will gradually increase in value until a maximum is reached, which is the maximum output the valve is capable of delivering." Consult *The Wireless Age*, June 1919, p. 15, article on "Wireless Telephone Transmitter for Seaplanes."

In general De Forest gives the explanation of the vacuum tube oscillator as follows: "There is only one oscillating circuit. This circuit is such that a sudden change of potential impressed on the plate produces in turn a change in the potential impressed on the grid of such a character as to produce in its turn an opposite change of value of potential on the plate. Thus the to and fro action is reciprocal and self-sustaining."

In some respects the operation of the vacuum tube oscillator is perhaps analogous to the oscillator previously described. Another example of a self-perpetuating oscillation circuit is that due to placing a telephone receiver before the mouthpiece of a telephone transmitter when a shrill whistle or howling is often established. This phenomenon is especially noticeable in the transmitter and receiver of the acousticon type. This effect is seemingly due to a series of reactions somewhat similar to, but much more complex than those that occur in an electric door bell, another device which self-perpetuates its own vibration; when its circuit is closed by the push-button. In the case of the telephone howler let us assume in explanation of its action that a movement of the diaphragm of the receiver toward its magnet tends to weaken the air pressure on the diaphragm of the transmitter, and hence weakens the pressure of the carbon of the transmitter. This causes a weakening of the current allowing the diaphragm of the receiver to fall away, with the further result that the air column is compressed, this tending to increase the pressure on the carbon again and also increasing the current strength in the circuit, whereby the diaphragm of the receiver is again attracted, which actions are repeated over and over. Investigation of this phenomenon indicates, as might be expected, that it is dependent upon the fundamental set of vibration of the receiver and transmitter, the length of the air column enclosed between them and also the oscillation period of this circuit. The above references to the attraction of the diaphragm of the receiver and to its falling away are perhaps rather broad terms, when it is considered that as near as can be calculated the amplitude of vibration of the said diaphragm in reproducing speech is about the one twenty millionth of an inch. While this phenomenon has no direct bearing on the vacuum tube oscillator it is interesting as somewhat analogous thereto and hence may tend to simplify the explanation of the device.

Colpitts' Vacuum Tube Oscillator, Modulator and Repeater.— In Fig. 5 is shown an arrangement due to Colpitts of a vacuum tube and telephone transmitter with other circuits and apparatus for providing a high frequency vacuum tube oscillator, modulator and repeater of radio and audio frequencies. In vacuum tube operation the circuits into which energy is put is termed the input circuits; those that give out energy, the output circuit. In Fig. 5 the input circuit consists of the grid G of the vacuum tube VT, modulator coil r', battery B and filament F, as indicated by the letter i. The output circuit indicated by letter o consists of the plate P, filament F, condensers C C and the primary coils of repeating coils or transformers T, T', and battery B', which battery supplies current to plate P, through an inductance or choke coil K; b is the usual heating battery. The secondary winding S of the repeating coil or transformer T' is connected through condenser C' with the input circuit. The primary winding p of transformer T' is in series with the secondary of another transformer T'' which latter is coupled with the telephone transmitter circuit *TC* as shown. The arrangement acts as a generator of high frequency currents by reason of the inter-action of the input and output circuits through the transformer *T'* and the circuit *S C'*. These high grequency currents are modulated by the audio frequency currents due to the operation of telephone transmitter *TC* through the transformers T^2, T^3, and are transmitted by the transformer or repeating coil *T* into the line or aerial *A* to which the secondary coil of *T* may be connected. Consult Colpitts' United States Patent No. 1,137,884, 1915.

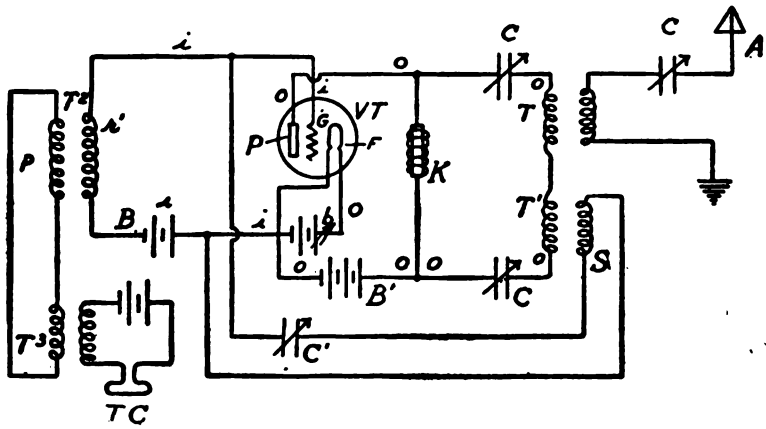

Fig. 5.—Colpitts' Oscillator, Modulator and Repeating Device.

Two or More Stage Vacuum Tube Circuits.— A combination of a transformer and amplifier tube is termed a one-stage amplifier. The number of transformers and amplifiers, in series can be further increased, but since static and other stray currents are also amplified a practical limit is soon reached. In practice seven stage amplifiers have been successfully utilized and a much greater number of amplifiers in series have been employed experimentally.

In Fig. 6 is shown a vacuum tube receiving circuit with a detector tube *VT* and a two-stage amplifier method, *T' VT'*; T^2 VT^2, employed in the United States Signal Corps service. The incoming oscillations are detected by tube *VT* and are successively transformed and amplified by transforming *T'*, vacuum tube *VT'*, and T^2 V^2; telegraph or telephone signals being received in the telephone receiver *TR*.

As noted in an article on «Radio Frequency Amplifiers» (in *Electrical World*, p. 570, 22 March 1919), «to build a reliable and efficient amplifier of more than three stages at any one frequency is practically impossible, since very grave difficulties are met with in keeping it from howling or oscillating. It is, however, quite practicable to amplify a radio signal at its radio frequency, pass it through a detector tube and then amplify the resulting audio frequency current. This not only gives the increase due both to the radio and the audio frequency amplifiers, but in addition increases the detector tube efficiency since within limits the efficiency of detection increases with the signal strength. Thus the receiver usually works out best in seven stages, three raido, one detector and three audio stages. Properly designed sets of this kind operated non-oscillating and without regeneration, will give signals more than 10^{14} times as strong as would be obtained with a simple one tube detector. By using a regenerative feed back much higher amplification can be realized, but the operation becomes less stable.»

The degree of amplification due to the vacuum tube amplifier varies under different conditions of battery, circuit connections, etc. In the case of an amplifier made for the United States Signal Corps, the power of the output signal was from 40,000 to 60,000 times that of the input signal. In general it may be taken that the increase in audibility is according to the square of six per amplifier. Thus if one amplifier increases audibility six times, two amplifiers will increase it 36 times, and so on. It has been stated that by «the use of successive vacuum tube amplifications, energy increases of 10,000,000,000,000 times have been obtained and that a six stage amplifier permits the feeble energy derived from a telephone receiver

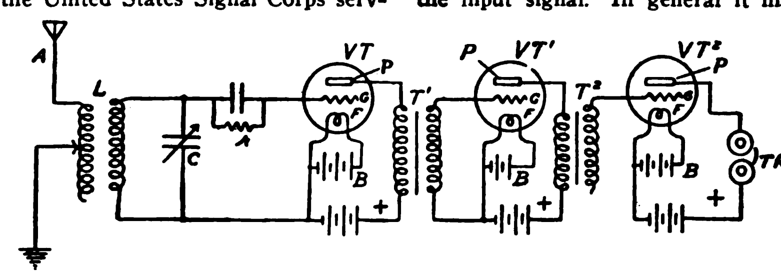

Fig. 6.—Receiving Circuit with Detector and Two-Stage Amplifier.

when employed as a transmitter to light an ordinary tungsten lamp, or to produce a sparking potential of several thousand volts." The amplifying power of the vacuum tube is, however, not an instance in which something is seemingly obtained for nothing. In this respect it is not comparable to the microscope or telescope. Rather, as pointed out by Batsel, its amplifying effects are obtained in a manner analogous to the increase of power in a direct current generator due to an increase of current or potential in the field circuit of the machine, which in turn increases the density of the magnetc field in which the armature rotates. The increased power in the dynamo output is disproportionately greater than the increase of current in the field circuit and is supplied by drawing upon the mechanical energy that revolves the shaft of the dynamo. Analogously the batteries that supply the heat for the filament and the electric potential for the plate are drawn upon to supply the power developed by the vacuum tube. In the case of the direct current generator the power is controlled by the magnetic field; in the vacuum tube the output is controlled by the grid potential through the agency of an electric field.

The transmitting and receiving vacuum tubes employed in wireless telegraphy and telephony are differently constructed and require varying amounts of current. Thus one type of receiving tube used by the United States Signal Corps requires for filament operation 1.1 ampere supplied by a four-volt storage battery, while the plate circuit is supplied by a 30-volt dry battery of 15 cells. The filament in the transmitting tube takes normally 1.36 amperes at seven volts. The battery for the plate circuit of this tube ranges from 250 to 350 volts. The power output of this tube is three to five watts. Consult article by Bown (*Electrical World*, 22 Feb. 1919).

Wireless Telephony in Aerial Service.— The exigencies of the Great War led to rapid development in wireless telephone apparatus and methods for army and navy needs in this country and abroad. There was especial need for wireless telephony in the aerial service and great progress was made in meeting these demands. For the latter purpose apparatus of minimum weight was necessary. The dimensions, for example, of a complete outfit for the use of the United States Signal Crops, containing vacuum tubes, transformers and plate circuit dry batteries are nine inches by seven inches by five inches, and it weighs eight pounds. The input transformer used in this set is of the shell type, wound with 6,000 feet of No. 40 enameled wire with paper insulation between the layers of wire, and weighs two pounds.

In Figs. 7, 8, respectively, are given illustrations of transmitting and receiving types of three electrode vacuum tubes used by the United States Army and Navy signaling departments in the late war. In Figs. 9, 10 are illustrations of airplane transmitting and receiving wireless telephone sets utilized by the United States Signal Corps. Wireless telephone communication between flying machines in the air and between the planes and ground stations; also by means of wire telephony between the men in the airplane itself, was daily

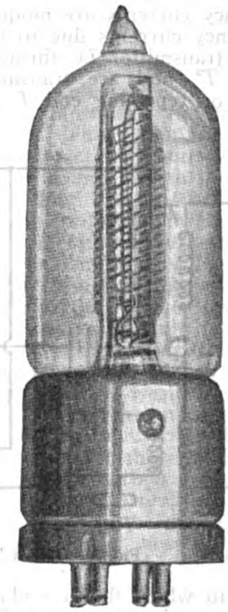

FIG. 7.—Receiving Type Vacuum Tube.

becoming of more importance toward the close of the war, and many valuable improvements were developed to facilitate this communica-

Multiple Wireless Telephony.— In wire telegraphy the term duplex telegraphy signifies a system in which two messages are sent over one wire simultaneously in opposite directions. By diplex telegraphy is meant the sending of two messages in the same direction over one wire simultaneously. The term multiplex telegraphy usually covers telegraph systems by which more than two messages are transmitted over one circuit at the same time in either direction. In wireless telegraphy the term «duplex telegraphy» is applied to means by which two wireless messages are sent in opposite directions at once from two wires on one supporting tower, or preferably from two wires on separate towers, and again preferably with the respective transmitting and receiving aerials separated a distance of 25 or 50 miles, in which latter case the transmitting and receiving apparatus are connected by land wires, thus making it possible to localize the transmitting and receiving operators in one room. This is termed remote or distant control. The actual adjustments of the wireless apparatus are made by attendants at the transmitting and receiving antennæ. Utilizing remote control methods during the late war, the high-power wireless transmitter stations at Annapolis, Md., Tuckerton, N. J., New Brunswick, N. J., and Sayville, L. I., were operated by four operators in one room in the Navy Department building, Washington, D. C.

The term multiplex wireless telephony may also be utilized as mentioned in the case of duplex wireless telephony, but preferably it refers to the sending of two or more wireless messages simultaneously from different antennæ at nearby stations, say, ships of a fleet, and their reception on the antennæ of different ships of a fleet at a distance. One of the best known multiplex telephone systems for this purpose is due to R. A. Heising. The description of this system will perhaps be simplified by the interpolation of a brief allusion to the Gray Harmonic Multiplex Telegraph system, formerly in use on land lines.

The Gray Harmonic Multiplex Telegraph.— By means of this system it is possible to transmit over one wire simultaneously four or more messages by means of electrical vibrations. In this system four tuning forks of different rates of vibration, say, 264, 320, etc., per second, are each given control of a battery by contact points suitably fixed on the forks. These batteries are arranged in series in a main line circuit. The tuning forks are kept in constant vibration by an electromagnetic device similar to that of the ordinary electric door bell, the forks being used as the armature of the magnet. When in operation these forks open and close the circuits of their respective batteries at a rate corresponding to the fundamental vibration of the forks, and thereby set up four different trains of electric impulses in the main line circuit, of frequencies equal to those of the respective vibrating forks. A Morse telegraph key is arranged to control the impulses set up by each fork in such a manner that a series of short and long electric pulsations corresponding to the dots and dashes of the Morse telegraph alphabet may be transmitted over the main lines by each key.

At a receiving station four electromagnets are placed in series in the main line circuit. The armatures of these instruments are iron reeds, fastened at one end, and attuned to vibrate at rates corresponding with their respective vibrating forks at the transmitting station. Hence, each reed will select and respond only to the pulsations of current transmitted by its respective vibrating fork. Contact points controlling a local current are also attached to the armatures of the receiving magnets and by this means the transmitted dots and dashes are received by a Morse telegraph sounder in practically the usual way.

Obviously, when all of these differing rates of current impulses are being transmitted at one time over one wire the resultant composite wave must be complex to a degree. Yet the Gray Harmonic telegraph system was in successful operation for several years between New York and Chicago on the lines of the Postal Telegraph Company. Indeed the degree

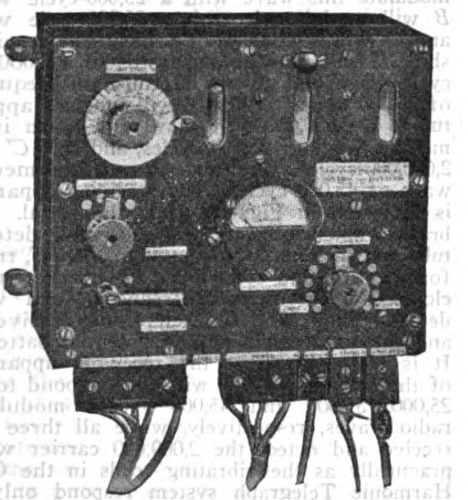

FIG. 9.

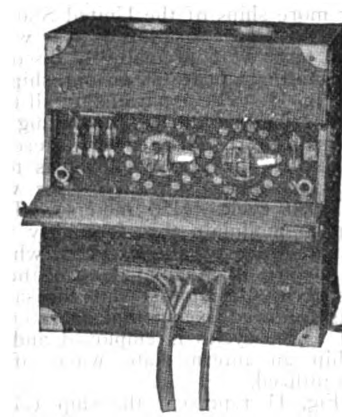

FIG. 10.

Airplane Transmitting and Receiving Set adopted by the United States Signal Corps.

of complexity of the resultant current referred to did not end with the operation of the functions outlined in the foregoing remarks. For, in addition to the four pulsatory circuits mentioned, an ordinary Morse duplex system was superposed on the vibrating system, this giving a sixtuplex telegraph system capable of transmitting six messages over one wire simultaneously.

The Heising Multiplex Wireless Telephone System.— In this system an arrangement measurably analogous to the foregoing is employed for setting up electric oscillations of different frequencies, which differing rates of oscillations are simultaneously radiated as a compound wave in space from the aerials of nearby transmitting stations and are selected and received at the receiving stations by suitably attuned wireless apparatus, in a manner to be described.

This system was installed experimentally on three or more ships of the United States navy, but owing to the declaration of war with Germany the tests were prematurely discontinued. The transmitting apparatus on one ship is outlined in Fig. 11. The apparatus on all the ships was similar, but certain of the tuning circuits on each ship were adjusted to different rates of oscillation. The plan employed is to transmit from the three ships a carrier wave of say 2,000,000 cycles (150 meters). Then on one ship to modulate this frequency with an intermediate wave of 25,000 cycles, which frequency in turn is modulated with the waves due to speech. On another ship the same procedure is followed except that an intermediate wave of 35,000 cycles is employed and on the third ship an intermediate wave of 45,000 cycles is utilized.

Let Fig. 11 represent the ship (A) using wave modulates at R the amplitude of the 25,000 cycle frequency set up by the oscillator-tube VT'. In turn this modulated 25,000 cycle frequency after amplification in power tube VT^2 is, through transformer T^2 caused, at condenser C, to modulate the 2,000,000 cycle carrier wave developed by oscillator VT^3. This doubly-modified carrier wave after increased power amplification by the tube VT^4 is delivered by the transformer T^4 to the antenna A. The batteries and other devices used in this system are not shown in the figure.

To avail of this arrangement each of the three ships or other stations equipped with this apparatus will transmit a carrier wave of 2,000,000 cycles. But one ship, say A, will modulate this wave with a 25,000-cycle wave. B will modulate it with a 35,000-cycle wave, and C with a 45,000-cycle wave. The receiving ship A' will tune his apparatus to a 2,000,000-cycle wave and to an intermediate frequency of 25,000 cycles. Ship B' will tune his apparatus to a 2,000,000-cycle wave and to an intermediate wave of 35,000 cycles, and ship C' to a 2,000,000-cycle wave and to an intermediate wave of 45,000 cycles. The receiving apparatus is indicated in Fig. 12. A is the aerial. The bracket m encloses the 2,000,000-wave detector tube and the appropriate tuning coils TC, transformers RC and condensers C. Bracket n encloses the intermediate frequency and voice detector tube VT', the telephone receiver R and the usual filament and potential batteries. It is plain then that the receiving apparatus of the ships A', B', C' will only respond to the 25,000, 35,000 and 45,000 speech modulated radio waves, respectively, while all three will receive and detect the 2,000,000 carrier wave, practically as the vibrating reeds in the Gray Harmonic Telegraph system respond only to

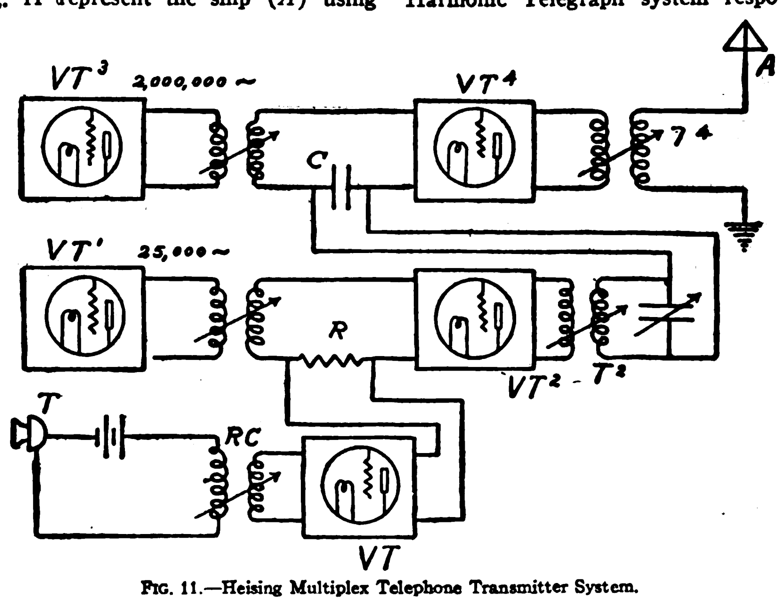

FIG. 11.—Heising Multiplex Telephone Transmitter System.

the speech modulated wave of 25,000 frequency. T is a microphone transmitter. The speech waves set up by this transmitter is repeated by the transformer or repeater coil RC into an amplifier VT. This amplified speech the particular train of impulses to which they are attuned.

This system of non-interfering multiplex wireless telephony is not, however, limited to the sending of three messages or conversations simultaneously in the same neighborhoods. For, by using carrier waves of say, 189 and 239 meters in length, in addition to the wave length of 150 meters, and by modulating each of these two additional carrier waves with intermediate frequences of 25,000, 35,000 and 45,000 cycles it will be feasible to carry on nine separate wireless conversations simultaneously between the ships equipped and placed as indicated in the foregoing.

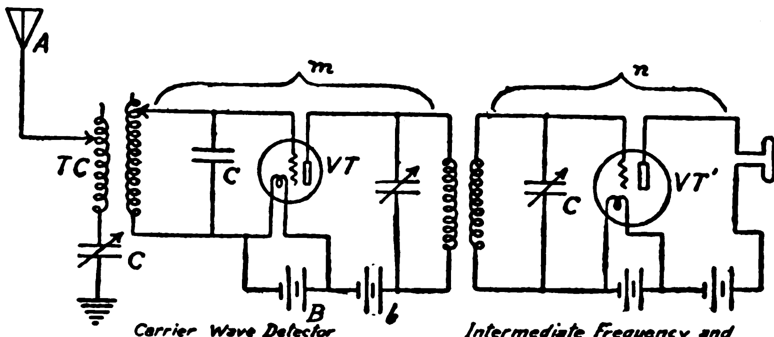

FIG. 12.—Multiplex Wireless Telephone Receiving Circuits.

Tests with apparatus somewhat similar to that just described showed that two-way wireless telephone conversations could be carried on between ships at a distance of about 40 miles, the power of the outfits being low. The limit of speaking distance was about 150 miles. By two-way conversation is meant the ability to converse in either direction, one speaker at a time on one circuit. Apparatus to permit this two-way conversation was provided on the ships. The object in resorting to the short-wave lengths of 150 and 189 meters in the tests just described was to avoid interference or clashing with the regular wireless telegraph operation of the ships of the navy which use wave lengths of 600 to 1,200 meters.

In Fig. 13 is shown an arrangement of amplifying and power tubes such as referred to in the description of Fig. 11. *G* is a generator of high frequency oscillations which after transformation by coils *RC* may be modulated by the microphone transmitter *T*. These modulated oscillations are amplified by the tube *VT*, the output circuit of which is coupled through transformer *RC'* to the input circuits of a battery of two power vacuum tubes *VT'*, the output circuits of which in turn are coupled through transformer RC^2 to the input circuits of a battery of three power tubes VT^2. Similarly the output circuits of the latter tubes are coupled through the transformer RC^3 to the aerial *A*, from which the modulated high frequency oscillations amplified and increased in power are radiated into space. *BB* in the figure indicate the usual heating and potential batteries. The power tubes, it will be noted, are connected in quantity or multiple and not in series or cascade as in the case of amplifier tubes. See Fig. 6.

Long Distance Wireless Telephony.—An epochal series of experiments in long-distance wireless telephony was in 1915 conducted by the American Telephone Company in conjunction with the Western Electric Company and representatives of the United States navy and the French army. The most notable of these tests were perhaps those made between Arlington, Va., and the Eiffel Tower, Paris. Tests had been previously made between Arlington and Darien, 2,100 miles oversea, and between Arlington and Mare Island, near San Francisco, 2,500 miles overland. In the Arlington-Darien experiments speech was transmitted from New York City by land lines to Arlington, whence it was transmitted by wireless telephony to Darien. In the Arlington-Paris experiments difficulty was found in obtaining the use of the Eiffel Tower station, owing to the exigencies of the Great War which was then in progress. In these tests the Eiffel Tower station was used only for receiving. On 22 Oct. 1915, however. speech transmitted from

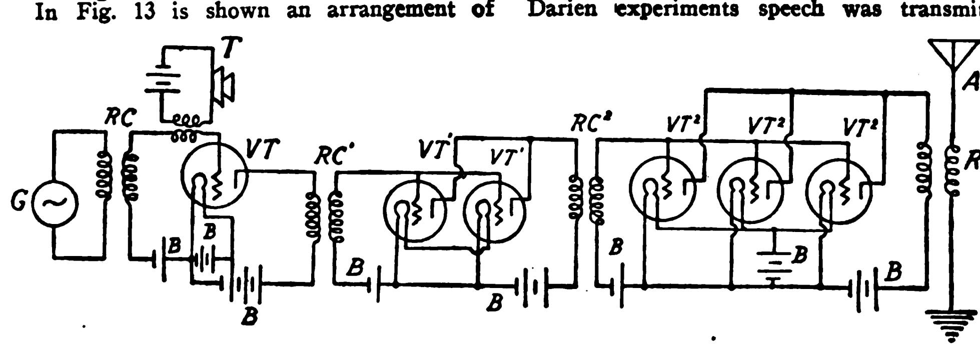

FIG. 13.—Transmitting Circuit Showing Amplifying and Power Vacuum Tubes.

Arlington was clearly received in Paris, a distance of 3,600 miles. The radio-wave length employed was 6,000 meters. The antenna current employed at the Arlington station was about 50 amperes. The speech transmitted on this and other occasions was also received, and the voice of the speaker clearly recognized by the wireless operator in Honolulu, 4,500 miles from Arlington.

The general plan of transmission adopted at Arlington was somewhat similar to that indicated in Fig. 12, but of course the number and capacity of the amplifier and power tubes used at Arlington was greatly in excess of that used in shipboard or ordinary wireless telephone practice.

The Future of Wireless Telephony.— In view of the rapid development of wireless telephony within the past 8 or 10 years it would be unwise to attempt to place a limitation upon the extent of the use of this art within the next decade. The possibility of transmitting wireless telegraph messages a distance of 12,000 miles, namely, from Carnarvon, Wales, to Sydney, Australia, has been demonstrated (2 Oct. 1918). Likewise the possibility of transmitting speech by ether waves a distance of 4,500 miles has been shown. These results are obtainable by the use of the vacuum-tube oscillators and amplifiers. As a distance of 12,000 miles is half way around the earth and as the ether waves in traveling that distance traverse both sides of the earth, it follows that this is equivalent to transmitting a message from one point to any other point on the earth. Since also it appears evident that by means of the three-electrode vacuum tube speech may be transmitted to any distance reached by radio-telegraph waves, it would seem that under favorable conditions it may be said that world-wide wireless telephony is now a possibility.

The high cost of very high-power vacuum tubes together with their low efficiency and limited durability is at present, however, likely to militate against their general use, but improvements in methods of construction of this apparatus will doubtless reduce its cost and increase its durability. The existing need of high and very expensive aerial wires in long distance wireless telegraphy and telephony is also a limiting factor to the extensive employment of those arts to very long distances.

Some of the chief obstacles to the extensive and successful use of wireless telegraphy and telephony in the past have been those due to statics and interference between or clashing of signals from different sending stations at nearby or even at remote stations. A great forward step toward the solution of the statics problem is that due to the Weagent anti-static devices. (See TELEGRAPHY, WIRELESS). The interference problem is still to be solved.

As already noted, by the use of selective tuning devices which only transmit and respond to waves or oscillations of a certain frequency, stations may cut out waves of other frequencies and thus avoid interference. Thus by the use of a standard wave length for certain circuits, as, following land telegraph practice, the ether route used by different wireless stations may be termed non-interfering; ether circuits may be and in fact are established very generally at the present time. Thus the regular wave lengths for a given trans-Atlantic circuit may be set at, say, 10,000 meters. Other stations using that wave length in the vicinity of that circuit to which the 10,000-meter wave length is assigned, would set up interference or clashing of signals. It is known, however, that a difference of 300 to 400 meters in the wave length is ample to avoid interference between such stations. For instance, a circuit employing a 10,000-meter wave length could operate side by side with a circuit employing a 10,400-meter wave length. For long-distance wireless telegraph and telephone operation, or, in other words, for high-power station work, long wave lengths are essential. The present minimum and maximum available wave lengths are, say, from 10,000 to 20,000 meters for long distance signaling. Since the signals from the very high-power stations are now received all over the world, it is obvious that if a difference of, say 400 meters, is required to prevent interference between any two such wireless circuits, the total number of available world-wide circuits would be limited to say 25.

It may be noted that for short-distance wireless signaling a difference in the respective wave lengths of about 20 meters is found sufficient to prevent interferences between circuits. Even in short distance signaling, however, were all stations to adhere rigidly to an allotted wave length in any designated zone the number of available wave lengths would ultimately be reached. While the foregoing conditions continue the limitations to wireless telegraphy and telephony will exist.

It is, however, not unlikely that improvements in this branch of electrical signaling will render it possible to operate transoceanic wireless telegraphy and telephony on a much closer margin than 400 meters. Indeed it has been noted by Alexanderson in the paper referred to that by improved arrangements of apparatus and circuits it will be possible to operate such circuits with a difference of but 1 per cent of the total frequency, instead of 4 per cent as at present. This would make it possible to increase the number of transoceanic circuits to, say, 100, roughly speaking. Again, by means of improved methods of directive signaling the number of parallel wireless circuits on one wave length will be increased by five. These improvements together with an increase in the speed of signaling to 100 words per minute generally, instead of 20 words as at present, will, it is estimated, increase the total capacity of the radio transoceanic traffic of the world 175 times.

In wire telephony interference of this nature does not occur, as measures are taken to prevent such interference (termed inductive interference between circuits) by using two parallel wires suitably transposed for each telephone circuit. (See TELEPHONE). The effect of induction between parallel Morse and printing telegraph circuits is not pronounced inasmuch as the receiving instruments employed on those systems are comparatively insensitive to weak induction currents from other lines.

Notwithstanding the real difficulties in the way of what may be termed universal wireless telephony for social, commercial and other purposes it is confidently expected by competent telephone engineers and inventors that its ultimate consummation is not beyond the possibility of practical realization. In the meantime wireless telephony if only available, commercially, for comparatively short distances, obviously could be installed to great advantage in the officer's room of every ship that floats ocean, lake, river or harbor, because of the fact that telephony requires no specially trained operator.

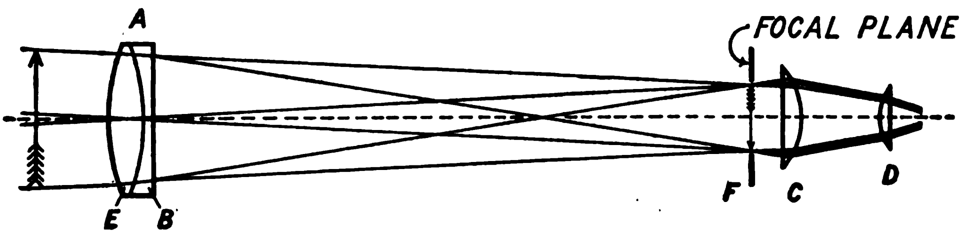

FIG. 1. — Astronomical Telescope.

TELEPHOT, or TELEPHOTE, any one of several theoretical instruments designed to reproduce scenes at a distance by photography and the aid of electricity. Telephotography has been an interesting field for inventors, but no commercially successful machine has been developed.

TELESCOPE. The telescope is an optical instrument by which the image of a distant object is magnified so that it may be examined as if it were but a fraction of its actual distance from the observer. This instrument was invented by the Dutch optician, Lippershey, early in the 17th century. The first use of it for astronomical observations was made in Florence, by Galileo, who in 1609 invented the type known as the Galilean telescope. His first instrument was constructed of two spectacle lenses set at the ends of a section of a leaden organ-pipe. Its power was three diameters. A second instrument had the power of eight diameters and a later one 30.

The many and widely varying forms of telescopes may all be grouped simply as tubes (Milton, seeing Galileo's in Florence, called it the «Optik Tube»), in which are placed the several combinations of lenses or reflectors; each combination, however, producing the one result, namely, first, gathering the light from the object and concentrating it at the focus in a brilliantly illuminated but small image; and, second, magnifying this image with a microscope called an eye-piece. One of the common types is the refracting astronomical telescope (Fig. 1), in which A is the object-glass or objective, and F the focus, where the small image is formed. The two lenses, C and D, form the microscopic eye-piece, which magnifies this image. The first reflecting telescope was the Gregorian, invented in 1663 by James Gregory. It has not survived. Fig. 2 represents the reflecting astronomical telescope as invented in 1669 by Sir Isaac Newton, and called the Newtonian Reflector. In this the light traverses the entire length of the tube, at the lower end of which it strikes the concave reflector A, which sends it back as a cone of rays to the diagonal reflector B; thence it travels to the focus F, where it is magnified by the eye-piece E, as in the refracting telescope. Fig. 3 represents the most popular form of reflecting telescope, called the Cassegrainian, invented by Cassegrain in 1672. The optical principles here are the same as in the Newtonian form except that the convergent cone of rays from the mirror A is intercepted by a convex reflector B and sent back through an opening in the centre of the mirror A to the focus F, where the image is magnified by the eye-piece as before. The Herschelian reflector was invented by Sir William Herschel (q.v.) in 1780. His great telescope, built in

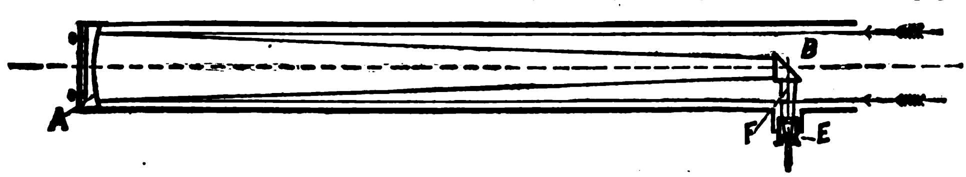

FIG. 2. — Newtonian (eye-piece on side of tube).

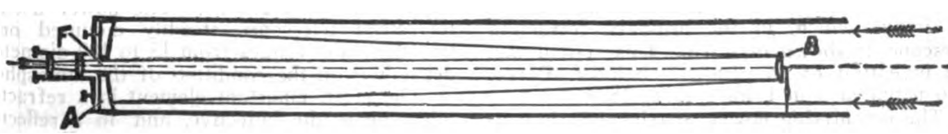

FIG. 3. — Cassegrainian (secondary mirror convex).

1789, had a mirror 48 inches in diameter and a tube 40 feet in length.

In these forms of telescope the image of the object as seen through the eye-piece is necessarily inverted, which is, of course, unimportant in astronomical observations, but is a defect to be overcome in the terrestrial instrument. The most common type of terrestrial telescope is the Spy Glass (Fig. 4). The objective A has the same office as in the refracting astronomical telescope, and forms an illumined image of the object at the focus F. This image is then magnified by a compound eye-piece made up of several lenses B, C, D and E, which carry the light to the eye in such manner as to erect the image and show it in its natural position. Fig. 5 represents the Galilean telescope, which is the same in principle as the ordinary opera glass. In this case the objective A condenses the light from the object observed, and would naturally make a small image at F, but the cone of rays, before reaching the focus, is intercepted by the double concave eye-piece C, and thence conveyed to the eye in erect position. Fig. 6 shows the Porro Prism instrument, the most modern and efficient form of terrestrial telescope. The objective and the lenses are in the same relation to each other as was first illustrated in the astronomical telescope, Fig. 1. Two double-reflecting, 90-degree prisms are inserted within the cone of rays between the eye-piece and the objective (Fig. 6); their mission being to erect the image which, in the ordinary refracting telescope, is shown inverted. This system was the invention of the Italian engineer, Porro, who patented it in France about 1850.

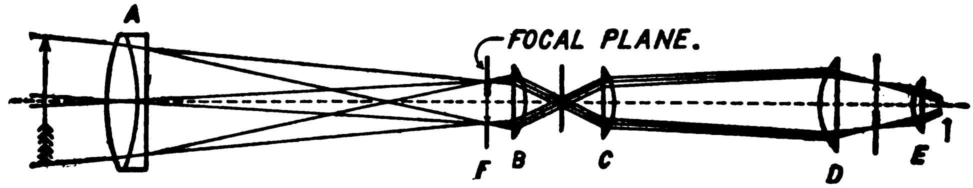

FIG. 4. — Terrestrial Telescope (spy glass).

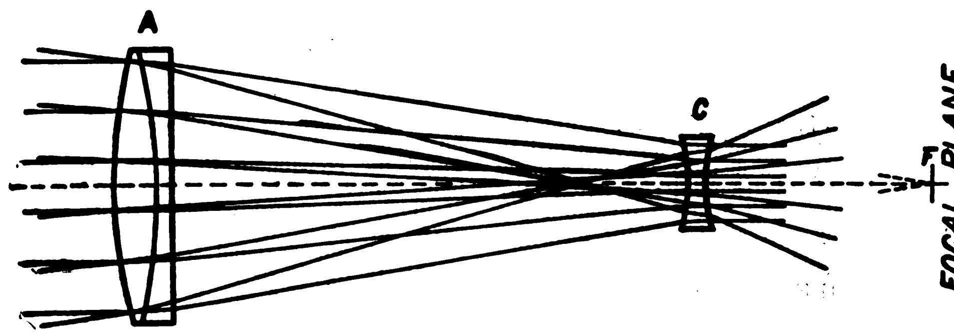

FIG. 5. — Galilean Telescope (opera glass).

The magnifying power of telescopes is usually expressed in diameters and is indicated by the ratio of the focal length of the objective to that of the combination of lenses forming the eye-piece. For example, the Lick telescope has a focal length of 56 feet or 672 inches. If, therefore, an eye-piece of one inch focus is used in this telescope, the power resulting will be 672 diameters, and eye-pieces of longer or shorter focus will give correspondingly lower or higher powers. The practical limit of power in telescopes of the highest degree of accuracy is usually considered to be about 100 diameters per inch of aperture. Thus the 36-inch Lick telescope may be practically used with an eye-piece which would give a power of 3,600 diameters. Such high powers are, however, seldom required and can be used only in the clearest atmosphere. By far the larger proportion of astronomical observations are made with powers of less than 1,000 diameters. In telescope observations, the two elements "power" and "light," while equally important, are always in opposition. Thus an object viewed with a power of 100 diameters is four times as brilliantly illuminated as would be the case if an eye-piece giving 200 diameters were used. It follows, therefore, that the observer will use the power best adapted to his purpose, both as to magnification and light.

The telescope giving the minimum power is the opera glass, usually magnifying two and one-half or three diameters, which is sufficient for indoor use, while for outdoor use the Galilean binocular has a power of four or five diameters, and the prism binocular of six, eight, 10 or even 12 diameters. The eight-power is, however, considered as high as can be held in the hands with sufficient steadiness to give the best results. The power used in terrestrial telescopes steadily mounted on a tripod usually ranges from 15 to 100 diameters, depending on the condition of the atmosphere.

The most important element in a refracting telescope is the objective, and, in a reflecting telescope, the mirror or speculum. The objective of the early refracting telescope was a double-convex lens, which could not give a distinct image because it separated each ray of light into its various prismatic colors, and each color, having a refracting power different from

Yerkes Telescope

the others, found a focus of its own. The red ray, being most refracted, reached its focus first; next came the yellow ray, then the green and last and nearest of all to the eye-piece, the blue ray made its image. When a star is viewed with such a telescope the image seen consists of a yellowish point at the centre, surrounded by a mixture of green and blue light, with red outside. This difficulty in refracting telescopes, called chromatic aberration, checked the progress of astronomy for 150 years, until, in 1750, the English optician, Dolland, invented the achromatic objective as shown in Fig. 1. In this diagram E is a double-convex lens of crown glass and D a flint-glass lens of nearly plano-concave form. The difference between the crown and flint material in light refraction and dispersion, together with the compensating form of the two lenses, results in clear and distinct "definition," the image of the star being sharply outlined and colorless. Optical glass for such lenses is of special manufacture. The world's supply comes from three makers, one each in England, France and Germany. The newer objectives are made of several thin lenses cemented together, usually four in number and alternately crown and flint glass. Some makers are using five lenses successfully, though which much difficulty. The mirror or

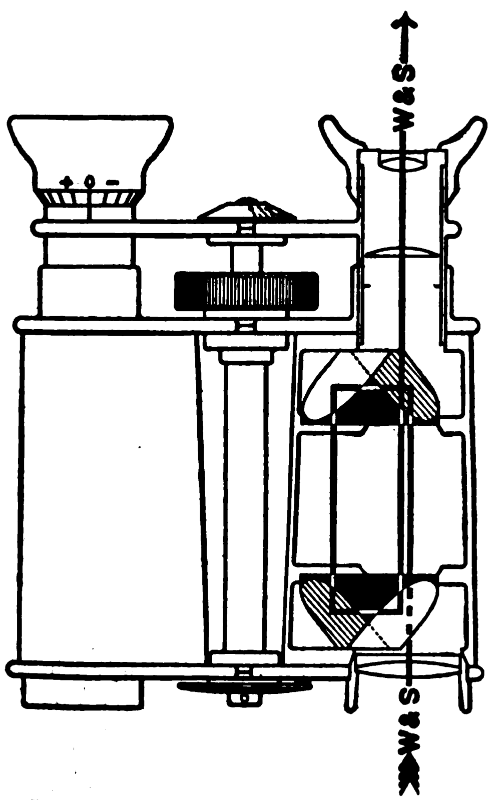

FIG. 6.—Universal Prism Field Glass (sectional view).

speculum of the reflecting telescope is made from a casting of ordinary glass of sufficient thickness to be handled without flexure, preferably one-sixth of the diameter of the disc, although one-eighth is a commonly accepted proportion in the case of very large discs. The reflecting surface is ground and polished, with great precision, to a parabolic form of the focus required, and then, by a chemical process, coated with silver, which may be easily renewed when tarnished or otherwise injured.

The making of the optical parts of telescopes is a rare art, which, however, has been cultivated with peculiar success in America. Alvan Clark and Sons of Cambridge, Mass., attained world-wide fame in this connection during the lifetime of the gifted men composing the firm. At the present time the largest reputation as a maker of large telescopic objectives belongs to John A. Brashear of Pittsburgh, Pa.

The telescope tube is usually carried by an equatorial mounting. This form of instrument has its principal or polar axis set parallel to the axis of the earth, its inclination, therefore, corresponding to the latitude of the observatory. At right angles to the polar axis is the declination axis, which, in turn, carries the telescope tube at right angles to itself. Each axis is supplied with a graduated circle, indicating, respectively, the position of the star in hours, minutes and seconds of right ascension, and in degrees, minutes and seconds of declination. It will be evident that when the tube is pointed to a star in any part of the visible heavens, a revolution of the polar axis from east to west, in sidereal time, will make the telescope follow the apparent motion of the star. A driving clock, which is usually located inside the column of the instrument, controls the revolutions of the polar axis so that the star observed remains steadily in the field of vision. The equatorial principle has been applied to photographic telescopes in such manner as to allow the continuous exposure of the photographic plate during the entire night, if desired. One of the most ingenious forms of mounting is the Equatorial Coudé. In this instrument the polar axis is enlarged so as to serve as the main tube of the telescope, the eye-piece being at the upper end where the observer can sit comfortably in his warm room and observe any star in the visible heavens as easily as he uses his microscope.

An elbow is rigidly attached to the lower end of the tube. At the intersection is an accurately polished mirror set at an angle of 45 degrees. At the outer end of the elbow is another mirror, similarly set. The objective is so placed that the light it gathers from the star is reflected by the mirrors through the tube to the eye-piece. The combined movements of the polar axis (the telescope tube) and the objective and mirror carried on the elbow enable the observer to bring into view any star in the visible heavens. The polar axis, with its elbow carrying the objective and revolving in sidereal time by means of a driving clock, follows the apparent motion of the star in the usual way. Two of these instruments are in successful use in the Paris Observatory.

It will be evident that the equatorial telescope with its various modifications as above described, while giving facilities for examining and photographing the heavenly bodies, does not enable the astronomer to determine with required accuracy the positions of the stars and planets. These fine measurements are secured only by special forms of telescopes. The Meridian Circle is one of the most approved instruments for this purpose. From the middle of the tube trunnions extend on either side, carrying finely graduated circles and terminating in accurately ground pivots which are exactly at right angles to the optical axis of the tube. Two piers are so set as to form a rigid and accurate support for these pivots, east and west, carrying the tube so that the movement of the telescope is in the true meridian only. In the exact focus of the telescope a fixed system of cross-hairs or wires is placed. The best materials for this purpose are taken from the cocoon of the field spider, the web being only one five-thousandths of an inch in diameter. Finely drawn platinum wires are also used. These vertical spider webs are equally spaced and so adjusted that the central wire is exactly in the optical axis of the telescope as measured east and west. A horizontal wire is adjusted exactly in the optical axis as measured north and south. Parallel to these central wires there are two movable wires, one horizontal and one vertical, each governed by a micrometer screw.

In measuring transits of stars for determining right ascension, or for time, the telescope, by means of the graduated circles, is set to the declination of the star required, and when the star appears, its transit across each of the wires is recorded on a chronograph, by the observer tapping an electric key. In determining declinations, the telescope, by means of the graduated circles, is set to the approximate declination of the star to be observed, and when the star appears at the edge of the field, the observer carefully adjusts the telescope until the star seems to be exactly bisected by the horizontal wire as it threads its way across the field. By reading the fine circle the declination of the star is obtained. Other types of telescopes for similar observations are known as transits, zenith telescopes, mural circles, etc., but the illustrations given will suffice.

Even with all the caution used in the construction of these delicate instruments, errors are sure to develop, due to refraction, flexure of the tube, variation resulting from changes in temperature and other contributing causes, for all of which allowance must be made in the final reduction of the observations. About the middle of the last century Professor Airy, then Astronomer Royal at Greenwich, designed and constructed a vertical telescope, which he believed would eliminate the errors so manifest in his other instruments. He named it the «Reflex Zenith Tube.» The principle is shown in Fig. 7. Every part of the instrument is stationary and no part need be touched when in use by the astronomer. The light from the star as it passes the zenith is concentrated by the objective upon a surface of mercury in the base of the column, by which it is reflected back through a hole in the objective; the cone of rays then meets a diagonal prism, is reflected at right angles and enters the eye-piece to be observed as in other instruments. Contrary to the expectations of the Astronomer Royal, errors in the observed position of the stars were still manifest and the most careful investigations failed to trace them to their source. The instrument was, therefore, discarded. Fifty years later, Professor Chandler, of Cambridge, Mass., discovered that the pole of the earth «wobbles» slightly, causing a variation in latitude. The results of his observations were compared with the Airy observations of a half century before, and the supposed errors of the «Reflex Zenith

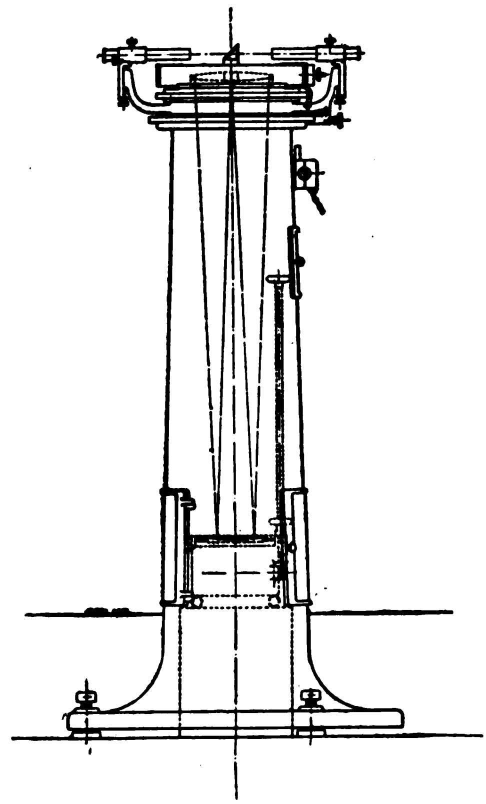

FIG. 7.—Reflex Zenith Telescope.

Tube» were at once traced to the variation in latitude. The old instrument which had been condemned is thus proven to be correct both in theory and practice. It, therefore, represents the latest development in astronomical telescopes, and a large Reflex Zenith Tube is now in the service of the University of Pennsylvania.

In recent years the mounting of great equatorials has passed from the domain of the instrument-maker to that of the engineer, who finds abundant scope for ingenuity and technical expertness in combining very massive and so, rigid, construction with very delicate mechanism. At the present time the largest telescopes in the world are owned and made in America.

The table on following page gives a list of the larger refracting telescopes in the equipment of the more important American observatories.

While the refracting telescope still holds its advantages for photographic astronomical work the tendency of late years has reverted to the reflecting telescope for visual work. Astronomers prefer it because of the much clearer images obtained, due in large part to the entire absence of the secondary spectrum. The images formed by the best refractors have a turbid quality as compared with the clean crispness of the reflector. As in the case of the refracting instruments, America boasts the largest reflectors. The largest of all is the

Hooker reflecting telescope of the Mount Wilson Observatory, Pasadena, Cal., with a clear aperture of 100⅜ inches (2.549 meters) and a primary focal length of 507.5 inches (12.891 meters); it can be used directly on the axis either (a) as a focal plane instrument, or (b) in the Newtonian form; at its secondary foci it may be used (c) as a Cassegrain instrument with a focal length of 1,606 inches (40,792 meters), or (d) as a Coudé with focal length of 3,011 inches (76.480 meters). Celestial objects from 65° north to 53° south declination can be observed at the principal focus. The telescope is mounted after the English fashion, the skeleton tube containing the mirror at its lower end swinging between the sides of the open polar axis yoke which has a bearing at either end resting on cast-iron pedestals built up from the main concrete pier below. The mounting was designed by Mr. Pease and other members of the observatory staff, assisted by Prof. Peter Schwamb of the Massachusetts Institute of Technology. The pier is 33 feet high while the intersection of the axes is 50 feet above ground. Both the declination and right ascension bearings are composite; in part, of spherical type, serving to define the axes, while the remainder carries the load. The declination load is carried by means of counterweight systems while the polar axis is supported by means of steel drums built integral with the axis and floating in cast-iron tanks filled with mercury. The tube complete weighs 35 tons and the total moving parts weigh 100 tons. They are constructed of cast and structural steel throughout and in as large units as could be machined as a whole. The larger portions of the mounting, some weighing 10 tons, were made in Quincy, Mass., and their transportation up Mount Wilson to an elevation of 5,700 feet was a difficult feature in the erection of this instrument. The mirror is 101.2 inches diameter, 12¾ inches thick and weighs about 9,000 pounds. It was cast in Saint Gobain, France, and figured by G. W. Ritchey in the observatory optical shops. It is mounted on a counterweight support system in the rear and on four edge arcs at the sides. To control its temperature it is surrounded with a lining of cork board built integral with its cell, and a system of piping is installed within this through which liquid at any desired temperature may be circulated from tanks in the pier below. Fans serve to equalize the temperature around mirror and coils. When it becomes necessary to resilver the mirror it is removed from the tube and lowered in its cell by an electric elevator into the pier, where all apparatus and material is at hand and where the temperature may be controlled. The telescope has motor-driven fast and slow motions, while the diurnal motion is supplied by the typical form of driving clock having a conical pendulum isochronously governing a falling weight. This operates through a worm and a worm wheel (17 feet in diameter) cut and ground with high precision. The instrument is controlled, settings are made and the dome is turned from a station on the pier at which the readings of the circles are made; the "remote" system of electrical control is used throughout, and most of the operations are duplicated by auxiliary controls at the three observing stations or foci. To reach the principal focus an observing platform is provided which travels along the shutter opening. The dome is of structural steel throughout, 100 feet in diameter, 100 feet high and weighs 730 tons. The rotating portion weighing 500 tons is carried on 28 trucks and is traction, driven by two motors at opposite sides. The trucks and rails are carefully machined to conical surfaces to eliminate vibration at the telescope when the dome is moved. The shutter is in halves which open sideways and permit free working of the telescope from the zenith to the horizon. The walls and dome are of double construction and are ventilated at the top to prevent excess heating during the summer. A 10-ton crane is provided to assist in the erection and in the transfer of the various auxiliary sections of the tube.

The second largest reflector in the world is the 72-inch instrument set up in 1918 on Little Saanich Mountain on Vancouver Island, British Columbia, in the Dominion Observatory there. The mirror of this instrument was ground by the John A. Brashear Company of Pittsburgh, from a disc of glass cast in Belgium and shipped out of that country two days before the war broke out. The mirror is parabolic, 13 inches thick at the rim with a hole 10⅛ inches in diameter through its centre. It weighs 4,340 pounds and has a focal length of 30 feet. Observations may be made from the side of the upper part of the tube, from the side at the lower end or through the opening at the centre of the mirror. The telescope with all its fittings weighs 55 tons and is moved by an amount of electric current barely sufficient to light a 16-candle power electric lamp. The mounting was built by Warner and Swazey. The only other telescope of this size in existence is that of Lord Rosse set up upon his estate in Ireland in 1842. Its first mirror was of speculum metal and was replaced by a 72-inch silvered glass mirror in after years. For a long period it was the largest telescope in the world; but was abandoned for optical reasons.

There are three 60-inch reflectors in the Western Hemisphere, the newest one erected at the National Observatory of the Argentine Republic near Cordoba. The mirror was made by the John A. Brashear Company in 1916. In 1904 Harvard University secured the 60-inch reflector made by Dr. A. A. Common of Ealing, England. This instrument is of the Cassegrainian type and has a rectangular tube. The mounting is peculiar, the telescope being supported in position upon the end of a hollow cylinder which floats in a well or deep basin of water. The cylindrical float is 18 feet long and seven and two-thirds feet in diameter and arranged to float constantly at an angle with the horizon equal to the elevation of the celestial pole at Cambridge—about 45 degrees. The instrument weighs over 20 tons, but is so delicately balanced that it may be moved in any direction with the greatest ease by its electrical controls. The eye-piece of the instrument is detached from the telescope and housed in the second story of an adjacent building, the light from the principal mirror being directed to it by accessory mirrors.

The 60-inch reflector of the Mount Wilson Observatory, constructed by Dr. Ritchey in 1908, was placed in commission in December of that year. The instrument complete weighs 21½ tons, nearly all of which is ingeniously supported upon a float in a basin of mercury, of which it displaces the equivalent of 50 cubic feet, although the entire amount of mercury in the basin is but 635 pounds. The controls are electric and may be manipulated from several stations about the instrument.

Another fine telescope which should be mentioned in this connection is the 48-inch reflector built by Sir Howard Grubb and located at Melbourne, Australia.

For more detailed descriptions of these wonderful instruments and their achievements the files of the astronomical journals are recommended.

WORCESTER REED WARNER, F.R.A.S.,
Of the Warner and Swasey Company, Cleveland, Ohio.

TELFORD, tĕl'fŏrd, **Thomas,** Scottish engineer: b. Eskdale, Dumfriesshire, 9 Aug. 1757; d. Westminster, 2 Sept. 1834. At 14 he was apprenticed to a mason and on the expiration of his time worked as a journeyman at that trade, but subsequently removed to Edinburgh and there applied himself to the study of architecture. In 1782 he went to London, where he was befriended by Sir William Pulteney, through whom he was appointed surveyor of the public works in Shropshire. He now became a civil engineer and in 1793 was entrusted with the construction of the Ellesmere Canal, to connect the Mersey, Dee and Severn. In 1803 and 1804 the Parliamentary commissioners for making roads and building bridges in the Highlands of Scotland, and also for making the Caledonian Canal, appointed him their engineer. Under the former board 1,200 bridges, two of 150 feet span, were built and 1,000 miles of new road were made; and under the latter board the Caledonian Canal was constructed. Under other commissioners he built over 30 harbors, some of which, as at Aberdeen and Dundee, are upon an extensive scale. He was also employed in England, superintending the construction of five large bridges over the Severn, of eight canals, and the execution of numerous important works for the metropolis. In 1808 he was employed by the Swedish government to lay out a system of inland navigation through the central parts of Sweden and to form a direct communication by water between the North Sea and the Baltic. He also built the road between Warsaw and Brest-Sitovski in Poland. The greatest monument of his engineering skill is the Menai Suspension bridge, connecting Caernarvonshire with the island of Anglesea, which was opened on 30 Jan. 1826. In 1828–30 he superintended the drainage of nearly 50,000 acres of the Fen country. He invented the Telford pavement. See ROADS, IMPROVEMENT OF.

TELHARMONIUM, an electrical instrument devised to produce music at any distance from a central station. The device was invented by Dr. Thaddeus Cahill (q.v.) and operates on the principle of the telephone, but the receiving instrument is not held to the ear. The music is produced through the medium of dynamos transmitting vibrations to any number of receiving stations. The operator plays on a keyboard similar to that of an organ, the keys controlling electric currents at varying speeds of alternation and producing the notes of practically any instrument with great purity and sweetness.

TELL, tĕl, **William,** Swiss peasant of Bürglen, near Altorf, celebrated in legend for his resistance to the tyranny of the Austrian governor, Gessler. The stories connected with him, with those relating to the origin of the Swiss Confederation, first appear in the 15th century. According to them, Gessler, the tyrannical Austrian bailiff of Uri, one of the forest cantons, pushed his insolence so far as to require the Swiss to uncover their heads before his hat (as an emblem of the Austrian sovereignty), and condemned Tell, who refused to comply with this mandate, to shoot an apple from the head of his own son. Tell was successful in his attempt, but confessed that a second arrow, which he bore about his person, was intended, in case he had failed, for the punishment of the tyrant, and was, therefore, retained prisoner. While he was crossing the Lake of the Four Cantons, or Lake of Lucerne, in the same boat with Gessler, a violent storm threatened the destruction of the skiff. Tell, as the most vigorous and skilful helmsman, was set free, and he conducted the boat successfully near the shore, but seized the opportunity to spring upon a rock, pushing off the bark. He had fortunately taken his bow with him, and when the governor finally escaped the storm, and reached a rocky defile on the road to Küssnacht, Tell shot him dead. The death of Gessler was the signal for a most obstinate war between the Swiss and Austrians, which was not brought to a close until 1499. Tell was present at the battle of Morgarten, and is supposed to have lost his life in an inundation in 1350 while attempting to save a friend. Such is the legendary story of William Tell. Investigation has broken down the proofs of his existence. There is no mention of him by any contemporaneous historian; his name is first met with in the chronicles of the second half of the 15th century, and none of the Tell ballads are of an earlier date. Similar stories in regard to the shooting of the apple occur in Saxo Grammaticus, the Danish historian, and in Icelandic literature, not to mention the old English ballad of Adam Bel, Clym of the Cloughe and Wyllyam of Cloudeslè. Besides, the many contradictions between the various personages, dates and places, and the widely differing representations of the event, show the gradual development of the legend. The untiring industry of historical scholars has not been rewarded by the finding of the name of Tell in the archives and church registers of Uri, and although an uninterrupted series of charters exists relative to the bailiffs or governors of Küssnacht in the 14th century, there is no Gessler among them. The Tell chapels were erected or called by his name generations after his death; the document which speaks of the assemblage in 1388 of 114 persons who knew him personally, and of the erection at that time of a Tell chapel on the shore of the Lake of Lucerne, was not known until 1759. Consult Hisely's 'Recherches Critiques' (1843); Rochholz's 'Tell und Gessler in Sage und Geschichte' (1877); Gisler's 'Die Tellfrage: Versuch ihrer Geschichte und Lösung' (1895). See SWITZERLAND, *History*.

TELL CITY, Ind., city in Perry County, on the Ohio River, 125 miles southwest of Indianapolis, on the Southern Railroad. There are deposits of coal and clay in the vicinity, and manufactures include furniture, iron products, woolens, flour and tobacco. The city was founded by the Swiss Colonization Society in 1857. Pop. 3,369.

TELL EL AMARNA, Egypt, a district near the east bank of the Nile, 190 miles above Cairo, comprising the site and environs of the ancient city of Akhenaton, known also as Ekhaton and Akhet-Aton, built by Amenophis IV, who later was known as Akhenaton or Ikhnaton. The city was built by Amenophis about 1360 B.C. as a new capital of the empire in place of Thebes after he had abandoned the religion of Ammon for that of Aton. It grew rapidly but was abandoned upon the death of Amenophis, the court returning to Thebes as its capital and to the worship of Ammon. The most important ruins are those of the palace and the House of Rolls, and there are remains of the temple. About 300 clay tablets containing valuable records of the time of Amenophis and his father were discovered in the House of Rolls in 1887. To the northeast and to the south of the ruined city are tombs hewn in the sides of the hills which abound in sculptured scenes picturing mainly the worship of the sungod. The tomb of Meri-Ra, high priest of the sun, has two spacious chambers and a façade nearly 100 feet long. The tomb supposed to be that of Amenophis is in a ravine about midway between the north and the south tombs. Consult Petrie, F., 'Tell el-Amarna' (1894); Davies, N. de G., 'Rock Tombs of Tell el Amarna' (1903–08); Petrie, W. M. F., 'Syria and Egypt from the Tell el Amarna Letters' (1898).

TELL EL KEBIR, Egypt, village in the northeastern portion of the country, on the Sweetwater Canal, 18 miles southeast of Zagazig. It was the scene 13 Sept. 1882 of a battle between the English forces commanded by Sir Garnet (later Lord) Wolseley and the Egyptians under Arabi Pasha, which resulted in the utter defeat of the Egyptians.

TELLER, tĕl'ėr, **Henry Moore,** American senator: b. Granger, Allegany County, N. Y., 23 May 1830; d. Denver, Colo., 23 Feb. 1914. He was educated at Alfred University, New York, taught school, and after admission to the bar practised law in Illinois and Colorado. He was United States senator from Colorado 1876–82, Secretary of the Interior 1882–85, and was a member of the national Senate from 1885, except for a brief interval 1896–97, up to 1909. He was especially prominent as a silver advocate, and had the unusual experience of serving his constituents as a nominee of the Republican and later of the Democratic party.

TÉLLEZ, tĕl'yăth, **Gabriel,** Spanish dramatic author, better known by his pseudonym, EL MAESTRO TIRSO DE MOLINA: b. Madrid, between 1570 and 1572; d. Soria, 12 March 1648. He studied at Alcala and remained for some time at Toledo, whence some of his works are dated, also in Galicia and in Seville. The date of his profession as a Brother of Charity is unknown, but we know that he had become superior by 1619. In 1634 he was named *Definidor general* of Castille. His first poetical work, 'Los Cigarrales de Toledo' (1624) is a collection of tales in which there is a semblance of the influence of Boccaccio. This influence is clearer in 'Los tres maridos burlados,' which is an admirable adaptation of the 'Decameron.' Instead of a second part of the 'Cigarrales' promised by the author there appeared in 1635 a new collection ('Deleitar aprovechando') of religious stories mixed with 'Autos,' of which 'El Colmenero divino' is one of the best efforts in religious drama. For a long time Téllez devoted himself to this species of composition. In 1620 he dedicated to his friend Lope de Vega 'La Villana de Vallecas' and four years later he stated that he had written well nigh 300 comedies. He excelled in the religio-theological dramas of his period and also in historic dramas, farces and *comédies d'intrigue*. He had a penchant for epigram but was capable of reaching the highest conceptions and frequently sounded tragic depths. Some of his works are equal to Calderon's or Lope's best and in recent years critics have begun to do him full justice. An eloquent proof of his merit is that some of his works have been attributed for centuries to Lope or to Calderon. Such was the case of 'El Burlador de Sevilla y Convidado de Piedra,' an admirable scenic portrayal of the legend of Don Juan, which, although universal as proved by Farinelli, has taken on the character of a purely Spanish legend through this work of Téllez, which has been widely imitated in other literatures. It is his best work and in order of importance may be mentioned 'La prudencia en la mujer'; 'Marta la piadosa'; 'El vergonzoso en Palacio'; 'Don Gil de las calzas verdes'; 'El amor y la amistad,' and 'La villana de Vallecas.' It has been said that his feminine characters are lacking in amiable traits. He was to a great extent free from the stylistic vices of his period and was often imitated by Calderon. It is difficult to comprehend the obscurity into which his works and reputation fell soon after his demise. To-day we possess about 80 of the 400 pieces we know came from his hand. He also wrote historical works including 'La Genealogia del Conde de Sástago' (1640); 'La Cronica' of the Brothers of Charity. (See EL BURLADOR DE SEVILLA). The best editions of his works are those of Augustin Durán, of Hartzenbusch, 'Teatro escogido de Tirso de Molina' (12 vols., 1831–41); by Romanos (1848); and Rivadeneira 'Comedias escogidas de fray Gabriel Téllez.' Consult Cotarelo, C., 'Tirso de Molina: Investigaciónes bio-bibliográficas' (Madrid 1883); Morel-Fatio, A., 'Etudes sur le théatre de Tirso de Molina' (in *Bulletin hispanique* 1900); 'Nueva biblioteca de autores españoles' (Madrid 1906–07); Armesto, 'La leyenda de Don Juan' (ib. 1908).

TELLICHERRY, tĕl-ĭ-chĕr'ĭ, or **TELLICHERRI,** India, a seaport and garrison town in the Malabar district of Madras, 45 miles northwest of Calicut. The main buildings include the castle — now a jail — the North Malabar district court, custom-house, churches and government offices. The entire area, on a picturesque site, covers about five square miles. The principal exports are sandal wood, coffee and cardamons, spices, cocoa and cocoanuts. The factory of the East India Company was founded in 1683. There are missions and other schools; also Brennan College founded in 1862. Pop. 27,883.

TELLURIUM, an element discovered by Mueller von Reichenstein (1782) in a specimen of gold ore from Austria. Klaproth named it from the Latin *tellus,* meaning the earth. Tellurium occurs free, but most commonly in company with gold, silver, lead and bismuth. Native tellurium is found in considerable quantity in Boulder County, Colo. The other important minerals containing tellurium are sylvanite, calaverite, pelzite, hessite and tetradymite. They are found principally in Austria, and in the United States in Colorado and adjacent States.

Tellurium is a silver white metal, atomic weight 127.6, melting point about 453° C. and specific gravity 6.25. It is brittle, not changed by exposure to the air and when heated a little above its melting point it boils and condenses again in the cool portion of the retort as metallic drops. In chemical properties it is very like sulphur. It unites with chlorine readily, forming $TeCl_2$ and $TeCl_4$. The oxides TeO_2 and TeO_3 are analogous, yet differ considerably from SO_2 and SO_3. Tellurious and telluric acids and the salts derived from them are also known. Tellurium forms a compound with hydrogen analogous to H_2S and possessing an even more disagreeable odor.

This element resembles sulphur in imparting very undesirable properties to metals even when present in very small amount. If tellurium and any of its compounds are introduced into the human system they give the breath a very strong and disagreeable garlic-like odor. To obtain the free element the ore is digested first with sulphuric acid; hydrochloric acid is then added in small quantity and the whole treated with sulphurous acid which precipitates the tellurium.

TELPHERAGE, aerial transportation, as in a cable or elevated railway, by electric power, arranged for automatic operation. Both the system and the word «telpherage,» which means «distance carrying,» were introduced by the late Fleeming Jenkin. He recognized the ease with which the electric motor could be adapted to automatic transportation of materials and he devised a system which when put into service gave satisfaction. This consisted of two overhead cables, mounted on stout poles, along which light carriers were hauled by means of one or more electric motors. To transmit current to the motors the cables were cut into sections, adjacent sections of one cable being insulated from each other, but cross-converted with sections of the other cable so as to form two continuous conductors, each lying alternately on the right and on the left of the system. The trains were somewhat longer than the sections of cable so that one end rested on one conductor while the other was on the second, thus completing the electric circuit.

Modern telpherage systems are more elaborate than Jenkins'. As usually constructed, a light steel framework supports a system of light elevated rails, from which buckets or carriers are suspended, hanging on wheels on the rail or rails. Small electric motors are placed on the carriers. The current is transmitted to the motors by means of a small trolley wire erected over the running cable or rail. Sometimes a double trolley system is adopted. The telpher or towing vehicle is usually equipped with two motors. These may be placed on opposite sides of the cable or side by side. The driving wheels are mounted directly on the motor shafts, as gearings are not used. The carrier way is attached to the telpher or to a trailer and is often fitted with a third motor for hoisting the load. When heavy loads are to be carried two supports may be used, each having one or more running wheels. When the system is not automatic it is controlled from one station or an operator is carried with the train. Where the weights to be transported are light, wire cable is employed, and often the cable is supported between the posts by a suspension cable. In any case a rail is used instead of a cable when a corner is to be turned and in running through buildings where the cable construction would be difficult, or where the weight and traffic is sufficient to warrant the cost.

The advantages claimed for the telpherage system are economy in cost of transporting and a capacity for moving large quantities of material with a low cost of construction as compared with a railway. Further, the system may be erected overhead and out of the way. Telpherage systems are now used in industrial works of all kinds for carrying materials in a building as well as outside. The system may also be adapted to other work, such as excavating trenches, canal construction, etc. Consult Clark, Chas. M., 'Telpherage'; 'Transactions American Institute Electrical Engineers' (Vol. XIX, p. 391).

TELUGU, tĕl'oo-goo, or **TELINGA,** a language of India, belonging to the Dravidian group, and spoken by about 20,000,000 of people in Madras, Hyderabad, Mysore, Bombay, Central Provinces, Burma, Berar and other parts. The Telugu are the most numerous branch of the Dravidian race, but are less enterprising than the Tamils, who occupy the country to the south of them. The language is allied in roots to the Tamil language, but differs considerably otherwise. See INDIA; TAMIL.

TEMBULAND, tĕm'boo-lănd, South Africa, a district or dependency of the Cape Colony, in the east of which it is situated, on the Indian Ocean, one of the Transkei districts, adjoining Pondoland and Griqualand East; chief town Umtata. Pop. 232,000 (5,179 Europeans).

TEMENOS, anciently a sacred plot of ground; a piece of land marked off and consecrated to God. Any tract of land allotted to a temple or sanctuary.

TEMESVAR, tĕm'ĕsh-văr, Hungary, on the Bega Canal, 75 miles northeast of Belgrade. It comprises a citadel and suburbs — four in number. Noteworthy are the castle, cathedral, synagogue, bishop's residence and town-house. The manufactures include woolen goods, oil, paper, tobacco, leather, etc., and there are grain-mills, distilleries, etc. The fortress has sustained many sieges; memorable is that of 1849, when it was invested and bombarded by the insurgents. Pop. about 72,500.

TEMPE, tĕm'pē, **Vale of**, Greece, in Thessaly, a beautiful valley on the Peneus, flanked by Olympus at the north and Mount Ossa at the south. It has been immortalized by the classical poets.

TEMPERA. See DISTEMPER; MURAL PAINTING; PAINTING, TECHNIQUE OF.

TEMPERAMENT, *in music*, the system or principle of tuning voices or instruments in accord with the rule of fixed tones, universally adopted since the middle of the 19th century and first advocated by J. Sebastian Bach (q.v.) early in the 18th century. In the system of equal or even temperament, the standard interval is the mean semitone, that is the 12th part of an octave. This neutralizes the «wolf» or harsh discords of uneven temperament which otherwise exist, among all the tones of voice or instrument, so that the only exactly true intervals become octaves and the number of key scales 12, the relative pitch of the tones of the ideal scale being fixed with mathematical precision. The voice or instrument using the intervals of such a scale is said to be modulated or tuned in pure or just temperament. No further adjustment is required if these tones only are used. Modulation into another key, however, requires that some other tone than the original one shall be the keynote and one or more passing notes are necessary to arrive at the key desired (see MODULATION. For the superseded system of tuning see MEANTONE or MESOTONE TEMPERAMENT; MODE; also WELL-TEMPERED CLAVIER). Consult Groves, 'Dictionary of Music and Musicians' (Vol. V, pp. 53–65, New York 1911).

TEMPERANCE. This word has long been used to characterize the movement for the temperate use of intoxicants and for the activities of societies of abstainers and those favoring a restriction of the use and sale of alcoholic beverages. The records of all the early peoples of the world contain references to the evils of intoxication. The Buddhists, Taoists and Confucians taught temperance. «Look not thou upon the wine when it is red . . . At the last it biteth like a serpent,— and stingeth like an adder.» (Prov. xxiii, 31–32). The ancient philosophers and founders of the great world religions neither taught nor practised total abstinence and these conditions furnished the religious reasons for advocating «temperance» rather than «total abstinence» from intoxicants. With the development of the manufacture of spirituous or distilled liquors, containing a much larger percentage of alcohol than those of natural fermentation, the evils of intoxication multiplied and temperance sentiment developed and increased. At first the agitation against liquor was sporadic, yet there was a pronounced sentiment developed in both Europe and America in the 18th century. In 1743 Lord Lonsdale made a speech in the English House of Lords, urging the necessity for a temperance reform. In 1760 Smollett called the attention of the English people to the signs «Drunk for 1d» and «Dead drunk for 2d.» He made an urgent appeal for improvement in the condition of the low alehouses. Yet it was not until 1829 that record is found of a temperance society in Great Britain, at New Ross, County Wexford, Ireland. In 1830 several temperance societies came into being in English cities and the British and Foreign Temperance Society was founded in 1831. It lasted until 1850, but in the meantime its work was taken up by others. Father Theobald Mathew (q.v.), of Cork, Ireland, began his campaign for temperance about 1838 and within three years he gathered about him more than 4,000,000 followers. The best evidence of the thoroughness of his work is that the consumption of liquors in Ireland fell off one-half during the period of his activity. In 1843 he was called to England and in 1850 to America, where he founded the numerous Father Mathew Total Abstinence Societies.

There had been considerable temperance agitation in the States before Father Mathew's arrival. The Washingtonian movement started in Baltimore in 1840 and John B. Gough (q.v.) had begun his wonderful talks for temperance. The influence of Mathew and Gough was evident in the formation of the Independent Order of Good Templars, founded in 1851 in Utica, and spreading rapidly all over the United States and to foreign countries. A woman's crusade for temperance started about 1870 and crystallized in the National Woman's Christian Temperance Union, founded in Cleveland in 1874 and now having 12,000 local unions throughout the United States. Frances E. Willard (q.v.) who was prominent in the work, founded the world's Woman's Christian Temperance Union in 1883, and it has become the largest and most influential movement for temperance and prohibition. It can scarcely be said, however, that the United States has led in temperance societies. Great Britain and her colonies far exceeded America in the number of societies organized, doubtless partly because her territory is so widely distributed. A list of prominent temperance societies in 1905 included United Kingdom 62, Germany 12, Australia 11, Switzerland 11, United States 10, Austria-Hungary 8, Holland 6, Sweden 6, Denmark 5, France 4, Belgium 2, etc.

Temperance agitation has influenced legislation for 75 years, but still the use of intoxicants has gone on with little interference except locally. As a result temperance agitators have gradually come out stronger and stronger for prohibition of both the manufacture and sale of intoxicants and the temperance movement has merged into the Prohibition movement, though in its inception Prohibition was the work of the more radical reformers. See PROHIBITION.

Temperance Legislation.— Legislation against the liquor evil in America dates from 1642, when the colony of Maryland passed a law making drunkenness a misdemeanor, punishable by a fine of 100 pounds of tobacco. As sentiment against intoxication developed the license system was adopted, as a temperance measure, being popular in communities also because it furnished a revenue for the local government. Soon the license system won the approval of the liquor sellers, for it stopped competition in their business, resulted in uniform prices and, therefore, contributed to money-making. Though advanced and introduced by advocates of temperance, the license system was fostered and grew directly through the efforts of the liquor-sellers. Temperance workers then began to advocate no license and a vast amount of legislation developed in the different States over licenses, their revocation or suspension, at the will of the people. Restrictive legislation took the form of local option laws and after the War of 1861–65 the local struggles at the polls of half the cities and towns in the country for years were centred mainly about the question of license or no-license. The establishing of local option in a community had a tendency to drive the lovers of liquor to the neighboring towns where there was license; thus the temperance towns lost their license fees, and saw their bibulous citizens going to other places to drink and also to trade. Often the result was that the financial pressure caused a return to license. There was great wavering between license and no-license almost all over the country. The first State to recognize that this irregular system could be overcome only by the States acting as a unit was Maine, which in 1851, under the influence of the Gough and Mathew movements, adopted State local option, and as a State continued to refuse to license the liquor traffic. Kansas and North and South Dakota followed, and in 1881 Maine placed the prohibitory clause in her constitution and ended the agitation for a return to licensed liquor-selling.

But in other States the contests at the polls continued regularly. Indiana was the first State to pass a local option law in 1832, and several other States had followed by 1850. By 1900 one-third of the country was under local option, and in 1911 local option existed by enactment in 33 of the States. Between 1890 and 1910 appears to have been the most active years with State legislatures in passing laws to restrict and regulate the liquor traffic. Most of the States passed Sunday closing laws, though allowing the hotels to sell liquor to their customers with meals. There was legislation permitting wives and children of drunkards to bring civil suits against any selling liquor to their provider. There were laws against the locating of saloons within so many feet of churches, schools or polling places. But these laws were largely honored in the breach. Sunday closing never was effective in the large cities, except spasmodically, as some mayor or chief of police became active. Public sentiment condoned the open backdoor as a rule, and it was and is (1918) the common practice with saloons in large cities. In country liquor shops the selling on Sunday is confined to those who are known personally to the proprietor to be safe.

The effort to improve conditions by high license was equally ineffective. When this was proposed the argument was that nine-tenths of the saloons would go out of business, and that the evil would be confined to those who had the liquor habit and who would drink anyway. This proved to be sophistry. The communities got more money by the high license system and it caused the liquor forces to become more active in politics, until in very many cities and towns a man could rarely be chosen to public office unless he was acceptable to the liquor interests.

A perpetual difficulty with obtaining temperance by all these various methods of legislation was that they failed to strike at the manufacture or the transportation of liquor. Though Maine prohibited liquor selling for years, the agents of the United States government obtained large sums in revenue from liquor that went into Maine, carried there with no attempt to stop it, by the express companies. And this form of nullifying the no-license law in local option communities was notoriously common. The no-license law only stopped the sale of liquor as a beverage over the counter; the individual still had a right to buy it by the barrel, and have it expressed to his home, and give it to his friends, and the best hotels were permitted to place it on their tables as part of the food supplied. The fact that some thousands of statutes in the different States were useless in attaining the end of temperance at length became apparent to the most obtuse. The manufacture and consumption of liquors in the United States had a slow and steady increase all through these years of antagonistic legislation, up to 1913, since which date there has been a very slight per capita reduction. The per capita consumption of malt liquors during the past 100 years in the United States slowly and steadily increased up to 1907, after which it fell off a small fraction. The per capita consumption of distilled liquors had a slight but steady decrease from 1865 to 1896. Thereafter it increased until 1907, since which it has been variable. But this trifling decrease in distilled liquors was evidently but a change to malt liquors, for the latter grew as the former reduced, and the whole calculation is based on per capita use, the volume of liquors made and sold being always on the increase up to 1907, and the falling off then appeared to be due more to financial stringency than to moral suasion or obedience to law. All these experiences with legislation that accomplished little or nothing taught the public that they were being fooled, and that the powerful financial interests in the liquor trade were always able to guide legislation or block it, or prevent its enforcement, so that in the end the trade was unharmed. As a result agitation for temperance legislation practically ceased, and those who opposed the liquor traffic worked for Prohibition (q.v.).

TEMPERANCE, Sons of, or THE ORDER OF THE SONS OF TEMPERANCE, was organized in the city of New York, 29 Sept. 1842. It is composed of subordinate, grand and national divisions. It has four national divisions — one for North America, one for Great Britain and Ireland and two for Australia. In the course of its existence it has had nearly 4,000,000 members on its rolls. Its fundamental and inalienable principle is total abstinence from all intoxicating liquors and beverages.

TEMPERING, the art of imparting to metals, by means of heat treatment, a definite degree of hardness. The term is now applied almost exclusively to certain kinds of steel, which are used in the manufacture of tools. It is said that the ancients could harden and temper copper; but this art, if it ever really existed, is now lost. The effects of thermal changes upon steel vary greatly with the quality of the steel and with the exact nature of the treatment. It is necessary to distinguish clearly between «annealing,» «hardening» and «tempering.» Any steel (except those varieties that are alloyed with silicon, tungsten and certain other elements) may be annealed, but it is essential that the steel shall contain a certain amount of carbon, in order that it may be capable of being hardened and tempered. If steel is raised to a red heat and is then allowed to cool very slowly, it becomes relatively soft, so that it can be filed and turned in a lathe. This process is called «annealing,» and it has usually been held that the slowness of the cooling is the essential thing in the softening process. There is excellent reason for believing, however, that the exact temperature to which the steel is exposed before it is cooled has a much greater influence than the rapidity of the cooling. It has been shown, for example, by the researches of Brinel, Tschernoff, Le Chatelier, Heyn, Ridsdale, Stead and others that steel which has acquired a dangerously crystalline character from annealing for a long time at too low a temperature in a slightly oxidizing atmosphere, or from long continued heating at high temperatures, may have its original structure and properties restored by the simple artifice of heating it to a certain critical temperature (which is about 1,600° F.), and then allowing it to cool; the rate of cooling, in this case, being a matter of comparative unimportance. Steels may sometimes be had which do not need special treatment to render them fit for use in certain classes of tools; the tool being ready for use after it has been forged and allowed to cool by natural exposure to the air. In general, however, a tool steel must receive special treatment in order to fit it for the work in hand; this treatment being given after the tool has been forged to shape. The process of tempering then consists of two steps, the first of which consists in imparting to the cutting edge of the tool a degree of hardness that is too great for the work for which the tool is to be used, while the second step consists in reducing (or «tempering») this hardness, until it attains a value that experience has shown to be satisfactory. The tempering of an ordinary tool may be described as follows: The finished tool is heated to a bright red, care being taken to have the heat extend back some distance from the cutting edge. The cutting edge of the tool is then immersed in water to a slight depth and kept there until it has cooled sufficiently to remain wet when withdrawn from the water. By this means the steel is rendered exceedingly hard throughout the chilled part; that is, in the vicinity of the cutting edge. If it were used in this condition, however, the edge would be too brittle and would be likely to break in service. To reduce the hardness to the proper value, the tool, immediately after being withdrawn from the water, is brightened up near the cutting edge with a piece of emery cloth, or in some similar manner, and the cleaned area is then watched while the heat from the unquenched part spreads toward the cutting edge. The oxidization of the steel, as the edge becomes hotter and hotter from conduction, causes a play of color to become visible, which serves as an index of the temperature. These colors run from the hot portion of the tool toward the quenched cutting edge. In the order in which they proceed, they may be described as pale yellow, straw yellow, brownish yellow, light purple, dark purple and blue. When the proper color reaches the cutting edge, the whole piece is again quenched, and the «tempering» is complete. The colors that are used for different implements are as indicated below:

Very pale yellow (about 430° F.): Steel-engraving tools, turning tools, hammer faces, planer tools, wood-engraving tools.

Straw yellow (about 460° F.): Dies, taps, drills, punches, reamers.

Brown yellow (about 500° F.): Gouges, plane irons, twist drills, cooper tools, wood-boring cutters.

Light purple (about 530° F.): Augurs, surgical instruments, cold chisels, edging cutters.

Dark purple (about 550° F.): Axes, gimlets, needles, hack-saws, screwdrivers, springs, wood saws.

Some tools are of such a shape that they cannot be tempered in the manner here described, but must have their temper «drawn» to the desired color by reheating the piece between hot iron plates, or in a hot iron ring. Springs are often tempered by a different method, known as «oil tempering.» In carrying out this method, the piece is first hardened by heating to a bright red heat and then quenching by plunging the whole piece in water or in oil. The article to be tempered is then wetted with oil and gradually and uniformly heated until the oil upon it blazes up, when the piece is again quenched in the oil. This process of heating to the ignition point of the oil and then quenching is repeated until it has been performed three times, after which the piece is said to be «oil tempered,» and is ready for use.

In the early days of steel-working in the United States, it was common to import water in casks from Sheffield, England, for hardening and tempering purposes, as it was believed that there is some special virtue in the water that had been used for so long, and with such eminent success, in that city. There was probably little or no foundation for this belief, and yet it is known that substances that may be in solution in the water that is used for quenching often have an important influence upon the product. Many artisans dissolve salt or cyanide of potassium in the water that they use for this purpose, and there is considerable ground for the belief that such dissolved substances do exert an influence upon the character of the product, which is out of all apparent proportion to the strength of the solutions containing them. In particular, it may be noted that there is a deeply-rooted belief among blacksmiths and other artisans who work with metals that a piece of steel cannot be hardened by heating it and then quenching it in water that contains soap, even in small amounts.

The art of tempering cannot be adequately presented in a short article, and those who are skilled at it maintain (probably quite justifiably) that the only way to learn it is by actual experience in the shop. Different steels may require radically different treatment, and special implements (razors, for example) may call for years of study before they can be tempered satisfactorily.

ALLAN D. RISTEEN.

TEMPEST, The. Although certain internal evidence, notably the verse-test, has caused most scholars to believe that ‹The Winter's Tale› was the last of Shakespeare's plays, there will always be reason in thinking that ‹The Tempest› (written in 1610 or 1611) best represents the final mood of Shakespeare as he turned from the writing of his plays to the last years of his life in Stratford. It is certainly one of the group of romantic comedies which Shakespeare wrote after the completion of his tragedies; and in the character of Prospero we are warranted in seeing an adumbration of Shakespeare's personality as he looked out upon the world from the heights of his later years. He, like Prospero, broke his wand and buried his book deeper than did ever plummet sound. After all, while life may be tragical as presented in the series of plays from ‹Hamlet› to ‹Timon of Athens,› it is also full of sunshine and humor and the forgiveness of enemies and the reconciliation of the forces of good and evil. ‹The Tempest› is such a representation of life. While some of the scenes of the play suggest definitely Milan and Naples, Tunis and the intervening Mediterranean Sea, the enchanted island upon which Prospero lived is on none other than the uncharted deep that voyagers were bringing within the compass of man's imagination. In the grotesque figure of Caliban, the magic of Prospero and the spirit-like world of Ariel, there is the atmosphere of the strange world that stood out in definite contrast with the fixed limits of the European world. More particularly, Shakespeare was indebted to the story of a fleet of ships that had set out from England in 1609, was wrecked in the Bermudas a few weeks after and finally reached the newly-established colony in Virginia. While, as has been suggested, he might have heard from returning seamen stories of this wreck and of the strange happenings in the New World, he was especially indebted to Silvester Jourdan's ‹The Discovery of the Bermudas,› published in 1610. Professor Alden has recently made good his contention that the real source for the description of the storm and for the incidents that take place upon the strange island is found in a letter written by William Strachey, dated 15 July 1610, and which, though not published until 1625, was, from contemporary evidence, seen by Shakespeare. The parallelisms between the play and the letter are most striking and certainly tend to show that the author's indebtedness to contemporary sources was far greater than has been generally supposed. The ideal commonwealth suggested by Gonzalo, while based upon Florio's translation of Montaigne's essays, a new edition of which was published in 1610, bears a striking resemblance to conditions in the Virginia colony as portrayed in the letter.

However far one may go in the acceptance of these parallels, the play is none the less the creation of Shakespeare's genius. While it is lacking in the perfect technique of some of his plays, and especially in the closeness of dramatic structure, it is a great poem and it lends itself to allegorical interpretation as do few of the plays. Caliban is a monumental representation of a primitive type of humanity, rejoicing in unrestricted freedom and in the saturnalia of license. Ariel, more than Puck, represents the spiritual forces of nature under the domination of superior wisdom and for the service of man. Prospero, both in his magical art and in his intellectual and spiritual greatness, is an anticipation of the triumphant victory of man at his best over all the forces of the world. There is no greater utterance of Shakespeare than the words in which Prospero, looking out from the serene heights which he has reached, expresses the ultimate truth about man and the universe:

> "We are such stuff
> As dreams are made on, and our little life
> Is rounded with a sleep."

EDWIN MIMS.

TEMPLAR, Knights. See MASONIC FRATERNITY, THE.

TEMPLE, Frederick, English prelate, archbishop of Canterbury: b. Santa Maura, Ionian Islands, 30 Nov. 1821; d. London, 23 Dec. 1902. He was the son of an English army officer who died while he was a child, and under his mother's care was well educated in youth, so that he obtained a «double first» at Oxford and was elected Fellow and tutor of his college. After his ordination in 1846 he took charge of Kneller Hall, Twickenham, and from 1848 to 1858 was school inspector. In the latter year he was made headmaster of Rugby and became one of the most powerful and influential successors of Arnold. The publication of ‹Essays and Reviews,› in which series Temple led off with ‹The Education of the

World,' roused a storm of acrimonious controversy, but did not shake confidence in the headmaster of Rugby, who was appointed bishop of Exeter in 1869, was translated to London in 1885 and succeeded Archbishop Benson in 1896. Equally as schoolmaster and as bishop he was a strict disciplinarian, an untiring worker, a blunt, just and sincere man whose plainness of address did not obscure the massive learning with which his mind was stored. The great controversial storms of the century had spent their fury in the English Church before he reached the primacy, but his incumbency was not uneventful. The Tractarian movement was in its last phase of ritualism, and Temple handled ritualists with firmness and moderation. He took part in the queen's diamond jubilee (1897) and in 1902 placed the crown on the head of her successor. His writings are 'Sermons in Rugby Chapel' and Bampton Lectures for 1884 on 'The Relations between Religion and Science,' of which it may be said that they were up to the standard set by previous lecturers and were not unworthy of the future primate of All England. He died in harness, never recovering from the effort he made in a strong appeal in the House of Lords uttered in favor of the public education bill.

TEMPLE, Oliver Perry, American lawyer and author: b. Green County, Tenn., 27 Jan. 1820. He was graduated from Washington College, Tenn., in 1844, and admitted to the bar in 1846. He was a Union leader in East Tennessee during the Civil War; was a chancellor of Tennessee, 1866–78, and retired from the bar in 1881. His publications include 'The Covenanter,' 'The Cavalier and the Puritan' (1897); 'Union Leaders of East Tennessee' (1903), etc.

TEMPLE, Richard Carnac, English civil servant and antiquary: b. Allahabad, India, 15 Oct. 1850. He was educated at Cambridge University. He served in the Burma War 1887–89 and received a medal for bravery. From 1887–93 he was engaged by the Indian government to raise and fit out volunteer regiments. He has published 'Wide Awake Stories' (1884); 'Legends of the Panjab' (1883–90), etc., and is a member of philological and other learned societies.

TEMPLE, Sir William, English statesman: b. London, 1628; d. Moor Park, Surrey, 27 Jan. 1699. He was educated at Cambridge, spent six years on the Continent and returning in 1654, and not choosing to accept any office under Cromwell, occupied himself in the study of history and philosophy. On the Restoration he was chosen a member of the Irish convention, and in 1661 was returned for the county of Carlow. The following year he was nominated one of the commissioners from the Irish Parliament to the king, and removed to London. On the breaking out of the Dutch War, he was employed in a secret mission to the bishop of Münster which he executed so much to the satisfaction of the ministers that in the following year he was appointed resident at Brussels, and received a baronetcy. With De Witt he concluded the treaty between England, Holland and Sweden (February 1668), with a view to oblige France to restore her conquests in the Netherlands. He also attended, as Ambassador Extraordinary, when peace was concluded between France and Spain at Aix-la-Chapelle, and subsequently residing at The Hague as Ambassador, enjoyed the friendship of De Witt, and also of the Prince of Orange, afterward William III. A change of politics led to the recall of Temple in 1671, who, refusing to assist in the intended breach with Holland, retired from public business, and employed himself in writing his 'Observations on the United Provinces,' and part of his 'Miscellanies.' In 1674 Temple was again Ambassador to the States-General, in order to negotiate a general pacification. Previously to its termination in the Treaty of Nimeguen (in 1678), he was instrumental in promoting the marriage of the Prince of Orange with Mary, eldest daughter of the Duke of York, which took place in 1677. In 1679 he was recalled from The Hague, and shortly afterward was elected to represent the University of Cambridge in Parliament. In 1681 he retired from public life altogether. He was on friendly terms with William III who occasionally visited him. (For his relations with Swift see SWIFT, JONATHAN). His 'Memoirs' are important as regards the history of the times, as are likewise his 'Letters,' published by Swift after his death. His 'Miscellanies' consist of essays on various subjects: 'Gardening,' 'The Cure of the Gout,' 'Ancient and Modern Learning' (which provoked much controversy at the time), 'Health and Long Life,' 'Different Conditions of Life and Fortune,' 'Introduction to the History of England,' 'Poems and Translations,' etc. Consult Courtenay, 'Life of Temple' (1836); Macaulay's 'Essay' and Forster, 'Life of Swift' (Vol. I, 1875).

TEMPLE, Tex., city in Bell County, on the Gulf, Colorado and Santa Fé and the Missouri, Kansas and Texas railroads, about 220 miles northwest of Galveston, and 35 miles southwest of Waco. It was founded in 1882 by the Gulf, Colorado and Santa Fé Railroad, and was chartered as a city the same year. It is in an agricultural and stock-raising region and has considerable manufacturing interests. The chief manufacturing establishments are agricultural-implement works, cottonseed-oil mills and cotton compresses, flour mills, chewing gum and candy factory and lumber mills. The city has handsome churches, public and parish schools, Saint Mary's Academy, two kindergartens, a business college, three large hospitals and a public library. The four banks have a combined capital of $580,000. Pop. 10,993.

TEMPLE, London, England, a district of the city lying between Fleet street and the Thames, and divided by Middle Temple Lane into the Inner and the Middle Temple, belonging to separate societies (see INNS OF COURT), each with its hall, library and gardens. The name is derived from the Knights Templars, who had their headquarters in England here. The two temples are separated by a wall from the rest of the city, and have entrance gates which are closed at night. The district is occupied, with few exceptions, exclusively by barristers and solicitors. In former times the members of the Temple were famous for the masques, revels and banquets which they gave in their halls. To these entertainments there are many allusions in the old poets; kings attended them, the benchers joined in them and directed the students to dance. Among famous members of the Temple have been Beaumont, Sir Walter Raleigh, John Ford, Wycherley, Congreve, Cowper, Blackstone, Sheridan, Coke, Littleton, Clarendon, Somers and Eldon. Goldsmith and Johnson had chambers here, and here Charles Lamb was born and passed the first seven years of his life.

TEMPLE, a name applied in religious history particularly to the temple built by Solomon at Jerusalem as a House of the Lord, and to the temples which succeeded it, more especially the magnificent structure, erected by Herod the Great, which is often mentioned in the New Testament. Solomon's Temple was built with the aid of an architect and skilled workmen from Phœnicia. The temple was an oblong stone building, 60 cubits in length, 20 in width and 30 in height. On three sides were corridors, rising above each other to the height of three stories, and containing rooms in which were preserved the holy utensils and treasures. The fourth or front side was open, and was ornamented with a portico, 10 cubits in width, supported by two brazen pillars, Jachin and Boaz (stability and strength). The interior was divided into the most holy place or oracle, 20 cubits long, which contained the ark of the covenant, and was separated by a curtain or veil from the sanctuary or holy place, in which were the golden candlesticks, the table of the shew-bread, and the altar of incense. The walls of both apartments and the roof and ceiling of the most holy place were overlaid with wood work, skilfully carved. None but the high-priest was permitted to enter the latter, and only the priests devoted to the temple service the former. The temple was surrounded by an inner court, which contained the altar of burnt-offering, the brazen sea and lavers, and such instruments and utensils as were used in the sacrifices, which, as well as the prayers, were offered here. Colonnades, with brazen gates, separated this court of the priests from the outer court, which was likewise surrounded by a wall. This temple was destroyed about 586 B.C. by the Assyrians, and after the return from the Babylonish captivity some 70 years later, a second temple of the same form, but much inferior in splendor, was erected. Herod the Great rebuilt it, beginning the work about 20 B.C., of a larger size, surrounding it with four courts, rising above each other like terraces. This being the temple of the time of Christ possesses great interest. The lower court was 500 cubits square, on three sides surrounded by a double, and on the fourth by a triple row of columns and was called the court of the Gentiles, because individuals of all nations were admitted into it indiscriminately. A high wall separated the court of the women, 135 cubits square, in which the Jewish females assembled to perform their devotions, from the court of the Gentiles. From the court of the women 15 steps led to the court of the temple, which was enclosed by a colonnade, and divided by trellis-work into the court of the Jewish men and the court of the priests. In the middle of this enclosure stood the temple, of white marble richly gilt, 100 cubits long and wide, and 60 cubits high, with a porch 100 cubits wide, and three galleries like the first temple, which it resembled in the interior, except that the most holy place was empty, and the height of Herod's temple was double the height of Solomon's. Rooms appropriated for different purposes filled the upper story above the roof of the inner temple. This edifice was destroyed by the Romans in 70 A.D., and for many centuries the long-consecrated height has been occupied by the Mosque of Omar.

The Egyptians, Greeks, Romans, Persians, and other ancient nations had temples for the worship of their gods, and the Mexicans and Peruvians, at the time of the arrival of the Spaniards in the New World, had splendid temples. On the sacrificial platforms of Aztec temples thousands of victims perished annually. The Greek and Roman temples were, as a rule, models of architectural grandeur and beauty. The word «temple» is sometimes, but not often, applied to Christian places of worship as a special designation, although frequently used in a figurative sense. The Mormons designate as «The Temple,» the large structure in which they worship at Salt Lake City. Consult Fergusson, James, 'The Temple of the Jews' (1878); Smith, G. A., 'Jerusalem' (1908). See ARCHITECTURE.

TEMPLE, Order of the. See ORDERS, ROYAL.

TEMPLE BAR, London, England, an arched gateway which formerly stood between Fleet street and the Strand, and divided the city from the liberty of Westminster. (See LONDON). It was a structure of the Corinthian order, designed by Sir C. Wren, and built in 1670 of Portland stone. Over the gateway, on the east side, were statues of Queen Elizabeth and James I; and on the west side, of Charles I and II. The heads of persons executed for high treason were formerly exhibited on this gate. Here, also, on particular occasions, the corporation of London received the royal family, the heralds' proclamations, or any distinguished visitors. When the sovereign came in state the lord-mayor here delivered to him the sword of state, which was returned, and after this he rode bareheaded, immediately in front of the royal procession. As the gate seriously obstructed a crowded thoroughfare, it was removed in 1878, its site now being marked by the heraldic monster, a «griffin.» The gate has been re-erected at Theobald's Park, Cheshunt.

TEMPLE UNIVERSITY, an institution of higher learning founded at Philadelphia in 1884 by Russell H. Conwell, pastor of the Baptist Temple. It was chartered by the State in 1888, and empowered to grant degrees in 1891, its name being changed from Temple College to Temple University in 1907. It was designed to offer instruction to young men whose occupations kept them busy during the day, and at first only evening instruction was offered; in 1891 a day school also was added. There are 18 departments with a range from kindergarten and academic to the highest university courses. Instruction is arranged in morning, afternoon and evening classes in all branches except medicine and dentistry, in which there are only day classes. The university is non-sectarian, but is of a strongly religious atmosphere, and accomplishes a notable work in assisting those who could not otherwise obtain high educational advantages. In 1918 there were 321 instructors; 2,192 students attending and 306 with the colors.

TEMPO (time), *in music*, the relative rate of movement or degree of quickness with which a piece of music is to be executed. The degrees of time are indicated by certain words such as *lento* (slow), *adagio* or *largo* (leisurely) *andante* (walking pace), *allegro* (gay or quick), *presto* (rapid), *prestissimo* (very rapid), etc. *A tempo* is the proper time. (See MUSIC). The word is also used in chess to indicate the period of a move, especially when the move is wasted.

TEMPORAL BONE See ANATOMY; SKULL.

TEMPORAL POWER (OF THE POPE). By this expression, in its generally received signification, is understood the sovereign civil rule which was exercised by the popes over the states of the Church with varying vicissitudes from the middle of the 8th century down to the year 1870, when the last remnant of the papal states was annexed to the United Kingdom of Italy.

The formal establishment of the temporal power dates from the year 754, when Pepin, king of the Franks, bestowed upon Pope Stephen II (who had sought his aid against the oppression of the Lombards) independent sovereignty over some 20 cities, thus constituting what was henceforth known as the state or patrimony of Saint Peter. Though apparently a new departure — one possibly unlooked for on the part of the Pope himself — this addition of a temporal to the spiritual rule of the bishop of Rome was in reality but the natural outcome of pre-existing civil and political conditions. Among these may be mentioned the fact that the Roman Church was already in possession of numerous and extensive landed estates or patrimonies situated for the most part within the bounds of the Italian peninsula, and which were controlled or administered by the popes through their agents.

This state of things had gradually developed from very early beginnings, for we find that even during the period of the persecutions, the local church of Rome (whether organized legally as a burial society, or simply as a body corporate, holding property under the general laws of the empire) possessed not only the great cemeteries now known as the Catacombs, but also other property, as is clear from the edict of Milan. By a law of 321, the Emperor Constantine granted to all persons capable of making a will the right to bequeath property to the Church, and he himself gave an example of generosity in this respect by endowing munificently the various basilicas of Rome. Similar bequests in one form or another were made by wealthy Christians throughout the empire, one of the principal uses to which the property thus acquired was applied being to relieve the distress occasioned by the depredations of the barbarians who began to overrun Italy from the beginning of the 5th century. In this way the Roman Church had become very wealthy, and the popes were already great landed proprietors, owning vast estates in various parts of Italy and elsewhere long before any form of political papal sovereignty had been thought of. Meanwhile, through the favorable legislation of the Christian emperors, the political rôle of the popes and of bishops in general, was assuming an ever-growing importance. The bishop of a city was not only the official protector of the poor, of prisoners and of slaves; he had also in virtue of his office a voice concerning various points of civic administration. Even in provincial affairs he enjoyed important rights and privileges. Thus, among other things, we find that appeal could be made from the decision of an imperial magistrate to the tribunal of the bishop. Such being the political status of bishops generally, it is easy to understand that the powers granted to and exercised by the Roman pontiffs were still more extensive. To them, in particular, recourse was had against the exactions of the rapacious Byzantine governors who ruled in the different Italian provinces, and in this connection, as well as in other ways, the vigilant protection of the popes proved beneficial to the people. It must be remembered that during this period the civil and political situation throughout the peninsula was in a condition bordering on the chaotic. The chronic state of unrest and insecurity which resulted from the incursions of the barbarians and the deplorable inefficiency of the imperial administration, made the interference of the popes in civil matters a real practical necessity. Theirs was the only authority that commanded general respect, and the common weal demanded that they should look after the material as well as the spiritual interests of their flock. That such was the true condition of affairs is amply shown forth in the papal correspondence of the time, especially in the letters of Gregory the Great (590–604). It is also worth noting that though they had ever-growing reasons to be dissatisfied with Byzantine rule, the popes (even those who succeeded Gregory) continued to remain faithful to the idea of a world-wide Christian empire, and exercised their influence to maintain in Italy its authority and prestige. But, as is well known, many of the emperors of that period were more preoccupied with theology than with matters pertaining to civil administration, and their repeated attempts to impose upon the bishops of the West subtle formulas of orthodoxy led to frequent conflicts, in some of which popes were violently dragged away to prison or death. Thus Silverius and Vigilius, Pelagius and Martin became the victims of imperial tyranny. On the refusal of Sergius I to accept the decrees of the Emperor Justinian II the latter commanded the protospatharius Zachary to arrest the Pope and bring him a prisoner to Constantinople, but the public spirit in Italy was already in revolt against this arrogant, high-handed policy, and the army interfered to prevent the execution of the imperial mandate. Again, in 727, Leo the Isaurian sent his edict against the use of images to Pope Gregory II with orders for his deposition in case he should refuse to comply. Gregory responded by denouncing the edict and excommunicating the exarch; again the soldiers arose in his defense, and the efforts of the imperial officers to carry out their instructions cost them their lives. In 733 the emperor confiscated all the Church's estates in Sicily, Bruttium, Lucania, Calabria and Naples; others were confiscated by the Lombards, and no security remained even for the inhabitants of Rome. The empire was unable to defend its subjects — worse than that, it even oppressed and plundered them. The only refuge left to the Romans and their spiritual as well as actually temporal head was to seek the aid of the friendly king of the Franks. It is not clear whether Pope Stephen II in taking this step had already in view the establishment of a civil principality under his own rule or not, but be that as it may, just then the relations between the papacy and the emperor were further strained by the publication of a fresh edict against the use of images emanating from a synod of Constantinople. A continuation of the old régime seemed no longer possible, the army of Pepin arrived in Italy in the summer of 754, and the independent state of Saint Peter was established, with the Pope as its civil ruler, in the same year. In view of the circumstances, it may be truly said that this distinction was bestowed upon the bishop of Rome in recognition of a twofold prerogative, namely, his prestige as head of the Church and defender of orthodoxy against Eastern aggression, and his character of national benefactor.

The papal dominion as constituted by the grant of Pepin comprised the cities of Ravenna, Rimini, Pesaro, Fano, Casena, Forli Commachio and 15 other towns. In 1053 the duchy of Benevento was annexed, and between that period and the end of the 13th century the authority of the Roman See was acknowledged by many other free towns in Italy. In 1278 the Emperor Rudolf I confirmed the acquisitions made thus far, defined the boundaries of the papal states, and recognized the Pope's exclusive authority over them by absolving the inhabitants from their oath of allegiance to the empire. The papal dominion then included Perugia, Bologna, Bertinoro, the duchy of Spoleto, the exarchy of Ravenna and the marche of Ancona, but many of the towns were more or less independent. The Romagna was annexed at the end of the 15th century. Under Alexander VI and Julius II were added Faenza, Parma, Placentia and Reggio, and the papal states received their final additions in the 17th century, namely, Urbino, Ronciglione and the duchy of Castro. In 1797 the Romagna was seized by Napoleon and incorporated into the Cisalpine Republic. The following year Rome itself was taken by the French and the papal states were erected into the Roman Republic. Pius VII regained possession of his states in 1800, but they were soon retaken by the French, and finally (1809) incorporated with France, Rome being reckoned the second city of the empire. After the downfall of Napoleon (1814) Pius VII returned to Rome and was formally reinstated in his office of temporal ruler by the treaty of Vienna, mainly through the friendly support of the non-Catholic powers Russia, Prussia and England. In 1830 a rebellion broke out in Ancona and Bologna, the reason alleged by the insurgents being that the clerical rule in the provinces contrasted too unfavorably with the preceding French administration. This revolt was quelled through the aid of Austria, but another uprising occurred soon after, and the Austrians took occasion thereby to occupy the northern legations, while at the same time the French placed a garrison in Ancona. Occasional minor disturbances occurred between these events and 1848, when Pius IX, on account of an insurrection, was obliged to flee to Gaeta and Rome was declared a republic. The Pope was again restored to power through the armed intervention of France, Austria, Spain and Naples, and the Austrians occupied the northern legations or Romagna on his behalf until 1859, when their army was withdrawn. Soon after the province repudiated its allegiance to the Pope and its annexation to Sardinia was proclaimed. The French still continued to hold Rome in subjection to papal authority and Pius IX, with a view to withstand any further encroachments upon his dominions, raised an army, which was placed under the leadership of the able French general, Lamoricière. In the meantime Garibaldi and his followers, whose aim was the political unification of the Italian states under the rule of Victor Emmanuel, were conducting a successful campaign in Sicily and Naples. The news of this caused an outbreak in Urbino and the Marches in favor of Victor Emmanuel. The Sardinian troops came to the aid of the insurgents and after two encounters with the troops under Lamoricière compelled the latter to surrender with his whole army after a week's siege in Ancona (1860). The revolted provinces of Umbria, Urbino and the Marches, as well as the isolated provinces of Benevento and Pontecorvo, situated within the kingdom of Naples, were immediately annexed to Sardinia. Finally, on 20 Dec. 1870, the French troops having been withdrawn on account of the war with Prussia, Rome was entered practically without resistance by the troops of Victor Emmanuel, and the last vestige of temporal power disappeared. Victor Emmanuel having been proclaimed king over united Italy, took up his residence in the papal palace of the Quirinal and Pius IX withdrew to a life of seclusion (in the Vatican). considering himself as a prisoner unable to leave his retreat without compromising his dignity as head of the Church, or even giving occasion to riots and bloodshed. He never ceased to protest emphatically against the spoliation of his rights as a temporal ruler and against the presence of the king and his court in the papal city. Leo XIII, though departing in many respects from the policy of his predecessor, maintained nevertheless throughout the same uncompromising attitude toward the question of the temporal power, and the same policy was steadfastly affirmed by his successor, Pius X. Such are, in briefest outline, the main facts pertaining to the origin and history of this ecclesiastico-civil institution. It is beyond the scope of the present article to appreciate or criticize the motives either of those who labored to maintain it or of those who more or less directly sought its abolition. Still less pertinent to the purpose in view would be a speculation on the probable restoration of the same in the future. It must be granted that, considering the present political situation in Europe, the probability of a restoration of the temporal power, at least in its ancient form, seems rather remote. For all practical intents and purposes the different powers recognize as a *fait accompli* the incorporation of the papal dominions into the kingdom of Italy; though, on the other hand, it still remains true that this state of affairs has never yet received any formal, international ratification. Furthermore, the necessity, or even the utility, of such a restoration is a point concerning which there is considerable divergence of opinion even among Roman Catholics. It is a question concerning which no authoritative dogmatic pronouncement has been formulated by the Church; however, the firm and unmistakable attitude of the popes toward it cannot be looked upon by Catholics otherwise than deeply significant. All, even the most ultra-montane, must, of course, admit that the possession of a temporal sovereignty is not an essential prerogative of the successor of Saint Peter, since for so many centuries before it was established the Church was able to develop and fulfil so efficiently her mission in the world. Yet this temporal sovereignty is regarded by many as the means providentially established to protect the necessary independence of the Pope and the free exercise of his functions as spiritual head of the Church. Others, while admitting the main principle involved (namely, that the Pope should be free in his spiritual capacity) take a somewhat different view of the case. They remind us that the temporal power was the outcome of peculiar and to a great extent abnormal conditions. It was the best and perhaps the only solution at the time, and for centuries afterward of a vexed problem, partly political, partly religious; but at the same time it is not proved that had the conditions been otherwise some other régime of papal supremacy just as satisfactory would not have developed. But be that as it may, it is claimed that at least in the present social and political conditions of the Christian world, so different from those of the Middle Ages, the desired independence in spiritual matters can be secured without imposing on the Pope the burden of a temporal as well as a spiritual sovereignty. When, however, it is asked how this can be done, no very clear or satisfactory answer is forthcoming. It is plain from the nature of the case, as well as from past experience — notably the sojourn of the papacy at Avignon — that to have the Pope under the control or protection of any secular prince is dangerous for the best interests of religion. If the head of the Church be not himself an independent sovereign, it is hard to conceive a situation in which he would be free from undue political or national influence, especially if he is to be either the subject or guest of some temporal ruler. It is for a similar reason that the founders of the American Republic wisely determined that the seat of the central or federal government should be located not in any of the States, but in a separate independent district, exempted from State jurisdiction, thus insuring greater freedom of action to the governing body whose duty it is to legislate impartially in the interests of the entire nation. These and other reasons are urged by the advocates of the temporal power and when it is not unreasonably objected that during the third of a century that has elapsed since the occupation of Rome by Victor Emmanuel the Pope has always enjoyed full freedom in the exercise of his spiritual jurisdiction; that never before has the moral influence of the papacy been so powerful and far-reaching, etc., the answer is made that while all this is true, there is nevertheless no sufficient guaranty that this liberty will continue to be granted in the future; that, moreover, the present situation of the papacy is certainly abnormal, and that the increase of moral influence is due in great part to the fact that the popes have maintained a firm attitude, refusing to become the allies of the Italian government. Not a few are of the opinion that in the present political status of the civilized world a system of international guaranties would be a much more effectual means of securing for the Pope the permanent free exercise of his spiritual jurisdiction than could result from a restoration of the temporal power. However that may be, the most thoughtful statesmen allow that the problem is complicated and delicate — that no solution thus far arrived at or suggested is free from grave practical difficulties. The temporal power of mediæval and later times was certainly not without grave drawbacks and disadvantages as regards the interests of both rulers and subjects. That it has been the occasion of many evils and abuses, that it has often been a real impediment to the spiritual efficiency of the papacy few impartial students of history will venture to deny; yet it will doubtless be as readily admitted that being given the circumstances of the period the temporal power was a most useful, even necessary, factor in the evolution of Christianity; and whatever may be thought of its adaptability to future contingencies it will not be a matter for surprise to find that so many are still convinced of its permanent necessity, at least until something better shall have been devised to meet the exigencies of the case, and shall have demonstrated its superiority by actual experience.

TEN COMMANDMENTS. See DECALOGUE.

TEN KATE, Jan Jacob Ludewijk, Dutch poet: b. The Hague, 1819; d. 1889. See KATE JAN JACOB LUDEWIJK TEN.

TEN THOUSAND A YEAR, a novel by Samuel C. Warren (q.v.) published in 1841. This story, though regarded by critics as «ridiculously exaggerated and liable to the suspicion of being a satire on the middle classes,» has held a certain place in fiction for more than half a century. The plot is ingenious, the legal complications are managed in a way that won the admiration of accomplished lawyers and the story with all its faults contrived to arouse and maintain the reader's interest. In 1902 it was reissued in an abridged form as 'Tittlebat Titmouse.'

TENACITY, the property or quality of resistance to disrupting force; the quality by which the molecules of a body resist either tensile or crushing strain. When the tenacity is slight the object may be brittle, when it is great it adheres together firmly. Compare TENSILE. See STRENGTH OF MATERIALS.

TENAFLY, N J., borough in Bergen County, 16 miles northwest of New York, on the Erie Railroad. The Happy Land and Bethmore summer outing homes for children are situated here as well as the Mary Fisher Home for the Aged. It is a residential town, forming a suburb of New York, and there are manufactures of decorative burlaps. Pop. 3,050.

TENAINO, tē-nī'nō. See SHAHAPTIAN INDIANS.

TENANCY, a beneficial interest in some form of real property, or the relation of the lessee of land to the lessor of the same. This relation may be established without that the lessor be the holder in fee simple of the realty in question. At the present time the status of a tenant is usually created by a form of conveyance known as a lease; this is now required to be in writing in most jurisdictions. It usually contains covenants or stipulations respecting the use to which the realty may be put, the rent or compensation to be paid the lessor, the making of repairs, etc. The law also regulates the relations of the tenant to his landlord in some important respects. Thus the tenant is protected against eviction by the landlord. The tenancy may be sub-leased unless there is a restriction in this regard in the lease. A surrender or breach of the lease terminates a tenancy. See LANDLORD AND TENANT.

TENANT. See RENT, LAW OF.

TENANT-RIGHT, in British law, a right possessed by the tenant, at the expiration of his tenancy, for reimbursement for improvements, and often of considerable monetary value. It is largely governed in England by statute. Tenant-right prevailed in some parts of Ireland by custom for many years, and was formally incorporated into the law by an act passed in 1870. It is also applied to the preference given to old tenants over strangers in leases from the Church, the Crown or corporations.

TENASSERIM, tĕ-năs'ĕ-rĭm, India, a maritime division of lower Burma, stretching in a narrow strip from the Salwin River 500 miles southward into the Malay Peninsula, between Siam and the Bay of Bengal. Area, 36,086 square miles. It is for the greater part a mountainous wilderness. Within its territory are the Mergui Archipelago. Maulmain is the chief town on the north and Tavoy in the central area. The chief product is rice, though the mountains are rich in minerals. The natives are chiefly Burmese Buddhists. Pop. about 1,400,000.

TENCH, a small cyprinoid fish (*Tinca vulgaris*), familiar in European fresh waters, especially slow-running and muddy rivers. The color is a greenish olive, tinted with a golden hue; the average length about 12 inches. The flesh is soft and rather insipid.

TENDA PASS, or **COL DE TENDA,** Italy, a pass of the Maritime Alps, Piedmont, in the province of Cuneo, between Tenda and Limone, on the carriage road from Nice to Cuneo. Its highest point is 6,195 feet above sea-level.

TENDER, in law, a formal offer of compensation or damages made in a money action. A tender may be made through an authorized agent, and to make it valid the money must be actually produced. Making a tender may have the effect of freeing the defender from subsequent expenses if the tender is found sufficient. A tender made to one of several joint claimants is held as made to all. A legal tender is one of legal money of the country, originally confined to coin, but extended to authorized paper money. A payment in foreign notes or «trade» dollars, or a large sum in bronze pennies, is not a legal tender.

TENDON, or **SINEW,** a band of white fibrous tissues by which a muscle is attached to a bone or other hard part. Tendons are disposed in elastic bands or layers flattened or rounded, and more or less elongated. When very much flattened and membraneous, they are called aponeuproses and sometimes fasciæ. They glide smoothly in sheaths, especially in the extremities; in some cases many are enveloped in a single sheath, in other situations they are kept in place by an annular ligament, as in the wrist and ankle. One of the most important is the Achilles tendon (q.v.), at the heel. One of the most beautiful contrivances in the human body is the manner in which the superficial flexor tendons in the fingers stop short at the middle phalanx and divide to allow the tendons of the deep flexor to pass through to the terminal phalanx, thus securing compactness and beauty of shape, with freedom and extent of motion. Contractions of tendons are frequently remedied by subcutaneous tenotomy; torticollis (q.v.) is also benefited by the division of the tendon of the sternomastoid muscles. Inflammation of the tendon sheaths, or tenosynovitis, about the wrist or ankle is a common and painful affection usually due to strain or over exercise. Rest and mild counter irritation are the principal elements in the treatment. The violent strain of a tendon, less than a rupture, is called a sprain (q.v.). When a tendon is ruptured or cut nature makes an effort to rejoin it by growing or depositing new tissue in the gap.

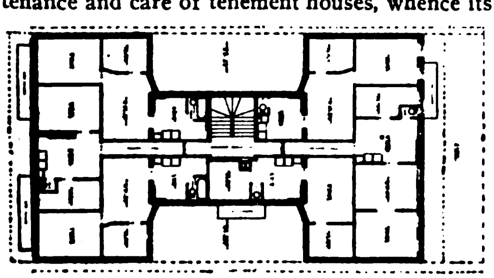
TENDRAC. See TANREC.

TENEBRÆ, in the Roman Catholic Church the matins and lauds of Wednesday, Thursday and Friday of Holy Week, sung on the preceding evenings. The ceremony dates from the 8th century. The services begin with 15 lighted candles which are extinguished one by one until the last, which is hidden, the church meantime being darkened. The growing darkness as a candle is extinguished after each hymn betokens the fading light of the world as Christ was leaving it, while the light of the hidden candle brought forth at the end of the service indicates the coming resurrection and that death could only appear to triumph over Christ. In English mediæval churches 24 candles were used at the service.

TENEDOS, tĕn'ĕ-dŏs, Asia Minor, an island in the Ægean Sea, off the Troas Coast, belonging to Turkey. It lies at the entrance to the Dardanelles, hence has figured in naval operations on several occasions. It is six miles long by three miles wide, is of volcanic formation, with rugged surface, but highly fertile, and celebrated for its wine. Pop. 5,000.

TENEMENT HOUSE, a multiple dwelling arranged for the occupation of several families, each of which can live independently and do its cooking within its apartment. The legal definition varies somewhat in different cities. In New York, Philadelphia, Washington, Buffalo and other cities, it is such a house for more than two families. In Chicago, Boston and Saint Louis the line is drawn at more than three families. Tenement house is a generic term, including what are popularly called apartment houses and flat houses or flats, as well as tenements. The attempt has sometimes been made in framing tenement-house laws or regulations to distinguish between apartment and tenement houses, but no satisfactory line of separation has ever been suggested, nor is there any legal regulation properly applicable to tenement houses, as popularly defined, which should not equally apply to apartment houses, or which presumably would not be adopted by intelligent owners of such houses from motives of self-interest.

Tenement-House Reform.—A movement to better the housing conditions of the working classes in cities, which originated about the middle of the 19th century and has gradually become national in character in the United States and Great Britain. In the United States it has taken the form of the regulation by State law or city ordinance of the construction, maintenance and care of tenement houses, whence its



A tenement with no room opening on a court narrower than 12′ 6″, with every room light and well ventilated, and with separate water-closets for each apartment and baths for some

title. In Great Britain this movement has been directed to all kinds of houses, including tenement houses, and is usually called by its more generic title of «Housing Reform.» The initiative of the movement has been benevolent impulse, but the strong forces behind it which have given impulse to that initiative and have united to carry the movement forward have been the same which have evolved sanitary and building regulations and are founded quite as much on self-interest as altruism.

History.— The movement for tenement-house reform in the United States naturally began in New York, its largest city, where the need for regulation first became apparent, and may be said to date from 1842, when Dr. John H. Griscome, the city inspector of the board of health, called attention to tenement conditions in a special report on the sanitation of the city. It has since extended to almost all large cities in which tenement houses have been erected, and has taken the form sometimes of State law, as in New York and Massachusetts, or more often of city ordinance, as in Chicago and Philadelphia. The legislation in New York is the result of the investigations and recommendations of successive State commissions, and the scope of inquiry of the last commission, which is typical, has been «To make a careful examination into the tenement houses in cities of the first class; their condition as to the construction, healthfulness, safety, rentals and the effect of tenement-house life on health, education, savings and morals of those who live in tenement houses and all phases of the so-called tenement-house question in these cities that can affect the public welfare.» The chief subjects of tenement-house regulation may be grouped under three general classes: protection against fire and means of escape in case of fire, light and ventilation and sanitary protection, the latter including water supply, water-closet accommodation and the prevention of overcrowding.

Fire Protection — Protection against fire is almost universal. Structural provisions directed to this end are contained in the building laws of all cities. In New York, Philadelphia, San Francisco, Jersey City, Providence, Syracuse and Nashville all tenements must have fire escapes. All tenements over two stories in height must have fire escapes in Saint Louis, Baltimore, Louisville, Minneapolis, Saint Paul, Denver, Toledo and Columbus. In Chicago, Cleveland and Cincinnati this rule only applies to tenements over three stories in height. In many cities tenements must be fire-proof throughout when over a certain height. In Philadelphia this is true of all over four stories; in Washington of those over five stories; in New York, Buffalo, Louisville, Minneapolis and Denver of those over six stories in height. In Boston the limit is 65 feet.

Light and Ventilation are protected by minimum open spaces and by a limitation of the percentage of a lot which can be occupied by a building. In Philadelphia there must be open spaces at the side or rear, equal to one-fifth of the lot area, and the minimum width of all spaces is eight feet. In Buffalo, under the local law in force before the general State act of 1901 was passed, the minimum width of any outer court was six feet in two-story buildings, eight feet in three- and four-story buildings and one additional foot in width for each additional story. The minimum interior court was 8 by 10. In Boston, a clear open space at the rear must be left equal to one-half the width of the street on which the tenement fronts and there must be two open spaces at least 10 feet wide. In some cities the required court area is expressed in square feet, without regard to minimum width or length and increases proportionately with the height of the building. This principle is adopted in New York, where the minimum width of exterior courts in buildings five stories high is six feet on the lot line and 12 feet between wings and the minimum area of interior courts on the lot line in buildings of the same height is 12 by 24. These dimensions are increased or decreased according as the building is higher or lower. Tenement houses in New York must have an open yard at least 12 feet wide in the rear. The maximum percentage of lot area which may be occupied by the building differs, properly, according as the lot is an interior or a corner lot. As respects interior lots, this limitation in New York and Buffalo is 70 per cent; in Boston 65 per cent; in Philadelphia 80 per cent. The height of rooms is almost universally regulated, the minimum usually being eight feet. The height of tenements is limited in many cities. In New York it is limited to one and one-half times the width of the street on which it faces.

Water Supply.— In New York water must be furnished on each floor. In Philadelphia and Buffalo, on each floor, for each set of rooms. In Boston, Chicago, Jersey City and Kansas City, in one or more places in the house or yard. Water-closet accommodation is very generally prescribed. In Philadelphia and in New York, under the law of 1901, there must be one for every apartment. Under the previous law in New York, there must be one for every two families. In other cities the unit is the number of persons. It is 20 persons in Boston, Baltimore and Denver; 10 persons in Rochester.

Law Enforcement.— The enforcement of Tenement-House Law in American cities is usually vested in existing city departments to which it is most germane. These provisions, which relate to the construction of new buildings and the alteration of old ones, are naturally enforced by a building department or by whatever part of a city government has charge of the enforcement of building regulations. Sanitary regulations are, for a like reason, usually enforced by a board of health or by whatever city officer supervises the enforcement of health laws in general. In the city of New York previous to 1901 the enforcement of such regulations was divided between the building department, the health department, the fire department and the police department. Under such divided responsibility many of them were not enforced at all, and the enforcement of others was extremely lax. Moreover, the tenement-house problem in New York was an exceptionally large one. Of its population at that time of nearly 3,500,000, nearly 2,500,000, or more than two thirds, lived in tenement houses as legally defined. Under these circumstances the State commission of 1900 recommended the establishment of a separate tenement-house department in the city of New York. This department was established under the new charter of the city which went into operation in 1902 and centres in itself all the municipal duties toward tenement houses and their inmates, as such, which were previously divided among the other city departments.

Model Tenements.— The erection of model tenements, so-called, of large size, from motives primarily philanthropic, has been less frequent in the United States than in Great Britain. The best known and earliest are the "Home Buildings" and "Tower Buildings," which were erected by Alfred T. White in Brooklyn; the first named in 1879. The erection of these buildings, which have been financially successful from the start, was an epoch in the cause of tenement reform. It led indirectly to the Tenement-House Law of 1879. Among the most successful model tenements are those of the City and Suburban Homes Company of New York. In the United States 616 cities now take an active interest in housing, and in 124 model housing enterprises have been launched.

Great Britain.— The movement for housing reform in Great Britain has had a somewhat different direction from its American counterpart. The evils there have been more largely slum conditions than those resulting from tall buildings and unventilated and unlighted rooms. The particular evils of the tall tenement practically exist only in Edinburgh and Glasgow. Consequently English and Scotch effort has been directed mainly toward the demolition of unsanitary areas and more recently, the erection of municipal tenements by the city governments themselves. These movements, at first local, and authorized under local acts, such as the Glasgow Improvement Act of 1866 and the Liverpool Sanitary Amendment Act of 1868, have been made general by the Housing of the Working Classes Act of 1890 and many slum areas have been destroyed and municipal tenements built in their place, notably in the cities of London, Glasgow, Manchester, Liverpool and Edinburgh. Tenement-house regulation in Great Britain emphasizes the same general subjects and follows the same lines as American regulation. Limitations upon height are general and more drastic than in America. Such houses are limited in London to 80 feet, without special consent of the council and may not exceed the distance between the front wall of the building and the opposite side of the street in streets less than 50 feet wide. In Edinburgh they are limited to one and one-quarter times the width of the street; in Liverpool and Glasgow to the actual width of the street; in Manchester to two stories in streets of less than 30 feet in width and to three stories in wider streets up to a width of 36 feet. Tenement regulations on the Continent usually form part of the general building regulations. The regulations for Paris and Berlin are very elaborate, but proceed under the same general lines as in English and American cities. In Berlin, houses fronting on the street may only be as high as the width of the street. In Paris a somewhat greater latitude is allowed in this particular.

No American city has imitated the English example of building municipal tenements, nor has such action ever been seriously proposed. Serious objections to any such extension of the sphere of municipal activity would exist in any American city. Moreover, municipal building would discourage and restrict building by private enterprise, which has proved sufficient to meet the demand. The problem is too large for any American city to deal with it successfully by the use of any amount of public funds likely to be put at its disposal for such purposes. Halfway measures by preventing private enterprise would only increase the evil which they sought to remedy.

TENERIFFE, tĕn-ėr-ĭf', the largest of the Canary Islands. It is 60 miles long, 10 to 25 miles wide and has an area of 782 square miles. The coasts are precipitous and the interior rises in the volcanic Peak of Teneriffe or Pico de Teyde, to a height of 12,192 feet. This mountain has been quiescent for two centuries. The soil is very fertile and produces dates, coco-palms, fruit, grain, cotton, sugar and grapes. The chief town and the capital of the Canary Islands is Santa Cruz de Tenerife, situated on the northeastern coast. The Spanish government has established there a large wireless telegraph station. Pop. of the island about 180,000. See CANARY ISLANDS.

TENIERS, tĕn'yėrz (Fr. tä-nē-ār), **David,** THE ELDER, Flemish artist: b. Antwerp, 1582; d. there, 29 July 1649. Having studied under Rubens, he went to Rome and remained there 10 years. On his return to his native country he occupied himself principally in the delineation of fairs, shops, rustic sports and drinking parties, which he exhibited with such truth, humor and originality, that he may be considered the founder of a style of painting which his son afterward brought to perfection. He also painted some landscapes with scriptural or mythological figures in the foreground. A picture from his hand was sold in 1886 for $2,275. His 'Dutch Kitchen' in the New York Metropolitan Museum gives a fair example of his style. This canvas is 45½ by 39 inches and, therefore, much larger than the majority of his pictures.

TENIERS, David, THE YOUNGER (son of the preceding), Flemish artist: b. Antwerp, 15 Dec. 1610; d. Brussels, 25 April 1690. He received his early instruction in his art from his father and his style was improved by copying 200 pictures in the gallery of Archduke Leopold William to whom he had been appointed painter. This copying degenerated into servile imitation and he produced such perfect facsimiles that they deceived even connoisseurs, and he has been styled the «Ape of Painting.» Yet he had also a strong vein of originality and his paintings of low life in Flanders are excellent examples of genre. Although refined in mind and manners and patronized by such men as Prince John of Austria, son of the Emperor Charles V, he preferred to immortalize by his brush the card table and drinking party of boors and was to the last the enthusiastic painter of the pot-house and the guard-room with its rollicking soldiery. There are at least 2,000 of his pictures at present in existence, six of them being hung in the New York Metropolitan Museum of Art, though none of these latter excepting 'A Marriage Festival,' can be called representative of the artist's style and quality. Like Rubens, some of whose manner he inherited from the teaching of his father, a pupil of the former, he was a rapid executant; many of his works are mere sketches, others elaborated with exquisite virtuosity. His touch is light but sure and his coloring exceptionally fine, while for animation and power of expression he remains the first of Flemish genre painters. His works are highly prized and his 'Village Fete' was sold in 1850 for $15,750. Consult Rosenberg, 'Teniers der Jüngere.'

TENNANTITE, an isometric, metallic mineral, isomorphous with tetrahedrite. It is essentially a copper sulph-arsenite, differing from tetrahedrite into which it passes by insensible gradations, only in the preponderance of arsenic instead of the antimony which distinguishes the latter. Its color and streak are usually iron-black; it often has a brilliant metallic lustre; its hardness varies widely from 3 to 4.5; its specific gravity is also quite variable, 4.4 to 5.1. It occurs in fine specimens in the mines of Cornwall, England, in Bolivia and Colorado. When sufficiently abundant it constitutes a valuable copper ore.

TENNESSEE, tĕn-nĕs-sē («THE VOLUNTEER STATE»), a southern-central State of the United States. Kentucky and Virginia lie to the north; North Carolina to the east; Georgia, Alabama and Mississippi to the south; and Arkansas and Missouri to the west. Its length on the northern side is 436 miles; that on the southern side is 100 miles less. The area is approximately 42,050 square miles, of which something like 300 miles are covered by the water of streams. The southern boundary of Tennessee was intended to follow the 35th parallel, but all parts of it lie from a fraction of a mile to a mile south of that line, excepting the 45 miles east of Tennessee River, between Alabama and Tennessee. That part of the northern boundary between Tennessee and Mississippi rivers is on the parallel of 36° 30'. Immediately east of Tennessee River, the northern boundary is 12½ miles north of parallel 36° 30'. Eastward from this point the boundary is not straight but on the whole approaches that line, coming within approximately five miles of it, in the middle of Claiborne County. Here there is a jog of about a mile to the north. There is a similar but somewhat greater one in the eastern part of Sullivan County. It was the intention to make the crest of the Great Smoky or Unaka Mountains the eastern boundary between Tennessee and North Carolina. The most eastern point of the State is in Johnson County, and is approximately 81° 41¼′ W. longitude. The western boundary is the middle of the Mississippi River as the channel ran in 1763, at the time of a treaty between the British and French. The most western point is in Shelby County, and is approximately 90° 28′ W. longitude.

Surface Features.— Tennessee has eight well-defined natural divisions: (1) On its eastern borders rises in great ridge-like masses and treeless domes the main axis of the Appalachian chain, the loftiest peaks of which reach an elevation of 6,600 feet above the sea. Many beautiful valleys and coves nestle amid this grand range of mountains, which is known as the Unaka or Smoky Mountains, and which has an area, approximately, of 2,000 square miles. (2) Adjoining these mountains on the west is the second natural division, called the Valley of East Tennessee, which lies between the Unakas on the southeast and the Cumberland Mountains on the northwest. This valley has a fluted bottom, made up of a succession of minor ridges and valleys with a northeast-southwest trend. Viewed from the mountains on either side, these minor ridges and valleys melt into a common plain. This valley has an area of 9,200 square miles and is of great agricultural value. It is the southwestward extension of Shenandoah Valley of Virginia. (3) Next in order, going westward, is the Cumberland Plateau, which rises 2,000 feet and more above the sea, and 1,000 feet above the last-mentioned division. It forms a bold escarpment, on its eastern edge presenting a gray, rocky, formidable rampart. Its western edge is irregular and jagged, notched and scalloped by re-entrant coves and valleys which are separated by finger-like spurs, pointing for the most part in a northwesterly direction. Most of the northern part of the plateau is cut to pieces by deep, narrow ravines, between which are sharp-topped ridges. The southern half is divided lengthwise into two parts by the deep-cut Sequatchie Valley. The area of this division is 5,100 square miles. (4) Resting against the western edge of the Cumberland tableland and including the elevations bordering the Tennessee River in its return across the State are the Highlands, or Rimlands, having an average elevation of 900 feet above the sea. For the most part this division is a flat plain furrowed by numerous ravines traversed by streams. Its area is 9,300 square miles and it surrounds, in an irregular circle, the next division. (5) Surrounded by these Highlands lies the Central Basin, elliptical in shape, with an area of 5,450 square miles. It is the finest agricultural region in the State, and is on an average of 300 feet lower than the Highlands that border it. (6) The valley of the Tennessee River comes next on the west. Its surface is broken and irregular, and it stretches across the State from south to north on both sides of Tennessee River. It has an average width of 12 miles and an elevation of 350 feet. Its area is approximately 1,200 square miles. (7) The slope of West Tennessee constitutes the seventh natural division and differs from all the other divisions mentioned in having but few hard rocks, these occurring only in a narrow belt north of Savannah and bordering the Tennessee River. It is a great plain, that with the exception of a belt about 20 miles wide next to Tennessee River, slopes gradually toward the Mississippi. For the most part, the surface is gently rolling, but in places is furrowed with low valleys bordering streams that flow in sluggish currents to the Mississippi. Its area is 8,850 square miles, with an average elevation of 500 feet. It abruptly terminates in a line of bluffs that overlooks the great alluvial plain or bottom lands of the Mississippi River, next to be mentioned. (8) The Mississippi Bottoms constitute the eighth and last of the natural divisions of the State. It is a low, flat plain, studded with lakes and originally clothed with dark forests. Much of its area lies below the high water of the Mississippi, and as a result there are many swamps and marshes. The area of this division is 950 square miles, and its elevation above the sea is 300 feet.

A very singular topographic feature already referred to is Sequatchie Valley, which is a deep trough extending in a northeasterly direction from the south boundary of the State, dividing the southern end of the Cumberland tableland into two unequal arms, the eastern one being known as Walden's Ridge. The valley has its head about midway between the northern and southern boundaries of the State, and is about 60 miles long and from three to five miles wide. It is enclosed by rocky walls, approximately 1,000 feet high, and through its centre flows the beautiful Sequatchie River.

The highest point in the State appears to be Mount Guyot, which is near the corner of Cocke and Sevier counties, and which stands 6,636 feet above sea-level. Other points that exceed 6,000 feet are Mount Henry, Roan Mountain, Clingmans Dome, High Knob, Mount Le Conte, Mount Curtis, Mount Safford and Master Knob. They all, with few exceptions, are on or near the line that separates Tennessee from North Carolina. There are a few points near the eastern border of the Cumberland Plateau which rise above 3,000 feet.

The Allegany range of Pennsylvania and Virginia becomes the Cumberland Plateau in Tennessee, and Sand Mountain in Alabama. The Blue Ridge of Pennsylvania, Virginia and North Carolina takes the name of Unaka or Smoky Mountains in Tennessee. Many of the long, straight valleys of the valley of East Tennessee lying between the parallel ridges and overlooked by them are rich, populous and beautiful — centres of industry, intelligence and a diversified system of agriculture. Taking the State altogether it will be seen that the topography is greatly diversified. The great elevations on the east are offset by the low valley of the Mississippi on the west. Between these are three great plateaus and two marvelously fruitful valleys, all differing in height, area, soils, climate and products. It is indeed a State of the greatest variety in natural features.

Drainage.— The Mississippi, the Tennessee and the Cumberland form the great drainage basins of the State. The Tennessee and Cumberland are tributaries of the Ohio, which in turn flows into the Mississippi so that all the streams which drain the State, with the exception of a few insignificant ones that flow

TENNESSEE.

through a small area next to the Georgia line, find their way through the Mississippi into the Gulf of Mexico. Of all the streams in the State, the Tennessee and its affluents, the Holston, the Clinch, the French Broad, the Elk and Duck rivers may be considered the main arterial currents and with their tributaries they drain over 40,000 square miles, about 32,000 of which are in the State of Tennessee. The Tennessee River is formed by the junction of the Holston and French Broad rivers, four and one-half miles above Knoxville, Tenn., flows thence southwest into and through northern Alabama and from the northeast corner of Mississippi, nearly due north, entering the Ohio at Paducah, 652 miles from the junction of French Broad and Holston rivers. Its principal tributaries are the Clinch, navigable for 60 miles, the Hiwassee, navigable 41 miles, the Little Tennessee, the Duck and the Elk. The Tennessee is navigable from the junction of the French Broad and Holston rivers to its mouth, except during extreme low water of late summer and fall. Formerly the three main obstructions to navigation at low water were Hale's Bar, 33 miles below Chattanooga, Muscle Shoals, six and one-half miles above Florence, Ala., and the Calbert and Bee Tree Shoals, Riverton, Ala. The Hale's Bar lock and dam, built at a cost of about $11,000,000, dam of solid concrete, 1,200 feet long and about 52 feet average height, lock 60 feet by 267 feet, lift at low water 37.5 feet, forming a pool which gives a depth of 6 feet in front of Chattanooga, 33 miles up the river, was completed and opened to navigation in 1913. This lock and dam was built largely by the Chattanooga and Tennessee Power Company and supplies an enormous amount of electric energy. There is now a lateral canal having a depth of five feet, in two sections, around Muscle Shoals, and a canal with a depth of seven feet around Colbert and Bee Tree Shoals. The river is now navigable the entire year from Riverton to the mouth, 226 miles, for steamboats of three feet draft. There are other shorter sections in which navigation is possible the year round. The traffic on the river in 1914 was 967,528 tons, valued at $21,120,489, consisting principally of general merchandise, livestock, farm products, timber, ore, sand and gravel. The Cumberland River was given its name by a party of Virginians, under Dr. Thomas Walker. They penetrated this section in 1748 and gave the name Cumberland to the river, mountains and gap of that name, in honor of the royal English Duke of Cumberland, then Prime Minister. The Indians called it the Warioto, and the early French traders the Chauvanon (the river of the Shawnees).

The Cumberland River rises in the Cumberland Mountains in Harlan County, southeastern Kentucky, near the Virginia line, and flows thence in a devious great U-shaped course down into Tennessee, curving thence up again into Kentucky, entering into the Ohio near Smithland, Ky., 688 miles from its source. After leaving its mountain sources it flows westerly through the highlands of southeastern Kentucky. Where it cuts its way from the highlands it forms the beautiful Cumberland Falls with a drop of 66 feet. A few miles below these falls it passes over Smith Shoals through a wild gorge, with side walls about 300 feet in height. The scenery along the Cumberland from Carthage, Tenn., to its head is amongst the finest in America. Two hundred and twenty miles of this section, i.e., from Carthage to Burnside, Ky., has good steamboat passenger service for six months of winter and spring. On this navigable stretch may be seen the old Indian town site and the old burial caverns at the mouth of Caney Fork, rugged Sand Shoals, Seven Sisters (a stretch of seven towering cliffs in Clay County, Tenn.), the Natural Bridge near Burksville, Ky., the historic battlefield of Fishing Creek, where the Confederate General, Zollicoffer, lost his life. It is a quaint river. Nearly every one of its beautiful scenic reaches has its legendary story. This portion of the navigable river above Carthage reaches that interesting mountain and highland section, the home of the moonshiners. It is like stepping back into the language, thought and customs of the 18th century.

The Cumberland is navigable from Burnside, Pulaski County, Ky., to its mouth, a distance of 518 miles, for about six months in the year, for boats of three feet draft, and nine months for gasoline boats drawing one foot. From Lock 21 to Burnside, Ky., a distance of about 20 miles, it is navigable the year round. In 1908 the Federal government completed a series of seven locks and dams which rendered the river navigable for the entire year from Nashville, Tenn., to Carthage, Tenn., a distance of 120 miles, and since 1914 has locked and dammed the entire stretch from Nashville to the mouth of the river, a distance of 193 miles. The traffic on Cumberland River for year 1914 was 467,-486 tons, value, $9,023,206. This consisted principally of corn, wheat, livestock, general merchandise, lumber, logs, sand and gravel.

The Mississippi River supplies approximately to the State 200 miles of navigation. The Holston, French Broad, Clinch, Elk and Duck rivers, all tributaries of the Tennessee, are floatable in high tide for logs and flatboats for many miles, though rarely navigable for steamboats. Obey's River and Caney Fork, tributaries of the Cumberland, and the Obion, Forked Deer, the Hatchie, tributaries of the Mississippi River, are navigable for 20 miles or more at high tides. Tennessee has approximately 1,200 miles of navigable waters. See also *Water Power Resources of Tennessee* in this article.

Geology.— Contrary to the popular opinion, all the rocks of Tennessee that show at the surface are of sedimentary origin excepting some in three small areas near the North Carolina line, in the northeastern part of the State, which are of igneous origin. Being of sedimentary origin, they are in layers or beds, and consist of sandstones, conglomerates or pudding stones, limestones, shales, slates, sand and clay. In the Smoky Mountains and the valley of East Tennessee, these beds by the slow but enormous pressure that has been brought to bear upon them from the southeast have had their original horizontal position replaced by great folds that extend in a northeast-southwest direction. Though this pressure was slow, at times and in places it was exerted so fast that the rock beds could not adjust themselves to it by bending, but instead snapped along lines parallel with the folds, thus permitting those beds on the southeast side, little by little, to be shoved up on those of the opposite side. Thus layers that originally were hundreds or in places even thousands of feet apart vertically now rests with their broken edges in contact with each other. Such displacements are known as faults, and there are many of them in the Great Valley of East Tennessee scores of miles long. Indeed some of them run the whole length of the valley, and into the other States at either end. It is this folding and faulting that gives direction to the Great Smoky Mountains themselves, to the valley of East Tennessee and the ridges and minor valleys within it, and to the eastern escarpment of Cumberland Plateau.

The general lay of the rock beds beneath the Cumberland Plateau is that of a syncline or trough, with gradually sloping sides, but this simplicity of structure is broken in the south half by a pronounced arched or anticlinal structure. It is along this arch that Sequatchie River has carved out the valley of the same name.

The general lay of the rocks beneath and bordering the Central Basin is that of an elliptical flat dome with its highest part in the centre of Rutherford County. The direction of the major axis of this dome is northwest-southeast, or roughly parallel with the folds of East Tennessee and the direction of Cumberland Plateau. The sides do not slope uniformly, but are billowy. This dome is the counterpart of a similar one in Kentucky and adjoining territory in southwestern Ohio and southeastern Indiana. In the southeastern corner of Stewart County there is a small structural dome upon which a depression, known as Wells Creek Basin, some two miles wide, has been excavated by the same natural processes that formed the Central Basin. The rock layers on the sides of this dome stand at a much higher angle than those beneath the Central Basin, of which it otherwise is a miniature duplication. The lay of the hard rock beds in West Tennessee, which there are far beneath the surface, is not known, but they probably dip at a low angle to the west, as do the unhardened beds of sand and clay, above them.

The oldest rocks of the State are of Archeozoic Age, and occupy three small areas along the border in Johnson, Carter and Unicoi counties. They include several formations and consist, for the most part, of gneiss, schist and granite. The remainder of the Great Smoky Mountains is composed of rocks of Cambrian Age of which there are several formations. They consist of sandstones, quartzites, conglomerates, limestones, shales and slates. Without the disturbance that has affected the region, these rocks would be overlain in the valley of East Tennessee by the younger Ordovician ones, but the folding, faulting and denudation the area has suffered has in places brought these to the surface in long, narrow belts and smaller irregular patches. Of the Ordovician formations in East Tennessee there are several, the oldest being the upper part of the Knox dolomite, a formation that in places exceeds 3,000 feet in thickness. The lower part is of Cambrian Age. Like the Cambrian rocks, and for the same reason, those of Ordovician Age in the valley of East Tennessee lie for the most part in northeast-southwest belts. Because of the Sequatchie anticline and the erosion upon it, rocks of Ordovician Age are exposed in the floor of the valley as they are in that of the Central Basin, and for the same reasons. Those of East Tennessee are limestone, marble and shale, while those in the Central Basin, which include 12 formations, are nearly all limestone. The Knox dolomite occurs nowhere at the surface in the Central Basin, but owing to greater uplift and probably to reduction in thickness of the overlying formations, it does occur in Wells Creek Basin. Limestone of Silurian Age occurs in narrow belts in the valley of East Tennessee, along the eastern escarpment of Cumberland Plateau, on the western side of the Central Basin, along the streams that flow through the western part of the Highland Rim and along Tennessee River. Black shale of Devonian Age, known as the Chattanooga shale, overlies the Silurian limestone and has the same distribution, except that it occurs in certain places where the former is absent, as on the northern, eastern and southern borders of the Central Basin. The rocks of the Highland Rim and the lower ones of the Cumberland Plateau are of Mississippian Age and consist of chert, shale and limestone. Those of the upper part of the Cumberland Plateau are of Pennsylvanian Age and are composed of shale, sandstone, conglomerate and coal beds.

West of the Tennessee, most of the formations are unconsolidated sand and clay. The lowest and oldest is of Cretaceous Age. Of these there are four formations, which outcrop in north-south belts, within 30 miles of the Tennessee. Westward from the Cretaceous border the surface formations are of Eocene Age, with the exception of the loess and the alluvium bordering the streams. The former, which covers a belt of 30 miles wide next to the Mississippi bluffs, is of Pleistocene Age, and the latter is Recent. The thickness of the Cretaceous and Eocene beds is not known, but a well reported to be 2,000 feet deep on the edge of Reelfoot Lake did not reach through them.

The geological history of Tennessee like that of all other land areas, is one of many changed conditions. At times possibly all of it was land. At others most or all of it was beneath the sea. At still others some parts were above and some beneath the sea. When above, the land was being worn away; when below, the material that forms the rocks was put down in the ocean bed, in layers. There are long periods which are not represented by rocks anywhere in the State and others represented only in part, depending upon whether the State was all land or part land and part water. In Lower Cambrian times, the area probably was all land excepting the part covered by the valley of East Tennessee; in Upper Cambrian, it probably was all sea; in the very long period covered by Ordovician, Silurian, Devonian, Mississippian and Pennsylvanian times, there were many changes that brought more or less of the area, now above the sea, now beneath it. During Triassic and Jurassic and Lower Cretaceous times, the area probably was land. In Upper Cretaceous times, the western third of the State, possibly more, was beneath the sea, as was West Tennessee in Eocene times. Since Eocene times, none of the State has been submerged, excepting possibly the western part for only a relatively short time.

Mineral Resources.— Tennessee is rich in mineral resources. In the order of their importance the 10 leading minerals are coal, copper, zinc, iron, cement, clay, marble, phosphate, limestone and barytes. Coal is mined in the Cumberland Plateau; pig iron is produced in East Tennessee and on the western Highland Rim, in Middle Tennessee; copper, at Ducktown in the southeastern corner of the State; cement, at Richard City and Kingsport; phosphate, in Middle Tennessee; sulphuric acid at Ducktown; brick and tile, in all parts of the State; marble in East Tennessee; gas, coke and the by-products, in East Tennessee; zinc in East Tennessee. Besides these, there are at least 12 others of importance and 20 that are known to occur, though not in commercial amount. There is a large reserve of coal, iron, copper, marble, phosphate rock and zinc. Clay, cement material and many other products of lesser importance, are inexhaustible. Seven million tons of coal are mined yearly. The State produces more copper than all States east of the Rocky Mountains except Michigan. The best ball clay in America is found in inexhaustible quantities in the western portion. One million dollars worth of iron is mined yearly, with one-half billion tons in reserve. Tennessee produces more marble than any State except Vermont or Georgia. One Tennessee plant makes more lime than either North Carolina, South Carolina, Georgia, Florida, Mississippi, Louisiana or Kentucky. There is more phosphate rock in Tennessee than in all States east of the Rocky Mountains together.

Forestry, Fish and Game. *Forestry.*— The forests of Tennessee contain untold wealth in various hardwoods. Prior to 1907 but little attention had been given to this valuable asset. The fifty-fifth general assembly enacted the first general Forestry Law (chap. 397, Acts 1907). This measure received the highest commendation of the Forestry Department at Washington and has proved of inestimable benefit in checking and suppressing forest fires in the State. Under its requirements railroad rights of way were cleaned up and thus ceased to be a constant menace to private property. Prior to 1907 a majority of the forest fires were traceable directly to these railroad rights of way which had grown up in grass and brush liable to be ignited by any passing train. Tennessee is divided into three grand divisions: the western division largely bottom lands, the middle division uplands and the eastern division mountain lands. The rich alluvial lands of the western division produce a heavy timber growth differing from the forests of other sections and consist mainly of oak, cottonwood, hickory and gum. Along some of the water courses in the overflow region are found cypress trees of great value. The upland forest of the middle division consists of mixed hardwoods, largely oak. The best timber has been culled during the process of cultivation of the soil. The tree growth of value is largely to be found in woodlots, the remainder of the land being devoted to agriculture. Large bodies of timber are rare. Great diversity of tree species is found in the eastern division — the mountain region of Tennessee — due largely to differences in elevation, abundant rainfall and different exposures. Three types may be noted: ridge, slope and cove. In the first type is found chestnut, white oak, black oak, black gum short leaf pine and black locust. On some of the high ridges are found balsam and spruce and at lesser elevations black, red and post oak. The slope type consists largely of chestnut, oak, white, black, post oak and hickory. There is also to be found some short leaf pine, sour wood and black gum. The cove type represents the heaviest growth and greatest variety. Topography and soil both favoring. Here is, found yellow poplar, basswood, magnolias and black walnut. In addition chestnut, white oak, beech, sugar maple, hemlock, red oak and hickory, together with a sprinkling of black birch, bitternut, locust, ash, buckeye, sour wood, elm, cherry, sassafras and sycamore. Certain coves contain many of the above species and others few. Forest fires prior to 1907 were very destructive but are not to be compared to those of the Northwest. The necessary brevity of this article leaves much of interest unsaid.

Game.— In the early days Middle Tennessee was termed by the Indians the «Happy Hunting Grounds.» Until some years after the war the whole State was blessed with an abundance of game of many species, deer, bear, wild turkey, grouse and quail. Among the migratory birds, ducks, geese, snipe and plover were found in great numbers during the winter and spring months. By the year 1900, however, conditions had been so changed through the activities of market hunters, «game hogs» and game dealers that it was difficult to find game sufficient to afford any sport. This fact impressed upon conservationists the necessity of some law to prevent extermination. The first general Game Law (chap. 169, Acts 1903) met with violent opposition in the general assembly and passed by a narrow margin. The act to protect non-game birds (chap. 118, Acts 1903) was also passed at this session. The benefits of the Game Law, however, were speedily made so manifest that by 1905 the legislature created the Department of Game, Fish and Forestry (chap. 455, Acts 1905) and added to the law of 1903 many important features (chap. 515, Acts 1905). By 1907 game had greatly increased. A close season on deer was established and several hundred deer in a private park near Nashville were purchased and freed. They soon scattered and under protection have greatly increased. Public sentiment now secured the passage of the first general Fish Law (chap. 489, Acts 1907) and Forestry Law (chap. 397, Acts 1907). Both of these measures had been «side-tracked» in the preceding legislature. In 1909 an attempt was made to legislate the State warden out of office. The Supreme Court declared the measure unconstitutional (14 Cates, 43). In 1915 another like effort was made and again the Supreme Court sustained the incumbent of the office (Howser v. Fullton). Tennessee is cursed with factional politics. Reelfoot Lake, now the property of the State, can be made one of the finest game and fish preserves in the country. It has long been an El Dorado for hunters and fishermen. Public sentiment now strongly favors game and fish laws. It is necessary for their enforcement. Without public sentiment back of it, any law is practically a «dead letter.» With the establishment and operation of the game farm, the outlook for game in Tennessee is encouraging.

Fish.— Few States in the Union have as numerous streams so well adapted for fish as

Tennessee. Many flowing into the rivers are fed by cold springs and are unexcelled for bass, trout, land-locked salmon and perch. Prior to the movement in 1903 for the protection of game and fish, little attention was given this valuable asset. Seining was frequent and dynamiting not uncommon. Little attention was ever paid to local laws. It was not until 1907 that the general Fish Law was passed (chap. 489, Acts 1907). This law was sought to be amended in 1915 (chap. 152, Acts 1915) and the State warden also removed from office. The Supreme Court held this could not be done, but did not pass upon the other features of the bill.

It has been a hard struggle to protect fish in Tennessee. The people have not been educated to the need of their protection. The fine waters, and particularly Reelfoot Lake, should supply fish food in greatest abundance at reasonable cost. The introduction of German carp, like the English sparrow, has been a great misfortune. Eradication of either seems impossible. There has also been a decrease of fish from the pollution of streams. This is a common act, but most uncivilized practice. The agencies at work are too varied for enumeration. The development of manufacturing industries with no restrictions upon disposal of waste is fast ruining many fine streams and the fish have become uneatable from the tainting of the water. The mountain streams of the eastern division, where the population is not sufficient to cause damage by sewage, are often affected by sawdust. Seining, dynamiting and pollution are combining to destroy the fish of the State. Drastic measures must be adopted. It is feasible to keep wastes out of the waters and it is possible to turn them into profit through valuable by-products. A campaign of education as well as law is essential to accomplish the needed results.

Soils.— The soils of the Great Smoky Mountains are mostly rich clays and loams. Those of the valley of East Tennessee are mainly red to brown clay and loam that are very productive, though there are narrow belts derived from certain formations that are poor. Those of the Cumberland Plateau are in parts sandy and in others clayey. The former are not productive and should never be cleared; the latter are not strong, but are susceptible of great improvement. Those of the Highland Rim are in parts fairly good, in others poor, but all can be improved and brought to a high state of cultivation. Those of the Central Basin are very productive clays and loams, and most of the area is in a high state of cultivation. The soils of the western slope vary from those that are sandy and of little worth, through loams and clays that are fairly good and susceptible of great improvement to the rich loess area near the Mississippi, and the rich though narrow alluvial bottoms of the Mississippi, Tennessee and smaller streams.

Agriculture.— The area of Tennessee is 42,022 square miles, or 26,912,000 acres, of which 21,000,000 are farm lands and more than one-half of this is improved.

Principal Crops and Stock.— Diversified farming is general throughout the State, although specialization is practised in some sections. Corn, cotton and wheat are the great staples, leading in importance in the order named. Clover, timothy, soy beans, cow peas, herd's grass, lespedeza, vetch and alfalfa are grown for hay.

The production of strawberries and tomatoes has become one of the paying features, especially in Gibson and adjoining counties. From these and other points vast quantities of vegetables and fruits are shipped to the Northern markets. The entire State offers the conditions necessary to successful fruit culture.

Stock are fed and fattened on a large scale, and this industry is increasing in importance. Hogs are an important product. Poultry raising is extensive, and dairying is generally followed near the larger cities and towns.

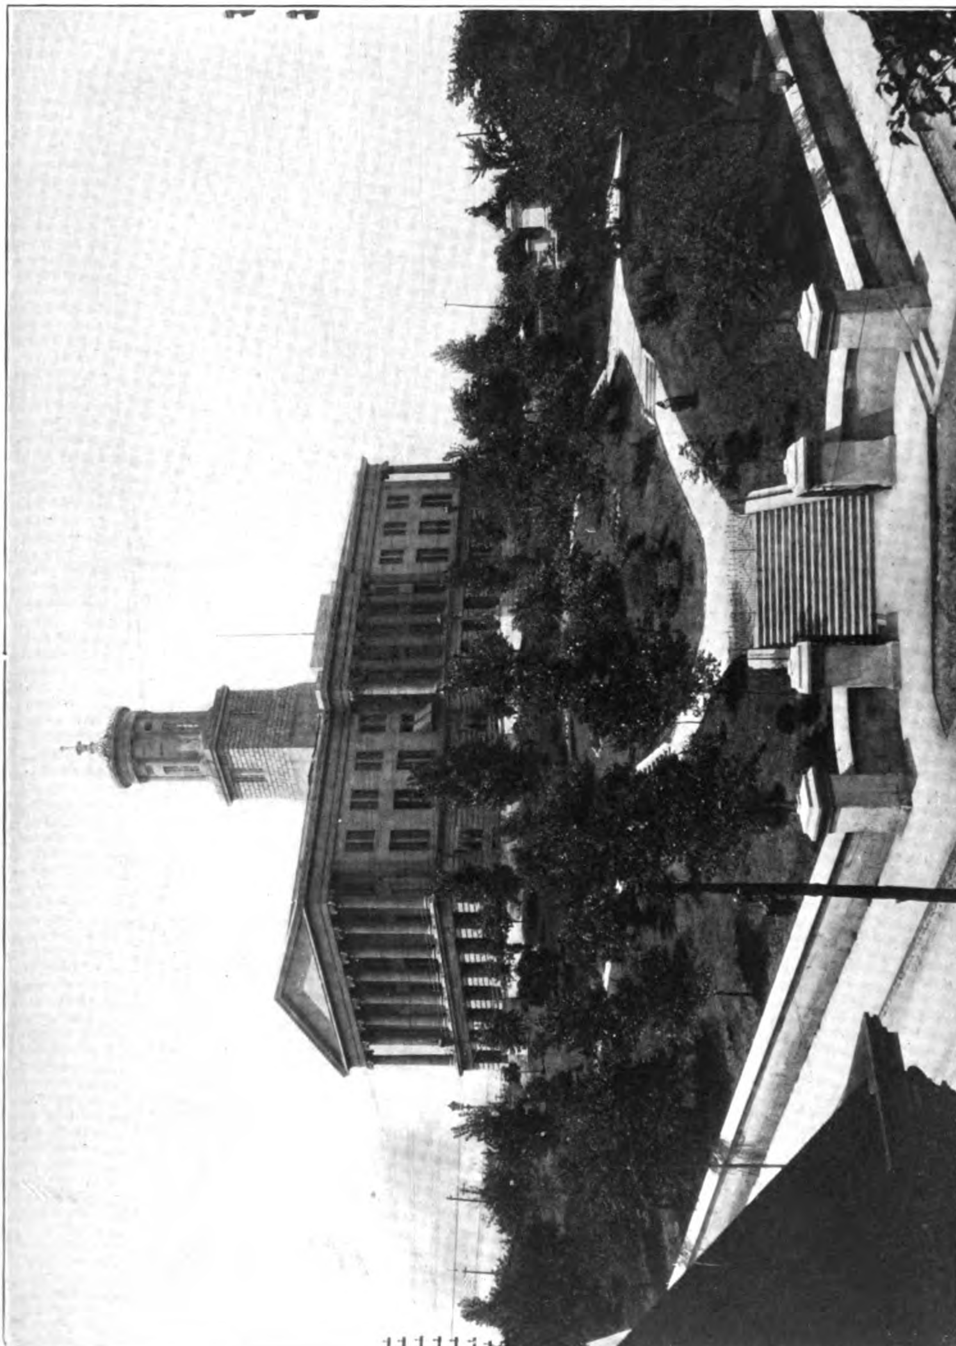
Stock raising in all its branches is generally followed, but this industry is far short of its possibilities. Some advantages the stock raiser enjoys in this State are an agreeable climate, an abundance of excellent food, easily produced, a long outdoor grazing season and a market in which the demand is always in excess of the supply. In short, as a stock-raising country, Tennessee has no superior and but few equals among the States of this Union. The blue-grass section of the State has bred some of the fastest running and the finest harness horses in the world.

Agricultural Department.— The office of commissioner of agriculture of Tennessee was established 14 Dec. 1871. It was then known as the Bureau of Agriculture. W. H. Jackson was elected president and J. B. Killebrew secretary. These men in 1874 issued a comprehensive report of nearly 1,200 pages, with 'The Resources of Tennessee' as its title. The growth of the department has been steady and has become of supreme importance to the State, in view of the fact that of a population of 2,279,000, 80 per cent are farmers and planters who more than ever before have become interested in scientific farming and farming not only as a means of livelihood but as a prosperous business.

The soils of Tennessee are well adapted to diversified farming and respond bountifully to modern methods. In fact, as an all-around crop-producing State Tennessee is not excelled in any other region in the United States in the variety, profusion, character and quality of its farm products. Wonderful possibilities exist in the soils, climate, physical structure and drainage of the agricultural areas. Frequent demonstrations of great crops are reported to the Agricultural Department from each of the three grand divisions of the State, sometimes made on ordinary soils with ordinary cultivations, sometimes on the richest soils with intensive methods applied in the preparation of the land and the cultivation of the crop, exemplifying the versatility and capacity of such lands and the progress of their development.

There are three assistant commissioners of agriculture, who hold office by appointment of the commissioner, and whose work is under his direction. The appropriations by the State to cover the salaries and expenses of the various offices under the commissioner's direction approximate $35,000.

Scientific farming is making rapid strides in Tennessee, and the State's splendid citizenship has become fully awakened to the truism that "co-operation is essential to success." This is



State Capitol at Nashville

fully demonstrated at the farmers' institutes, one great meeting being held annually in each of the three grand divisions of the State — East Tennessee in May, West Tennessee in September and Middle Tennessee in December. It has been truthfully said that there is a "new-born intelligence in even the most secluded rural districts"; farmers who were averse to changing methods of agriculture which have prevailed for ages have awakened to the sense of isolation; they are discarding the old methods and adopting the new. In their homes they are establishing new conditions, making them places not merely of shelter but of comfort and luxury. The tractor and the automobile are rapidly displacing the old-time implements and the buggy. The annual value of farm products approximates $150,000,000; value of domestic animals, $107,000,000; value of all farm property, $614,000,000. It is worthy of note that every crop scheduled in the Federal census is grown to some extent in Tennessee.

Industries.—Although Tennessee has always been, and still is, essentially an agricultural State, the progress it has been making in manufactures strongly indicates marked pre-eminence in industries in the years to come. This pre-eminence would seem to be a necessary corollary to the development of its great natural resources; and it is to be noted that its present progress is along these lines. Approximately $175,000,000 is the capital invested in Tennessee manufacturing generally.

According to the census of 1909 the total number of industries in the State of Tennessee was 4,609, and of these 1,917 were represented by establishments making lumber and timber products. If to these be added the industries that use these products, such as car and carriage factories, approximately one-half of the manufacturing establishments of this State depend upon the natural resources of timber. The inference naturally is that Tennessee is a well-wooded State, and such is the fact. Of the more than 26,000,000 acres in Tennessee, approximately 15,000,000 are woodlands. Three counties have each more than 200,000 acres of virgin forests; and while much of the wooded area of the State is second and third growth, there is still an enormous quantity of virgin trees in the less accessible areas; so much as doubtless to furnish material for the manufacture of lumber and wood products for many years to come. Tennessee has $16,000,000 capital invested in the timber business and 1,500,000 board feet are cut yearly.

In value of products, the flour-mill and grist-mill industry stands but little below that of lumber and timber products. The soil and climatic conditions of the State are conducive to the production of wheat and corn; but this industry does not depend upon local supplies of raw material; for much wheat and corn are shipped into Tennessee mills from the West and the Northwest, and the milling in transit privilege enjoyed for many years by Nashville, Tennessee's largest milling centre, has tended to stimulate this industry and place it upon a permanent and stable basis.

Other manufacturing industries of Tennessee in the order of their importance are: Foundry and machine-shop products; printing and publishing; cars and general shop construction and repairs by steam railroad companies; oil, cottonseed and coke; iron and steel blast furnaces; textiles, and a very large list of other industries aggregating 4,775 establishments in 1914 and covering almost all articles manufactured to meet the ordinary demands of modern life.

The summary of the manufactures of Tennessee for 1914, prepared by the Bureau of Census, gives the following statistics: Number of establishments, 4,775; persons engaged in manufactures, 88,514; proprietors and firm members, 5,142; salaried employees, 8,999; wage-earners (average number employed during the year), 74,373; primary horse power, 286,857; capital, $211,423,000; services, $44,910,000 (including salaries $11,828,000, wages $33,082,000); materials, $123,430,000; value of products, $212,071,000; value added by manufacture (value of products less cost of materials), $88,641,000.

This summary shows a consistent increase in the census report of 1914 as compared with that of 1909. In the order of their importance, from a percentage point of view, the increases for the several items named are as follows: Salaries, 28.8 per cent; capital, 25.9 per cent; materials, 18.7 per cent; primary horse power, 18.4 per cent; value of products, 17.7 per cent; wages, 17.1 per cent; value added by manufacture, 16.3 per cent. It must be borne in mind that the United States census with reference to manufactures excludes hand trades, building trades and neighborhood industries and takes account only of establishments conducted under the factory system. Furthermore, they cover only establishments having annual products valued at more than $500. The four large cities of the State, Nashville, Memphis, Chattanooga and Knoxville, have more than one-fourth of the total establishments of the State. In these cities are most of the very large manufacturing enterprises, such as the following in Nashville: Milling, printing, car-shop construction, stoves and ranges, fertilizer, tobacco and lumber. In Memphis lumber and allied wood-working industries, industries connected with cotton, particularly cottonseed oil mills, molasses mills. In Chattanooga iron and steel manufactures, hosiery mills, knitting mills, wood-working plants. In Knoxville marble enterprises, wood-working establishments, hosiery mills, knitting mills. Speaking generally, the outlook for manufactures in Tennessee is exceedingly encouraging, and it is likely that in the years to come this State will be a very large manufacturing State. This result will be brought about largely by two causes, cheap hydro-electric power and proximity to great natural resources.

Transportation.— Growing out of the agitation for internal improvements about the year 1830, the State undertook with enthusiasm the promotion of railroad development. The South Carolina Railroad, chartered in 1828, the construction of which began in 1829, doubtless furnished an impulse to the movement The desire was for an outlet to some Southern port for the products of agriculture and industry. The first railroad chartered in the State was the Memphis Railroad Company, a proposed line from Memphis to Pulaski, on 12 Dec. 1831. The line was never built. In 1836 the Hiwasse Railroad was chartered and ground broken in 1837, probably the first work ever done on a railroad in the State. This line now forms a part of the Southern Railway between Knoxville and Chattanooga and was completed in

1856. In 1845 the Nashville and Chattanooga Railroad Company was chartered and the track between Nashville and Chattanooga was finished in 1853, the first complete line of railroad operated in the State. In 1845 a great commercial convention was held at Memphis, over which John C. Calhoun presided, out of which grew the Memphis and Charleston Railroad, now a part of the Southern Railway.

The steam railroad mileage of the State for the fiscal year ended 30 June 1914, exclusive of switching and terminal companies, was 4,105.55, or 1.63 per cent of the total mileage of the United States. The State had 9.85 miles of line for each hundred square miles of territory and 18.42 miles of line for each 10,000 inhabitants. In 1870, with 1,492 miles, it ranked 12th in its proportion to the total mileage, In 1914 its standing in this respect was 29th, while as to mileage on the basis of territory it was 28th and on population 38th. Prior to the Constitutional Convention of 1870, the State gave large aid to railroad development and up to the Civil War period, had issued bonds for that purpose amounting to approximately $15,000,000.

For the calendar year 1914 the State levied taxes against 39 railroad corporations, having an assessed value of distributable and localized property of $90,787,256.25, upon which the tax for State purposes alone was $317,755.40. Excluding the special excise taxes of the government, the railroads in the State pay in annual taxes approximately $448 per mile of road. The six railroads of the State operating or controlling more than 50 miles of line, and which embrace about three-fourths of the total mileage, are as follows: Louisville and Nashville Railroad Company, 1,888 miles, including the Nashville, Chattanooga and Saint Louis Railway, with 899 miles; the Southern Railway Company, 985 miles, including the Mobile and Ohio Railroad Company with 119 miles, and the Virginia Southwestern Railway with 101 miles; the Illinois Central Railroad Company with 351 miles; the Tennessee Central Railroad Company, with 294 miles; the Cincinnati, New Orleans and Texas Pacific Railroad Company with 143 miles, and the Carolina, Clinchfield and Ohio Railroad with 55 miles. The freight rates of the State are equitable and the majority of the railroads have a maximum passenger rate of two and a half cents per mile. For the most part, the railroads are assisting to an unusual degree in the development of the resources along their lines.

The street railway mileage in the State in 1914 was 389.9, and had an assessed value for taxation of $14,607,388.89.

The Water-Power Resources of Tennessee. — To state in definite figures the amount of power which can and ultimately will be obtained from the rivers of Tennessee is an impossibility. Any comprehensive scheme of water-power development must, for its realization, ignore political boundaries. For this reason it is not possible to segregate the water-power resources of one State from those of the neighboring States. Furthermore, the quantity of power to be obtained from any given stream is wholly a question of the extent of possible storage of water in reservoirs, the construction of which forms an essential part of the water-power development. This question of reservoirs is itself complex, for it involves questions of vested rights, the agricultural value of lands to be flooded, the relocation of railroads which are already so situated as to render a great many otherwise attractive water-power projects impossible of realization, and other questions of a technical nature no less vital to even an estimate of the amount of power potential in a single river.

Such figures, therefore, as may be presented are to be regarded merely as estimates, and the following table, which has been compiled with great care from all the data available, must be so interpreted.

Summary of the Water Power Available for Development, Without Storage, Wholly Within Tennessee. Minimum Horse Power During the Six High-Water Months.

STREAM	Location	Horse power
Tennessee River	Shellmound to Chattanooga	58,800
Tennessee River	Chattanooga to Knoxville	*50,000
Hiwasse River	From Ocoee River to State Line	69,490
Ocoee River	From mouth to State Line	55,230
Clinch River	From Emory Creek to State Line	35,080
Powell River	From mouth to State Line	8,400
Little River	From mouth to source	4,190
Tellico River	From mouth to source	12,360
Little Tennessee River	From mouth to State Line	87,550
French Broad River	From mouth to State Line	60,000
Citico Creek	From mouth to source	4,000
Abrams Creek	From mouth to source	6,320
Little Pigeon River	From mouth to source	16,360
Nolichucky River and tributaries	From mouth to State Line	67,500
Pigeon River	From mouth to State Line	22,600
Holston River	From mouth to South Fork	56,000
South Fork Holston River	From mouth to State Line	13,500
Watauga River and tributaries	From mouth to State Line	39,800
Small tributaries of Tennessee River		32,340
Tributaries of Cumberland River		74,000
Minor additional streams		15,370
Small water powers not considered by United States Geological Survey †		40,000
Total		828,890
Total available for two-thirds of the time		1,020,000

* The United States Geological Survey ascribes 175,000 horse power to the Tennessee River from Chattanooga to Knoxville; but inasmuch as the interests of navigation would not permit of the development of all of this power, this figure has been reduced to 50,000. According to the report of the chief of engineers of the United States army, 20,000 horse power could economically be developed at a point about six miles from Knoxville.

† J. A. Switzer has estimated the small water powers of the State capable of being developed by individual farmers in units of 25 horse power and less to total 75,000 horse power. (Consult "Resources of Tennessee," Vol. I, No. I). For the purpose of this summary this figure has been reduced to 40,000 horse power.

The total amount of power which a comprehensive plan of development, such for instance as will be necessitated in the future by the exhaustion of cheap coal, will render available is undoubtedly more than double the above figure; quite probably more than triple the figure.

Present Development.— The large developments already completed within the State are comprised in the following table:

COMPANY	Location	River	Installed capacity
Chattanooga and Tennessee River Power Co.	Hales Bar	Tennessee	58,800 horse power
Tennessee Power Co. (two plants)	Parksville and Caney Creek	Ocoee	45,000 horse power
Tennessee Eastern Electric Co	Near Greenville	Nolichucky	16,000 horse power
Watauga Power Co	Near Elizabethton	Watauga	3,200 horse power

The Tennessee Power Company has constructed a third water-power plant, to develop 80,000 horse power, located on Caney Fork, a tributary of the Cumberland River.

Undoubtedly the dominant power interests in the State are those of the Tennessee Power Company. This company, beside owning the three water powers above, leases the plant of the Chattanooga and Tennessee River Power Company at Hales Bar, owns the steam power-plants of the Chattanooga Railway and Light Company, the Nashville Railway and Light Company and a third steam plant at Cleveland. It also holds an undeveloped water-power site, above the two already mentioned, on the Ocoee River. It has the most extensive transmission line in the State. This line connects all of the power-houses with each other and with the cities of Chattanooga, Nashville, Cleveland and Knoxville; and the company has a practical monopoly of the power business in the three first named places and it furnishes power to the Knoxville Railway and Light Company, which supplies the power requirements of Knoxville. Its transmission lines total over 300 miles.

The Tennessee Eastern Electric Company furnishes power to Greenville, Jonesboro and Johnson City; it has steam plants at Greenville and Johnson City and it operates the street car system of the last named place. The Aluminum Company of America, operating under the name of the Knoxville Power Company, has constructed a series of water-power plants on the Little Tennessee River which yield approximately 400,000 horse power. Of these plants, only one is located within Tennessee, the rest being situated in North Carolina, but almost all the power is utilized in the company's reduction works, located at Maryville, Tenn.

State Finances.— 1. *Bonded Indebtedness of the State.*— The status of interest-bearing debt of State up to 1 July 1915 and 1 Oct. 1915 was as follows:

4½ per cent temporary loan refunding bonds, 1 July 1915	$9,381,000
6 per cent temporary loan refunding bonds, 1 Oct. 1915	1,400,000
Short term notes, issued in 1915, 3 per cent interest, 1 July 1915	1,000,000
Total	$11,781,000

July and October 1915, being maturity dates, at which time refunding was due. The above indebtedness was converted into and sold as serial bonds, running 40 years bearing 4 per cent and 4½ per cent interest, averaging 4.28 per cent interest.

Bonds held by charitable and educational institutions:

5 per cent certificates of indebtedness	$14,000
6 per cent certificates of indebtedness	622,000
Total	$636,000

2. *State Tax.*— Both personal property and real estate, 35 cents.

3. *Aggregate assessed valuation of property* in Tennessee for 1913–14 was $560,997,621.

4. *Sinking Fund.*— Upon the adoption of the serial plan of retirement of bonded indebtedness, which of course provides for the semi-annual payment of interest and a portion of the principal, the sinking fund plan was abandoned. The interest payment and proportional payment of principal is stipulated in serial plan or contract, which obligation cannot be postponed by legislation and obviates the necessity of a sinking fund.

Assessment of 1913–14, railroad, telegraph, telephone and street railways:

Railroads	$90,787,256
Telephone and telegraph	6,362,425
Street railways	14,607,388
Increase 1915 combined properties	2,253,000
Total	$114,010,069

The estimated value of property owned by the State in 1883 was $1,579,475; estimated value in 1914, $5,316,378.

Sources of Revenue.— Taxes on polls, on property, on incomes, on sales of land, on exercise of privileges, on litigations, from fines and forfeitures, from merchants, from peddlers and from collateral inheritance tax. All taxes must be uniform.

Exemptions.— One thousand dollars, personal property, each resident taxpayer; United States, State and municipal property not used for rental; religious, charitable, scientific, literary and educational property, subject to certain minor limitations; agricultural and mechanical associations worth less than $10,000; all public thoroughfares and parks dedicated to public use; all growing crops, direct product of the soil.

Banks and Banking.— The following figures largely exhibit the condition of banks in Tennessee in March 1916:

	National	State
Number of banks	107	406
Capital paid in	$14,570,000	$14,216,359 02
Surplus and undivided profits	8,715,000	5,445,373 85
Actual cash	5,004,000	4,126,099 71
Total reserve	18,569,000	26,684,153 41
Deposits	76,035,000	74,712,165 89
Total resources	129,228,000	102,040,044 78

Tennessee has a modern banking law. The State banks are regarded with exceptional confidence by the public. It is optional with the State banks to assume double liability of stockholders. The State under its constitution cannot become the owner in whole or in part of any bank.

Government.—The separation of the powers of government into legislative, executive and judicial departments was specifically recognized in 1776, 1834 and 1870; and the 1796 constitution, also, without mentioning it, so organizes the government. Under the 1776 constitution the legislature elected the governor, who was given no veto power until 1870. Until 1853 the judges of the principal courts were elected by the legislature. Not until after 1834 were the justices of the peace elected by the people. The North Carolina and early Tennessee courts adopted with little hesitation the doctrine of judicial review of legislation. The power of the legislature has been made subject to gradually increasing limitations, both procedural and relating to the variety and scope of its enactments. In 1870 the reaction against the arbitrary acts of the reconstruction governors resulted in a decrease of the powers accorded the governor.

The constitution of Tennessee has reflected its economic and social history. The simple agricultural commonwealths of the 18th century, after securing the people against the encroachments upon their «rights» which had become so frequent under royal governors, demanded only an outline of the frame of government and a few other elementary provisions such as the regulation of the suffrage. The power of the land speculators showed itself clearly in the requirement of a specific land tax in 1796. The enthusiasm for internal improvements was apparent in the constitution of 1834; reaction against its abuse, and against prevalent careless methods of dealing with corporations, in the constitution of 1870. The relative decline of agriculture and the vast increase of mining and manufacturing interests, as well as the trend of population city-ward furnish the economic background for a new convention.

Education.— The public school system controlled by a State board of education; the denominational schools and colleges, the private preparatory schools and the several city systems constitute the means of education. Educational upbuilding has been marked since 1873 which is the time of the beginning of the three chief agencies within the State, namely: (1) The system of public schools, inaugurated by the State legislature; (2) The establishment of George Peabody College for Teachers by the Peabody Board of Trust, and (3) The founding of Vanderbilt University. The general growth of education has been from the eastern boundary of the State toward the west. Of the three grand divisions — East, Middle, West — East Tennessee has had the highest and most general development, while Middle Tennessee is second and West Tennessee the lowest.

Public Schools.—The University of Tennessee is the head of the public school system with all departments located at Knoxville, except the medical and dental colleges which are at Memphis. The department of agriculture maintains, jointly with the United States Department of Agriculture and the State department of agriculture, an extension division which takes to every county experts of every kind needed for farm development. Farm demonstration agents are employed in the counties receiving this service. Support is received from the Morrill Act Fund of 1890; the Nelson Fund, Act of 1907; the Land Grant Fund, Act of 1862; the Hatch Fund, Act of 1887; the Adams Fund, Act of 1906, and from the appropriations of the State legislature — aggregating an annual expenditure of from $350,000 to $400,000. An attendance of 1,000 students is maintained beyond that of the Summer School of the South which annually registers 1,500 attendance. Control of the university is centered in a board of trustees appointed by the governor, one from each Congressional district of the State.

The State board of education has under its direction the normal schools, the high schools and elementary schools through the officers of instruction. This board is appointed by the governor and consists of nine members, with the stipulation that not more than three members shall be from any one grand division of the State. The offices filled by the board are: The State superintendent of public instruction, State high school inspector, presidents of the normal schools, teachers of the normal schools, supervisors of elementary schools, conductors of teachers' institutes and the examiners of teachers' examination papers. Other duties of the board are: Examine teachers under a uniform State law; examine applicants for the position of county superintendent of schools; apportion the school fund as outlined by law; adopt schoolbooks, both elementary and high school; outline all courses of study; certificate all teachers, county superintendents and graduates of the elementary and high schools, and to issue such regulations as may be needed under legal provisions in the general supervision of the public school system.

The school fund is derived from county levies, which vary in amount, and are collected by the county trustees. However, one and one-half mills on the dollar of assessed property are mandatory for all counties through a State enactment. Also, the general education fund established in 1909 provides that 33⅓ per cent of the gross revenues of the State be expended for school purposes, same to be divided as follows: 61 per cent for elementary schools apportioned to the counties on a per capita basis; 10 per cent for county supervisions, consolidated schools, industrial work, salaries of county superintendents; 6 per cent to county high schools; 2 per cent to the Cookeville Polytechnic Institute; 1 per cent to school libraries; 13 per cent to normal schools; 7 per cent to the State University. A poll tax of $2 supplements this fund. The aggregate fund is approximately $8,000,000 — apportioned by the State Board of Education to a school population of 780,000 with 12,000 teachers whose average salary is $50 per month for a term of 130 days. Four normal schools are maintained, one of which is for negroes — with an annual total enrolment of 2,500. Seventy-one counties of 96 have county high schools with an enrolment of 12,500.

The Roman Catholic Church maintains 25 parochial schools, with 4,170 pupils, one college for boys with 350 students, five academies for girls with 619 pupils, two orphan asylums with 325 orphans, making a total of 5,464 young people now under Catholic care out of a Catholic population of 19,000.

Private Schools.— The famous Webb School at Bellbuckle is the pioneer of college preparatory schools in the territory southwest of the river Ohio. Others of the same type whose special purpose is to train boys for college are Branham and Hughes School at Spring Hill; Morgan School at Fayetteville; Hawkins School, Gallatin; Castle Heights, Lebanon; Battle Ground Academy, Franklin; McTyeire School, McKenzie; McFerrin School, Martin; Massey School, Pulaski; Peoples-Tucker School, Springfield; Montgomery Bell Academy, Nashville; Duncan School, Nashville; Bowen School, Nashville; Wallace School, Nashville; Baylor School, Chattanooga; McCallie School, Chattanooga; Columbia Military Academy; University School, Memphis; Sewanee Military Academy; Industrial School, Huntingdon.

Higher Institutions.— The following colleges are strongly supported and enjoying prosperous administrations: Vanderbilt University, Nashville; George Peabody College for Teachers (General Education Board), Nashville; University of Chattanooga (Methodist); Carson-Newman College, Jefferson City (Baptist); Milligan College (Disciple), Tusculum, (Presbyterian), Greeneville; Washington College (Presbyterian); University of Tennessee, Knoxville (State); Cumberland University, Lebanon (Presbyterian); Southwestern Presbyterian University, Clarksville (Presbyterian); Union University, Jackson (Baptist); Tennessee College, Murfreesboro (Baptist); University of the South, Sewanee (Episcopal); Maryville College, Maryville (Presbyterian); College of the Christian Brothers, Memphis (R. C.); Saint Cecilia's Academy, Nashville (R C.); Sacred Heart Institute, Memphis (R. C.).

Junior Colleges.— Several institutions have organized regular junior college curricula as follows: Ward-Belmont, Nashville; Buford College, Nashville; Martin College, Pulaski; Hiawassee College, Madisonville, and the State normal schools at Murfreesboro, Johnson City and Memphis.

Higher Institutions for Negroes.— The highest standards of efficiency are attained in the colored institutions which take their place alongside similar schools for the white race. Fisk University, Nashville (Congregational); Roger Williams, Nashville (Baptist); Walden University, Nashville (Methodist); Lane College, Jackson (Methodist); Knoxville College; Turner College, Shelbyville; Industrial Normal School, Nashville (State); Academy and Industrial School of the Immaculate Mother, Nashville (R. C.).

Charitable Institutions.— The following institutions receive their support from the State: The Central Hospital for Insane located near Nashville; the Western Hospital for Insane located at Boliver; the Eastern Hospital for Insane located at Bearden; the Reformatory for Boys located near Nashville; the Tennessee Industrial School located near Nashville; the Tennessee Confederate Soldiers' Home at Hermitage; three of the larger counties in Tennessee have their own industrial schools, namely, Shelby, Knox and Hamilton.

Throughout the State are a great many institutions which derive their support through voluntary contributions from individuals, or through societies organized for that purpose, such as the Masonic Home located near Nashville, the Odd Fellows Home at Clarksville and the Old Woman's Home at Nashville. Many counties in the State maintain charity institutions such as county asylums, poorhouses. The State has also in the past given aid to private institutions such as the Tennessee Children's Home, Finding Society and the School for Blind Girls.

Penal Institutions.— Penal institutions are the penitentiary, or State prison, to which persons convicted of felonies are sentenced; and county jails used for the detention of persons awaiting trial, or those who have been convicted of felony and are temporarily held until they may be conveyed to the penitentiary. Sentences for terms less than one year are to the county jail, and persons fined by the criminal courts and failing to pay such fines are also imprisoned therein. Under the law a county jail may be declared to be a workhouse, in which case the prisoners may be worked on the highways during the term of their sentences, or until their fines shall be paid according to a schedule of valuation placed upon their labor. The cities also have workhouses for the punishment of infractions of city ordinances authorized by State law. Workhouse prisoners may be transferred from one county to another, and hence the labor of prisoners from several counties may be applied to highways in one county together, an arrangement due to the fact that in most counties there are very few county prisoners.

The penitentiary, or State prison, was established under an act passed in 1829, and began to receive prisoners in 1831. It was conducted under the direct management of the State until 1870, except when held by the United States military forces from 1862 to 1865, and except when under an abortive lease in 1867–68. From 1870 to 1897 the lease system was in force, although the State at the same time employed a superintendent, wardens and physicians, to look after the interests of the prisoners and State, as well as could be done under the system.

The act of 1893 provided for a change to the State account system, with a provision permitting the hiring out of a part of the convicts at the main prison under contracts for labor by the day; also for the purchase of farm and coal lands. A farm of 1,100 acres, lying in a large bend of the river six miles below Nashville, was bought and a commodious modern prison was erected thereon. Later 2,400 acres were added to this prison farm. For coal mining purposes the State purchased the Brushy Mountain tract of 12,000 acres in Morgan and Anderson counties, and later purchased «Herbert Domain» of 10,000 acres in Bledsoe and partly in Cumberland, White and Van Buren counties. This latter tract is supposed to contain good coal, but it has not been opened. In the same act the State is forbidden to mine by convict labor except in the State's mine. A large number of convicts are employed at Brushy Mountain, the number on 1 Dec. 1914 being 616, while those in the main prison at the same time were 1,243; total, 1,859. White convicts were 651, colored 1,208. Females 62, all at Nashville.

At the main prison two-thirds of the convicts are employed in manufacture, blacksmithing, farming, clerical and domestic work, etc., under direct management; one-third are similarly employed under contracts with outside parties, but all are kept under the eye of trusted State officials to see that the humane provisions of the law are carried out.

During 1915–16 200 convicts were hired to Campbell County, and 50 to Williamson, and employed in working on public roads at 10 cents an hour. This new departure seems to be successful; there is a strong movement so to employ the mass of the convicts in the future. The Indeterminate Sentence Law is in force.

In 1915 an act was passed creating the Board of Control, with its office at Nashville, whereby the several public institutions of the State, as the penitentiary, State Reformatory, Tennessee Industrial School, asylums for the insane, deaf, dumb and blind schools, are brought under one board for their better and more uniform management. The statistics of the operations of this board have not been issued for 1915–16.

For a number of years following 1897, when the new system for the prison went into effect, profits over expenses were large, often running over $200,000 net profits a year, but in more recent years the receipts have not much exceeded expenses.

While the convicts were employed under the lease system and many of them confined in the old prison which was, from 1887 to 1897, within the city limits of Nashville, the death rate was high, being at times over 3 per cent; the report to the end of 1914 shows a death rate of 9.3 per cent.

There are two institutions which are semi-penal in character, the Tennessee Reformatory for Boys and the Tennessee Industrial School. The reformatory is in a different part of Davidson County from the main prison, but is in a way connected with it, and to it are committed young convicts with a view to reformation and schooling. The judges of the Criminal Courts may send any convict under 18 years of age to this reformatory, and nearly all such are so disposed of. The population of the reformatory is 497.

The industrial school is designed for the care of young persons who are without the care of guardians or provident parents and such as are found wandering or loitering in company of evil repute. The pupils or inmates of the industrial school number 860. Several different counties maintain institutions of the same kind, and they are recognized by the courts. The discipline is of great value, and there are many pupils who have not been placed in the school by reason of any complaint against them.

The act of 1911 establishes the Juvenile Court and divides young offenders and unfortunates into two main classes, namely, delinquent and dependent. Delinquents are those who have committed some penal offense, while dependents are such as have been mentioned herein in connection with the industrial school. The heads of the Juvenile Courts in the largest cities are the city judges, but in nearly all the counties this position is assigned to the judge or chairman of the County Court. No person under the age of 16 years can now be tried and sentenced, in the first instance, to the penitentiary, jail or workhouse, it being the duty of the judge of the Criminal Court whenever a person of such age is indicted to turn such youth over to the Juvenile Court. The Juvenile Court shall send him to the reformatory, industrial school or other institution of the kind, or may commit him to the care of a guardian, for a definite period; and shall retain supervision until the youth shall be of age. The person accused has free legal counsel, and his parents may defend for him. If the youth prove totally intractable, after due effort at reformation, he may be tried later as any other criminal and sentenced to prison. By the act of 1915 capital punishment was abolished.

Archæology. *Eolithic and palæolithic Man.* —When and from whence primitive man first came into the section now known as Tennessee is still undecided. It is claimed, and also denied, that remains of man of same geological age and culture as that of the earliest and rudest of eolithic and palæolithic man of Europe have been found in several sections of the United States, but no well-authenticated finds of such have been made in Tennessee. If eolithic or palæolithic man ever existed on this continent, the caverns and rock-shelters of the Cumberland and Tennessee valleys offered ideal places for their abodes. These were about the right distance below the great ice fields — which reached to the Ohio River, at or near the end of the last great Ice Age — to offer practically the same climate and shelter in which eolithic and palæolithic man were found in Europe.

The Mound Builders.— Formerly it was believed that the ancient mounds and fortifications of this section were built by a long-vanished people, of lighter complexion and different race from the Indians. This belief originated from some of the early Indians telling the whites that the Indians did not build the mounds, but they were built by an earlier white race, who lived here before the Indians came, and the Indians conquered and exterminated them. Modern research has proved this to be untrue. It is now well established that these great earthworks were built by Indians.

The contents of these mounds show them to have been erected by men of the same habits of life, same degree of barbarism, same religious customs as the Indians found here by the first whites. In fact many of these mounds contain articles of European make, which the Indians had obtained from the whites. DeSoto in 1540 found the southern Indians using these mounds for sites for their religious houses, and for the residences of their chief men.

Scattered along the larger water courses of Tennessee are probably over 100 of these ancient mounds. Each mound is usually accompanied by a village site and hundreds of ancient graves. These remains are of widely different ages and show somewhat different artifacts and customs. It is probably true that there are as many ancient Indian graves in Tennessee as there are white graves. The ancient population of Tennessee was probably never, at any one time, over 20,000; but Indians have roved over this section, changing town sites in some instances, for several thousand years, giving rise to the many remains of widely different ages.

Principal Indian Tribes.— At the time the whites first visited this section Cherokees, Shawnees and Chickasaws were the principal tribes inhabiting Tennessee.

The Cherokees.— The Cherokees were a strong separate tribe of the Iroquoian stock. They at one time held the entire southern Allegheny region in southwestern Virginia, western North Carolina, west-South Carolina, northern Georgia, northeastern Alabama and East Tennessee. De Soto found them in this section as early as 1540 and they probably had been here long before. The Cherokees also claimed all the land between Tennessee and the Cumberland River and on to the Ohio River, but had few or no towns in that region. The Cherokees aided by the Chickasaws drove the Shawnees from the region around Nashville, about the year 1710. The Shawnees gradually moved north of the Ohio. The feud between the Cherokees and the Shawnees continuing, both parties ceased to hunt or live to any large extent in the disputed territory in Middle Tennessee. So, for nearly 60 years after 1710, this fertile section was unoccupied and became full of game. The whites were attracted by the game, rich soil and comparative freedom from Indians, and began settlements under General Robertson, at what is now Nashville, about 1779. The Cherokees were gradually forced to give up their lands and emigrate to Texas and the Indian Territory, while a few remained in the mountains of western North Carolina, and 1,376 are now living on Qualla Reservation in Swain County, N. C., and 300 on Cheowah Reservation in Graham County, N. C.

The Shawnees.— The Shawnees have a most interesting history. They originally came from the north and were of Algonquian stock. In the year 1669 when we first begin to have any authentic history of them, we find a part of the tribe living in the Cumberland Valley in Middle Tennessee, and ranging from the Tennessee River on the south to the Kentucky River on the north. One of their principal towns was on the present site of Nashville; another, and earlier one, at what is now Castalian Springs, in Summer County, Tenn. The Shawnees at this time were living in friendship with the Cherokees, and it is claimed by the Cherokees that the Shawnees were occupying this territory by their permission. About 1707 war arose between the Shawnees and the more powerful Cherokees. In consequence small bodies of Shawnees were continually leaving and seeking their friends and kindred north of the Ohio River. The last of the Shawnees left in the Cumberland Valley attempted to leave their home at Nashville, and join their brethren in the north about 1710. These were ambushed by the Cherokees and their allies — the Chickasaws — on Cumberland River just above the mouth of the Harpeth, and practically all this body of Shawnees were slain. Some of the Shawnees from the Cumberland, after living for a time in Kentucky, formed a settlement at Shawneetown, Ill. About 1730 these removed to Ohio and joined other Shawnees. About 1750 these western Shawnees were joined by the eastern branch of the tribe. This eastern branch had originated in the north, later emigrated to the headwaters of the Santee and Peedee rivers in South Carolina. Gradually driven thence by the warlike Catawbas, during the period 1690 to 1720, they drifted north, building the old Shawnee towns of Winchester, Va., and Oldtown, Md., on their way. They finally established themselves in Lancaster County, Pa. They made a treaty with William Penn in 1701. It is said they had a copy of this treaty 50 years later. The eastern and western branches of the tribe having joined in Ohio, they became the allies of the French, and for nearly 40 years were constantly at war with the English, or the citizens of the newly-formed United States. Many of the expeditions sent to the country north of the Ohio during the War of the Revolution were against the Shawnees, and most of the bloody work in northern Kentucky was done by the Shawnees. When peace had been declared after the War of Revolution a considerable body accepted the invitation of the Spanish government to settle near Cape Girardeau, Mo., in what was then Spanish territory. Another party of Shawnees settled on White River in Indiana. From this last section of the tribe sprang the great Tecumseh and his twin brother, Tenskwatawa, the Prophet. The Prophet was defeated by Harrison at the battle of Tippecanoe in 1811. The warlike spirit of the Shawnees was broken by this overwhelming defeat. About 1825 the various sections of the tribe began moving west to a reservation in Kansas. About 1845 a large part of the Kansas section moved to the Canadian River country of the Indian Territory.

Military History.— Tennessee is designated the «Volunteer» State — a name acquired in the war with Mexico. Her military history begins at King's Mountain during the Revolution. Creasy in his 'Fifteen Decisive Battles of the World,' says the battle of Saratoga is the decisive one in our Revolutionary struggle; if that is so, King's Mountain is second in importance to that engagement alone.

This battle was fought on 25 Sept. 1780. The force was under the command of Cols. John Sevier, Isaac Shelby and William Campbell, and composed entirely of East Tennessee mountaineers, who rendezvoused at Sycamore Falls on the Watauga River, several days before their departure to intercept the British forces under the command of Col. Patrick Ferguson, who was advancing from the Carolinas to join the army of Lord Cornwallis in Virginia. The victory of the Tennesseans was complete. Ferguson was killed and his whole army either killed or captured. His sword and sash are among the relics in the Tennessee Historical Society at Nashville, also the gun with which he was killed. This battle prevented the junction of the two British forces and hastened the surrender of Cornwallis to General Washington at Yorktown, which ended the war and gave us our independence.

Tennessee became a State in 1796. Since

that date it has taken an active and leading part in all the wars in which the country has been engaged. In the War of 1812 she furnished 28,000 troops and had double the number of any other State in the battle of New Orleans, fought by General Jackson — one of her sons — on the 8 Jan. 1815, in which the British commander, General Packenham, was killed. In the several Indian wars east of the Mississippi — in the States of Florida, Georgia, Alabama and Tennessee — she furnished nearly all of the soldiers engaged, as well as the commanding officers — Jackson, Houston, Coffee and Carroll. The happy ending of these wars gave peace and security to life and property to the people of these States against the torch, tomahawk and scalping knife of the cruel, treacherous and relentless savage.

The principal battles in these Indian wars were Tallahatchee, Tuscaloosa, Emuckfau, Erotochapco, on the Tallapoosa River, and the decisive battle of the Horseshoe, which ended the Creek War — their noted chief and leader, Red Eagle, being captured.

The next link in her military history is the part she took in the Mexican War of the 40's. Under proclamation of President Polk, Gov. Aaron V. Brown called for the enlistment of 2,800 troops. The number of 30,000 immediately responded, which gave gave to her the title of the «Volunteer» State. Two regiments of infantry were accepted, the First Tennessee, under Col. William B. Campbell, and the Second, under Col. William T. Haskell, together with several cavalry companies. She furnished one major-general, Gideon J. Pillow. The principal battles in which her troops took part were Cerro Gordo, Cherubusco, Molino del Rey and Chepultepec, entering the city of Mexico under the command of Gen. Winfield Scott. During our Civil War Tennessee was one of the principal battle grounds, Virginia being the other. Her geographical limits and location between the two contending sections — extending rhomboidal in shape — nearly 500 miles, from the Great Smoky range on the east to the Mississippi River on the west — necessarily made her soil the theatre of action of the two hostile armies and for numerous raids and engagements of cavalry and mounted infantry of both sections. The result was there were 454 engagements or affairs-at-arms within her borders, more than in any other State, during her fighting period, from 12 Dec. 1861, when the first clash of arms occurred at Morristown in East Tennessee, till the last engagement on 12 June 1865 at Plum Butte.

These affairs-at-arms include such conflicts as the battles of Forts Henry and Donelson — the former on the Tennessee, the latter on the Cumberland — Shiloh, Murfreesboro, Fort Pillow, Island Ten, the naval battle at Memphis, the two battles of Missionary Ridge, the closing scenes of Chickamauga and the battles of Franklin and Nashville in December 1864.

Her regiments of infantry reached the number of 84. The total number of troops furnished to both armies were 145,000, 30,000 of which were in the Union army. She had 27 regiments, 15 battalions and 84 miscellaneous companies of cavalry, making a total of 126 cavalry commands and 28 companies of light or field artillery; thus showing that Tennessee furnished more soldiers during our Civil War than any other Southern State, North Carolina furnishing a few thousand more to the armies of the South than she did.

She had in active service 1 lieutenant-general, 9 major-generals, 33 brigadier-generals and 153 colonels, with lieutenant-colonels and majors in proportion. She had nine general officers killed in battle — to wit: Zollicoffer, Hatton, Smith, Tyler, Strahl, Carter, McCulloch, Adams and Rains.

The semi-military organizations of bivouacs and chapters had their origin in Nashville. The celebrated Ku Klux-Klan (q.v.), which worked for peace and security, not only for her own people, but for the entire South, also originated in one of her towns — Pulaski — in the county of Giles.

To show to what extent Tennessee was the theatre of active hostilities from 1861 to 1865, the general government maintains seven cemeteries in the State, in which 42,000 Federal soldiers are buried.

In the War with Germany in 1917–18 the State's gross quota was placed at 22,158; enlistment credits totaled 7,592; total enlistments, 11,899; the net quota, 14,528. The total number of registrants under the Selective Service Law was 188,946, of whom 54,827 were called for examination. Of these 15,909 were accepted, making the ratio to those called for examination 29.02 per cent. There were 34,069 colored registrants, of whom 7,940 were called for examination and 2,866 were accepted. The aliens from Entente countries, who registered, numbered 794; 73 were from neutral states; 44 were alien enemies.

State Formation.— The State of Tennessee was formed out of the western half of North Carolina. The first white men of whom we have any account to set foot on Tennessee soil were De Soto and his band of adventurers, in 1541. In 1662 La Salle built a fort which he called Prudhomme, where Memphis now stands. Fort Loudon on the Little Tennessee River, 30 miles below Knoxville, was built and occupied by the British in 1756. In 1760 it was surrendered to the Indians on condition that the troops and their families should be allowed to return to the Eastern settlements, but most of them were treacherously massacred the morning after leaving the fort. In 1769 Capt. Wm. Bean and his family built a cabin at the mouth of Boon's Creek. His son Russell was probably the first white child to be born in Tennessee. Within a few months a number of families from eastern North Carolina and Virginia located in the same vicinity. It was called The Watauga Settlement. In 1771 Parker and Carter set up a store to trade with the Indians where Rogersville now is. This was called The Carter Settlement. The next year Jacob Brown established a store on the Nollichucky River. In a short time many settlers built cabins around these stores. Another settlement was made on the Holston River, which soon became an important centre. These pioneers being far from the mother State, without government and without protection, in 1772 organized themselves into the Watauga Association, the purpose of which was to protect themselves and to dispense justice among the colonists. The leaders were John Sevier and James Robertson. The Watauga Association was the foundation of the Commonwealth of Tennessee. Roosevelt says that these were the first white men of America to establish a free and independent community on the continent. In the Spring of 1776 Nancy Ward — a friendly Indian woman — informed the whites that 700 Indian warriors who had been supplied by the British with arms and ammunition for the purpose, under Dragging Canoe and Old Abraham, were preparing to attack Heaton's and the Watauga forts and destroy the settlers. The Indians were defeated in two battles. The settlers, when the Revolutionary War began, named their country Washington District and voted themselves indebted to the United Colonies for their share of the general expenses of the war.[s] In August 1776 113 of the pioneers signed a petition to be annexed to North Carolina. All but two of these signed with their own hands. Two made their «marks.» In November following four delegates from Washington District were sent to the Provincial Congress of North Carolina. In 1777 Washington District became Washington County and embraced all of what is now Tennessee. The battle of King's Mountain 3 Oct. 1780, which has been termed the turning point in the Revolutionary War, was chiefly won by the Tennessee patriots under John Sevier and Isaac Shelby. In 1784 North Carolina ceded to the United States that part of her territory which is embraced by the present State of Tennessee and gave Congress one year in which to accept or reject the grant. No arrangements satisfactory to the frontiersmen were made for a government, which caused great dissatisfaction among the people who decided to set up a government of their own. At this time there were three counties, Washington, Sullivan and Greene. Each county selected delegates who met at Jonesborough, the oldest town in the Territory August 1784 and elected John Sevier president, and Landon Carter secretary. The convention resolved to form a new State and provided for another convention to form a constitution and start the new government. Instead of a new constitution the convention adopted that of North Carolina. The new State was given the name Franklin. Sevier was elected governor and all other officers, civil and military, were elected. The governor of North Carolina issued his proclamation ordering the people to disband and return to their allegiance to the mother State. The people were divided, some favoring Franklin and others North Carolina. This division in public sentiment engendered much bad feeling and strife. Sevier tried to persuade North Carolina to agree to the independence of Franklin and to have Congress recognize it, but failed in both. In 1788 Sevier was arrested and Franklin collapsed. A general pardon was granted to the disaffected people. Sevier was elected to the senate of North Carolina and was restored to his former office of brigadier-general of Washington District.

A party of men called «the long hunters» explored Middle Tennessee — the Cumberlanc country — in 1778. They made a clearing at Bledsoe's Lick and planted corn the following year. In 1779 James Robertson, called «the Father of Middle Tennessee,» with a number of others, settled where Nashville now is. Their families came by water, down the Holston, the Tennessee, up the Ohio and the Cumberland, a distance of a thousand miles the next spring. Several other settlements were made the same year. On 13 May 1780 each settlement sent representatives to Nashborough where a compact of government was entered into and signed by 256 men, only one of whom was unable to sign his name. James Robertson was chosen chairman and was practically the governor of the new settlements. In 1783 the Cumberland settlements were organized into Davidson County, N. C. The county embraced all of Middle Tennessee north of Duck River. A court was established. Nashborough was changed to Nashville and was made the seat of government for the county in 1784. At that time Spain claimed Alabama, Mississippi, Tennessee and western Kentucky and closed the Mississippi River to the commerce of the settlers whom the Spanish treated as intruders. The Spanish supplied the Indians with arms and ammunition and incited them to acts of hostility against the whites. From the summer of 1780 to 1794 the frontier people were in constant danger, many of them, men, women and children, being killed and much property destroyed or stolen. After the cession by North Carolina and its acceptance by Congress in 1790, Robertson was made brigadier-general of the district. Governor Blount was ordered by the President to permit no attacks on the Indians. The Spanish became angered and refused to complete a treaty for the free navigation of the Mississippi. Robertson learned that the Spanish traders were buying American scalps from the Indians and were instigating raids on his people. His brother, his son and many others were killed and others wounded. These last acts so incensed the whites that Robertson ordered an attack on the Cherokee towns below Chattanooga. Five towns were destroyed and many Indians killed. Then came peace for the pioneers. The Secretary of War severely condemned this act of just retribution, which injustice so incensed the people in the West that many of them favored setting up a separate government, or casting their lot with Spain. One of the first acts of North Carolina, after becoming a State of the Union, was to make to Congress a second cession of her western territory. This was on 25 Feb. 1790. The cession was accepted on 2 April. On 8 June President Washington commissioned William Blount governor of the Territory belonging to the United States south of the river Ohio. In 1775 an enumeration disclosed the fact that there were more than 60,000 inhabitants in the Territory. A constitutional convention was called and completed its labors 6 February and the people asked to be admitted into the Union as a State. The act admitting Tennessee was approved by Washington on 1 June 1796.

Constitutional History.— Tennessee as already stated was originally the Western Territory recognized as belonging to North Carolina and, during its early settlement, lived under the nominal jurisdiction of that province and later of that State, whose political institutions it was to inherit. In several instances temporary compacts were drawn up by isolated communities until the jurisdiction of North

Carolina could in fact be extended to them. The insurrectionary state of Franklin adopted the constitution which North Carolina had framed on declaring its independence in 1776. After the cession of North Carolina's western possessions to the United States, the organic law of the land was the act of Congress for the government of the Territory Northwest of the River Ohio, made applicable to the Southwest Territory by a separate act.

With this experience in constitution-making and having before them the newly-adopted Constitution of the United States, the people of Tennessee sent their representatives to a convention at Knoxville in 1796 to form the constitution under which they were to live as a State of the Union so soon as Congress should recognize their demand for Statehood. Like the North Carolina constitution, it was adopted in committee and not submitted to popular vote. William Blount, governor of the Southwest Territory, was president of the convention and Andrew Jackson, a prominent member, is said to have suggested that the name of the new State should be Tennessee.

The constitution of 1796 remained unchanged until 1834 when another convention, with William B. Carter as chairman, met in response to a genuine popular demand for alterations that would bring the constitution in accord with growth of the State and the spirit of the times. A new instrument was drawn up and submitted for adoption to the electorate as established by it.

Amendments were adopted in 1853 and 1865 and in 1869 a convention to meet the following year was called by the legislature. John C. Brown was made president by the convention. In 1897 a proposal by the legislature to hold another election was disapproved by the voters and in 1904 a number of amendments submitted by the legislature were likewise rejected.

Aside from the inevitable constitutional evolution through court decisions, legislative and administrative action and the changing conceptions of the people, the rapidly changing political and social life of the last generation has met with no constitutional response. Previous to the Civil War, however, the naturally gradual development of the Tennessee constitution corresponded with the growth of State constitutions generally. In length and complexity it advanced from the less than 5,000-word instrument adopted by North Carolina in 1776 to the 14,000-word constitution of 1870. The North Carolina constitution placed property qualifications on both voting and office-holding. In 1796 what amounted to manhood suffrage was established for freemen. The 1834 constitution omitted all property qualifications but disfranchised free negroes. The 1870 constitution contains much added detail, but few changes of general importance. The 18th century declarations of the rights of individuals have continued almost unchanged to the present.

Civil and Political History.— During the early years of Statehood the two problems of chief importance were the danger from the Indians and the settlement of land titles. The two early centres of Tennessee were far apart, divided by rough mountainous country. It was many years before one could journey from Knoxville to Nashville without crossing land in the possession of Indian tribes. Strip by strip was bought from the Indians by the United States government. The region between the Tennessee and the Mississippi rivers known as "the Western District" was not open to white settlement until 1818; the last lands held by the Cherokees, constituting the southeastern corner of the State, were not purchased until the treaty of New Echota.

Land titles were derived from North Carolina. Ownership was acquired through military warrants by which the State undertook to pay its soldiers in land, or by purchase, through which means much of the North Carolina paper currency was redeemed. Liberal rights of preemption were given to squatters. Upon the cession of the Tennessee country to the United States, and the later erection of the State of Tennessee, there arose a long and complicated dispute to which North Carolina, Tennessee and the United States government were parties. This matter of the public lands gravely affected the development of public support of education, internal improvement and banking. In the earlier period speculation in land also was a noteworthy factor.

For many years John Sevier was the most prominent figure in the State's life. His influence was identified with East Tennessee, the oldest section of the State. As the middle and western parts were settled, Indian wars and national affairs brought into prominence the personality of Andrew Jackson, but when Jackson became President resentment against some of his actions and against his efforts to continue domination over Tennessee politics led to the rise of a vigorous Whig party, which usually prevailed in national elections. From 1835 to 1855 Tennessee was a bitterly contested State. Its relatively large population and the closeness of its vote gave it a prominence in national politics. Hugh Lawson White, John Bell, Andrew J. Donelson were nominees for the Presidency or Vice-Presidency who were unsuccessful. James K. Polk was elected President in 1844, and Andrew Johnson Vice-President in 1864. The prominence of these, and a host of other men, was due to the fact that Tennessee in this period constituted a type and was a true representative of the West.

Within the State, matters of internal improvement, especially railroads, banking, education, were prominent in political discussion. The State was almost entirely agricultural, the population of the towns being relatively very small. Slavery existed all over the State. In East Tennessee, however, there arose a decided anti-slavery movement which ran its course when the most active opponents of the system emigrated from the State. Physical differences left a positive stamp upon the attitude of the different parts of the State toward slavery. East Tennessee had relatively few slaves: the western district, on the contrary, developed like Mississippi. Sentiment in the State was conservative and devoted to the Union. Secession was refused by popular vote until after Lincoln's call for troops; then a fever of sympathy with the States of the South swept over Tennessee with the exception of the eastern region where Andrew Johnson and William G. ("Parson") Brownlow, always hitherto the bitterest political enemies, now joined in support of the Union. The course of military events soon led to the domination of East Tennessee, strongly Unionist in sympathy, by Confederate forces who kept open the line of communication from the Southwest to Richmond, while the Federal successes at Fort Pillow and Fort Donelson threw Middle and West Tennessee into the possession of the Federal authorities under whom Andrew Johnson was appointed governor. The régime of Unionist East Tennessee was perpetuated after the war in the administration of Governor Brownlow, which was characterized by enormous additions to the State debt and by rigorous repression of those formerly in control of the political affairs of the State. This state of affairs did not come to an end until 1870, when the Democratic party again came into control. Since then Republican East Tennessee has been dominated by the Democratic remainder of the State, except when some particular question such as the settlement of the State debt or the establishment of State-wide prohibition have divided the Democratic party and brought about the election of a Republican governor. In politics, in recent years, the prohibition question has had first place, and other matters have not received due attention. The constitution has not been amended since 1870. A notable advance was made, however, in the field of public education with the establishment of a system of county high schools and State normal schools.

LIST OF GOVERNORS.

William Blount	Territorial governor till	1796
John Sevier	Democratic-Republican	1796–1801
Archibald Roan	" "	1801–03
John Sevier	" "	1803–09

Ben W. Hooper	Republican	1911–15
Thomas C. Rye	Democrat	1915–19

Population.— Tennessee has a population of 2,184,789 (census 1910). The government figures show that of this population about 80 per cent are of the farming class. Density of population, 52.4 per square mile. Of the entire population of the State, 20 per cent reside in the cities of 2,500 and upward. Of the total population 78.3 per cent are white and 21.7 per cent negroes. In the total population of the State there are 1,081,290 females and 1,103,491 males. The total voting population is 552,668, 78 per cent being white. The total number of children of school age (6 to 20 years) is 738,-478. The total number of illiterates in the State (over 10 years) is 221,071, representing 13.6 per cent of the total population, as compared to 20.7 per cent in 1900. The total number of dwellings in Tennessee is 444,814. Total number of families, 462,553. Average number per family, 4.7.

Immigration.— Immigrants to the State are heartily welcomed with that geniality and hospitality which the new South has inherited from the old. Tennessee is not dominated by the arrogance of wealth, neither is it overbalanced by its city population. Prejudice of the country against the town or of town against country is a thing of the past. The numerous commercial organizations offer inducements to capital with the assurance that though a stone wall might be built about the State, yet its resources are so great and diversified that even then 10 times its present population would have available every necessity, every comfort and every luxury. In conclusion, it may be said truly that Tennessee is large in area, in wealth, in industries and truly magnificent in its possibilities, and the day for indulging provincialism is forever gone.

GEORGE C. PORTER.

TENNESSEE, a large river formed by the Holston from Virginia and the French Broad from North Carolina, which unite near Knoxville, in eastern Tennessee. It flows southwest, entering Alabama in the northeastern part of the State and continuing southwest to the centre of Marshall County, where it turns northwest and flows across the northern part of Alabama, re-entering Tennessee in Hardin County. From here the course of the river is nearly due north across the State of Tennessee and the western part of Kentucky, to the Ohio River, which it enters at Paducah, Ky. The length of the river is about 800 miles; from the source of the Holston to the mouth of the Tennessee is about 1,200 miles; the area drained is about 40,000 square miles. It is navigable, without artificial aid, to Florence, in Lauderdale County, Ala., a distance of 280 miles from Paducah. Just above Florence are the Muscle Shoals, about 20 miles long, which are navigable for about one month in the spring. A canal has been built to overcome this obstruction to navigation. Above the Shoals, the river is navigable for light-draft steamers nearly all the year. The navigable waters of the upper course of the river, together with the Holston, are about 930 miles. The principal tributaries are the Clinch, Duck, Elk, Hiawassee and Sequatchie rivers. The Tennessee is the largest tributary of the Ohio River, entering the Ohio 10 miles from the mouth of the Cumberland River. See BOUNDARIES OF THE UNITED STATES.

TENNESSEE, Army of the, one of the divisions of the Federal army in the Civil War. After the battle of Shiloh (q.v.) it was commanded by General Halleck and later by Grant, Sherman and others.

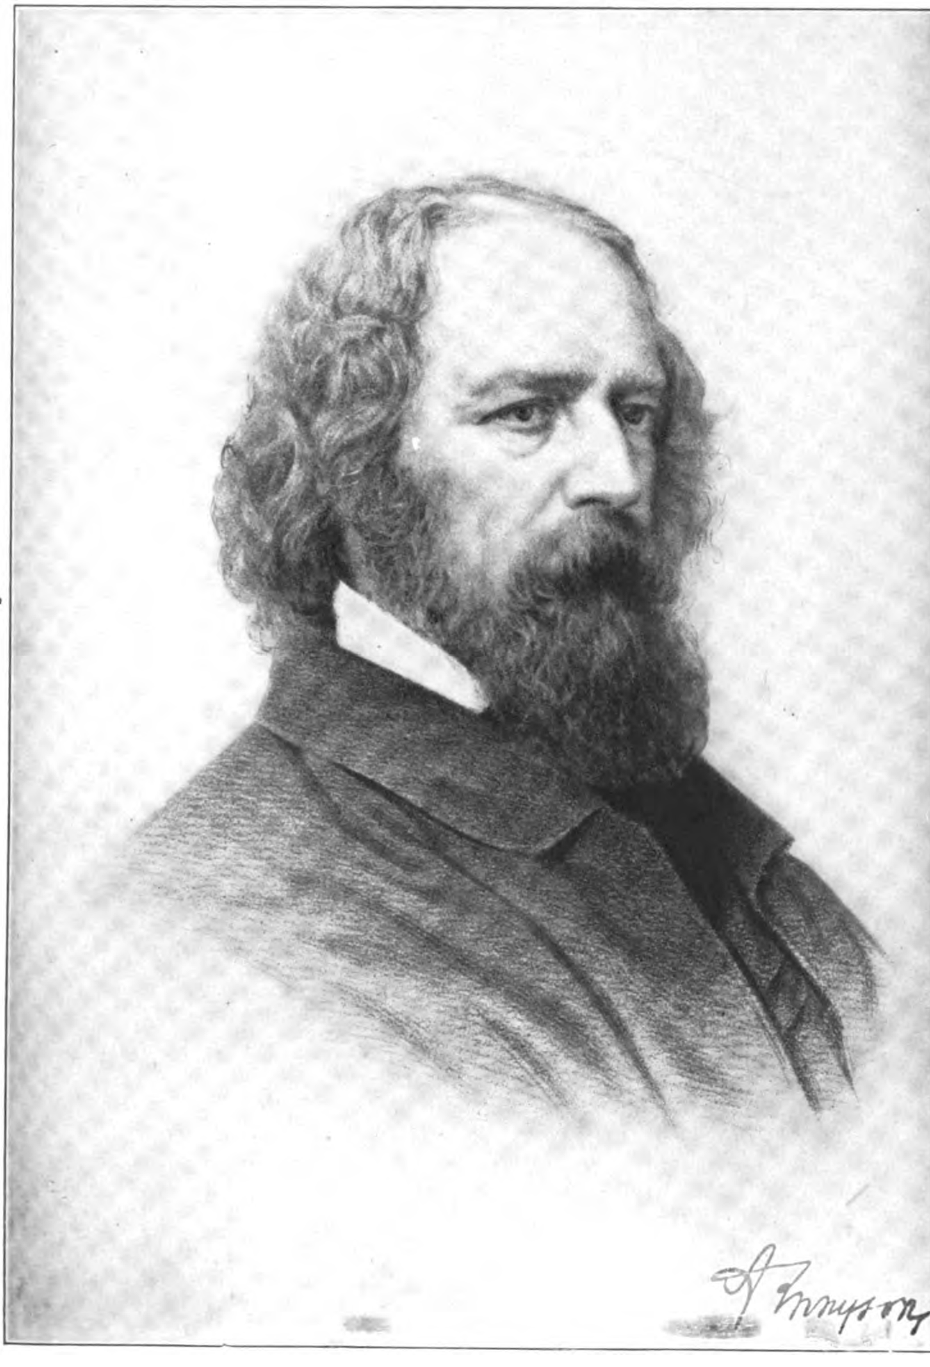
TENNESSEE, University of, the State university located at Knoxville, Tenn. It was established in 1794 as Blount College, a nonsectarian institution and was incorporated by the first general assembly of the Territory southwest of the Ohio; in 1807 the name was changed to East Tennessee College and in 1840 to East Tennessee University. In 1869 the State legislature gave to the university the control of the Congressional land grant of 1862; in 1879 it was further recognized as a State institution by an act connecting it with the public schools of the State, and in that year its name was changed to the University of Tennessee. The board of trustees consists of 14 members appointed by the governor and confirmed by the senate for a term of 12 years from each Congressional district and two each from Knoxville and Memphis; the governor, the commissioner of agriculture and superintendent of public instruction are additional members ex officio. The university is coeducational. It comprises colleges of liberal arts, agriculture, including experiment stations, engineering and law at Knoxville; colleges of medicine, of dentistry and school of pharmacy at Memphis. Military science and drill are a part of the curriculum and are required of the men students in the freshmen and sophomore classes. In 1902 a teachers' summer school was opened on the university grounds with the co-operation of the university authorities. (See SUMMER SCHOOL OF THE SOUTH). The university has a division of extension, including agriculture, home economics, public health, rural engineering and education. Short winter courses are given in the agricultural, home economics and engineering departments. The campus proper at Knoxville contains 39.9 acres, at Memphis 1.7 acres, and the university farms contain 1,634 acres; there are 18 buildings, including dormitories on the campus. The productive funds amount to $427,000; the annual income to approximately $500,000; the library contains 40,000 volumes. The students number 2,000 to 2,500 normally and the faculty over 200.

TENNESSEE CENTENNIAL EXPOSITION, held at Nashville, Tenn., in celebration of the State's 100th anniversary of its entrance into the Union. Its dominant purpose was to show the history and development of the State and to emphasize its resources. The site chosen was West Side Park, a former race-course, a tract of about 200 acres. More than 100 buildings were erected, and the departments included agriculture, art, commerce, customs, education and hygiene, government, history, machinery, minerals, forestry, transportation, women's work, etc. The president of the exposition was John W. Thomas. The total attendance was 1,786,714; the receipts were $1,101,285, exceeding by $39 the disbursements. Consult Justi, 'The Official History of the Tennessee Centennial Exposition' (1898).

TENNIEL, tĕn-nēl', SIR **John,** English cartoonist: b. London, 1820; d. 1914. He received no regular art training. In 1845 he was selected by open competition to paint a fresco in the Houses of Parliament at Westminster, but he is better known as a book-illustrator and a cartoonist in *Punch,* on whose staff he worked during the 50 years 1851–1901. He also illustrated a number of important books. He was knighted in 1893. His cartoons are unique as contributions to a comic paper, being of classic severity in line and expression and often tinged with a tragic seriousness of meaning which exhibits their author as not only a great caricaturist but also a great painter. Yet nothing can be more powerful than the political satire which characterizes the majority of them, a satire whose geniality neither deadens the life nor blunts the point of their irresistible humor.

TENNIS. See LAWN TENNIS; RACKETS.

TENNYSON, Alfred, LORD, English poet: b. Somersby, Lincolnshire, 6 Aug. 1809; d. Aldworth, near Haslemere, on the border of Sussex and Surrey, 6 Oct. 1892. His boyhood was passed at his father's country rectory, in an atmosphere that was full of poetry and music; and at a very early age he began to try his wings in verse. Some of his youthful efforts were published in partnership with his elder brother Charles, in 1827, in a volume entitled 'Poems by Two Brothers.' Two years later he entered Trinity College, Cambridge, and became a member of an intimate society called 'The Apostles,' which included some of the most brilliant young men in England. Among them was Arthur Henry Hallam, the closest friend of Tennyson. In 1829 he won the Chancellor's Medal with a poem in blank-verse called 'Timbuctoo'; and in the following year he published 'Poems, Chiefly Lyrical,' a slender volume of new and delicate melodies.



ALFRED TENNYSON

Soon after his father's death in 1831, he left college without taking his degree, and for 60 years that followed he gave himself to a poet's life with a clear resolution which never wavered.

His volume of poems published in 1832 marked a distinct growth in strength and skill. It was but a tiny book, but there was a quality in it which more than made good a lack of quantity. 'The Lady of Shalott,' 'Œnone,' 'The Lotos-Eaters,' 'The Palace of Art,' and 'A Dream of Fair Women,' revealed the presence of a true dreamer of dreams, gifted with the magic which translates visions into music. 'The Miller's Daughter,' 'The May Queen,' and 'New Year's Eve,' showed the touch of one who felt the charm of English rural scenery and common life with a sentiment, so fresh and pure and deep that he might soon be able to lay his hand upon the very heart of the people.

But before this highest potency of the poet's gift could come to Tennyson, there was need of a baptism of conflict and sorrow, to purify him from the mere love of art for art's sake, to save him from becoming an over-dainty weaver of exquisite verse, and to consecrate his genius to the severe and noble service of humanity and truth. This liberating and uplifting experience was enfolded in the profound grief which fell upon him in Arthur Hallam's sudden death at Vienna, in 1833. How deeply this irretrievable loss shook the poet's heart, how closely and how strenuously it forced him to face the mystery and the meaning of life in lonely spiritual wrestling, was fully disclosed, after 17 years, in the famous elegy, 'In Memoriam.' But the traces of the conflict and some of its fine results were seen even earlier, in the two volumes of 'Poems' which appeared in 1842, as the fruitage of a decade of silence. 'Ulysses,' 'Morte d'Arthur,' 'St. Simeon Stylites,' 'Dora,' 'Locksley Hall,' 'A Vision of Sin,' 'The Two Voices,' and that immortal lyric, 'Break, Break, Break,' were not the work of

"An idle singer of an empty day."

A new soul had entered into his poetry. His Muse had been born again, from above. He took his place with the master-minstrels who sing with a full voice out of a full heart, not for a coterie, but for the age and for the race.

It was the recognition that Tennyson really belonged to this higher class of poets — a recognition which at first was confined to a clear-sighted circle, but spread by degrees to the wider reading public — that prepared an expectant audience for his first long poem, 'The Princess,' which appeared in 1847. The subject was the eternal "woman question," treated in the form of an epic, half heroic and half humorous; the story of a king's daughter who sought to emancipate (and even to separate) her sex from man, by founding a wonderful woman's college, but was conquered at last (or at least modified), by the love of an amorous, chivalrous, dreamy prince, who wooed and married her. The story is unconvincing. The blank verse in which it is told has beauty, though it is often too ornate. The conclusion of the poem is a superb tribute to "the eternal womanly." But the little interludes of song which are scattered through the epic shine as the chief jewels in a setting which is not all of pure gold.

In 1850 the long-delayed and nobly-labored elegy on the death of Hallam was given to the world. It is hardly too much to say that 'In Memoriam' stands out, in present vision, as the most illustrious poem of the 19th century. Certainly it has been the most frequently translated, the most widely quoted, and the most deeply loved. It is far more than a splendid monument to the memory of a friend. It is an utterance of the imperishable hopes and aspirations of the human soul passing through the valley of the shadow of death. It is a unique group of lyrics, finished with an exquisite artist's care, which is only surpassed by the intense and steady passion which fuses them into a single poem. It is the English classic on the love of immortality and the immortality of love.

In the same year with the appearance of this poem happened the two most important events of Tennyson's career. He was married in June to Miss Emily Sellwood, a lady of rare and beautiful endowments, who proved herself through a long life of unselfish devotion the true partner of a poet's existence. And he was appointed in November to succeed Wordsworth as poet laureate.

His first official poem was the stately 'Ode on the Death of the Duke of Wellington,' in 1852. The majestic march of the verse, its freedom, its organ-toned music, its patriotic vigor, and the lofty solemnity with which it closes, give it a higher place than can be claimed for any other poetical production of an English laureate for a public occasion. 'The Charge of the Light Brigade,' written in 1854, was a trumpet-note that rang through England and echoed around the world.

'Maud' was published in 1855. It is a lyrical monodrama, in which the hero, a sensitive and morbid man, with hereditary tendency to madness, tells the story of his redemption from misanthropy and despair by the power of a pure love, unhappy but victorious. The variety of the metrical forms in this poem, the passionate tenderness of the love songs, the beautiful truth of the descriptive passages, and the intense personality of its spirit give it a singular charm, which is felt most deeply perhaps by those who are young and in love. Tennyson himself said "I think 'Maud' is one of my most original poems."

In 1859 began the publication of the epical sequence called the 'Idylls of the King'; the largest and in some respects the most important of the works of Tennyson. The first group contained 'Enid,' 'Vivien,' 'Elaine' and 'Guinevere.' The second group appeared in 1870, and consisted of 'The Coming of Arthur,' 'The Holy Grail,' 'Pelleas and Ettare' and 'The Passing of Arthur.' In 1872 'Gareth and Lynette' and 'The Last Tournament' were published; and in 1885 'Balin and Balan' was printed in the volume entitled 'Tiresias and Other Poems.' The division of 'Enid' into two parts — 'The Marriage of Geraint' and 'Geraint and Enid' — makes the epic, as it now stands, consist of 12 idylls. Each of these clothes an ancient legend from the Arthurian

Cycle in the richest and most harmonious of modern blank verse. The idylls are so far independent that any one of them might stand alone as a complete poem. But there is a connecting thread running through them all in the threefold love-story of Arthur, Guinevere and Lancelot, and in the history of the Round Table. The underlying motive of the whole series is to shadow forth the war of Sense against Soul. The idylls are to be interpreted, therefore, as movements in a symphony, the theme of which is the rightful royalty of man's spiritual nature, seeking to establish itself in a settled reign of law, and constantly opposed by the disorderly and disintegrating elements of humanity. In 'The Coming of Arthur' it is doubt that threatens the kingdom; in 'Gareth and Lynette' the conflict is with false ambition; in 'The Marriage of Geraint,' with pride; in 'Geraint and Enid,' with jealousy; in 'Balin and Balan,' with suspicion; in 'Merlin and Vivien,' with lust; in 'The Holy Grail,' with superstition; until at last the poison of unlawful love has crept through all the court, and Arthur's Round Table is dissolved in ruin — but not without a vision of peace for the king who has kept his soul unstained, and a dim promise of new hope for some future age, when he shall return to bloodless victory.

Tennyson has not allowed the ethical purpose of these poems to confuse their interest or bedim their beauty. They are not in any sense an allegory. The tales of love and knight-errantry, of tournament and battle and quest, are vividly told in the true romantic spirit, lighting up the olden story with the thoughts and feelings of to-day. There is perhaps a touch of over-elaborateness in the style; but after all the figures stand out as distinctly as they ought to do in such a large tapestry. In the finer idylls, like 'Guinevere' and 'The Passing of Arthur,' the blank verse moves with a grandeur and dignity, a broad, measured, fluent harmony, unrivaled in England since Milton's organ voice was stilled.

The rest of Tennyson's poetical work includes his dramas — 'Queen Mary,' 'Harold,' 'Becket,' 'The Cup and the Falcon,' and a few others — and several volumes of miscellaneous poems: 'Enoch Arden' (1864); 'The Lover's Tale' (1879); 'Ballads' (1880); 'Tiresias' (1885); 'Locksley Hall Sixty Years After' (1886); 'Demeter' (1889) and 'The Death of Œnone,' published posthumously in 1892. The great age to which his life was prolonged, the unswerving fidelity with which he devoted himself to the sole pursuit of his chosen art, the freshness of spirit which made him delight in labor to the very last, and the fine versatility of mind with which he turned from one field of production to another — brought it to pass that both in amount and in variety of works Tennyson stands in the front rank of English poets; but two can be thought of — Shakespeare and Robert Browning — who produced more.

In 1883 a title of nobility was offered to Tennyson through Mr. Gladstone. This honor, which he had declined at least once before, he now accepted; and in January 1884 he was admitted (we can hardly say elevated) to the peerage — taking his title, Baron of Aldworth and Farringford, from his two country houses, in Sussex and in the Isle of Wight.

It would be difficult, of course, to characterize the style and estimate the value of such a varied and fertile poet in a brief essay. But there are certain qualities in the poetry of Tennyson which are unmistakable and vital.

1. His diction is singularly lucid, smooth and melodious. He avoids sharp and strident effects. Not only in his choice of metres, but also in his choice of words and cadences, we feel a musical influence controlling his verse. Sometimes this results in a loss of force or definiteness. But it makes his poetry, whether in the long swinging lines of 'Locksley Hall,' or in the brief simple measures of the shorter songs, eminently readable. Any one who recites it aloud will find how natural it is to fall, as Tennyson always did, into a rhythmical tone, almost like chanting. This close relation of his poetry to music may be felt also in the quality of subtle suggestiveness, of intimate and indefinable charm, which makes his brief lyrics as perfect as anything of their kind in the world's literature. He has the power of expressing the vague, delicate, yet potent emotions, the feelings that belong to the twilight of the heart, where the glow of love and the shadow of regret are mingled, in verbal melodies as simple and as magical as the chime of far-off bells, or the echoes of a bugle-call dying among the hills.

2. He has an extraordinary truthfulness and delicacy of touch in natural description. This appears equally in minute, pre-Raphaelite work, where he speaks of the color of the buds on different trees in early spring, or in the way in which a wave-crest is reflected in the smooth hollow before it breaks; and in wide, vague landscapes, where he renders the turbulence of the coming storm, or the still glory of an autumnal morning, in a few broad lines. Add to this the quality of blending and interfusing all his epithets and descriptions with the sentiment of the poem, so that they do not distract the feeling but enhance and deepen it, and you have one of the traits by which the poetry of Tennyson is most eagerly distinguished.

3. His range of imaginative sympathy, as shown in his ballads and character pieces, is very wide; but it moves for the most part along natural and normal rather than strange and eccentric lines. His dramatic lyrics differ in this respect from those of Browning. Tennyson expresses the feeling of the philosopher in 'Lucretius,' of the peasant in 'Rizpah,' of the child in 'The Children's Hospital,' of the old sea-fighter in 'The Revenge,' of the intellectual adventurer in 'Ulysses,' in order to bring out in each, not that which is exceptional and rare, but that which is most deeply human and typical.

4. His work reflects with singular fidelity the scientific and social movements of the age. The discoveries and inventions of modern times are translated into poetic language and turned to poetic use. In his verse the earth moves, the planets are molded of star-dust and the mystery of an unfinished creation is still in evolution. It is possible, often, to assign dates to his poems by an allusion to some newly-seen moon or comet, or some critical event in the social history of mankind. It is true that he mistrusts many of the new devices to bring in the millennium. He takes a dark view of some of the elements of 19th century civilization. But still he feels the forward movement of the world;

and his poetry mirrors truly the spirit of modern optimism — with shadows.

5. As in its form, so in its spirit, the verse of Tennyson expresses a constant and controlling sense of law and order. He is in the opposite camp from the poets of revolt. Harmony is essential to his conception of beauty. His patriotism is sober, steadfast, thoughtful, law-abiding. His love moves within the bounds of order, purity and reverence. His conception of power is never akin to blind force, but carries within itself the higher elements of intelligence and voluntary restraint.

> Self-reverence, self-knowledge, self-control, —
> These three alone lead life to sovereign power.

6. The poetry of Tennyson is pervaded by a profound religious spirit. His view of the world — his view even of the smallest flower that blossoms in the world — is illuminated through and through by his faith in the Divine presence and goodness and beauty. He cannot conceive of a purely physical universe. Nothing that he has written could have been written as it is, if he had been an atheist or an agnostic. Even his poems of doubt and conflict are the resurgent protests of the heart against the cold negations which destroy personal trust in the unseen God, in whom we live and move and have our being. His method of dealing with religious subjects is not theological, like that of Milton or Wordsworth; nor philosophical, like that of Browning or Arnold or Clough. Tennyson speaks more from the side of the feelings, the ultimate spiritual instincts and cravings of humanity. The strongest of these is the desire and hope of a life beyond the grave. To this passion for immortality he gives full play, and it evokes some of the strongest and sweetest tones of his music. From 'The Deserted House' to 'Crossing the Bar,' his poetry is an evidence of his conviction that death cannot end all. This faith in the life that is to come elevates and purifies his conception of the life that now is. It gives a new meaning to duty and to love. And when we think of the many noble poems in which it has found expression,—'The Two Voices,' 'The May Queen,' 'Locksley Hall,' 'Enoch Arden,' 'The Leper's Bride,' 'Guinevere,' 'In Memoriam,' 'Vastness,' 'Wages,' — we may well call Tennyson the poet of the endless life.

His influence upon the thought and feeling of the age has been far-reaching and potent. He has stood among the doubts and confusions of these latter days as a witness for the things that are invisible and eternal,— the things that men may forget if they will, but if they forget them, their hearts wither and the springs of poesy run dry. His verse has brought new cheer and courage to the youth of to-day who would fain defend their spiritual heritage against the invasions of materialism. In the vital conflict for the enlargement of faith to embrace the real results of science, he stood forth as a leader. In the great silent reaction of our age from the desperate solitude of a consistent skepticism, his voice was a clear-toned bell, calling the unwilling exiles of belief to turn again. And when he passed away from his quiet home at Aldworth, with the moonlight falling on closed eyes and voiceless lips, the world mourned for him as for a mighty prophet, and rejoiced for him as a poet who had finished his course and kept the faith. See ENOCH ARDEN; IDYLLS OF THE KING; IN MEMORIAM; LOCKSLEY HALL; MAUD; PRINCESS, THE.

Bibliography.— EDITIONS: Standard editions of Tennyson are the Cambridge edition by W. J. Rolfe (Boston 1898); Cabinet edition (1 vol., ib. 1899; id., 12 vols., ib. 1902); Household edition (ib. 1899); Riverside edition (7 vols., ib. 1904); New Popular edition (3 vols., ib. 1906); Globe edition (New York 1907); Eversley edition, by Hallam, Lord Tennyson (6 vols., ib. 1908); Everyman's Library (ib. 1910); 'Works of Tennyson, with Notes by the Author,' edited with Memoir by Hallam, Lord Tennyson (ib. 1913); The Farringford edition, by Eugene Parsons; Athenæum Press edition (select poems), by Henry Van Dyke and D. L. Chambers (1903). CONCORDANCES AND BIBLIOGRAPHIES: Baker, A. E., 'Concordance to the Poetical and Dramatic Works of Alfred, Lord Tennyson' (London 1914); Brightwell, D. HENRY VAN DYKE,
Professor of English Literature, Princeton University, and former United States Minister to the Netherlands and Luxembourg.

TENNYSON, Frederick, English poet: b. Louth, 5 June 1807; d. Kensington, 26 Feb. 1898. He was elder brother of Alfred Tennyson (q.v.). He published several volumes of poems of considerable merit, namely: 'Days and Hours' (1854); 'The Isles of Greece' (1890); 'Daphne and Other Poems' (1891); and 'Poems of the Day and Year' (1895).

TENNYSON-TURNER, Charles, English poet: b. Somersby, Lincolnshire, 4 July 1808; d. Cheltenham, 25 April 1879. He was an elder brother of Alfred Tennyson (q.v.), with whom he collaborated in the 'Poems' of 1827. He took the additional name of Turner by royal license on succeeding to property at the death of a great-uncle. He became vicar of Grasby, Lincolnshire, in 1837, and published 'Sonnets' (1864); 'Small Tableaux' (1868), and 'Sonnets, Lyrics and Translations' (1873). In 1880 these were republished with additions, under the title 'Collected Sonnets, Old and New.' These writings manifest that he possessed much poetic genius. His greater brother regarded some of his sonnets as among the finest in the language, among them being 'The Rookery'; 'Letty's Globe'; 'Orion'; and 'The Lion's Skeleton.'

TENOCHTITLAN, tĕn-ŏch-tĕt-län', the ancient name of the City of Mexico. See MEXICO.

TENOR, the highest natural adult male voice. Its compass generally extends from C in the bass to G or A in the treble. Professional singers may take from C to C. The qualities of the tenor render it suitable to the expression of tender and delicate sentiments. In a vocal composition of four parts the tenor forms the second middle part, deeper than the alto, but higher than the bass; but in the song of four male voices the tenor, as the first voice, leads the chief melody, and as the second is the higher middle voice. The clef of this voice is the C clef on the fourth line of the stave, but the treble or G clef is commonly used, though an octave too high. A singer having a high-pitched voice, or a musical part for such a voice, is also termed tenor, and sometimes a viola tuned between the bass and the alto is so named. See VOICE AND VOICE CULTURE.

TENORITE, the native black oxide of copper, CuO. It occurs on the lavas of Vesuvius in small black scales of brilliant metallic lustre. Melaconite is an earthy, massive variety, resembling wad, formed by the decomposition of chalcopyrite and other copper ores. It occurs in Ducktown, Tenn.; Morenci, Ariz., and elsewhere.

TENOS, tē'nŏs, Greece. See TINOS.

TENSAS, a river in the southwestern part of Alabama, the eastern channel through which the united waters of the Tombigbee and the Alabama rivers pass to Mobile Bay. The western channel is called Mobile River (q.v.). At the mouth of the Tensas is Fort Blakely where took place an engagement between the Union forces and the Confederates, 25 March 1865. See FORT BLAKELY, SIEGE AND CAPTURE OF.

TENSKWATAWA. See TECUMSEH.

TENT, a portable dwelling-place formed of flexible material, as blankets, hides or more commonly canvas, stretched with cords on poles. Tents are chiefly used in Europe and the United States as shelters for soldiers, although the first hunters in this country, following the Indians, made partial use of them. The most common form of tent is the A tent, having a ridge-pole, across which a canvas is slung and sloped to form the main roof, the sides being fastened by cords to stakes in the ground, and flies or wings being hung for sides. When a hoop is used instead of a ridge-pole as the main support it is a bell-tent. The circus tent usually has two, three or more main masts, with ridge-poles or ropes between them, and a vast spread of canvas reaching to the ground.

TENT-CATERPILLARS, caterpillars of some moth of the genus *Clisiocampa,* specifically the apple-tree or spring species (*C. americana*) of the northeastern States. The moth is of medium size and plain colors. Its eggs are laid in autumn in the form of bands of 300 to 400 glued about the twigs of fruit-trees. They hatch early in spring, and the caterpillars begin to spin across nearby forking twigs a triangular silken web or tent, in which they take shelter and grow; many other trees as well as those of the orchard are affected. They go out in the daytime to feed on foliage and at night gather inside the web, which should be burned at night when it is populous, or destroyed by a spray of kerosene. The caterpillars become full grown in June, and then are about two inches long, hairy, with a white dorsal stripe and with numerous fine crinkled black lines on a yellow ground, united below into a common black band, with a blue spot on the side of each ring. Then the caterpillars spin their dense white fuzzy cocoons behind the loose bark, or boards, and the moths appear about July 1. Another species, often very destructive to the foliage of shade-trees, is the forest tent-caterpillar moth (*C. disstria*), whose caterpillars are to be distinguished by a row of spots instead of a line along the back. The more common tent-caterpillars of the Pacific Coast are the larvæ of the early *C. californica* and of the later *C. constricta,* both orchard-pests. The last-named live in colonies but do not make tents.

TENTACULIFERA, a sub-class of the *Infusoria* having no cilia in the adult condition but provided with them during the embryonic period. The distinguishing feature of the group is found in the so-called tentacles which are very highly differentiated organs, some adapted for sucking and some for piercing, while some again are adhesive. They are emitted from the entire surface of the body or occur in groups at the angles. Such tentacles are elongate, capable of protrusion and retraction, and usually have the distal end expanded into a sucker. In structure a tentacle is tubular with a semi-fluid plasm in the axis and a firm outer portion. When partly retracted a band of contractile protoplasm appears as a spiral ridge around the outside. There are several branching forms such as *Dendrocometes*, sessile on the gill plates of small fresh-water crustacea, and *Dendrosoma*, a larger colony, attaining sometimes a length of two millimeters and presenting superficially an extraordinary resemblance to a zoophyte. In the latter the nucleus extends as an axial structure branching throughout the entire colony. Young forms are produced by division or gemmation, and are free-swimming by virtue of a ciliary covering which is replaced by the tentacles when the organism settles down in a permanent environment.

TENTH CENTURY. The tenth is commonly rated in history as one of the lowest of centuries in achievement. Undoubtedly fewer monuments and documents representing physical or intellectual accomplishment have come down to us from it than from corresponding periods. The principal reason for this is to be found in the almost continuous invasions of the Northmen who at this time disturbed most of the western European countries. They established themselves in France under Rollo in the early part of the century. They landed on the English coast in larger numbers than ever, they invaded Ireland and destroyed particularly the monasteries and schools. They sailed around into the Mediterranean and made incursions on the cities and established themselves in Sicily and southern Italy. No wonder that the monastic chroniclers were not active and that men were discouraged over making attempts at progress. While these sea robbers came from the North the Saracens from Arabia were making similar incursions in the East and the eastern portion of the Mediterranean. It was the state of unsettledness of mind induced by the attacks of these two sets of invaders and the inhibitions set up by their savage cruelties and not, as is sometimes said, the persuasion that the world was to come to an end in the year 1000 which dulled the efforts of the generations of the time.

The 10th century was, notwithstanding, a significant transition period in which occurred many events that were to be fundamentally constructive for modern history. The Northmen consolidated their power in Russia and are usually said to have given a name and a certain stability to the government of the country at this time. They explored Greenland and probably landed on the American continent in the region known as Vineland, somewhere south of Labrador, before the year 1000. Their invasion of England was to lead to the establishment of Canute's empire in the next century and their presence brought about a consolidation of some of the warring peoples of Europe and an improvement in political conditions. They introduced a new racial element into the life of what we know as France and the Normans, as they were called, became an extremely important factor in the subsequent history of Europe. At the same time the Arabs in Spain became leaders in the intellectual life of Europe and their schools in Cordova of geometry, chemistry, astronomy and medicine made that city a centre of learning famous throughout the world. Cordova laid the foundation of that profound Arabic interest in science and medicine which in the following two centuries gave us Abulcasis, Avenzoar, Averroes and Avicenne and was to mean so much for the stimulation of the scientific spirit of Europe. There was a great Arabian physician in the East too, Rhazes, the first to describe smallpox, whose books are still famous in the history of medicine.

In spite of the ever recurring incursions of the Northmen the political development of Europe at this time is of special interest to modern history. The 9th century saw the breaking up of Charlemagne's Empire by divisions among his sons as well as among the sons of succeeding rulers to whom unfortunately the government by the Frankish custom was parceled out. The result was that France without a firm central authority was in a highly disturbed state all during the 10th century. The feature of European history most interesting for our time is the bitter rivalry between the Germans and the French over the possession of Lorraine which culminated nearly a thousand years ago. The German emperor of that time, Otto, invaded and devastated all the country of the Franks almost to Paris, then was forced to make a disastrous retreat and the greater part of his army perished in a battle on the Aisne.

England after the magnificent reign of Alfred continued for some time to grow in peace and prosperity. Alfred's son Edward (reigned 901–25) conquered Mercia and East Anglia, strengthened the government and protected his people against invasion by the building of many strongholds. He encouraged town development and patronized learning, founding schools, though the tradition of any connection between the Saxon schools of this time and Oxford or Cambridge is mythical.

Æthelstan (925–40) further extended the Saxon rule so that all of the old Saxon Heptarchy (seven kingdoms) came under his dominion. He commanded in the "great battle" famous in subsequent history against an allied army of Danes, Scots, Gaels and warriors from the Orkney Islands. These Northern peoples with their great claymores always struck terror into their enemies before this but Saxon troops proved capable of withstanding their charge. Æthelstan came to be looked upon as one of the most important kings of Europe and royal alliances with his family were eagerly sought, his sisters Edwina and Editha marrying the kings of France and Germany. He may be called the first king of all England. In the second half of the century, however, the Northmen landed in England in large numbers and gradually secured a firm foothold. The Danes under their king, Sweyn, threatened to overrun the country and their withdrawal was obtained only by paying a ransom. Needless to say this only proved to be a bait for more invaders from the Northern countries.

A more hopeful development came at the end of the century with the introduction of Hungary into European history. Stephen, one of the chiefs of the Hungarians, was with his father received into the Church and proceeded to make his people Christian. He was crowned as king (997) and his reign is mainly in the next century, but the spirit which led him to correspond with Bruno of Querfort and Odilo of Cluny and to found a series of hospices for pilgrims in Jerusalem, Rome, Ravenna and Constantinople so that travelers from his country might have a refuge when they visited these cities, was a product of the 10th century. He encouraged learning and did much to break the savage spirit of his people. His court became a refuge for the English royal family when Canute conquered the English and he deeply influenced Saint Margaret of Scotland. The tradition of social helpfulness established by him culminated in Saint Elizabeth of Hungary in the next century.

The one country in western Europe in which the Northmen were unable to gain foothold was Spain. When the Northmen landed at Galicia they devastated the country for a while, but were defeated and almost exterminated learning a lesson that kept Spain from being seriously disturbed by the Scandinavians after this. This century witnessed also the beginning of the expulsion of the Moors. The foundation of the little Christian kingdom of Leon was the initial step in this and the prelude to the heroic age celebrated in the Spanish chronicles and ballads. Abderrahman III (891–961) under whom as caliph of Cordova, Mohammedan power in Spain rose to its greatest height, was defeated in 940 by Ramiar II, king of Leon and Asturias (died 950), in the great battle on the plain of Simancas (31 July 939). After this the Christians continued to advance in power and the Arabs to recede.

The most interesting character of the period is Dunstan, archbishop of Canterbury, proclaimed saint by popular estimation of the good work he did for his people. He was probably born early in the century of a well-to-do family. In his youth he was a favorite at court until jealousy led to his banishment. Disillusioned with worldly success he became a hermit at Glastonbury but after a time the fame of his life as a solitary led the king to recall him as an adviser. Dunstan took advantage of his place at court to encourage learning and patronize art. He himself was deeply interested in the arts and crafts and the making of beautiful things and after his death he became the patron saint of the goldsmiths' guild. He is said to have taken part in the making of bells and organs as well as the altar vessels. Nothing delighted him more than the teaching of boys in the cathedral school and he encouraged manual training as well as intellectual development. The rich who saw his good work provided him with funds in abundance and he used them for the building and restoring of churches and the establishment of schools. He reformed monastic life which had suffered severely during the disturbed period while the Northmen were landing in England. Dunstan was most famous, however, for his care of the poor and the needy. He was often called upon to act as judge in law suits and his maintenance of the rights of widows and orphans made him popular. He died in 988 and until the martyrdom of Saint Thomas of Canterbury was the favorite saint of the English people.

The most significant intellectual event of the century was the writing of a series of plays by Hroswitha, a Benedictine nun of Gandersheim, South Germany. Her reasons for writing them, as given in the preface, makes it very clear that there must have been much more of interest in literature, classic and recent, at this time than is usually thought. Hroswitha declared: "There are many Christians (and we cannot relieve ourselves entirely of this reproach) who charmed by the choice eloquence of the language, prefer the vanity of secular books to the wisdom of the Holy Scripture. There are others who though attached to the sacred writings and full of contempt for other pagan productions, yet cannot keep from reading time and again the fictions of Terence and won by his charm of diction stain their souls by the knowledge of criminal actions. It is for this that I, 'the strong voice of Gandersheim,' do not hesitate to imitate in my writings a man whom so many permit themselves to read in order to celebrate in the measure of my feeble intellect the virtues of Christian women while employing the same form of composition which served the ancients to describe shameful conduct."

The ideas thus expressed are so modern that it is surprising to find them thus simply set forth in the 10th century. Hroswitha called her plays comedies because they end happily, though the happiness comes in heaven through martyrdom. They were probably meant, as the preface would seem to indicate, more for reading than presentation, though they are some comic scenes that would tempt the employment of the actors' art. One of Hroswitha's comedies anticipates the morality plays of subsequent centuries in their introduction of abstract characters personified. Wisdom, the mother, and her three daughters, Faith, Hope and Charity, came to Rome to influence the citizens for good and are put to death by the Emperor Adrian. Besides the dramas Hroswitha wrote a series of poems in Latin verse, one of which is the story of Theophilus who sold his soul to the devil and is one of the early forms of the Faust legend. She also wrote a chronicle and seems to have been in high favor at court. The *editio princeps* of Hroswitha is by Celtes (1501). At first he was suspected of having written most of the plays, but there is no doubt now of their antiquity. The work throws light on the feminine education of the time. Manifestly the convents, of which there were many in the Rhineland, contained a number of religious women deeply interested in the intellectual as well as the spiritual life.

The beginnings of some of the important developments in commerce date from this century. Merchants were honored by Æthelstan who conferred the rank of Thane on anyone who had made three voyages over the sea with a ship and cargo of his own. The British fleet organized by Alfred at the end of the 9th century developed and in King Edgar's time (959–75) some 360 sail in three squadrons made a circuit of the island. Even this sea power was not able to protect England from invasion by the Danes, however, who under Sweyn gained a foothold (circa 985) and in the next century England was ruled by Canute. Flanders became the seat of manufactures of linens and woolens for Europe and the republics of Venice and Genoa began their great commercial careers in connection with the trade from the East. The Moors in Spain under Abderrahman III built some beautiful buildings and adorned their cities and set an example which was to prove an inspiration for the many students who came down to the Spanish Peninsula to make their studies at famous Moorish schools.

PRINCIPAL EVENTS OF THE TENTH CENTURY.

905. Edward the Elder, King of the Angles and Saxons, second son of Alfred the Great, makes peace with the Danes settled in East Anglia and Northumbria, and establishes the "Laws of Edward and Guthrum."
909. Northmen from Norway and Denmark, from this year on, through the century, continue to ravage the Russian, German, British, Irish and French coasts, and although disastrously repulsed from Spain, extend their depredations to Italy. They establish colonies in Normandy, France, under Rollo, in England and in the northern Scottish islands.
911. Conrad, duke of Franconia is elected emperor of the Franks.
918. Henry the Fowler becomes Henry I., King of Germany.
919. Germany and north Italy are divided into dukedoms and principalities. The third or Saxon dynasty commences. Henry I extends his territory; increases civic rights; creates several margravates. The silver mines of Hertsburg are discovered. Industry and wealth increase. Edward the Elder, King of the Angles and Saxons, is "chosen as father and lord" by Scots, Northumbrians, Danes, Norwegians and Welsh after victorous campaigns.
924. Edward the Elder dies and is succeeded by Æthelstan who consolidates the Saxon Heptarchy.
929. Otto of Germany, eldest son of Henry I, marries Edith, daughter of Edward the Elder, and sister of Æthelstan, King of England.
934. Henry I of Germany stems the Hungarian invasion.
936. Otto I, the Great succeeds his father Henry I as King of Germany.
942. Otto concludes peace with Louis IV of France after war over Lorraine.
953. War again breaks out over Lorraine and is ended by Otto's brother Bruno, Archbishop of Cologne.
955. The Hungarians are finally driven out of Germany, Otto defeating them in a brilliant victory at Lechfeld. Otto also defeats the Slavs who had ravaged Saxony.
959. Hugh Capet is made Duke of France.
968. Hroswitha, dramatist, Benedictine religious, and "the strong voice of Gandersheim," presents her 'Carmen de gestis Oddonis' to the emperors Otto I and Otto II.
971 Edward the Martyr becomes King of England.
978. Edward is assassinated at the instigation of his stepmother.
983. Greenland is colonized from Iceland by Northmen who send Christian missionaries there. They also reach Vineland on the North American continent.
987. On the dissolution of the Franconian Empire and the termination of the second dynasty, Hugh Capet the founder of the third dynasty is elected King of France.
988. Saint Dunstan, archbishop of Canterbury, dies.
997. Stephen I is crowned King of Hungary and enters into friendly relations with Christian leaders of Western Europe.
999. Austria becomes a Margravate. The Grecian Empire loses territory to the Bulgarians on Mount Hæmus and resists Russian invasion. The Turks in possession of Egypt and Syria extend their empire and give the title of Sultan to their rulers.
1000. Civilization advances. Villainage or serfdom is abolished in Western Europe. The principal towns become republics. Hereditary estates on a military basis are established. The dukes and counts become kings. Arabic learning attains a high standard. The Institutions for education founded by Charlemange are almost obliterated in the upheavals of the Franconian Empire, but faith and learning are safeguarded by the Church, for the intellectual advance and uplift of humanity.

JAMES J. WALSH,
Author of 'The Thirteenth Greatest of Centuries.'

TENURE is a legal term denoting the manner in which the title to real estate is held. It originated during the feudal system of England and defined the relation which existed between the lord of the manor and the tenant. The term tenure in its modern signification is extensive and may import mere possession of real property, or the particular manner by which same may be held. A tenure paid for in services was formerly known as socage. See also FEUDAL SYSTEM.

TENURE OF OFFICE, the manner by which an office is held, as well as the duration of its term.

TENURE OF OFFICE ACTS. (1) An act of 15 May 1820 which provided a four-year term for certain officers, such as collectors of customs, etc. (2) An act of Congress passed in 1867, vetoed by President Andrew Jackson and passed over his veto on 2 March. The chief provision of the act was that requiring the consent of the Senate to the removal of any officer appointed with its advice and consent. In case of the misconduct of officers thus appointed, except judges, when the Senate was not in session, the President might suspend such officer and designate another to perform his duties until the Senate should act in the case. Many other objectionable provisions were included in the bill, which was aimed at limiting the power of President Johnson. The latter's disregard of the act in removing E. M. Stanton from the Secretaryship of State was one of the main grounds of his impeachment. Under Grant's administration in 1869 many sections of the act were stricken out, and in 1887 it was practically repealed altogether. (See JOHNSON, ANDREW). Consult McLaughlin and Hart, 'Cyclopedia of American Government' (New York 1914), and 'Statutes at Large' (III, 582; XIV, 430; XVI, 6; XXIV, 500).

TEOCALLIS, tē-ō-kăl'ĭs, the ancient temples of Mexico, of which there are extensive remains. They are distinguished by a pyramidal base, square in plan, and rising in stories or terraces, or in an incline of 45 degrees, to an upper platform, on which the temple stands. The most extensive is the pyramid of Cholula, near Mexico, said to have been built before the arrival of the Aztecs. In plan it measures 1,440 feet each way, and has four terraces, reaching a height of 177 feet. Its area is nearly four times that of the great Egyptian pyramid, but in strength of material and skill of workmanship it is vastly inferior, and is now merely a mass of ruins. At Palenque, in Yucatan, is a better-preserved temple. The pyramid rises in an incline, consisting of an unbroken flight of steps, 280 feet square and 60 feet high. The temple is 76 feet wide in front and 26 feet deep and is ornamented with bas-reliefs in stucco and hieroglyphic tablets.

TEOSINTE, a fodder-plant. See GRASSES OF THE UNITED STATES.

TEPHROITE. A mineral consisting of manganese ortho-silicate $2MnO.SiO_2$, contains 70 per cent MnO.; abundant at Franklin Furnace and Sterling Hill, N. J.

TEPIC, tä-pēk', Mexico, (1) A territory on the Pacific Coast between the states of Jalisco and Sinaloa, organized under Mexican government in 1889; area, 11,275 square miles. It is a mountainous country inhabited by tribes of semi-independent Indians. It includes the volcano of Ceboruco, still active. The Santiago and Mezquital rivers flow through it. There are rich mineral deposits, little operated. Pop. about 175,000. (2) The capital, Tepic, lies about 25 miles inland from the port of San Blas, with which it is connected by a railroad. It stands on a commanding plateau, and manufactures cotton-cloth and tobacco, and has a population of about 17,000.

TEPLITZ, tĕp'lĭts, or **TÖPLITZ**, tėp'lĭts, Bohemia, a watering place in a mountain valley, 30 miles southeast of Dresden. Its interesting features are the castle with its beautiful grounds, the town church, bathing establishment, Rathhaus, etc. Its mineral baths are the most celebrated of the country. They consist of 12 hot springs, alkalo-saline, and are of great efficacy in rheumatic affections. The Triple Alliance between Austria, Russia and Prussia against France was signed here in 1813. Pop. 27,000.

TERAMO, tā'rä-mō, Italy. (1) Capital of the province of its own name, at the confluence of the Tordino and Vezzola, 40 miles northwest of Chieti. It is a bishop's see, and the cathedral dates from the 14th century. Municipal offices and the exchange are the principal buildings. The remnants of Roman baths, theatre, temples and aqueducts indicate the site of the ancient Interamna. The manufactures include wax, pottery, leather, straw hats, ornamental furniture and cream-of-tartar. The ascent of the Gran Sasso is made from this point. In 1460 a fierce battle was fought here between the Milanese allies of the king of Spain and the forces of the Duke of Anjou of France. The ruins of the castle of San Flaviano, in the plains nearby, mark the site of this conflict. Pop. of the commune about 25,070. (2) The province lies in southern Italy, and is traversed on the west by the Abruzzi Mountains. Several streams flow through the province to the Adriatic. Wine, grain, oil and silk are the chief products, and the fisheries are important. The Ancona-Brindisi Railway follows the coast, with a branch to Teramo, the capital. Pop. 320,000.

TERAPHIM, small images or objects similar to the household gods of the Romans, and which are mentioned in several places in the Bible. The reverence paid to them appears to have been very ancient. They were human in form, and from being merely venerated, or used as aids to devotion, might easily become objects of idolatry. The earliest mention of teraphim is in Genesis (ch. xxxi, 19), where Rachel is said to have stolen her father's teraphim, which Laban (ver. 30) calls his gods. In the story of Micah (Judge xv, 5) the word occurs in our Authorized Version. It was a teraph that Michal, David's wife, put into the bed (1 Sam. xix, 33) to deceive the messengers of Saul. Josiah is represented (2 Ki. xxiii, 24) as putting away the teraphim. In Ezek. xxi, 21 they are represented as used by the king of Babylon for purposes of divination. Consult Benziger, I., 'Hebraische Archaologie' (Tübingen 1907).

TERATOLOGY, that branch of biological and anatomical science which treats of abnormalities or monstrous growths in the structure of plants and animals. While ancient writers dealt with such deviations from normal types of structure, malformations appealed to their imagination as portentous objects of satanic origin, rather than to their deficient scientific sense as subjects of investigation. Early in the 18th century superstition began to give way to physical observation, and the study of character and causation in monstrosities became an important branch of natural history. Defect in the germ is regarded by many embryologists as the original cause of some human anomalies, hereditary persistence of certain deformities in numerous cases resulting. Other malformations are believed to be due to diseased organs, as the brain or the uterus, and to various fœtal disorders. Consult Moquin Tandon, 'Eléments de teratologie végétale' (1841); Fisher, 'Diploteratology,' in 'Transactions' of the Medical Society of the State of New York, 1865–66–67–68; Masters, 'Vegetable Teratology' (1869); Penzig, 'Pflanzenteratologie' (1890–94).

TERBIUM, one of the "rare earth" elements found chiefly in the minerals samarskite and gadolinite. It belongs to the yttrium group and has an atomic weight of 158.8. Its symbol is Tb.

TERBORCH, tĕr'boorH, **Gérard**. See TERBURG, GÉRARD.

TERBURG, tĕr'boorg, **Gérard**, Dutch painter: b. Zwoll, near Overyssel, 1608; d. Deventer, 1681. His father, a historical painter, who had resided some time at Rome, gave him his first lessons in painting. He continued the study of his art at Haarlem, and afterward visited Germany, Italy, Spain, England and France, leaving everywhere proofs of his talents as a painter of portraits and of interiors. On the meeting of the European Peace Congress at Münster he painted in 1648 'The Plenipotentiaries Discussing the Treaty' which contains 69 portraits; it is now in the English National Gallery. The Spanish Ambassador at the congress took him to Madrid, where he painted the king and many of the nobles. From Spain he went to London, and afterward to Paris. He then returned to Overyssel, married one of his nieces and became burgomaster of Deventer. His portraits are remarkable for elegance. He excelled in painting textile fabric, particularly satin and velvet. His interiors are mostly of the houses of the rich. Few of his pictures are to be found and they are exceedingly costly, his 'Glass of Lemonade,' a small canvas, 25¾ by 20¾, fetching in 1878 the price of $9,720.

TERCEIRA, tĕr'sā'rä, the third in size of the Azores Islands, situated 84 miles northwest of Saint Michaels; area 225 square miles. It is volcanic and mountainous, with steep cliffs along the shores, the highest point being about 3,500 feet. The soil is fertile, producing wheat, corn and grapes. The capital is Angra, with a pop. of 11,000. Pop. of the island about 50,000.

TERCENTENNIAL EXPOSITION AT JAMESTOWN. See JAMESTOWN TERCENTENNIAL EXPOSITION.

TEREBRATULA, a genus of brachiopods (q.v.). The shell exhibits a punctated structure, due to the presence of numerous minute canals in the shell-structure itself. The ventral valve has a prominent "beak," which is perforated for the stalk. Some species still exist in our seas, although the genus dates back to the Devonian age.

TEREDO, or **SHIP-WORM**, a small marine bivalve boring mollusk (*Teredo navalis*), which excavates burrows in wood under (salt) water, attacking the timbers of piers and vessels in immense numbers, and riddling them to such an extent that they are rendered utterly useless, in a surprisingly short time, if left unprotected. It abounds destructively throughout the Mediterranean and Baltic seas, and on both shores of the Atlantic. Its steady burrowings once almost caused the inundation of a large part of Holland. Along the sea-front had been built a system of dikes, made principally of timber. In three years breaks were being patched up; in five, whole sections gave way. Only the heroic efforts of the whole seaside population saved the Dutch from one of the worst catastrophes in their history. The timbers were completely honeycombed, so rotten that the wood could be crushed in the hand.

North America suffers as much as Europe from this pest. All down the New England Coast piles are attacked and destroyed. In this region two years forms the average life of a piece of submerged timber. Channel buoys are left in the water only six months in the year, then a new set is put in and the old one dried. The zone of the ship-worm's devastation is comparatively large. Wood is attacked between points well above low-water mark and points 10 or more feet below it. The hardest oak offers no more difficulty than the softest pine, and the toughest knots are traversed. Teak alone resists the attack.

The agent of this vast amount of damage much resembles a worm, but is a true mollusk. Its long, whitish body, tapering toward the posterior end, is found imbedded in a shell-lined burrow. Individuals of this species sometimes attain the length of 10 inches, are one-quarter inch in diameter. Such size, however, is rare, four inches being the average length.

The "head" end of the animal is covered with a white bivalve shell. This protects the vital organs of the little creature, and from its interior opening projects a short "foot" which is probably the instrument by which the burrow is dug and lined with its pearly coating. Two pallets shaped and fastened to the posterior end of the body, much as leaves are fastened to the stem, close the teredo's hole, and protect from attacks the soft portions of the animal. Between these two plates lie the siphon tubes — used for inhaling and exhaling water. Through the lower of these (bronchial) is drawn the water breathed by the animal, and likewise those minute animalcules which serve it for food. The dorsal tube serves as the organ of excretion. Through it passes a stream of vitiated water carrying along the fæces and the wood excavated. Surrounding both the pallets and the siphon tubes is a much wrinkled muscular band, by which the teredo adheres to its "burrow."

The appearance of the teredo burrow is very peculiar. Outwardly the piece of timber infested shows a number of very small holes. Inwardly it resembles nothing more than a Swiss cheese. The channels run in all directions, sometimes so close to each other that the wood separating them is as thin as paper. But between the holes there is always a partition, for the animals never interfere with each other. Their sense of hearing seems to enable them to tell when they are approaching the outside of the wood or are nearing another burrow and they turn aside. The holes are always lined with irregularly laid shell and they generally go with the grain. Like many other mollusca the teredo passes through a long series of complicated metamorphoses before arriving at full maturity. The eggs, from the beginning of the breeding season in May, are confined in the gill cavity. Here they have their first period of growth. From the gill cavity the embryos are discharged in the form of free-swimming animals covered with vibrating cilia or hairs, by which they swim. In this stage they are almost exactly like ciliated infusoria. Next they lose these locomotive filaments and develop a rudimentary bivalve shell. In the third stage their relation to other bivalves is apparent in their resemblance to the common mussel. They have a mantle and shell covering their entire body and another sort of cilia replaces those lost. This bivalve character is further accentuated by the development of a long foot used for creeping and by the appearance of eyes and organs for hearing. These eyes, however, disappear as the animal elongates and the locomotive cilia are lost. In this stage the young teredo, settling on some convenient piece of wood and starting with a hole about the size of a pin-head, begins his burrow, and enlarges it as he goes on, until he has reached his full growth.

The fact that the ship-worm does not use as food the wood it excavates, but simply passes it through its body, has much to do with the failure of many attempts to make wood teredo-proof by poisons. Up to date creosote and dead oils are the remedies which have given the best results. The piece of lumber to be so treated is first steamed. Next the air is exhausted and the poisonous or noxious compound is forced in under a pressure of 400 pounds to the square inch. Usually, however, this system fails of the desired result. At Christiania, timbers poisoned in this manner were found to be, three years later, quite riddled with teredo. In some instances, however, piles so treated have been known to remain free from ship-worms for as many as 15 to 20 years.

Although poisoned timbers are often used for such structures as government docks (which must be as permanent as possible), for ordinary piers and for submerged work, the expense of so treating the wood is generally greater than the cost of periodical renewal. Of course the most thorough defense would be one which prevented the entrance of the young animal. Copper-sheathed vessels are quite free from its attacks, while copper paint, creosote or coal tar frequently applied has the same effect. Piles may be defended by broad-headed nails closely driven, for the ship-worm seems to avoid entering any wood impregnated with iron rust.

A large species of teredo (*T. gigantea*), from Sumatra, has been found to measure from four to six feet, and to have a diameter of about three inches. It bores into the solid mud, and does not appear to destroy timber like its smaller neighbor. Consult Cooke, 'Mollusca' (London 1898); Verrill 'Invertebrates of Vineyard Sound' (Washington 1875).

TEREK, tĕ-rĕk', Russia, a river in Circassia, which rises in Mount Kasbek, at the north of the Caucasus, among icy glaciers. It follows a northwesterly course through a narrow valley, then turns east and after dividing into numerous branches enters the Caspian Sea by a delta. Its entire length is nearly 400 miles, only a small distance being navigable. The main tributaries are the Ardon, Uruch, Malka and Baskan on the left; the Sunsha, Assa and Argun, on the right. A series of small fortifications for protection against the mountain tribes are built along the river from Mosdok to the foot of the pass over the Great Caucasus, where the descent is made into Georgia.

TERENCE, tĕr'ĕns (PUBLIUS TERENTIUS AFER), Roman writer of comedies: b. Carthage, Africa, between 185 and 195 B.C.; d. probably in Greece, 159 B.C. While yet a child he was bought by Publius Terentius Lucanus, a Roman senator, who took him to Rome and gave him a good education. His master having emancipated him the young African now assumed the name of his benefactor. Lælius and Scipio Africanus (the destroyer of Carthage and Numantia) admitted him to their intimacy, and as some aver, assisted him in the composition of his plays. About the year 161 he went to Greece, where he is said to have translated 108 of Menander's (q.v.) comedies. Six comedies of Terence's alone are extant — the 'Andria,' the 'Eunuchus,' 'Heautontimorumenos,' 'Phormio,' 'Hecyra' and the 'Adelphi,' his last piece, brought out in Rome the year before his death. The comedies of Terence were much admired by the cultivated Romans for their exquisite style, the language of Cicero, Cæsar and the orators, and were likewise esteemed for their maxims and moral sentences. If we compare him with Plautus, his only important predecessor, we miss what Cæsar styled the "vis comica," that sparkling wit and humor which made Plautus the model of Molière. On the other hand Terence has the finer vein of sentiment, the more subtle power of characterization and the purer latinity. He was indeed the founder of polite comedy, the comedy of society in Europe and his influence has been felt throughout the whole history of literature. Most of his plays follow closely the originals of Menander, but from the fragments of Menander which remain they do not appear to be mere translations. The comedies of Terence have been translated into English by the elder Coleman and several others. (See ADELPHI). Consult The edition of Bentley (1726); Vollbehr (1846); Dziatzko (1884), and Conradt, 'Die metrische Composition der Comödien des Terentius' (1876).

TERESA, tĕ-rē'sa (Sp. tā-rā'sä) **Saint** (properly **Theresia**), Spanish conventional re former: b. Avila, Old Castile, 28 March 1515; d. Alba, 4 Oct. 1582. Her attention was drawn in childhood to lives of saints and martyrs and when she and her brother were children under 10 they set off into the country of the Moors in hopes that some infidel would seize and kill them on account of their faith and that they would thus obtain the crown of martyrdom. Defeated in their object they attempted to become hermits. Her father, a nobleman, Don de Cepeda, placed her, after the death of her devout mother, in a monastery of the Carmelites at Avila when she was 16 and though she lived for some years there without any of her early religious enthusiasm, a change came over her at 20 and she took the veil. Her new spirit of devotion was deepened by reading the 'Confessions of Saint Augustine' and being much distressed by the apparent decay of discipline which she saw around her, she founded in 1562 another convent at Avila, dedicating it to Saint Joseph and introducing a new order, the Discalced or Barefooted Carmelites, also called Teresians. She began by making this a genuinely mendicant order, but modified this detail of the rule in obedience to her superiors. From this mother house there sprang 16 other institutions of the same order. She spent the later part of her life in traveling from one to another of these branch houses and the staff, cross and rosary she wore on these pilgrimages are still preserved at Avila. She was seized with her last illness in the palace of the Duchess of Avila, but at her own request was carried to her convent of San José, where she expired surrounded by her followers. Gregory XV canonized her (1622) and appointed 15 October as her festival and Philip III declared her the second patron saint of the monarchy, Saint James (Santiago) being the first. This decree was confirmed by the Cortes in 1812. She also has a worldwide reputation as a mystic, and among the most famous books of devotion which the Roman Catholic Church can boast are her five works: 'Discourso o Relacion de Su Vida' (1562); 'El Camino de la Perfeccion' (1563); 'El Libro de las Fundaciones'; 'El Castillo Interior' (1577), and 'Santos Conceptos del Amor de Dios.' These have been translated into most of the languages of Europe. Consult 'Saint Theresa' (edited by Cardinal Manning, 1865); Graham, 'Santa Teresa' (1894); Jameson, 'Legends of the Monastic Orders'; Senonville, 'Sainte Thérèse et son Mysticisone' (1893); Joly, 'Saint Teresa' (1903); 'Vie de Sainte Thérèse, Ecrete par Elle-Même' (15th edition, edited by Jules Peyré, 1904).

TERHUNE, tėr-hūn', **Albert Payson,** American fiction writer, traveler and journalist: b. Newark, N. J., 21 Dec. 1872. He was graduated from Columbia in 1893 and in 1893–94 traveled on horseback through Syria, investigating leper settlements, living among the Bedouins, etc. He has been connected with the New York *Evening World* since 1895 and is an expert writer on historical topics. His publications include 'Syria from the Saddle' (1896); 'Dr. Dale: a Story Without a Moral' (with his mother, "Marion Harland," 1900); 'Caleb Conover' (1907); 'The Fighter' (1909); 'Dad' (1914); 'Damon and Pythias'; 'Columbia Stories'; 'Stories of the Superwomen'; 'The Woman' (1912); 'Dollars and Cents' (1915); 'The Years of the Locust' (1915), etc. He is originator and author of the New York *World's* famous Popular Educational Series that has been running in 50 American newspapers since 1906.

TERHUNE, Mary Virginia Hawes («Marion Harland»), American novelist and writer on domestic science: b. Amelia County, Va., 31 Dec. 1831. She began to write for the press when 14 and in 1856 was married to Edward Payson Terhune. She conducted *Babyhood,* for two years, established the *Home-Maker* in 1888, was a department editor on the staff of *Saint Nicholas* and *Wide-Awake* and later on the staff of the Philadelphia *North American.* Her novels have enjoyed a wide popularity and her cook-books and articles on household management are of practical value and extensively circulated. The latter include ‹Common Sense in the Household› (1872); ‹The Dinner Year-Book› (1877); ‹Marion Harland's Model Housewife›; etc. She was the originator of the movement to finish the monument over Mary Washington's grave and wrote in furtherance of her purpose ‹The Story of Mary Washington› (1892). Her other works include ‹Alone› (1854); ‹The Hidden Path› (1855); ‹Nemesis› (1860); ‹Husbands and Homes› (1868); ‹Loiterings in Pleasant Paths› (1880); ‹His Great Self› (1892); ‹More Colonial Homesteads› (1899); ‹Dr. Dale,› with her son, A. P. Terhune (1900); ‹Distractions of Martha› (1906); ‹Where Ghosts Walk› (1910); ‹The Long Lane› (1915), etc.

TERLINGUAITE, a native oxychloride of mercury, occurring in minute monoclinic crystals in the recently-discovered mercury deposits of Terlingua, Texas. It is transparent, has a sulphur-yellow color, brilliant adamantine lustre, hardness between 2 and 3, specific gravity 8.7. It is intimately associated with the other new mercury minerals, eglestonite and montroydite. See *American Journal of Science* IV, Vol. XVI, September 1903.

TERM, *in law,* (1) a limited or specific extent of time. (2) The time during which a court may legally transact business. In the United States terms vary according to the volume of judicial business and the available judges. (3) The time set for the payment of rents. (4) An interest or estate in land for a fixed time, as a year. If the term is for life it is a freehold and, therefore, treated as realty in law; if for years only, it is merely a personal interest and, therefore, personalty. (5) In Scots law, the period within which a party is compelled to produce evidence to support the allegations in his pleading.

TERMINAL MORAINE. See Moraine.

TERMINI IMERESE, Sicily, in the province of Palermo, 23 miles southeast of the city of Palermo, a seaport, on the northern coast, on a high and fertile point, near the San Leonardo River. It contains a museum, where are preserved antiquities of the ancient *Thermæ Himerensis,* founded 408 B.C., by the Carthaginians. Some ruins of the once-famous baths, as well as fragments of a theatre and an aqueduct, still exist. The chief products and exports include macaroni, corn, oil, olives, etc. There are important fisheries and good thermal saline baths. There is a school of navigation and a technical school, also a picture gallery. Pop. 21,000.

TERMINUS, a boundary stone or landmark, personified as the god who guards boundary lines and landed property. Jupiter was worshipped in Italy as Jupiter Terminus. The origin of this worship was attributed to Numa, who ordered that every one should mark the boundaries of his land by stones consecrated to Jupiter Terminus and should offer upon them every year at the festival of the Terminalia sacrifices of cakes, meal and fruit. This law also applied to the state, but the public termini were neglected in the later period of Roman history, while the termini of private property long retained their sacred character. A terminus stood in the temple of Jupiter in the capitol. On Roman coins a Terminus is represented like the Greek Hermæ, a square column surmounted by a head.

TERMITES, WHITE ANTS, or DUCK-ANTS, a family of insects composing the order *Isoptera,* which have a superficial resemblance to ants, though far removed from them in structure, being allied to the Mayflies. They also resemble ants in being social insects, living in colonies and building «nests» or «hills.» They are widely distributed in tropical countries, but also occur in the temperate parts of North and South America and a few have established themselves in Europe. Their food consists for the most part of wood, especially in a state of incipient decay, but they also eat a great variety of substances, including dead comrades and excrement. The termite society consists for the most part of wingless, sexually immature individuals, children, potentially of both sexes, which do not grow up. Besides these workers there is a less numerous caste of large-headed, blind, strong-jawed soldiers, but these are not so well differentiated as among the true ants. The workers collect food, form burrows and tunnels, build «hills» and care for the males, females, eggs and larvæ. The males and females have wings, which the latter lose after impregnation. Then, indeed, the female or queen undergoes a remarkable change, becoming enormously distended with eggs and sometimes attaining a length of two to five inches or more — «a large cylindrical package, in shape like a sausage and as white as a bolster.» As only the abdomen swells, the resulting disproportion between anterior and posterior parts is very striking. The queen is extremely prolific, having been known to lay 60 eggs in a minute or about 80,000 eggs in a day. In the royal chamber a male is also kept. It is hardly necessary to say that the queen could not leave if she would. But to understand this imprisonment we must notice that in spring the young winged males and females leave the nest in a swarm, after which pairing takes place; the survivors becoming the imprisoned «rulers» and parents of new colonies.

Fritz Müller has shown that besides the winged males and females there are (in many cases) wingless males and females which never leave the termitary in which they are born, being kept as complementary or reserve reproductive members, useful should not a winged royal pair be forthcoming. Sometimes this casualty occurs and then the wingless pairs become parents. The complementary kings die before winter; their mates live on, widowed, but still maternal, till at least another summer. Müller points out that, though the production and parentage of wingless males and females involves less mortality, the winged males and

ART IN TERRACOTTA

1. Cornice and honeysuckle moulding in the treasury at Olympia. 2. Water-spout from Pompeii. 3. Cornice from a temple at Selinus. 4. Vase decorated in relief from Campania. 5. Vase from Southern Italy. 6. Roman stamped terracotta (Head of Hermes). 7. Greek figure in clay from the Pourtlès collection. 8. Wine-pitcher from Athens (Winged Dionysian Eros). 9. Athena enthroned (archaic). 10. Juno Caprotina (Etruscan tile). 11. A dancing-girl with castanets.

females probably cross with those from other nests, thus securing the advantages of cross-fertilization. The workers are diligent in tending the king and queen, in removing the laid eggs and in feeding the larvæ.

In general appearance and size a wingless termite is ant-like, but the winged forms are much larger and flatter and their wings are quite different. The workers have large, broad heads and strong jaws adapted for gnawing; the soldiers have still larger heads and longer jaws. Besides the jaws and the two pairs of maxillæ the head bears a pair of beaded antennæ, two eyes and two ocelli, but the workers and soldiers are blind. The thorax has the usual three segments and bears simple legs; the abdomen consists of nine segments.

The most remarkable termitaries are those of *Termes bellicosus*, abundant on the west coast of Africa and called "ant hills." They are sugar-loaf-like in shape, 10 to 20 feet in height, and, though built of cemented particles of earth, are strong enough to bear a man's weight. Internally there are several stories and many chambers, some for the workers, one for the king and queen, others for the eggs and young, others for storing supplies of compacted minced wood. But the termites do not all build such gigantic nests; although some build homes on the branches of trees, out of masticated woody material, which are larger than barrels.

In Africa *Termes bellicosus* and *T. arborum* are common species. A few species, all probably introduced, occur in Europe. In America only one species is known in the eastern United States, the almost ubiquitous *T. flavipes*, which does an enormous amount of damage by eating out the interior of beams and floors, in old houses; destroying furniture, boring galleries through and through stored books and papers and ruining many other articles in which their presence is not suspected until no more than a shell remains.

VII–IX, 1873–75); Grassi, 'Memoria sulla Società dei Termiti' (Accad. Lineei, Roma, 1892); Sharp, 'Cambridge Natural History' (New York 1895); Howard, 'Insect Book' (New York, new ed., 1914).

TERMS OF OFFICE. See ELECTORAL QUALIFICATIONS.

TERN, or **SEA-SWALLOW,** any of many small gulls (q.v.; also *Laridæ*) distinguished by the long, slender and straight bill and by the narrow nostrils, which exist at its base. The wings are long and pointed and the tail is forked. The common tern (*Sterna hirundo*) is a familiar visitant to North Atlantic coasts. It is a very active bird, seeming to have a ceaseless flight, and feeding upon small fishes. Its average length is 15 inches, the long forked tail constituting a considerable element in this measurement. The color is black on the head and neck and ashy gray on the upper parts generally. The under parts are white, the legs, feet and bill being red. These birds have, however, nearly disappeared from the eastern shores of the United States, owing to their ceaseless persecution in their breeding places by egg-hunters and plume-hunters. About 80 species of terns exist in various parts of the world.

TERNATE (tĕr-nä'tē) **ISLANDS.** See MOLUCCAS, OR SPICE ISLANDS.

TERNI, tĕr'nē, Italy, in the province of Perugia, on an island, 50 miles north of Rome, in the midst of the Apennines, anciently known as Interamna. It is surrounded by the Nera River. The main buildings are the cathedral and other churches, convents and some Roman antiquities, chief of which is an amphitheatre. The celebrated falls or cascades of Velino or Terni near the city, 800 feet high, constitute the main attraction for visitors. They were constructed by the Romans to prevent inundations of the Velino River, by forming an outlet for the surplus water. Terni is a prosperous manufacturing town and it has important iron and steel works. The chief products of its works are silk and woolen goods, armor-plate, projectiles, steel castings, rails, guns, etc. This is the birth-place of Tacitus, the historian, and of the emperors Tacitus and Florian. Pop. 33,000.

TERPANDER, Greek musician: b. Antissa, Lesbos, 7th century B.C.; d. probably in Sparta. He was reputed to have gone to Sparta at the command of the Delphic Oracle. He was awarded the prize in the musical feasts of the festival of Apollo Carneius in 676 or 672 B.C. He is considered the founder of Greek classical music and was the originator of lyric poetry. He is reputed to have increased the number of strings on the lyre from four to seven, but this is probably an error, as evidence indicates an earlier date for that change. He was famous also as a teacher and a composer.

TERPENES, tĕr'pēns, a member of a class of hydrocarbons having the common formula $C_{10}H_{16}$, and found in the natural essential or ethereal oils obtained from a great variety of plants. They are usually liquids boiling between 340° and 375° F., of an aromatic odor and but slightly soluble in water. Two of the most important are pinene, the chief constituent of oil of turpentine, and limonene, which is found largely in the oils of orange, lemon, citron, bergamot, etc. Camphene is a solid terpene obtained by abstracting the elements of water from camphor. The camphors, two important examples of which are ordinary camphor and menthol, are oxygen derivatives of certain terpenes. See HYDROCARBONS.

TERPSICHORE, tĕrp-sĭk'ō-rē ("delighting in the dance"), one of the Muses, the originator and patroness of the art of dancing as accessory to the singing or recitation of lyrical poetry. She is generally represented with the lyre and plectrum, crowned with flowers and in a mirthful attitude.

TERRA ALTA, W. Va., city situated at the extreme western edge of the Allegheny plateau, 60 miles west of Cumberland, on the main line of the Baltimore and Ohio Railroad. It lies at an altitude of 2,500 feet, overlooking the beautiful Cheat River region, and is fast becoming a popular summer resort. There are two banks with combined resources of $1,100,000. The value of the city's taxable property is placed at $1,200,000. Its educational estab-

It is a very active bird, seeming to have a ceaseless flight, and feeding upon small fishes. Its average length is 15 inches, the long forked tail constituting a considerable element in this measurement. The color is black on the head and neck and ashy gray on the upper parts generally. The under parts are white, the legs, feet and bill being red. These birds have, however, nearly disappeared from the eastern shores of the United States, owing to their [illegible] persecution in their breeding places by [illegible] and plume-hunters. About [illegible] species of terns exist in various parts of the world.

TERNATE (ter-nä'tē) **ISLANDS.** See Moluccas, or Spice Islands.

TERNI, tĕr'nē, Italy, in the province of Perugia, on an island, 50 miles north of Rome in the midst of the Apennines, anciently known as Interamna. It is surrounded by the Nera River. The main buildings are the cathedral and other churches, convents and some Roman antiquities, chief of which is an amphitheatre. The celebrated falls or cascades of Velino, [illegible] Terni near the city, 500 feet high, constitute the main attraction for visitors. They were constructed by the Romans to prevent inundations of the Velino River, by forming an outlet for the [illegible] water. Terni is a prosperous manufacturing town and it has important iron and steel works. The chief products of its works are silk and woolen goods, armor-plate, projectiles, steel castings, rails, guns, etc. This is the birth-place of Tacitus, the historian, and the emperors Tacitus and Florian. Pop. 3[illegible]

TERPANDER, Greek musician: b. Antissa, Lesbos, 7th century B.C.; d. probably in Sparta. He was reputed to have gone to Sparta at the command of the Delphic Oracle. He was awarded the prize in the musical feasts of the festival of Apollo Carneius in 676 or 672 [illegible]. He is considered the founder of Greek classical music and was the originator of lyric poetry. He is reputed to have increased the number of strings on the lyre from four to seven, [illegible] this is probably an error, as evidence indicates an earlier date for that change. He is famous also as a teacher and a composer.

TERPENES, ter'pēns, a member of a class of hydrocarbons having the common formula $C_{10}H_{16}$, and found in the natural essential ethereal oils obtained from a great variety of plants. They are usually liquids boiling between [illegible] and [illegible] F., of an aromatic odor and but slightly soluble in water. Two of the most important are pinene, the chief constituent of oil of turpentine, and limonene, which is found largely in the oils of orange, lemon, citron, bergamot, etc. Camphene is a solid terpene obtained by abstracting the elements of water from camphor. The camphors, two important examples of which are ordinary camphor and menthol, are oxygen derivatives of certain terpenes. See Hydrocarbons.

TERPSICHORE, terp-sik'ō-rē ("delighting in the dance"), one of the Muses, originator and patroness of the art of dancing as accessory to the singing or recitation of lyrical poetry. She is generally represented with the lyre and plectrum, crowned with flowers and in a mirthful attitude.

TERRA ALTA, W. Va., city situated at the extreme western edge of the Allegheny plateau, 60 miles west of Cumberland, on the main line of the Baltimore and Ohio Railroad. It lies at an altitude of 2,500 feet, overlooking the beautiful Cheat River region, and is fast becoming a popular summer resort. There are two banks with combined resources of $1,100,000. The value of the city's taxable property is placed at $1,200,000. Its educational estab-

ART IN TERRACOTTA

1. Cornice and honeysuckle moulding in the treasury at Olympia. 2. Water-spout from Pompeii. 3. Cornice from a temple at Selinus. 4. Vase decorated in relief from Campania. 5. Vase from Southern Italy. 6. Roman stamped terracotta (Head of Hermes). 7. Greek figure in clay from the Pourtalès collection. 8. Wine-pitcher from Athens (Winged Dionysian Eros). 9. Athena enthroned (archaic). 10. Juno Caprotina (Etruscan tile). 11. A dancing-girl with castanets.

lishments comprise a public and a high school. The annual receipts and expenses of the municipality amount to about $7,500. Pop. 2,000.

TERRA BAIXA. See MARTA OF THE LOWLANDS.

TERRA COTTA, hard baked clay or earthenware of exceptionally good quality, of uniform texture, hard and durable. The 'English Dictionary of Architecture,' completed before there was much use in England of materials made with cement, speaks of it as artificial stone; but the term has also been used largely for that ancient earthenware of which are made the painted Greek vases which are so important in the history of art, and the inferior but still interesting pieces of Etruria. In common usage, however, the term is employed for such baked clay as is used in connection with architecture, whether in actual building, as where a hollow mass of the baked clay takes the place of a stone, or where a solid casting in the same material is used for molded string-courses and the like, in this way replacing bricks. It differs from brick in being harder, of better quality and molded to some special form or ornament.

Terra cotta is exposed without a coating of glaze or enamel, and its brown color constitutes the typical article. Japanese figures — groups, vases and the like — which were called «imitation bronze» when they were first brought to western countries are really terra cotta. They are often very beautiful in design, having the same vigor of modeling and perfect finish of all their parts which is found in the Japanese bronzes. The raku-yaki, that interesting brown ware which is used for tea-jars and tea-bowls and is the joy of the collector, is also a variety of terra cotta.

In the European Middle Ages terra cotta, unglazed, and also covered by a colored enamel, was used for roof tiles, and also for the much more elaborate pieces employed for crestings, and especially for those finials (in French *épis*) which are used where the hips of the roof meet the ridge and where in this way a salient point is produced. These finials often include the wind-vane which, however, would be commonly of wrought iron. The custom of using terra cotta in these ways lasted into the time of the revival of classic architecture, and some of the most interesting pieces are French of the 16th century; the custom not disappearing until the complete establishment of pseudo-classic uniformity of design throughout Europe. Chimney tops pierced with decorative openings through which the smoke might issue were also made of terra cotta and the custom still lingers in those simply built houses of Italy, Greece and Switzerland, where chimneys are built of hard baked earthenware tiles set in strong cement mortar and in this way made very light and thin.

Purely decorative pieces were also made of this material; but in the way of architectural adornment the most important development was in that Della Robbia ware (q.v.) which, however, is not often spoken of as terra cotta because it is covered completely by an opaque enamel which receives a most brilliant and effective polychromy, adding in this way color to sculpture in the most emphatic and interesting way known since antiquity. Still such pieces as the door-heads of many churches in Florence and elsewhere and the magnificent altar-backs; the lavabos or washing-fountains and the like throughout central Italy are among the most effective pieces to be found in that region. The most extensive and splendid work in Della Robbia ware is the broad frieze of the Hospital at Pistoja.

In the 18th century terra cotta, which had always been used by the French sculptors for the permanent form of many works of art, received a fresh impulse from the practice of Jean Antoine Houdon (q.v., see also UNITED STATES, SCULPTORS OF), Claude Michel (q.v.) (called Clodion) and others, among whom should be named certain makers of medallions as well worthy of study as the bronze medallions of the Italian Renaissance. In modern French practice portrait busts are very frequently made in baked clay, the same artistic quality being given them as to works in bronze or marble. The difficulty caused by the shrinking of the piece in the drying and subsequent baking is only to be met by extreme care in the selection and preparation of the material. The piece shrinks, but it may be made to shrink uniformly and without disturbing the symmetry.

Modern architectural terra cotta continually comes to the front as a material allowing of much richer treatment at a reasonable price than carved stone; but for some reason it never becomes very general in its application. A large business building in New York had its roof brackets or consols made of this material before 1855. The old Boston Museum of Fine Arts contained much decorative terra cotta brought from England and this front was completed about 1865. The constant demand for fireproof materials by means of which the exterior of a large building may remain without serious damage in spite of a hot fire across the street has made concrete, brick and terra cotta the obvious material for the facing; but stone, marble and granite still retain their places in many structures.

In making monumental figures, groups, designs, etc., of terra cotta the steps are: Mixing and kneading the clay; molding; retouching, for taking off any blemishes; baking; coloring and sometimes gilding. Modeling by hand is now rare, except in designing for a mold. The high grade work acquires its perfection largely by careful retouching. Baking requires to be performed slowly to permit evaporation of the moisture without injury. The coloring is mostly done after firing, solid body colors being employed, as browns, blues and reds, with occasional black or bright colors for sane detail. Some of the Roman terra cottas are in a fine state of preservation though dating back 2,000 or more years.

Within recent years there has been a marked increase in the use of terra cotta, often colored, for ornamenting steel and concrete buildings and for roof-tiles. Consult Strack, H., 'Brick and Terra Cotta Work During the Middle Ages' (Boston 1914); Walters, H. B., 'The Art of the Greeks' (London 1906) and the 'Annual of British School at Athens.'

TERRA DI LAVORO, tér-rä dē lä-vō'rō. See CASERTA.

TERRA VERDE, or **VERTE** (Italian «green earth»), a green mineral pigment used by painters in oil. A deposit of this earth is found in the neighborhood of Verona, Italy. There is a similar deposit in the island of Cyprus. The native green found in Italy is a silicious earth colored by protoxide or iron of which it contains about 20 per cent, and it is of extreme value as a permanent and brilliant tint in landscape painting.

TERRACES, successive benches or levels along the sides of valleys. A valley may show one or several terraces, varying greatly in height and in width. If composed of rock they are known as rock terraces. These may result from the presence of hard layers of flat-lying rock, as on the sides of the Grand Canyon of the Colorado. In other cases they are the results of successive uplifts, a narrower valley each time being incised within the broader older valley, leaving a remnant of the older valley bottom as the terrace. Alluvial terraces are composed of stratified gravel, sand or clay. Their history is usually more complex. After a given valley has been eroded, the first step is the filling of its basin with alluvium to some depth. This may be brought about by many causes. Particularly did it occur during glacial times, when the streams flowing away from the ice front were overloaded, filling their valleys with glacial outwash. Any cause which, after the valley is filled, will start the rivers to eroding, will obviously leave a gravel bench on one or both sides of the river. This renewed erosive activity may, in the case of glaciation, be merely the melting away of the glaciers, with the consequent return to normal conditions. It may be the result of uplift and rejuvenation of the streams, or it may result from climatic or other causes.

TERRACINA, tĕr-rä-chē'nē, Italy, in the province of Rome, on a gulf of the same name, near the Pontine marshes, about 18 miles northwest of Gaeta, and 56 miles southeast of Rome. It is a historical town lying on the Appian Way. It was sacked in 409 and again in 595. It is the see of a bishop and has a cathedral and handsome episcopal palace. The cathedral is built in the Italo-Byzantine style and incorporates the pillars of an ancient temple. Excavations have revealed the remains of a splendid temple of Venus. The main occupation consists in the fisheries. Pop. of the commune about 12,000.

TERRAPIN. See Diamond-back Terrapin; Turtles.

TERRAPIN, tĕr'ă-pĭn, a tortoise of the family *Emydidæ*. There are several different members of the family, all of which are fresh-water or tide-water. The name is also applied to the "elephant terrapin" of the Golapagos. Terrapin is held in great favor by epicures, especially in the United States.

TERRE HAUTE, tĕr'ē hōt (French, meaning "high land"), Ind., city, county-seat of Vigo County, on the Wabash River, and on the Chicago and Eastern Illinois, the Evansville and Terre Haute, the Evansville and Indianapolis, the Chicago, Terre Haute and Southeastern, and the Cleveland, Cincinnati, Chicago and Saint Louis railroads. It is 178 miles south of Chicago, 163 miles northeast of Saint Louis, 182 miles northwest of Cincinnati, and 72 miles west of Indianapolis. There are more than a dozen lines of railroads entering the city, two of which were built in 1905. It is one of the most prominent railroad and manufacturing cities of the Middle West. Terre Haute is one of the oldest settlements in the State; in 1816 it was laid out as a city, and in 1833 was chartered.

Topography.— The city is beautifully laid out on an elevated plateau, amid picturesque surroundings. It is connected with the west side of the river by several handsome railroad bridges, and for the use of the general public there was constructed a fine bridge (contract price, $27,000). There are several parks; the broad streets in summer time present a forest appearance. The residential part has many fine edifices in most beautiful surroundings.

Industries.— The city is in a rich agricultural region and in the centre of coal fields comprising over 2,000 square miles, containing a fuel supply which, at the present rate of consumption, will not be exhausted for 200 years. Coal is shipped from here to points within a radius of 400 miles, and it is a distributing point for about 1,500 carloads per day. The city is the industrial and commercial centre for a large portion of the western part of Indiana and the eastern part of Illinois. The manufacturing industries embrace rolling mills, foundries, distilleries, breweries, flour mills, hominy mills, car works, railroad shops, glass factories, stamping works, feed mills, tool works, fencing works and carriage factory. In the vicinity are large deposits of shale and clay and a number of clay plants are in operation nearby. In 1910 (government census) the total number of manufacturing establishments was 170; total capital invested in plants, $10,371,000; average employees yearly, 5,017; annual wages paid to employees, $3,219,000; cost of material used during year, $8,657,000; total annual value of products, $21,793,000. Owing to the failure of the natural gas supply in many places, there has been since 1910 an influx of manufacturing industries to take advantage of the cheap fuel and the railroad facilities. This accounts for the large increase in population.

Public Buildings.— The prominent public buildings are the government building, the county courthouse, city hall, opera house, the Union station, the schools, churches, charitable institutions, hotels and several business houses.

Charitable Institutions and Organizations. — The Rose Ladies' Aid Society cares for a large number of the poor, and has charge of the Home for Old Ladies. This home has an endowment of $100,000. The other institutions and organizations for the relief of the needy are Saint Anthony's Hospital (building cost $160,000), in charge of the Sisters of Saint Francis; Saint Ann's Orphan Asylum, in charge of Sisters of Providence; Rose Orphan Home, endowment, $200,000, building, $130,000; Union Hospital (Protestant), endowment, $25,000; Rose Dispensary, endowment, $200,000; and a number of church aid societies.

Education.— The educational institutions are the Indiana State Normal School, which annually enrolls over 1,000 pupils; the Rose Polytechnic Institute, founded by Chauncey Rose and opened in 1883; two high schools, 26 public elementary schools, Roman Catholic and Lutheran parish schools; Saint Joseph's

Academy (Roman Catholic); Saint Mary's of the Woods, a school for girls; a public library and libraries connected with the Normal School, and the Polytechnic Institute.

Banks and Finances.— The three national banks have a combined capital and surplus of about $2,000,000; one savings bank has deposits amounting to $1,700,000; and three loan and trust companies have capital and surplus of $1,205,000. The average annual cost for municipal maintenance and operation is $400,000. The public schools cost annually about $200,000; the police department $29,000; the fire department $40,500; for municipal lighting and streets $50,000.

Government.— The city is governed by a special charter granted by the legislature. The mayor and common council appoint or elect the administrative officials. The mayor appoints the boards of public works and public safety; the school board is elected by the council. The chief departments are fire, police, waterworks and municipal lighting. Pop. 75,000.

TERRELL, tĕr'ĕl, **Joseph Meriwether,** American politician: b. Greenville, Ga., 6 June 1861. He was admitted to the bar in February 1882, and in 1884 and 1886 was elected to the Georgia house of representatives. He was chosen United States Senator from Georgia in 1890, and was attorney-general for that State 1892–1900. He resigned in 1902 to accept the nomination for governor of Georgia, to which office he was elected in October of that year.

TERRELL, Tex., city in Kaufman County on the Texas Midland and the Texas and Pacific railroads, about 30 miles east of Dallas. It was settled in 1872 by Robert Terrell. It is an agricultural and stock-raising region, being one of the largest wagon cotton markets in the world. Chief manufacturing establishments are the Texas Midland Railroad shops, cottonseed-oil mills, cotton gins, cotton compresses, flour mills and factory for the manufacture of ladies' house dresses, sun bonnets and aprons. There is a large trade in wheat, oats, cotton, vegetables, fruits and livestock. The principal buildings are the North Texas Hospital for the Insane, schools, Carnegie Library, Elks Home, Federal building and city hall. There are eight churches. The educational institutions are the Texas Military College, a select training school for boys with both cavalry and infantry drill; two high schools (one for white and one for negro students), graded and ward schools and one private primary school. Three banks, with a combined capital of $600,000. The city has commission form of government, with initiative, referendum and recall features and government in hands of commission of five, one from each of the three wards of the city and two from the city at large, the functions of mayor being invested in the chairman of the commission. Commissioners elected for two years, two being elected one year and three the next. Pop. 8,500.

TERRES MAUDITES. See La Barraca.

TERRESTRIAL, or **CONTINENTAL, DEPOSITS,** those laid down on land in contrast to marine sediments laid down in the ocean. They may be alluvial, formed by rivers on flood plains; glacial, formed by glaciers; eolian, wind-blown material such as sand dunes; or lacustrine, laid down in lakes. Terrestrial deposits, like marine, may consist of gravels, sands and clays, forming conglomerates, sandstones and shales. Terrestrial limestones are rare, though they may form in swamps, or as wind-blown shell fragments, as the eolian limestones of Bermuda. Continental deposits are not likely to be as extensive or as regular in composition as marine beds, since the conditions under which they are formed are more variable. They are often marked by rain prints and sun cracks and by fossils of land plants and animals. See section on *Sedimentary Rocks,* in article on Rocks.

TERRESTRIAL MAGNETISM. See Magnetism.

TERRIER, the name of several small breeds of dogs. Terriers were originally used for unearthing the fox and for killing rats and other vermin, and several kinds are still employed in these and similar occupations. Some are good watch-dogs, and others are useful as retrievers. The most popular variety is the fox terrier, which came into fashion about 1863. It is generally white, with a smooth, dense, hard coat; its chest is deep and not broad; neck fairly long; nose black; ears small, V-shaped, pendulous. The maximum weight is about 20 pounds, and in accordance with a cruel practice the tail is frequently docked. There is also a wire-haired variety of the fox terrier. The bull terrier, for show purposes all white since 1860, is a larger animal produced by crossing a terrier with a bulldog. It has a long, tapering head, black nose, long and slightly arched neck, wide and deep chest, short, close, stiff, glossy coat and a comparatively short, tapering tail. The Boston terrier is a new and popular American breed, of great docility, kindness and quality. The Irish terrier, a trifle larger than the fox terrier, is of a reddish-yellow, wheaten or light-brown color inclining to gray, with a hard, wiry coat free from silkiness. Its chest is deep and medium wide; head long and flat; nose black; ears V-shaped and pendulous; neck long and slightly arched; and its tail usually docked and carried high. The Scotch terrier, a smaller animal, has a rather short, wiry, very dense coat of various colors, such as steel-gray, brindle or grizzled, black, sandy and wheaten. It has a tapering muzzle, black nose, small, prick or half-prick, sharp-pointed ears, short thick neck, broad and deep chest, uncut tail carried high with slight bend. The Skye terrier, the smallest of useful terriers, may be of any color. Its coat is double, the under part consisting of short, close, soft hair, and the outer part of long, hard hairs, free from curl or crisp. It has a long head, black muzzle, prick or pendent ears, deep chest, long and gently crested neck and short legs, and its tail may be carried either high or low. The Clydesdale or Paisley terrier is a kind of prick-eared, silky-coated Skye terrier. One of the modern varieties is the Welsh terrier, about the size of the fox terrier, with a close, wiry coat of a black-and-tan or black, grizzle and tan color. There is also an English white terrier, not unlike a small bull terrier. The Dandie Dinmont is a favorite small one, of a pepper or mustard color, with a moderately long coat consisting of hardish and soft hair mixed but without wiriness. Its large head is covered with soft, silky hair; nose black or dark; ears large and pendulous; tail of moderate length, with a regular upward curve. The Bedlington terrier is a slightly larger form, somewhat similar to the Dandie Dinmont. The black-and-tan or Manchester terrier has the head long, flat, tapering; nose black; ears small, V-shaped, hanging; neck long and tapering; chest narrow and deep; tail of moderate length, tapering; coat close, smooth, short, glossy; color jet-black and mahogany tan in different parts. He was produced by long years of skilful selection by the Manchester mill-hands of England, and is one of the smartest, pluckiest vermin-killers and most interesting pets on the list. The Schipperke resembles it, but is of German origin. One of the largest of the terriers is the Airedale, with pendulous ears, deep chest, high tail, hard and wiry coat, lying straight and close, and of a tan, black or dark grizzle color. The Yorkshire is the best known of the small top terriers. Consult Lee's 'Modern Dogs' (1896); Huntington, 'The Show Dog in America' (Providence 1901). See Dogs.

TERRIGENOUS, derived directly from the land, a term applied to those marine sediments like sands and clays, which are of direct land origin, as contrasted with pelagic deposits accumulating in the deep sea as the result of organic agencies, which extract their substance from solution in sea water. See section on *Sedimentary Rocks* in article on Rocks.

TERRITORIAL COURTS. See Court.

TERRITORIAL EXPANSION. See United States — Territorial Expansion of the.

TERRITORIAL WATERS. See International Law.

TERRITORIES, in the United States, certain parts of the national domain which have not been formed into States. Starting with 13 States it has been the policy of the United States in taking in new territory to require of the inhabitants evidences of fitness for self-government. This nation first added to its territory by the Louisiana Purchase, in 1803, 828,000 square miles. Florida and another territory to the total of 72,000 square miles were annexed in 1819; Texas in 1845; Oregon in 1846; the Mexican cession in 1848; Gadsden Purchase (30,000 square miles) in 1853; Alaska (591,000 square miles) in 1867; the Philippine and Hawaiian Islands in 1891; Guam and Porto Rico in 1898 and later (about 125,000 square miles); the Panama Canal Zone (436 square miles) in 1904; the Danish West Indies (now the Virgin Islands) of 142 square miles in 1917.

Of the above only the District of Columbia, Alaska and Hawaii are regarded technically as «territories.» The others that have not been granted Statehood are held as «possessions,» it having been decided by the United States Supreme Court in 1901, in the «Insular Cases,» that Congress can create appropriate forms of government in regions outside the States and legislate differently for such possessions.

The Philippines are at present governed by a commission of seven members appointed by the President. The commission is vested with the power of legislation and administration subject to the veto power of Congress. As yet no legislature has been established but the act of Congress passed in June 1902, under which the Philippines are now governed, provides that within two years following the date of the enactment of the said law, if a state of pacification exists in the island, an election shall be held for members of a legislative assembly of which the upper house is to consist of the members of the Philippine Commission. As soon as this is done the powers of local legislation now exercised by the Philippine Commission will pass to the legislative assembly. As yet no great degree of local self-government is allowed nor are the islands represented at Washington either by a commissioner or delegate. The inhabitants are not citizens of the United States and the determination of their political and civil status is left to Congress. The Samoan Islands and Guam are governed by military and naval governors, respectively. Of the unorganized domestic Territories Alaska has a governor, judiciary and other officers, appointed by the President, but has neither legislature nor delegate in Congress. A measure of local self-government has recently been allowed incorporated towns of 300 inhabitants. The District of Columbia is governed by three commissioners, two of whom are appointed by the President from civil life and the third is detailed from the engineer corps. They have general charge of the administration of the District, including the appointment of local officers. The law-making body, as in the case of Alaska and the Philippine Islands, is Congress, but the District has no delegate in the House of Representatives. Half the expense of governing is borne by the United States, the other half by residents.

Hawaii has obligated itself to incorporate the inhabitants into the American Union as soon as consistent with the principles of the Constitution. All the States thus far formed out of territory acquired from foreign nations except Texas and California have passed through the territorial stage. No general rule exists as to the period of pupilage through which the inchoate State shall be required to pass. In some instances, as in the case of Kansas, it has been as short as four years, while on the other hand Arizona and New Mexico after 60 years of territorial status were finally admitted as States. The nearest approach to a general rule is the requirement that the population of the Territory shall be as great as the ratio of representation in Congress, but this has often been disregarded, usually for political reasons. Thus Nevada was admitted for political purposes when its population scarcely exceeded 20,000, while Utah was refused admission long after its population exceeded the Congressional ratio. For a more detailed discussion of this subject see the articles on each separate State and Territory.

TERROR, Mount, Antarctic Regions, a volcanic mountain situated close to Mount Erebus (q.v.) on the coast of Victoria Land, in lat. 77° 30′ S. and long. 167° E. Its height is 10,883 feet. It was discovered in 1841 by Sir James Ross and named after one of his ships.

TERROR, Reign of, the period of the French Revolution extending from the downfall of the Girondists, June 1793, to that of Robespierre (q.v.), 27 July 1794. For an account of it see FRANCE — HISTORY B.C. 58 TO A.D. 1796.

TERROR, The White, the period of Bourbonist reprisals at the second Restoration. (See LOUIS XVIII). It was so called from the white flag (*le drapeau blanc*) of the Royalists. An «Edict of Amnesty» was published on 24 July 1815 but 57 were exempted from it — 19 to be tried by courts-martial on capital charges and 38 to be either exiled or brought to justice, as might be determined. In southern France there was rioting, assassination and pillage. This was especially true in Nismes and the surrounding region, where the victims were largely of the Reformed faith. The government was slow to intervene and the Allies were compelled to take matters into their own hands, a detachment of Austrian troops occupying the department of the Gard. In other districts there were similar outbreaks. Consult Vaulabelle, 'Histoire des Deux Restaurations' (1844 et seq.), and Daudet, L. M. E., 'La Terreur Blanche' (1878).

TERRY, tĕr'ĭ, **Alfred Howe,** American soldier: b. Hartford, Conn., 10 Nov. 1827; d. New Haven, 16 Dec. 1890. He was educated at Yale Law School and began practice in 1849. He had been a member of the State militia prior to the Civil War and at the call for volunteers he with his regiment, the 2d Connecticut, responded and was engaged in the battle of Bull Run. Being made a brigadier-general, he served in 1862–63 in the operations near Charleston. He commanded a corps in the Army of the James and fought at Chester Station, Drewry's Bluff and the siege of Petersburg and was entrusted with the military part of the second attempt on Fort Fisher, January 1865, co-operating with the admiral. The successful storming of the fort resulted in his being made a brigadier-general in the regular army. He captured Wilmington and was a departmental commander after the war. General Terry became major-general in 1886 and retired in 1888.

TERRY, Benjamin Stuytes, American educator and historian: b. Saint Paul, Minn., 9 April 1857. He was educated at Colgate University (A.B. 1878; A.M. 1881) and pursued theological studies at Hamilton and Rochester seminaries, resulting in his ordination as a Baptist minister 31 Aug. 1881. He occupied pulpits at Perry, N. Y. (1881–83) and at Fairport, N. Y. (1883–85). From 1885 to 1892 he was professor of history at Colgate University and took the degree of Ph.D. at Freiburg in the latter year. Directly thereafter he assumed the chair of English history at the University of Chicago. He is member of several historical societies and author of many historical articles in standard magazines. His best-known books are 'A History of England from the Earliest Times to the Death of Victoria' (1901) and 'A History of England for Schools' (1903).

TERRY, Charles Sanford, British historical writer: b. 1864. He was educated at Kings College school and Clare College, Cambridge, graduating B.A. 1886, and M.A. 1891. He lectured in history in several noted schools and was professor in the University of Aberdeen in 1898–1903. He became a well-known writer and authority on historical subjects, his best known publications being 'Life and Campaigns of Alexander Leslie, First Earl of Levin' (1899); 'The Rising of 1745' (1900; new ed., 1903); 'The Chevalier de Saint George' (1901); 'The Cromwellian Union' (1902); 'The Young Pretender' (1903); 'John Graham of Claverhouse' (1905); 'The Scottish Parliament' (1906); 'Craig's De Unione,' trans. with notes (1909); 'A Short History of Europe' (3 vols., 1911–15); 'Bach's Chorals' (2 vols., 1915); 'The Army of the Solemn League and Covenant' (2 vols., 1917). He also prepared catalogs of the publications of the Scottish historical clubs and an index of papers relating to Scotland.

TERRY, David S., American jurist: b. Todd County, Ky., 1823; d. Lathrop, Cal., 14 Aug. 1889. He served in the Texan War against Mexico under Gen. Sam Houston and in the war between the United States and Mexico; went to Calaveras County on the discovery of gold in California; and after some experience in mining studied law and began practice in Stockton. Elected an associate-justice of the California State Supreme Court in 1855, he became chief justice in 1857. He strongly opposed the procedure of the «vigilance committee.» In 1859 he killed Senator D. C. Broderick in a duel near San Francisco. Broderick had been an uncompromising opponent of the extension of slavery, particularly in Kansas, had taken active part in the bitter California campaign of 1859 and in one of his speeches made certain strictures resulting in a challenge. After service in the Confederate army during the Civil War Terry resumed practice in San Francisco.

TERRY, Ellen Alice, English actress: b. Coventry, Warwickshire, 27 Feb. 1848. Her parents were both actors and she made her first appearance at the age of eight, under the management of Mrs. Charles Kean at the Princess Theatre, London. A little later she won high praise as the young Prince Arthur in 'King John.' During the periods of 1860–63 and 1867–68 she acted with various stock companies, first appearing with Henry Irving in 1867, as Katherine to his Petruchio in 'The Taming of the Shrew.' She was married early in life to G. F. Watts, the painter, but the union was shortly dissolved, and she was married to E. A. Wardell in 1864, and again on 3 May 1907 to James Carew. She was absent from the stage 1868–74 and in 1875 won her first great success as Portia in a revival of 'The Merchant of Venice' at the old Prince of Wales Theatre. This she shortly followed with the title rôle in W. G. Will's play, 'Olivia,' the result being that Henry Irving made her his leading lady and the long artistic partnership at the Lyceum Theatre was commenced. Some of her impersonations at the Lyceum have been Ophelia, Portia, Desdemona, Juliet, Beatrice, Lady Macbeth, Cordelia, Margaret in Will's 'Faust,' the Queen in Will's 'Charles I,' Pauline in 'The Lady of Lyons,' etc. In company with Irving she has several times visited the United States and has been invariably successful. While still with Irving she joined Mrs. Kendal and Beerbohm Tree in a revival of 'The Merry Wives of Windsor' at Her Majesty's Theatre in 1902. She was honored by a jubilee performance at Drury Lane Theatre, London, in 1906. She published 'The Russian Ballet' (1913). Consult her autobiography, 'Story of My Life' (New York 1908).

TERRY, Henry Taylor, American lawyer: b. Hartford, Conn., 19 Sept. 1847. He was graduated from Yale in 1869 and was admitted to the bar in 1872. In 1878 he became professor of law at the Imperial University, Tokio, Japan, but returned to New York in 1884 and resumed practice the following year. In 1894 he again went to Japan and resumed his former position of professor of law. In 1912 he resigned his professorship and was made professor emeritus. He returned to the United States but did not resume active pratice. He is the author of 'First Principles of Law' (Tokio 1879); 'Leading Principles of Anglo-American Law' (Philadelphia 1884); 'The Common Law' (Tokio 1895), besides various articles in American and English legal journals. He received decorations from the emperor of Japan, the Order of the Sacred Treasure (II) and of the Rising Sun (III).

TERRY, Milton Spenser, Episcopal clergyman: b. Coeymans, N. Y., 22 Feb. 1840; d. 1914. He was educated at the Charlotteville Seminary and at the Yale Divinity School. He held various pastorates near New York between 1863 and 1884 when he was made head of the department of Hebrew and Old Testament exegesis and professor of Christian doctrine in the Garrett Biblical Institute at Evanston, Ill. Wesleyan University gave him the degree of S.T.D. in 1879; in 1871 he was made a member of the American Oriental Society and in 1883 of the Society of Biblical Literature and Exegesis. In 1881 he published 'Man's Antiquity and Language,' which was followed by a number of scholarly publications in steady succession, notably 'Biblical Hermeneutics' (1883); 'Sibylline Oracles' (1890); 'The New Apologetic' (1892); 'Biblical Apocolyphics' (1898); 'Moses and the Prophets' (1901); 'The New and Living Way' (1904); 'The Mediation of Jesus Christ' (1902); 'The Primer of Christian Doctrine' (1906); 'Biblical Dogmatics' (1907); 'The Shinto Cult' (1910); 'Baccalaureate Sermons and Addresses' (1914). He also published several Biblical commentaries.

TERTIARIES, tẽr'shĭ-ā-rĭz, members of the Third Order of various religious societies in the Roman Catholic Church. They are generally lay members of religious orders who follow ordinary avocations and duties in their communities, yet participate in certain work of a given order. Shortly after the institution of the Franciscan Order by Saint Francis of Assisi in the beginning of the 13th century, numbers of lay people were affiliated with the Franciscans under certain rules and restrictions, which bound them more systematically to a life of penance and devotion than ordinary persons living in the world. In the course of time many of these Tertiaries desired to take solemn vows, live in community and still follow the regulations of the Third Order. In this way rose various Tertiary congregations, which gradually united under the one government. Benedict XIII in the beginning of the 18th century recognized these Tertiary congregations and the laity affiliated with them as "a true and proper order, uniting in one seculars scattered all over the world and regulars living in community." Leo XIII recommended the Third Order in an especial manner to the faithful throughout the world, as a means of personal sanctification to be embraced by lay people who desired to lead a more devout life.

The Dominicans also had their Tertiaries, instituted by Saint Dominic himself, though in what year is uncertain. It was known as the Military Order of Christ, originally composed of knights and noblemen, whose duty it was to wage war against heretics. After the death of the founder this became the order of the penitents of Saint Dominic, for both sexes, and constituted the third order of Dominicans. These Tertiarians, without making any solemn vows, had the assurance of great spiritual privileges through the observance of a few fasts and prayers; they continued, also, in the enjoyment of their civil and domestic relations. Some few companies of Dominican sisters of the Third Order, particularly in Italy, united in a monastic life, and became regular nuns; the most celebrated of whom is Saint Catharine of Sienna. Other religious orders after the example of the Franciscans and Dominicans also established tertiary affiliations; the Augustinian hermits in the beginning of the 15th century, and later on the Minims, the Servites, the Carmelites and the Trappists. At the present time there are numbers of the laity throughout the world affiliated with the third orders and observing their regulations while still following their secular vocations in the world. See DOMINICANS.

TERTIARY PERIOD, the space of time, geologically considered, immediately preceding the present, and occupying the earlier and larger part of the Cenozoic era; also the rock system then formed. It is preceded by the Cretaceous. Tertiary strata were at first confounded with the superficial alluviums of Europe and it was long before their real characters were realized. They occur most generally in patches,—some of them of marine origin, others of fresh-water or of continental derivation. Rocks of this age were first described by Cuvier and Bronginart in 1810 from the Paris Basin, where they are well developed and highly fossiliferous. The shells found in these deposits were recognized as different from those of the modern time, though related to them, while the bones of quadrupeds were found to be of extinct species. Similar strata from many other parts of Europe were subsequently found. Those of Italy were found in low hills flanking the Apennines on both sides from the plains of the Po to Calabria and called by Basterot, who studied them, the Subapennines. The fossils of these beds were of a more modern type than those of Paris or London. In the neighborhood of Bordeaux, in the south of France, another series of Tertiary strata were discovered and described by M. de Basterot in 1825. The several hundred species of shells described from these beds were found to differ mostly from those of the Paris Basin and those of the Subapennines, and to possess an intermediate character between the two. Subsequently it was found that strata contemporaneous with those of Bordeaux overlie the Parisian formation in the valley of the Loire, and underlie the Subapennine beds in Piedmont.

In 1828 and 1829 Lyell conceived the idea that the Tertiary beds might be subdivided according to the percentage of living species in each. For this purpose, he and M. Deshayes, a well-known French conchologist, compared some 3,000 Tertiary with about 5,000 living species. The result arrived at was, that in the lower strata, or those of London and Paris, there were about 3½ per cent of recent species, in the middle Tertiary of the Loire, Bordeaux, etc., about 17 per cent of recent species and in the upper Subapennine Tertiary from 35 to 50 per cent of living species. These results were published in 1833. In formations still more modern, which Lyell studied in Sicily, where they attain a vast thickness, the percentage of living species was found to be 90 or 95. To these four series Lyell applied the names Eocene, Miocene, Older Pliocene and Newer Pliocene. A still later formation (Post-Tertiary) was called Pleistocene, in which the shells were all of recent types, but the mammals partly of extinct species. The most important recent modification of this nomenclature has been the introduction of the term Oligocene by Beyrish to include strata formerly classed partly as Upper Eocene and partly as Lower Miocene. The generally recognized divisions from the base up are now given as Eocene Oligocene, Miocene and Pliocene. At present much less stress is laid upon the numerical method of subdivision employed by Lyell and Deshayes. As the various deposits of the typical Tertiary beds of Paris, London, the Loire Basin and the Subapennine series became well known, a standard of comparison became established, by which similar deposits of other regions could be determined. This is the method employed to-day in deciding to which division a given deposit should belong.

The general characteristics of geography, vegetation and animal life of the Tertiary were similar to those of the present time, but land areas were of less extent and were more largely occupied by interior fresh-water basins. The climate of the early Tertiary was evidently warmer and more moist than that of the period following it, types of plants now strictly tropical then covering areas now under Arctic latitudes and influences. In the United States the Atlantic and Gulf costal plain underwent repeated submergence and emergence. During the first half of the period, the site of the Pacific Coast Ranges was largely under water, but in mid-Tertiary the Coast Ranges were upheaved, and the coast line took nearly its present form. The great western interior had undergone upheaval at the close of the preceding period (Cretaceous) in the formation of the Rocky Mountains. During Tertiary these underwent extensive erosion, building, on the great plains and in the intermontane basins, fairly thick beds of terrestrial gravel, sand and clay. A few lake deposits were also formed. Volcanoes were active during much of the period, from the Rocky Mountains westward, forming thick beds of ash and very extensive lava flows, as on the Columbia Plateau in Oregon and Washington. Marine Tertiary beds are found on the Atlantic and Pacific coasts. The most important of these are the strata of the Atlantic coastal plain with its expansion in the Gulf of Mexico. On the Atlantic Coast the Eocene beds are mostly clays and greensands which rest unconformably upon the Cretaceous strata and are unconformably overlain by the Miocene beds. All of these beds are highly fossiliferous, shells predominating. In the Miocene is a great bed of diatomaceous earth (q.v.) from 200 to 300 feet thick. In South Carolina, Pliocene beds make their appearance. No Oligocene strata are known from the Atlantic Coast. On the Gulf Coast the Eocene is well represented and rests upon the Cretaceous. It consists mainly of marls, greensands, clays and sands. Both Oligocene and Miocene are represented on the Gulf Coast. The Oligocene is characterized by a warm-water or subtropical fauna. The Miocene beds of the Gulf States represent the advent of the colder water fauna from the North. Pliocene beds of the age of those formed in South Carolina are extensively developed in Florida.

Tertiary deposits are well developed in the interior of the United States between the Mississippi River and the Rocky Mountains. They consist of non-marine strata, partly lacustrine, partly eolian and partly made up of wash from the mountain sides in the form of coarse alluvial cones or fans. In these deposits numerous bones of extinct mammalia are found, of which extensive collections have been gathered in the various museums of the country, particularly in the American Museum of Natural History in New York. Most of the deposits are in isolated basins, and can only be correlated by their vertebrate fauna. On the Pacific Coast, all the epochs of the Tertiary are represented, being in part marine, in part terrestrial.

Life of the Tertiary.—At the close of the Cretaceous period all the flying reptiles and dinosaurs, and most of the marine reptiles, seem to have become extinct; and the Tertiary formations, so far as known, yield only forms of *Vertebrata* essentially similar to those of the present day. Among fishes, all of the existing suborders and many of the existing families or even genera seem to occur in the Eocene. Among the invertebrates, ammonites, belemnites and most of the crinoids had passed away when the Tertiary era began; and forms came in, whose descendants are now familiar to us. The *Mammalia* suddenly appeared as the dominant type on all the continents and the evolution of many of the minor groups can be traced. Primitive tapirs and primitive horses, with four toes (*Orohippus* and *Eohippus*) occur. Among the Oligocene mammals may be mentioned the *Mesohippus*, or horse with only three functional toes. The peculiar *Oreodon* occurs in beds above the *Titanotherium* and represents a type intermediate between hog and deer in structure. Early camels, the earliest true carnivores, early bats, squirrels and rodents and marsupials also occur in these beds. *Miohippus*, a still more modified horse, occurs in the John Day and the Deep River beds; in the latter also occurs the oldest mastodon. In the Loup Fork beds occur *Procamelus*, *Mastodon* and dogs of the genus *Canis*. Consult Dana, 'Manual of Geology' (New York 1895); Zittell, 'Textbook of Paleontology' (New York 1900–04); Cope, 'Vertebrata of the Tertiary Formations of the West' (Washington 1884); Williams, 'Geological Biology' (New York 1895); Woodward, 'Vertebrate Palæontology' (London 1898, which contains an extensive bibliography). CHARLES LAURENCE DAKE.

TERTIUS GAUDENS (Lat.), a diplomatic phrase meaning a mischief-maker; a third party who rejoices while two others are quarreling and hopes to profit by their dissensions.

TERTULLIAN (Quintus Septimius Florens Tertullianus), ecclesiastical writer: b. Carthage, c. 160; d. c. 250. The son of a pagan centurion in the proconsular service, he received a fine literary education and became as conversant with Greek as with Latin. He studied law and probably practised it, his writings disclosing intimate knowledge with juristic terms and methods. In early manhood (not later than the year 197) he was converted to Christianity by the admirable courage of the martyrs, although the precise date is not known. He was married, but this did not prevent him from being ordained priest, probably of the church at Carthage. About the middle of his career he publicly joined the Montanists and the vigor which he had displayed in defense of the faith against paganism was then displayed against the Church. Saint Jerome mentions certain affronts of the Roman clergy which may have provoked the fall of the great apologist. Since Tertullian was of a fiery nature, extreme and inclined to rigorism, the new prophecy (as Montanism was styled) with its severity in morals and in discipline had a natural and powerful attraction for him. But his restless spirit could not long be satisfied with Montanism and he became the leader of a separate sect, called after him Tertullianists. Tertullian was the most fecund, original and powerful genius in all the history of Christian Latin literature, which he in fact created. Nearly all of his works are of a polemic character and this brings out strikingly his penetrating intelligence, vast knowledge and inspiring eloquence. His style is energetic and concise, sometimes at the expense of clearness. Saint Jerome says that he is full of ideas but difficult to read. However, his works were seldom quoted until after the 16th century renaissance. It is not easy to draw a hard and fast line between Tertullian's Catholic and Montanistic works. To the years 197–198 belong the apologetic writings 'Ad nationes' (2 books), 'Apologeticum,' 'Ad martyres,' 'De testimonio animæ' and 'Adversus Judæos.' Other works of approximately the same period, but of less certain date, are 'De præscriptione hæreticorum,' 'De oratione,' 'De baptismo,' 'De pœnitentia,' 'De spectaculis,' 'De cultu feminarum,' (2 books), 'De idololatria,' 'De patientia' and 'Ad uxorem' (2 books). The Montanistic writings, including those tinged with Montanism as well as those wholeheartedly Montanistic, are 'De corona militis,' 'De fuga in persecutione,' 'De exhortatione castitatis,' 'De virginibus velandis,' 'Adversus Hermogenem,' 'Adversus Valentinianos,' 'Adversus Marcionem' (5 books), 'De anima,' 'De carne Christi,' 'De resurrectione carnis,' 'Adversus Praxean,' 'De pallio,' 'De pudicitia,' 'De monogamia,' 'Scorpiace,' 'De jejunio' and 'Ad Scapulam.' Tertullian's 'Apologeticum,' addressed about the year 197 to the governors of the provinces of the empire in favor of the Christians, if not the first of the Latin apologies in point of time (see FELIX, MARCUS MINUCIUS), is one of the first in the importance of its subject and its literary beauty. Some important works of Tertullian have been lost, notably the lengthy Montanistic work 'De ecstasi.' The Vienna 'Corpus script. eccl. lat.' contains an edition of Tertullian's works and the 'Ante-Nicene Library' contains translations of nearly all of his works.

Bibliography.— The patrologies of Bardenhewer and others and the bibliography of Chevalier; D'Alès, 'La théologie de Tertullien' (Paris 1905); Monceaux, 'Histoire littéraire de l'Afrique chrétienne' (Vol. I, Paris 1901); Turmel, 'Tertullien' (Paris 1905); Hoppe, 'Syntax und Stil des Tertullian' (Leipzig 1903); Fuller, John Mee, 'Tertullianus' (in Smith and Wace's 'A Dictionary of Christian Biography,' Vol. IV, London 1887).

HERBERT F. WRIGHT,
Sometime of the Department of Latin, Catholic University of America.

TESLA, tĕz'lä, **Nicola**: b. in Smiljan, province of Lika, Austrian Croatia, in 1857; early education in Gospich; graduated from Real Schule, Karlstadt, in 1873; studied at Polytechnic School, Gratz, capital of Croatia, with the intention of becoming a professor of mathematics and physics, but became interested in electricity and took up and completed an engineering course. He afterward studied philosophy and languages at Prague and Budapest, keeping up meantime his electrical and engineering studies. For some time he was employed in the government telegraph engineering department as an assistant and while there invented several improvements which attracted notice. Then he became engineer for a large lighting company in Paris and next turned his attention to the United States as a promising field for electrical talent and experience. Here he formed a connection with the Edison Company at Orange, N. J., but gave up this engagement in order to be entirely free in his electrical work. He has made himself well known by his many practical inventions and the boldness and brilliancy of his ideas as to the possibilities of electrical science. These ideas, which have aroused widespread interest, have also in some degree diverted attention from the many useful contributions of Tesla to the world's fund of scientific achievement, most of which have been developed in the Tesla laboratory in New York, which he established for the purpose of independent electrical research.

Tesla's researches in electrical oscillation created a new field of electrical investigation, the full possibilities of which have by no means been exhausted. He was the first electrician to conceive an effective method of utilizing the undulating current, converting electrical into mechanical energy more simply, effectively and economically than by the direct current. He invented the modern principle of the rotary magnetic field, embodied in the apparatus used in the transmission of power from Niagara Falls. He has also invented many new forms of dynamos, transformers, induction coils, condensers, arc and incandescent lamps, the oscillator combining steam-engine and dynamo, etc. Consult Martin, T. C., 'Inventions, Researches and Writings of Nicola Tesla' (1894) and the files of electrical trade journals.

TESORETTO. See TREASURY, THE LITTLE.

TESS OF THE D'URBERVILLES, the best known of the novels of Thomas Hardy, was published in 1891. The sub-title, «A Pure Woman Faithfully Presented,» explains Hardy's thesis. Though technically guilty of an offense against society and ultimately hanged for the murder of her seducer, the heroine, Tess, is represented throughout as the victim of circumstance or, more exactly and more characteristically of the author, as the victim of a constant and malignant fate. This is personified in the brutal and emotional Alec D'Urberville, but it is also quite as destructive in the egoistic temperament of her husband, Angel Clare. The main point appears in the oft-quoted phrase in the last paragraph of the book, «'Justice' was done and the President of the Immortals (in Æschylean phrase) had ended his sport with Tess.» The tragedy, as in all of Hardy's more sombre stories, is intense and powerful. As in the best of the author's novels, there is the usual fully and delicately drawn background of local scenery and custom. The characters are carefully drawn and are vivid portraits of local types and individuals. The novel is rich in rural and farming scenes, of which the description in the second of the seven «phases» of the book is extraordinarily skilful and beautiful. On publication, 'Tess of the D'Urbervilles' attracted a great deal of attention by reason of its subject, the treatment of which was thought to be over frank and too searching an attack on conventions, but the literary and poetical skill of the author has been never better displayed than in the descriptions of customs, life and character.

WILLIAM T. BREWSTER.

TEST-PAPER, slips of unsized paper soaked in solutions of vegetable coloring matters, used as indicators of the presence of acids or of alkalis, and, in some instances, of special chemical compounds. The most common test-paper are litmus and turmeric papers; the former papers are colored with an aqueous solution of a blue substance obtained from various species of lichens, the latter with a solution in spirit of a yellow powder obtained by grinding the roots of a species of Curcuma cultivated in India and Java. Blue litmus is reddened by acids, the blue color being again restored by alkalis; turmeric is turned brown by alkalis. There are also pheno-phthalein and amido-benzol paper, which cannot be classed as vegetable coloring matters, though organic, while the use of papers soaked in inorganic compounds is not infrequent in analytical laboratories.

TESTAMENT. See BIBLE.

TESTICLE, one of the two genital glands of the male in which the spermatozoa and some other of the constituents of the semen are formed; a testis. The term is also applied to either of the posterior tubercles of the optic lobes or corpora quadrigemina. The testicle proper lies in the scrotum, is of an oval form and is mostly invested with a pouch or closed sac of serous membrane, the tunica vaginalis, derived from the peritoneum during the descent of the gland from the abdomen into the scrotum. The organ consists of a central portion or body, an upper enlarged extremity, the globus major or head, and a lower extremity, the globus minor or tail. Lying upon the posterior border of the testicle is a long narrow flattened body, the epididymis. To this border is attached the spermatic cord, composed of arteries, veins, lymphatics and nerves, connected together by areolar tissues and invested with fasciæ. This cord ends in the internal abdominal ring. It is accompanied by the vas deferens, the excretory duct of the testis (a continuation of the epididymis), which passes through the ring into the pelvis to the base of the bladder, where it unites with the duct of the vesicula seminalis to form the ejaculatory duct, which terminates in a slit-like orifice in the prostatic portion of the urethra. Underneath the tunica vaginalis is the tunica albuginea, or fibrous covering of the testicle, and beneath this coat is the tunica vasculosa, or vascular tunic, composed of a plexus of blood vessels held together by delicate areolar tissue. The glandular structure of the testis consists of from 250 to 400 lobules, each composed of from one to three or more minute convoluted tubes, the tubuli seminiferi. These tubules unite into larger tubes, which carry the seminal fluid from the testis to the epididymis.

The testicle is subject to hypertrophy, atrophy, injuries, acute or chronic inflammation, cystic diseases, fibroma, malignant disease and neuralgia. Inflammation of the testicle (orchitis), as that of the epididymis (epididymitis, q.v.), is usually attended with much pain and swelling and a feeling of weight and great discomfort. The use of a properly fitting suspensory bandage affords much relief; but the treatment of diseases or disorders of the testicle should be entrusted to a physician. (See also SPERMATOZOA). The removal of both testicles renders a man impotent — a eunuch. Castration is the surgical operation of removing the testicles, and is performed on horses, steers, etc., to render them more docile and tractable. It is generally recognized that castration reduces the will power and interferes with various brain functions.

TESTIMONY, in general, the evidence given by a witness orally in a legal proceeding; from the Latin *testimonium* (testimony); *testis*, a witness. It may be secured during a trial in court, or before a duly authorized commission. Although commonly so used «testimony» is not synonymous with «evidence» which is of broader significance and may include papers marked in a proceeding. Testimony is usually deduced through questions asked directly by counsel which may be followed by cross-examination and redirect examining. (See EVIDENCE). Consult Wellman, F., 'The Art of Cross-Examining' (New York 1903); Wrottesley, F., 'The Examination of Witnesses in Court' (London 1910, rev. ed.).

TESTIMONY, Psychology of. Applied psychology recognizes three groups of problems bearing on certain evidence in law. These deal with the report of a witness; the possibility of learning if he is concealing important facts; and the mental condition of the accused. Both lawyers and judges understand that differences in evidence given when both perception and memory are concerned do not necessarily imply dishonesty. Psychology shows that individual differences may be expected and that by carefully comparing the effect of such differences a fair amount of accuracy may be attained. By carefully questioning observers of an enacted scene it has been found that errorless reports are an exception, that a narrative form gives greater accuracy and that both range and accuracy in reporting increase with practice and may be thus made nearly perfect. The «reaction» experiment has given excellent results but still lacks perfection. If it is desired to learn whether the mind of a witness or accused person is normal, the usual mental tests may be applied with good success. See CRIMINOLOGY. Consult Gross, H., 'Criminal Psychology' (Boston 1911); Jung, C. J., 'The Association Method' (in *American Journal of Psychology,* Vol. XXI, Worcester 1910); Munsterberg, H., 'On the Witness Stand' (New York 1908); id., 'Psychology, General and Applied' (New York 1914); Whipple, G. M., 'The Observer as Reporter' (in *Psychological Bulletin,* Vol. VI, Baltimore 1909).

TESTING, in chemistry. See ANALYSIS.

TESTING MACHINES. Testing machines are employed to determine the physical properties of metals, and other materials such as cement, used for engineering and structural purposes. They are used especially in the testing of steel. The prime requisite of a material to be used in engineering operations is the property termed «strength,» which is its capability to withstand the action of forces that might be applied to it in various ways so as to produce tensile, compressive, bending, shearing and twisting strains. Very often the force applied is a combination of two or more of these strains or stresses, and the metal is called to withstand also the effects of abrasion or wear. Physical tests are of two general classes — those made to determine the suitability of a grade of material for a particular purpose, and those by which the effects of differences in chemical composition, and different methods of manufacture, on the properties of the material, are studied scientifically.

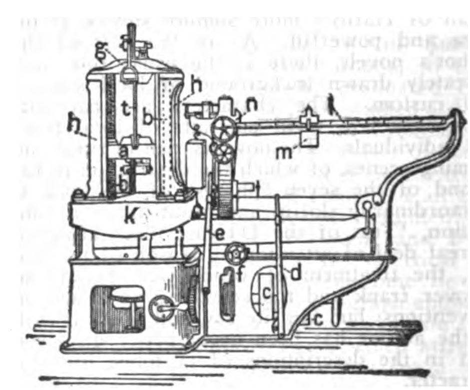
The most satisfactory method that may be employed for this purpose is to actually load a specimen of the material under test and gradually increase that load up to the breaking weight, and observe the effects thus produced. Such a method, however, is too slow and cumbersome, since the loads required for even the simplest commercial tests are very seldom less than 50,000 pounds, and loads ranging from 150,000 to 250,000 pounds are commonly used, and make the direct application of weight impracticable in most cases. Therefore, various machines have been devised by which any load, from the smallest that will perceptibly affect the specimen, up to the breaking load, may be readily applied and its weight accurately determined.

Of these three are two general types — those by which the specimen is loaded by means of a hydraulic press, and those employing a screw generally combined with a train of gearing.

The most perfect testing machine, for straining, rupturing or crushing pieces of metal, without injury to the machine, while exactly measuring or weighing the strains, is the Emery testing machine, which has frictionless hydraulic weighing heads, and is large and expansive of construction. It is used for government tests of important materials. Its disadvantages are due to the difficulty of keeping the heads filled with a suitable liquid, the difficulty of keeping the packing of the plungers in good order and the intermittent application of the load by the strokes of the pump.

In both types the load is applied in such a way that it acts through some form of weighing machine which enables the operator to determine instantly the weight of the load or the amount of the force being applied.

The general construction of the screw machine is shown by the accompanying illustration of the Riehlé machine, which may be readily used to subject a suitable specimen to any one of the three classes of strains — direct tension, direct compression and the transverse or bending, so that the weight of the load can be accurately determined.



Riehlé Testing Machine.

Referring to the illustration, the operation of the machine may be described as follows: The sliding head (a) may be moved up or down by the two screws (bb) which are operated by power derived from any convenient source and transmitted by belts on the pulleys (cc). These pulleys are loose on their shafts, and being provided with a cross belt on one and an open belt on the other rotate in opposite directions. The lever (d) actuates friction clutches which connect either of the pulleys with its shaft, so that the motion is communicated to the screws by gearing and thus raises or lowers the sliding head (a). By using the lever (e) and the hand wheel (f), the gears may be so combined as to give various speeds to the sliding head (a) as may be required in different classes of tests. The stationary head (g) is supported by columns (hh) which rest upon the platform (k) of the scale. The weighing beam (l) of the scale carries a movable counterpoise (m) which works on rollers along the beam. A hand wheel (n) operates a screw or chain which lies along the top of the beam and enables the operator to move the poise out along the beam gradually as the load is increased and thus observe constantly the weight of the load being applied. In some cases the poise may be arranged to be moved automatically by means of gearing operated by electrical connections, the circuit being made or broken by the action of the beam as it rises or falls.

In making a tensile test, the specimen is held between two pairs of jaws, one in each of the heads (a) and (g), as shown at (t). The head (a) is then drawn down by the screws, and the pull on the specimen presses the standards of the head (g) down upon the platform of the scales and causes the weighing beam to rise. In a compression test, the specimen is placed upon the platform of the scale and the sliding head is drawn down upon it. In a transverse or bending test, the specimen is placed on two supports carried by a heavy frame which is placed upon the platform of the scale, and the load is applied by means of a projection on the under side of the sliding head which presses upon the centre of the specimen when the head is drawn down.

Another machine of the screw type in extensive use is that built by Tinius Olsen. It is similar in principle to the Riehlé, but it employs four screws to operate the sliding head.

These machines are not only used to test metal specimens, but may also be used to test wood, cement and other classes of building material. In testing cement, small briquets of the material are made with a predetermined cross-sectional area at the centre and are then subjected to the tests as any other specimen.

In the testing of metals, the tensile test gives the simplest and most reliable data for determining the properties of the greatest interest in engineering operations.

TESTUDINATA, an order or sub-class of *Reptilia* (q.v.) containing the turtles or tortoises. See CHELONIA.

TESTUDO, among the ancient Romans a cover or screen which a body of troops formed with their oblong shields, by holding them over their heads when standing close to each other. This cover somewhat resembled the back of a tortoise, and served to shelter the men from missiles thrown from above. The name was also given to a structure movable on wheels or rollers for protecting sappers in undermining the defenses of an enemy.

TETANUS, a disease characterized by spasm of some or all of the voluntary muscles. The spasms vary in rigidity, and strong exacerbations attend their recurrence. Tetanus is a true toxæmia, and occurs in several varieties, the most familiar of which is lockjaw (trimus), whence it is commonly called by this name. The disease in all its forms (tetanus neonatorum, puerperal tetanus, idiopathic, traumatic and rheumatic tetanus) is caused by the tetanus bacillus, which was discovered by Nicolaier in 1884. Kitasato cultivated it in 1889. The bacillus is a slender rod, round-ended, existing in surface soil, dust, manure, etc., and as a rule occurring singly except in cultures. It lodges in some wound, often a slight and unnoticed wound, and the production of the disease is always a proof of its presence. Except in rare instances, the bacillus does not pass beyond the point of infection into the body. The real nature of the tetanus poison has not yet been determined, but its virulence is deadly in the extreme, and it is rapidly absorbed by the body in which it has found lodgment. It is carried through the body in the blood.

In milder cases the spasm of tetanus may be localized in certain muscles. Various theories regarding the action of the poison have been held by pathologists and the satisfactory explanation is still being sought by specialists in bacteriology and toxicology. Following childbirth, tetanus may infect both mother and child, and the average death rate from this disease, always high, is especially so among children. Surgical operations are sometimes followed by tetanus, but antiseptic surgery has doubtless lessened its frequency, and among diseases it is regarded as rare. Within about 10 days after an injury resulting in the infection, it sets in, the muscles at the back of the neck and those of mastication being usually first affected. The patient can neither masticate nor freely open his mouth. Often the progress to general rigidity of the muscles is very rapid, and convulsions of extreme violence ensue. Respiration is arrested, and death is often caused by this suspension. In other cases it results from spasm of the glottis, or from exhaustion produced by the violence of spasms.

There is no satisfactory treatment of tetanus, but such as physicians adopt is both local and general. Nothing is more important than careful cleansing of wounds, however slight, for precautionary purposes. Antitoxic disinfectants must be used, capable of destroying the poison produced by the bacilli as well as the bacilli themselves. Iodine solutions should be thoroughly applied to every tetanus wound. Potassium bromide, chloral, calabar bean, morphine and antimony produce good results, and opium and chloroform are employed for their quieting effects. Amputation is sometimes resorted to. Increase of fluids in the body by drinking or by intravenous injection, and corresponding increase of diuresis aid in eliminating the poison. Antitoxin serum (see SERUM THERAPY), prepared from the blood of the immunized horse, has proved a true remedy for tetanus, and many cures have been affected by its early administration. Preventive methods, especially those of inoculation, are now receiving the earnest attention of specialists. Consult Wallace, 'Indian Medical Record' (1891); Roux, 'Annales de l'Institut Pasteur' (1893); Bassano, 'Recherches experimentales sur l'origine microbienne du Tetanos' (1900); Moschcowitz, «Tetanus» in 'Annals of Surgery' (1900), Osler, W., 'Annals of Medicine' (New York 1915).

TETON MOUNTAINS, Wyoming, a very high and rugged granite range on the west side of Jackson Hole south of Yellowstone Park in the northwestern part of the State. The highest peak, Grand Teton, is 13,747 feet above sea-level. It is 17 feet higher than Fremont Peak and 38 feet lower than Gannett Peak of the Wind River range, the latter the highest point in Wyoming and the northern Rocky Mountain region.

TETRACHORD, *in music*, a scale-series of four notes. The word in its present use signifies a half of the octave scale. The fundamental system in ancient music was the tetrachord, or system of four sounds, of which the extremes were at the interval of a fourth. It was superseded by the hexachord. See MUSIC.

TETRADYMITE, a native bismuth telluride, often containing some sulphur and a trace of selenium. It occurs in pale steel-gray, metallic, foliated masses, in scales or more rarely in small rhombohedral crystals. It is soft enough to mark paper, its hardness being 1.5 to 2; while its specific gravity is high, 7.2 to 7.6. It occurs in Austria, Sweden and various localities in Virginia, North and South Carolina, Georgia, Arizona and Montana. It is also called telluric bismuth.

TETRAGRAMMATON, a Greek term meaning «the word of four letters,» and applied to the sacred Hebrew name of the Deity. It was considered improper to pronounce the divine name, and, therefore, an abbreviation of four letters was substituted, the most favored being «Y H W H,» which occurs 5,989 times in the Masoretic text of the Bible. The true name of God was uttered by the ancient Jewish priests only during worship in the temple. On the day of atonement the service required the high priest to pronounce it 10 times; but it was held to be impious to pronounce the sacred name promiscuously, hence this tetragrammaton «Y H W H» came to be pronounced by readers as Ya be, Iabe, Yave, Yahn, Iae, Yah, etc. For some reason it also became customary in reading aloud to say «Adonai» when the four letters occurred and this led to the substitution of Adonai for Y H W H. According to the best authority it should be pronounced as if written «Yahweh.» The letters of the tetragrammaton were made use of in various magic rites. Several illuminating articles on the names of God will be found in the Jewish Encyclopedia. Consult also Herzog-Hauck, 'Real-Encyclopädie' (Vol. VIII); Jacob, 'Im Namen Gottes' (Berlin 1903). Hence applied to other words of four letters expressive of a Godhead.

TETRAHEDRITE, or GRAY COPPER, a common and valuable ore of copper and silver. It is essentially a copper sulphantimonite, differing from tennantite into which it passes by insensible gradations only in the preponderance of antimony instead of the arsenic which distinguishes the latter. Its color and streak are usually steel gray; it often has a brilliant metallic lustre; its hardness varies widely from 3 to 4.5; its specific gravity is also quite variable, being from 4.6 to 5.1 in ordinary tetrahedrite, 4.5 to 5 in the argentiferous varieties (freibergite), 4.7 to 5.03 in the mercurial varieties (schwatzite). It crystallizes in the isometric system and owes its name to the fact that its crystals are invariably of tetrahedral habit. It occurs in fine specimens at many localities in Austria, Germany, England and Colorado, and is very widely distributed in massive form in copper and silver mines all over the world.

TETRARCH, tĕt'rärk or tē'trärk (Greek *tetrarches*), a term which meant the ruler of one-fourth of a country, but which was applied by the Romans to subordinate princes with small territories, especially in Palestine and other parts of Syria in the early years of Christianity. The two sons of Herod the Great, Philip and Herod Antipas, who received the lesser shares of his realm, were called tetrarchs, while Archelaus, who received the principal portion, had the title of ethnarch.

TETRAZZINI, Luisa, Italian soprano: b. Florence, 1874. While yet a child she learned perfectly several operas from hearing an elder sister (afterward wife of Campanini) practice them. She studied at the Liceo Musicale in Florence and after but three months training made her début in 'L'Africaine' in 1895, taking the part of 'Inez.' She afterward sang in several Italian cities and her continental successes were so great that she was called «the second Patti.» Finally she made such furor at Covent Garden that Oscar Hammerstein secured her in 1908 for the Manhattan Opera House in New York. Her operatic triumphs were continuous and she made a number of successful concert tours. As a singer she is noted for a voice of phenomenal power and great flexibility, coupled with unequaled ability as a coloratura soprano.

TETUAN, tĕt-oo-än', Morocco, a town on the northern coast of Africa, 33 miles southeast of Tangiers. It is defended by a castle. It is the only open port of the country on the Mediterranean, and lies a short distance south of Gibraltar. It is well built and many of the handsome private residences are the homes of Moorish exiles from Spain. The town is surrounded by fine vineyards, groves and orchards. The Hebrew merchants carry on a lively trade in fruit, wool, silk, girdles, leather and cotton. Provisions are exported to Ceuta. Pop. 25,000.

TETZEL, tĕt'sĕl, or **TEZEL, Johann**, agent for papal indulgences: b. Leipzig, about 1455; d. there, August 1519. He entered in 1489 the order of the Dominicans, and was ordained priest toward the end of the century. He soon began to appear in public as a preacher and gained a great reputation for his oratorical gifts. When in 1514 Leo X issued a bull granting an indulgence to all who would contribute to the building of Saint Peter's Church at Rome, Tetzel was selected to preach it in those provinces subject to the jurisdiction of the archbishop of Mainz. Luther came out in 1517 with his theses against this practice. These were answered by Tetzel and the students of Wittenberg burned the answers in the market place. Tetzel himself received a severe reprimand from the papal chamberlain, who was sent to settle the dispute, but was vindicated at Rome from the charges that had been brought against him. He died of the plague in the Dominican Convent at Leipzig. His life has been the occasion of much controversy owing to the part he took at the outbreak of the Reformation, but recent historical investigation has done much to rehabilitate his character. His life has been written by Hoffmann (1840); by Körner (1880), and on the Roman Catholic side by Gröne (1860) and Hermann (1883).

TETRYL. Tetryl is an explosive substance having the formula $NO_2.C_6H_2.N.CH_3.NO_2$, whose scientific name is tetranitrous thylaniline or preferably trinitrophenyline thylnitramine. Another common name in use for it is tetralite. It is prepared by dissolving dimethyl aniline in sulphuric acid and treating this solution with nitric acid. Pure tetryl looks like flour with a faint yellow tint. It fuses about 130° C. and solidifies at 128.7°. Its heat of formation is —40.8 calories. It is more powerful than TNT or picric acid but more sensitive than either. It is used as reinforcement in fulminate detonators, as the explosive core in detonating fuse, as a booster for high explosive shells and as a component of some ammonium nitrate explosives such as Fortex but is too costly for general use. It is somewhat poisonous, producing an irritation of the skin.

TEUFFEL, toif'fĕl, **Blanche Willis Howard,** Baroness von, American novelist: b. Bangor, Me., 21 July 1847; d. Munich, Germany, 7 Oct. 1898. She was educated in New York, but in 1878 she removed to Stuttgart, Germany, where she engaged in teaching and also edited for several years a magazine printed in English. She was married to Baron von Teuffel in 1890. Her publications include a book of travel, ‹One Year Abroad› (1877), and among her novels are ‹One Summer› (1875); ‹Aunt Serena› (1886); ‹No Heroes,› a story for boys (1893); ‹Seven on the Highway,› short stories (1897), etc.; and her works published posthumously are ‹Dionysius the Weaver's Heart's Dearest› (1899), and ‹Garden of Eden› (1900).

TEUTOBURGER WALD, toit'ō-boorg-ĕr vält, Germany, in Westphalia, a series of wooded hills, which begin on the left bank of the Diemel, near Warburg, and pass northward in the direction of Driburg, then northwest toward Örlinghausen, Bielefeld and Halle, finally Lengerich and Tecklenburg, and disappear in broken hills near Bevergern. Under the name of Egge they are steep and high and appear like a long wall; the highest point is Völmerstod (1,400 feet). There are, however, two lower parallel ranges. The second part is the Lippische Wald, also called Osning, believed by some authorities to be the real Teutobürger Wald. The third section includes the Ravensberg, Osnabrücken and Tecklenburg Mountains. The name is taken from Tacitus' annals, where an account is given of the defeat of the Roman general Quinctilius Varus by Arminius in the 1st century A.D. The Hermann monument on the Grotenburg commemorates this victory.

TEUTONES, tū-tō-nēz. See Germany.

TEUTONIC KNIGHTS, one of the three great military and religious orders which originated at the time of the Crusades. Its name was derived from a German hospital founded at Jerusalem in 1128. The Teutonic order adopted the Augustine rule of life, and, in addition to the ordinary monastic vows, the members took upon themselves special obligations to fight against enemies of the Christian faith, and to attend sick and wounded pilgrims. The order received charters from the Pope and the emperor entitling it to the same privileges as the Templars and Knights of Saint John. The distinguishing garb of the order was a white mantle with a black cross. The members were required to be Germans of honorable birth. Its first seat was at Acre, but it soon acquired, by gift and conquests, considerable territories in Germany, including a large part of what is now the kingdom of Prussia. When Prussia became a secular duchy the order continued to exist as an ecclesiastical body, possessing 11 bailiwicks in different parts of Europe, with a total area of 850 square miles, and 88,000 population. France seized the territories of the order, west of the Rhine, in 1801, and Napoleon suppressed the order in 1809, its lands being annexed to the states within which they were situated. About 1840 the order was revived in Austria, where it has since engaged in ambulance service in time of war. The bailiwick of Utrecht still exists, having survived the decree of Napoleon, but the Dutch representatives of the order have become Protestants. See Crusades; Germany; Prussia; Orders, Religious.

TEUTONIC LANGUAGES. The Teutonic, or Germanic, languages are unmistakably of a common origin. They comprise English, German, Frisian, Flemish, Dutch, Swedish, Danish, Norwegian, Icelandic and Gothic. The latter prevailed from the 4th to the 7th centuries A.D. over a large portion of the southwest and southeast of Europe, and in it we find the oldest written documents; however, both the Goths themselves and Gothic are now wholly extinct. German again includes both High and Low German, with their varying dialects, often differing very materially in their structure from each other. All these tongues, though deriving as they do from a common source, have differentiated greatly in historic times, so much so that most of them are quite unintelligible to the members of the other branches. Again, as far as written records are concerned, these date from very different periods. Thus, we know the Bible translation of Bishop Ulfilas (Wolf) of the Ostrogoths, parts of which in a fair state of preservation are kept in the University Library of Upsala, Sweden, and dating from the 4th century. This translation manifestly shows that Gothic even at that early time was a highly articulate language. Anglo-Saxon literature takes its rise in the 7th century, though some earlier fragments are probably incorporated in later works. The earliest German records date from the 8th and that of the Dutch from the 9th century. Frisian, a subdivision of certain very marked characteristics, does not become known to us by as much as a line till the 12th century, and in that century, too, the Scandinavian tongues for the first time make an appearance in preserved records, though it is not till the 15th century really that much of this is visible. Not until the last-mentioned period, either, do Swedish, Danish and Norwegian begin to contrast sharply in their interior construction and phonetics. Icelandic went its own course, on the other hand, being little influenced, by reason of geographical remoteness, by the cognate tongues further south. However, these northern idioms are at least rich in comparatively early inscriptions, in Runic characters, and afford much food to the philological searcher. Likewise both inscriptions and other early literary remnants discovered in the northern lands exhibit all the various stages of development, back even to a few types (like Icelandic), more archaic and rude than Gothic and dating from as early as the 3d century A.D. Moreover, some deductions as to the general style of the various early Teutonic dialects spoken by those tribes with whom the Romans came into contact from B.C. 150 to about A.D. 350 may be drawn from the proper names of the chiefs and other men of prominence, as these names were usually emblematic and compounded of descriptive adjectives or nouns, and these would show that on the whole during these 500 years the Teutonic vernaculars were fairly constant and not subject to rapid changes.

Certainly, the Germanic languages stand out clear and well-defined as a separate group of the Indo-European family, their nearest relationship being, in some respects, with the Italic and Celtic, in others with the Slavic tongues, and forming part of the western division. Most characteristic for the Teutonic idioms, from the philological point of view, is their manner of using the Indo-European explosive sounds. In some combinations consonants were lost or new consonants injected; *n*, for example, was eliminated before the *x*; final explosives and nasals were thrown out; their vowel system was in a general way a close assimilation to that of most other Aryan languages. The accent in the Teutonic tongues shifted, after remaining indeterminate for ages, to the first syllable. This must have been as early as about B.C. 100. Alliteration was employed a great deal, both in ordinary prose and in poetry, and this as far back as the time of the Cheruski, during the Augustean era of Rome. Alliteration also served to distinguish leading families or tribes from each other, the letter *s*, for instance, serving the Sigambri as a special mark of this nature. It was similar in the case of other Teutonic idioms. The phonetic characteristics, too, seem to have become fixed about the beginning of the Christian era. Dialectical differences existed even then, but were not nearly so pronounced as they have become since, a fact which the most ancient Runic inscriptions emphasize. On the whole, the Teutonic languages in their most primitive forms with which we are acquainted were more melodious, certainly richer in full vowels and not so overburdened with consonants as we find them now. Gothic, which at a very early stage became separated from the body of the language by reason of far wanderings and long-continued influences exercised on it by the adjoining and surrounding Latin and Greek populations, underwent a number of important euphonic changes. So much so indeed that after the lapse of some three or four centuries of this influence Gothic, as spoken both by Ostrogoths and Visigoths, as also by the Vandals, Gepidæ and other eastern Teutonic tribes, must have become scarcely intelligible to their kin who had remained on Germanic soil. This becomes reasonably certain by comparing the Bible translation of Ulfilas with contemporaneous specimens of German or Scandinavian. The latter two linguistic bodies, however, seem to have undergone their greatest internal alterations during the 6th and 7th centuries A.D. The vernacular of the Vandals, Gepidæ, etc., does not appear to have seriously differed from the Gothic. As for the chief parts of the early Germanic grammar, of the three numbers in vogue in Indo-European languages, the dual does not seem to have ever been used in the Teutonic idioms. Of the eight cases taken over from early Aryan, the vocative, the instrumental and the locative were made use of sparingly. As to the conjugation of verbs, the Teutonic system was simpler than in most of the Indo-European languages. The old Middle Voice is absent. In the early forms of the verb the Teutonic languages employ but two tenses, the present and the preterite; in lieu of the future a periphrase, a preposition or a perfective verb had to do duty. On the whole, therefore, it is undeniable that the Teutonic group of languages shows many peculiarities setting it apart from all others. Of course, side by side with those joint features set forth above, went on the process of individual development for each of the dialects and separate idioms, these growing at last into distinct languages. Most plainly this process of individualization may be observed in the comparatively rapid growth of the Scandinavian tongues. In the early Middle Ages the inhabitants of Scandinavia all spoke nearly alike and understood each other without serious trouble. Within the space of two centuries complete differentiation had been effected. In a sense, the Flemish and Dutch idioms show in their grammar forms an arrested development, due in a measure to political separation from the neighboring parent stock; in phonetics both differ very materially from the German.

Professor of German Language and Literature.

TEUTONIC ORDER, The. See ORDERS, ROYAL.

TEUTONIC RACE. See GERMANY.

TEWFIK PASHA, tū'fĭk păsh'ȧ, **MOHAMMED,** khedive of Egypt: b. 15 Nov. 1852; d. 7 Jan. 1892. He was declared heir apparent in 1866, when the sultan granted the right of primogeniture to the Egyptian reigning family, and in 1879 he succeeded to the throne on the abdication of his father, Ismail Pasha.

He was a ruler chiefly in name, the control of the government being virtually in the hands of foreign powers. A national party was formed of which Arabi Pasha, Minister of War, was at the head, and the friction between the khedive, who favored the English, and Arabi resulted in an insurrection in 1882. Through the intervention of England the uprising was quelled and a species of constitutional monarchy was adopted, giving an English financial adviser a place in the council in 1883. During the Mahdi troubles in 1884 Tewfik was forced to give up the Sudan. He was a man of simple tastes, married but one wife and was deeply interested in educational advancement and in the improvement of public works.

TEWKSBURY, Mass., town in Middlesex County, on the Boston and Maine Railroad, five miles south of Lowell. It has large horticultural interests, a chemical factory and contains the State infirmary. It was founded in 1654 and formed a part of the town of Billerica from which it was taken and incorporated 23 Dec. 1734, being named after the ancient town in Gloucestershire, England, famous for its abbey. Pop. 5,265.

TEXARKANA, tĕks-är-kăn'a, Ark., and Tex., twin city, one in Bowie County, Tex., the other the county-seat of Miller County, Ark., on the Saint Louis, Iron Mountain and Southern, Kansas City Southern, or «Port Arthur Route,» Saint Louis Southwestern, or «Cotton Belt Route,» Texas and Pacific, Texarkana and Fort Smith and the Memphis, Dallas and Gulf railroads, about 180 miles southwest of Little Rock, the capital of Arkansas, and 28 miles north of the Louisiana boundary. The cities are separated by the boundary between Texas and Arkansas, but they are one commercially, industrially and in all except the city governments. The name indicates unity; the first syllable is from the first syllable in Texas, the second from the first syllable in Arkansas, the last two from the last two syllables in Louisiana. Both the cities were settled in 1873; became incorporated towns in 1880 and cities of the second class in 1887. Texarkana, Ark., became a city of the first class in 1904. The post office serves for both cities and is designated as «Texarkana, Ark.-Tex.» The cities are in an agricultural and lumbering region and are an important distributing centre for a large extent of country. The chief industrial establishments are railroads and railroad shops, employing about 1,500 persons, lumber works, 500 employees, and other manufacturing establishments are numerous. Two large creosoting plants are near the city. Cotton and cotton products, lumber, grain and livestock are shipped from Texarkana in large amounts. The principal public buildings are the Government building, the Miller County, Ark., courthouse and jail, the Y. M. C. A. building, Railroad Hospital (cost $200,000), sanatoriums and the churches and schools. The United States court for the Western District of Kansas and United States court for the Eastern District of Texas, each hold annually two regular terms in the city within the district.

There are 31 churches, representing 17 different denominations. In each city are a high school, grammar schools, kindergartens and parish schools. Saint Agnes Academy, in Arkansas, was established in 1877; Saint Rose of Lima Academy is in Texas; Texarkana Industrial College opened in 1904. There are excellent banking facilities and good newspapers. The majority of the inhabitants are American born; about 650 foreign born and 4,200 of negro descent. Pop. (Ark.), (1890) 3,528; (1900) 4,914; (Tex.), (1890) 2,852; (1900) 5,256. Since 1900 the cities have grown considerably and the United States census of 1910 showed the population to be about 9,790; the 1918 estimate is 12,500.

TEXAS, the most centrally located of the southern tier of the United States, is much the largest in the Union and is popularly known as the «Lone Star State.» It is bounded on the southeast by the Gulf of Mexico, on the east by Louisiana, on the east and north by Arkansas, on the north and east by Oklahoma, on the west and north by New Mexico, on the southwest by Mexico. It lies between lat. 25° 51′ and 36° 30′ N. and between long. 93° 30′ and 106° 40′ W., and extends, therefore, east and west nearly 800 miles, north and south nearly 750. Its land area is 262,400 square miles and its coast line nearly 400 miles. According to United States census estimates it had a population of 4,700,000 in 1919 and a total wealth of $6,859,909,141 in 1912. Texas is divided into 252 counties and is a political but not a physical geographic unit. The State was admitted into the Union in 1845, having been for 10 years previously an independent republic.

Topography.— The general surface slopes upward fairly uniformly toward the northwest from sea-level to 4,000 feet and more. The Gulf deepens but slowly off shore and long barrier islands enclose along most of the coast shallow lagoons and bays whose total area is about 3,500 square miles. Padre, Galveston and Matagorda islands and Matagorda Peninsula are the longest of these barriers. Dredged channels aided by jetties allow large vessels to enter Galveston and Corpus Christi bays and Sabine Lake. The southeastern and eastern third of the State is quite flat but is diversified by very low hills along its northwestern boundary which rises to 500 or 600 feet above sea-level and which is marked toward the south by the Balcones Scarp and toward the north by the White Rock Scarp. The middle third of Texas is mainly level or nearly level country, but is marked by numerous hills which, chiefly in the southwest, cluster thickly enough to make large areas of rather rough contour. Except for the Trans-Pecos region west of the Pecos River, the northwestern third of Texas, rising northwesterly from about 2,000 feet on the east to 4,000 feet on the west, is a part of the almost level great plains, but is cut more or less toward the east by the head streams of the larger rivers. West of the Pecos and nearer the Rio Grande, upon a plateau with an altitude of 3,000 to 4,000 feet, rise the Guadalupe, Franklin, Quitman, Davis, Organ, Chinati, Chisos and other mountains. Two peaks considerably exceed 8,000 feet and 18 are higher than any east of the Mississippi. The mean elevation of Texas is 1,700 feet.

Rivers.—As a consequence of the northwesterly rise all the rivers flow in a general southeasterly direction. The Canadian and the Rio Grande, with its tributary, the Pecos, rise in the Rockies outside Texas. The Red, the Brazos and the Colorado rivers rise on the Staked Plains. The Sabine, the Neches and the Trinity rise in the northeast, the Guadalupe, the San Antonio and the Nueces rise in the central part of the State. The Canadian and the Red rivers are parts of the Mississippi River system. The other rivers discharge into the Gulf along the Texas coast, all except the Brazos emptying into bays which they are silting up. Owing to slight and irregular rainfall over their upper drainage areas, the larger rivers are not well adapted to navigation, nor do the streams in general afford much constant water power. The Rio Grande divides Texas from Mexico, the Red and Sabine rivers dividing Texas partially from Oklahoma, Arkansas and Louisiana.

Geology.—Archeozoic rocks are represented only in the Llano, Van Horn and El Paso regions where, and in the Marathon region, limited exposure of Cambrian and Ordovician strata are to be found. Scarcely any Silurian and no certain Devonian rocks have been discovered. In north central Texas, Carboniferous strata estimated to contain 8,000,000,000 tons of bituminous coal and a vast quantity of recently discovered petroleum outcrop over an area of 13,500 square miles. West of the coal-bearing area the Permian Red Beds outcrop over 25,000 square miles. The Jura-Trias system is unimportant, outcropping only along the scarps of the Staked Plains. In the Trans-Pecos region are lesser outcrops of the Carboniferous, Permian and Jura-Trias. Exception being made of the Llano region and the Permian-Carboniferous areas, the middle third of Texas from the Rio Grande to the Red River is covered by Upper and Lower Cretaceous areas in the proportion of two to five. The long Balcones Scarp marks a fault which divides the Upper Cretaceous on the east from the Lower on the west. The Eocene and Pleistocene, separated by a narrow Oligocene and a Miocene-Pliocene strip, occupy all of southern and eastern Texas in about equal areas. West of the Lower Cretaceous and the Permian outcrop, northwestern Texas is almost wholly occupied by later Cenozoic strata. Eruptive lava sheets are to be found in the Trans-Pecos, where the mountains are of the Basin Range type; basaltic outbursts are to be found widely but sparsely scattered through the southern Upper Cretaceous. In the Llano region vast masses of granite are exposed. Some 23,000,000,000 tons of lignite are estimated to lie in the Eocene Beds. The marine Neocene of the Coastal Plain contains immense petroleum deposits, but petroleum has also been found in large quantities in the Eocene, Cretaceous and even the Carboniferous. Over a thousand square miles of the Eocene are some easily accessible beds of good limonite.

Climate.— The lines of equal rainfall run nearly north and south, the rainfall diminishing from 55 inches in the east to less than 10 inches in the west. The average for the State is not far from 33 inches. Wide variations from annual averages are common and very wide departures from monthly averages are almost the rule. Evaporation steadily increases from 45 inches at the east to 90 inches at the west. Obviously Texas ranges from humid to arid. Eastern Texas has about 60 per cent, western Texas over 70 per cent of the possible sunshine. The mean annual temperatures range from 55° (35° in winter, 75° in summer) in the extreme north (Panhandle country) to 72° (60° in winter, 84° in summer) in the extreme south. Over most of southern and eastern Texas the mean summer temperature is about 81°. Temperatures of 95° are not infrequent, the Texas extremes being 115° and —16°. In winter the mean temperatures at Amarillo and Brownsville differ by 24°, in summer by 9°. High temperatures are much modified by the high evaporation and by the Atlantic trade winds, which blow regularly through the summer but are frequently interrupted in winter by the oppositely directed northers which blow with great violence, sending the temperature down sometimes as much as 50° in a few hours. Snow and freezing occur along the coast only during the severer northers and last only a day or so. The climate on the whole is quite healthful.

Flora.— The large size, varied rainfalls and temperatures of Texas unite to produce a wide variety of plants and animals. A trace of the Canadian Life Zone is to be found on the tops of the highest western mountains, surrounded lower down by more abundant specimens of the Transition Zone. The Staked Plains, a narrow and irregular strip extending southeast to Kerr County, and most of the Trans-Pecos above 4,000 feet are in the Upper Sonoran Zone. The remaining nine-tenths of the State is in the Lower Austral (cotton producing) Zone. The western and larger half of the Lower Austral is Lower Sonoran, the rest is Austro-riparian. There is a semi-tropical Gulf Strip of the Lower Austral as well as arid and semi-arid areas in the Lower Sonoran. Cypress, tupelo, palmetto, hickory, magnolia, gums, oaks, osage orange, sycamore, willow, long, short and loblolly pine abound in eastern Texas. Elms, pecans, cottonwoods and willows along the streams with oaks, cedars, hackberries and mesquite elsewhere characterize the rest of Texas east of the treeless areas. Many species of cacti, especially the prickly pear, grow in the Lower Sonoran area. Wild flowers abound in species and individuals. The various native grasses largely support the great livestock industry.

Fauna.— Prairie dogs, jack-rabbits, cottontail rabbits, skunks, rats and mice and opossums are the commoner animals. The coyote is still not rare and deer, protected by law, are maintaining their numbers. The wild buffalo is extinct and the antelope, bear, panther and peccary are nearly so. Armadilloes are common in the south. A great majority of the North American species of birds have been found in Texas. Characteristic and common birds are the scissortailed fly-catcher, mocking bird, lark finch, red bird, meadow lark, swallows, doves, quails and turkey buzzards. The wild turkey is now rare. Thirty varieties of lizards and 30 of snakes are known. The horned toad is the most interesting lizard. Poisonous rattle-snakes, moccasins and coral snakes and the harmless garter, black, pilot, coachwhip and bull snakes are widely distributed. There is a remarkable variety of fish in the lower coastal streams where small alligators are still fairly common.

TEXAS.

Estimated population, 4,429,566

The ordinary Gulf fauna abounds off the coast where, as a consequence, very fine fishing is to be had. Tarantulas, centipedes and large red ants are the most commonly noticed invertebrates.

Agriculture and Stock Raising.—Although occupying a decreasing percentage of the population, as times goes on these industries still occupy 60 per cent of the male workers. About a sixth (28,000,000 acres) of the State is planted to crops each year, the remaining five-sixths mainly furnishing pasturage for stock. The number of farms, nearly 450,000 in 1916, has nearly doubled and the improved acreage has increased 50 per cent since 1890. The Black Prairie of the Upper Crétaceous is the most densely populated farming region, but the Permian Red Beds, and the Eocene and Neocene areas furnish large bodies of immensely fertile soil. Perhaps two-thirds of Texas is easily tillable. The use of fertilizers is still uncommon. Variations in rainfall and frost dates produce wide variations in the crop productions per acre. Very large crops and large sized fruits and vegetables are common. The average value of the crops is about $20 per acre. Intensive agriculture is beginning; the crops of the thousands of contestants for the annual prizes of the Texas Industrial Congress average about three times the State average.

The total value of farm property, $962,000,000 in 1900, $2,219,000,000 in 1910, has nearly trebled since 1900 and has quintupled since 1890. The total wealth of Texas was $6,860,000,000 in 1912, $2,836,000,000 in 1904, $2,106,000,000 in 1890. On the average, out of a thousand farmers, 425 are white owners, 408 are white tenants, 51 are negro owners and 116 are negro tenants.

The chief crop is cotton, about equal in value to all the other crops combined and raised over three-fourths of Texas. In 1912 the maximum crop so far, 4,880,000 bales, was produced. The value of the annual cotton crop ranges between 200 and 350 millions of dollars, Texas producing about a sixth of the world's crop. The corn crop averages, 100,000,000 bushels with wide variations. Wheat and oats vary much in amounts planted and in yields per acre — for wheat 12.8 bushels per acre and a 15,000,000 bushel crop and for oats 29.1 bushels per acre and a 40,000,000 bushel crop are averages. Nearly 10,000,000 bushels of rice are grown annually on 300,000 irrigated acres. The annual value of the Kafir corn, milo maize, sorghum and other forage crops is not far from $25,000,000. The production of sugar has declined to a few thousand tons. The fruit and vegetable crop exceeds $40,000,000 in value. Peaches, sweet potatoes, watermelons, tomatoes, onions, cabbages are raised in large amounts and Texas is by far the leading State in native pecans. Most of the other standard fruits and vegetables are raised in lesser amounts and there is the beginning of a citrus fruit industry along the coast. In 1917 the production of cotton was 3,125,000 bales which, excluding the seed, were valued at $375,000,000. The production in 1917 of the other principal crops in thousands of bushels and thousands of dollars was corn, 77,825, of value $129,968; wheat, 16,200, value $34,020; oats, 37,050, value $30,381; potatoes, 9,312, value $13,869; hypothetical value of all crops (United States Department of Agriculture) $684,856; average for five years, $421,277, over 20 per cent greater than any other State. The 1917 wool clip amounted to 10,045,000 pounds.

First in cotton and pecans Texas is also first among the States in cattle, sheep and goats. The United States estimates for 1918 are 1,128,000 dairy cows valued at $64,038,000; 4,660,000 other cattle at $179,667,000; 1,212,000 horses at $93,324,000; 808,000 mules at $86,456,000; 2,188,000 sheep at $16,410,000 and 3,068,000 swine at $43,259,000. Sheep and goat raising is largely confined to southwest Texas. Since 1890 the population of Texas has doubled, the number of mules and goats has more than trebled, the number of horses, swine and milch cows has remained nearly stationary, the number of sheep has decreased 50 per cent and the number of "other" cattle has decreased nearly as much.

Irrigation.— Plants fall into two fairly well-marked divisions — (a) numerous small plants widely scattered but chiefly in the west, which use the water from rivers, springs and waterholes to raise a wide variety of crops and (b) large plants, chiefly along the lower parts of the rivers, which irrigate thousands of acres under one management and sell water to individual farmers. In the southeast these large plants are almost exclusively rice producing; along the Rio Grande they raise everything but rice. The Elephant Butte Dam on the Rio Grande in New Mexico above El Paso is the only United States reclamation project directly affecting Texas where it will irrigate about 100,000 acres. Perhaps 5,000,000 acres in Texas are irrigable. About a million acres are under ditch and 600,000 acres irrigated annually, half in rice. Most of the water is pumped to the fields, the total capacity of the pumps being over 6,000,000 gallons per minute. Rice irrigation on a large scale is scarcely 15 years old and the acreage irrigated for other crops has quintupled since 1900. Farms irrigating for rice numbered 73 in 1900 and 1,088 in 1910; farms irrigating for other crops numbered 1,252 in 1900 and 4,150 in 1910. In arid Texas small irrigating plants have existed for centuries. Irrigation development has been particularly rapid since 1910 in the lower Rio Grande Valley but has not been without its backsets. The recently finished Medina Dam near San Antonio renders 60,000 acres irrigable. Between Hereford and Lubbock lies an area where irrigation water may be obtained from shallow wells. Similar but small areas exist elsewhere. There is an Artesian Belt in South Texas and various wells are sources of water for domestic uses.

Overflow lands amounting to 3,000,000 acres and swamp lands amounting to 5,000,000 acres exist. Drainage districts covering 2,000,000 acres have already been organized and 150 miles of levees have been built under a recent law authorizing community action in such matters.

Mining.— This industry is making great progress. The production of petroleum, which practically began at Corsicana in 1895, owing to the discovery of the rich Spindle Top field in 1901 and of other great fields in the succeeding years, has increased immensely but has been subject to considerable fluctuations. In the last two years the production of the older coastal and north Texas oil fields has increased and immense quantities of oil have been found in the central carboniferous region. Production leaped from 27,644,605 barrels in 1916 to 60,000,000 barrels in 1919. Oil and gas prospecting has been going on vigorously, stimulated by frequent successes. The production of most of the other minerals has had a slow but fairly uniform growth. In 1914 the total mineral production was $30,363,426, including 20,068,184 barrels of petroleum at $14,942,848; 2,247,773 tons of coal and lignite at $3,922,459; 12,433,-639 M. cubic feet natural gas at $2,469,770; 2,100,341 barrels of cement at $1,947,016. Clay products, lime, gypsum, cinnabar, salt, sulphur and various other minerals amount to the remaining $7,081,333.

Manufacturing.— Since 1900 the «value added by manufacturing» to the Texas raw products has nearly trebled. In proportion to population, in 1900 Texas manufactured a sixth, in 1915 a fourth, as much as the United States as a whole. Manufacturing has arisen chiefly in response to demands made by the immense raw products but has been retarded by scarcity of fuel and skilled labor. The major manufacturing industries are naturally based upon the major raw products. The large cotton crop supports nearly 4,000 gins (some very large) and 200 cotton-seed oil mills but only 20 cotton spinning establishments. Flour, grist and rice mills handle the entire crop of cereals but canning and preserving are far behind the opportunities offered by the large fruit and vegetable crops. There are a few large meat packeries slaughtering close to 1,500,000 animals a year. A few large petroleum refineries with a total capacity of 250,000 barrels per day are handling also much Oklahoma and Louisiana oil transported by pipe lines. The lumber area in the east, chiefly southeast, of over 50,000 square miles, upon which there is an estimated stand of 40,000,000,000 board feet of yellow pine and 20,000,000,000 hardwoods, supports about 400 sawmills and 400 other woodworking plants. About 2,000,000,000 feet of the yellow pine is being cut annually but the hardwood cut is scarcely 5 per cent of this amount. The major industries just listed include about two-thirds of the total manufacturing which, in general, is of a kind that involves only simple processes which may be done by machinery.

The manufacture of bricks and other clay products is widely and numerously scattered. Much ice is made in every town. No distilled spirits are made and no wool or mohair is woven. Dallas is second only to Nashville as a Southern publication centre. Dallas and Houston are somewhat ahead of Fort Worth and San Antonio as manufacturing places. The important manufactures of Dallas are cotton gin machinery, meat packing, flour and grist milling, cotton-seed oil and cake, leather and printing. In Houston, cotton seed, meat packing, rice cleaning, railway car repairing and brewing are the chief industries. Fort Worth leads in meat packing and flour milling, San Antonio led in brewing. In these four largest cities a third of the total manufacturing is done. Of the wage earners, 6 per cent are women, 2 per cent are children under 16 years.

The 1914 United States census statistics for Texas manufacturing are as follows:

Number of establishments	5,084
Persons engaged in manufacture	91,114
Primary horse power	335,791
Capital	283,544,000
Salaries and wages	59,179,000
Value of finished products	361,279,000
Value added to raw product by manufacture	108,135,000

Statistics for those industries where the value added by manufacture was in excess of $1,000,000 are as follows:

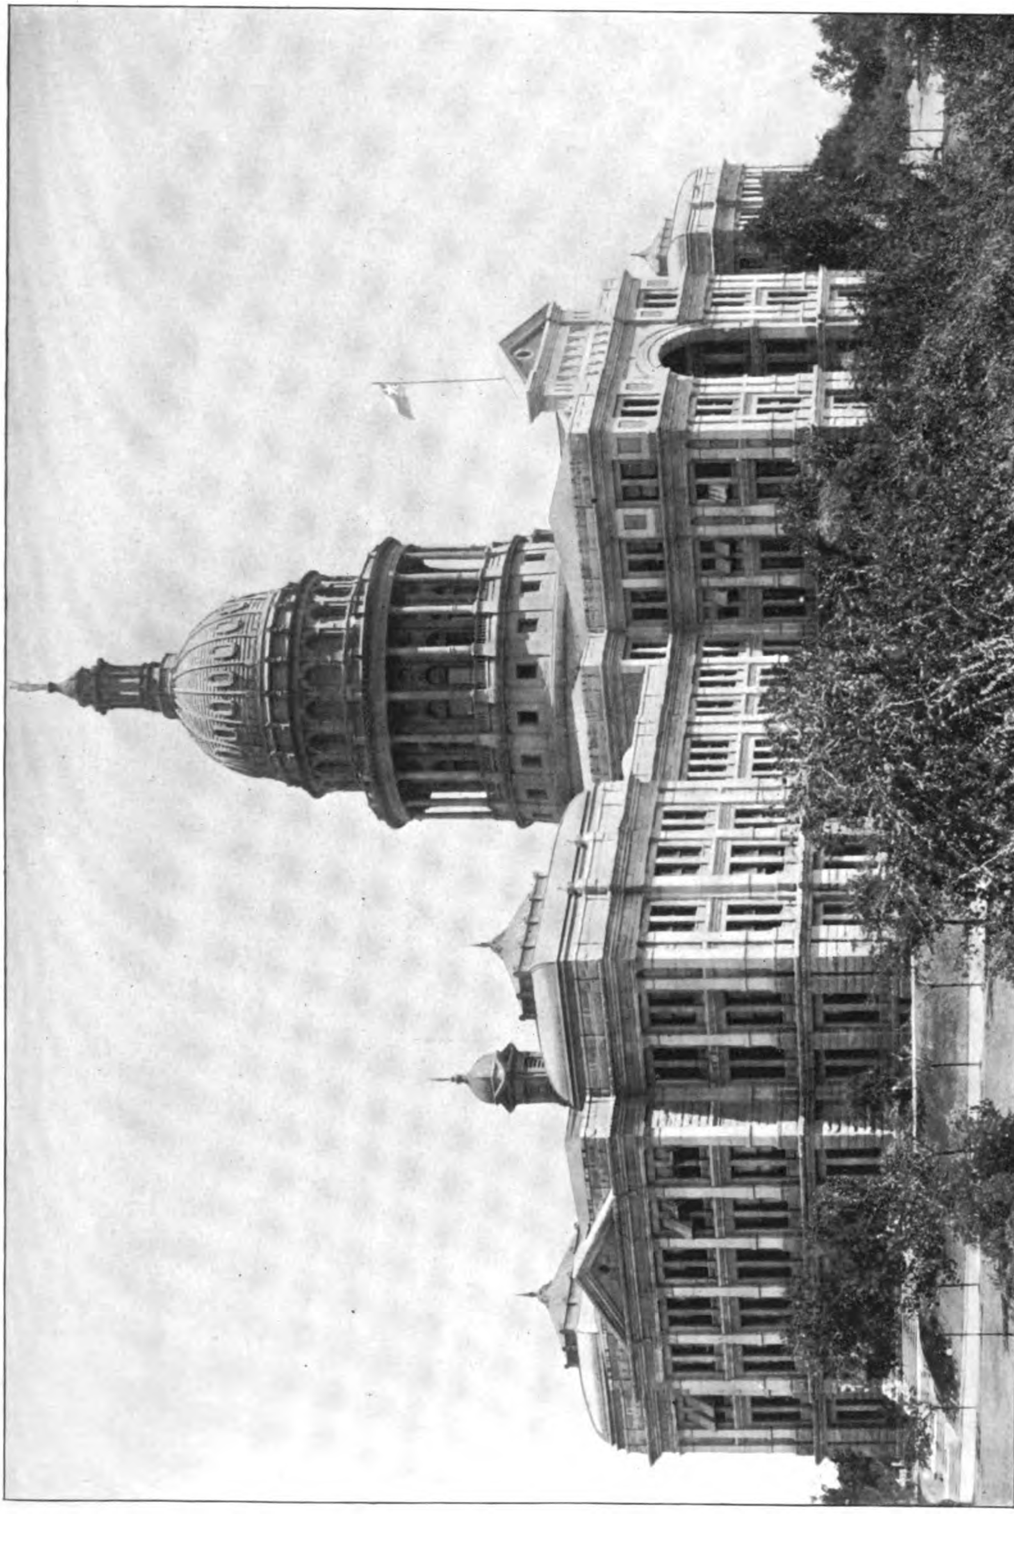
INDUSTRY	Number of establishments	Number of wage earners	Value added by manufacture
Lumber products	587	19,956	$17,101,000
Printing and publishing	1,188	4,690	11,054,000
Car repairing steam railroads	63	10,915	9,298,000
Slaughtering and meat packing	21	3,491	8,533,000
Oil, cotton-seed and cake	233	4,471	5,768,000
Liquors, malt	13	958	5,542,000
Flour and grist mill products	191	1,300	5,537,000
Foundry and machine shop products	174	3,026	4,743,000
Ice manufactured	255	1,926	3,668,000
Bread and other bakery products	530	1,949	3,361,000
Brick and other clay products	81	1,811	1,444,000

Cement, confectionery, sheet metal, cotton goods, artificial gas, leather and mineral waters are the other chief manufactures; the value added by manufacture in each case is slightly in excess of $1,000,000.

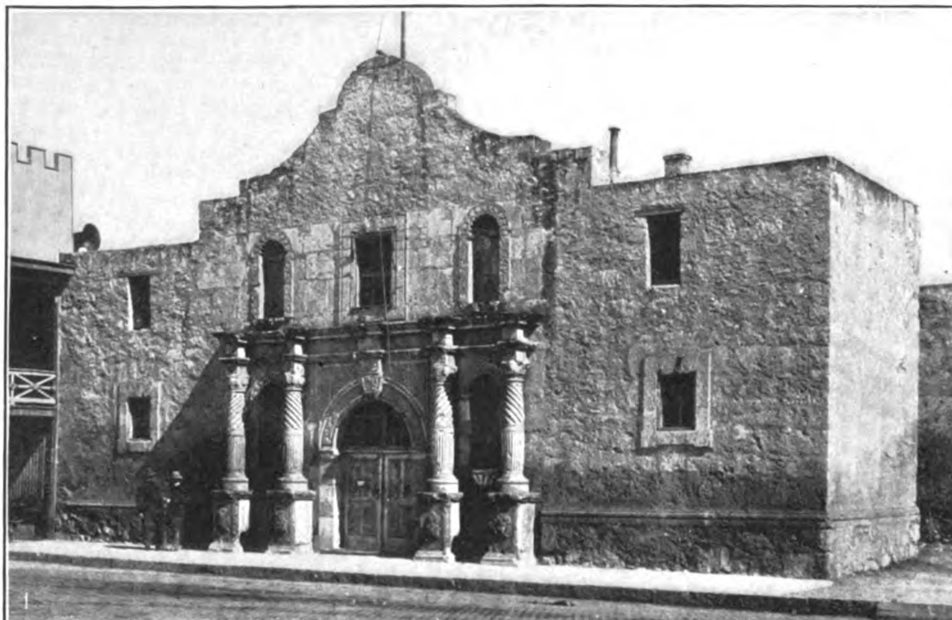
Transportation.— Before the Civil War less than 500 miles of railway were built. In 1919 there were over 15,800 miles in operation, not including 4,200 miles of side tracks. Railway building was greatly promoted by land grants until the public lands were exhausted in 1882. The leading systems are the Southern Pacific (mileage, 3,000), the Gould System, including the International and Great Northern and the Texas and Pacific (mileage, 3,000), the Santa Fé (mileage, 2,000) and the Missouri, Kansas and Texas (mileage, 1,500). The Texas Railroad Commission has authority to fix rates and otherwise to control intrastate railway traffic. The issuance of railway stocks and bonds is strictly controlled. Texas is first among the States in railway mileage, having half again as much per inhabitant and two-thirds as much per square mile as the United States as a whole. Numerous steamship lines connect Galveston with the great ports of the world. Some 500 miles of interurban and 700 miles of urban electric lines are in operation. From $10,000,000 to $15,000,000 are being spent each year upon the roads.

Commerce.— Cotton lint is the principal export, exceeding in value all the other exports combined. Most of this cotton goes to Europe via Houston and Galveston. In descending order the other chief exports are petroleum, cotton-seed products, cattle, lumber, horses, mules, rice, wool and mohair. The imports are chiefly machinery, clothing, vehicles, furniture and a wide variety of other manufactured goods. Pork, sugar, potatoes and a host of other foodstuffs are imported in considerable amounts. Strong efforts are being made to reduce such food importations by raising an increasing amount of crops other than cotton.
reduce such food importations by raising an
consumption about balance, cotton lint being

TEXAS



State Capitol at Austin



1 The Alamo, San Antonio, built in 1718   2 The Mission San José, near San Antonio, built in 1718

omitted from the count. This lint produces a balance of trade in favor of Texas of over $200,000,000 a year. Galveston is one of the 15 principal ports of the world; her imports and exports are mostly but not exclusively of Texas destination and origin.

Banks and Banking.— Law and public opinion opposing governmental banks, private banks, some of which are still flourishing, prevailed until 1865 when the first national bank was chartered at Galveston. In 1918 there were 511 national banks, with one of the 12 regional reserve banks at Dallas. The total capitalization of these banks is above $35,000,000; the total surplus is above $20,000,000; the total deposits are over $200,000,000. A State banking law went into effect in 1905 under which nearly 900 State banks have gone into successful operation. Their total capitalization is over $23,000,000, their surplus is over $12,000,000, their deposits are about $165,000,000. Depositors are protected either by a bonding system or by a State guaranty fund maintained by assessments on the banks collectively. Ten national banks have deposits in excess of $4,000,000 each; 10 State banks have deposits of over $1,000,000 each. There is no overwhelmingly preponderant bank. Interest rates are still rather high, kept up by rapidly rising land values, by large business profits and by other causes.

Government.— The present constitution was adopted in 1876 and has not been extensively amended since. The chief elective officials are the governor, attorney-general, treasurer, commissioner of the general land office, superintendent of public instruction and commissioner of agriculture, together with three railroad commissioners. The chief officials appointed by the governor are the secretary of state, adjutant-general, three penitentiary commissioners and 14 other officers whose duties relate to insurance and banking, taxes, revenues, public health, State purchasing, game, public buildings, labor, mines, pure foods, reclamation of lands, pensions, fires and masonry inspection. The judiciary is elective. In ascending order there are Justice and Municipal Courts, County Courts, District Courts, each with one judge or presiding official. Above these are nine Courts of Civil Appeals above which are the Court of Criminal Appeals and the Supreme Court. Each of these higher courts has three judges elected in rotation every two years for six-year terms. The legislature meets biennially and consists of a senate of 31 members elected alternately every two years for four-year terms and a house of 142 members elected for two-year terms. There have been numerous called sessions. The State is divided into four United States judicial districts and into 16 Congressional. Of the 18 congressmen two are, therefore, elected at large. Voting is restricted to males over 21 who have paid the poll tax and have lived one year in the State and the last six months in the district or county where the voting is to be done. The old convention system of selecting officials has been largely replaced by the general primary. The salaries of the State officials are not large. The governor has somewhat more power than is usual in the other States and he controls a considerable amount of patronage. He appoints nearly 40 State boards and a two-thirds vote of both house and senate is required to overcome his veto. In general the county is the local unit of government. Spanish influence has caused some civil law to be incorporated into the common law. Law and equity are not differentiated, common-law forms of pleading have been abolished, and a Penal Code and a Code of Criminal Procedure dates from 1856. Texas has been the pioneer in adopting the community property system, in exempting the homestead from liens, in the commission form of city government, in the regulation of railway stocks and bonds, in the regulation of farm tenant rents.

State Finances.— In 1915 the total assessed valuation was $2,755,171,793, upon which was levied a total State ad valorem tax of 55 cents on the $100. This tax, together with charter fees, poll and occupation taxes, etc., produced a total revenue from taxation of about $13,240,000. To this should be added an income of $2,140,170 arising from the State Permanent School Fund of nearly $68,000,000. The university and the Agricultural and Mechanical College possess endowments derived, like the Permanent School Fund, from the sale of State lands set apart for the schools in early days, which yielded an income of about $260,000. Expenditures were as follows: State departments, $1,633,505; judiciary, $1,057,197; eleemosynary institutions, $2,861,876; Confederate pensions and homes, $1,558,171; miscellaneous, $262,821; higher education, $1,754,077; public schools, $7,999,059. Income and expenditures are increasing at least 5 per cent a year. Of the ad valorem tax of 55 cents, five cents is specifically set aside for Confederate pensions, 20 cents for the public schools. The State debt is negligible, but the total debt of the counties exceeds $30,000,000; of the cities it is about $60,000,000. County tax rates are generally under $1 on $100 but in some cases the city rates reach $2.

Education.— To the $7,999,059 spent by the State on the public schools in 1915 should be added $6,387,866 raised by local taxation in counties, districts and cities and $518,628 derived as income from Permanent County School Funds, similar to the State Permanent Fund, and amounting to nearly $13,000,000. On about 1,100,000 children of free school age Texas spent in 1915 about $14 per child. There are nearly 25,000 teachers, of whom scarcely 1,500 hold college degrees, of whom about 3,000 hold certificates that would admit to standard colleges. The rural schools are open scarcely six months per year. There is such pressing need of improving rural education that the legislature of 1915 appropriated $1,000,000 for the purpose and it is probable that this amount will be increased in future. A compulsory law now going into effect will cause a much needed improvement in attendance. The high schools, between 500 and 750 in number, are of very unequal merit but are improving fairly rapidly. The training and the salaries of teachers are increasing. The value of the public school buildings exceeds $30,000,000. Receipts from sales of school building bonds were $2,847,891 in 1915; the amount collected by local taxation for redemption and interest on bonds was $1,719,682. There are numerous private secondary schools. The native white illiteracy was 6.1 per cent in 1900, 4.3 per cent in 1910; of negro illiteracy 24.6 per cent in 1910, 38.6 per cent in 1900.

There are State normals at Huntsville, Denton, San Marcos, Canyon City, Commerce and Alpine for whites and at Prairie View for negroes. The Girls' Industrial College is at Denton, the Agricultural and Mechanical College (which has income from the United States and from other sources not enumerated above) for boys is at Bryan, the University of Texas is at Austin with the exception of the medical department which is at Galveston and a school of mines at El Paso. These State higher schools, whose total enrolment, regular session, exceeds 8,000, are almost wholly supported by biennial legislative appropriations. There are nearly 50 private and denominational colleges of various grades, with an attendance in excess of 14,000. Chief among these are the new Southern Methodist University at Dallas and the Rice Institute (endowment over $10,000,000) at Houston, together with the much older Baylor University (Baptist) at Waco, Southwestern University (Methodist) at Georgetown, Austin College (Presbyterian, for boys) at Sherman, Trinity (Presbyterian) at Waxahachie and Texas Christian University at Fort Worth.

Charities and Corrections.— Three insane asylums, with a total of 4,000 inmates, are located at Terrell, Austin and San Antonio. There is an epileptic colony at Abilene; a blind institute, a deaf, dumb and blind institute for negroes, a deaf and dumb institute, a Confederate home, a woman's Confederate home and a farm colony for feeble-minded are at Austin; an orphan's home is at Corsicana; a juvenile training school for boys is at Gatesville and for girls at Gainesville; a tuberculosis sanitarium is at Carlsbad. In addition to these State-maintained institutions there are numerous denominational and private hospitals and retreats of very various kinds. The State penitentiaries, containing usually from 4,000 to 5,000 inmates, are at Rusk and at Huntsville, and, mainly through farming, are designed to be self-supporting, but have in recent years created large deficits.

Religion.—Accurate recent statistics do not exist. The best approximations are as follows: Baptists, 490,000; Catholics, 375,000; Methodists, 375,000; Presbyterians, 85,000; Disciples of Christ, 60,000; Lutherans, 35,000; Protestant Episcopals, 20,000; Jewish, 15,000; all other denominations, 45,000. Most of the negroes are either Baptists or Methodists. Other approximate church statistics are as follows: Churches, 9,500; church organizations, 12,500; Sunday-school teachers, 65,000; Sunday-school pupils, 600,000; value of church property, $27,000,000; seating capacity of the churches, 3,000,000; church debts, $1,350,000. The Y. M. C. A. and Y. W. C. A. hold property worth $1,700,000.

Population.— The first United States census taken was that of 1850 when the population was 212,592. In 1870 the population was 818,579; in 1890 it was 2,235,523; in 1910 it was 3,896,542. The present rate of increase is about 85,000 a year. Native white Americans form 73 per cent of the population, 51 of this 73 being native white Texans. Foreign born Europeans number 3 per cent, Mexicans 7 per cent, negroes 17.7 per cent (20.4 per cent in 1900). A large German element in the population of South Texas dates from 1848. In general Texas is Southern with a strong flavor of the West. The occupation percentages for the male workers (who number about 1,330,000 in 1915) are: Agriculture and stock raising, 60 per cent; manufacturing and mining, 14 per cent; trade and transportation, 15 per cent; professions, 3 per cent; all other occupations, 8 per cent. White farm tenantry and the percentage of women at work are increasing. The towns are increasing much faster than the country, 68 per cent as compared with 19 per cent during the last census decade. The five largest cities increased 107 per cent. Only 19 per cent of the people live in towns of more than 10,000 population. Sixty-six per cent of the population is rural. According to the estimates of the United States census for 1916, Dallas, San Antonio, Houston and Fort Worth have passed 100,000. El Paso is near 50,000 and Galveston 40,000; Austin, Waco and Beaumont have passed or are nearing 30,000. Between 20,000 and 10,000 in approximately descending order are Laredo, Denison, Sherman, Amarillo, Marshall, Abilene, Temple, Brownsville, San Angelo, Paris, Texarkana, Cleburne, Palestine, Tyler, Wichita Falls, Corsicana, Corpus Christi and Greenville.

History.— The first explorers were Spaniards, Cabeza de Vaca, 1528–36, and Francisco Vasquez de Coronado, 1540–42. Other Spanish gold hunters traversed the State occasionally during the next 140 years but it was not till 1682 that a still-existing Indian pueblo under Spanish auspices was found at Ysleta near modern El Paso, 200 years younger. La Salle, driven west by a storm while searching for the mouth of the Mississippi down which he had sailed three years previously, built in 1685 near Matagorda Bay a fort which was soon destroyed by the Indians. Four Frenchmen found refuge among the more peaceable Tejas Indians who, as a result, have their tribal name perpetuated as «Texas.» Alarmed by this accidental and unsuccessful French invasion, the Spaniards of Mexico established in 1690 the Mission San Francisco de los Tejas, near modern Nacogdoches, but this far-away mission was soon abandoned. Later various other scattered missions and forts were established, but in 1800 those at San Antonio, Nacogdoches and Goliad were the chief results of over 200 years of Spanish colonization. San Antonio, begun in 1718, became in 1730 the first civil European settlement in Texas.

The history of modern Texas begins in 1821. The Spaniards having failed really to settle the country, three abortive invasions between 1800 and 1821 by Anglo-Americans were shadows of coming events. In 1821 Mexico finished successfully her war of independence begun with Spain in 1810; in 1821 the United States gave up a claim to Texas arising from the purchase of Louisiana from France in 1803; in 1821 Moses Austin obtained permission to locate 300 American families but, dying, his son Stephen established the first permanent Anglo-American settlement at San Felipé de Austin on the lower Brazos River in December 1821. During the next 15 years probably 30,000

Americans came to Texas, settling mainly along the rivers between San Antonio and Nacogdoches southward to the coast. They came, sometimes bringing their slaves with them, because a fertile and unoccupied land was calling to them, not because, as has sometimes been maintained without evidence, they specifically planned to extend the slave-holding area. Remote from real Mexico, they practically governed themselves and formed no close or genuine ties with their adopted country. A federal Mexican republic resulting in 1824, Texas and Coahuila became one state divided into the departments of Saltillo, Monclova and Texas. Revolution and disorder prevailing continually in Mexico, when Santa Anna established there a dictatorship in 1835, the American Texans proclaimed a provisional government and declared in favor of a union with the Mexican liberals together with a restoration of the Federal Constitution of 1824. Santa Anna sent troops into Texas and war began. The desperate defense of the Alamo at San Antonio by 183 Texans under W. B. Travis in which the defenders were killed to a man and the battle of San Jacinto in which Santa Anna was defeated and captured by a Texan army under San Houston were the outstanding events of the war. Practical independence resulted and between 1836 and 1845 Texas was an independent republic, a unique experience for one of the States of the Union. In 1845, after a long conflict over slavery, Texas was annexed to the United States, retaining all her public lands and the right to subdivide into not more than five States. Claims to a portion of New Mexico were abandoned later for $10,000,000 which were used to pay the debts that the Republic of Texas had accumulated. The annexation of Texas brought on the war between the United States and Mexico which made the Rio Grande an international boundary. After a decade of peaceful statehood Texas abandoned the Union for the Southern Confederacy, furnishing probably 100,000 soldiers. The last battle of the Civil War was fought at Palmito, near Palo Alto, on the Rio Grande, 13 May 1865. Texas was not the scene of very active military operations; Federal troops attacked the coast but could not penetrate further. A reconstruction government of the usual type prevailed until 1874 when Gov. E. J. Davis was driven from office.

Since 1874 Texas has been Democratic by large majorities. The carpet bag constitution of 1869 was replaced in 1876 by the constitution now in force. In 1874 the Texas Rangers, a famous State constabulary, was organized to protect the frontier from Indians. The debt left by the Davis administration was paid during the succeeding Coke, Hubbard and Roberts administrations. In 1884 fence cutting wars that arose because of the rapid spread of barb wire demanded special and drastic legislative action. The old Capitol burned down in 1881 and 3,000,000 of acres of Panhandle public land was paid for a new granite Capitol begun in 1885. The most important struggle since Reconstruction days was that of 1892 when Gov. J. S. Hogg fought and won a hotly-contested campaign which resulted in the establishment of a railroad commission with large powers and the passage of anti-trust laws and laws re-

stricting the alien ownership of land. Prohibition, first voted on in a State election in 1887, has since been a much-fought issue. At present all of the people live under well-enforced local option laws. In 1896 the United States Supreme Court fixed finally the boundary of Texas by awarding Greer County in the forks of the Red River to what is now Oklahoma. Texas from time to time has suffered from river floods and from tropical storms along the coast. At Galveston in 1900 thousands of lives and much property were lost in a storm. Out of this calamity grew the Galveston Sea Wall and the commission form of city government. The supremacy of the Democratic party, threatened for a few years by Populism before the Democrats adopted free silver in 1896, shows no signs of failure. The political problems now before Texas are the development of a more efficient system of public schools, the reduction of farm tenantry, compulsory investment of life insurance funds in Texas securities, abolition of the fee system of paying county officials, penitentiary reform, reforms in legal procedure and better public roads.

PRESIDENTS OF THE REPUBLIC.

David G. Burnet, ad interim	1836
Sam Houston	1836–38
Mirabeau B. Lamar	1838–41
Sam Houston	1841–44
Anson Jones	1844–46

vey and Bureau of Economic Geology; Annual Report United States Geological Survey; North American Fauna 25, United States Department of Agriculture.

H. Y. BENEDICT,
Dean, University of Texas.

TEXAS, The University of, the head of the public school system of the State, is located at Austin, except the medical department at Galveston and a loosely connected school of mines at El Paso. The first step toward its establishment was taken in 1839 when the Congress of the republic set aside 40 acres for a campus in the future city of Austin and 50 leagues of public land as an endowment. In 1858 the legislature increased the endowment by adding $100,000 of United States bonds and lands amounting to 10 per cent of all the public lands granted to railways. The constitution of 1876 replaced this 10 per cent by 1,000,000 acres, to which the legislature added another 1,000,000 in 1883. The university was finally organized in 1881, located by a popular vote and opened to students in 1883. Before this the Agricultural and Mechanical College had been opened and although vaguely made a branch of the university by the constitution of 1876, has existed separately under its own board of directors. From its 2,000,000 acres, which are in West Texas and leased to cattlemen, the university has an income of nearly $170,000; fees and interest on $650,000 derived chiefly from land sales amount to about $50,000 more. The annual appropriation for running expenses from the legislature for 1919–20 is $950,000. The constitution prohibits the use of legislative appropriations to pay for buildings, and the act establishing the university limits the matriculation fee to $30, admits men and women on equal terms and prohibits any sectarian instruction or religious tests for officers or students. The government is in the control of a board of nine regents appointed by the governor with the consent of the senate, three every two years for terms of six years. The departments of the university are (1) the college of arts, (2) the department of law, (3) the department of engineering, (4) the department of medicine, including pharmacy and nursing, (5) the department of education, (6) the graduate department, (7) the summer school and summer normal, (8) the department of extension, (9) the bureau of economic geology and technology. The B.A., B.S., M.A., Ph.D., LL.B., LL.M., C.E., E.E., M.E., and M.D. degress are conferred. Provision is made for taking the B.A. and M.D. in seven years, the B.A. and LL.B. in six. Twenty courses, somewhat elective under a system of grouped studies, are required for the B.A. Fourteen and one-half high school units are required for admission, the department of law requiring in addition 10 college courses, the medical department also requiring 10. The LL.B. requires three years, the M.D. four years of nine months each. The summer school offers during the summer session of three months as many as possible of the courses of the regular session. In addition to the older collegiate subjects, courses in journalism, home economics, business administration, music and Slavic language are offered. The usual collegiate clubs, fraternities, associations, fellowships and scholarships abound, and an unusually broad system of student government prevails, accompanied by the honor system on examinations. The campus at Austin is surrounded by churches and an association of religious teachers give courses which are allowed to count toward the B.A. At Austin are the Main, Law and Engineering buildings, the library, two dormitories, a power-house, a chemical laboratoy and about 25 "shacks," cheap frame buildings which growth has necessitated and which are used for various purposes. At Galveston are the Medical College building, the five buildings of the John Sealy Hospital, a dormtory for women and a nurses' home. The library has over 150,000 bound volumes, including a number of rare first editions. The laboratories are well equipped. There are various funds, mostly small, and numerous special collections. During the regular session of 1918–19, 3,100 students were in attendance. In addition 500 other individuals were in the summer school, 500 in the summer normal and 700 doing correspondence work. The attendance has more than doubled since 1908. The voting faculty numbers 150, the whole staff over 350, the affiliated high schools nearly 300. Most of the Texas colleges officially use the affiliated list of the university.

TEXAS AGRICULTURAL AND MECHANICAL COLLEGE, located at College Station, Brazos County, Tex. It was established in 1871, receiving as an endowment 180,000 acres of land from the National government, in accordance with the Morrill Land Grant Act of 1862. Opened for the reception of students 4 Oct. 1876. The government of the college is vested in a board of nine directors, appointed by the governor for terms of six years. It offers 11 four-year courses leading to the degree of B.S., as follows: Agriculture, architecture, architectural engineering, chemical engineering, civil engineering, electrical engineering, general engineering, mechanical engineering, military engineering, textile engineering. A four-year course in veterinary medicine leading to the degree of D.V.M. is also offered. Two-year courses in agriculture and engineering are provided for students with limited preparation, who are over 18 years of age. Graduate work in agriculture and engineering is also provided. The college farm and grounds contain 2,500 acres, of which 750 are under cultivation; the grounds and buildings in 1916 were valued at $2,000,000; in 1915 and 1916 buildings to the value of $375,000 were erected, including a hospital, an assembly hall, a veterinary building, a stock judging pavilion and a steam plant. The library in 1916 contained 25,000 volumes; the enrolment for 1915–16 was 1,415, the faculty 103.

TEXAS BLUEGRASS. See GRASSES IN THE UNITED STATES.

TEXAS CHRISTIAN UNIVERSITY, located at Fort Worth, Tex. It was founded as a private institution in Thorp Springs, Tex., in 1875, and chartered under the name of the Add Ran College; in 1890 the college became the property of the Christian Church of Texas, and in 1895 was moved to Waco, Tex., and the name was changed to Texas Christian University. In the spring of 1910 the college was burned at Waco, and it was moved to Fort

Worth, Tex., that year, where it opened in the fall of 1910. The university now includes the following departments: (1) The Add Ran College of Arts and Sciences; (2) the College of the Bible; (3) the College of Business; (4) the College of Music; (5) the School of Oratory; (6) the School of Art; (7) the Preparatory School; (8) the department of domestic science; (9) the department of law; and (10) the College of Medicine, located at Fort Worth, Tex. The university is coeducational and is the school of the Disciples of Christ in Texas; no secret societies are permitted but the students maintain four literary societies and an athletic association besides other art and religious societies. The campus contains 50 acres on high ground above the city. The buildings include the Girls' Home (Jarvis Hall); Worth Hall, Clark Hall, Goode Hall, Brite College and the Medical College. The income is about $100,000 yearly; the library contains over 12,000 volumes and is a government depository; the students in all departments in 1915–16 numbered 710 and the faculty 78.

TEXAS FEVER, in cattle. See RINDERPEST.

TEXCOCO, täs-kō'kō. See TEZCUCO.

TEXEL, těk'sěl, Netherlands, an island, the largest in the West Friesian group, that separates Zuyder Zee from the North Sea. It is separated from North Holland by the Strait of Mars-Diep. Its area contains about 75 square miles, mostly fertile lands, which afford fine pasturage and fields for the growing of crops. Stupendous dikes protect the island. Sheep-raising is the chief industry, and the wool and cheese are noted products. Texel has an interesting war record. It was here that the celebrated victory of Admiral Blake was won over the Dutch in 1653. Another important battle was fought (1673) between united France and England against Holland. In 1797 the island was blockaded, and the Dutch fleet surrendered to Admiral Mitchell in 1799. Pop. about 6,500.

TEXIER, tĕs-yā, **Charles Félix Marie,** French traveler and archæologist: b. Versailles, France, 29 Aug. 1802; d. Paris, 1 July 1871. His works comprise 'Description de l'Asie Mineure' (1839–48) and 'Description de l'Arménie, de la Perse, et de la Mésopotamie' (1842–45).

TEXTBOOK AND ORAL TEACHING. See EDUCATION, ELEMENTARY.

TEXTILE DESIGNING. This term is used for the designing of textiles in which the pattern is obtained in the weaving and not by subsequent printing. The simplest patterns are in stripes and checks. By running 5 or 10 white threads and 5 or 10 gray threads alternately in the warp, stripes would be made. If the same thing was done also with the weft or filling, a checkered pattern would result. In arranging a pattern the designer first considers the weight of cloth desired and calculates what size of thread or «yarn» he will use, and how many threads there will be to the inch. He usually bases his design on the inch. Having an intimate knowledge of the loom harness, which determines the arrangement of the threads or «weave,» he knows its limitations and just what combinations are practicable. If he uses a plain weave, in which the threads interlace alternately, it is very easy to design checks and plaids. He may decide to use the twill, in which the shuttle carries the woof-threads over one and under two or more warp-threads. By carrying this twill principle a little farther, he may produce a diagonal cloth. If he is dealing with silk, and wants a glossy surface, he may decide on a satin weave, which reduces the number of crossings of warp and weft, permitting a close texture and a glossy finish on one side. Successful designs determine largely the stability of the cloth, for users judge a fabric mainly by the effect at first sight. The patterns must be harmonious or with artistic contrasts to please the various tastes. To sell at certain prices, they must have definite weights per yard, as buyers of large quantities will require 10, 12, 14, etc., ounces to the yard. The designing of silk, linen, wool and other fabrics involves many differences, which must be thoroughly understood. And carpet and rug designing is a different business, requiring complete knowledge of their manufacture. The designers of rugs try to imitate the higher priced hand-made rugs from the Orient, and often succeed admirably. Consult Beaumont, 'Color in Woven Design' (new ed., 1912). See WEAVING.

TEXTILE INDUSTRY. American.— In 1800 there were no textile mills, as the term is now understood, in the United States. Whatever the American people did in the way of manufacturing their own clothing was mostly done in the household; the spinning wheel and the handloom were utensils as familiar in the old-fashioned kitchens as the pots and kettles of the housewife. The homespun garments worn by our forefathers were fashioned out of wool grown on the home farm, carded by hand-cards, washed in tubs, spun and woven by hand, fulled and finished at home, cut up and sewed — all by the joint labor of husband, wife, sons and daughters. The finer clothes worn in those days were all imported; and as the colonies grew and multiplied, and their consumption of English textiles increased, the manufacturers of the mother-country foresaw a wondrous new market opening up before them. The desire to retain and increase that market for textiles, in the manufacture of which England already led the world, was far more prominent among the causes leading up to the American Revolution than its historians have yet discovered.

Colonial Homespun.— The homespun garments of colonial days were plain, and wore like iron; their ingredients were indicated in the name commonly applied to the cloth — «linsey woolsey.» It was a fabric of woolen weft, woven on a linen warp. Linen was much more commonly produced in the household than cotton fabrics, and wool was more in use than all other fibres combined. Cotton was a scarce commodity in Colonial America until long after the Revolution. It possessed a value equal to that of wool, and sometimes very much higher. What little of it was used prior to the 19th century was mostly imported from Barbados. When Samuel Slater started the first American cotton mill at Pawtucket, in 1793, he insisted upon using cotton from the Indies, because of the poor quality of the cotton then raised at home. No one dreamed, when the «Shipping and Commercial List and New York Price Current» first made its appearance, that America was destined to become the cotton-producing country of the world; nor did Slater's little mill of 250 spindles, which had then been in operation five years, give signs that it was the germ of an American industry which would consume annually within 100 years more cotton than all the world was then growing. The history of the textile industries during the colonial period is nowhere suggestive of the development which confronts and amazes the student at the opening of the 20th century, who finds them, with their subsidiary industries, employing more capital and creating a greater value of annual product than any other group, except iron and steel.

Expedients of the Colonists.— Our forefathers realized how important it was that the colonists should learn to clothe themselves. They resorted to all sorts of expedients, some of which smack strongly of state socialisms, to overcome the difficulties in the way. They offered bounties to increase the number of sheep and promote the growth of flax. In Massachusetts laws were passed making it compulsory that each family should spin a given quantity of yarn every year, under penalties of heavy fines. Gradually the household textile industries assumed an importance which alarmed the mother-country, and the Lords of Trade attempted by various restrictive orders to prevent and harass a development which threatened to destroy the colonial market for the chief products of British industry. Parliament passed an act in 1774 — which was shortly after the Arkwright inventions had inaugurated the modern factory system — forbidding the exportation, under heavy penalties, of any of the machines used in the cotton, silk, woolen or linen manufacture. This statute, which remained in force, with certain modifications, until 1845, was evidence of a puerile hope that the English people could keep the fruits of inventive genius bottled up in their little island, while England permitted her sons to carry their inventive ideas across the water.

First Woolen Factory.— Slater brought here his spinning machinery ideas; in the same way Arthur Scholfield, three years later, invented the first wool-carding machine, which he built and put into operation at Byfield, Mass., in 1794, thus fixing the date of the beginning of the factory manufacture of wool by machinery operated by power in the United States. American machinists and inventors did the rest. It is not to be denied, however, that the English statute did retard, embarrass and make trebly difficult the early development of our textile factories. A century ago the American textile industries were easily 100 years behind those of Great Britain.

Steps of Evolution.—It would be interesting to follow the evolution of the household industry, by slow and gradual steps, into the highly organized factory system of America to-day. First came the neighborhood fulling-mill utilizing the friendly services of the adjacent stream, and relieving the housewife of the labor of fulling and finishing the cloths and blankets accumulated by the busy shuttle during the long winter evenings. Then the carding-machine was added to the fulling-mill; the farmers for miles about brought their wool to be converted into rolls ready for the spinning-wheel. After Slater had successfully applied the Arkwright invention to the spinning of cotton at Pawtucket, here and there throughout New England little mills gradually appeared which spun both cotton and woolen yarns by water power. Handlooms were still used in all these mills until 1813, when the invention of a power-loom by Francis C. Lowell led to the building of the Waltham cotton factory by the Boston Manufacturing Company, and the American textile mill first took on the characteristics which have since increasingly distinguished it. Power spinning and weaving machines were rapidly applied to the manufacture of woolens, and it began to be seen that the household manufacture of textiles was disappearing before the greater economy and efficiency of the factory system. The transition was not rapid, and the ups and downs of our first textile mills were numerous and discouraging.

War of 1812.— The outbreak of the War of 1812, and the non-intercourse acts and embargo which preceded it, were the most potent factors in completing the transition. The total suspension of importations threw our people suddenly upon their own resources for their entire supply of clothing. Cotton and woolen mills were quickly built. High prices and the promise of quick fortunes drew many men with little or no knowledge of manufacturing into the business. All went well enough until the war ended; then followed collapse and ruin. The work of laying the solid foundations of textile manufacturing had all to be done over again. Imported cottons and woolens again invaded the market with a rush, and the domestic manufacturers found it impossible to compete with them either in quality or in price. Labor was unskilled and hard to get; knowledge and experience were sadly wanting; machinery was clumsy and defective; the country was poverty-stricken, and trade and the national finances thoroughly demoralized.

First Protective Tariff.— Then first began the great battle in Congress, which was waged more or less intermittently ever since, for the protection of the domestic manufactures by means of tariff laws. The Tariff Act of 1816 — the first of the series in which the principle of protection was recognized in the rates fixed as a distinct purpose of the law, conjointly with the raising of revenue — was much more favorable to the cotton than to the wool manufacture, because it applied the minimum principle to cotton cloths, which was in effect a specific duty of 6¼ cents a yard, while the simple ad valorem rate of 25 per cent was applied generally to woolen goods. From the date of that law the cotton manufacture began a healthy development, and it naturally grew much faster than the wool manufacture. The later tariffs were in like degree, as a rule, more favorable to cotton than to woolens; partly owing to this fact and partly to other causes, such as the much more delicate, complicated and expensive operations incident to the latter, the cotton manufacture has at all times except during the Civil War shown a greater prosperity and on the whole a more rapid development than its sister industry. But in both industries for many years it was an up-hill struggle against great odds. Few fortunes were made; many were lost, and the courage and tenacity of those early textile manufacturers deserve to be remembered.

From 1850.— In the last half of the 19th century there was an increase in the value of products of about six times, and not less than 10 times if it were possible to measure this product by quantity instead of by value. Even the largest figures convey an inadequate idea of the relative importance of our textile mills in the industrial economy of the nation, for these mills supply the materials for a great group of subsidiary factory industries, such as the wholesale clothing manufacture, the shirt manufacture, etc. When we aggregate these, and add to them the value of the products of the linen, jute, hemp and bagging mills of the country, we find that the product of our textile mills is larger in value than that of any single line of related industries, iron and steel excepted. The products of the textile mills and the factory products growing out of them are equal in value to more than one-ninth of all our manufactures.

Machinery and Diminished Cost.— The decrease in the cost of goods during the last half century has been one of the most striking phases of the development. This decrease is due in some measure, of course, to the decreased price of the raw materials from which they are made; but in even larger measure is it due to the remarkable advance in the methods of manufacture — to the new and more perfect machinery employed, in the invention of which American mechanical genius has contributed certainly as much as that of any other people, and perhaps more. All the fundamental inventions in spinning machinery were of English origin; so was the combing machine and the power loom. The English have a remarkable record in this respect, and the French and the Germans have also done much in the invention of labor-saving textile machinery. But the American record may be shown to surpass them all. The wool-carding machinery of all countries owes its chief improvements over the machines of a century ago to the invention of John Goulding of Worcester, Mass., whose patent, dated 1826, dispensed with the splicing-billy and produced the endless roll or sliver. Michel Alcan, the distinguished French writer, describes it as «the most important advance in the wool manufacture of the 19th century.» It was not a step,» he says, «but a flight.» The modern cotton spindle, making 10,000 revolutions a minute, is an evolution of our own mechanics. It has been shown that the saving effected by the new forms of spindle invented and adopted in the United States since 1870, when 5,000 revolutions a minute was the average speed, has been more than equal to the capacity of all the warp-spinning machinery in use in this country in that year, and to-day more than three times as much warp-yarn is spun in the United States as in 1870, a rate of increase without parallel since the earliest introduction of the cotton manufacture. The Lowell loom was the first successful application of power to the weaving of cotton, the Crompton loom to the weaving of fancy woolens and the Bigelow loom to the weaving of carpets. «Not a yard of fancy woolens,» wrote Samuel Lawrence, «had ever been woven by power looms in any country until it was done by George Crompton at the Middlesex Mills in 1840.» Every carpet ever woven was woven by hand until the power loom of Erastus Brigham Bigelow revolutionized the industry. Beyond these fundamental machines the American mechanisms for expediting processes, for automatic devices, for dispensing with intermediate help, have been so numerous that they have completely transformed the modus operandi of textile mills throughout the world. These mechanisms are more generally in use to-day in the best American textile mills than in those of any other country. So far as mechanical equipment is concerned, our best mills, whether cotton or woolen, are fairly equal to the best in any foreign country. It does not follow that textile manufacturing is done here, as a rule, with equal economy in cost.

Mills and Equipments.— In structural equipment the modern American mill is in some respects superior to the average foreign mill. It is not so massive a structure, nor so solidly built, brick being used here, while the English generally use stone; but in the lightness and airiness of its rooms, in economy of arrangement and in general completeness of equipment and care for the comfort and convenience of the operatives, it is usually superior. The lesson is fast being learned by our textile manufacturers that in these days of close competition and small profits successful manufacturing requires that buildings shall be of the latest design and the most approved management, and that machinery shall not only be modern in make, with every latest improvement, but must also be kept in perfect condition by constant renewal. Many parts of the machinery required for the equipment of our textile mills are still necessarily imported from England, because not made, or less perfectly made, in the United States. Our machine manufacturers have been advancing as rapidly in recent years as the textile mills themselves, and the time cannot now be far distant when every new mill built in America will be equipped throughout with American-made machinery. But here again the United States shows a firm grip and *exports* have reached beyond the million dollar mark. Textile machinery in 1914 was being made in 241 establishments valued at $30,437,689. In that year machinery was *exported* to the value of $1,308,048.

Variety of Fabrics.— The American textile mills now supply practically every variety of fabric made in the world, with the exception of linens and the very finest grades of other fabrics. Great sums of money have from time to time been invested by daring manufacturers in constructing plants for the manufacture of linen fabrics. The result has often been disappointment and failure. These obstacles are climatic in the first instance, flax being a fibre which requires more moisture than any other for its successful manipulation. Again, there is difficulty in obtaining a home supply of suitable raw material. Years of high protection have failed to persuade the American farmer into growing flax for fibre. The history of the linen manufacture in other countries seems to establish the fact that it is the one textile manufacture likely to remain segregated in a few localities like Holland and Ireland, where the fibre is grown on the spot, where the climate is peculiarly adapted and where the help has acquired an expertness born of generations of experience. Moreover, linen is the one textile the consumption of which has not appreciably increased with the growing perfection of textile machinery. The other fibres, less difficult to handle, more susceptible to cheap manipulation, continually encroach upon its uses.

Silk Industry.— Perhaps the most striking contrast to our experience with linen is that afforded by the silk manufacture. At first sight it would appear that this must be the particular textile industry which could not flourish in America. Since last century's whirlwind of speculative mania to cultivate the silkworm which swept New England in the thirties, and wrecked the fortunes of many too credulous farmers, we have settled down to the conviction that America cannot grow raw silk in competition with China, Japan and Italy. Moreover, the silk manufacture, like the linen, has always been highly specialized and localized. The city of Lyons, in France, had well nigh monopolized the manufacture, so far as it had escaped from the hand processes of the Eastern nations. The skill and taste of generations have been concentrated upon the production at these centres, of fabrics which in beauty of design, in richness of coloring, in delicacy of workmanship, alone among the fabrics made by modern machinery, rival the splendors of mediæval textile art. England has for centuries struggled in vain to place her silk manufacture on equal terms with it. Nevertheless we have built up in America, in the last 45 years, a silk industry which among machine-using nations is second only to that of France, and is to-day supplying our people with the bulk of the silken fabrics consumed by them. We owe this great achievement largely to the energy and the genius of the Cheney family, father and sons, of South Manchester, Conn. The Cheneys began the manufacture of spun silk nearly half a century ago. About the same time, John Ryle, sometimes called the father of the American silk industry, had become superintendent of a little silk mill in Paterson, N. J., which he afterward purchased and gradually enlarged. At first sewing silks only were made, then ribbons were added, and in 1842 Mr. Ryle built a number of looms for silk piece-goods — the first to be successfully operated in America; and the industry in all its branches has since developed so rapidly there that Paterson, which calls itself the Lyons of America, now occupies to this industry the same relation that Fall River does to the cotton manufacture and Philadelphia to the wool manufacture. During the Civil War the high duties stimulated the silk industry and diversified its product. The making of plain grosgrain dress silks was then started, and at the present time brocaded silks and satins are manufactured on a large scale; indeed there is no form of fabric into which silk enters which is not now produced in great variety. Especially noteworthy has been the recent development in the manufacture of silk plushes and all varieties of upholstery goods. The value of home-made silk goods was in 1880 just about equal to the foreign value of the goods imported. In 1890 the product had so grown that it was nearly double the value of the imports, and more than double the value of the product in 1880. During the next decade the rate of increase was accelerated. In Paterson is the largest silk-ribbon mill in the world. Another mill in that city, an outgrowth of the little mill operated by John Ryle, covers an acre and a half, and can nowhere be surpassed for size or completeness of equipment. See SILK AND SILK INDUSTRY (*History of the Industry in the United States*).

The consumption of raw silk in recent years is as follows (in pounds): 1914, 25,021,945; 1909, 17,729,306; 1904, 11,572,783; 1899, 9,760,-770. Statistics of the silk industry are given below:

	ESTABLISHMENTS	Wage-earners	Capital	Wages	Cost of material	Value of product
1914	902	108,170	$210,072,000	$47,109,000	$144,442,000	$109,569
1909	852	99,037	152,158,000	38,570,000	196,912,000	89,145

Other important statistics in the silk industry are the following: Amounts of spindles in use: *Throwing* (raw silk) in 1914, 677,960; 1909, 637,565; 1904, 624,686; 1899, 442,410. *Spinning and Twisting* in 1914, 2,023,491; 1909, 1,647,415. *Spinning of Spun Silk* in 1914, 107,251; 1909, 130,547. Thrown and spun silk in 1904 and 1899 amounted respectively to $1,394,020 and $1,213,493.

LOOMS	1914	1909	1904	1899
40 inches or less	26,431	28,426	50,449	36,989
Over 40 inches	44,549	35,214		
Velvet	2,524	1,196		
Ribbon	11,554	10,570	......	......
Jacquard looms	6,826	8,985	......	......

Cotton.—In the textile industry King Cotton still maintains supremacy. And the United States holds a proud position among her fellow-nations. The industry has shown a marvelous growth in the last quarter of a century, but the centres of production have shown frequent reduction of output in individual mills while collectively the advance has been aggressively steady. The first cotton mills were in New England but by 1860 the industry had spread into scattered sections as is shown by the following table which gives New England 52 per cent of establishments and 75 per cent of spindles:

COTTON MANUFACTURES 1860.

ESTABLISHMENTS	Cotton used in pounds	Spindles	Value of product
New England, 572	283,700,000	3,800,000	$79,400,000
Middle States, 540	87,100,000	1,000,000	26,500,000
South, 159	43,900,000	300,000	8,100,000
West, 22	7,900,000	40,000	1,600,000

This New England industry was centralized in Massachusetts and Rhode Island and factories were grouped largely at Providence, Fall River and Lowell with Manchester, N. H., also prominent and Philadelphia the largest cotton manufacturing city. This before the Civil War. The general technical growth up to 1890 has been briefly given above (more details of machinery can be found under title LOOM) with its greatly improved machinery inventions thus allowing larger output per man power, higher wages, and competition with European imports. But the radical changes occurring in the industry are shown by the fact that New England's 570 establishments in 1860 had fallen to 308 in 1905, though the number of spindles had increased from 3,859,000 to 13,911,000 in those years from the tendency of the smaller factories to lose ground and the rapid growth of the more prominent and highly capitalized mills. Then came the sudden mushroom-like growth of the Southern mills and the Northern cotton-mill owners feared that their industry was threatened by the competing field with its low-priced labor. From 1890 to 1905 we get the following statistics which show that the advance of the Northern industry maintained a healthy advance:

VALUE OF PRODUCT.

	1890	1900	1905
Fall River	$24,925,000	$29,286,000	$32,538,000
New Bedford	8,185,000	16,748,000	22,412,000
Lowell	19,789,000	17,046,000	19,384,000
Manchester	10,957,000	11,723,000	14,366,000
Pawtucket	3,955,000	5,635,000	10,099,000
Lawrence	6,047,000	8,151,000	5,745,000
Taunton	2,748,000	4,593,000	6,141,000
New England	$181,112,000	$191,690,000	$224,072,000

The number of establishments in the Southern States in 1860 was 165; by 1900, 550 and of much larger size; and the table following shows the extraordinary growth to 1910:

STATE	Establishments		Spindles		Looms	
	1880	1910	1880	1910	1880	1910
South Carolina	14	145	82,000	4,019,000	1,700	88,427
North Carolina	49	292	92,000	3,174,000	1,800	50,979
Georgia	40	139	199,000	1,939,000	4,500	35,069
Alabama	16	61	49,000	947,000	900	15,853
Tennessee	16	29	36,000	293,000	800	4,391
Virginia	8	14	44,000	329,000	1,300	8,694
Mississippi	8	19	19,000	177,000	600	3,586
Texas	2	16	3,000	112,000	100	2,331
All other	11	16	37,000	241,000	600	2,942
Total	164	731	561,000	11,231,000	12,300	212,272

The product of the Southern mills has been chiefly coarse yarn and cloth while the North has maintained its hold on the finer goods, and it still produces great output of coarse goods.

A general survey of the progress of the United States in its cotton industry is best told by the statistics. Thus we have for woven goods in square yards and values the following figures:*

	1899	1904	1909	1914
Square yards	4,485,605,418	5,056,779,590	6,267,561,279	6,810,712,349
Valued at	$239,668,011	$317,539,626	$447,167,319	$488,728,054

Other interesting figures are: The cotton consumption in the textile mills in pounds:

1914	2,679,934,778
1909	2,465,225,572
1904	1,981,804,446
1899	1,923,704,600

Cotton manufactures in 1914 were valued at $701,300,933; in 1909 at $628,391,813; 1904 at $450,467,704; 1899, $339,200,320. The equipment of spindles producing the above output was in 1914, 30,887,489; 1909, 27,425,608; 1904, 23,195,143; 1899, 19.050,952. These were used on the following number of looms (all classes): 1914, 676,661; 1909, 665,049; 1904, 559,296; 1899, 455,752.

Improved Spinning.— The improvements in spinning have been so rapid since 1870 that most of our large corporations have been compelled to replace their spinning-frames two or three times in that interval. A similar statement can be made regarding no other branch of textile manufacture; and it is probably true that if the American woolen mills had been forced, as the cotton mills have been, to abandon machinery as soon as it became in any degree obsolete, their ability to face foreign competition would be more nearly in keeping with that shown by our cotton manufacturers.

Large Corporations.— The conditions here narrated have thrown the cotton manufacture more and more into the hands of large corporations, which now almost universally conduct it. The wool manufacture, on the other hand, while it numbers some of the greatest corporations in the land, is still largely in the hands of individuals and partnerships, and the bulk of the mills are comparatively small in

* Not including lace, tape, webbing and "other cotton products." which give an added value of $44,186,551 for 1914; $36,936,969 for 1913; $26,454,297 for 1904, and $25,297,385 for 1903.

capacity. The more recent tendency in the wool manufacture, tor obvious reasons, is strongly in the direction of the corporate form of management.

Fine Cottons.— The quantity of fine cotton goods made in American mills continues to be very small in comparison with the whole production, and in the bulk of our consumption of this class of cottons is still imported. So there is ample room remaining for further development of the American cotton manufacture. Into this field we are entering with characteristic Yankee energy. Within comparatively few years mills have been successfully established in New England which spin yarns as fine as Nos. 150 or 200; and there are mills at New Bedford, Taunton and elsewhere which make, in wonderful variety, fabrics as delicate in texture and as artistic in design and coloring as any which reach this country from the machine-using nations of Europe.

Wool.— The range of products made in American wool factories is as wide as the multiform uses to which this most valuable of all the fibres is put. They divide themselves naturally into four great groups, leaving the hosiery and knit goods out of the classification: woolen mills, worsted mills, carpet mills and felting mills. There are the various subclassifications of spinning, weaving, dyeing and finishing mills, although, as a rule, all these separate processes of the manufacture of wool continue to be carried on jointly in this country, as the related parts of the one operation of manufacturing.

men who find the ultimate market for all the specialists who have been thus employed upon the goods. In this specialization of the different branches of the work exists the characteristic distinction between the American and the foreign textile mills of to-day. Investigation appears to show that the English method is far superior to the American, and that ultimately we must gravitate into the former, if we are to cut any figure in competition for the world's market. The manufacturer who devotes his whole energies to one particular thing, and studies to do that one thing as cheaply and as well as it can be done, can do it better and more cheaply than the manufacturer who is doing half a dozen different things at the same time. This is not a theoretical deduction, but an axiom founded upon prolonged experiment and experience. Bradford manufacturers who have tried both methods say there is always a gain in economy when the weaver buys his yarns, instead of spinning them himself. Obviously the English method requires a smaller investment in plant, secures a simpler and more perfect autonomy in operation, involves less waste and avoids the accumulation of superfluous raw material. The American woolen mill was evolved from conditions which rendered specialization originally impossible. It was situated in some isolated spot, drawn thither by a superior water power, with no railroad to facilitate quick transportation, and was necessarily a complete mechanical entity, however crude its machinery. In a word, it must perform under one roof all the processes necessary to convert the greasy wool into the finished cloth ready for the market. Thus there sprang up all over the country little woolen mills, each one independent in itself; as the country grew some of these little mills became large mills; other large mills grew up beside them; gradually grew centres in which the wool manufacture predominated; but conditions were long in appearing which tended to that specialization of processes which has marked the English method from the very introduction of automatic machinery. It followed that the American millowner, even of a small mill, was compelled to make a variety of goods, in order to use up advantageously all the grades of material which grew out of the sorting of his wool. Naturally he could not produce a variety of products as cheaply and as successfully as he could have manufactured one particular line upon which his whole attention was centred. These habits of manufacturing, forced upon us originally by the logic of the situation, are tenacious. We

WOOL MANUFACTURES, INCLUDING WORSTEDS, FELTS, CARPETS, ETC.

	1914	1909	1904	1899

Manufactured product	502,857,333	552,503,710	483,526,095	394,369,523

Specialization.— In the wool manufacture, as in the cotton and silk manufacture, we have many establishments which, in completeness of structure, in perfection of machinery, in all the details of mechanical equipment, and in sagacity of management, are nowhere in the world surpassed. Indeed, it is only in this country that we find, on a very large scale, textile mills in which are performed all the separate processes for the manufacture of great varieties of goods. Elsewhere they have learned that the greatest economy and the best practical results are secured by specializing the processes. Thus in Bradford, England, are enormous establishments which do nothing but comb wool into tops, either on commission or for sale. Other great mills do nothing but spin tops into yarn, and generally they confine their operations to a limited variety of yarns. Still others, buying their yarn, devote themselves exclusively to weaving. And, finally, a fourth class of establishments take the woven goods and dye and finish them for the merchants, who are the have been slowly breaking away from them, but it will be years yet before it is possible fully to outgrow them. In Philadelphia, which is the largest centre of wool manufacture, the progress of the evolution is very perceptible. There they have top-makers, yarn-makers, dyers and finishers, who do nothing else. And the result is apparent in the large number of small manufacturers in that city. The small amount of capital required to equip a little weave-shed permits enterprising superintendents and operatives to start in business for themselves. The comparative cheapness of production under such conditions enables them to hold their own against the big establishments with unlimited capital at their back.

American Woolen Specialties.— The bulk of the small wool manufacturing establishments in the United States are woolen mills proper, as distinguished from worsted mills. It is noticeable that the number and product of these woolen mills decrease from census to census as the worsted manufacture gets more firmly established here, and the more popular worsted fabric comes into wider use. But there are certain lines of woolen goods in the manufacture of which American mills have earned a world-wide pre-eminence. Prominent among them are flannels and blankets of every grade and variety. The American wools are peculiarly suited for these goods, and for many years past our American mills have practically supplied the home market. Other mills make a specialty of woolen dress goods for ladies' wear with equal success. The bulk of our woolen mills are, however, engaged upon the manufacture of cloths for the million — cassimeres, beavers, satinets, cheviots, etc., the cheaper grades which enter into the consumption of the wholesale clothing houses, goods in which, under the weight duties of recent tariffs, our American manufacturers have controlled the home market, and of which their production has been enormous. Many of these goods are woven upon a cotton warp, and into some of them enters more or less of the revamped wool known as "shoddy." We have much to learn, however, in the handling of this class of materials, before we shall equal the expertness of foreign manufacturers.

WOOLEN GOODS.

YEAR	Establishments	Wage-earners	Capital	Wages	Cost of material	Value of product
1914	501	49,165	$107,872,000	$24,204,000	$63,696,000	$103,816,000
1909	587	52,180	120,320,000	22,575,000	65,652,000	107,119,000
1904	792	72,747	140,302,000	28,828,000	87,831,000	142,197,000
1899	1,035	68,893	124,386,000	24,757,000	71,012,000	118,430,000

1879	1,990	86,504	96,096,000	25,836,000	100,846,000	160,607,000
1869	2,891	80,053	98,824,000	26,878,000	96,433,000	61,895,000
1849	1,559	39,252	28,119,000	....	....	....

Worsteds.— The worsted manufacture was late in getting lodgment in the United States and has been slow in assuming proportions commensurate with its importance abroad. Early in the forties there were two or three large worsted mills erected in New England for the production of worsted fabrics or stuff goods for women's wear; but the manufacturer made little headway until after the close of the Civil War, and it was not until about 1870 that we began making men's wear worsted goods. Since then the development of the manufacture along both lines has been phenomenal. In the manufacture of fine men's wear goods, both in woolens and worsted, a few American mills have been equally successful; their products sell side by side with the best makes of foreign goods. Another obstacle is the high cost of labor, which counts more strongly in fine wool goods than in the cheaper grades or in cottons and silks, because of the much greater care and skill and labor that must be bestowed upon their finishing. Woolen goods are from carded wool, worsted from combed wool. The popularity shown to worsteds has resulted in a great growth in that class of goods, checking the advance of the manufacture of woolen goods as is shown by the following tables:

WORSTED GOODS.

YEAR	Establishments	Wage-earners	Capital	Wages	Cost of material	Value of product
1914	298	109,527	$281,781,000	$51,749,000	$182,801,000	$92,897,000
1909	324	111,012	295,058,000	47,152,000	207,787,000	104,837,000
1904	226	69,251	162,465,000	26,270,000	109,658,000	56,087,000
1899	186	67,008	132,168,000	77,075,000	120,314,000	43,239,000
1879	76	18,803	20,374,000	5,683,000	22,014,000	11,536,000
1869	102	12,920	10,086,000	4,369,000	14,308,000	7,782,000
1859	3	2,378	3,230,000	544,000	2,443,000	1,258,000

Felted Wool.— The manufacture of felted wool is comparatively small here and elsewhere and the importations are comparatively insignificant in volume. Felted wool was the earliest form into which this fibre was manufactured, the primitive races discovering, before they had learned to spin and weave, that peculiar characteristic of wool which causes it to mat together, by the application of heat, moisture and pressure, into a firm and smooth texture, susceptible of a great variety of uses. Modern machinery has utilized this peculiarity for many purposes which, while limited, are economically important. Tablecloths and floor coverings, and hats for men's and women's wear, are the most ordinary; but they are also used for shoe linings, sheathing materials, polishing purposes, etc. The hat manufacture, formerly confined to wool for its raw material, has found that fur is better suited for this use; and the processes of manufacture are so different from those employed in spinning and weaving mills that the hat-manufacturing establishments, in which the United States has always been pre-eminent, are not ordinarily classed among the textile mills.

Carpets.—Perhaps our most notable achievement in the textile line has been in the carpet manufacture. Beyond question the United States is the greatest carpet-manufacturing nation in the world; if we leave out of account the hand-loom productions of the Eastern countries we excel all others not only in the quantity of our production, but in the variety of our carpets, in the excellence of design and workmanship, and in general adaptability to popular needs. The production includes two-ply and three-ply ingrains, Brussels, moquettes, tapestries, velvets, Smyrnas and the highest grades of Axminsters and Aubussons. The annual consumption of this product by the American people begins to approach 100,000,000 square yards. The popular reason assigned for this unique development is the general prosperity of our people, the high wages earned permitting families of all grades of life to indulge in the luxury of floor coverings to an extent elsewhere unknown. Stimulated by the lucrative market thus offered, American manufactures have made larger and more important contributions to the mechanism of the carpet manufacture than those of all other nations combined. The real development of the machine industry dates from the successful application of power to the weaving of ingrain carpets by the late Erastus B. Bigelow in 1844. Subsequently he invented Jacquard looms for weaving Brussels and Wiltons, which produced carpets pronounced by the jury at the London Exposition of 1851 to be «better and more perfectly woven than any hand-loom carpets that have ever come under the notice of the jury.» A still later invention of Bigelow's was for weaving tapestry carpets. His inventions are at the base of all the power-loom carpet-weaving now done in Europe. Subsequent inventors have greatly improved them and have added new inventions, such as those for weaving Axminsters and Smyrna rugs. By their skill and enterprise the American carpet manufacturers have not only retained the control of their own market, except in the matter of the Eastern hand-made rugs, but they have in some instances successfully forced their products upon the European markets.

In 1914 there were 97 establishments in the United States producing carpets and rugs of other than rags, keeping 33,100 persons engaged; the wage-earners numbered 31,309 and were paid $14,715,615. Capital employed was $85,153,828. Jute carpets and rugs were made to the added value of $1,172,257. Rag carpets produced had a value of $2,786,439. The growth of the industry is shown by the following figures:

	1914	1908	1904	1899
Carpets and rugs (other than rag)

Hosiery and Knit Goods.— In one other branch of the textile industry progress in the United States has outstripped the world — the hosiery and knit-goods manufacture. More machine-made knitted goods are turned out annually here than in all other countries combined. The explanation is somewhat the same as in the case of carpets. Our people wear more underwear than other people; they are not only obliged to wear more for climatic reasons, but they can afford to wear more; and the general desire for personal comfort in wearing apparel results in an enormous distribution of the products of these mills. The beginnings of the industry are well within the lifetime of many manufacturers still living. Until 1832 the knitting of socks and stockings remained mostly a household industry — the only form of textile work which the machine had not wrested from the housewife. In that year Egbert Egberts successfully applied the principle of knitting by power, at Cohoes, N. Y. His machine was simply the square stocking-frame of William Lee adapted to power. From that adaptation dates a revolution in underwear, which had previously consisted wholly of flannel, fashioned and sewed at home, according to the individual needs. The revolution gathered momentum gradually, as invention after invention — almost all of American origin — perfected the knitting-machine; but once the new industry was fairly and firmly established, it spread with amazing rapidity. The great variety of goods made facilitates the tendency, peculiar to this industry, toward the building of comparatively small mills, requiring but moderate capital; and it happens in consequence that these mills spring up all over the country and can now be found in nearly every State. Many of them employ only cotton as a raw material; others use chiefly wool; and still others manufacture what are known as merino knit goods or mixed goods — cotton mixed with wool in proportions varying from 50 to 75 and 90 per cent of cotton, according to the particular market sought.' The tendency to the larger use of cotton in these goods is perceptible, not necessarily because of greater cheapness or a desire to adulterate, but because the liability of wool to shrink, and its excessive warmth, lead many to prefer undergarments in which cotton is an equal or predominating material. In 1858 E. E. Kilbourne invented a machine for automatically knitting full-fashioned underwear; and this machine has gradually wrought a second revolution in the industry. The amount of hand labor now done is reduced to the minimum — to the mere sewing on of buttons, so to speak.

KNIT GOODS.

YEAR		Establishments	Wage-earners	Capital	Wages	Cost of material	Value of product
Power machines	1914..	1,491	150,145	$215,357,000	$59,605,000	$146,291,000	$111,750,000
	1909..	1,264	128,708	162,855,000	44,527,000	109,416,000	89,156,000
	1904..	1,079	103,715	106,663,000	31,536,000	76,594,000	59,964,000

Linens.— The line of textiles which has found the greatest obstruction in the United States to advance has been linens. The financial condition of this branch was unremunerative and its output, till 1890, when the manufacture of the flax product took on new energy, was nominal. But it has maintained headway ever since, as the statistics show. One drawback has been the difficulty of getting the American agriculturist to grow a flax crop, in spite of placing a high tariff on the raw stuff to tempt the grower. Matters have, however changed considerably already, the industry has obtained a firm foothold and the statistics show steady growth.

LINENS.

YEAR	Establishments	Wage-earners	Capital	Wages	Cost of material	Value of product
1914	21	3,567	$8,810,000	$1,386,000	$4,289,000	$6,960,000
1909	15	3,573	7,457,000	1,213,000	3,967,000	6,385,000
1904	15	3,811	6,294,000	1,325,000	3,741,000	5,856,000
1899	18	3,283	5,689,000	1,037,000	2,551,000	4,368,000
1889	5	1,940	2,734,000	528,000	1,595,000	2,880,000
1879	6	1,414	907,000	384,000	1,132,000	1,892,000
1869	10	1,746	2,325,000	424,000	1,121,000	2,179,000
1859	11	689	840,000	134,000	388,000	840,000

Statistics.— The value of all textile products in the United States for 1850 was $128,769,971 and this had increased to $931,494,566 in 1900. The census report for 1900 shows the following:

The number of cotton spindles in operation in 1900 was 19,008,352, as compared with 14,188,103 in 1890, and 10,653,435 in 1880. This striking increase is due in a large measure to the wonderful growth of the industry in the South since 1880, as before that date the cotton manufacturing industry existed there only on a most restricted scale. In fact, the growth of the industry in the South may be regarded as the one great fact in its history during the past decade. It has been fairly continuous and remarkably steady.

The totals of manufactures in the United States products, etc., in the textile industries follow:

YEAR	Establishments	Wage-earners	Capital	Wages	Cost of material	Value of product
1914	22,995	1,496,644	$2,810,848,000	$672,351,000	$1,993,058,000	$3,414,615
1909	21,723	1,438,446	2,488,463,000	592,261,000	1,745,516,000	3,060,199
1904	17,042	1,156,305	1,744,169,000	419,842,000	1,246,562,000	2,147,441
1899	17,647	1,022,123	1,340,634,000	341,652,000	894,846,000	1,628,606

The extraordinary growth of the exports of textiles from the United States of America is shown in the following table:

	1908	1912	1914	1916	1918
Silk, manufactures of	$720,368	$1,992,765	$2,307,605	$5,204,813	$12,140,750
Cotton, manufactures of:					
Cloth	14,268,083	31,388,998	28,844,627	46,381,390	103,416,102
Knit goods	1,482,751	1,858,836	2,546,822	20,546,822	15,353,165
Woolens:					
Carpets	63,074	57,152	....	....	....

The wonderful strides given in these figures for 1916–18, of course, reflect the consequences of the war cutting off Europe from her exports and the consequent enormous increase of our products in demand from South America and other foreign states.

Future Needs.—The American textile manufacturers have left little to be desired in the direction of cheapening textile products without deteriorating quality. They have built and equipped mills which rank with any in the world. They have planted on this continent machinery enough to supply all the textile wants of our people, except in a comparatively few lines of very fine fabrics. They have managed these mills with rare business sagacity, and as a rule with notable financial success. They have taken one specialty after another which had never been attempted here, and transported its manufacture from across the water, literally inventing anew the necessary machinery, as in the case of braids and plush goods, when they could not obtain it otherwise. They have taken these several textile industries, which have been localized and specialized in Europe for generations, and in less than a century have made them one of the chief corner-stones of our national wealth. They have contributed far more than their share to the mechanical development which makes the labor of a single operative stand for that of a regiment of hand-workers in the 18th century. They have fallen short only in contributing to the artistic side of textile industry. They have been imitators instead of originators, although there are among them many striking and gratifying exceptions to this rule. But American-made goods do not bear, generally speaking, any distinctive artistic characteristics which distinguish them as American-made; and, generally speaking, they are inferior in this respect to the best products of foreign looms. All this is natural — natural to a new country in which utility everywhere predominates over the ornamental. The next great forward step in our textile manufactures must be in the artistic rather than the mechanical direction, for there we recognize its weakest point. In the designing of patterns, in the use and application of dyes, in all that goes to impart to fabrics the artistic element, to lift the manufacture into an art, our textile mills are still far from the top of the ladder. This deficiency is not in any sense peculiar to the textile industries. It is an educational deficiency in which our people as a whole may be said to share. It is incidental to a crude country of limited facilities in art directions. What needs to be done is to supply more facilities.

Trade Schools.— In the centres where the textile industry has grown to be the predominating commercial factor the necessity of having training schools for operative artisans in recent years became obvious to the manufacturers. With the increasing size of the industrial establishments labor became more specialized and operators learned nothing of the technique outside of the special task of tending a machine or some other single restricted sphere of action, quick pace being the compass of the individual operative. Europe had long since filled the need for training expert artisans in all-round textile work to fill the place of chemists, designers, dyers, machinists, overseers, superintendents, etc. In 1872 the Lowell School of Practical Design was established. The Philadelphia Textile School was incorporated at Philadelphia in 1876 and gives a three-year course in all the various processes connected with the manufacture of cotton, wool and silk, including chemistry, dyeing and an ingrain-carpet course. In 1872 the Lowell School of Practical Design was established at Boston, and in 1878 the Rhode Island School for Design was formed in Providence, R. I., to teach technical designing for the textile trade. The Lowell Textile School, at Lowell, Mass., was organized in 1896 to teach all the branches of the industry. The New Bedford Textile School, at New Bedford, Mass., was formed in 1895 and opened in 1899. The Fall River institution called Bradford, Durfee Textile School was founded in 1900. The Industrial School at Lawrence opened in 1907 and provides the workingman with a practical education in the textile trade. And in the South several colleges have opened textile departments such as Clemson College, South Carolina (1898), the North Carolina College of Agriculture and Mechanical Arts, the Georgia School of Technology (1899), the Mississippi Agricultural and Mechanical College (1901) and the Agricultural and Mechanical College of Texas (1905). For further particulars see under TECHNICAL EDUCATION.

Foreign Textiles.— J. A. Hunter, a Halifax expert, said in 1915: «There are 145,000,000 spindles in the world spinning cotton; 56,000,000 are in England, 11,500,000 in Germany. The mule or intermittent spinning machine is the staple producer in England; the ring frame, or continuous machine, accounts for about half the spindles in Germany. . . . In 1907 Germany had an outturn of cotton yarn valued at $157,500,000, the British production $395,000,000 . . . In 1907 (according to the 1907 census) Great Britain wove 397,000,000 yards woolen cloth, Germany 270,000,000 yards. The mule is used in spinning finer yarns and the English, making fine goods, use more spindles, viz.: in 1909 England used 39,000,000 mule spindles against 7,900,000 ring spindles.» In that country spinning and weaving are generally products of different mills whereas the two processes are generally combined in the United States mills. In the ring-frame less skilled labor is required than with the mule hence the former is better adapted to this country. Again the output is greater upon the ring spindle giving, therefore, more output besides allowing cheaper labor.

In 1907 England's output of woolen tissues (all wool or mixed) amounted to 188,125,000 yards valued at $88,000,000. Her worsted tissues (all wool or mixed) were 209,109,000 yards valued at $86,655,000. Other products for that year were:

		Value
Damask, tapestry and other furniture stuffs (yds.)	6,901,000	$3,805,000
Flannels and delaines (yds.)	50,566,000	9,290,000
Carpets (yds.)	25,766,000	16,295,000
Rugs (yds.)	3,813,000	3,195,000
Blankets (pairs)	3,130,000	7,380,000
Shawls (by number)	1,142,000	1,220,000
Other woolen fabrics as coverlets, braids, etc	....	224,425,000

Of England's cotton product we have figures: for 1907: Piece goods 7,087,000 yards valued at about $411,620,000, of which were bleached goods (not dyed or printed) 2,200,062,000 yards; dyed, but not printed 1,142,524,000 yards; printed (dyed or not) 1,326,059,000. Her silks amounted to the following figures:

BROADSTUFFS	Yards	Value
Wholly silk (net or spun)	10,527,000	$4,345,000
Mixed	7,941,000	3,600,000
Made-up goods (neckties, etc.)	....	3,255,000
Ribbons, trimmings, etc	....	6,790,000

UNDERWEAR	Value
Shirts, pants, vests, etc	$13,615,000
Fancy hosiery (including cardigans, sweaters, etc.)	4,525,000
Hose, half hose, etc	22,040,000
Other hosiery	860,000
Gloves (cotton, wool, silk, etc.)	2,150,000
Entire quantity of hose made in 1907	72,045,000

England's exports were:

	1916	1917
Cotton piece goods	$443,939,450	$564,052,485
Other cottons	74,175,115	78,434,900
Wool manufactures	234,528,245	264,238,370
Silk	12,030,590	10,090,280
Other manufactured fabrics	79,089,715	84,719,850

In 1840 Germany had 658,358 spindles working which grew by 1860 to about 2,000,000. A recent report gave her 10,920,426 spindles for cotton spinning. In Crefeld, the centre of Germany's silk industry, were at last reports (1914) 65 factories making silk cloths and 28 factories producing velvets. The total German silk product has been estimated at about $29,013,833.

According to the last statistics available France had 7,500,000 cotton spindles. These were chiefly located, before the war, at Lille, Roubaix, Tourcoing, Epinal, Saint Dié, and in Normandy, at Rouen, etc. They employed about 130 power looms and 40,000 hand. Her silks were chiefly produced at Lyons for high quality goods. Silks of fine quality were also made at Saint Etienne and in Picardy. The Lyons industry employed from 85,000 to 90,000 operatives on over 20,000 power looms. They produced 2,500,000 kilograms of wrought silk and 1,000,000 kilograms raw silk. Production follows:

	Products valued at	
Lyons	409,000,000 fr.	$81,800,000
Saint Etienne	8,205,000	1,641,000
Picardy	4,600,000	920,000

in all about $84,361,000.

Foreign Schools.— England's textile operatives are supplied with technical training in such schools as Bolton Technical School, Bradford Municipal Technical College, Coventry Municipal Technical Institute, Halifax Municipal Technical School, Huddersfield Technical College, Keighley Institute, Yorkshire College at Leeds, Oldham Mutual Technical School, Rochdale Municipal Technical School, Salford Royal Technical Institute, etc. Germany has textile schools at Aix-la-Chapelle, Crefeld, Cottbus, Falkenburg, Muhlheim-on-Rhine, Berlin, Chemnitz, Muhlhaus, etc. In France technical education for the textile industries is given at Elbeuf, Tourcoing, Roubaix, Saint Etienne, Lyons, Flers, Sedan, Bohain. In Austria are textile schools at Asch, Schoenberg, Warnsdorf, Ruthenberg, etc. In Switzerland are textile schools at Wattwyl, Zürich, etc. In Italy we find such at Prato, Arguno, etc.

TEXTILE PRINTING. The decorating of fabrics by printing is one of the oldest of the arts. There are evidences that it was practised in Egypt 2000 B.C., and it was used in ancient Assyria, India and China. Opinions are divided as to the country of its origin, but there is no question that it came to mediæval Europe from India. Rich patterns of both silk and cotton were brought by early traders to the leading ports of Europe and inland. German manufacture appears to have begun in the 13th century. They printed principally silks and linens, and were addicted to gilt and silver designs. In the course of time the art spread to Switzerland, France and England. The print works at Jouy, near Versailles, France, were the first to become famous there. It is believed that fabrics were printed in England as early as 1620, but the first record of systematic manufacture was at Richmond-on-Thames in 1690. All this early printing was done from blocks by a method very similar to block printing for books. The designs were cut in the surface of a block, and if many fine lines were desired, the surface of the wood was cut away and thin strips of copper twisted and cut to the required form for the lines, and forced tight into the wood until the top of the copper was at the desired level. If a large solid surface of color was required, it was found better to surface the wood with felt, as it carried the ink better than the wood. That very beautiful results can be had by block printing on fabrics is evidenced by the fact that it is still practised by amateurs as a fad and by a few artistic workmen in large cities. Block printing was long done entirely by hand, the cloth being laid on the inked block, covered with felt or the like and impressed with a mallet or by rubbing. But presses for block printing became common in England in the 18th century and continued to be used long after the cylinder method of textile printing came into use. Several had the idea of printing with a roller, but Thomas Bell, of England, was the first to bring out a practicable cylinder machine, in 1783. His object was twofold, to print several colors at once and to do away with bad joints, which were all too common in block printing, wherever the pattern repeated. In 1785 he patented a six-cylinder machine, which was the prototype of the modern cylinder cloth-printing machines. Though vastly superior, the invention was accepted slowly, and in 1840 it is reported that there were but 516 cylinder machines in Great Britain as against 14,000 tables for block printing. Engraving on the cylinders was for a long time tedious and expensive, the first radical improvement here being Gormetz's engraving machine in 1828. The pantagraph machine for duplicating patterns on cylinders in enlarged size came in 1834, and thereafter the art of textile printing advanced very rapidly. The patterns or designs are now made on paper and transferred to the cylinders, and either cut in with the pantagraph or etched on copper. They are also sometimes made in soft steel and later hardened. A modern cylinder textile press has a great central drum around which the cloth travels. About this drum are a series of engraved cylinders with inking apparatus. The cloth is led in from a reel and passes under perhaps six or eight cylinders, receiving a color impression from each, in exact register, and is then led to a drying apparatus, that is commonly an enormous reel, with adjustments for keeping the printed surfaces apart until quite dry. Commonly the colors are put on lightly for surface effect, and in other cases the color is forced through the cloth, so as to get an effect on the reverse side. Most exquisite printing is done on silks, linens, woolens and cottons, as can be seen by any one who will visit the counters of any large dry-goods store. The tapestries, draperies, figured dress goods, cloths for upholstery, etc., produced by this process are endless, involving all the colors of the rainbow; in fact the perfection attained in the art is truly amazing. Consult Rothwell, 'Printing of the Textile Fabrics' (Philadelphia 1892); United States Bureau of Manufactures, 'Reports' on Cotton Goods (1912); Knecht and Fothergill, 'Principles and Practice of the Textile Printing' (London 1912); Beaumont, 'Color in Woven Designs' (1912). See TEXTILES; WEAVING.

TEXTILES, or TEXTILE FABRICS. Stuffs made by the weaving together of threads of any sort, so as to produce a material with a nearly solid surface. A fishing-net or the like is not a textile fabric because the cords which compose it are not woven together, but cross one another at equally distant intervals and are strongly knotted at those points. But mosquito-netting is a textile, although very open, because the threads are merely held by their own friction. On the other hand, if a basket is made by weaving together strips of wood or bamboo, such a material is hardly called a textile, but this merely because of its totally different usage. The cane seat of a chair is as truly woven as a piece of muslin or silk.

Textiles in the usual sense are made of the twisted fibres spun into thread of flax or linen, cotton, hemp, jute, silk or wool. The simplest weaving is that which produces our common cotton and linen cloth; that is to say, the threads are merely woven together, one up and one down, and all in the same manner, except that at the edge on either side of the piece what is called a selvage is produced to prevent the raveling out of the threads. From this to the most complicated fabric like brocade the differences are almost infinite, and it is only with the most elaborate diagrams and the fullest explanations that the process of weaving a figured *broché* silk or a velvet with patterns of pile upon pile can be explained. Carpet weaving (see CARPET) differs somewhat from ordinary textiles, and tapestry differs yet more and is often excluded from textile fabrics altogether.

The general nature of a loom is that the threads of the warp are divided into two sets, one of which is thrown upward, while the other is thrown down, and at the same moment a shuttle carrying a thread of the woof is driven through between the two sets of warp threads. The next movement of the loom reverses the two sets of warp threads, throwing the upper one down and the lower one up, compressing and drawing tight the woof thread into the loops which show on the surface of the stuff and go to form the surface, and the shuttle is driven through again in the opposite direction. The constant repetition of this forward and backward movement of the shuttle gives a strip of woven fabric which continually grows broader; and as each movement of the shuttle is made, an appliance drives the last thread of the woof back against the others, so that this growing strip of woven stuff is kept at a uniform state of firmness and solidity. It is in this way that the simplest fabrics of linens and cottons are made. If it be desired to produce a somewhat more elaborate weave, such as twilled material, this is done by raising two threads of the warp and dropping one; or by raising three threads of the warp and dropping one, and so on. In this way, as is evident, the threads of the woof are seen lying in loops or what seems to be stitches longer than those of the simplest weave, and these longer loops arrange themselves in a steplike diagonal across the woof of the stuff. It is clear that, by the increasing complications of such alternate liftings and lowerings of the warp threads, more patterns may be made. If, then, the threads of the woof are of a different color from those of the warp, there is produced a surface whose general color is half way between the two colors of warp and woof. If we take a step further in complexity and use three or four warp threads say, of red, while the rest remain white, and do the same thing with the woof threads, we produce stripes three or four threads wide; and where these stripes cross one another there will be a little square of the solid color of the three or four threads, while the stripes elsewhere remain of the halfway tint alluded to. Again if three threads of different colors are passed by the shuttle at one time, the threads of the warp also being grouped in threes, there will result a simple alternating pattern, which is often very attractive. Indeed, much of the primitive designing of early races is based upon such very simple productions of the loom; for it seems that the mind of man is never tired of a pattern produced by up and down, in and out, in their different combinations. In the most complicated pattern of a brocade, such as the Japanese send us occasionally, in which a row of dragons will alternate with a row of representations of «the sacred pearl» with its flames, and those again with a row of kylins or other fabulous monsters, all being interspersed with elaborate leafage, open flowers of the camellia and bursting fruits of the pomegranate, the same being reproduced in many colors — even in such a complex pattern it is readily seen that these figures are arranged in regular sequence, and that the colors are introduced in a definite and unalterable succession. Thus a blue thread of the woof may not appear more than once in each flower, of a certain row across a piece of stuff, and this appearance of the blue thread may be for a loop of a quarter of an inch long only, while all the rest of that blue thread is found to be hanging loose behind the finished fabric. Again this blue thread may not appear at all in six or seven inches of the length of the stuff, and then it may supply a wholly different detail of the pattern. Still that blue loop in the design as seen from the front or «right side» is found in each one of the flowers or animals which form the cross row of the pattern; and in the next row of similar flowers or animals (which may be two feet away in the length of the piece) this blue thread may be replaced by a crimson one, which will also appear at exactly the same intervals and at exactly the same point in each one of the flowers, or of a unit of design. It is interesting to take a piece of very rich fabric with an elaborate pattern and to examine it with a view to just such peculiarities of weave. Anyone who has watched a simple loom at work and has mastered the process may then understand in great measure the workings of the far more elaborate loom of the silk weaver, who is producing patterned fabrics.

In such weaving of patterns it is here assumed that the threads are dyed before the weaving is begun. The matter of printing colors upon calico, thin silk or the like is entirely apart from the consideration of textile fabrics. Printing is done from blocks with color, almost exactly as if the material receiving the pattern were paper instead of a woven stuff.

The simplest weave made in this way with colored threads is gingham, the name of which comes from the East, probably from India, with the invention of the weave itself. Checks, plaids and stripes are the natural patterns of gingham, but it is also practicable to produce various zig-zag and frets, and the stripes themselves may be variegated by patterns on their surface. Weaves of Persian and Chinese origin with threads and softer and more woolly than European twisted cotton threads are sometimes very attractive in color effect, woven exactly as gingham is woven.

Damask linen, such as is used for tablecloths and napkins, is peculiar in that the pattern is an elaborate twilled fabric in which the twill is arranged to make a pattern — often even of flowers and leaves. These patterns are seen merely by the difference of reflection of light upon the threads of the linen; for those threads which lie parallel in one direction seem brilliant from a given point of view, while those lying in the other direction look dusky. A change of the position of the beholder reverses this effect of light and dark. Moreover it is common that the same pattern is seen in reverse on the other side of the fabric. There is nothing to prevent damask linen being woven with dyed threads in parts of the composition, and occasionally tablecloths of such material come into fashion.

Brocade, a term generally used for very splendid material, means primarily a stuff — composed in part of threads which lie on the surface of the finished stuff (French *brochés*), appearing where the particular color is needed and disappearing again, as explained in the paragraph above. A brocade may be composed of threads all of one color. Thus the silks called *damassé* (French *Damassés*, or *Damassées*) have perhaps a pattern of dark green leaves relieved in shining threads upon a background of exactly the same dye, but looking different because of the different and less glistening character of the threads; this being caused not by the silk being differently spun, but because of the different treatment of the thread in the loom, the long loops lying flat and loosely, and reflecting the light in a different way from the hard pulled threads of the background.

Satin is a material with a silken surface of unusual and uniform glossiness, which is produced by alternately «raising and depressing four yarns of the warp across the whole of which the weft is thrown by the shuttle.» It will be noted that this is a modification of twilling, and the threads of satin are seen to lie in the same way as those of a twilled cotton. It is evident that such a surface is capable of many modifications. Thus there are some fabrics of silk and wool, or silk and cotton, in which the silk threads are thrown to the surface, lying in very narrow stripes or bands, which show glossy on the background, which also show only in very narrow stripes between the others. These fabrics take different names from year to year.

Again, there are Eastern brocades in which the background is composed entirely of the warp threads in a satin weave of one color; while the flowers of the pattern are made up entirely of the woof threads and these in many colors with gold.

There remains to be mentioned those weaves in which the warp threads only are seen in the finished stuff. The most common form of this is ordinary ribbed silk, in which the warp threads form loops (silks called gros-grain and by other special names), giving a rib running across the stuff. Thus a silk in longitudinal stripes of darker and lighter green, buff and brown, has all its woof threads of a dull brown; while the warp threads of the four colors named form visible ribs in which the colors are alternated in a very elaborate fashion, so that one stripe is made up of a small check in two colors, another is plain and solid, of one color; and in all this the only effect of the dark woof is to modify slightly the hues of the stripes by showing between the warp threads.

Velvet is made by carrying the threads of the warp over a rod called a needle, so as to produce a series of ridges or «ribs,» much as in the last paragraph; and then cutting all these ridges by a sharp instrument passed in as the «needle» is withdrawn. This cutting leaves the threads standing up to form the nap or pile, but they are left of different lengths or heights, and, therefore, the whole surface is most carefully sheared and sometimes this shearing is helped by singeing. Fustian, velveteen and corduroy are made by the same process. Plush is a material of the same character and produced in nearly the same way. When the ribbed surface is left without being cut, the term «uncut velvet» is used. This may be used for a part of the surface, while other parts are fully cut and brought to the smooth surface common to velvet. In this way most elaborate patterns are produced — figures being in the velvet pile upon the ground of uncut velvet. Again this may be carried further in producing what is called «pile upon pile» velvet, in which the pile of one part of the pattern is relieved upon the shorter pile of another part of the pattern and this again upon the uncut background. It is evident that such stuffs are of great cost. The beauty of the pattern may also be enhanced by the use of different colors. Thus the velvets of Genoa and of Venice of the 17th century and modern copies of the same may have a general surface or background of a satin-like texture, upon which the flowers and leaves of the pattern are raised in uncut velvet in ridges made of projecting loops, and upon this again is relieved a pattern of cut velvet, smooth and uniform in surface; both these surfaces, the uncut and the cut velvet, being woven with three, four or five colors, the threads being dyed beforehand in dark and light green, crimson, buff and the like. The resulting pattern will be of extraordinary richness, effective at a distance and also near at hand. Such pieces made in Venice at the close of the 19th century would cost about 60 francs a yard when woven 20 inches wide.

The further elaboration of decorative weaving by the introduction of other materials than those of twisted threads, is also of importance. Thus «gold thread,» as it is called, is commonly made of silver wire gilded and then pulled out or «drawn,» the silver and gold together, until it is very fine. This is apt to tarnish, the extremely thin gold disappearing with wear, and the silver not having the power of resisting impurities in the air. To avoid this, where a permanently metallic effect is desired, gold paper is used by the Orientals, the paper being sometimes brown, as it shows on the reverse side of the stuff, and the gilded surface showing on the right side. The less expensive Japanese brocaded silks are often woven in this way. On the other hand, the tarnishing of the metallic gold thread often adds a special charm to the effect of ancient stuffs.

As textile fabrics have been used by all men more advanced than the most degraded savages, the history of textiles is of infinite extent. Even textiles of decorative purpose, those woven in a somewhat complicated way, are of unknown antiquity. Decorative stuffs have been found in Egyptian tombs of very early epochs. The tombs of the lost races of South America have been found to contain beautiful weaves. The earliest painted vases found in Egypt show boats with sails, and although some of these sails were perhaps of skin, there are others in which the evident purpose has been to show a woven material. Western Asia has always been the home of the most beautiful designs in weaving, for at a very early time the people of the great plain through which the Tigris and the Euphrates run were producing fabrics with the most varied and splendid patterns. This tendency to use the Asiatic feeling for color decoration in work with the loom took two different forms in later times. The carpets and rugs woven with pile were brought from Syria into Europe at least as early as the 8th century A.D., and at a later time they were somewhat common in Europe, as is clear from the earlier Italian paintings, in which rugs of unmistakably Eastern design are seen to cover the foot-stool or the throne of a sacred personage. Other heavy stuffs used in the West for floor cloths and also for door and window curtains under the general name of kelim are woven without pile, the patterns being, therefore, much simpler, akin to those described above in connection with gingham and especially with twilled materials. Brocades of different kinds, and also solidly woven, very durable silk stuffs made with threads dyed of different colors, but woven in such minute patterns that the thread nowhere shows as *broché* on the surface, have been made for so many hundred years that the time of their introduction is hardly ascertained. Cotton stuffs woven in a similar fashion with very pretty effects of simple patterns are but little imported to Europe, but their use in the East adds a great charm to the popular costume. Finally the printing of cotton cloths with wood blocks has been practised for centuries, the pattern being admirably drawn and composed and the colors always interesting except where the effect of European commerce has been, first, to substitute the cheaper chemical dyes of Europe for the more permanent and more beautiful dyes of the East, and, secondly, to debase the color design through the orders given by the agents of Western importing houses. The growth of a beautiful textile industry in Europe and the United States is made difficult by the rapid changes of fashion which themselves are brought about by the great desire of large manufacturers to produce the material and the effect which will attract buyers. This tendency is aggravated by the unwillingness of the great dealers to keep in stock fabrics which are out of fashion, because they are very numerous, because a considerable stock of any one would be a troublesome thing to house and to show on occasion, and because «it costs too much to sell» goods that are not in constant demand. Everyone knows how often the material which at a certain time he found to be exactly what he needed cannot possibly be obtained a few years later. See WEAVING.

Bibliography.— The greater number of the books devoted to this subject are collections of plates, often in color and beautifully printed. These, however, give merely the design, while the nature of the stuff can only be guessed. It is rare that any discussion of the fabric or of the manufacture accompanies the plates. The best of these books is Fischbach's 'Ornamente der Gewebe.' The works on Costume (q.v.) often contain much of the same material. For Eastern carpets, Lessing's 'Alt Orientalische

Teppichmuster' (Berlin 1877) gives a number of fine designs collected from paintings of the Renaissance. Vincent Robinson's 'Eastern Carpets' (London 1882), and the second series of the same (London 1883), present a number of admirable specimens belonging to the author, who was a dealer on a large scale and also a collector on his own account. The colored prints are from excellent original drawings. Several books on Eastern rugs have been published during the last few years, of which we name Mumford's 'Oriental Rugs' (New York 1900). The beautiful stuffs known to have been used during the Middle Ages are treated by Francisque-Michel in 'Recherches sur le commerce,' etc., 'Des etoffes de soie,' etc. (2 vols., Paris 1852), and by Dr. Daniel Rock, in 'Textile Fabrics,' the South Kensington illustrated catalogue (London 1870). The same author has supplied the 'South Kensington Handbook' (London 1876). Fr. Bock's 'Geschichte der liturgischen Gewänder des Mittelalters' (Bonn 1859–71) is the standard work on the subject of church ceremonial garments, constantly cited by all writers. One of the most valuable works for the student of the technical side of textiles is 'The Draper's Dictionary,' by William S. Beck (London n.d.), and the modern fabrics in common use are intelligently treated by Caulfield and Saward in the 'Dictionary of Needlework' (London 1885), and also by Lady M. Alford in 'Needlework as an Art' (London 1886); Matthews, J. M., 'Textile Fabrics: Their Physical, Microscopical and Chemical Properties' (2d ed., New York 1907); Kinne and Cooley 'Clothing and Textiles' (ib. 1913); Woolman and McGowan, 'Textiles: A Handbook for the Student and Consumer' (ib. 1913).

RUSSELL STURGIS.

TEXTUAL CRITICISM, the science by which the texts of ancient writings are examined so as to decide upon their authenticity, their completeness and the degree of exactitude with which they represent the original words of the assumed author. This is sometimes called the Lower Criticism as distinct from the Higher Criticism; the former is destructive, or at least negative, in its results. The Higher Critic is constructive and builds up a theory regarding the nature, object, origin and authorship of a literary monument founded upon the material furnished by the Lower or Textual Critic. (See BIBLE — TEXT CRITICISM, Vol. 3, pp. 629–651; BIBLICAL CRITICISM. Vol. 3, pp. 669–671; ESCHATOLOGY, Vol. 10, pp. 490–493, and related references). Consult their bibliographies, also Cheyne, T. K., 'Critica Biblica' (1903); Driver, S. R., 'Introduction to the Literature of the Old Testament' (1891; 6th ed., 1897); Ginsburg, C. D., 'The Massorah' (1880–85) and 'Introduction to the Masoretico-critical edition of the Bible' (1897); Langlois, C. V., and Seignolos, C., 'Introduction to the Study of History' (1898); Loisy, A., 'Histoire critique du texte et des versions de la bible' (1892); Orr, J., 'The Problem of the Old Testament considered with reference to Recent Criticism' (1906); Smith, G. A., 'Modern Criticism and the Preaching of the Old Testament' (1901); also Barnes, H. E., 'History: Its Rise and Development,' Vol. 14, pp. 205–264; and Walsh, J. M., the histories of each century from the 1st A.D., to the 19th, in this work.

TEXTURE, as a term applied to rocks, signifies the size and mode of aggregation of the mineral particles that make up the rock, in contrast to structure, which applies to larger features, such as bedding, joints. etc. A brief description of those textures which are particularly useful in classifying rocks will be found in the article on ROCKS, in the section on *Igneous Rocks.*

TEZCUCO, tās-koo'kō, or **TEXCOCO,** Mexico, a town in the state of Mexico, situated on the northeast shore of Tezcuco Lake, 16 miles northeast of the national capital. The modern town has many handsome buildings, a number of manufacturing establishments and railroad repair shops. Cortes stopped here for a period in 1521 when he besieged Mexico. Tezcuco was one of the three confederated Aztec pueblos of the valley of Mexico, and for a time was the chief among them, yielding later the first place to Tenochtitlan. In its neighborhood are several ancient ruins, including remains of teocallis. Pop. about 6,000; (2) commune surrounding the town; pop. 16,000. (3) District in the state of Mexico, separated from the capital by a large lagoon; pop. about 60,000. (4) Lake or lagoon about four miles east of Mexico City, 13 by 9 miles, very shallow and surrounded by swamps.

TEZIUTLAN, tā-sē-oot-län', Mexico, the capital of a district of the same name in Puebla state, 50 miles from the Gulf and 12 miles east of Zacapoaxtla. Pop. of town, 8,200; of district, about 25,000.

THACH, Charles Coleman, American educator: b. Athens, Ala., 15 March 1860. He was educated in the schools of North Alabama and at the Alabama Polytechnic Institute from which he was graduated in 1877. He also pursued graduate work at Johns Hopkins University 1880–81. In 1881–82 he was professor of modern languages in Austin College, Texas, and from 1885 librarian and professor of English in the Alabama Polytechnic Institute. In 1902 he was chosen president of his alma mater which has long been the foremost scientific institution of the Southern States. President Thach has greatly expanded the institution since he became president. He was a member of the Alabama History Commission 1898–1900, whose report resulted in the establishment of a Department of Archives and History for Alabama. He is also a member of the State textbook commission and the Rhodes scholarship commission.

THACHER, James, American physician and surgeon: b. Barnstable, Mass., 14 Feb. 1754; d. Plymouth, Mass., 26 May 1844. He studied with Dr. Abner Hersey in Barnstable and in 1775 was appointed surgeon's mate in the Cambridge Hospital under Dr. John Warren. The following year he was made surgeon's mate in a regiment stationed on Prospect Hill and marched with it to Ticonderoga where he was attached to the general hospital while the place was held by the Continental army, retiring with it in charge of the sick and wounded to Fort Edward and to Albany. He was transferred to the field service at his own request, was made chief surgeon to the

First Virginia regiment in 1778 and the following year was transferred to a New England regiment. He was with the Continental army until the surrender of Cornwallis and was noted for his skill as a surgeon and for his lofty patriotism. On retiring from the army after the war he practised in Plymouth and became well known by his scientific and literary pursuits. He was the author of much professional and literary work. His ‹Military Journal during the American Revolutionary War› (1823) is an authority on that troublous time and is notable for the vindication of Washington for his conduct toward André. Other noteworthy publications are ‹Observations on Hydrophobia› (Plymouth 1812); ‹American Modern Practice› (Boston 1817)· ‹Practical Treatise on the Management of Pus› (1829); ‹American Medical Biography› (2 vols., 1828); ‹Essay on Demonology, Ghosts, Apparitions and Popular Superstitions› (1831); ‹History of the Town of Plymouth› (1832); ‹Observations Relative to the Execution of Major John André as a Spy› (1834).

THACHER, John Boyd, American writer: b. Ballston, Saratoga County, N. Y., 11 Sept. 1847; d. 1909. He was graduated from Williams College in 1869, and was a New York State senator 1884–85, and mayor of Albany, N. Y., 1886, 1887, 1896, 1897. He was an officer of the World's Columbian Exposition and became chief of its bureau of awards. His publications include ‹The Continent of America, Its Discovery and Its Baptism› (1896); ‹Charlecote — Or the Trial of William Shakespeare› (1896); ‹Little Speeches›; ‹Awards›; ‹Christopher Columbus, His Life, His Work, His Remains› (3 vols., 1903–04); ‹Outlines of the French Revolution Told in Autographs› (1905), etc.

THACHER, Thomas Anthony, American educator: b. Hartford, Conn., 11 Jan. 1815; d. New Haven, Conn., 11 April 1886. He was graduated from Yale College in 1835 and for three years taught in Connecticut and Georgia schools. In 1838 he became a tutor in Yale where he was chosen as professor of Latin in 1842 which position he retained until his death. During a sojourn in Germany he taught English to the Crown Prince of Prussia and to his cousin Prince Frederick Charles. Returning to Yale in 1845 he became active in college work and an important member of the faculty. He was famed as a classical scholar and wrote frequently on his specialty for various periodicals. He assisted in the compilation of Webster's dictionary and edited many Latin classics, notably Cicero's ‹De officiis› which he annotated (New York 1850). He also translated Medvigs' ‹Latin Grammar› and he wrote a ‹Sketch of the Life of Edward T. Herrick› (New Haven 1862).

THACKERAY, William Makepeace, English novelist: b. Calcutta, 18 July 1811; d. London, 24 Dec. 1863. His father, Richmond Thackeray, who was a judge and collector of revenues in India, came of a good Yorkshire family. His mother was Anne Becher, a Calcutta beauty belonging to a family well known in the India civil service. Richmond Thackeray died in 1816; William, his only child, remained with his mother for a year and was then sent to England to be educated. Five years later his mother, who had married Maj. Henry Carmichael Smyth, came to England with her second husband. Thackeray's relations with both were in later years exceedingly charming.

The little boy, who during his voyage had seen Napoleon at Saint Helena, was placed in charge of an aunt, and soon showed precocity. He was put to school under a Dr. Turner, where he is said to have got hints for the opening of ‹Vanity Fair,› and in 1822 he was entered at the famous Charterhouse. Here he remained six years, imbibing loyalty to the memory of such former scholars as Addison and Steele, watching and engaging in fights such as he described later — in one of these his friend George Stovin Venables broke the nose of the future novelist, who was growing up to his great height of six feet, three inches — reading and writing poetry, devouring novels, and making sketches — in short, doing everything but grounding himself in the classics as his schoolmasters wanted him to do. Although he was a good Horatian, he remained to the end a strictly modern spirit.

After studying a little under his stepfather and, perhaps, having some of the experiences described in the early pages of ‹Pendennis,› he went up to Cambridge in February 1829, matriculating in Trinity College. Here he read widely, particularly in the literature of his favorite 18th century; but he evidently preferred to the regular academic routine supper-parties the society of such fellow-students as the Tennysons, Arthur Hallam, Spedding and R. C. Trench (q.v.). He also tried his hand at college journalism, writing parodies and other skits in the weekly *Snob.* In short, he went his own gait, which was a trifle, but not injuriously, unsteady. He left Cambridge after two years of residence without taking a degree.

He had already during his vacations submitted to the charms of Paris, and, with his natural turn for art, he had little inclination to follow his relatives' advice that he should study law. His income from a fortune left by his father, perhaps £500 a year, was ample for his needs, so he resolved to travel and study on the Continent. In 1830 he spent some months in Weimar, where he saw Goethe and learned enough of the ways of natives and travelers to describe ‹Pumpernickel› in after years. His studies, whether of literature or of the civil law, do not seem to have been exhaustive or exhausting.

By the close of 1831 he had returned to England and began the study of law in the Middle Temple. Trips to Cambridge, visits to the theatre, pipes with Alfred Tennyson and Edward FitzGerald (q.v.), and light reading seem to have distracted his attention from Blackstone, but the Temple itself impressed him as every reader of ‹Pendennis› knows. He also did some electioneering for his friend, Charles Buller, and formed an acquaintance with that interesting writer, William Maginn (q.v.), which probably led later to his introduction to the group of men who were making *Fraser's Magazine* popular. When he came of age he closed his law books and spent some time in Paris. Then he took up definitely a literary career, becoming interested early in 1833 in the

WILLIAM MAKEPEACE THACKERAY

National Standard. He soon bought it and went to Paris to act as its correspondent, contributing also stories and reviews, which in recent times have been unnecessarily exhumed. The venture proved unsuccessful, and Thackeray, who had lost money by it as well as by bank failures and by gambling (he had met his own «Mr. Deuceace») seems to have felt compelled to try seriously to make his living. He had always had a turn for drawing, inherited probably from his father, and he determined that the life of an artist in Paris would suit him admirably. Accordingly in 1834 he established himself in that city, and although he acquired no great skill in his new profession, he enjoyed the society of relatives and friends and laid up knowledge of the French capital which he afterward put to good use in his 'Paris Sketch Book' and in 'Philip.' He seems also to have begun his contributions to *Fraser's Magazine* by 1835, if indeed he did not contribute to it in August and September 1832, the burlesque of Bulwer's 'Eugene Aram' entitled 'Elizabeth Brownrigge,' an early study precluding 'Catherine' and 'Barry Lyndon.' Early in 1836 he was working on a Paris newspaper; then, again in conjunction with his stepfather, he helped to start a new newspaper in London, *The Constitutional,* which did not survive a year. Thackeray, who had previously issued his first separate publication, the eight satirical drawings entitled 'Flore et Zéphyre' (1836) acted as Paris correspondent once more, and seems to have taken his duties quite seriously. It was time, for on 20 Aug. 1836 he had married at the British embassy at Paris a young lady of Irish family who had fascinated him by her singing, Miss Isabella Gethen Creagh Shawe. The imprudence of the marriage became all the more apparent when it was found that *The Constitutional* had swallowed the remains of Thackeray's fortune; but he would never admit his rashness and he worked hard enough ever after in support of his wife and children to be absolved from all reproaches.

He appears to have written for *Galignani's Messenger,* and then to have gone to London, where his first daughter (afterward Mrs. Ritchie [q.v.]) was born. He reviewed books for *The Times* and contributed articles and stories to *Fraser's* and other magazines, displaying an abundance of energy and cleverness, but, partly through anonymity and the use of pseudonyms, attracting little attention. From November 1837, to August 1838, the 'Yellowplush Correspondence' appeared in *Fraser's* and later in the latter year was pirated in America, a country which appreciated Thackeray before England did. There was surely enough humor and satiric power in his early work to have gained it more cordial recognition; but there was also much irony, which rarely makes a writer popular, and there were attacks on favorite authors like Bulwer that could not have been relished in some quarters. At any rate it seems certain that when in 1839 N. P. Willis (q.v.) engaged him to write for *The Corsair,* a short-lived New York weekly, Thackeray was almost as unknown as his younger rival, Charles Dickens, was famous. The ironical 'Catherine,' which finished its Course in *Fraser's* in February 1840, and ought to have shown contemporaries how well its author knew the 18th century and could follow the lead of Fielding, the two volumes of the 'Paris Sketch Book' (1840), and the abruptly ended 'Shabby Genteel Story,' the germ of 'Philip,' were all creditable to 'Mr. Michael Angelo Titmarsh,' as Thackeray had begun to sign himself, but were not yet unmistakable products of a mature genius.

'A Shabby Genteel Story' was cut short by the severe illness of Mrs. Thackeray, which followed the birth of her third daughter, later Mrs. Leslie Stephen. On returning from a trip to Belgium her husband found her strangely changed in mind. There were hopes that she might recover, and Thackeray gave her very constant attention, at home, in Ireland and on the Continent; but it was of no avail. She was finally placed with a kind family and survived her husband about 30 years. The two little girls, for one daughter had died in infancy (cf. 'The Great Hoggarty Diamond,' 1841) were sent to his mother in Paris, and Thackeray set himself to work all the harder in order that he might ensure their support and that of his wife, should his own life be cut short. He had no thought of freeing himself by law, and, although suffering deeply as such a tender-hearted man was bound to do, he went about his work cheerfully, solacing himself as well as he could with club life and enjoying Bohemian haunts such as the «Cave of Harmony,» described in 'The Newcomes.'

In 1841 he published his interesting small volume 'The Second Funeral of Napoleon' and collected his 'Comic Tales and Sketches,' unsuccessfully in both cases. In 1842 he made a tour of Ireland, which yielded materials for his 'Irish Sketch Book' of 1843, and also for a much better book finished at Malta in 1844 at the end of the voyage to the East described in 'Notes of a Journey from Cornhill to Grand Cairo' (1846). This better book was a story which has never been widely popular, but which competent judges have pronounced to be the best of Thackeray's works, 'The Luck of Barry Lyndon.' It was published in *Fraser's* in 1844 and did not meet with enough favor to warrant its being put between covers until 1856, long after its author had become famous, when it appeared in the third volume of 'Miscellanies in Prose and Verse.' The public has never liked a villain for a hero and is uncomfortable in the presence of a writer with a genius for irony, hence Thackeray's masterly memoir of an irrepressible Irish rascal, although it gives a brilliant picture of European life, high and low, in the 18th century and is perhaps inferior only to 'Jonathan Wild' as a piece of sustained irony, will probably continue to be praised by the critics and eschewed by the general reader.

Meanwhile Thackeray had formed a connection that gave him not only a reliable source of income, but also an organ in which he could publish anything he cared to draw or write, with the result that his creative faculty was stimulated and made copious. From June 1842 until 1851 he was one of the most important members of the staff of *Punch,* which had begun its career in July 1841. 'Miss Tickletoby's Lectures on English History,' with which his contributions practically began, naturally fell rather flat, but his copy improved, his sketches were generally appreciated and no one was more at home at the famous 'Punch' dinners, where the policy of the journal was shaped. His first great success was made with 'Jeames's Diary,' November 1845. This satire on railway-stock gambling was followed by the famous 'Snobs of England, by One of Themselves,' which began on 28 Feb. 1846 and ran for a year. Thackeray discovered snobs in altogether too many quarters, perhaps, and he has been accused of overlooking one at home; but it was only natural that he should work a good vein to the point of exhaustion and some of his papers were very clever. Most of them were reprinted as 'The Book of Snobs' in 1848. His next series, to-day more attractive to some readers, was his 'Prize Novelists,' excellent burlesques, which ran from April to October 1847, and took off, without malice and with very great cleverness, such popular writers as Bulwer, Disraeli, G. P. R. James, Lever and Cooper. One, 'Crinoline, by Je—mes Pl—sh, Esq.' was a takeoff of Thackeray himself. These were only the leading things he contributed to *Punch*. Probably they are not so attractive to many readers to-day as some of his ballads and songs — particularly such a perfect piece of occasional poetry as 'The Cane-Bottomed Chair.'

His increasing success enabled him in 1846 to take a house and bring his daughters back from Paris to a home of their own. In this house, 13 Young street, he wrote 'Vanity Fair,' which was published, as the fashion then was, in monthly parts. In January 1847, it began to appear in yellow-covered pamphlets issued by the publishers of *Punch*, and it ran till July 1848, when a double number was given. This method of publication was bad, because it did not force the author to complete his work and thus get the opportunity to see and criticize it as a whole before committing himself to type. It conduced also to spasmodic writing and to padding. Most of Thackeray's longer stories show the evil effects of the part system, and so do the novels of Dickens and Lever.

At first 'Vanity Fair' did not greatly attract the public, although now the opening chapters that introduce Becky Sharp are usually found very interesting. Contemporaries, of course, could have no idea that she was destined to become one of the great heroines of fiction, and they knew Thackeray, not as a distinguished novelist, but as a clever satirist and burlesquer and draftsman. Before 1848, however, readers were awake to the fact that they had another great novelist in their midst. Charlotte Brontë and the *Edinburgh Review* acclaimed him, and he became something of a literary lion. To this day 'Vanity Fair' is regarded by many people as his most important though not his most artistic work, and readers still divide into partisans of Dickens and of Thackeray, the latter usually winning the suffrages of the more critical.

Meanwhile Thackeray, again rivaling Dickens — the rivalry was of the friendliest kind save for one episode to be mentioned later — had published several Chrismas books: 'Mrs. Perkins's Ball' (December 1846) the success of which is said to have helped 'Vanity Fair,' 'Our Street' (1847), 'Dr. Birch and His Young Friends' (1848), 'Rebecca and Rowena' (1849), the clever but perhaps superfluous skit upon 'Ivanhoe,' and 'The Kickleburys on the Rhine' (1850), which was attacked in *The Times* and effectively defended in a preface to the second edition.

In November 1848 the first part of 'Pendennis' appeared. It was not concluded until December 1850, owing to a severe illness which Thackeray had in the autumn of 1849. It is the most autobiographical of his novels, and much ingenuity has been displayed in discovering the supposed originals of his characters. Maginn, for example, is thought to have been represented in Captain Shandon. It is more certain that 'Pendennis' is an effective presentation of literary life in London in Thackeray's day, and that he had no intention of running down his brother authors, as some critics accused him of doing. With all its merits 'Pendennis' suffers, as do 'Vanity Fair,' 'The Newcomes,' and 'The Virginians,' from its sprawling length.

Efforts had been made to supply Thackeray with a permanent, definite income by securing him an appointment as a magistrate or in the postal service; but his well-meaning friends had failed. In 1851, disliking the stand taken by *Punch* against Napoleon III, he resigned from the staff. Although he still continued to contribute, it seemed advisable to secure another source of income. This he found in lecturing. In May and June 1851 he delivered six lectures before distinguished audiences in Willis's Rooms, on his favorite humorists of the 18th century. They were successful when delivered, and, in their collected form (1853), rank high among his works, for their charm of style and their rare sympathy. They were subsequently delivered in other places in Great Britain, and then, on 30 Oct. 1852, Thackeray sailed (in company with A. H. Clough (q.v.) and James Russell Lowell) to deliver them in America.

Just as he was starting he received a copy of the novel he had been working upon for months, reading in the British Museum for materials and laboring carefully upon his style. 'The History of Henry Esmond, Esq.' was not published in parts, and hence is the most artistic of Thackeray's novels, with the exception of 'Barry Lyndon.' Its subtle study of feminine character, its nice balancing of romance and the realism that accompanies a minute knowledge of a period such as Thackeray possessed of the 18th century and particularly of the reign of Queen Anne, its attractive though perhaps somewhat over-labored style, and above all its pervading atmosphere of tender sentiment, have made it not only a classic historical romance but the favorite book of many Thackerayans, to whom it is idle to point out that perhaps the novel is after all masterly tour-de-force, that the essential vigor of Thackeray's genius is better displayed in the superb irony of 'Barry Lyndon' and in the unflinching portrayal of human vices and follies that makes 'Vanity Fair' memorable.

In America, Thackeray was most cordially received, and by his genial manners he won many friends. He lectured in the chief cities North and South and sailed for home in April 1853, much richer in purse (£2,500). Fortunately he did not attempt to turn his visit to greater account by writing a book upon it, as Dickens had done years before.

The next two years were spent in good part on the Continent. The idea of 'The Newcomes' came to him in Switzerland, and during a protracted stay in Rome, where he had a bad attack of fever, he wrote that charming burlesque for children 'The Rose and the Ring' (1854). The novel for older children, with its delightful old-child figure, Colonel Newcome, was published in monthly parts from October 1853 to August 1855 inclusive; and is said to have netted Thackeray £4,000. The spasmodic mode of composition affected the structure detrimentally, but Thackeray's satiric power and his increasing mellowness of sentiment were excellently blended, and the book may fairly be called a masterly presentation of domestic life. The character of Colonel Newcome, who has some of the traits of Thackeray's stepfather, is said by late critics to be grossly exaggerated. «Charmingly idealized» would seem a better phrase in view of the appeal the old man has made and still makes to thousands of hearts.

In October 1855 Thackeray again sailed to the United States, where he again remained until the following April, lecturing on 'The Four Georges' with great success and repeating with less 'The English Humorists.' In 1856 he delivered the 'Georges' throughout England and Scotland, and enjoyed the society of his children and his numerous friends, making other lives bright, although his own was somewhat clouded by the precarious state of his health. In July 1857 he stood as the Liberal candidate for Parliament from Oxford and was defeated by a small majority, accepting his disappointment gracefully. In November 1857 the quasi-sequel to 'Esmond,' for which he had gathered material in America, the only partially successful 'Virginians,' began to appear and ran its course in monthly numbers until October 1859. It was at least a notable link between the mother and the daughter country and, although it shows plainly the effects of Thackeray's increasing bodily sufferings, it probably deserves more praise than it usually receives.

At this time one of the most unpleasant incidents in Thackeray's life occurred. Edmund Yates (q.v.), a rising journalist, published in June 1858 a sketch of Thackeray that was not altogether pleasing to the latter. Thackeray replied in a stinging letter; Dickens was unfortunately drawn into the affair on Yates' side; Thackeray laid the correspondence before the committee of the Garrick Club; the committee and the club took it too seriously; and Yates, refusing to apologize, was dropped from the club. Dickens seems to have been in the right, Thackeray unintentionally in the wrong. Alienation between the two ensued; fortunately a few days before Thackeray's death, they met by accident and shook hands spontaneously.

In 1860 a long-cherished desire of Thackeray's was fulfilled. His publishers, Smith and Elder, began to issue *The Cornhill Magazine* in January, and made him editor. The first number had an enormous sale and he was as delighted as a boy. He secured Anthony Trollope and other good contributors, but for his own part was forced to content himself with printing 'The Adventures of Philip' instead of a great historical romance of the age of Henry V about which he had dreamed. Neither 'Philip' (1861, 1862) nor 'Lovel the Widower' (1860, 1861) was altogether worthy of his genius, but the delightful essays known as 'Roundabout Papers' (collected, 1863), and to a less extent 'The Four Georges' (not reprinted until they appeared in the Collected Works, 1867–69) surely were. Thackeray soon found the cares of editorship — especially the duty of refusing contributions even from a writer like Mrs. Browning, too onerous, and he was too old to become methodical; so he resigned in April 1862. His health steadily declined — though one finds little trace of the fact in the admirable chapters of 'Dennis Duval' (1867), which was running in *The Cornhill* at the time of his death. In November 1862 he was seriously ill. With his white hair he passed for an old man, although he was about 52½ years on that fatal night of 23 Dec. 1863, when he went early to bed without suspecting that death was so near. An effusion of blood took place in his brain, and he was found dead in the morning. On 30 Dec. 1863 he was buried simply at Kensal Green.

Thackeray, as has been said, was very tall — «a colossal infant,» Motley called him, with «white, shiny, ringletty hair . . . a roundish face» and «a little dab of a nose upon which it is a perpetual wonder how he keeps his spectacles.» He was as attractive to his friends as he still is to the admirers of his genius. Perhaps he was too much of a Bohemian in some respects, but as a father and a genial, kind-hearted man it would be hard to name his superior. As a man of letters his rank is, of course, very high. Besides being one of the chief of English novelists, he was a draftsman of ability, though not of genius, an excellent writer of society and satiric verse, an eminent lecturer, a charming letter writer, one of the best of the English essayists, a born provider of burlesques and comic skits for the public of his day — in brief, he was an author of varied and copious genius, a master of humor, of satire, and of sentiment, and in addition a critic of limited though by no means small intellectual powers and an admirable stylist. Unfortunately the task of appraising the value of his work has been rendered difficult by the extravagant worship of his partisans. Many of the volumes that have been added to his works since his death represent merely his talents as a journalist, not his genius as a writer, and even his best books are often defective in structure or in strength. We are still too near him to be able to tell whether he will finally outrank Dickens as a creative force in literature or whether he will rank with Fielding as a portrayer of characters and manners. We are not too near to perceive that he is not so important in the evolution of fiction or so cosmopolitan and heroic a figure as Sir Walter Scott. But his place is certainly with this small group of illustrious novelists. See BARRY LYNDON; HENRY ESMOND; NEWCOMES, THE; PENDENNIS; VANITY FAIR.

Bibliography.— Thackeray's works have appeared in many editions — notably that of 1883–84 in 26 volumes, and the 'Biographical Edition,' with valuable introductions of Mrs. Richmond Ritchie, 13 volumes, 1898–99. Quite a Thackeray revival occurred after the publication of Mrs. Ritchie's edition — editions being superintended by Mr. Lewis Melville (important for completeness, faithfulness to the older texts, and bibliographical information), by Mr. Walter Jerrold, and by W. P. Trent and J. B. Henneman (the Cornhill Edition, 1904, 30 vols., with introductions and bibliography). The chief lives of Thackeray are those by Anthony Trollope ('English Men of Letters,' 1879), by Herman Merivale and F. T. Marzials ('Great Writers,' 1891), by Lewis Melville (2 vols., 1899) and by Charles Whibley (1903). There are numerous volumes of Thackerayana and separate reprints of early works, as well as several special bibliographies, such as M. H. Spielmann's 'The Hitherto Unidentified Contributions of W. M. Thackeray to Punch' (1900). His correspondence with the Brookfields was collected in 1887. Consult also the article by Leslie Stephen in the 'Dictionary of National Biography,' and for criticism, W. C. Brownell's essay in 'Victorian Prose Masters' (New York 1901); Benjamin, L. S., 'Some Aspects of Thackeray' (Boston 1911).

William P. Trent,
Professor of English Literature, Columbia University.

THAI, an East Indian word meaning "free," and the general designation of certain peoples of Farther India, including the Thos, Muongs, Shans, Laotians and Siamese. Although widely diverging in certain characteristics, they speak languages derived from the same stock, and are evidently of common descent. The Siamese, the best known and most civilized of the Thai group, are considerably mixed with Malays, Hindus and other races, and are of medium stature and broad-headed. The Laotians are shorter in stature than the Siamese, and their skulls are less distinctly of the broad-headed type. Consult Diguet, 'Etude de la Langue Tai' (Paris 1896). See Laos; Shan States; Siam.

THAIS, thā'ĭs, a Greek hetæra: b. at Athens, who accompanied Alexander the Great on his expedition to Asia. She is said to have instigated Alexander to set fire to the citadel of Persepolis, the residence of the Persian kings, in revenge for the injuries done to her native city by Xerxes; but this anecdote, though immortalized by Dryden, is probably untrue, as we know on the authority of Arrian that it was his intention to sack the place and burn the citadel on grounds of state policy. After the death of Alexander, Thais became the mistress of Ptolemy Lagi, and, according to Athenæus, was afterward married to him. She was celebrated for wit and repartee, and many anecdotes are recorded of her talent.

THALBERG, täl'bĕrg, **Sigismund**, Swiss pianist: b. Geneva, 7 Jan. 1812; d. Naples, 27 April 1871. He was the natural son of Prince Moritz Dietrichstein and Baroness von Witzlar. He studied piano playing. At 14 was an accomplished player. In 1830 he made his first concert tour in Germany and in 1835–45 toured in Belgium, Holland, England, Russia and Spain, while in 1855–56 he visited South America and the United States. His playing was notable for its beauty of tone and the charm of its legato, rather than for brilliancy or fire. To him belong certain innovations in playing, accepted on account of his prominence though not original with him; such for instance as that of playing the cantilena in strongly accented notes by the thumbs, while the disengaged hand plays arpeggios or octave-passages above and below the melody. His operas, 'Florinda' (1851) and 'Cristina di Suezia' (1855) were both failures. He composed many piano pieces, including fantasies on themes from various operas. His 'Studies' for the pianoforte are highly valued by teachers.

THALENITE, a native yttrium silicate, having the formula $H_2Y_4Si_4O_{15}$, recently discovered in Österby, Sweden. It occurs in tabular, monoclinic crystals of a flesh-red color; hardness 6.5; specific gravity 4.23.

THALER, tä'lėr. See Dollar.

THALES, thā'lēz, Greek philosopher: b. Miletus, Asia Minor, about 625 to 640; d. about 543 B.C. He was the earliest philosopher of Greece, and founder of the Ionian school. He traveled in Crete, Phœnicia and Egypt, where he calculated the heights of the pyramids, and received instructions from the priests. From them he probably acquired a knowledge of geometry, in which he excelled his teachers. He is the father of abstract geometry, being the first to demonstrate that a circle is bisected by its diameter; that the angles at the base of an isosceles triangle are equal; that two straight lines cutting each other produce opposite and equal angles; that the angle of a semi-circle is a right angle, etc. After his return from Egypt he was reckoned among the seven wise men, and his sayings such as γνῶθι σεαυτόν ("know thyself") were in the highest repute among the ancients. To the Ionians he gave the wise counsel to form a general confederacy for the purpose of resisting the Persian power, and to make Teos the seat of the union. He also dissuaded the Milesians from entering into an alliance with Crœsus against Cyrus. His philosophical doctrines were preserved only by oral tradition, until Aristotle committed them to writing several hundred years after his death. He considered water the element of all things. His most important pupils were Anaximander, Anaximenes and Pherecydes. Consult Allman, G. J., 'Greek Geometry from Thales to Euclid' (1877); Diels, H., 'Parmenides Lehrgedicht' (Berlin 1897).

THALIA, thă-lī'ạ, "the blooming one," one of the nine Muses. She was the Muse of comedy and pastoral poetry, and is usually represented with the comic mask and the shepherd's crook in her hand. One of the Graces was also called Thalia. See Graces.

THALLIUM, a metallic element discovered by Sir William Crookes (1862) in a deposit obtained from the lead chambers of a sulphuric acid works at Tilkerrode in the Harz. On examining this deposit with the spectroscope the discoverer observed a single sharp and brilliant green line, which was afterward shown to be characteristic of this element. Crookes gave the element the name of thallium from the Greek *thallus*, a green twig. Thallium is found in many natural sulphides such as those of iron, copper, zinc, bismuth, etc. An important mineral containing it is Crookesite, a compound of sulphur, copper, silver and thallium. When iron or zinc sulphide is burned in the process of making sulphuric acid, the thallium burns to its oxide which collects in the flues or in the lead chambers. To obtain metallic thallium from this flue dust, it is dissolved in dilute sulphuric acid, filtered, and hydrochloric acid added. The slightly soluble thallium chloride separates. This is changed to the sulphate, purified at the various elements accompanying thallium and the thallium sulphate decomposed by electrolysis or by action of zinc. Thallium, symbol Tl, has an atomic weight of 204.18, specific gravity 11.19 and fuses at 561° F. A freshly cut surface has a brilliant silver white lustre which is quickly lost by the oxidizing action of the air. It is softer than lead and is malleable. The metal dissolves readily in sulphuric or nitric acids, but only slightly in hydrochloric acid. It forms two classes of compounds: the thallous compounds derived from the oxide Tl_2O, and the thallic compounds from Tl_2O_3. The salts of the first class resemble the corresponding salts of potassium and sodium. The chloride, however, resembles those of silver and lead in its insolubility in water. Thallium compounds give a green color to a non-luminous name. They are very poisonous, resembling lead in physiological action. Thallium and its compounds are used in the manufacture of thallium glass, the high refractive power of which makes it valuable in the preparation of optical instruments and of artificial gems.

THALLOPHYTA. See BOTANY; PALEOBOTANY.

THALWEG, the lowest line of any valley or drainage course. In valleys with rivers, it is the actual stream course, in dry valleys it is the gully through which storm waters run off.

THAMES, tĕmz, Canada, a river in the southwestern part of Ontario, rising in Perth County, and flowing southwest, 160 miles, into Lake Saint Clair, about 30 miles east of Detroit, Mich. It is navigable, 18 miles to Chatham, by boats of considerable size, but has a difficult bar at the mouth. On the banks of this river, about 30 miles above Chatham, a final stand was made by General Proctor and Tecumseh, when pursued by General Harrison in the War of 1812. The position chosen was poor and very favorable to the American advance. On 5 Oct. 1813 Harrison with 3,000 men attacked and by a vigorous charge of cavalry under Colonel Johnson drove the British in great confusion from the field. Tecumseh was slain and General Proctor himself barely escaped capture. The Americans lost 47 and the British 48, besides 33 Indians; 477 prisoners were captured. The results of the battle were: the Indian Northwestern Confederacy was destroyed; the British power in Upper Canada was broken and practically all that had been lost by the Americans at Detroit was regained.

THAMES, thāmz, Conn., a river in the southeastern part of the State, formed by the junction of the Quinebaug, Shetucket and Yantic rivers at Norwich, whence it flows south about 15 miles to the Long Island Sound. Near its mouth on the right bank lies the city of New London. It is really a tidal estuary, a wide and beautiful waterway navigable for large vessels to its head, and an important avenue of local commerce.

THAMES, tĕmz, England, the most important and famous river in Great Britain, rising in Gloucestershire, and flowing in an irregular eastward course into the North Sea. It separates the counties of Gloucester, Oxford, Buckingham, Middlesex and Essex on the north from Wilts, Berks, Surrey and Kent on the south. Its total length, measured from the Nore Light, is 217 miles, of which 180 miles are navigable. The upper waters around Oxford are known to the poets as Isis. The river passes the cities of Oxford, Reading, Maidenhead, Windsor, Chertsey, Kingston, and passes through the heart of London. Below London it widens gradually into an estuary, which, at the mouth, is 27 miles wide. The river is navigable for the largest vessels up to the east end of London, where the great Victoria, Albert and West India docks have been constructed. The upper course is connected by an extensive canal system with the Severn River and the middle counties. Pike, perch; roach, dace and other fish are caught in quantities. The surface of the Thames from Oxford is largely taken up by pleasure craft on holidays in fine weather, and the regattas held then are world famous. The Medway is the largest tributary. The Cherwell flows in at historic Oxford 112 miles up stream; the Pang flows in at Pangbourne 51 miles from the mouth, and the Kennet at Reading, six miles farther down. The water supply of London is taken mainly from the Thames. The natural flow is about 350,000,000 gallons a day, and the water companies take about 130,000,000 of this. Naturally the utmost care is taken to preserve the water from pollution by sewage. In passing through London the water front of the river is vastly increased by the method of constructing docks cut out in rectangles from the land. In no other way could the 40 miles of water front be made to serve the enormous business of London.

THAMES, Battle of the, in the War of 1812. On 12 Sept. 1813 General Harrison, who was still at Seneca on the Sandusky River (see FRENCHTOWN, BATTLE OF), received word of Perry's victory on Lake Erie (see ERIE, LAKE, BATTLE OF; PERRY, O. H.) and began to prepare for his campaign against Detroit. By dint of hard work Harrison recruited his army to 6,500 troops, commanded by Brig.-Gens. Duncan McArthur and Lewis Cass, Lieut.-Col. James V. Ball, Gov. Isaac Shelby of Kentucky and Col. Richard M. Johnson (qq.v.). At Malden and Detroit Proctor had 983 British regulars and at Amherstburg were 3,500 Indians, but when Harrison landed at Middle Sister Island, Proctor burned the public property at Detroit, and on 24 September withdrew to Sandwich. Three days later Harrison occupied Malden, then entered Sandwich, Proctor having evacuated, and began energetically to pursue the retreating British, who on 5 October made a stand on the Thames River, a mile from the Moravian town and about 30 miles above Chatham. The British formed with their left near the road to Detroit, and their reserve with a six pounder between the road and the river, while the Indians were on the right near a swamp. Harrison divided his troops as follows: Gen. George Trotter's brigade of 500 men in front, with right on the road and left on the swamp; Gen. John E. King's brigade 150 yards to the rear; and still further in the rear David Chile's brigade as reserve, the whole under Maj.-Gen. William Henry. *En potence* on Trotter's left were Gen. Joseph Desha's three brigades, facing the Indians in the swamp. In front, directly facing the British, was R. M. Johnson's mounted regiment. Johnson divided his regiment, sending half under his brother, James, to take the cannon. So impetuous was the charge that James' cavalry broke through the first British line and penetrated to the rear of the second, almost capturing Proctor and taking many prisoners. R. M. Johnson meanwhile crossed to attack the Indians but owing to the underbrush was forced to dismount his men. He drove the Indians toward Shelby's Kentuckians who poured such a terrific fire into them that, after Tecumseh had fallen, they gave way on all sides and were pursued a considerable distance. This ended the battle. The Americans loss was 17 killed and 30 wounded; the British lost 48 killed and wounded and 33 Indians, besides 477 prisoners. Proctor's shattered army fled 100 miles to Ancaster where on 17 October the fugitives were stopped. This destroyed the Northwestern Indian Confederacy; broke the British power in Upper Canada; regained for the Americans all they had previously lost at Detroit, and enabled Harrison to reinforce the army at Buffalo, then preparing to invade Canada from that point. (See York; Fort George; Stony Creek; Chrystler's Farm, etc.). Harrison returned to Detroit and later Cass was appointed by the President governor of Michigan Territory. Consult Wiley and Rines, 'The United States' (Vol. V, pp. 398–401); Adams, Henry, 'Administrations of Jefferson and Madison' (Vol. VII, pp. 128–143); Young, Bennett H., 'Battle of the Thames,' in 'Fison Club Publications,' No. XVIII; 'American State Papers, Military Affairs' (Vol. I); Montgomery, Henry, 'Life of Harrison'; histories of the war by McAfee, Breckenridge, Richardson, Lossing, Ingersoll; Dawson, 'Battles of the United States'; Armstrong, John, 'Notices'; Brown, S. R., 'Campaigns'; McMullen, 'History of Canada'; Slocum, 'The Ohio Country'; Brannan, 'Official Letters'; Fay, 'Official Accounts'; biographies of Cass, by Hickman, Smith and McLaughlin.

THANATOPSIS («a view of death»), the earliest American poem to present a thoroughly noble thought in a thoroughly noble form, was written by William Cullen Bryant — then about 16 — in 1810, published, without the poet's knowledge, in the *North American Review* in 1817 and greatly revised for Bryant's 'Poems' of 1821. From the first it was regarded as a masterpiece, and it speedily won a hold upon the popular mind which has hardly been surpassed by that of any other serious native poem. Without question, the large, simple idea of the piece has had much to do with its fame. There is consolation for most human beings in the reflection that death, though unavoidable, is also common to all, and that the whole of mankind shall eventually lie in the splendid earth. Perhaps Bryant's answer to the question which had been tormenting him — How can one be reconciled with death? — is more stoical, more pantheistic, than many of his readers have suspected: he offers no promise of immortality and refers to no deity higher than nature. But the sincerity and eloquence of 'Thanatopsis' lift it above argument. Its language is pellucid and harmonious, its diction full of felicity, its images — especially those derived from American landscape — magnificently outlined, its blank verse stately, its rhythms in close accompaniment with its swelling emotions. It is the distilled essence of late Puritanism, preoccupied still, as the Puritans had been, with the thought of death, and yet so far freed from their particular doctrines and biases as to be able to utter a universal thought in universal terms.

Carl Van Doren.

THANE, the name of an ancient rank among the English or Anglo-Saxons. A freeman not noble was raised to the rank of a thane by acquiring a certain portion of land (five hides for a lesser thane), by making three voyages at sea or by receiving holy orders. Offices, whether connected with the constant personal service of the king or only during his residence in the thane's district or with the administration of justice, were entrusted only to the thane, whose landed property was a guarantee for his conduct. The Anglo-Saxon thanes were the predecessors of the Norman barons.

THANKSGIVING DAY, in the United States, an annual festival of thanksgiving for the mercies of the closing year. The day is fixed by proclamation of the President and the governors of States. The President's proclamation makes the day a legal holiday in the District of Columbia and in the Territories. In 1789 the Episcopal Church formally recognized the civil government's authority to appoint such a feast and in 1888 the Roman Catholic Church also decided to honor a festival which had long been nearly universally observed — though nowhere with such zest as in the New England States, where it ranks as the great annual family festival, taking the place which in England is accorded to Christmas. The earliest harvest thanksgiving in America was kept by the Pilgrim Fathers at Plymouth in 1621 and was repeated often during that and the ensuing century; Congress recommended days of thanksgiving annually during the Revolution and in 1784 for the return of peace — as did President Madison in 1815. Washington appointed such a day in 1789 after the adoption of the Constitution and in 1795 for the general benefits and welfare of the nation. Since 1863 the Presidents have always issued proclamations appointing the last Thursday in November as Thanksgiving Day.

THAPSIA, a genus of umbelliferous plants, either perennial or biennial. The decompound leaves are doubly or trebly pinnatifid, the flowers are small, yellow, white and purple, in many-rayed compound umbels, without involucre, and often without the small-bracted involucels. The most important *Thapsia* is the deadly carrot (*T. garganica*), supposed to have been the source of the gummy accretion called «asadulcis» by the ancients and esteemed by them as a drug. A resin is obtained by evaporating the tincture, and the amber-colored resin produced in Algeria is called bon-nafa. Thapsia was formerly employed as an acrid counter-irritant in plasters, for rheumatic and similar pains. *T. decipiens* is the black parsley of Maderia, with a thick umbrella, or palm-like, crown of finely-cut foliage three or four feet across.

THASO, thā'sō, or **THASOS**, an island at the northern end of the Ægean Sea, off the coast of Macedonia. Its area is 167 square miles. It is nearly round and about 16 miles in diameter. Excepting some low strips along the shore adapted to agriculture, it is covered by thickly wooded mountains, which in ancient times yielded gold and marble. The forests contain wool valuable for shipbuilding. Corn, fruit, oil and wine are produced; wax, honey and a superior marble are exported. It was settled by the Greeks about 700 B.C. About 463 the Athenians captured the city, razed the walls and took away the shipping. The Romans freed the territory after the battle of Cynoscephalæ, 197 B.C. The Phœnicians were attracted to the island at an early epoch by the gold-mines; and an Ionic colony settled there in 8 A.D. The island since then has changed hands several times and now has an Egyptian ruler. The capital, ruins of which are still to be seen, was on the northern coast, on the site of the present landing-place of Limena. The population is distributed mainly through 10 villages and totals about 12,000.

THATCHER, thăch'ėr, **Henry Knox**, American naval officer: b. Thomaston, Me., 26 May 1806; d. Boston, Mass., 5 April 1880. In 1823 he entered the navy as midshipman and became a lieutenant 1833. In both attacks on Fort Fisher in 1862 he commanded the first division of Commodore Porter's fleet. After the Civil War he commanded the Gulf squadron until 1866 and the squadron of the Pacific from 1866–68. He was made rear-admiral in 1866 and was retired 1868.

THAUN, or **THAON**, **Philippe de**, early Anglo-Norman poet: b. probably near Caen, France, about 1100. He wrote a versified ecclesiastical calendar known as 'Li Cumpoz' and his is the earliest work of this period (about 1115) that is known. His most important work was written about 10 years later and is known as 'Li Bestiare' or 'Physiologus.' This also was in rhyme and but one copy is known. In it the creatures are grouped and treated symbolically. The manuscript was dedicated to Adelaide, queen of Henry I, and the work is valued chiefly as a linguistic relic. Consult Walberg's 'La Bestiare de Philippe de Thaün' (Paris 1900).

THAW CASE, a criminal trial noted in legal annals as «the most notorious case in the recent history of American criminal law.» Harry Kendall Thaw, son of a distinguished and wealthy Pittsburgh, Pa., family, 25 June 1906, shot and killed Stanford White, a distinguished architect, in the roof garden of Madison Square Theatre, New York. The murder was the outcome of Thaw's marriage to Evelyn Nesbit, an artist's model and actress, who accused White of abusing her. A long-drawn-out trial resulted, notable for Thaw's plea of insanity, his escape from Matteawan State Hospital for the Insane, his flight into Canada, his ejectment from the country and subsequent arrest in New Hampshire and repeated trials following. In the original trial Thaw was sent to Matteawan, 1 Feb. 1908, and was kept there until 17 Aug. 1913, when he escaped by alleged conspiracy with his keepers. After a long legal battle, in which noted lawyers were concerned, Thaw finally was brought back to New York State, indicted for conspiracy and acquitted. Later he was declared sane and taken to his Pennsylvania home where he remained because of the refusal of the local authorities to agree to his extradition.

THAXTER, thăks'tėr, **Celia Laighton**, American poet: b. Portsmouth, N. H., 29 June 1835; d. island of Appledore, Isles of Shoals, 26 Aug. 1894. She spent her childhood and much of her later life at the Isles of Shoals. In 1851 she was married to Levi Lincoln Thaxter, who was accustomed to visit the island long before they had become a popular summer resort. Her first published poem, 'Landlocked,' was printed by Lowell in the *Atlantic*. The motive of subsequent verse is also generally the sea and coast scenery, though the arts, particularly music, claimed some of her attention. Its note is one of much original power. Her works are 'Poems' (1872); 'Among the Isles of Shoals,' prose sketches (1873); 'Poems' (1874); 'Drift Weed' (1879); 'Poems for Children' (1884); 'The Cruise of the Mystery' (1886); 'Idyls and Pastorals' (1886); 'The Yule Log' (1889); 'An Island Garden,' a prose diary (1894); 'Letters' (1895); 'Stories and Poems for Children' (1895). A collected edition of the 'Poems' appeared in 1896. Consult the 'Letters'; also an article in the *New England Magazine* (Vol. 24, pp. 166–72).

THAXTER, **Roland**, American botanist: b. Newton, Mass., 28 Aug. 1858. After receiving a Harvard education and securing his Ph.D. there, in 1888 he became a professor of biology and botany in the university and a noted authority on the fungous diseases of animals and on cryptogamic botany. From 1885 to 1891 he was expert mycologist of the Connecticut Agricultural Experiment Station. He was chosen American editor of the British 'Annals of Botany'; elected president of the American Botanical Society and in 1912 made a member of the National Academy of Science. He has contributed to many scientific publications dealing with his specialties.

THAYER, thăr, **Abbott Handerson**, American figure painter, who also has painted animals and landscapes: b. Boston, 12 Aug. 1849. He was a student at the École des Beaux Arts under Lehman and Gérôme from 1875 to 1879. Upon his return to America he was made president of the Society of American Artists. He was the discoverer in 1894 of the Laws which underlie Concealing Coloration; and published in 1909 'Concealing Coloration in the Animal Kingdom' (written by his son, Gerald H. Thayer). He is a member of the National Academy of design, of the American Academy of Arts and Letters and of the L' Insigne Reale Accademia Romana delle Belle Arti Denominata di San Luca. Among his popular works are 'A Young Woman' (in the Metropolitan Museum, New York); 'A Virgin' (National Gallery, Washington, D. C.); 'Winged Figure' (Albright Gallery, Buffalo); and 'Caritas' (in the Boston Museum).

THAYER, **Alexander Wheelock**, American biographer: b. South Natick, Mass., 22 Oct.

1817; d. Trieste, Austria, 15 July 1897. He was graduated from Harvard in 1843 and from the Law School in 1848. For a time he was assistant in the Harvard Library, and while there determined to write a life of Beethoven. In 1849 he went to Europe to collect material for this work and lived abroad the greater part of his life. In 1859–82 he was United States consul at Trieste, Austria, and after that devoted himself entirely to his literary work. The first volume of his 'Life of Beethoven' appeared in 1866; the second in 1872; the third in 1879 and the fourth was nearly completed at the time of his death; it was published in German, although originally written in English. It deals with the life and character of the man Beethoven rather than with his musical work; and is very detailed, exact and impartial. Thayer also wrote 'Signor Masoni' (1862), and 'The Hebrews and the Red Sea' (1883).

THAYER, Benjamin Bowditch, American mining engineer: b. San Francisco, Cal., 20 Oct. 1862. He was educated in the Harvard Scientific School and on graduating in 1885 at once began active work in connection with the Anaconda Copper Company, of which he became president. He later was made vice-president of the Amalgamated Company which absorbed it. He was president of the American Institute of Mining Engineers in 1914 and the following year was named on the United States Naval Consulting Board, where he did much good work.

THAYER, Eli, American educator and inventor: b. Mendon, Mass., 11 June 1819; d. Worcester, Mass., 15 April 1899. He was graduated from Brown University in 1845; became principal of the Worcester Academy; and in 1848 founded The Oread, an institute for young ladies in Worcester. He was a member of the State legislature, 1853–54, and of Congress, 1856–61, and conducted an «Emigrant Aid Company» which settled portions of Kansas on the anti-slavery basis. Subsequently he acquired manufacturing interests in Massachusetts and received patents for a section safety steam boiler, a boiler-cleaner and a hydraulic elevator. Besides his Congressional speeches (1860), he published a volume of 'Lectures' (1886), and 'The History of the Kansas Crusade' (1889).

THAYER, Ezra Ripley, American advocate and educator: b. Milton, Mass., 21 Feb. 1886; d. September 1915. He took his LL.B. degree at Harvard in 1891 and was admitted to the bar in Boston directly afterward. His progress was rapid and he became Dane professor of law at the university and dean of the Law School. He was a member of a noted firm of attorneys and was particularly interested in raising the standards of his profession.

THAYER, James Bradley, American author and lawyer: b. Haverhill, Mass., 15 Jan. 1831; d. Cambridge, Mass., 14 Feb. 1902. He was educated in local schools and graduated at Harvard in 1852. He devoted his life to teaching but after securing his LL.B. degree from the university in 1856 rose speedily in the law, to which he was admitted in that year. In 1873–93 he was Royall professor in Harvard and from 1893 to 1902 held the chair of World professor. Iowa University gave him its LL.D. degree in 1891; Harvard in 1901. In 1861–65 he was secretary of the Loyal Publication Society, and was also fellow of the American Academy of Arts and Sciences and a member of the Massachusetts Historical Society. Besides many contributions to scientific publications he was author of 'Letters of Chauncey Wright' (1877); 'A Western Journey with Emerson' (1884); 'Cases on Evidence' (1892); 'The Origin and Scope of the American Doctrine in Constitutional Law' (1893); 'The Teaching of English Law in Universities' (1895); 'Cases in Constitutional Law' (2 vols., 1895); 'The Development of Trial by Jury' (1896); 'Preliminary Treatise on Evidence at the Common Law' (1898), etc.

THAYER, John Adams, American publisher: b. Boston, 20 Feb. 1861. He had a common school education in Cambridge and became a noted printer and typefounder. In various responsible capacities he was connected with such representative publications as the *Ladies' Home Journal, Munsey's Magazine,* the *Delineator,* etc. After a residence in Paris from 1906 to 1911 he again became a publisher, notably to the *Smart Set Magazine.* His best known publication is 'A Publisher's Life Story' (1910; rev. ed., 1912).

THAYER, John Milton, American soldier, lawyer and politician: b. Bellingham, Mass., 24 Jan. 1820; d. 1906. He graduated at Brown University in 1841 and became a member of the Massachusetts bar, removing in 1854 to Nebraska where he was made a member of the territorial legislature in 1860. Previous to entering on political life he was a territorial brigadier-general and fought successful Indian campaigns, placing the Pawnees on a reservation in 1859. In the Civil War he also was a brigadier-general and led a Nebraska regiment. For services at Vicksburg, he was brevetted major-general. Returning to Nebraska in 1865 he was elected to the United States Senate (1867) and afterward was appointed by Grant as governor of Wyoming Territory. In 1866 he was elected governor of Nebraska and also was made department commander of the G. A. R. for his State. Brown University conferred on him the honorary A.M. degree in 1847 and the University of Nebraska gave him its LL.D. in 1902.

THAYER, Joseph Henry, American educator: b. Boston, Mass., 7 Nov. 1828; d. Cambridge, Mass., 26 Nov. 1901. He was graduated from Harvard in 1850, from Andover Theological Seminary in 1857, and was pastor of the Congregational Church at Salem, Mass., in 1859–64, being absent from his charge for nine months in 1862 when he served as a chaplain in the Union army. In 1864 he accepted the chair of sacred literature at Andover, which he resigned in 1882 to become professor of New Testament criticism at Harvard. He published 'A Greek-English Lexicon of the New Testament' (1869); 'A Biographical Sketch of Ezra Abbot' (1884); 'The Change of Attitude Toward the Bible' (1891); 'Books and Their Use' (1893); etc.

THAYER, Sylvanus, American soldier: b. Braintree, Mass., 9 June 1785; d. South Braintree, 7 Sept. 1872. He was graduated at Dartmouth in 1807, and at West Point in

1808. For four years he was occupied, chiefly around Boston and New York, in the construction of coast-defenses. During the War of 1812 he served as chief engineer of the Northern army on the Niagara frontier and at Lake Champlain, and as chief engineer and brigade-major in the defense of Norfolk, Va. After a tour of observation in Europe, where he studied fortifications and military schools, he became superintendent at West Point, a position which he held from 1819 to 1833. He was made president of the board of engineers, and placed in charge of the construction of defenses and harbor improvements around Boston. Upon these duties he was occupied during the remainder of his active service. He was retired 1 June 1863, having been commissioned colonel in the preceding March. He gave funds for a public library and an academy in his native town, and for founding the Thayer School of Civil Engineering at Dartmouth. In 1877 his remains were taken from South Braintree, where they were first buried, and interred at West Point, where in 1833 a statue was erected in his honor, bearing an inscription in which he is called the «Father of the United States Military Academy.»

THAYER (WHITNEY), Eugene, American organist and composer: b. Mendon, Mass., 11 Dec. 1838; d. Burlington, Vt., 27 June 1888. He was for nearly 20 years a resident in Boston, where in April 1869 he gave the first free organ recital in the United States, and removing to New York in 1881 became organist of the Fifth Avenue Presbyterian Church. Besides a 'Festival Cantata' he composed a mass in E flat, many organ pieces and much vocal music. He received the degree of doctor of music from Oxford.

THAYER, William Makepeace, American Congregationalist author: b. Franklin, Mass., 23 Feb. 1820; d. Franklin, 7 April 1898. He was graduated from Brown University in 1843, and was pastor of the Congregational Church in Ashland, Mass., from 1849 until 1857, at which date he resigned and devoted himself to writing. He was a member of the State assembly 1857–58 and 1863–64, and engaged in editorial work 1858–72. His publications, very popular in their day and chiefly for juvenile reading, include 'The Bobbin Boy' (1859); 'Youth's History of the Rebellion' (1863–65); 'Men Who Win' and 'Women Who Win' (1869); 'From Log Cabin to White House'; 'From Tannery to the White House' (1885).

THAYER, William Roscoe, American author: b. Boston, 16 Jan. 1859. He was graduated from Harvard in 1881; was assistant editor of the Philadelphia *Evening Bulletin* 1882–85; and was editor of the *Harvard Graduates Magazine* 1892–1915. He has published 'Confessions of Hermes' (1884); 'Hesper' (1888); 'The Dawn of Italian Independence' (1893); 'Poems: New and Old' (1894); 'Throne Makers' (1899); 'History and Customs of Harvard University' (1898); 'A Short History of Venice' (1903); 'The Life and Times of Cavour' (2 vols., 1911); 'The Life and Letters of John Hay' (2 vols., 1915); 'Germany versus Civilization' (1916); 'Letters of John Holmes' (1917); 'Out of Their Own Mouths' (1917); 'Collapse of Superman' (1917); 'Theodore Roosevelt' (1919). He is an overseer of Harvard College; vice-president American Historical Association; member National Institute of Arts and Letters; Fellow, American Academy of Arts and Letters; Fellow, American Academy of Arts and Sciences, and corresponding secretary, Massachusetts Historical Society.

THAYER, William Sydney, American physician: b. Milton, Mass., 23 June 1864. He was graduated at Harvard in 1885 and took his degree as doctor of medicine there in 1889. He was for some time a member of the medical staff of the Johns Hopkins University and visiting physician at the hospital there. He is a member of several medical societies at home and abroad, and has made valuable researches in fevers and was first to report the third heart sound at his clinics. In 1917–18 he was with the Russian mission to Petrograd. He is the author of several medical and surgical works, notably 'Lectures on Malarial Fever' (1897).

THAYER SCHOOL OF CIVIL ENGINEERING, a department of Dartmouth College (q.v.).

THEAGENES (thē-ăj'ĕ-nēz) **AND CHARICLEA,** kăr-ĭ-klē'ą, a Greek romance written by Heliodorus, bishop of Trikka, in the 4th century. The story recounts the love and adventures of Theagenes, a Thessalian and Chariclea, daughter of the queen of Ethiopia, and is the foundation of many later romances both by the early Greek fablers and the later French novelists, including Achilles Tatius among the former, and Gomberville, Scudéry and D'Urfe among the latter. It was translated into English by Thomas Underdown (1577), and into French by Jacques Amyot (1586).

THEATINES. See ORDERS, RELIGIOUS.

THEATRE (Greek, «a place for seeing,» from θεᾶσθαι, to regard or look at), literally any building used for purposes of exhibition, but now generally applied to a place in which dramatic and musical performances are given. The theatre may be considered as a form of architecture which found its earliest expression in the classic ages of Greece and Rome, and after a long eclipse has again become important within the last 250 years. The term theatre also comprises the whole mass of dramatic literature and its theatrical representation. In this article it is proposed to deal (1) with the theatre as an architectural edifice from its earliest beginnings down to the present. For the treatment of the theatre as a form of artistic expression see DRAMA.

The Theatre in Architecture.— The theatre had its origin among the Greeks. Its germ was the ring in which dithyrambs and phallic songs were performed by choruses in honor of Dionysus. These were performed in an orchestra or circular dancing place, on all sides of which the spectators were ranged. Later a table was introduced, on which the leader of the chorus stood while he carried on a dialogue with the rest of the *choreutæ* in the intervals between the choral odes. This table was the first and most rudimentary form of stage and the date of its introduction is about 560 B.C. Next an actor, a single actor, was introduced by Thespis and, as he played many different parts, a tent had to be erected in which he should be able to change his mask and dress. Out of this tent arose ultimately the stage buildings of the Greeks, which, even after they became elaborate structures of stone, retained the name *skēnē*, "tent or booth" (cf. English *scene*).

Greek Theatrical Architecture.— From the remains of various Greek theatres which have been excavated it is possible to reconstruct, at least in its main features, one of these edifices. In the centre the orchestra formed an exact circle in the middle of which stood the altar of Dionysus. Later the circle was cut on the side next the stage. Round the orchestra, in size rather more than a semi-circle, the seats for the audience rose tier upon tier like a modern baseball field-stand. These seats were at first of wood, but owing to a collapse of the benches in 499 B.C., it was resolved at Athens to erect a permanent stone theatre. This was the theatre of Dionysus, which exists to-day, although it has been partly reconstructed. It consists of three parts — the orchestra, stage buildings and the auditorium. The orchestra was occupied solely by the chorus. Behind it rose the stage buildings, usually a long, narrow rectangle, facing the audience; the most ancient one at Athens was 55 yards long and only 11 yards deep. But then little scenery was used. In front the buildings represented a palace or a temple. There were usually three doors opening on to the stage, which was a wooden platform, standing 8 or 10 feet above the orchestra. On it the actors appeared. The auditorium was of great extent as the theatre was intended to accommodate practically the whole population of the city in which it stood. The rows of seats in consequence were of enormous size, the theatre of Dionysus at Athens holding 27,500 persons, and that at Megalopolis being computed to seat 44,000. In order to obtain the necessary slope for the tiers of seats as well as a natural substructure for the same the Greeks always chose some natural hollow, where the shape of the ground aided the design of the architect. Tiers of seats rose one above another, divided vertically by passages for access and in many cases horizontally also. The lowest or first row of seats at Athens is of marble, and was reserved for persons of distinction; the rest are of ordinary stone. Between the auditorium and the stage were the passages of entrance (*parodoi*) which in some instances were of great breadth. The back-wall was called the *scena*, the side-walls, or wings, in each of which was an entrance door being called *paraskēnia*. The stage was called the *proscenium*. A flight of steps, later two, connected the stage with the orchestra and these steps, continued out of sight beneath the orchestra floor, were the means by which apparitions from the lower world ascended. The front of the stage nearest the orchestra was called the λογεῖον (*logeum*). The back-wall represented a suitable background or setting for the play, and, before the performance, was covered by a curtain (*aulaia*) which was let down, not drawn up as is usual to-day. When the action of the play required a different scene, the back of the stage was covered with painted curtains or boards. At either end of the stage were large revolving triangular prisms, each side of which bore a different scene, thus providing three sets of wings. In dealing with the early Greek theatre it must always be remembered that the stage was only of secondary importance, the orchestra being deemed the chief point of interest. There was a certain amount of machinery, of which the most famous was a species of crane by which a god could be let down from on high or drawn up again as occasion required. The Greek theatre was open to the sky and attendance at it was a species of religious observance; performances took place only on festal days, when the whole population turned out to witness them. The acoustic properties appear to have received little attention. Actors used a species of megaphone device, concealed in their masks, in order to make their voices carry to a distance. Besides the theatre at Athens Greek theatres existed also at Epidaurus, Delphi, Syracuse and Megalopolis.

Roman Theatres.— The Roman theatre was largely founded on Greek models. It was long before a permanent theatre was erected in Rome because it was thought that such a costly display was not in harmony with the simplicity of the republic. At an early period dramatic performances took place in temporary wooden structures and amid such surroundings the comedies of Plautus and Terence were first produced. Toward the close of the republic vast wooden theatres were erected in Rome. Pompey was the first to construct one of stone. His theatre, which may be taken as the Roman model, near the Campus Martius differs structurally from the Greek model. The orchestra was a semi-circle and there was no altar. Singing and dancing were transferred to the stage and the orchestra space was occupied by seats for prominent persons. The stage was enlarged. The seats were built of masonry, not excavated out of a hill side or planted on a natural slope. The use of the arch and of concrete by the Romans facilitated this mode of building and under Roman hands the theatre first became an architectural unit, with auditorium, stage and stage buildings, all joined in a single structure. There are extensive remains of Roman theatres; among the most celebrated are those of Rome, Orange, France, Ephesus, Miletus, Cnidus, Tauromenium and Nimes. Roman theatres were frequently much smaller than the Greek and there were frequently arrangements to protect the audience from the sun's rays by an awning.

The Roman theatre of the empire period degenerated into sheer lasciviousness and the rise of Christianity brought a new and redoubtable foe to this kind of spectacle. The Fathers inveighed against the public spectacles and clerics were forbidden to be present. Thus gradually the new morality gained headway and the theatre ceased to be a feature of the social life of the people.

Middle Ages.— During this period the drama existed only in the form of mysteries and miracle plays and was under the management of the Church. Theatres were not required. Plays were presented generally in cathedrals or monasteries, and the most elaborate scenery used was a three-story scaffold representing heaven, earth and hell. Strolling players also gave performances in temporary booths. This period is, therefore, entirely barren as regards theatrical architecture.

From the Renaissance to the Present.—With the revival of learning in the 16th century came also a revival of the drama, and theatres began to be built. The earliest was probably a playhouse of some sort in the Hôtel de Bourgogne, Paris, which was built about 1548 for the Confraternity of the Passion; but the first regular theatre was that which Bramante constructed at Rome in the Grand Court of the Vatican about 1580. Then came the Teatro Olimpico at Vicenza, designed by Palladio, and finished in 1584; while the earliest theatre built on modern lines was constructed by Aleotti at Parma in 1618. In all the early Continental theatres, the construction was founded on Greek models, but in England a simpler idea served. Here the earliest dramatic performances took place in booths, tennis-courts or in the open courtyards of inns; and it was not till the end of the 16th century that the first permanent building was erected for theatrical purposes. This was «The Theatre,» built by Burbage in Shoreditch in 1576, which was founded not on any classical model, but on the innyards, in which the actors had been accustomed to play. The stage was literally a stage — a platform erected against one side of the building — and on three sides of this platform the spectators stood or sat in the pit (then called the yard), while all round it ran the galleries or boxes (then called rooms) exactly like the galleries of an innyard. There was no provision for scenery. The door at the back of the stage, which communicated with the dressing-rooms, etc., and was the general entrance for the actors, was hung with curtains, and there seem to have been curtains running on rods, some distance up the stage which could be drawn and undrawn to indicate an inner apartment, but the locality in which the scene was laid was indicated only by a placard stuck up bearing such an inscription as «A garden,» «This is a forest,» etc. Properties, or furniture were, however, largely used to give verisimilitude to the action. These properties seem to have been pushed on the stage in the calmest fashion. Thus in Middleton's 'Chaste Maid in Cheapside,' one stage direction runs, «A bed is thrust out upon the stage, Alwit's wife in it,» and a similar action is indicated in the stage-direction, «Enter Anne in bed,» in Davenport's 'New Trick to Cheat the Devil.' In the stage there were traps apparently to a considerable extent; while behind and on a higher level was a platform which did duty for any elevated part of the supposed scene. In the Elizabethan theatre the stage was strewed with rushes, or, upon very special occasions, was matted; and on it the young «bucks» or gallants sat on stools, showing their dress and figure to the audience, and effectually destroying anything resembling dramatic illusion. After the Restoration, under Charles II, who was familiar with the French stage, the English theatre came more into line with the Continental. The stage was gradually withdrawn closer and closer to the proscenium opening, until, by 1750, the appearance of the interior of Drury Lane was not seriously different from that of to-day. Movable scenery, which was invented by Baldassare Peruzzi early in the 16th century, had long been used in masques, but it was not till 1661 that it was used to illustrate a regular stage-play in England. Meanwhile theatrical architecture was developing on the Continent along classic lines.

The first theatre in America was opened at Williamsburg, Va., 5 Sept. 1752. Others followed at Annapolis, Md., and in Nassau street, New York, in 1753, Albany, 1769, Baltimore, 1773, Charleston, S. C., 1774, Newbern, N. C., 1778, and Boston, 1792. Modern theatres are comparatively small because it has been found that the voice cannot be distinctly heard without straining more than 90 feet in front of the speaker. Little change was made in theatrical architecture during the 19th century. In the latter half of the century sumptuous houses were erected on the Continent and in England and America, of which the most celebrated was the Paris Grand Opera. Notwithstanding the vast size of the building, the auditorium contains only 2,194 seats. By far the greater part of the building is occupied by a vast number of rooms, halls, staircases, shops, etc., appurtenances designed for the convenience and pleasure of the spectators and of those connected with the theatre. In magnificence and costliness the Paris Grand Opera was easily the first theatre of the 19th century. In the opening decades of the 20th century several monumental playhouses were erected in England, and in the United States; of these one of the most remarkable if not the most beautiful in design and appointments is the Century Theatre, New York. In this century also playhouses began to be constructed once more as isolated buildings in which exterior design played a large part. The interior arrangements of modern American theatres are superior in comfort and convenience to those of Europe, although the latter are often lavishly decorated. In America, seating, heating, ventilation, exits and fireproof construction receive the most careful attention. The largest theatre in America is the New York Hippodrome, which seats over 5,000 and is used for spectacular entertainments. The modern theatre contains like its prototypes the two essentials of auditorium and the stage. To the auditorium are now appended corridors, foyers, lounging-rooms, etc., also an outer lobby, vestibule and approaches. The auditorium is generally of the horseshoe type, but in many recent constructions the rows of seats on the ground floor and balcony are kept straight. A special development is the modern opera-house with as many as five balconies and a large number of boxes. In the modern playhouse there are few boxes; the ground floor has a steep pitch so that the spectators in each row may view the stage clearly over the heads of those in the row in front. The first balcony is more steeply pitched than the ground floor, and the second and succeeding balconies still more. Lavish decoration after the Italian and French models is giving way to straight lines and bare walls with a simple color scheme. The acoustic problem is one of the most serious with which the architect of theatres has to deal. The stage is now the most elaborate part of the theatre. The opening on the auditorium is from 25 to 35 or 40 feet wide and from 14 to 22 feet high. The stage is frequently twice the height of the proscenium so that all scenery («drops,» etc.) may be hung above the proscenium opening when not in use. The set-scene is now in very general use and to a great extent eliminates the necessity for a high stage. The set-scene is built so solidly and reproduces the conditions of nature with such completeness as scarcely to make any demands on the imaginative faculty of the spectators. If a room is represented, the walls and ceiling are built with marvelous solidity, a chandelier hangs from the centre of the ceiling; the doors shut with an unmistakable bang; the windows open and close better than they sometimes do in actual life. In elaborate plays whole pieces of scenery are raised through large transverse openings in the stage by means of platforms called *bridges*. These work in and out of the *well* or cellar, a space under the stage nearly as deep as the proscenium opening is high. Above the stages are the *flies*, larger lateral galleries, in which the scene-men («fly-men») work their ropes and pulleys. Higher still is the *Grid-iron*, an open line of strong beams from which various borders or drops are hung. Above this is the barrel-loft or rigging-loft, in which are the drums, pulleys or windlasses by which the curtains and clothes are worked. With the extensive use of elaborate scenes and the demand for rapid shifting there has been developed the revolving stage, which is a circular platform about 40 feet in diameter and revolving on a shaft embedded in concrete. This circular platform is capable of holding about four sets which can be brought before the audience by revolving the platform. The sliding stage is one of double width and which is moved laterally so that on the concealed half the following scene may be set up while the play proceeds on the exposed half.

Perhaps the greatest change in the modern as compared with the older theatres is in the lighting arrangement due to the introduction of electricity. The lights in the trough below are called footlights, those above border lights. There are sets of bulbs in white and in two or more colors. Dimmers are used to lower the intensity of the bulbs. All lights (except perhaps the spotlights) are now controlled from a single switchboard at the side of the stage. Recently several open-air theatres have been constructed in America. Some of these are of the ancient type, as that at Berkeley, Cal., while others are of the so-called garden type in which the landscape architect plays a leading rôle. There is a good example of the garden type at Vassar College. Among recent innovations in theatrical structure are the little theatres, some of which seat only 100, and the portmanteau theatre, an approach to the mediæval traveling theatre, but more artistic and better adapted to the present-day intimate form of drama.

THEATRE, The American. In order to convey to the reader a fair understanding of the progress of the American theatre since 1795 it is perhaps necessary to state something about its beginnings, which, indeed, previous to 1750, are involved in much obscurity. Tony Aston, an English stroller of some celebrity, visited the Southern and Middle colonies about 1730, and gave entertainments at New York and perhaps other places; and there is some evidence that a company of comedians acted plays in New York in 1732; but it was not until 1749 that an organization came into existence of which we can form any definite judgment. This company attempted to open a playhouse in Philadelphia, and Addison's 'Cato' was actually performed; but the performers were arrested and admonished by Recorder Allen to give up the undertaking. Thomas Kean was the principal actor in both tragedy and comedy, and one Murray seems to have been associated with him in the management. Finding Philadelphia too inhospitable, the players went to New York, where they were advertised as the company of comedians from Philadelphia, and gave the first theatrical season of which we have any connected account. The performances were given in a «convenient room» in a house belonging to Rip Van Dam in Nassau street, and extended over a period of more than a year — from 5 March 1750 to 8 July 1751. The first play was 'Richard III,' in which Kean played Richard. So far as is known, the company appeared in 15 plays and nine farces. Although Mr. Kean formally announced his withdrawal from the stage to resume his business of writing, he was with a company called the «Virginian Comedians» at Annapolis in the summer of 1752, when Lewis Hallam and his London players arrived at Williamsburg, Va. Besides Mr. Kean there were other members of the New York company among these «Virginia Comedians.» Perhaps this disposes of the claim usually made for Hallam's company as being the first regular theatrical organization in America.

Lewis Hallam, who brought a company of comedians from London in 1752, was not an actor of any consequence in England, nor is it likely that his wife, known to the American stage successively as Mrs. Hallam and Mrs. Douglass, was an actress of recognized ability there.

The Hallam company reached Yorktown in June 1752, and began playing at Williamsburg on 5 September following, the opening pieces being 'The Merchant of Venice' and 'Lethe.' The only other play the Hallam company is known to have performed at Williamsburg was 'Othello,' 9 Nov. 1752. From Williamsburg Hallam went to New York, where he arrived in June 1753, and played until the following March. Mrs. Hallam played the leading parts in both tragedy and comedy, while her daughter, Miss Hallam, was put forward in farces. Hallam seldom appeared. The great Shakespeare rôles were divided between Malone and Rigby, the former playing Shylock and Lear, and the latter Richard and Romeo. From New York the company went to Philadelphia, where the engagement was limited to 25 performances. This ended the theatrical campaign of Lewis Hallam the elder, who retired with his family to Jamaica, where he died soon afterward.

A year or two after Mr. Hallam's death his widow married David Douglass, who organized a theatrical company in Jamaica in 1758 for another American campaign, with Mrs. Douglass as his chief attraction. Besides his mother, young Lewis Hallam was the only member of Mr. Douglass' company who had previously appeared in the New York and Philadelphia theatres. He had already become a full-fledged tragedian, although he was only in his 20th year, sharing the leading parts in tragedy and comedy with Mr. Harman, as Rigby had previously shared them with Malone. Mrs. Harman, who was a daughter of Charlotte Charke and a granddaughter of Colley Cibber, was also with the company, and next in consequence to Mrs. Douglass. The low comedian was Owen Morris, who was identified with the American theatre for a full half century — 1759–1809. After his arrival in New York, Douglass had much difficulty in obtaining permission to open the theatre that he had built on what was called Cruger's Wharf, and it was not until 28 Dec. 1758 that he began a brief season with the tragedy of 'Jane Shore.'

During the following spring and summer Mr. Douglass built a theatre at Vernon and Smith streets in Philadelphia, which he opened 25 June 1759, and maintained with considerable regularity until the close of the year. He had obtained authority to act from Governor Denny, and the compact was kept, although the opposition to the theatre was so great in the province that an act prohibiting plays was passed by the assembly to go into effect 1 Jan. 1760. After Philadelphia was closed against him, Mr. Douglass went to Annapolis, where he played an engagement. The company also performed in other Maryland towns, and at Newport and Providence in 1761. In the autumn Mr. Douglass built another theatre in New York, in what was then Chapel (now Beekman) street, where he gave performances from 19 Nov. 1761 to 26 April 1762. This ended his first attempt to achieve the mastery of the colonial stage. In his few years of management Douglass had become an actor of considerable authority, attempting such parts as Sir John Falstaff in 'King Henry IV' and Mercutio in 'Romeo and Juliet.' In the latter young Hallam played the lover to his mother's Juliet. In the last New York engagement, Mrs. Hallam, the wife of the youthful tragedian, was seen in a few parts, but the pair separated soon afterward.

It has always been understood that after his retirement from New York in 1762 Mr. Douglass did not venture upon the continent again until 1766, when he built the Southwark Theatre in Philadelphia. On the contrary, he appeared in Charleston in November 1765 and remained there until the following April. Lewis Hallam was not with the company, and, with the exception of Mrs. Douglass and Miss Hallam, the performers were all new to the stage. Only three of the new players were still with Douglass when he reached Philadelphia — Messrs. Woolls and Wall and Miss Wainwright. With the opening of the new theatre in Southwark, Philadelphia, began the theatrical organization afterward known as the "Old American Company." Lewis Hallam was once more in the lead. Mr. Morris and Mrs. Harman were again with the company. During this season a so-called comic opera, 'The Disappointment,' said to have been written by Col. Thomas Forrest, afterward a distinguished officer in the Revolutionary army, was announced for production, but it was withdrawn because it contained "local reflections." As a recompense for its withdrawal, 'The Prince of Parthia,' by Thomas Godfrey, Jr., was produced 24 April 1767. This was the first tragedy written and played in America. The season was noteworthy for the first appearance in America of John Henry, who was the partner of Lewis Hallam after the Revolution in the management of the Old American Company.

While the company was playing in Philadelphia, Mr. Douglass built a new theatre in John street, New York, which was the second of the permanent theatres in the colonies, the Southwark being the first. The first season at the John street house lasted from 7 Dec. 1767 to 2 July 1768. The company alternated between these two theatres down to the time of the Revolution; but Mr. Douglass found the patronage of the two cities inadequate as early as 1770–71. In the latter year he made a tour to the southward as far as Williamsburg, Va., playing at Fredericksburg, Suffolk and other towns, and building a theatre at Annapolis, where the company played an engagement in the autumn of 1771. In 1773 Douglass also built a theatre at Charleston, S. C., which was the last of the many buildings he erected for theatrical purposes. The company played at Charleston from 22 Dec. 1773 to 19 May 1774. In October following the Continental Congress passed a resolution forbidding theatrical performances, in view of the impending Revolution, and the organization was disbanded. Hallam went to England, where he appealed to the London public at Covent Garden Theatre as Hamlet in 1775. His mother, Mrs. Douglass, died in Philadelphia at the close of 1774, and Mr. Douglass returned to Jamaica, where he became a magistrate.

It is an interesting fact, showing the theatrical activity before the Revolution, that while the American Company was acting in New York and Philadelphia in 1766–69 there was a company in the South giving performances at Annapolis and Williamsburg. This company was known as the "Virginia Comedians" in 1768, when it gave a long season at the Virginia capital; but it assumed the name of the "New American Company" when it was at Annapolis from January to June 1769. The leading spirits of the Virginia Comedians were Messrs. Verling and Bromadge, and Mrs. Osborne, who had played with Douglass at Charleston in 1765–66, and Mr. Godwin, who was with the American Company at the Southwark in Philadelphia in 1766–67. All these were with the New American Company, with the exception of Mr. Bromadge. A number of bills of the Virginia Comedians at Williamsburg in 1768 have been preserved.

The most important annals relating to the American stage that have escaped the destroying hand of time are a collection of playbills made by Thomas Llewellyn Lechmere Wall — Mr. Wall of Douglass' company. These cover 40 years of the theatrical life of the actor and are especially valuable for the complete information they afford in regard to the Baltimore Company, organized by Wall and Lindsay in 1782. Wall was perhaps the only member of the American Company who remained behind when Douglass returned to Jamaica in 1774. He was also the only manager who undertook to produce plays before the close of the Revolution. In 1781 he was at Annapolis giving entertainments with the assistance of his wife and daughter when the French army was on the march to Yorktown. For one of his performances at that time he succeeded in securing the services of the band belonging to the regiment of Count de Chaleur. Later in the year he went to Baltimore, where he repeated his Annapolis entertainments, and in conjunction with Adam Lindsay, a tavern-keeper at Fell's Point, built a theatre, of which Lindsay and Wall were the nominal managers, with Wall as the stage director. The company was formed on what was afterward known as the «commonwealth plan.» The theatre was opened 15 Jan. 1782 and continued open without important interruptions until 9 July — 42 nights. In all 19 plays and 14 farces were produced, and the total receipts for the season were $14,209, an average of $338.50 per night. With the exception of the Walls the players were all new to the American stage, and, it may be assumed, were all amateurs.

The second season at the Baltimore theatre extended to 7 Feb. 1783. On the third night of the season at Baltimore, Mr. and Mrs. Dennis Ryan appeared in 'Douglass.' Ryan dominated the company from the outset, and when Wall retired from the management, 7 Feb. 1783, he assumed the reins, keeping the theatre open from 11 February to 9 June. From Baltimore Ryan carried his company to New York and opened the theatre in John street. Wall was with Ryan's company, which remained until the British evacuation, giving two performances in October 1783, while the military players gave a performance for Mrs. Ryan's benefit. In the winter Ryan again opened the Baltimore theatre, the season extending from 7 Dec. 1783 to 14 Feb. 1784. The only noteworthy event of this season was the first production of the 'School for Scandal' in America, 3 Feb. 1784, with Mrs. Ryan as Lady Teazle. After the close of the Baltimore season in 1784, Ryan took the company to Richmond, where he played a long engagement. Mr. Heard, who was the original Sir Peter Teazle in this country, joined the forces of Hallam and Henry, while other members of the organization found professional employment in the South during the rest of the century.

After the Revolution both Lewis Hallam and John Henry sought to control the theatres that had been built by Douglass; but Hallam was the first to present a company of comedians to the New York public, opening the John Street Theatre 24 Aug. 1785. Hallam proposed a partnership with Henry, and the firm of Hallam and Henry, which ruled the American stage during the next seven years, came into existence. The John Street Theatre reopened under their management 21 Nov. 1785. Henry engaged in England a number of capable actors and actresses whose names are part of the history of the American stage, while Wignell not only succeeded in building in Philadelphia the first really handsome and complete theatre in the United States, but put into it the best company of players that had as yet been tempted to cross the Atlantic.

An incident of the Hallam and Henry partnership, previous to the reorganization of the company, that needs to be noted here is the production of the first American comedy, 'The Contrast,' by Royall Tyler. This piece, which was first produced in New York 18 April 1787, was written for Wignell, who wished to play a Yankee character. Wignell's Jonathan deserves remembrance as the forerunner of the long series of stage Yankees that afterward became popular with American audiences. The comedy was printed in Philadelphia, and was often played by strolling companies before the close of the century.

The only really important recruits engaged by Mr. Henry in England were Mr. and Mrs. Hodgkinson, of the Bath and Bristol theatres, and Mrs. Wrighten, who had long been a favorite singer and actress at Drury Lane. Hodgkinson was a man of great talent and versatility, and the best actor seen in America up to that time and for many years afterward. He made his début as Don Felix in 'The Wonder,' at Philadelphia, 26 Sept. 1792, succeeded Henry as one of the managers of the Old American Company in 1794, and was active as actor and manager in New York until after the opening season at the New Theatre in 1798. Mrs. Hodgkinson, known at Bath and Bristol as Miss Brett, was an actress of merit, and in this country eclipsed both Mrs. Henry and Mrs. Hallam, the wives of the managers by whom the Hodgkinsons were engaged. Mrs. Wrighten was known in America as Mrs. Pownall. She died at Charleston in 1796, after introducing her two daughters to the stage in this country. One of them, Caroline, married Alexander Placide, who had been a rope dancer in England. She was the mother of the famous Placide family of actors. It was during this period that William Dunlap became prominent as a dramatist and adapter of plays. His first comedy, 'The Father,' was produced at the old John Street Theatre, 7 Sept. 1789. Dunlap became associated with Hallam and Hodgkinson in the management of the New York company in 1796, and he was afterward for a brief period the sole manager of the New Theatre, better known as the Park.

After leaving the Old American Company, in the beginning of 1792, Thomas Wignell associated himself with A. Reinagle, a musician who came to American in 1786, in the project of building the New Theatre in Philadelphia, afterward known as the Chestnut Street Theatre. The house was modeled after the theatre at Bath, and was completed early in 1793; but owing to the yellow-fever epidemic it was not opened by the company of players engaged by Wignell until 17 Feb. 1794. Among the actors and actresses comprising the Philadelphia company were Mr. Fennell, a young tragedian of much promise; Mr. and Mrs. Whitlock, the latter a sister of Mrs. Siddons; and Miss George, who was the wife of Sir John Oldmixon, and was known to our stage as Mrs. Oldmixon. This company remained intact without any important changes or additions for three years, playing alternately in Philadelphia and Baltimore; but in the autumn of 1796 Mr. Wignell brought three important recruits from England — Mrs. Merry, the famous Miss Brunton of Covent Garden Theatre, who had become the wife of Robert Merry, the Della Cruscan poet; Thomas Althorpe Cooper, then a young man of 20 but destined to be the manager of the New York theatre for many years; and William Warren, who had been a strolling player in England, and who became the successor of Wignell in the management of the Philadelphia theatre. Mrs. Merry became a widow in 1798. She soon afterward married Wignell, and after his death she became the wife of Warren, who survived her many years.

A fortnight before the formal opening of the Philadelphia theatre by Wignell's company a new theatre in Boston, scarcely inferior to the Philadelphia house, was opened by an English company engaged and brought over by Charles Powell. This theatre was in Federal street and was built by subscription. It was destroyed by fire in 1798. Powell's company was a feeble one, and he closed his second season in 1795. Powell was succeeded by Col. John S. Tyler, a brother of Royall Tyler, the author of 'The Contrast,' who managed the house on behalf of the stockholders from January to May 1796. The season proved a failure; but the theatre was reopened in September by John Brown Williamson, an English actor, whose wife was popular in London as Miss Fontenelle; but neither he nor his wife nor a stronger company than had as yet been seen in Boston availed to make the season successful. One reason for this was that a new theatre, known as the Haymarket, had been built through the exertions of Charles Powell, and opened by him for the first time 26 Dec. 1796. Among Powell's English recruits for the Boston Haymarket were Mr. and Mrs. Giles L. Barrett, the parents of the famous New York comedian, George H. Barrett; Mr. and Mrs. Simpson, afterward New York favorites; and Mrs. Simpson's three daughters, the Misses Westray, of whom Juliana became Mrs. William B. Wood; Eliza, successively, Mrs. Villiers and Mrs. Twaits; and Ellen, Mrs. Darley. Powell again failed at the Haymarket, and the house passed into the control of Hodgkinson, Hallam and Dunlap, under the personal direction of Hodgkinson. The New York company occupied it in the summer of 1797, after which it was abandoned. The Haymarket deserves to be remembered for the production of two American war plays — 'Bunker Hill,' by John Daly Burke, 20 Feb. 1797; and 'West Point Preserved,' the first of the André pieces, by William Brown, on 17 April following. Dunlap's 'André' was not produced in New York until 30 March 1798. This epoch, 1792–98, was also remarkable for theatrical activity in the South. Not only had the Baltimore company, including Mr. and Mrs. Ryan and Mr. Wall, played a long engagement at Richmond as early as 1784, but in 1790 John Bignall and Thomas Ward West were the managers of a company called the "Virginia Comedians." This organization maintained its existence for many years, its circuit extending from Richmond and Norfolk to Charleston. Bignall, who was held by his Southern admirers to be the best actor on the continent, died in 1794. His real name was Moneypenny, and he had been a stroller in England in the same company with William Warren, of the Philadelphia theatre. After Bignall's death West became the sole manager of the company and piloted it over the Southern circuit for a number of years. In 1795 there was a rival theatre in Charleston, conducted by Mr. Jones, who had been previously at the Boston Theatre. His principal actress was Mrs. Whitlock, who had just retired from the Philadelphia company. A Frenchman, M. Sollee, succeeded to the management of this theatre, and organized a company in Boston to play in Charleston for the season of 1795–96. Mr. and Mrs. Whitlock, Mr. and Mrs. Placide and Mrs. Arnold — afterward Mrs. Poe and the mother of Edgar Allan Poe — were in the company.

The prosperity which had given to America three splendid theatres within five years — the Chestnut Street in Philadelphia, the Park in New York, and the Boston Theatre in Federal street, Boston, rebuilt immediately after its destruction in 1798 — was followed by a period of depression that was severely felt over all the country. At the close of the century Wignell was in jail for debts incurred through the Philadelphia theatre, and Dunlap, who had undertaken the sole management of the New York theatre to retrieve previous losses in New York and New England, lost his entire private fortune in the venture. Mr. Barrett was induced to undertake the management of the new Boston Theatre in 1799, but he failed dismally.

In all these cities theatrical enterprises were experimental for several years, but in every case a manager was finally found in the local company who succeeded in placing the theatre on a sound business and artistic basis. Mr. Warren, after he became Wignell's successor in Philadelphia, associated with himself in the direction of the Chestnut Street Theatre a popular young member of the company, William Burke Wood. This partnership lasted until 1825. In New York the young tragedian Cooper retrieved the fortunes of the Park Theatre and made the house a paying one for a number of years. In Boston, Snelling Powell, a brother of Charles Powell, secured control after other attempts had failed, including the assumption of the management of the Boston Theatre by Charles Whitlock in 1800. John Bernard, an English actor of some repute who joined the Philadelphia company in 1797, was for a while Snelling Powell's associate in directing the Federal Street Theatre; but for many years Powell's partner was Mr. Dickenson, who was an actor of moderate ability, but a man of sound judgment and an excellent manager. These were the dominating theatres in the United States during the first quarter of the century, and their influence in giving tone and character to theatrical enterprises in the country was felt down to 1850.

The Old American Company was designed to be permanent in organization, but all the early managers, from Douglass to Wignell and Hodgkinson, aimed at controlling a circuit of playhouses modeled after the provincial circuits in England. The building of the new theatres in Philadelphia, New York and Boston resulted in giving companies that were permanent in organization permanence of home. These were the real stock-company days, but a tendency toward the star system was manifested almost from the outset. In 1796 Mrs. Whitlock played what was essentially a star engagement at the Boston Theatre; it was limited to 12 nights, for which she was paid $450 and allowed a benefit. Hodgkinson played star engagements in all the leading cities between 1798 and 1805, and Cooper followed Hodgkinson's example, and was a star from youth to old age. But the first star to shine with extraordinary effulgence in the American theatrical firmament was George Frederick Cooke. He was the first English actor of great reputation who came to America to play the leading rôles of tragedy and comedy with the stock companies in the principal cities. In view of this the star system, as it ruled in the American theatres for the next half century, may be said to date from his appearance here in 1810–11.

Simultaneously with Cooke's performances in the theatres of Philadelphia, New York and Boston were the star engagements of John Howard Payne. Cooke played three engagements in Philadelphia — in all 39 nights. His highest receipts for any one night were $1,475, his lowest $474. His average for his last Philadelphia engagement of 12 nights in 1811 was $807.50. Payne played to an average about the same time of $442, while Cooper's Philadelphia average was $509. Young Payne's popularity rapidly diminished, and in 1812 he performed to receipts that fell as low as $255. After Cooke the next English star to appear in America was Holman, in 1812; but he came at a time of serious depression in consequence of the war with Great Britain, and the impression that he made fell far below his expectations. Then came Incledon and Phillips as musical stars, and after them the Wallacks, Henry and James W., and finally, to close the first decade of the star system in America, 1810–20, Edmund Kean. The great English stars who came to this country during the next three decades were Junius Brutus Booth and William Charles Macready, 1820–30; Fanny Kemble and her father, Charles Kemble, and Charles Kean, 1830–40; and Tyrone Power, James R. Anderson and Macready, again in the fullness of his fame, 1840–50. This long period had developed only two American stars of surpassing brilliancy — Edwin Forrest and Charlotte Cushman.

The century opened with about half a score of theatres in the leading American cities, only three of which, as already described, were worthy of the name or of the drama. Between 1800 and 1850 about 20 theatres were built in New York, none of them superior to the Park, and only one, the Bowery, in any sense its rival, until Burton established himself in Chambers street in the last decade of the epoch. The only new theatres of importance in Philadelphia during the same period were the Walnut Street and the Arch Street theatres, the former erected for a circus in 1808 and fitted up for theatrical uses in 1820, and the latter built in 1826. The theatres built in Boston in these 50 years were the Tremont, the American Amphitheatre,— afterward the Warren and National—Kimball's Museum, the Eagle and the Howard Athenæum. Baltimore had nothing better than the old Holliday Street Theatre during this epoch, and Washington was without a place of amusement worthy of the drama until 1835. The theatre builder of the period in the South and Southwest was James H. Caldwell. He built the American Theatre in New Orleans in 1823, and afterward erected the Camp Street and Charles Street theatres. Mr. Caldwell also built theatres in Cincinnati, Saint Louis, Natchez, Huntsville, Nashville and Petersburg. Another manager, John S. Potter, was concerned in building as many, or more, theatres in the South and Southwest; but, after all, the theatrical activity of a century resulted in an approximate number of theatres in actual use at its close not exceeding 50.

The figures that show the periods of prosperity and the intervening periods of depression are not easily obtainable, those that are in existence being widely scattered through books and newspapers or in private hands. The losses were sometimes heavy even in the early enterprises. The Philadelphia company in 1797 played 14 weeks in New York with a loss of $2,350; but, on the other hand, Caldwell, in 1818, cleared $10,000 in four months in Petersburg, Va. The receipts of the Park Theatre, New York, for the season of 1832–33 reached nearly $150,000, Fanny Kemble and her father drawing $56,000 for 60 nights, an average of $933 per night. In 1833–34, when the receipts at the Park fell to $135,000 for the season, the Kembles averaged $732 per night; but in 1834–35, without the Kembles, the season's total was over $160,000. At this time the star system was at its height of favor, with both managers and the public; but its effects were disastrous in cities where there were rival theatres outbidding one another for the best stars. This was especially true of the managers of the three rival theatres in Philadelphia who for nearly 20 years continued to cut one another's throats for the benefit of stars of no great magnitude. Wood, in his 'Recollections,' cites an example of the effects of the system. One of Fanny Ellsler's engagements in Philadelphia yielded $10,869.25, out of which the *danseuse* received $6,436. The money paid to the other dancers, the ballet and for the ordinary expenses of the house brought the expenditures up to $11,826, involving a loss to the manager of $1,000 for 10 nights. This system finally culminated about 1846, when nearly all the theatres in the country were ruined. But it was divided patronage as well as the excessive percentages of the stars that made the theatres in Philadelphia, New York and Boston unprofitable; for in the South, where Caldwell had a monopoly in his own field from Richmond to New Orleans the profits were very large, notwithstanding the frequent engagement of stars like Cooper, Booth and Forrest. This contrast receives additional emphasis from the fact that Caldwell was the only manager produced by the first century of the American theatre who died rich.

The closing years of the 19th century witnessed a partial revival of the old stock companies in their purity and simplicity, without the intervention of great stars, and it has also witnessed the nearly complete abolition of this form of theatrical organization. In the theatres managed by William Wheatley, John S. Clarke, and, for a time, by Mrs. John Drew in Philadelphia, by James H. Wallack in New York, and by Moses Kimball in Boston, stock companies were maintained. Later on, Lester Wallack, Augustin Daly, M. H. Mallory, Daniel Frohman, Charles Frohman and A. M. Palmer in New York, and R. M. Field in Boston, kept together for years organizations which were managed upon the pure stock system. Throughout the country generally the theatres for a while employed stock companies, but mainly for the purpose of supporting traveling stars. This continued until after the close of the Civil War, when the impetus given to business enterprises of all kinds was felt in renewed theatrical activity not only in the cities, but all over the country. What is known as the combination system (that is, a traveling company made up of a star and a supporting company), which began about 1869 and reached its highest development before 1876, involving the destruction of the stock companies in all except a few theatres, was the consequence of this theatrical revival. Nearly every inland town and city from Maine to California built a theatre, with the expectation that traveling companies would occupy it at intervals. The demand thus created could be supplied only by the combinations.

One of the first results of this new state of things was the banishment from the managerial office of all, or nearly all, the actor-managers. Their places were filled by business men, who, while they may have lowered, in a sense, the artistic character of the theatre, have raised its financial standing to a point which, during the first century of its existence, seemed beyond its reach. The theatre in America was no longer a haphazard thing, living from day to day on uncertainty. It became a business conducted on the principles which govern other forms of commercial enterprise, and is as stable, as sound and as certain of adequate rewards as any. Indeed, so abnormal has been the development of the business character of the theatre that it has excluded from general managerial attainments everything else. Very few of the managers throughout the country ever undertake the original production of plays, or take the trouble to acquire the artistic knowledge requisite for this kind of work. New York chiefly, and in a lesser degree Chicago and Boston, are the play-producing centres. A few New York managers and the play-producing stars select and bring forth all the plays and gather together all the companies which, supplemented by the imported attractions, keep the theatres of the country supplied with entertainment during the season. The advantage of this system is that playgoers everywhere are furnished with well-trained and perfectly equipped companies, appearing in plays which have been tried and found to be worthy. The local manager, free from the worries and cares incident to stage-work, devotes his time and attention to the comfort of his patrons at the front of the house, and to the strict conduct of business there. The results are well-regulated and comfortable auditoriums and good order in all the business departments of the theatre.

A remarkable aspect of the American theatre, from a commercial point of view, is the enormous profit it has yielded and continues to yield to home and foreign celebrities. Among American actors, Edwin Forrest acquired and left behind him a great estate, from the remnant of which was established the Forrest Home, near Philadelphia, a retreat for aged actors, noble in its purpose and efficient in its benefaction; Charlotte Cushman, resting for long periods in England and Italy, left a fortune of $600,000; Edwin Booth, having made and lost more than one competency, renewed his financial successes in his declining years, and left $750,000 to his heirs, after having founded the Players' Club at a cost of $200,000; Mary Anderson retired from the stage after a few seasons of brilliant and uninterrupted triumph, to enjoy a happy marriage in her youth, her labors having brought her a fortune of $500,000; Joseph Jefferson, blessed with that continuous vitality often found among the children of the stage, had in 1902 acquired a fortune of $1,000,000. Among foreign actors, William C. Macready owed to America the realization of his dream of retirement from a profession he affected to loathe; Sarah Bernhardt acquired here a fortune which enabled her to defy the authority of the house of Molière and to establish a theatre of her own in beautiful Paris; Tommaso Salvini, adding his great earnings here to his modest ones in other lands, became the richest actor Italy has ever known; and Henry Irving has found in his frequent visits to our country a public eager and willing to fill his coffers to overflowing with the rewards so justly due to his unequaled managerial achievements and to his undoubted genius as an actor. In the moving picture field Charlie Chaplin passed everybody else, and his income is stated to be fully $1,000,000 annually. The list of the well-rewarded favorites of the public might be greatly extended, but this glimpse of results is sufficient to make clear the profits and prosperity of the American stage, and to indicate the extent of its commercial advancement during the century.

The development of the theatre in all its departments, especially since 1860, has been vast. From not more than 100 in 1800, and fewer than 800 in 1860, the number of actors and actresses in the United States increased so immensely that in 1888 it was estimated at 4,500, and now probably exceeds 10,000. This number represents only the performers engaged in presenting the drama in its higher forms. It does not include the managers, who number several hundred, as compared with 25 or 30 in 1850 and six or eight in 1800. If the exponents of variety and vaudeville and the other employees in the amusement business are added, the number of people who gain a livelihood by giving public entertainments will not fall below 30,000; including stage hands and all the persons who derive their support from the theatre, the number may be roughly estimated at 100,000. This vast army of workers is well organized, generally well paid and reasonably prosperous. It has numerous charitable and social organizations, which are models of their kind. The Actors' Fund, the Actors' Order of Friendship, the Players' Club, the Green Room Club, the Lambs' Club, the Professional Women's League, are institutions of which any profession might well be proud; and there are numberless others of equal merit supported by the amusement makers of the United States. There are about 1,000 regularly organized theatrical companies on tour through the United States during the season, and the number of theatres of all kinds is 10,000.

In New York City there were in 1918, the following theatres: in Manhattan borough, about 50 theatres worthy of the name, the largest being the Hippodrome (seating 5,000), followed by the Manhattan Opera House (3,500), Metropolitan Opera House (3,366) and Century (2,890); and about 50 vaudeville and motion picture houses of the best class, the larger ones being the old Academy of Music (3,400), Strand (3,300), Audubon (2,653) and Lexington (2,559). In Brooklyn borough there are about a score of good theatres and some 30 first-class vaudeville and motion picture houses, the largest being the Halsey, Keeney, Ridgewood and Prospect, each of them seating 2,500. There are perhaps a thousand other minor theatres and picture houses.

The improvement which has taken place in the construction of theatres in America within the past 35 years is worthy of especial notice. The tragic disaster in Brooklyn on the night of 5 Dec. 1876 awakened the attention of managers and of the public authorities in the different States to the flimsiness of construction which marked even the best theatres of the period. The result was the passage of new and most stringent laws, involving requirements which, while they seemed onerous, perhaps, have resulted in giving to America the best and safest theatres in the world. Even the older theatres, built before the new regulations, have been so altered under the direction of the authorities that they are now comparatively free from danger. In New York, where these regulations are perhaps the strictest, there is a larger number of absolutely safe theatres than in any city in the world; while for beauty and convenience combined with safety it is impossible to find elsewhere such theatres as the Century, Strand, Gaiety, New Amsterdam, Victoria, New York, Knickerbocker, Empire, American and Metropolitan Opera House. As the older houses pass away they are replaced by absolutely fireproof structures if replaced at all.

Perhaps the most marked change that has taken place in the American theatre during the last hundred years is in the character and number of its patrons. Attendance upon the theatre was looked upon even 60 years ago by at least seven-tenths of the people of the United States as almost a sin. The fashionable ungodly and the lowest and most depraved made up the audiences. We have seen how, in the Revolutionary period, theatres were closed by act of Congress, doubtless because, in those days of danger, the fathers of our country felt that they would help their cause by propitiating the Almighty, who was supposed to frown upon godless amusements. But in the last three or four decades this unreasonable prejudice against the most enjoyable and least harmful of all forms of amusement has so materially lessened that it is estimated by a good authority that not more than one-tenth of the people refuse to patronize the theatres as a matter of principle. It is true that a clergyman now and then inveighs against the stage in the old-fashioned, puritanical way; but his words, in all likelihood, fall upon ears that the night before were listening to the sorrows of 'Camille' or were taking in the laughter-provoking catch-lines of 'The Private Secretary.' Indeed, the element of moral usefulness in the theatre is no longer successfully derided.

The phenomenal development of the moving picture theatre has made many changes in the stage since the dawn of the 20th century. Those theatre managers who clung to the regularly staged productions of the old school suffered in business, and there were years of depression and numerous failures. Some tried to bring back the crowds by going the limit in presenting plays exhibiting crime, and for a few seasons there was scant decency in many American playhouses. When this failed, the more sensible managers accepted the moving picture as an adjunct, and many utilized it as a vaudeville feature. The war also had a disintegrating influence; many of the younger actors put on the uniform and were lost to the profession. War plays were called for, and a few strong productions resulted. The number of new plays produced in America is small, however. About 100 are staged annually in New York City, and perhaps a dozen in other cities. Those that run more than 100 nights are voted to be great successes. The remainder of the performances in New York are either reproductions of European authors, or old plays revived. It is not possible to catalogue the best plays that come and go, though many of them will be found by reference to DRAMA. See also MOVING PICTURES.

NAMES OF SOME FAMOUS ACTORS.

Professional	Real
Abingdon, Wm. L.	Pilgrim, Wm. Lepper.
Abott, Bessie	Story, Mrs. T. W.
Adams, Maude	Kiskadden, Maude.
Albani, Mme	Gye, Mrs. Ernest.
Alda, Frances	Gatti-Casazza, Mrs. G.
Alexander, Sir George	Sampson, Sir George.
Allen, Viola	Duryea, Mrs. Peter.
Anderson, Mary	Navarro, Mrs. A. F. de.
Anglin, Margaret	Hull, Mrs. Howard.
Arliss, George	Arliss-Andrews, George.
Arthur, Julia	Cheney, Mrs. Benj. P.
Ashley, Minnie	Chanler, Mrs. Wm. A.
Baird, Dorothea	Irving, Mrs. Henry B.
Barrymore, Ethel	Colt, Mrs. Russell G.
Barrymore, John	Blythe, John.
Bateman, Kate	Crowe, Mrs. George.
Bates, Blanche	Creel, Mrs. George.
Bentley, Irene	Smith, Mrs. Harry B.
Bernard, Sam	Barnett, Sam.
Bernhardt, Sarah	Damala, Mme.
Blair, Eugenie	Downing, Mrs. Eugenia.
Blauvelt, Lillian Evans	Pendleton, Mrs. W. F.
Booth, Rachel	Powers, Mrs. Jas. T.
Buffalo Bill	Cody, William F.
Burke, Billie	Ziegfeld, Mrs. Florenz.
Burnett, Frances H	Townsend, Mrs. S.
Burroughs, Marie	Livingston, Mrs. Francis M.
Burt, Laura	Stamford, Mrs. Hy. B.
Busley, Jessie	Joy, Mrs. E. C.
Cahill, Marie	Arthur, Mrs. Daniel V.
Calvé, Emma	Gaspari, Mme. Alnor.
Cameron, Beatrice	Mansfield, Mrs. Richard.
Cameron, Violet	De Bensaude, Mrs.
Campbell, Mrs. Patrick	West, Mrs. G. Cornwallis.
Carle, Richard	Carleton, Chas. N.
Carter, Mrs. Leslie	Payne, Mrs. Wm. L.
Carus, Emma	Everall, Mrs. Harry J.
Castle, Vernon	Blythe, Vernon Castle.
Cavalieri, Lina	Muratore, Mrs. L.
Chase, Pauline	Drummond, Mrs. Alex.
Claire, Ina	Fagan, Miss.
Claxton, Kate	Stevenson, Mrs. Chas. A.
Coghlan, Gertrude	Pitou, Mrs. A., Jr.
Coghlan, Rose	Sullivan, Mrs. John.

THEATRE, Stage Mechanics of. A theatre stage is that visible part of a platform arranged at one end of an auditorium which is enclosed by scenery and framed within and viewed through an opening or arch. The stage and all that may be arranged upon it should be preservative of the lines of sight and hearing of the spectator and auditor.

From earliest times either an elevation or platform, or a depression or pit, have been usual for representation or entertainment before spectators. The earliest choral dances in the circle or pit evolved into the Greek classic theatre, with its skene or house of two or three stories, which filled the background of the scene, the action being within the semi-circular chorus place or pit in front.

The mechanism of the ancient theatre was very exact in every respect. The religious character of the performance established fixed and usually theologic meanings for everything done or said in the play. The scenery was probably limited to painted curtains at the back and revolving triangular prisms at entrances. Machinery for startling effects was, however, usual. The Roman invasion resulted in the extension of the stage more and more forward, until it became a platform sufficiently large to hold the chorus and entire group of performers.

The ancient Greeks bore the same relation in art and theatricals to the world of their time as the modern French do to-day; consequently even the traveling companies of the various nations followed crudely the methods of performances usual with the Greeks, and, indeed, the general conduct and character of the modern theatre has in many important respects followed the original classic traditions. The entrances and exits on the modern stage, much of the symbolic values of parts of the stage and the arrangement of stage movement are directly inherited from the old Greek theatre: In later mediæval times a portable stage or cart was used. But little advance can be noted in stage mechanism until after the time of Shakespeare and of Molière, when modern inventions began to appear. Richard Wagner and the Germans revolutionized stage settings and theatrical architecture, as notable in Wagner's Theatre in Baireuth and the Burg Theatre in Vienna. The Germans' leadership in applying science to and otherwise improving stage mechanics has been followed by every European nation, notably in England, by Sir Henry Irving, whose system of lighting is especially remarkable in the conveyance of the feeling of atmosphere to the senses of the spectators. In America Steele Mackaye was progressive in improving the mechanism of the stage. Later, the proprietors of the New York Hippodrome developed most elaborate and complicated mechanisms for spectacular productions.

While the use of gas and movement of scenery in grooves had been universal during the past century until 1875, yet in many theatres to-day such modes of lighting and scene shifting are still retained. In the theatres of to-day, where electricity and the most modern machinery are employed, the following are the terms and uses of the stage machinery:

The Stage.

Rake, The.— The scale or rise of the stage floor, from the curtain line to the back wall. A modern stage is generally built with a slight downward incline toward the audience. The "Rake" of the scenery is the perspective line; a gradual decrease in the height of each piece of the sides of a scene representing an interior or room and extending up stage.

Proscenium Arch, The.— The architectural arch and sides behind which descends the curtain — as it were a massive frame to the picture which the curtain-rise reveals.

BRIDGE.— A longitudinal section of stage, built as a trussed bridge so that it can be taken out, raised or lowered as necessary for effects. Bridges are counterbalanced like elevators, and designed to carry much live weight.

APRON, THE.— That space of the stage from the curtain line down to the footlights. A distance usually of four or five feet. The apron in modern theatres is often almost eliminated.

TORMENTOR, THE.— The foremost piece of scenery standing slightly out, both sides of the stage, back of the proscenium sides. It is often red and intended as the matting to the picture framed.

FRONT DRAPERY, THE.— A short curtain stretching across the proscenium arch, intended to blend with the tormentors at the required height from the ground, once the curtain has risen, thus forming an arch matting to the picture.

FLY GALLERIES, THE.— Galleries that are built along the side walls of the stage. The height of these galleries above the stage varies according to the proportions of the stage and building. On an average they are erected some 30 feet from the ground. One of these side galleries is occupied — ordinarily the left side gallery — by the fly-men, a crew of men employed there to operate the ropes (called lines) whereby the divers pieces of scenery are either raised or lowered into position.

PAINTER'S GALLERY, THE— A long narrow bridge extending from one fly gallery to the other alongside the back wall of the stage. It is always movable and can be hoisted or lowered down any distance by means of ropes and is for the purpose of touching up scenery which may necessitate fresh daubs of paint. The scenery to be painted is hung or set flat against the back wall of the stage, and the painter's bridge is then raised or lowered in front of it, according to necessity.

RIGGING LOFT, THE.— A timber flooring some few feet beneath the roof above the stage: a network of small beams for the purpose of attaching pulleys thereto — whereby pieces of scenery, borders, etc., may be raised from the ground or lowered. The rigging loft is ordinarily built 50 feet above the stage, sometimes even higher; this to afford more room for the hoisting and retention of stacks of scenery above the setting. The pulleys are attached to the rigging loft in rows of threes, from the front of the stage to the back of the stage. In each row one pulley occupies the centre of the rigging loft; the two others occupy the left and the right of the central pulley and are stationed half way between the central one and the edge of the rigging loft. To each of these numerous rows of pulleys are affixed long ropes, one end of which is carried down by a small weight, while the other end is securely fastened in the fly galleries, usually the left gallery.

PINS, COUNTERWEIGHTS, SAND-BAGS.— The "Pin" is a bar of cast iron, 15 inches long by 1¼ inches in diameter. Pins, sand-bags and counterweights are attached to the loose end of the rope which drops toward the stage from the rigging loft. These weights are usually removed when a piece of scenery is fastened to the rope in their place.

NOISE MACHINES.— A tumble-box filled with old iron, stones, etc., that can be made to deliver almost any degree of loud noises. Also a sheet iron apparatus that when shaken resembles thunder in the sound emitted.

SNOW MACHINE.— A mechanism for dropping a shower of small bits of white paper to imitate falling snow.

LINES.— The ropes that are thus held in the rigging loft and manipulated from the fly gallery.

CENTRE LINE, THE.— The rope attached to the pulley stationed in the centre of the rigging loft, and dropping toward the centre of the stage.

LONG LINE, THE.— The rope attached to that pulley which is farthest from the side from where it is being manipulated in the fly gallery.

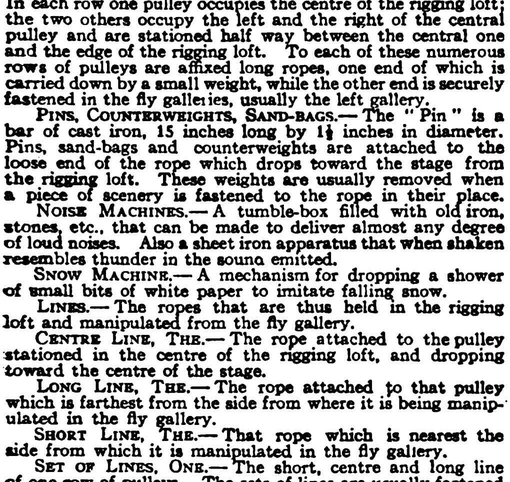
SHORT LINE, THE.— That rope which is nearest the side from which it is manipulated in the fly gallery.

SET OF LINES, ONE.— The short, centre and long line of one row of pulleys. The sets of lines are usually fastened together on the pegs in the fly gallery.

TRAPS.— A concealed opening in the floor of the stage.

STAGE POSITIONS.

The stage is divided into imaginary lines and spaces — which enable the performers to cross, inter-cross and



circle around each other without confusion — and as well the stage carpenter to erect his scene, and the stage-hands to set their furniture in the proper places.

It is assumed that there are four entrances. These are counted 1, 2, 3, 4, from down stage up.

N. B.— Though there may be but one entrance on one side of the interior setting — direction may possibly be given to set a fireplace or window R.2. (right second); that is to say, where right second entrance should have been had it existed.

EXPLANATION OF THE ABBREVIATIONS.

R. 1. E.— Right first entrance.
R. 2. E.— Right second entrance.
R. 3. E.— Right third entrance.
R. 4. E.— Right fourth entrance.
L. 1. E.— Left first entrance.
L. 2. E.— Left second entrance.
L. 3. E.— Left third entrance.
L. 4. E.— Left fourth entrance.
C.— Centre of stage.
D. C.— Down centre line.
U. C.— Up centre line.
U. R. C.— Up right centre line.
R. C.— Right centre line.
D. R. C.— Down right centre line.
U. L. C.— Up left centre line.
L. C.— Left centre line.
D. L. C.— Down left centre line.
D. R.— Down right of stage.
D. L.— Down left of stage.
L.— That side of the stage which is left of a person facing the audience.
R.— That side of the stage which is right of a person facing the audience.
U. R.— Up right of stage.
U. L.— Up left of stage.

THE SCENERY.

WING, A.— A single piece of scenery, ordinarily 5 feet 4 inches wide by 18 feet high.

FLAT, A.— A double wing, either hinged or battened together.

BORDERS.— Strips of canvas hung crosswise above the stage by means of a set of lines. These may either represent the sky, the branches of trees and foliage, etc.

CEILING.— A square of canvas set to a light frame of wood which is lowered by means of a double set of lines— one set "up stage" (back of stage), the other "down" (front of stage), until it rests squarely upon the interior set.

BOX SET, A.— A complete interior setting.

DROP, A.— A large canvas representing the back-ground of the setting. In the case of a complete exterior setting, the drop extends the full width of the back of the stage; in the case of an interior setting, where, for example, only a window and a door present a view of the outside, the drop may be much narrower.

TAB, A.— A narrow drop, hung by a single line.

JOG, A.— A narrow piece of scenery, wherewith two flats or wings of an interior setting may be joined, either for extension or to form a quadrangle.

RETURN PIECES.— Two wings affixed to an interior setting, which turn off stage, back of each side of the proscenium opening.

BACKINGS.— Either a wing, or two wings hinged together, set back of some opening, window or door.

MASKING PIECES.— A piece of scenery, tab, drop or wing, set behind an opening to conceal either the scenery or the bare stage immediately behind it.

BRACES.— Two narrow strips of wood, five feet long, either permitted to slip alongside each other or made fast to each other by means of a turn-screw once the desired extension is reached. The top end has a small iron grip attached, in the shape of a ram's horns; the lower has a narrow short blade of steel intended to trail flat upon the ground and containing a hole sufficiently large to admit a screw-pin. The grip at the top of the brace is first introduced into a screw-eye attached to the back of a piece of scenery; then the desired length of the brace is secured by means of the centre screw, so that it reaches the ground obliquely; lastly, then, the screw-pin fastens the brace securely to the ground: and thus may scenery be held in position.

LASHLINES.—Pieces of light rope fastened at the side of the wooden frame near the top of a wing or flat, for the purpose of fastening this wing or flat to the next one.

THE LIGHTS.

FOOTLIGHTS (of the stage.)— Rows of lights along the front edge of the stage.

BORDER LIGHTS.—The illumination of a series of electric bulbs in a long tin reflector, extending the full width of the stage and hung up in the air, by means of a set of lines, back of the canvas borders. There are usually four border lights, more or less, according to the depth of the stage and the style of the play: No. 1 border light is hung close to the curtain down stage; No. 4 is hung well back of stage; the other two, Nos. 2 and 3, occupy the intersecting positions.

STRIPS.— Several electric bulbs set to a narrow strip of wood, varying in length according to necessity — usually our feet long, which may be movable and hung anywhere back of the setting.

BUNCH LIGHT.— Several electric bulbs inside of circular and movable tin-reflector.

BOX CALCIUM.— An oval, sheet-iron box with an open front 18 inches by 14 inches, set upon a long steel rod encased in a tubing — for the purpose of raising or lowering. The box is painted white within and contains carbon holders and carbon sticks — and is for the purpose of throwing a wide flood of white or colored light.

MEDIUMS.— A light frame of wood, the size of the opening of the box calcium. The space within this frame is filled with a thin sheet of gelatine: the gelatine being colored either red, blue, green, amber, etc. Thus sunset glow, moonlight, sunlight effects may be secured by the use of a different medium.

LENSES.— A sheet-iron hood, set to a steel rod and operated in the same way as the box calcium, but for the purpose of throwing a shaft of light: that is, a moonbeam, a sunbeam.

POCKETS.— Concealed, safety, steel pockets in the floor of the stage, on both sides, for the purpose of connecting wires, leading to calciums, bunch lights, etc. Usually there are three pockets on each side of the stage.

THE SWITCH-BOARD.— The electric board — usually on the prompt side — where all connections are made for the electricians to operate all the lights from a single place.

For greater detail consult Gerhardt, W. P., 'Theatres: Their Safety, Comfort and Healthfulness' (New York 1915).

J. M. EDGAR HART,
Instructor of the American Academy of Dramatic Arts.

THÉÂTRE FRANÇAIS, tā-ätr frän-sā. See COMÉDIE FRANÇAISE.

THEATRE LIBRE, lēbr, in France, a theatre for the populace, subsidized by the government and admission to which is practically free to all citizens of the republic.

THEATRICALS, Amateur. See AMATEUR THEATRICALS.

THEBAN CYCLE. A series of old Greek epic poems dealing with Theban legends. They include 'Thebais,' which tells the story of the house of Labdacus and the attack of the Seven on Thebas; the 'Epigone,' which relates the capture of the city, and the 'Œdipœdia,' which tells the story of the hero Odipus. The poems average about 6,000 lines each.

THEBES, thēbz (Egyptian *Net,* the *No* of the Bible; Greek *Thebai* or *Diospolis*), Egypt, a famous ancient city, whose ruins are situated on the banks of the Nile, 350 miles southeast of Cairo, near the modern villages of Karnak and Luxor. The ruins are among the most magnificent in the world. The largest is the great temple of Ammon at Karnak on the east bank of the river. It was begun during the Twelfth Dynasty and enlarged by the kings of the succeeding dynasties down to the time of the Ptolemies. It stands within a large enclosure which also contains several minor temples. An avenue of sphinxes leads to the main entrance, which is a huge pylon, 142 feet high. This leads into a court measuring 276 by 338 feet, and traversed by a double line of colossal columns. A second pylon leads into the great hall or hypostyle, whose roof was supported by 134 columns in 16 rows. The columns of the two central rows are 78 feet high and 33 feet in circumference. All were brilliantly painted and sculptured, and many of the columns still retain their bright colors. Other pylons lead into the inner courts, one of which contains two obelisks 97½ feet high and a colossal statue of Osiris. One of the obelisks is still erect. The entire structure is 1,200 feet long and about 350 feet wide. At Luxor, also on the east bank of the river, and a short distance south of Karnak, there are fine ruins of another temple of Ammon, built by Amenophis III and his successors. On the west bank the principal ruins are the Tombs of the Kings, hewn into the solid rocks of the hillside; the Ramesseum, a temple of Ammon built by Rameses II, and containing a colossal statue of that king; and the two Colossi of Memnon, 64 feet in height. One of these is the celebrated «vocal statue.» Numerous other remains of tombs and temples are scattered over the neighborhood on both sides of the river. After the expulsion of the Hyksos Thebes became the capital of Egypt and remained so until the beginning of the Twenty-first Dynasty. It declined in importance after this with the exception of a short period in the 7th century B.C., when it was again the capital. The Ptolemies repaired its great buildings and so did the Romans. In 27 B.C. an earthquake worked havoc with its ancient ruins. Since then Thebes is nothing more than a collection of ruins inhabited by a few Arab families of Fellahin, who obtained a precarious livelihood by guiding travelers over the ruins or rifling the tombs for antiquities. Consult Davies, N. de G., 'Five Theban Tombs' (in Archæological Survey of Egypt, 'Memoir 21,' London 1913); *Bulletin* of the Metropolitan Museum of Art (New York 1914); Lepsius, Karl, 'Denkmäler Aus Aegypten und Aethiopen' (Berlin 1850–59); Mariette, A. E., 'Monuments of Upper Egypt' (London 1877); Naville, E. H., 'Deir El-Bahari' (London 1894-1906). See also EGYPT.

THEBES (Greek, *Thēbai*), Greece, the principal city of Bœotia, was situated on an elevated plateau, south of Mount Phaga, its site now being occupied by the unimportant modern town of Thivæ (pop. 3,500), at the junction of the road leading north from Athens, with the transversal road leading from the Strait of Euripos on the east to the Gulf of Corinth on the west. It was one of the most celebrated cities of Greece, the birthplace of Pindar, Epaminondas, and Pelopidas. Cadmus, leading thither a Phœnician colony, is said to have founded the city by building the citadel called Cadmeia (1500 B. C.). The principal name in the legendary history of Thebes is that of Œdipus. The first recorded event in its history took place in 728 B.C., when Philolaus drew up a code of laws for the Thebans. During the Persian wars it lost much of its influence in Greece through its perfidious leagues with the Persians. In the Peloponnesian War the Thebans rendered important services to the Spartans; but they afterward, through jealousy of the Spartan power, joined the confederacy against them in 394. In 382, though peace then prevailed, Phœbidas, the Spartan commander, treacherously possessed himself of the Cadmeia, which was held by the Spartans until Pelopidas and Epaminondas headed a conspiracy which resulted in the death of the tyrants (378 B.C.). Open war now broke out between Sparta and Thebes, which resulted in the humiliation of the former by the crushing defeat of Leuctra (371). Thebes, under the brilliant leadership of Epaminondas and Pelopidas was now the leading state in Greece, but its supremacy departed when the former fell at the battle of Mantinea (362 B.C.). On the rise of the Macedonian power Thebes entered into an alliance with the Athenians and other Greeks against Philip. After the battle of Chæronea (338 B.C.) it was obliged to receive a Macedonian garrison. On Philip's death an insurrection broke out in Thebes and an attempt was made to drive the Macedonians from the Cadmeia. But Alexander hastened to their relief, captured and destroyed (336 B.C.) the city, and reduced the inhabitants to slavery. Twenty years afterward Cassander rebuilt Thebes; but it never recovered its former importance. In the war of the Romans against Mithridates, king of Pontus, it joined the latter out of gratitude to Athens, and was severely chastised by the Romans under Sulla. From this time the Thebans as a power in Greece gradually disappear from history. In the 11th and 12th centuries it was again in a prosperous condition as a result of the introduction of silk manufacturing. It was sacked by the Normans in 1146. Consult Baedeker, Karl, 'Greece' (4th Eng. ed., Leipzig 1909); Fabricius, E., 'Theben' (Freiburg 1890); Müller, M., 'Geschichte Thebens' (Leipzig 1879); Stern, E. von, 'Geschichte der spartanischen und thebanischen Hegemonie' (Dorpat 1884).

THECLA, thĕk'la, **Saint,** the female protomartyr of the Church. Born of a noble family of Iconium in Lycaonia, she was converted by the preaching of Saint Paul, followed him to Antioch and devoted herself to a life of virginity. As a consequence, she suffered a series of persecutions from her fiancé and her parents, who eventually denounced her to the authorities as a Christian, and she was thrown to the wild beasts in the theatre; but the fierce animals refused to hurt her, and she also escaped unscathed from the flames to which she was subsequently exposed. After the death of Saint Paul she lived to a ripe old age in a cell near Seleucia. She is the heroine of a Christian romance of the 2d century called 'The Acts of Paul and Thecla.' (See APOCRYPHA). Consult Schlan, 'Die Akten des Paulus und die ältere Theklalegende' (1877); Schmidt, C., 'Acta Pauli' (Leipzig 1905); Ramsay, 'The Church in the Roman Empire' (London 1893).

THECOPHORA, a suborder of *Chelonia* (q.v.), containing all except the leathery turtles (*Athecæ*). It is defined by anatomical characters, the most conspicuous of which is the exclusive possession of horny epidermal shields or plates on the shell. Consult Gadow, 'Amphibia and Reptiles' (New York 1901).

THEFT, is a term sometimes used as synonymous with larceny, although it is less technical, and a wider term, and signifies the secret and felonious abstraction of the property of another with the intention of converting it to the taker's use, and without the consent of the owner. See LARCENY.

THEINE, $C_8H_{10}N_4O_2$, more often called caffeine, an alkaloid found in tea, coffee, Paraguay tea, guarana, etc. It may be prepared synthetically by action of methyl iodide on theobromine. Usually obtained from tea dust which contains from 2 to 4 per cent white silky needles, slightly soluble in cold water and alcohol, possessing a somewhat bitter taste, and forming salts with acids. It is used in medicine as a nerve stimulant.

THEISM, the doctrine of the existence of a God or Gods. It may take the form either of monotheism or polytheism and is opposed only to atheism, which denies the existence of such divine beings. From its use to express the belief of cultured Christian peoples, the term has been given a more restricted meaning. Thus, theism has been identified with monotheism, as implying belief in one God, and hence is distinguished from all forms of polytheism. Further, theism is distinguished from pantheism on the one hand and deism on the other. Pantheism (q.v.) merges God with the world-process and thus practically denies his personality. Deism (q.v.) emphasizes the personality of God, but conceives him as existing apart from the world of his creation. Theism endeavors to rise above both of these extremes and embrace the truth contained in each. On the one hand it maintains the personality of God and his transcendence of the world. On the other it insists upon the immanence of God, upon his presence in the world as its controlling and life-giving agency. Thus the God of theism is at once the Author and the Preserver of the world. In every age and among every people of history some form of theism is to be found as the basis of religious observance. This belief is refined and developed with the progress of thought and civilization and the direction of this development is generally in the line above mentioned, from polytheism to monotheism, and on to a comprehensive theism. Thus the traditional polytheism of Greece broke down under the influence of philosophic reflection; but this reflection itself culminated in the theistic philosophy of Aristotle. As the theoretical basis of religion and the ultimate explanation of the universe, theism has always had a prominent place in systematic reflection. In the earlier centuries of the Christian era it was the topic of supreme importance and the best effort of theologians and philosophers was given to its discussion and exposition. As a result, certain proofs for the existence of God were formulated, the most important of which possess considerable historic interest. We may mention three of these arguments: (1) The Ontological argument, first proposed by Anselm, infers the existence of God from the idea of a most Perfect Being. The presence of this idea in the human mind entails the existence of such a Being, for existence is one of the perfections necessarily contained in the idea of Most Perfect Being. (2) The Cosmological argument was adapted from Aristotle, and proceeds upon the principle that every effect must have a cause. The world is such an effect. It is impossible to suppose that the series of natural causes goes back to infinity, and consequently we are compelled to assume the existence of a Divine First Cause, adequate to account for the existence of the world. (3) The Teleological argument is based upon the evidences of design in the world, and infers therefrom the existence of a designing mind as its Author. These formal arguments were subjected to a destructive criticism by the philosopher Kant at the end of the 18th century. He attempted to show how they depended one upon the other, and all contained contradictions and inconsistencies. Kant held that the moral argument was the only possible proof for the existence of God. This argument maintains that the existence of right and duty presupposes the existence of a God who will ultimately proportion happiness to virtue and vice versa. Kant's criticism was effective in destroying the force of the three above-mentioned proofs in their traditional formulation. Evolutionary science has also contributed to lessen the force of the cosmological and teleological arguments in their earlier and cruder statement. If the present complex condition of the world is the result of a slow process of development from a simpler condition, the need for a First Cause of the present world is less apparent. If present organic structures owe their existence to their utility (that is, are the result of natural selection), their purposiveness is explained by natural causes. But all such criticism, including that of Kant, is effective rather against the form than the substance of theistic argument. It has led only to a reconstruction of old arguments and their statement in a more adequate and convincing manner. Thus it would seem that the arguments for the existence of God are rather stronger than weaker, as the result of criticism. We can only indicate in outline what form some of these arguments have taken in recent years. (1) Belief in God is justified by the needs of human thought. The constant endeavor of the human mind, in its thought, is to introduce more perfect unity, more complete system, into its knowledge. The idea of God by virtue of its all-inclusiveness, is required as the final instrument of organization to make this unity complete; for by it the self and the world are adjusted as elements of one universal life. Thus the idea of God proves its own reality by its function in knowledge. (2) The existence of God is evidenced by the nature and development of the world. In the natural world we have a series of events related as cause and effect, and each dependent upon the other. Since each component part is dependent upon and determined by some other part, it is impossible to conceive the whole series as standing alone. It is rather by its very nature dependent, and requires for its existence and support some ground or underlying principle that is self-determined. From the nature of the world as dependent and relative, therefore, we are led to believe in the existence of an Underlying Principle that is self-determined and absolute. If we consider next the development which the natural world has undergone we see its culmination in man with his intelligence and civilization. The character of the underlying principle or ground of any process will, of necessity, be more completely manifested as the process unfolds. Thus the intelligence and personality of man, as the outcome of the natural order, reveal to us the intelligence and personality of its Ground. (3) The ideals of human activity, both theoretical and practical, presuppose the existence of a God. The thought of man has an ideal, Truth, for which it ever strives. Yet Truth exists in no single human mind, neither is it the possession of the race. Truth as an end is too real to be imaginary, but if real it must exist somewhere. We are forced then to assume a divine mind in which Truth exists in all completeness. The same is true of the Good, the ideal of human conduct. That Good which, as moral ideal, exercises absolute authority over all men, is relative neither to individual desires nor to the desires of a society of individuals. Here, too, we are obliged to assume a Divine Personality whose plans are realized in the moral order and whose purposes are represented in the moral ideal.

Cornell University.

THEISS, tīs, or **TISZA,** tĭs'ŏ, Hungary, the largest tributary of the Danube and one of the most important of the country, rises in the Carpathians, being formed by the junction of numerous small mountain streams. Its course is first northwest, then southwest and west, until, after a circuitous course, it empties into the Danube. Its entire length is 800 miles, 300 of which are parallel to the Danube. The principal affluents are the Maros and Bodrog. The cities on its route are Tokay, Szolnok and Szegedin, which frequently suffer from its overflow. A memorable inundation was that of 1879, when Szegedin was overwhelmed and the entire population lost everything; the loss including many lives. Tokay is at the head of navigation. A canal connects its lower course with the Danube while the Bega Canal connects it with the Temesvár. Its basin has an area of 56,600 square miles, covering all the eastern part of Hungary and most of Transylvania.

THELLUSSON, těl'lŭs-sŏn (Fr. tā-lü-sôṅ), **Peter,** London merchant: b. Paris, 27 June 1737; d. London, 21 July 1797. He settled in London in 1762 and opened a commission house, and later acquired a large fortune by trade with the West Indies. The singular terms of his will, dated 2 April 1796, gave occasion to the passing of an act of Parliament known as the Thellusson Act. He left to his widow and family about £100,000, and the remainder, amounting to more than £600,000, he left to trustees, to accumulate during the lives of his three sons, and the lives of their sons. On the death of the last survivor the estate was to be divided equally among the eldest male lineal descendants of his three sons then living. If there were no heir the property was to go to the extinction of the national debt. This will, being contested by the heirs at law, was finally established by a decision of the House of Lords 25 June 1805. An act of Parliament, however, was soon after passed (39th and 40th George III, ch. xcviii), restraining the power of devising property, for the purpose of accumulation, to 21 years after the death of the testator. Thellusson's last surviving grandson died in 1856 and the final disposal of the property was not settled without an expensive and protracted lawsuit lasting until 1859; when in consequence of mismanagement and the costs of litigation the surviving heirs received but a small sum.

THEME, in music, is the subject or leading melody in a composition; in a fugue it is successively repeated or imitated in the same or in a different key by the various parts. Originally simple, themes are frequently more or less disguised by groups of ornamental notes, called variations, which serve too often merely to show off the performer's flexibility of voice or nimbleness of fingers. See MUSIC.

THEMIS, thē'mĭs, in Greek mythology, a Titaness, daughter of Uranus and Ge (Heaven and Earth); according to some, of Helios, or the Sun. Possessed of the gift of prophecy she was for a time a dweller in the oracular temple at Delphi, but she left it to become consort to Zeus. She became bv him the mother of the Hours (Horæ) and the Fates (Moiræ). The guardian of divine law and order, as established by the gods, she relentlessly pursues all who encroach on the rights of others, and her daughter Dike, the goddess of justice, is often confounded with her. She was honored at Athens, Rhamnus, Delphi and other Greek cities. In art she is pictured as a stately personality, with the cornucopiæ and scales. Consult Ahrens, 'Ueber der Göttin Themis' (1864); Harrison, J. E., 'Themis: A Study of the Social Origins of Greek Religion' (Cambridge 1912); Hirzel, R., 'Themis, Dike und Verwandtes' (Leipzig 1907).

THEMISTOCLES, thē-mĭs'tō-klēz, Greek general and statesman: b. Athens, about 514 B.C.; d. Magnesia, Asia Minor, 449 B.C. He early displayed unusual ability and great ambition. The ostracism of Aristides in 483 was in part due to his influence, and he thereupon became the political leader in Athens. He was elected archon eponymus in 481, and when the second invasion of Greece by Xerxes was threatened he obtained command of the Athenian fleet, which through his exertions had been built from the income derived from the Laurium silver mines. He consented to fight under the Spartan commander in the battle off Artemisium and when, through neglect of his advice, the pass of Thermopylæ was forced and the Persian hordes overran Bœotia and advanced upon Athens, he persuaded the Athenians to convey their women and children to places of safety, abandon the city to the Persians and those capable of bearing arms to take to the ships. The exiles, among whom was Aristides, were recalled and the command of the Greek fleet was entrusted to a Spartan, Eurybiades. The battle of Salamis (480) resulted in a signal victory for the Greeks and Themistocles, to whom the success was mainly due, now became the leader not only of Athens but of Greece. One of his greatest services to his country was the skilful manner in which, by diplomacy and artful parleying with the Spartans, he gained time for the rebuilding of the walls of Athens. From this time the glory of Themistocles declines. He had gained the hatred of the Spartans by building the walls of Athens so strongly and he was now accused by them of treasonable negotiations with the Persians. He was acquitted of this charge, though he was ostracized in 471 by his countrymen, who had become aware of his unscrupulous character and his inordinate love of riches, which he was accused of gratifying by unjust means. He retired to Argos, thence fled to Epirus, and ultimately sought protection at the Persian court, where he gained high favor with the reigning monarch, Artaxerxes Longimanus. He was deeply engaged in plans for the subjugation of Greece by the Persians, which he had promised Artaxerxes to compass, when, knowing the impossibility of fulfilling his promises, according to some accounts, he took poison; others, however, ascribe his death to natural causes. His career shows a curious admixture of noble and sagacious statesmanship and sordid ambition. He was possessed of great eloquence and was undoubtedly the savior of Athens and Greece at the crisis of Salamis. Consult Bauer, 'Themistokles' (Merseburg 1881); Grote, 'History of Greece' (1907); Wecklein, 'Ueber Themistokles' (Munich 1892); also any standard history of Greece.

THÉNARD, tā-när, **Louis Jacques**, French chemist: b. Louptiere, Champagne, 4 May 1777; d. Paris, 21 June 1857. He studied chemistry in Paris under Fourcroy and Vauquelin, becoming the assistant of the latter, who procured him a professorship at the Collège de France (1804). Subsequently he succeeded Fourcroy in the chair of chemistry at the Ecole Polytechnique, as well as in his seat in the Academy. In 1825 he was made a baron by Charles X and in 1832 a peer of France by Louis Philippe. It was while attempting to verify a theory he had propounded in the lecture-room that he made his important discovery of the peroxide of hydrogen. He worked with the chemist Gay-Lussac (q.v.), and made noteworthy original investigations, including those of the compound ethers, of bile and of sebacic acid. He discovered the method of preparation of a cheap cobalt blue, since known as «Thénard's blue.» His chief publications are a 'Treatise on Elementary Chemistry' (4 vols., 1813–16) and 'Physico-Chemical Researches' (with Gay-Lussac, 1816).

THENARDITE, a mineral identical in composition with the artificial sodium sulphate, Na_2SO_4. It is brittle, of vitreous lustre, white color, transparent to translucent, hardness 2 to 3, and specific gravity 2.68. It crystallizes in the orthorhombic system, often in tabular, cross-twinned forms, with distinct basal cleavage. It is entirely soluble in water; natural crystals speedily absorb water and effloresce. It often occurs dissolved in the waters of salt lakes, from which it is separated in crystal form during the summer season by evaporation. The most important American localities of this type are Borax Lake, California, and Rhodes Marsh, Nevada. Vast deposits exist on the Rio Verde in Arizona. It is of value in the preparation of soda.

THEOBALD, thē'ō-bâld, **Lewis**, English dramatist and Shakespearean scholar: b. Sittingbourne, Kent, 2 April 1688; d. London, 18 Sept. 1744. His classical attainments were considerable and by 1715 he had published translations of Plato's 'Phædo'; the 'Electra,' 'Ajax' and 'Œdipus Rex' of Sophocles and the 'Plutus' and 'Clouds' of Aristophanes. He made attempts at verse and tragedy, but succeeded in neither. In 1725 Pope published his edition of Shakespeare and in 1726 Theobald appeared with a work entitled 'Shakespeare Restored, or a Specimen of the many Errors as well Committed as Unamended by Mr. Pope in his late edition of this Poet: designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever published.' Though Pope made grudging use of the manifestly improved readings suggested by Theobald in his second edition, he never forgave the detection of his incompetence as an editor and in the first edition of the 'Dunciad' Theobald figured as hero. In 1733–34 Theobald published an edition of Shakespeare in seven volumes, in the preparation of which he had the assistance of Concanen, Thirlby and Warburton. Textual criticism of Shakespeare owes much to him, for he was the first to discard corrupted readings and in his emendations displayed knowledge, tact and good sense. Subsequent editors have depended much upon him and have adopted his corrections. At the time of his death he was engaged on an edition of the works of Beaumont and Fletcher, six plays of which he had already completed. Consult Collins, 'Essays and Studies' (London 1895); Nichols, 'Illustrations of Literature' (Vol. II, pp. 204–654).

THEOBROMA CACAO. See COCOA.

THEOBROMINE, $C_7H_8N_4O_2$, a white crystallizable alkaloid found in the chocolate prepared from the seeds of the cocoa tree. It forms salts with acids, is bitter, soluble in alcohol, slightly so in water. It is closely related to caffeine, the active principle of tea and coffee, into which it can be readily changed. Caffeine may be considered as theobromine in which one hydrogen atom has been replaced by the methyl group (CH_3). It is not used to any extent in medicine, although it has a slight sedative action on the nervous system.

THEOCRACY (from Gr. *Theos,* God, and *kratos,* power) is that government of which the chief is, or is believed to be, God himself, and the laws the commandments of God. The priests in such a government are the promulgators and expounders of the divine commands, the representatives of the invisible Ruler. The most notable theocratic government of all times was that established by Moses among the Israelites. The Puritan government of Massachusetts was also called a theocracy, owing to the claim that it was conducted on the principle of obedience to divine laws, and the requirement that all should contribute to the support of the Church and attend church services.

THEOCRITUS, thē-ŏk'rĭ-tŭs, Greek bucolic poet: b. Syracuse, according to others at Cos, and flourished about 280 B.C. He was a pupil of Philetas at Cos. Having gone to Egypt, he was treated with much distinction by Ptolemy Philadelphus, in whose praise he wrote Idyls 14, 15 and 17, but afterward returned to Syracuse, where he appears to have been on terms of some intimacy with Hiero II. We have under his name 30 idyls, or pastoral poems, of which, however, several are probably by other authors. The most doubtful are 12, 23, 26, 27, 29. He is to be considered the creator of this species of poetry as a branch of Greek literature, though the elements of it existed before his time among the Dorians both of Sicily and Greece. Most of his idyls have a dramatic form and consist of the alternate responses of musical shepherds. They present fresh and vivid pictures (εἰδύλλια, little pictures) of common life in Sicily, and are marked by considerable comic and, though to a less extent, tragic power. They are of a different sort from the affected compositions representing the «imaginary shepherds of a fictitious Arcadia.» Writing generally in the Doric, though in two cases (Idyls 28, 29) in the Æolic, dialect, which is peculiarly adapted to the simplicity of rural life, his language is strong and harmonious. His metre is chiefly the heroic hexameter. Besides the idyls he wrote a poem called 'Berenice,' of which only five lines and a word are extant, and 22 epigrams in the Greek Anthology. He was imitated by Virgil (q.v.) in the 'Eclogues'; Tennyson's indebtedness to him has been well shown by Stedman in a chapter of the 'Victorian Poets' (1876). (See THEOCRITUS, BION AND MOSCHUS, IDYLS OF). The best editions of his works (which are usually joined with those of Moschus and Bion) are those of Meineke (1856); Paley (1863); Wordsworth (new ed. 1877) and Fritzsche (3d ed. by Hiller, Leipzig 1881). There are renderings into English verse by Chapman (1866) and Calverley (Cambridge 1869) and into prose by Lang (with introduction, New York 1880). The 7th and 11th idyls are translated in verse by Leigh Hunt ('A Jar of Honey,' 1848). Consult, besides the above-mentioned works, Christ-Schmid, 'Geschichte der griechischen Litteratur' (Vol. II, 5th ed., Munich 1911); Fritzsche, 'Zu Theokrit und Virgil' (1860); Knapp, 'Theokrit und die Idyllen-Dichtung' (1882); Wright, W. C., 'A Short History of Greek Literature' (New York 1907).

THEOCRITUS, BION, AND MOSCHUS, Idyls of. Theocritus is one of the great names contributed by Greece to the literature of the world. He is the most excellent of pastoral poets, and to those later born he has always been «the glass of fashion and the mold of form»— to Bion, to Moschus, to Virgil, to the English, Italian, Spanish and French poets of the Renaissance (and there were many), who were pleased to write of shepherds, their pipes, their loves and their lamentations. His are the flowers from which all the bucolic poets of Europe have sucked their honey. He lived in Sicily in the earlier part of the 3d century B.C. An epigram, written in his name, probably by some one else, says: «I, Theocritus, who wrote these idyls, am a citizen of Syracuse, a man of the people, the son of Praxagoras and Philinna.» It also appears certain from references in his poems that he lived for a time in Alexandria, then the intellectual capital of the Hellenic world, and also on the island of Cos. Beyond this nothing is known of him.

The poems that have come down to us under his name are 32 idyls, not all complete, usually classified as bucolics, mimes, epics and lyrics and 20 odd epigrams. The term idyl comes from a Greek word which is itself a diminutive of another Greek word meaning «form» or «style,» or merely «poem,» and only a few of these idyls are what we call pastorals.

the others are little pictures or sketches on various subjects. His first idyl is a dialogue between Thyrsis and a goat herd, in which Thyrsis sings the famous 'Lament for Daphnis.' The second tells how a passionate, jilted woman attempts by magic rites to regain the love of her deserting lover. The next declares a goatherd's love for Amaryllis. Three are poetic contests between herdsmen. Two, VI and XI, are about the love of the Cyclops, Polyphemus, for the sea nymph Galatea; another is about Hercules and Hylas. Two others are eulogies on Hiero, lord of Syracuse, and on Ptolemy Philadelphus, king of Egypt. Number XIX is a very brief poem that tells how a bee stung the little god Eros; and several others are probably spurious.

Perhaps the most famous are the 1st, 2d and 15th. The first because of the 'Lament for Daphnis,' which served as a model for Bion's 'Dirge of Adonis,' for Milton's 'Lycidas,' for Shelley's 'Adonais' and Matthew Arnold's 'Thyrsis.' The second, in the opinion of Sir Gilbert Murray, is «realistic, beautiful, tragic, strangely humorous and utterly unforgettable, and has remained a unique masterpiece in literature.» The 15th is probably the most interesting to English readers; it is certainly the most entertaining. Matthew Arnold calls it «one of the best and happiest of Theocritus's idyls.» It is really a little play, of which the two chief dramatis personæ are Syracusan women, living in Alexandria. One comes to get the other to go with her to a notable religious celebration in honor of Adonis, which the queen of Egypt has arranged with unusual magnificence. The celebration is to be in the palace, where a beautiful picture of Adonis is to be exhibited and a famous prima donna is to sing a hymn to Aphrodite and Adonis. The two women and their maids make their way through the crowded streets, squeeze into the palace with difficulty and hear the hymn. The scene is most lifelike.

And it is mainly this quality of lifelikeness that, in the bucolic idyls, distinguishes Theocritus from Virgil and all his other imitators. We need not suppose that Sicilian shepherds really spoke as Thyrsis and Daphnis speak, or even like the less elegant Battus and Corydon. But Theocritus uses language not too far from truth and depicts the Sicilian country, with its flowers and rustic objects, in a realistic way; whereas his imitators are all artificial, and many, especially during the Renaissance, ridiculously so forsaking all semblance of reality. The scenes in which their Phyllises and Corydons make love or lamentation might well be in Marie Antoinette's drawing room; but his shepherds drive their flocks afield in the meadows near Girgenti, or over the plains of Catania.

No translation of Theocritus can give more than a rude idea of the original. Strictly speaking, poetry cannot be translated; and in a translation of Theocritus not only is the music gone, but his words are so accurately chosen that the foreign equivalents are merely makeshifts. For English readers perhaps the best translation of the 15th idyl is that in Matthew Arnold's essay on 'Pagan and Mediæval Religious Sentiment,' and for the other idyls, the prose versions by Andrew Lang. Edmund Clarance Stedman translated four, the I, X, XIII and XIX, following the hexameters of the originals. Many other translators in prose and verse have tried their hands, and some with a reasonable measure of success.

Bion is an imitator of Theocritus. Little that he wrote remains: there is the 'Dirge of Adonis,' half a dozen short idyls and some fragments; he himself is a shadow. From the poem, a 'Lament for Bion,' attributed to Moschus, it appears that Bion was born in Asia Minor near Smyrna, and possibly that he traveled in Thrace and Macedonia, also that he lived in Sicily and died by poisoning, and that Theocritus mourned him. But modern criticism denies that the 'Lament' was written by Moschus, denies the story of poisoning, and puts Bion about 150 B.C. The 'Dirge of Adonis' is by far the most celebrated of his poems; for if the earliest suggestion for 'Lycidas,' 'Adonais' and 'Thyrsis' comes from the 'Lament for Daphnis,' it certainly comes by way of the 'Dirge of Adonis.' The poem is a lament by Aphrodite over the dead Adonis; in part it is passionate to frenzy, with an element of Asiatic extravagance, but in other parts florid, pretty, elegant and artificial. His other poems, for the most part, are love songs, delicate, sweet and elegant.

Moschus seems more shadowy still. His fame is united to that of Theocritus and Bion, as one of the three chief pastoral poets of Sicily; and this union in renown has been strengthened by the common practice of publishing their works together. To Moschus were usually attributed six or seven idyls, 'Eros,' 'The Runaway,' 'Europa,' the 'Lament for Bion,' 'Megara, the Wife of Hercules,' and others. The 'Lament for Bion' is the poem on which his fame has chiefly rested. It represents the poet as Bion's pupil, and is framed upon the models of the 'Lament for Daphnis' and the 'Dirge of Adonis,' it is pathetic, delicate and imaginative. But the style is too ornate to befit a contemporary of Theocritus, and seems to prove that the poem belongs to a later age. Modern criticism, therefore, takes away its authorship from Moschus and that of the *Megara* as well. Moschus himself is now believed to have lived at Syracuse about 150 B.C. The authoritative text of 'Bion and Moschus' is that by U. von Wilamowitz-Möllendorff, 'Scriptorum Classicorum Bibliotheca' (Oxford 1905).

No translation of any of these poems gives more than a rough and ready idea of the original. The more imaginative the poet, the more delicate his workmanship, the less the translator can imitate him. This is as true of Bion and Moschus, or whoever wrote the 'Lament for Bion,' as it is of Theocritus.

HENRY D. SEDGWICK,
Author 'Essays on Great Writers,' etc.

THEODICY, a term of Leibnitzian philosophy, in which the existence of physical and moral evil is made reconcilable with the existence of a righteous God, the controlling providence of the best of possible worlds. See LEIBNITZ.

THEODOLITE. See SURVEYING.

THEODORA, thē-ō-dō'rạ, Byzantine empress consort of Justinian I: b. 508 A.D.; d. 548. She was, according to the dubious evidence of Procopius, the daughter of Acacius, a bear-ward at Constantinople, and had already been by turns actress, dancer and harlot, when she won the heart of the austere and ambitious Justinian, to become in succession his mistress, his wife and the sharer of his throne (527). Never thereafter did the breath of scandal touch her name; she became Justinian's trustiest counsellor, bore a chief share in the work of government, and saved the throne by her high courage at the crisis of the Nika riots (532). «Now every man must die once,» said she in council, «and for a king death is better than dethronement and exile. . . . If you wish, O emperor, to save your life, nothing is easier; there are your ships and the sea. But I agree with the old saying that 'empire is the best winding-sheet.'» She lavished her bounty on the poor. Consult Débidour, Antonin, 'L'Impératrice Theodora' (Paris 1885); Diehl, Charles, 'Justinien et la civilization byzantine au sixième siècle' (Paris 1901); id., 'Théodora, impératrice de Byzance' (3d ed., Paris 1904); Gibbon, Edward, 'Decline and Fall of the Roman Empire' (ed. by J. B. Bury, Vols. IV and V, 1912); Mallet, C. E., 'The Empress Theodore' (in *English Historical Review*, Vol. II, London 1886).

THEODORE I, thē'ō-dōr, of Corsica, otherwise Baron Theodore de Neuhoff, German adventurer: b. Metz, about 1686; d. London, 11 Dec. 1756. He was the son of a Westphalian nobleman and engaged in the French, Swedish and Spanish service successively. In 1732 he went to Florence as chargé-d'affaires for Emperor Charles VI, and taking part in a Corsican uprising against Genoa through funds furnished by the Bey of Tunis, was proclaimed king of Corsica in 1736. Soon after, however, he was driven to flight, but made two subsequent attempts to reinstate himself in 1738 and in 1743. In 1749 he settled in London, where his creditors put him in prison; but his release was gained through the support of Walpole. By his wife, an Irish lady whom he robbed and deserted, he had one son known later as Colonel Frederick, author of 'Memoires pour servir à l'historic de Corse' (1768) Consult Fitzgerald, 'King Theodore of Corsica' (London 1890).

THEODORE II, or NEGUS, king of Abyssinia: b. province of Kwara, 1818; d. Magdala, 14 April 1868. Originally named Kasa or Kassai, he led a revolt in 1854 against Ras Ali, ruler of Abyssinia, whom he defeated. Later he was crowned, under the title of Theodorus, king of kings, of Ethiopia. He was a man of strong personality, an enemy of Islamism, a ruler and a reformer. He became intolerant of any power other than his own and with the quick suspicions of a barbarian took offense at what he considered as slights. His quarrel with Great Britain was brought on by the injudicious conduct of the English consul, Captain Cameron, sent to him in 1861 and by the failure of the English government to respond to his overtures regarding the reception of his Ambassador at the English court. He finally imprisoned Cameron and also Hormuzd Rassam, a Turk but an English subject, sent to treat with him concerning Cameron's release. As a condition of setting the prisoners at liberty Theodore requested that certain skilled artisans be sent him, together with presents that he had been led to expect. The English detained the artisans and presents at Massowah, awaiting the release of the prisoners; but as they were not delivered up, war was declared, and an expedition under Sir Robert Napier began a progress toward Magdala in the latter part of 1867. The city was reached, and active hostilities began on 10 April 1868. On the 14th the city was taken and Theodore was found dead. The besiegers were informed that he had committed suicide. See ABYSSINIA and consult *Westminster Review*, New Series, No. 65.

THEODORE OF MOPSUESTIA, Greek ecclesiastical writer: b. Antioch, about 350; d. 428. He studied rhetoric under Libanius, philosophy under Andragathus and sacred literature under Flavianus of Antioch, Diodorus of Tarsus and others. Early in life he followed the example of his fellow-student and intimate friend, John Chrysostom, in turning monk, although he had been on the point of marrying a lady of Antioch named Hermione. After being ordained priest he distinguished himself as an opponent of Arius Apollinaris and others. From Antioch he removed to Tarsus and in 392 was chosen bishop of Mopsuestia in Cilicia. In 394 he preached before the Emperor Theodosius at Constantinople and was present at the council held in that city at that date. He was a voluminous writer, the most important of his works being commentaries on the Bible and polemical treatises. These were held in great repute among the Syrian churches and many of them were translated into Syriac, Arabic and Persian. His views approximated to those of Pelagius, and Nestorius was to be his disciple. In the Eastern Church, accordingly, he was condemned as a heretic at the Fifth Ecumenical Council, held at Constantinople 553. For fragments of Theodore's works consult Migne, 'Patrologia Græca' (Vol. LXVI. Consult also Harnack, A., 'History of Dogma' (Vols. III, IV; Boston 1898); Kihn, H., 'Theodore von Mopsuestia' (Freiburg 1880); Wace and Piercy (eds.), 'Smith's Dictionary of Christian Biography' (Boston 1911); Wright, W., 'Syriac Literature' (London 1894).

THEODORET, thē-ŏd'ō-rĕt (Greek, Θεοδώρητος), church historian and theological writer: b. Antioch, late in the 4th century; d. 457. He was educated in a monastery near Antioch, where he had Nestorius and John of Antioch for fellow-pupils. After 25 years' study and retirement he succeeded Isidorus (423) as bishop of Cyrus, a city about two days' journey from Antioch. He endeavored to play the part of mediator between Nestorius and Cyril of Alexandria, but could effect no reconciliation. In 431 Nestorius was deposed by the Council of Ephesus, an act which Theodoret at first protested against, but later on excused. When the Nestorians were prosecuted with relentless severity, he stood forth as the champion of Nestorius against Cyril and his successor Dioscurus. The latter accused Theodoret of Nestorianism, pronounced a public anathema upon him in the church of Alexandria and (449) procured his deposition at the so-called robber council of Ephesus, a sentence which was reversed by the general council of Chalcedon (451). The most important of his works, of which a complete edition was published by Schulze and Nösselt (1769–74), consist of commentaries on the Old Testament and on the Pauline epistles; 'Ecclesiastical History,' in five books, beginning with the history of Arianism under Constantine the Great and ending with the death of Theodore of Mopsuestia; 'Religious History,' a narrative of the lives of the hermits, called the Fathers of the Desert; 'Eranistes,' three dialogues against the Eutychians, and 'History of Heresies.' Consult Binder 'Études sur Théodoret' (Geneva 1844); 'Gaisford, 'Theodoreti Historia Ecclesiastica' (1854); Harnack, A., 'History of Dogma' (Vol. IV, Boston 1898); 'The Nicene Fathers' (ed. by Schaff and Wace, Vol. III, New York 1892).

THEODORIC I, thē-ŏd'ō-rĭk, king of the Visigoths. He was chosen successor to Wallia about 419 A.D., and became desirous of extending his kingdom, especially so as to embrace the neighboring Roman cities of Arles and Narbonne. For this purpose he made war against the Romans after the death of Honorius in 423 and continued with varying results until 437, when he entered into an alliance whose exact terms are unknown. By 450 he came into closer alliance with the Romans in the endeavor to check the advance of Attila, who led his barbarian army across Lorraine and Champagne and captured the city of Orléans. Theodoric and Aëtius, the Roman general, encountered Attila near the village of Moirey, a few miles from Troyes, and fought the battle generally known in history as that of Châlons-sur-Marne, in 451. Theodoric was killed by an arrow; but the progress of Attila was checked and western Europe was saved from the domination of barbarism.

THEODORIC II, son of Theodoric I. He was a member of the party who wished to remain on terms of peace with Rome and when his brother, Thorismund, who had succeeded Theodoric I, began to levy war against the Romans he took part in a rebellion that ended in the murder of Thorismund and his own elevation to the throne. As vassal of the Roman emperor Avitus he made an expedition against the Sueves, conquered and put to death their king and was in a fair way of completing the conquest of Spain, when Avitus was deposed and killed and Theodoric ceased his efforts. In 466 he was murdered by his younger brother, Euric.

THEODORIC THE GREAT, king of the Ostrogoths: b. about 454; d. 526. His father, Theodemer, was one of the three brothers who jointly ruled the Ostrogoths settled in Pannonia, and he sent him, when only eight years of age, to Constantinople as a hostage, to secure the conditions of a treaty between the Goths and the Emperor Leo. After residing 10 years with that emperor he was restored to his father, then sole monarch of the Ostrogoths. On the death of Theodemer, about 474, he succeeded to the crown and began a course which, after menacing the safety of the Greek empire, and Constantinople itself, terminated in an expedition against Odoacer, who had assumed the title of king of Italy. After several bloody engagements the latter was finally induced to yield, on condition that he and Theodoric should govern Italy with equal authority (493). The murder of Odoacer at a banquet soon followed this agreement; on which Theodoric caused himself to be proclaimed king of Italy, and he governed with extraordinary vigor and ability. He attached his soldiers by assigning them a third part of the lands of Italy, on the tenure of military service; among his Italian subjects he encouraged industry and the arts of peace. He improved the administration of justice, issued edicts to protect the public monuments at Rome and elsewhere, and assigned revenues for the repair of the public edifices. Like his ancestors he was an Arian, but was indifferent to controversy and never violated the peace or privileges of the Roman Catholic Church. The particulars of the government of this memorable prince, who shed a short-lived lustre on the Gothic name, are recorded in 12 books by his secretary, the senator Cassiodorus, a man of learning, who induced his illiterate master to become a patron of letters. The senators Boethius and Symmachus were both put to death on the mere suspicion of an intrigue between a senatorial party and the imperial court. This cruel act had no sooner been perpetrated than Theodoric was seized with remorse, and a fever ensued, which terminated his life in three days. The ordinary residence of this king was at Ravenna, above which city his daughter Amalasuntha erected a splendid monument to his memory. Consult Dahn, Felix, 'Die Könige der Germanen' (Vol. III, Würzburg 1866); Gibbon, Edward, 'Decline and Fall of the Roman Empire' (Vol. IV, ed. by J. B. Bury, London 1912); Hodgkin, Thomas, 'Ostrogothic Invasion' (in 'Italy and Her Invaders,' Vol. III, London 1885); id., 'Theodoric the Goth' (New York 1893).

THEODOSIA. See FEODOSIA.

THEODOSIUS (thē-ō-dō'shĭ-ŭs) **THE ELDER,** Roman general: d. Carthage, 376. He was the father of the Emperor Theodosius I (q.v.), called «The Great.» By birth a Spaniard, he rose to high rank in the Roman army and in 367 was sent by Valentinian I to Britain, where he repelled the invasions of the Picts and Scots, strengthened the military defenses and restored order. He formed the country between Hadrian's wall and the Forth and Clyde into a new province, which he named Valentia, and then returned to Rome. He was later stationed on the Upper Danube, where he was victorious over the Alemanni, and in 372 he quelled the revolt in Africa led by the formidable Moorish chieftain Firmus. He was beheaded at Carthage in 376 by order of Valens, on some unknown and probably unjust charge.

THEODOSIUS (surnamed THE GREAT), Roman emperor: b. Spain, about 346; d. Milan, 17 Jan. 395. At a very early age he obtained a separate command; but on the execution of his father he sought retirement, until selected by the Emperor Gratian, in 379, for his partner in the empire. To his care were submitted Thrace and the eastern provinces, which he delivered from an invasion of the Goths, whom he signally defeated in two battles, concluding a peace with them in 382. On the defeat and death of Maximus at Aquileia (388) he became the sole head of the empire, Gratian having been previously killed in the war against Maximus. He administered the affairs of the West in the name of Valentinian, the son of Gratian, then a minor. He entered Rome in triumph in 389, and passed three years in Italy. In 390 a sedition took place in Thessalonica, which resulted in the murder of the governor and several of his officers. The resentment of Theodosius was natural and merited; but the manner in which he displayed it was in the highest degree detestable and inhuman. An invitation was given in the emperor's name to the people of Thessalonica to an exhibition at the circus, and when a great concourse of spectators had assembled they were massacred by a body of barbarian soldiery to the number, according to the lowest computation, of 7,000. Theodosius was at this time at Milan, of which Saint Ambrose was bishop, and this prelate, on account of such an atrocious proceeding, resolutely refused him communion for eight months. About this time the emperor crowned his merits, as a foe to paganism, by demolishing the celebrated temple of Serapis and all the other heathen temples of Egypt, and he issued a final edict prohibiting the ancient worship altogether. On the murder of Valentinian by Arbogastes and the advancement of Eugenius in his place (392), the emperor carried on a war against the latter, which finally terminated in his defeat and death. Theodosius did not long survive this success. Consult Gibbon, 'Decline and Fall of the Roman Empire' (London 1912); Hodgkin, T., 'Italy and her Invaders' (Oxford 1892).

THEODOSIUS II, Roman emperor, son of Arcadius and grandson of Theodosius I: b. 401; d. 450. He became emperor in 408, but proved a weak ruler, and the actual government was in the hands of his sister and of his wife during the greater part of his reign, in which the Theodosian code of laws was compiled. He was killed by a fall from his horse and was succeeded by his sister, Pulcheria.

THEODOSIUS III, emperor of Constantinople. He held the unimportant post of collector of the revenue when he was nominated to succeed Anastasius, and he was crowned in 716. He resigned in favor of Leo the Isaurian in 717 and retired to a monastery. Consult Gibbon, E., 'Decline and Fall of the Roman Empire' and 'Cambridge Mediæval History' (Vol. I, New York 1911).

THEOGNIS (thē-ŏg'nĭs) **OF MEGARA,** Greek elegiac poet. He lived between 540 and 500 B.C. There are 1,389 verses preserved under his name, of importance in enabling us to understand the state of parties and the problems of society in the Greece of that time. They were translated by Frere (1842) and are found in the original in Bergk's 'Poetæ Lyrici Græci.'

THEOGONY, a poem treating of the generation and descent of the gods. The most ancient Greek theogony known to us is that of Hesiod, the earlier Theogonies of Musæus and Orpheus having perished.

THEOLOGICAL DETERMINISM. See DETERMINISM.

THEOLOGICAL EDUCATION. See EDUCATION, THEOLOGICAL.

THEOLOGICAL SEMINARY OF THE REFORMED CHURCH OF AMERICA, New Brunswick, N. J., originally located in New York City from its organization (1784), afterward at Flatbush, L. I. (1796), was established on the present site in 1810. The general Synod conducts it and it now has an endowment of nearly $1,000,000. Its buildings include the Peter Herzog Hall for dormitory purposes; the James Suydam Hall, used for lecture rooms, gymnasium and museum, and the Gardner A. Sage Library which contains nearly 60,000 volumes. There also are several buildings for the teaching force.

THEOLOGY, the science of religion. This term, together with the corresponding personal term, antedates the Christian era, having been used by classic writers both Greek and Roman. In the view of Aristotle, Cicero and others the man who appeared to be specially conversant with the divine nature was fitly called a theologian. Among those honored with this name were Pherecydes of Syros and Epimenides of Crete.

Definition and Scope.— In the modern use of the term a narrower and a broader signification may be distinguished. The former, paying special respect to the etymology of the word, includes in theology simply discourse about God. It was in this restricted sense that the word was employed by the classic writers and a corresponding usage had place in the first Christian age, when, for example, the evangelist, John, on the ground of his relatively full reference to the divinity of the Christ, was called «the theologian.» It was understood that the subject matter of theology pertains to such transcendent themes as the Logos and the Trinity. In the broader signification theology includes not only discourse about God, but also an exposition of whatever in man's nature seems to bring him into distinct relation with God; likewise an exposition of whatever in man's experience and destiny may be regarded as founded on this relation. In this sense it is the theoretical counterpart of religion, and corresponds very well to the following description by Gladstone: «Theology is ordered knowledge, representing in the region of the intellect what religion represents in the heart and life of man.» While resort is still occasionally made to the restricted sense, as when, for instance, theology is put in antithesis with anthropology, the broader signification is far more commonly the one intended in current usage. It is evidently, therefore, the signification which should give the standard for the present discussion.

In a precise determination of the scope of theology a question will arise, in the first place, as to the measure of consideration which it is appropriate to bestow upon the ethnic religions. Manifestly, if theology is the theoretical counterpart of religion, it will not do to neglect so large an area of religious facts as is included in the ethnic systems. A secure and well-rounded theory of religion must take account of all accessible religious facts, whether inside or outside of the pale of historical Christianity. At the same time it is to be noticed that the central tenets of Christianity, as they appear in the sacred oracles and have generally been held, unmistakably presume upon the pre-eminence and finality of the Christian religion. Anyone, therefore, who regards himself as scientifically obligated to accept these tenets, on the score of a clear preponderance of evidence in their behalf, will of necessity be convinced that he fulfils the demands of a scientific theology in taking subordinate account of the ethnic systems, that is, so far as respects formal recognition of them within his own theological structure. It is not needful, indeed, that he should deal with these systems in a tone of radical disparagement. As a matter of fact, the industrious research which for the last quarter of a century or more has been bestowed upon the great ethnic religions, such as Zoroastrianism, Buddhism, Brahmanism and Confucianism, has served distinctly to enlarge appreciation for their contents. At the same time, the farther this research has proceeded the more indubitable has it made the proof that Christianity has no occasion to look to any outside religious province for an appreciable supplement to its teachings. The conclusion follows that the Christian theologian deals normally with the ethnic systems when he simply accords to them a place in branches auxiliary to some of the main divisions of theology. In so far as they have modified Christian history they make matter for a branch auxiliary to historical theology. In so far as they supply data for a philosophy of religion they help to constitute a branch auxiliary to systematic theology.

A second important question under the theme of scope or province concerns the relation of theology to philosophy. That the one is under practical compulsion to enter the domain of the other is apparent upon both rational and historical grounds. Their tasks are closely related. Philosophy may be defined as an attempt to get at ultimate truth by rational processes. Theology attempts, within limits, the same thing. It undertakes to get at ultimate truth in so far as that truth has religious worth or significance. Theology may enter upon its task with a more positive presumption in favor of written revelation than that which belongs to the philosophical starting-point. Still, if it is to maintain a scientific character, it cannot take that presumption as a mere matter of course. On the contrary, it must treat the same as a subject for searching inspection. Now this inspection will naturally lead sooner or later to the great problem of the conditions of rational certainty. Thus the initial task of theology in approving or rating the authority of sacred oracles conducts into a province of philosophical inquiry. And what occurs at this point is repeated at various other points. The development of the deeper themes of theology involves in general a use of philosophical premises, either metaphysical, psychological or ethical. A veto against such use is impotent. A Tertullian may exclaim, "What has Athens to do with Jerusalem? What concord is there between the Academy and the Church?" But before the echo of his voice has died away he will be likely to get onto the ground of Athens, and to be borrowing from the Academy or some kindred source. From beginning to end Christian history testifies to the tendency of theological construction to utilize philosophical points of view. Among the early Fathers the more speculative were manifestly influenced by the Platonic philosophy. A little later the Neo-Platonic philosophy became an appreciable factor in theological thinking, and through the writings of the pseudo-Dionysius was introduced to the thinkers of the mediæval period. At the crowning period of mediæval scholasticism Aristotelianism was decidedly in the ascendant, insomuch that Aristotle was often cited under the simple designation of "the philosopher." In the modern period the Cartesian philosophy, the Leibnitz-Wolffian, the Lockian, the Kantian, the Hegelian and others have unmistakably claimed spheres of influence in the theological domain. It appears, therefore, that a discreet choice of philosophical affiliations is the best that theology can do. It may enter into too close an alliance with a specific philosophy. It may fail to observe the due balance between a speculative bent and a sane regard for historical data. But it will and must draw largely from the resources of philosophy if it is to be fundamental and comprehensive.

A further question on the scope of theology concerns the relation of this branch to the domain of natural science. That a relation obtains to which a measure of significance may be attached is undeniable. It is not to be overlooked, however, that the field of natural science comes into less extensive contact with theology than does the field of philosophy. In so far as science moves in a physical or sub-human range, it touches upon matters that are of only subordinate theological import. It may enforce a revision of the theory of creation which has been read into or elicited from the biblical narrative; but of how small theological consequence is a conclusion on the precise method of creation, so long as God in his absolute supremacy and man in his dignity and worth are left to the contemplation! It may enlarge the view of the operation of secondary causes in the production of organic forms, and so may require some modification of the putting of the argument from design; but that involves no challenge to any theological tenet or interest, since the vast range of orderly results in nature must still be seen, as many of the most eminent naturalists confess, to demand ultimately an ordering intelligence. In short a close scrutiny of the subject will reveal that the findings of the physical sciences can neither displace the foundations of the central tenets of theology nor supply foundations to these tenets. Their function is exhausted in modifying one and another peripheral matter or adjunct of the theological system. Probably the greatest result which has come from that quarter is an offspring of the doctrine of evolution and consists in an enlarged tendency of the theological mind to expect, in relation to the kingdom of God in the world, tokens of the law of consecution and graduated progress. Undoubtedly the theologian does well to take note of the approved findings of natural science; but large expectations of contributions from that quarter are not likely to be fulfilled. It is in the constitution and experiences of man, and in the philosophical interpretation of both the world of nature and of personality, that theology must find its principal basis. Among the human experiences that come into the account those which make up the substance of sacred history may of course claim a distinct primacy. In other words, the Bible may be rated as the foremost treasury of theological data.

Scientific Value and Rank.— One and another system of theology, as actually developed, may be remote from a scientific character. But intrinsically scientific construction is just as feasible and appropriate in the field of theology as in any other field. Where a contrary impression has obtained it has generally been due to one of three causes. Either the agnostic maxim that religion has the unknown for its proper field has been adopted, and in consequence theology, as the theoretical side of religion, has been pictured as devoid of substantial foundation; or theology has been associated with arbitrary authority; or a strained antithesis between reason and faith has been contemplated.

As respects the maxim which embodies the first of these grounds of objection, it must be pronounced a gratuitous negation of religion. It is a negation of religion, for sheer mystery offers no means of attachment. In the words of Pfleiderer, «a religion of nothing but mystery is an absurdity.» The maxim is also perfectly gratuitous. As John Fiske has said: «None can deny that religion is the largest and most ubiquitous fact connected with the existence of mankind upon earth.» Is so vast a department of human experience to be regarded as utterly incompetent to supply any valid grounds of induction? Are the concurring thoughts, aspirations and satisfactions of the elect spirits of the race to be rated as void of all rational suggestions? Is no sure basis of conviction to be found in the illuminated and transcendent consciousness of the Christ? Such questions need no formal reply. Theology doubtless has a great border-land of mystery. And so has biology. Indeed it is characteristic of most of the sciences that they impinge upon mystery. Alongside a domain of certainty they include areas which can claim at best only a high degree of probability. On the score of mystery, therefore, no good reason is apparent for expelling theology from scientific fellowship.

The second ground of objection of the scientific character of theology is sufficiently met by the affirmation that arbitrary authority is an interloper in the theological domain. If it has ever installed itself there, it has been in the exercise of rank usurpation. Theology in its true character has no partnership with arbitrary authority. While it may make large account of positive revelation, it does not turn that revelation into a fence against investigation but uses its content for what it proves itself to be under the tests of mental scrutiny and prolonged application to the exigencies of man's deeper life.

To the third objection a reply of similar tenor is to be made. The assumption of an antagonism between reason and faith, and of an obligation to sacrifice the former to the latter, is an assumption which a sane theology must emphatically repudiate. It is very true, doubtless, that reason cannot take the place of faith any more than theory can take the place of action. But it is equally true that faith cannot endure to be in known antagonism to reason. An assent which, from the standpoint of the one rendering the same, does not appear to be sanctioned by reason, is no real assent. Only that which is competent to take captive man's rational personality is able to induce a faith that is anything more than a sham or a shadow. Quite as much as any other branch of learning theology is free to emphasize the demand for rationality in faith. The challenge to its scientific character is thus seen to fail as respects each of the cardinal objections mentioned.

In an unbiased valuation of theology too rigid an association will not be made between substance and form. Integrity of substance is compatible with a variety of forms. Theology in no wise rebels against a poetic garb. Far as are the picturesque discourses of Jesus from the scholastic form, they are deeply based in theology. Filling all their background is one of the most pronounced conceptions of God, as well as the most beautiful that was ever set before the contemplation of men. All religious discourse which is to avoid the charge of emptiness and impotency must in like manner enclose a substantial theological content. As Phillips Brooks has said, «No exhortation to a good life, that does not put behind it some truth as deep as eternity, can seize and hold the conscience.»

Even in its formal character theology may be rated as second in interest to no department of thought and study. The facts and truths with which it more directly deals are the deepest in man's being and the highest above the human plane. It utilizes the most significant findings of a large proportion of the branches of learning. It takes into consideration the greatest treasures of past history, and gathers up the data for the farthest possible outlook into future destiny. It gives ample room for speculative acumen, but at the same time includes the themes that are of all the most intensely practical.

The Organic Arrangement of Subject Matter.— The best arrangement of the several divisions and branches of theology is obviously the one which is characterized by simplicity as well as by comprehensiveness and self-consistency. The very subtle scheme is likely to please its inventor in a much higher degree than the theological world at large. Among plans of arrangement which meet in good measure the combined demands of simplicity and comprehensiveness those of Heinrici and Hagenbach are worthy of special mention. The former draws a distinction between «historical» and «normative» branches, the one being made to include the specifically biblical branches as well as the history of Christianity since biblical times, and the other comprising, as principal subdivisions, Systematic Theology and Practical Theology. The idea of the historical branches is to exhibit the whole deposit of religious truth and fact; the idea of the normative branches is to afford means of guidance in religious teaching and work. That there is a certain fitness in the distinction between the two lines of study is undeniable. Still the distinction is not beyond criticism. One who accredits a high degree of authority to the Bible may well be reluctant to exclude the designation of «normative» from one and another biblical branch. Especially may he hesitate to exclude that designation from Biblical Dogmatics. In view of this ground of exception to Heinrici's nomenclature the plan of Hagenbach — which divides the whole theological domain between Exegetical, Historical, Systematic and Practical Theology — may be regarded as having at least an equal claim to appreciation. Aside from its intrinsic merits, a motive for giving this plan the preferred place in the present connection is found in the fact that it is very largely reflected in the curricula of theological institutions.

Each of the divisions in the fourfold scheme of Hagenbach contains a somewhat indeterminate number of specific branches. A measurably complete list for Exegetical Theology may be given as follows: (1) Biblical Philology or Linguistics, which treats not only of the biblical languages, but also of languages so far cognate with the biblical as to be able to furnish means of understanding the peculiarities of the latter. (2) Biblical Archæology or the science of Biblical Antiquities. (3) Canonics, or the branch which gives the history of the canon, or collection of sacred books, and also the principles which enter into the determination of the proper compass of that collection. (4) Biblical Criticism, which in one division is textual, and in another literary and historical. The former seeks to ascertain the true and original text; the latter is occupied with the investigation of the biblical books for the purpose of ascertaining their authorship, their date, their relation to other writings, canonical or uncanonical, the degree of their historical trustworthiness and the special stage which any one of them may represent in the development of the biblical religion. The two forms of criticism are frequently distinguished as the Lower and the Higher. (5) Biblical Introduction, in which the fruits of criticism are utilized for a more or less detailed characterization of each of the two Testaments and also of the individual books which they contain. (6) Hermeneutics, or the science of biblical interpretation. (7) Exegesis, or the presentation in detail of the results of an examination into the meaning of biblical texts.

Historical Theology includes in its biblical part the following divisions: (1) Old Testament History; (2) the Life of Christ; (3) the History of the Apostolic Age; (4) Biblical Theology of the Old Testament; (5) Biblical Theology of the New Testament. Etymologically considered Biblical Theology might denote other than a historical branch, being taken as the equivalent of Biblical Dogmatics. But as actually treated it is a historical discipline, its object being to set forth the genesis of doctrine and its movements through the various stages which may be discerned in the Old and the New Testament respectively. In its post-biblical part Historical Theology falls into two main divisions, General Church History, and the History of Christian Doctrine. The former admits of a great number of subdivisions, it being possible to award a monographic treatment to such themes as missions, polity, discipline, worship, and art. In its earlier section General Church History includes in particular Patristics and Christian Archæology, of which the former gives an account of the lives and writings of the fathers (usually of the first six centuries), and the latter furnishes a systematic presentation of monumental and documentary evidence on the art, institutions, rites, customs and characteristic modes of thought and feeling in the early Christian community. To the History of Doctrine the most important subsidiary branch is Symbolics, or that which treats of the creeds. As an auxiliary branch the History of Philosophy takes the first rank.

Systematic Theology, which has, in its Christian character, the office of furnishing an orderly presentation and justification of the whole body of teachings or beliefs which belong to the Christian religion, includes three principal branches, namely, Apologetics, Christian Dogmatics and Christian Ethics. It may also include Biblical Dogmatics, Polemics and Irenics, though the subject matter covered by these titles can conveniently be appropriated within other branches. An auxiliary to Systematic Theology of special significance is found in the Philosophy of Religion. Of the several branches named, Christian Dogmatics is so far central and prominent as often to be styled Systematic Theology. Being free to gather its evidence from every field, and aiming to present in organic form the whole doctrinal content of the true religion, it commands in the field of theology the maximum intellectual interest.

In Practical Theology the leading branches are Liturgics, Homiletics and Pastoral Theology. The last-named is of wide compass, including besides the general theme of pastoral care such subsidiary branches as Catechetics, Ecclesiastical Polity, Ecclesiastical Discipline, and Theory of Missionary Work. Recently the interest in sociological study has created a motive to subjoin a branch which might be entitled Christian Sociology.

Prominent Stages and Representatives.— In the broad view three great epochs in the progress of theology are distinguishable, namely, the Greek, the Latin and the Modern. The last might also be called with relative propriety the Protestant, since the motive-power for its developments has been supplied in large part from within the domain which bears that title. The development of the Latin type was in part contemporary with the shaping and manifestation of the Greek type; still the former appears clearly second in order, since its initial stages were synchronous with the culminating stages of the latter. Greek theology had run its course and come essentially to a standstill before the more characteristic systems of Latin theology were elaborated by the mediæval scholastics. The two undoubtedly had very much in common. The same great creeds were acknowledged in the Latin as obtained in the Greek division of Christendom, and the dogmatic grounds which were alleged ultimately for the severance of fellowship were of subordinate import. Still Greek theology stood in measurable contrast with Latin. It took on the whole a more genial view of the divine relation to the non-Christian world. It was less inclined to a sombre conception of man's native guilt and moral impotency. It accentuated to a special degree the thought of a divine incarnation and of the intimate connection between God and man provided for by means of the incarnation. The same thought was by no means foreign to Latin theology, but in its domain it was given, relatively speaking, less prominence, since it was made to share the field with the greatly emphasized conception of divine rulership. The standpoint of the one affiliated with a mystical theory of an interior life; the standpoint of the other was more legal and governmental. Both admitted the ideas of priestly mediation and sacramental efficacy, at least after the initial stage; but it accorded with the genius of Latin theology to work out the most consummate expression of these ideas in a thoroughly elaborated hierarchical and sacramental system. In the one authority came to be regarded as specially resident in the creeds and formularies of the past, in the other great prominence came to be assigned to the hierarchy, and especially to its head, as the perpetual embodiment of infallible authority. While this line of contrasts may legitimately be affirmed, it is to be understood that one and another point of difference cannot be taken too strictly, since in neither the Latin nor the Greek domain was theological thinking entirely uniform or homogeneous.

The Protestant era was initiated in a revision of the principle of authority which had been transmitted in Latin Christianity; and a fundamental feature of the theological activity of that era has consisted in carrying out this revision to its logical results. Original Protestantism accepted in common with the Latin communion the great outlines of doctrine contained in the ancient creeds, especially the Nicene and the Chalcedonian. But it accepted them upon a revised basis. What was that basis? In the last analysis it must be defined as the principle of free rational induction, in opposition to the principle of judicial determination by official authority. The primary appeal was indeed to the scriptural content and to the doctrine of justification by faith. But since no infallible tribunal was set over the Scriptures, the appeal thereto amounted practically to a transference of the main emphasis to the free rational process. As respects the doctrine of justification by faith, it looked evidently in the same direction, since it profoundly qualified the necessity of priestly mediation or of dependence upon the hierarchy. The assertion of this revised conception of authority, it is needless to say, was not designed to imply any challenge to the idea of supernatural revelation. Logically, too, the Protestant principle involves no necessity to challenge that idea. What it shuts out is official monopoly of revelation and authoritative determination of its import by official prerogative. In place of this it installs, as the proper ground of theological convictions, free rational induction, an induction which, to be properly carried out, must take full account of the data of history, reason and experience. The advocates of the Protestant principle admit the great difficulty of the task of ideal theological construction on the basis of that principle; but it is their conviction that exemption from the labor of a thorough-going induction ought not to be sought in the religious sphere any more than in other spheres. The seeking of relief in the attachment of infallible authority to some perpetual office in the Church they regard as quite useless and mistaken, since it is less difficult to accredit, on the basis of history, reason and experience, any worthy element of belief, than it is to prove the continuous existence of an infallible tribunal.

In a closer review of the progress of theology it would be necessary to notice a number of significant developments in each of the great epochs mentioned. Account would need to be taken of the peculiarities of the early Alexandrian, the Cappadocian, the later Alexandrian and the Antiochian schools in the Greek Church. In relation to the Latin Church attention would need to be given to the long history of the antithesis between Augustinian and anti-Augustinian tendencies; to the struggle between Jansenism and Jesuitism; to the conflict between Gallicanism and Ultramontanism. Within the Protestant domain there would be occasion to consider the early creative period of the Lutheran theology; the scholastic period in the 17th century; the Pietistic and Rationalistic movements in Germany; the implication of Lutheran theology with successive philosophies since the dawn of the 18th century; the controversies between Calvinism and Arminianism; the contrasts between High Church, Low Church and Broad Church parties in the Anglican Establishment; the wide-reaching tendencies born of the Wesleyan revival; the initiation in Germany of the great movement of biblical criticism and its extension to other countries; and the rise and influence of the Ritschlian theology.

Among theological writers eminent for their representative position, or breadth of influence, or both, we may specify, in the Greek Church, Origen, Athanasius, Basil, Gregory Nazianzen, Gregory of Nyssa, Cyril of Alexandria, Theodoret and John of Damascus; in the Latin or Roman Church Augustine, Anselm, Peter Lombard, Alexander Hales, Albertus Magnus, Thomas Aquinas, Bonaventura, Duns Scotus, Suarez, Bellarmin, Petavius and Perrone; in the Lutheran Church, Luther, Melanchthon, Chemnitz, Gerhard and Schleiermacher; in the Reformed Church on the Continent, Zwingli, Calvin, Bullinger, Turretin, and Arminius; in England and her dependencies, Hooker Chillingworth, Pearson, Bull, Baxter, Owen, Howe, Butler, Wesley and Edwards.

HENRY C. SHELDON,
Professor of Systematic Theology, Boston University.

THEOPHRASTUS, Greek philosopher: c. 372-287 B.C.; was a student of Plato and successor to Aristotle as head of the Peripatetic school of philosophy. He conducted the school with much success for 35 years, and was highly honored at home and abroad. He was greatly interested in natural history and won renown for his writings on botanical subjects. His 'History of Plants' and 'Theoretical Botany' are preserved as also are fragments of his works on 'Mineralogy,' 'Fire,' etc. His best known work is 'Characters,' a series of sketches which has repeatedly been translated. Consult Zeller, E., 'Aristotle and the Earlier Peripatetics' (Eng. trans., London 1897); Gomperz, T., 'Greek Thinkers' (Vol. IV, Eng. trans. by Berry, New York 1912) and others. An especially notable edition of 'Characters' is that of the Leipzig Philological Society (1897).

THEOSOPHY, as its Greek derivatives signify, means Divine Wisdom — wisdom concerning God. It is that general system of thought which has appeared in all ages shaping itself in one form and another and which has attempted to explain the nature of God, the universe and man's relation thereto. Among the Orientals it is conspicuous in the philosophic systems of China, India and Egypt. It is seen in the works of the Gnostics, the Neo-Platonists and the Cabalists, and in the speculations of Böhme, Schelling, Eckhart and in the teaching of Kapila and Shankaracharya, Pythagoras and Plato, Valentinus and Plotinus, Simon Magus and Apollonius of Tyana, Paracelsus and Bruno. It represents a body of tradition which has been preserved from earliest times and is not only found in the philosophic and speculative writings of those above mentioned and many others, but has been taught from time to time by sundry religious and mystical orders, — in the Far East by the Gurus and Initiates, and in Greece by the various schools of the mysteries. During the Middle Ages traces of the teaching are to be found in Masonry and Mediæval Mysticism, and later in the Order of Rosicrucians, and it has at all times comprised the esoteric side of the great religions of the world.

The Theosophical Society.— In modern times this name is given to an amalgam of occult, Indian and modern spiritualism made by a Russian named Helena Petrovna Blavatsky (q.v.) who, on 17 Nov. 1875, aided by Col. Henry Steel Olcott of New York, founded in that city the Theosophical Society, and modern theosophical thought owes its origin and propaganda to the writings and efforts of herself and her colleagues in this society. The objects of the society as originally declared were to collect a library and diffuse information concerning secret laws of nature. Later these objects were remodeled, and as now framed are:

1. To form a nucleus of the universal brotherhood of humanity, without distinction of race, creed, sex, caste or color.
2. To encourage the study of comparative religion, philosophy and science; and
3. To investigate the unexplained laws of nature and the powers latent in man.

«Assent to or sympathy with the first of these objects required for membership, the remaining two being optional and intended to subserve the first. The society has no dogmas or creed, is entirely non-sectarian, and includes in its membership adherents of all faiths and of none, exacting only from each member the tolerance for the beliefs of others that he would wish them to exhibit toward his own. Their bond of union is not the profession of a common belief, but a common search and aspiration for truth. They hold that truth should be sought by study, by reflection, by purity of life, by devotion to high ideals, and they regard it as a prize to be striven for, not as a dogma to be imposed by authority. They consider that belief should be the result of individual study or intution, and not its antecedent, and should rest on knowledge, not on assertion. They extend tolerance to all, even to the intolerant, not as a privilege they bestow, but as a duty they perform, and they seek to remove ignorance, not to punish it. They see every religion as an expression of the Divine Wisdom, and prefer its study to its condemnation, and its practice to proselytism. Peace is their watchword as truth is their aim.» «There is no religion higher than Truth» is the motto of the society. The general headquarters of the society are at Adyar, Madras, India, the residence of Colonel Olcott, its president-founder.

Its Aims.— It is stated that in the foundation of the Theosophical Society and in the writing of her various works, Madame Blavatsky was directed and aided by certain Eastern adepts or sages, whose pupil she had been for many years, and that the purpose of the movement was to stem the tide of materialism and agnosticism, which then threatened to engulf the thought of the age, and to stimulate transcendental research. Doubtless the fullest and the most authoritative statement of the ends which the modern theosophical movement were intended to accomplish is to be found in the following letter written by one of those adepts to one of his Western pupils:

«You can do immense good by helping to give the Western nations a secure basis upon which to reconstruct their crumbling faith. And what they need is the evidence that Asiatic psychology alone supplies. Give this and you will confer happiness of mind on thousands. . . . This is the moment to guide the recurrent impulse which must soon come, and which will push the age toward extreme atheism, or drag it back to extreme sacerdotalism, if it is not lead to the primitive soul-satisfying philosophy of the Aryans. . . . You and your colleagues may help to furnish the materials for a needed universal religious philosophy; one impregnable to scientific assault, because itself the finality of absolute science; and a religion that is indeed worthy of the name since it includes the relations of man physical to man psychical, and of the two to all that is above and below them. . . . Its (the society's) chief aim is to extirpate current superstitions and skepticism, and from long-sealed ancient fountains to draw the proof that man may shape his own future destiny, and know for a certainty that he can live hereafter.» Since then a considerable literature has sprung up within the society which, it is believed, has to no slight extent influenced the thought of the closing decades of the 19th century and made possible the almost popular interest in the unseen world. Among the leaders of theosophical thought after the death of Madame Blavatsky were Mrs. Annie Besant, C. W. Leadbeater, A. P. Sinnett and G. R. S. Mead, — Mrs. Besant being Madame Blavatsky's successor in the esoteric as well as in the exoteric work of the society. Through the writings of these theosophists the so-called theosophical theories, which for centuries have seemed vague and speculative, besides being greatly amplified, have been presented in a form more definite than at any other time in the history of such thought, the teachings now no longer resting upon tradition and intuition, if indeed they ever did wholly so, but largely upon investigations made into the supra-physical realms of nature by highly developed men whose trained powers enable them to respond sympathetically to vibrations of a finer order than those which the normal man is able to sense, and to come thus into conscious relations with subtler regions of nature within and extending vastly beyond the physical world. The training whereby these powers are gained is begun in the esoteric department of the Theosophical Society and falls more especially under its third object, which deals with the unexplained laws of nature and the powers latent in man.

Fundamental Principles.—Among the facts asserted by some theosophical writers as being known to themselves and capable of verification by those who are willing to make the necessary sacrifices to gain the required powers are: (a) the existence of a few highly evolved men, called Adepts or Masters — not solely of any one nation, but of any of the advanced nations — who have gained these divine powers in their fullness; that they exist now as in the past; that they are substantially omniscient so far as the laws and conditions of our own solar system extend, and that their high stage of progress entitles them to advancement beyond human conditions, but that they of their own free will have chosen to remain in touch with humanity in physical incarnation, that they may aid in its evolution; that it is from the brotherhood of these great adepts that from time to time have come into the outer world the great world teachers and that in their keeping has been the Wisdom-tradition, which in every age they have caused to be expressed in suitable form; that there have always been pupils of these men, and that theosophical teaching is published to the world to-day at their instigation and through a few of their pupils; (b) the existence of a very subtle order of matter, far finer than the ether which transmits light, upon which is impressed photographically, so to speak, in the form of living pictures, every scene or happening, however great or small, which has ever occurred from the very beginning of things and throughout the extent of the universe; that to this subtle material has been given the name of the Akâshic Records, or the Memory of Nature; that not only does the trained observer who has acquired the power of sensing these conditions of the subtler medium of the universe, or of responding sympathetically to its vibrations, *see* vividly the particular occurrence to which he turns his attention, but he *hears* and *feels*, etc., just as did the actors in any particular event which may be under review, perceiving their thoughts and feelings as well as seeing and hearing the outward conditions of the scene; that thus he can accurately, in proportion to his powers of observation, perceive any occurrence of the past, no matter when it may have happened, and in this way can know the true events of history; that he may also direct his vision to any period in the life of a planet and trace out its various evolutionary processes, and that he may thus enter a limitless field of observation wherein he may learn at first hand of the obscurer laws of nature; (c) that by the exercise of their highly evolved powers the Adepts or Masters of Wisdom can make definite experimental research into the Akâshic Records in quite as real a sense as the physicist makes his investigations within the physical world, and that they are, with these and other powers possessed by them, enabled to ascertain and teach certain general principles as definite facts, all of which are now and have ever been known to them, and very many of said facts have to a more or less extent, been proven by the investigations of those of their pupils who have fitted themselves to do such work. In 'The Secret Doctrine' Madame Blavatsky mentions three such principles as being the fundamentals of theosophy; they are:

1. An Omnipresent, Eternal, Boundless and Immutable Principle, on which all speculation is impossible, since it transcends the power of human conception and can only be dwarfed by any human expression or similitude. It is beyond the range and reach of thought — unthinkable and unspeakable.

2. The Eternity of the Universe *in toto* as a boundless plane; periodically «the playground of numberless universes incessantly manifesting and disappearing» called «the manifesting stars,» and the «sparks of Eternity.»

3. The fundamental identity of all souls with the Universal Over-Soul, the latter being itself an aspect of the Unknown Root; and the obligatory pilgrimage for every soul — a spark of the former — through the cycle of incarnation, or necessity, in accordance with cyclic and Karmic law, during the whole term.

Cosmogenesis.—According to the theosophist all manifestation has its origin in the Absolute, of whom naught can be said save that "He is." As Mrs. Besant eloquently describes it in 'The Ancient Wisdom,' "Coming forth from the depth of the One Existence, from the One beyond all thought and all speech, a Logos, by imposing on himself a limit circumscribing voluntarily the range of His own Being, becomes the Manifested God, and tracing the limiting sphere of His activity, thus outlines the area of His Universe. Within that sphere the Universe is born, is evolved and dies; it lives, it moves, it has its being in Him; its matter is His emanation; its forces and energies are currents of His life; He is immanent in every atom; all-pervading; all-sustaining, all-evolving; He is its source and its end, its cause and its object, its centre and circumference; it is built on Him as its sure foundation, it breathes in Him as its encircling space; He is in everything and everything in Him. Thus have the sages of the Ancient Wisdom taught us of the beginning of the manifested worlds. From the same source we learn of the self-unfolding of the Logos into a threefold form; the First Logos, the Root of all Being; from Him the second, manifesting the two aspects of life and form, the primal duality, making the two poles of nature between which the web of the universe is to be woven—Life-Form, Spirit-Matter, Positive-Negative, Active-Receptive, Father-Mother of the worlds. Then the Third Logos, the Universal Mind, that in which all archetypically exists, the source of beings, the fount of fashioning energies, the treasure-house in which are stored up all the archetypal forms which are to be brought forth and elaborated in lower kinds of matter during the evolution of the universe. These are the fruits of past universes, brought over as seeds for the present." From the Third Logos comes forth the seven Great Logoi, sometimes called the Seven Spirits before the throne of God; and as the divine outbreathing pours itself ever further outward and downward, from each of these we have upon the next plane Seven Logoi also, together making up on that plane 49. Omitting the detail of intermediate hierarchies, it is said that to each of these 49 Logoi belong millions of solar systems, each energized and controlled by its own solar Logos. Thus the difference is vast between the Great Logoi, the Trinity standing next to the Absolute, and the Logos of a single solar system, though the latter is far greater and more sublime than mankind has ever yet conceived the Deity to be. It is said that what happens at the beginning of a solar system (such as our own) is, allowing for certain obvious differences in the surrounding conditions, identical with what happens at the reawakening after one of the great periods of cosmic rest. Before a solar system comes into existence we have on its future site, so to speak, nothing but the ordinary conditions of interstellar space, that is, the seven subdivisions of the lowest cosmic or universal plane. These, from the viewpoint within our system, are identical with the matter of the highest, or the atomic subplanes of each of our planes. Upon this matter is poured out the energy of the third aspect of the Logos of the system, called the Third Logos, resulting in the quickening of the vitality which pervades all matter, so that when electrified by it the atoms of the various planes develop all sorts of previously latent attractions and repulsions, and enter into combinations of all kinds, thus by degrees bringing into existence all the lower subplanes of each plane, that is, the six planes below the atomic subplane, until we have before us in full action the marvelous complexity of the seven planes of nature and their respective seven subdivisions as they exist to-day. These planes represent both the physical and the unseen parts of the system, the former being its most densified phase and each plane of the latter being made up of matter of a gradually ascending scale of fineness. These planes are called respectively, (1) the physical plane, (2) the astral plane, (3) the mental plane, (4) the buddhic plane, (5) the nirvanic plane, (6) the paranirvanic plane and (7) the mahaparanirvanic plane, each being a definite region of the system, and their various subdivisions appearing in a general way, the same as the subdivisions of the matter of the physical plane, namely, as solids, liquids, gases and four states of ether. The matter of the subtler planes, however, is permeable, one order freely interpenetrating another and all extending both within and without the physical. The properties of each plane are also said to have an additional dimension to the one next preceding it in density. Thus the physical plane having three, the astral has four, the mental five, and so on. As stated, the highest or seventh subdivision of each plane is the atomic matter of that plane, that is, is homogeneous and cannot be further subdivided without undergoing an entire change of properties. Thus in breaking up the ultimate physical atom, it assumes the properties of the matter of the complex lowest subplane of the astral plane; in breaking up the astral atom it becomes of the lowest grade of matter of the mental plane, and so on. After the matter of all the subplanes of the system is by the action of the Third Logos formed and vivified, there is poured out upon it the energy of the second aspect of the Logos of the system, called the Second Logos, and is sometimes known as the monadic essence. The effect of this outpouring is to build the forms of the seven kingdoms of nature—the three elemental or pre-mineral, the mineral, the vegetable, the animal and the human. On the downward arc of its mighty curve this monadic essence simply aggregates round itself the different kinds of matter of the various planes, so that all may be accustomed and adapted to act as its vehicles; but when it has reached the lowest point of its *involution* or immeshing in matter and turns to begin the grand upward sweep of *evolution* toward divinity, its object is to develop consciousness in each of these grades of matter in turn, beginning with the physical—the lowest. When in the highest animal life this monadic essence or evolving soul mass reaches the ultimate limit of evolution in that type of forms, it is met by a third outpouring of Logic energy, that of the first aspect of the Logos of the system, called the First Logos, resulting by this union in the formation of the numberless human Egos—the individualization of the One Self in man. It is the presence within man of this third outpouring of the Divine Life, this spark of the One Self, that guarantees to him immortality, which, from this point on, the Ego, or real man, wins through innumerable incarnations in physical bodies.

Anthropogenesis.—As the worlds are septenary in their constitution, so also is man. He has on the physical plane (1) *a physical body,* the dense or visible portion of which is composed of solids, liquids and gases, and the etheric portion thereof is formed of the four subdivisions of ether. Pervading these is (2) *vitality,* derived from the sun and specialized by the etheric part. On the astral plane he has (3) *an astral or desire body.* And on the lower four levels of the mental plane he has (4) *a mind body.* These four principles constitute the personality, or what is often called the lower quaternary. On the three upper levels of the mental plane he has (5) *a causal or higher mental body,* the storehouse of all his experiences, past, present and future; on the Buddhic plane, (6) *a buddhic or bliss body,* wherein the inherent unity of all life is directly perceived, not as an intellectual concept, but as a sublime experience, and on the nirvanic plane he has (7) *a nirvanic or Atmic body,* the body of absolute reality. These last three constitute the Reincarnating Ego, the individuality, the soul which lives and grows throughout the period of solar manifestation. The other two planes may be termed the planes of the Self, or pure spirit. The matter of the various planes of nature entering into the composition of man's sundry bodies is vivified with the involving life of the monadic essence, the law of whose progress is to sink deeper and deeper into matter, while the law of the evolution of the Self using these bodies as vehicles of his consciousness is upward and out of matter. This apparent opposition of forces in man gives rise to the usual ideas concerning his lower and higher natures, and explains the meaning of evil. One's desires, thoughts and emotions are not himself, but the changing phantasmagoria of the living essence of his lesser vehicles which it is his business to learn to control and purify, until they become perfect instruments for his use,—for the real man within is none other than the changeless, eternal Self.

When the human Egos began their long pilgrimage of incarnations they at first took bodies on planets other than the one on which we now live. There are in our solar system seven planetary schemes of evolution, each the realm of a planetary Logos, and they are called, in the order of their distance from the sun, (1) the Neptune scheme, (2) the Uranus scheme, (3) the Saturn scheme, (4) the Jupiter scheme, (5) the Earth scheme, (6) the Venus scheme and (7) the Vulcan scheme. Each scheme consists of a chain of seven planets and each proceeds on independent lines, there being no intermingling of their activities during their normal course. The first and fifth of this series have each three physical planets, the others one each. The two physical planets of the first scheme besides Neptune are as yet unseen by the telescope. The two of the fifth, in addition to our earth, are Mars and Mercury. The non-physical planets in the schemes are of the matter of the astral and mental planes. Each scheme of evolution is worked out by means of seven Manvantaras or periods of manifestation, each manvantara consisting of seven Rounds, each round consisting of seven World Periods (following each other on seven planets in succession) and each world period consisting of seven Root Race Periods, any one of the latter covering periods of millions of years. The present humanity on this planet has passed four times around the planets of its chain, and through a fraction over four root race periods. The last planet occupied by us during the present round was Mars and the next will be Mercury. The two root races next before the present fifth root race of this planet were the Atlantean and the Lemurian races. The fifth root race has thus for developed as far as its fifth subrace and it stated that the beginnings of a new subrace, the sixth, may be found to-day in America.

Reincarnation and Karma.— Omitting all mention of the interesting career of the reincarnating egos through the primigenous conditions of the first three rounds of our own planetary chain and even of the first four root races of this present fourth round, it will suffice to show that among the undeveloped subraces of the present fifth root race reincarnation takes place within a brief period after the death of the body; that after each death there is a stay of more or less duration on the astral plane followed quickly by another physical incarnation. Later on as the life experiences bring greater growth to the incarnating soul, when he has developed some of the finer emotions, his stay in the invisible world is prolonged by an additional period in a specially protected and blissful region of the mental plane called «devachan,» the heaven world. Here his stay is proportional to the degree of his nobler earth experiences, usually lasting, for the average man of substantial attainments who has lived to a good age, about 15 centuries. Upon the ending of this devachanic life there remains only the reincarnating ego, the lower bodies constituting the personality having disintegrated on their respective planes; but the principles or qualities animating them have meanwhile left their impress upon the ego. In sending forth his next personality the action of the ego is colored and limited by the stamp upon it of these characteristics developed by the previous personality, so that the new personality begins his life cycle at the highest stage of growth reached by the previous one. This process of reincarnation goes on in «the three worlds» for vast periods of time, not on one planet alone, but on many, as the human life-wave passes from one to another — from one whose life processes have begun to wane to another more fitted to be the field of higher human possibilities, until at length the end is attained for which all manifestation seems to have been caused — the perfect growth of the soul, the unfoldment of all his potential divinity. The ethical law which governs the conditions of our lives, physical and supra-physical, is called Karma, and it is ineradicably operative in Reincarnation. It may be defined as the law of action and result. By virtue of the operation of this law, effects which cannot be ascribed to any immediate cause may be traced to causes existing in other incarnations of the same ego, thus establishing one's ultimate, personal responsibility for whatever may befall him. Furthermore, owing to this law, one may and does at each moment of his present life produce by his own actions, feelings and thoughts definite effects in the subtler order of things, resulting in conditions for his next earth life wholly of his own making.

Thoughts build character.
Desires make opportunities.
Actions make environments.

So that whatever one may suffer or enjoy, attain to or fall from is brought about as the result of his own action, in obedience to this law of absolute justice. It is the alternate experience of pleasure and pain which man encounters during his stages of ignorance that develops within him wisdom; and the opportunities guaranteed to him for the accomplishment of this end through Reincarnation and Karma are well nigh limitless. These two doctrines are perhaps the most far-reaching of all the theosophic teaching, as they seem to clear up a host of perplexing questions and establish the basis for a satisfying philosophy.

Propaganda.—Among the results of theosophic propaganda is the restoration to the Western world of the said doctrines of Reincarnation and Karma, and the elimination of the many perversions of them existing in the East. Another is the occult proof produced of the definite objective reality and potency of thoughts and emotions, showing that these forces are as to their respective planes as visible and real as physical objects are on the physical plane, and that every thought is a living, active entity, persisting for a length of time proportional to the strength that is put into its creation and wields a greater or less influence on those with whom it may come into touch. (See Mr. Leadbeater's 'Man Visible and Invisible,' illustrated, and Mrs. Besant's 'Thought Forms,' illustrated). Still another is the order which it has brought out of the chaos of the apparently unrelated data of metaphysics, mysticism and the neo-psychology, including the facts of clairvoyance, clairaudience, mesmerism, hypnotism, telepathy, astrology, apparitions, psychometry and the like. And still another is the establishment by irresistible evidence of the basic unity of all the great world religions and their fundamental relation to an unprejudiced and open-minded science. To help the religions to clear away their non-essential accretions, to sink into insignificance doctrinal differences, to bring to the fore their points of unity, to study their doctrines and traditions in the spirit of brotherliness and to help each from his own particular standpoint is one of the chief ends to which the theosophist bends his efforts. He does not seek to found a religion, but to expound those we already have, and so give them a deeper meaning and a richer life. While the theosophist limits himself to no particular form of creed, yet the following three truths may be said approximately to include the broad scope of his belief:

1. God exists, and He is good. He is the great lifegiver who dwells within us and without us, is undying and eternally beneficent. He is not heard, nor seen, nor touched, yet is perceived by the man who desires perception.
2. Man is immortal and his future is one whose glory and splendor have no limit.
3. A Divine law of absolute justice rules the world, so that each man is in truth his own judge, the dispenser of glory or gloom to himself, the decreer of his life, his reward, his punishment.

Occultism.— Unless he finds the religion to which he happens to be connected insufficient to meet the demands of his higher nature, the theosophist is apt to seek through the esoteric side of his philosophy the gateway of Occultism, in order that he may prepare himself for a more serious religious life. Occultism, as distinguished from the Occult Arts, or Magic, is that system of endeavor which, teaching the methods whereby the personality, or lesser, or more human side of man may be made to expand and embrace his higher or divine nature, leads its votaries along a difficult and narrow pathway of rigid virtue and mental and emotional control, and so requires a firm moral foundation upon which to build the extraordinary powers pertaining to the unseen world. The true Occultist possesses unselfishness, justice and true knowledge; he has compassion and wisdom; his desire nature is purified and his habit of mental concentration fixed; «the contents of his consciousness are something more than his five-sense perceptions *plus* the deductions he draws from them by his reason, and such vague ideas and intuitions as he may possess.»

Through Occultism the aspirant, wearying of the phenomenal world, seeks to outstrip his fellows in evolution and within a few strenuous incarnations to accomplish what the mass of humanity in the normal course will only attain to in long reaches of time, namely, the highest adeptship or liberation from the «wheel of rebirth.» In doing so he treads a path which, according to occult teaching, has three great divisions:

1. The probationary period, before any definite pledges are taken or initiations (in the full sense of the word) are given. This carries a man to the level necessary to pass successfully through what in theosophical books is usually called the critical period of the fifth round.
2. The period of pledged discipleship, or the path proper, whose four stages are often spoken of in Oriental books as the four paths of holiness. At the end of this the pupil obtains adeptship — the level which humanity should reach at the close of the seventh round.
3. What may be called the official period, in which the adept takes a definite part (under the great Cosmic Law) in the government of the world, and holds special office connected therewith, but none of the details of this period can be made known.

The probationary path has five stages but the division between its stages are less decidedly marked than those of the higher groups, and perfection is not required in anything during this period, only a serious effort toward it. In the *first* stage the candidate for adeptship acquires a firm intellectual conviction of the impermanence of mere earthly aims; in the *second* a perfect indifference to the fruits of his own action; in the *third* (a) perfect control of mind, (b) of conduct, (c) a generous tolerance, (d) endurance, (e) one-pointedness, (f) confidence in his Master and himself; in the *fourth* an intense desire for union with the highest; and in the *fifth* he gathers up and strengthens his previous acquisitions for the next great step, which will set his feet upon the path proper as an accepted pupil. During his life on the probationary path the pupil will have received much teaching from his Master, usually imparted during the sleep of his physical body, while he himself is clad in his astral body in full consciousness on the astral plane. He will also have been taught while thus functioning in the astral world to bring help, instruction and comfort to the inhabitants of that world, who having laid aside their physical bodies at the gateway of death have passed beyond the physical plane. This phase of occult work is sometimes called that of the *Invisible Helpers* and is performed, be it understood, by men still having physical bodies and who have developed this power of functioning consciously outside the same on inner planes. The pupil will further have been trained in mediation, and this effective practice both in waking consciousness and outside the physical body during its sleep will have quickened and brought into active exercise many of the higher powers.

When the pupil has developed the fifth qualification of the probationary path he is ready for initiation upon the part proper, henceforth to serve his Master, whom he now meets face to face, in helping forward the evolution of the race, his life, «to be offered up on the altar of humanity, a glad sacrifice of all he is, to be used for the common good.» This path consists of four distinct stages and the entrance to each is guarded by an initiation. Ere the second initiation can be passed the pupil must lose the sense that the separated, personal self is a reality, and must feel himself one with all; he must destroy doubt and superstition by knowledge; ere he passes the third he must bring into full working order the inner faculties, those belonging to the subtler bodies; now he needs to incarnate but once again; ere the fourth is passed he rids himself of desire and aversion and sees the One Self in all. At this stage he needs to return no more. The fourth initiation admits him to the last stage of the path where he throws off all clinging to life in form and all longing for even formless life. Then he casts off the «I-making» faculty — pride, irritability and ignorance, and henceforth dwells on the plane of unity. The man is then perfect, is free, the liberated one. He has won Nirvana. «He has completed man's ascent, he touches the limit of humanity; above him there stretches hosts of Mighty Beings, but they are superhuman; the crucifixion in flesh is over, the hour of liberation has struck and the triumphant 'It is Finished' rings from the conqueror's lips, . . . he has vanished into light nirvanic. But being now Master of Compassion as well as Master of Wisdom, he returns from that light to earth, henceforth to devote himself to the service of humanity with mightier forces at his command than he wielded while he trod the path of discipleship, bending all his sublime powers to the quickening of the evolution of the world. Such an one was the Buddha — such the Christ and such the few Great Souls who tread the earth to-day, secluded from its external strife, yet pouring down upon mankind from the great heights of their sublime advancement inestimable blessings, guiding by means of their divine powers whole races and nations, but unknown to all but the few earnest souls who come to them through the ancient gateway of Occultism, the portal of which has throughout all time stood ajar for the resolute pilgrim.»

Before the cycle of time shall close and all manifestation cease, the greater portion of mankind will have reached this high stage of growth. And then shall all be gathered unto Him for the great Cosmic rest only after æons and æons of time, to emerge again with Him, to be the Architects and Builders of future universes. Such are a few of the teachings of the Ancient Wisdom, given forth at this time as Theosophy and Occultism.

The materials for the above sketch have been drawn more or less literally from the above-mentioned works.

A. P. Warrington,
Fellow of the Theosophical Society.

THEOTOKOS, a title given to the Virgin Mary by a decree of the Third Ecumenical Council, which met at Ephesus 431 to condemn the Nestorian heresy. The term means «bringing forth God» and is intended to formulate the fact implied in the annunciation of the angel to Mary "that holy thing which shall be born of thee shall be called the son of God." Theotokos (Latin, *Deipara*) implies that the child of Mary was of divine nature from the moment of his conception; that he was not born mere man, to whom, as Nestorius taught, the divine nature was subsequently imparted.

THERA, thā'rạ or thē'rạ, an island in the Ægean Sea, belonging to the Grecian Archipelago, the most southerly of the Cyclades. It is of volcanic formation and presents many interesting phases. New islands are formed from time to time, by its volcanic action, notably the last in 1866. Scientists have given the island considerable attention and many observations have been made and records kept. The soil is very fertile.

THERAMENES, thĕ-răm'ĕ-nēz, Athenian politician of the 5th century B.C. He first became prominent in 411 as a member of the Council of 400, but perceiving the inevitable downfall of that government he joined the opposing party and assisted in its overthrow. In 410 B.C. he was in command of a portion of the Athenian fleet, with which he cruised about and exacted tribute from the neighboring islands, and later he joined the fleet under Thrasybulus, with whom he took part in the battle of Cyzicus. He subsequently served with Alcibiades, participated in the siege of Chalcedon in 408 B.C. and in the capture of Byzantium. After the battle of Arginusæ, in 406, he repaired to Athens, and in order to exculpate himself for not saving the crews of the ships accused his colleagues of neglect, and through his testimony they were sentenced to death. In 404 B.C., when Athens was besieged by the Spartan general Lysander, Theramenes was sent as an envoy to negotiate terms with Sparta. He purposely remained on his mission for three months, during which time Athens was reduced to dire extremity and was forced to make peace upon such terms as to place her at the mercy of the Lacedæmonians. He was elected one of the Thirty Tyrants (q.v.) after the peace, and at first heartily supported the measures of the government. The violent measures of Critias and his colleagues, however, induced him to form an opposing party, which rapidly increased in strength. He was accused by Critias of being a public enemy, dragged to prison and forced to drink the hemlock.

THERAPEUTICS, that branch of medicine which deals with the treatment of disease. Natures cures; physicians treat. This is an old dogma as true to-day as it was when uttered over 2,000 years ago by a famous Greek physician. Scientists have termed that power of the human body the *vis medicatrix naturæ,* by means of which nature tends to right her own disordered organs, and it is important to recognize this all-important function of the body, and not to interfere by overzealousness in the use of potent agents with nature's own slowly acquired powers of self-restoration. An innocuous and half-hearted therapy, however, is not the logical system, even if such reconstructive powers of nature are granted. The modern conception of disease does not admit of ready characterization. In the articles on disease and pathology (q.v.) it is attempted to define what is meant by disease, but such definitions are far from being satisfactory because of the immense variety of diseased conditions, their manifold causation and their devious progressions. In all disease certain groups of physiological functions are altered, and in the attempt to aid nature to bring these disturbed physiological activities to a normal condition the chief work of the therapeutist lies. It makes little or no difference what the agencies may be that are used — often, as has been said, none are necessary — yet the ideal of the therapeutic art is to restore to normal condition, as far and as quickly as possible, the disturbed bodily functions. While it is true that the physician of to-day employs many of the agents used by physicians thousands of years ago, there is a far greater precision and a much more comprehensive series of ideas concerned in their use by the well-equipped modern therapeutist than was possible to his early predecessors. The one aim of the physician throughout the centuries has been the alleviation of suffering and the restoration of the diseased to health or to comfort; and notwithstanding the many small cliques and divergences of opinion, the progress toward scientific therapeutics has been steady and increasingly satisfactory. At the outset of this summary of therapeutics it may be well to consider for a moment the different classes of agents at hand by the use of which, singly or combined, the physiological functions of the body may be modified, and thus be made useful in the healing art.

Expressed categorically, the different therapeutic agents or systems are: (1) Suggestion-therapy; (2) Dietotherapy; (3) Physicotherapy; (4) Mechanotherapy; (5) Pharmacotherapy; (6) Surgicotherapy. Each of these will be briefly discussed.

Unquestionably the oldest and yet strongest therapeutic agent is suggestion. The power to heal by faith is not the special property of any sect or class, nor the exclusive right of any system. Belief in gods and goddesses, prayer to idols of wood, of stone, of gossamer fiction, faith in the doctor, belief in ourselves engendered from within or from without — these are all expressions of the great therapeutic value for healing that resides in the influence of mental states on bodily functions. These will not move mountains; they cannot cure consumption; they do not influence a broken leg, nor an organic paralysis; but suggestion, in its various forms, may be and is one of the strongest aids to all therapeutic measures. Of its abuse by designing hypnotists, blackmailers, clairvoyants and a motley crew of parasites, space does not permit particularization. The human mind is credulous — it believes what it wants or wills to believe; and the use of suggestion in therapeutics is one of great power for good and for evil.

The treatment of disease by diet constitutes another large branch of the therapeutic art. Modern chemistry has resolved all foods and drinks into their elements, and has given the physician valuable aids in the treatment of a large number of diseases. Many obscure disorders, such as diabetes, gout, myxœdema, obesity, etc., are closely allied with certain defects in the metabolism of certain physiological systems of the body. Many of these are best treated by a dietary regimen, combined, it may be, with other means. Many of the minor disorders of the digestive tract (see DIGESTION) are best treated by regulation of the diet.

By physicotherapy is meant the use of certain physical agents such as heat, cold, light, electricity, etc. Certain forms of application of the agents are termed (a) hydrotherapy (q.v.), in which heat and cold are applied by means of water; (b) phototherapy (q.v.), in which light is used in the treatment of disease. Sunlight, electric light, ultra-violet rays (Finsen's light), X-rays, radio-active substances — these all exert on the tissues of the body certain influences that, properly applied, may bring about restoration of disordered functions, and thus aid nature in curing disease.

Mechanotherapy is the use of mechanical movements in treatment. Massage, vibration, gymnastics, Swedish movements, etc., are some of the different forms in use. Under the name of osteopathy (q.v.) it is attempted to elevate one of the oldest aids to treatment, in use by the Greeks, Chinese, etc., to the rank of an exclusive system.

Under the terms pharmacotherapy and surgicotherapy are included the treatment of disease by drugs, so-called, and by surgical means. So far as treatment by means of drugs is concerned, it is interesting to note that practically all drugs act on the tissues of the body in some chemical or physicochemical manner. They may have a certain selective action on certain tissues of the body. Thus the large group of the alcohols, comprising ethers, aldehydes, chloroform, hypnotics — such as trional, sulphonal, veronal, urethane and a large number of others — have a selective action on the nervous tissues of the brain, benumbing their activities and causing drunkenness or anæsthesia or sleep, according to the dose or other conditions. Others act on sensory nerves, diminishing pain; such are cocaine, opium, antipyrin, acetanilid, phenacetin, cannabis, etc. Again, other remedies are chiefly on the intestines, giving the large group of cathartics, and so the entire list of drugs might be analyzed. Given a knowledge of the selective or generalized action of the drugs, the power that they may exert in correcting abnormal physiological activities is solely a matter of application and in accordance with the correct interpretation of the cause of the disturbed functions will the therapeutic application be of direct value or not. In other words, drugs are nothing more than chemical agents which may be used to modify certain physiological activities; if by their well-known power in modifying these activities other morbid activities may be corrected, they are agents for good. For a consideration of surgicotherapy, see SURGERY, HISTORY OF GENERAL.

One other phase of therapeutics remains to be considered. It has been pointed out that nature has resources of her own for overcoming certain types of disease. Can these natural powers be so played upon or affected as to increase their operation? Along this line new paths have been opened up since the recognition of a large class of diseases known as infectious. Bacteriology (q.v.) has taught that disease organisms (bacteria) cause the disturbance (disease) in the body not so much by their physical presence as by the extremely virulent poisons that they form. It is the struggle of the human body to get rid both of bacteria and poisons that makes the disturbance which is called the disease. Thus the diarrhœa of typhoid is one of nature's efforts to throw off poisons; the high temperature and crisis of pneumonia is a supreme effort of the body, which sometimes succumbs under it, to deal a death-blow to the pneumococcus, the micro-organism that causes the disease. The high temperature in malaria (q.v.) unquestionably kills off a great many of the parasites in the blood.

But in addition to these larger and more palpable efforts on the part of nature to overcome the invader, a series of subtle and intricate defenses are at work in the blood-serum, some of the elements of which are known. Thus in some diseases there is elaborated in the blood-serum a direct chemical antidote, an anti-toxin, to the poisons of the invading bacteria. Such a protective power is found in diphtheria (q.v.). (See ANTITOXIN). Vaccination, the discovery of which was almost the result of an accident, is a form of serum-treatment. (See SERUM-THERAPY). The details of the reasons why immunity is conferred by the modified smallpox of the cow are not yet known, as the true cause of smallpox is not indubitably proven, but the time is not far off when the different factors herein involved will be unearthed. A large number of other questions are concerned in this great question of natural and acquired immunity (q.v.).

Human progress has been likened to the advance of a drunken man, and it is certain that the ups and downs and side-lurches and backward steps in the path of therapeutics have been many; but withal there has been a broad blaze of progress. That which has been tried and been found to be true has been grasped and has become the heritage of the whole community. The physician class have shared with the people at large in the general movements; there have been many side-tracks from the broad road of therapeutics; innumerable *pathies* have had their little day or their 100 years; each in its turn has contributed what kernel of truth it possessed to the progress of the mass.

Editor of ‹Journal of Nervous and Mental Diseases.›

THERAPIA, a health resort on the Bosporus, nine miles north-northeast of Constantinople, of which city it is a suburb. It is the ancient *Pharmacia* («drug-cure») where tradition says Medea spread her drugs. One of the earlier patriarchs of Constantinople changed the name to Therapia («cure»). It marks the limit between what is locally called the Upper Bosporus and the Lower Bosporus. Here are the summer residences of European ambassadors, Turkish officials and wealthy Levantines.

THERESA, Saint. See TERESA, SAINT.

THERESIOPEL, tĕr-ā'zē-ō-pĕl, or **MARIA-THERESIOPEL,** mä rē'ä-tĕr-ā'zē-ō-pĕl (Hung. *Szabadka*), Hungary, a royal free town in the county of Bács-Bodrog, 25 miles southwest of Szegedin, in a broad plain between the Danube and the Theiss. The buildings worthy of notice are the churches of Saint Theresa, church of the Franciscans, a beautiful Greek church, town-house, etc., theatre, barracks, gymnasium and music-school. The industrial works include tanneries, linen and leather manufactories and dyeworks. Wheat, tobacco, wine and fruits are grown and cattle-raising is important. There is a brisk trade in horses, cattle, sheep, hogs, hides and wool. There is a fashionable watering-place in the vicinity. Pop. 94,610.

THERIAC, or THERIACA, a compound said to have been first prepared by Andromachus of Crete, who was physician to the Emperor Nero. It was supposed to be an antidote to poison, and continued in use throughout the Middle Ages. As prepared in Venice and other places it was a compound of 64 drugs, pulverized and reduced by means of honey to an electuary.

THERIODONTIA, a sub-order of the *Theromorpha* (q.v.), large extinct carnivorous reptiles, with shortened coracoid and double-headed ribs.

THERMÆ, thėr'mē (from the Greek *thermai*, signifying originally warm or hot springs), properly warm baths, but also applied generally to the baths of the ancients. During the Roman Empire the buildings for this purpose were constructed with great splendor and adorned with paintings, statuary, libraries, gymnasia and public walks. The baths of Nero, Titus, Caracalla and Diocletian at Rome were distinguished for the magnificence and luxury displayed in their construction. See BATH HOUSES.

THERMAL SPRINGS. See SPRING.

THERMIC FEVER. See SUNSTROKE.

THERMIDOR, thėr-mĭ-dôr' (Fr. tĕr-mē-dôr), the 11th month of the year in the calendar of the first French republic. It commenced on 19 July and ended on 17 August. See CALENDAR.

THERMIT, a name given by Goldschmitt to a mixture of fine aluminum filings or powder and iron oxide. When this mixture is ignited by some suitable means the aluminum unites vigorously with the oxygen of the iron oxide, forming a very pure variety of steel and a slag consisting mostly of aluminum oxide. This union of finely divided aluminum with oxygen gives a very intense heat, about 3,000° C. Besides the ordinary thermit (iron oxide and aluminum filings) other mixtures may be prepared from aluminum and the oxides of nickel, cobalt, chromium, manganese, etc. When these are ignited in a properly prepared crucible violent reaction takes place, the oxygen of the oxide being taken up by the aluminum, leaving a very pure metal, nickel, cobalt, etc. This process is now much used to get metals from those oxides that heretofore have resisted all ordinary methods of reduction. When ordinary thermit is ignited the temperature produced is so high that the iron and the slag are left in a molten and highly-heated condition. If this iron is allowed to flow on to another piece of iron or steel it will heat it enought to soften it and the whole will harden to a homogeneous mass. In this way it can be used to replace broken parts of machinery, to mend broken or cracked propeller shafts, to weld together railroad rails so as to form one continuous rail, etc. Some of the important features in this process are its cheapness, ease of execution and the fact that machinery, etc., can be repaired in position. The method is to surround the part to be repaired with an ordinary mold box; a magnesia-lined crucible with a plug in the bottom is placed over the opening; the thermit is placed in the crucible, ignited and as soon as the violent reaction has subsided the plug is pulled and the white hot metal allowed to flow into the mold. Iron tubes can be welded together by placing the ends in a mold and allowing the thermit product to flow in in such a way that the liquid slag first comes in contact with the tubes. The slag forms a protective covering which prevents the hot iron from uniting with them, though it does allow the tube ends to become hot enough to unite as one piece. Railway rails can be joined where they lie on the track, and large pieces of broken machinery in mines or on shipboard can be readily repaired without removal.

THERMO BAROMETER. See THERMOMETER.

THERMO-CHEMISTRY, or THERMAL CHEMISTRY, that branch of physical chemistry which deals with the thermal changes which occur when chemical reactions take place or when a body or system (such as a solution) undergoes certain kinds of physical change. Its precise limits are not easy to define, since the subject merges into ordinary chemistry on the one hand and into thermodynamics on the other. Any chemical operation can be considered from two points of view, according as we are interested in the modification that it produces in the nature of the substances that are involved or in the quantity of energy which is absorbed, liberated or otherwise transformed at the same time. It is the province of thermo-chemistry to investigate the transformations of energy that occur in such cases. The complete discussion of the energy-transformations that accompany a given chemical change should include the consideration of every type or form of energy which may be present; but the investigations which have hitherto been made have related chiefly to the quantities of heat which are liberated or absorbed, and it is to this circumstance that the science owes its present name, «thermo-chemistry.»

The quantity of heat that is liberated or absorbed during a proposed chemical reaction can be determined by causing the given reaction to take place in the interior of a calorimeter. The particular form of calorimeter that is to be used will naturally depend to a considerable extent upon the nature of the reaction that is to be studied. If the problem consists in the determination of the quantity of heat that is liberated when two given liquids are mixed, the calorimeter commonly consists of a platinum vessel, capable of containing from 500 to 1,000 cubic centimeters, placed inside of another vessel of silver; the space between the two vessels being filled with water. The liquids that are to be examined are brought to the same temperature as nearly as possible, and are then mixed in the platinum vessel. The rise of temperature of the calorimeter being noted, and the masses and specific heats of the various parts of the calorimeter (and its contents) being determined by separate experiments, we are then in position to calculate the quantity of heat energy liberated by the reaction. For detailed information with regard to the various kinds of calorimeters that are used, and for a discussion of the sources of error to which such instruments are liable, reference must be made to extended works upon heat and thermo-chemistry. (See the references at the end of this article).

In thermo-chemical work, the unit of mass is almost invariably the gram; and the gram is always understood, when no other unit is specifically mentioned. The unit of heat is also understood to be the calorie, which, for thermo-chemical purposes, is defined as the quantity of heat required to raise the temperature of one gram of water by one Centigrade degree, when the temperature of the water is in the vicinity of 18° or 20° C. The notation that is employed in expressing the results of a thermo-chemical experiment upon the heat that is developed by a given chemical reaction is simple. The formulæ of the substances that react are written within square brackets, and separated by a comma or a colon; it being understood that the number of grams that are present of any one substance is equal to the molecular weight of that substance. A sign of equality is written after the bracketed formulæ, and on the right hand side of this sign the number of calories of heat generated or absorbed by the reaction is written; a positive sign being prefixed (or suffixed) when heat is evolved, and a negative sign when it is absorbed. The indices that are attached to the symbols of the various elements are written above those symbols, instead of below. For example,

$$[H^2,O] = +68,360$$

signifies that when two grams of hydrogen and 16 grams of oxygen, both at about 18° C. and under ordinary atmospheric pressure, combine to produce 18 grams of water (also at 18° C.), the quantity of heat that is evolved is sufficient to raise the temperature of 68,360 grams of water by one Centigrade degree; the temperature of the water being about 18° C. When a compound is broken up into its constitutent parts, the bracketed formulæ are preceded by a negative sign. Thus the expression,

$$-[H,Cl] = -22,000$$

signifies that when, by any means, 36.5 grams of hydrochloric acid are decomposed so as to set free 1 gram of hydrogen and 35.5 grams of chlorine, the change is accompanied by the absorption of a quantity of heat that would be sufficient to raise the temperature of 22,000 grams of water by 1° C.

The "heat of formation" of a substance is the quantity of heat given out when the substance is formed from its constituents; it being taken as negative when the formation of the substance is accompanied by the absorption of heat. In general, any given substance may be prepared in various ways, from different materials or constituents; and in such cases the heat of formation will be different, according to the particular substances that are regarded as constituents. For example, sulphuric acid might be prepared from sulphur, oxygen and water, according to the equation

$$S + 3O + H_2O = H_2SO_4,$$

or from sulphur dioxide, oxygen and water, according to the formula

$$SO_2 + O + H_2O = H_2SO_4,$$

or from sulphur trioxide and water, according to the equation

$$SO_3 + H_2O = H_2SO_4;$$

and the heat of formation will be different in these several cases, if we regard the immediate materials from which the acid is prepared as the "constituents" of the acid. But if the acid is prepared from the elements sulphur, hydrogen and oxygen (all three being taken in certain standard initial physical states in each instance), then the heat of formation will be the same, whether these elements combine directly to form the acid, or whether the oxides of sulphur and hydrogen are first produced, and these subsequently combine to form the acid. In fact, the principle of the conservation of energy shows that when a body or a system of bodies passes through a succession of changes, either physical or chemical in nature, so as to pass from one given initial state to another given final state, the total change in the internal energy of the body or system is identically the same, whatever the nature of the transformations may be, by which the change is effected. Hence it follows that whenever the heat that is emitted or absorbed in the course of a reaction represents nothing but the decrease or increase in the internal energy of the system, the total quantity of heat that is emitted or absorbed will be entirely independent of the way in which the transformation takes place. If, however, the system performs external mechanical work in passing from its initial state to its final state, the heat energy that is actually given off will be less than that corresponding to the change in the internal energy by the amount which is expended in performing the external work. In many of the reactions that are considered in thermo-chemistry, the external work that is performed is too small to be of any material significance, and in these cases the heat energy that is emitted or absorbed in the passage from one state to another may be logically regarded as independent of the kind of transformation that the transition involves. In some cases, however, and particularly when the systems under consideration are partly or wholly gaseous, the external work that is performed is great enough to require serious consideration, and to obtain accurate results this work must be estimated and allowed.

The application of the principle of the conservation of energy to the determination of the heat of formation of a substance, when that heat cannot be directly observed, may be illustrated by the case of phosphorus. We have, when ordinary phosphorus is burned to the pentoxide,

$$[P^2, O^5] = +369{,}100;$$

which signifies that when 62 grams of ordinary phosphorus (the atomic weight of that element being 31) are burned to pentoxide, 369,100 calories of heat are emitted. A similar experiment with amorphous phosphorus gives the corresponding relation

$$[P^2, O^5] = +326{,}800.$$

Evidently the internal energy of the amorphous variety is less than that of the ordinary variety, since when both are converted into the same thing the amorphous phosphorus gives out sensibly less heat. The difference of the foregoing numbers is 42,300; and dividing this by 2 (since the foregoing numbers apply to 62 grams of the phosphorus), we reach the final conclusion that when 31 grams of ordinary phosphorus are converted into the same mass of amorphous phosphorus, the conversion is attended by the emission of 21,150 calories of heat. Similar experiments have been performed in great number upon compounds that are isomeric with one another; and yet the data that are available do not warrant any but the broadest generalizations. It appears, for example, that the internal energy of a compound that admits of isomeric modifications depends (1) upon the symmetry of structure of the molecule, (2) upon the natures of the atoms which are directly joined in the molecule, and (3) upon whether or not each molecule in the compound exhibits its maximum valency toward the molecules of other kinds with which it may be associated. Thomsen endeavored to discover, by thermo-chemical methods, whether a single bond between two adjacent carbon atoms is stronger or weaker than a double or triple bond. His methods and conclusions are perhaps not always beyond criticism, but he was led to believe, from his experiments, that a triple bond between two adjacent carbon atoms constitutes a much weaker connection than either the single or the double bond. This particular conclusion, it may be said, is in harmony with evidence on this point that has been collected in many other ways.

The methods of thermo-chemistry have been applied extensively to the investigation of problems in the theory of solutions, to the study of the affinity between acids and bases, and to the elucidation of many of the difficult points of physical chemistry. These applications, however, assume a knowledge not only of experimental and theoretical physics and chemistry, but also, and more particularly, a sound understanding of thermodynamics. Consult Muir and Wilson, 'Elements of Thermal Chemistry'; Thomsen, 'Thermochemische Untersuchungen'; Naumann, 'Thermochemie'; Planck, 'Grundriss der Allgemeinen Thermochemie.'

ALLAN D. RISTEEN,
Director Technical Research, The Travelers Insurance Company, Hartford, Conn.

THERMO-DYNAMIC ENGINE, a name applied to any form of steam engine or gas engine.

THERMODYNAMICS, or **THE MECHANICAL THEORY OF HEAT,** that branch of physical science which treats of the relation of heat energy to energy of other kinds, and particularly of the convertibility of heat energy into mechanical energy, and the converse. In order to discuss, quantitatively, the conversion of one kind of energy into another kind, we must first have a definite method of measuring each of them. Mechanical energy (see ENERGETICS) is measured by determining the amount of work that a given quantity of it can perform; the customary unit employed for this purpose being the «foot pound» or the «metre-kilogram» in engineering practice and the «erg» in scientific work; the «erg» being defined as the quantity of work done in overcoming a resistance of one dyne, through a distance of one centimeter. The unit employed in the measurement of heat is almost universally the quantity of heat required to raise the temperature of some definite mass of water through one degree, on some stated part of the thermometric scale. The ordinary «British thermal unit,» which is used in engineering practice in English-speaking countries, is the quantity of heat required to raise the temperature of one pound of water by one Fahrenheit degree; and in countries that use the metric system, the engineering unit is the quantity of heat required to raise the temperature of one kilogram of water through one centigrade degree. As the specific heat (q.v.) of water varies slightly at different temperatures, these definitions are not absolutely definite, unless the part of the thermometric scale at which the experiment is to be performed is specified. Unfortunately there is no general agreement among engineers on this point; and for most purposes in practical engineering it is customary to ignore the slight variation in the specific heat of water and to consider the foregoing definitions to be sufficiently precise as they stand. For scientific purposes, where the greatest possible accuracy is required, this course is not permissible, and it becomes necessary to specify the particular degree through which the temperature of the water is to be raised. Even here there is no definitely established convention; but there appears to be a growing tendency to adopt the degree that extends from 14.5° C. to 15.5° C. In scientific work, too, it is customary to define the thermal unit in terms of a gram of water, instead of a kilogram; and the scientific heat unit (which is called the «small calorie,» to distinguish it from the «greater calorie» that is used in engineering) may be defined as the quantity of heat required to raise the temperature of one gram of water from 14.5° C. to 15.5° C. The quantity of heat required to raise the temperature of one gram of water from 3.5° C. to 4.5° C.—4.0° being the temperature at which water has its maximum density — is also known as the «therm.»

The science of thermodynamics is founded upon two general, fundamental laws, which, so far as we are aware, are absolutely rigorous and which are respectively known as the «first» and «second» laws. These we shall consider in order.

The «first law of thermodynamics» is nothing but a special application of the general principle of the conservation of energy. (See ENERGETICS). It states that whenever heat energy is converted into mechanical energy (or the reverse), then for each unit of one kind of energy that disappears there is always a perfectly definite and constant quantity of energy of the other kind which appears. Mayer and Joule discovered this fact independently, about the year 1840. There has been in the past some considerable controversy as to the credit that should be assigned to these respective investigators. We cannot enter into this discussion, but the reader who desires to follow it up will find an admirable and very fair statement of the facts of the case in two papers on the Copley medalists of 1870 and 1871, in Tyndall's 'Fragments of Science.' Joule did a vast amount of experimental work for the purpose of determining the exact value of the «mechanical equivalent of heat,» as the constant is called, which expresses the number of units of mechanical energy that are equivalent to one unit of heat; and in the course of his labors he tried many different experimental methods. (Consult 'The Scientific Papers of James Prescott Joule'). His best known method consisted in stirring a known mass of water and measuring the rise in temperature so produced as well as the quantity of mechanical work expended in the stirring. He concluded that the temperature of one pound of water is raised by one Fahrenheit degree by the expenditure of 772 foot-pounds of mechanical energy. This constant, which is known as «Joule's equivalent» and is denoted by the symbol J, has played an all-important part in engineering and scientific work for more than half a century. A better value of it was obtained by Rowland in 1879 (consult 'The Physical Papers of Henry Augustus Rowland'); but the prestige of Joule was so great that the superiority of Rowland's work was not generally recognized for many years. Rowland's method was similar to that of Joule, but he worked with far better apparatus, and took advantage of the advances that had been made since Joule's work was done, both in calorimetry and in thermometry. It was in the course of this work that Rowland made the discovery that when temperature is defined in accordance with the scale of the normal, constant-volume air thermometer, the specific heat of water has a minimum value at a little above 30° C.,— a discovery which implies a high degree of precision in the experimental methods employed, and which has been abundantly verified by later investigators. Rowland's value of the mechanical equivalent of heat may be stated as follows: Taking as the unit of heat the quantity of heat required to raise the temperature of one kilogram of water from 14.5° C. to 15.5° C., the mechanical equivalent is 427.4 kilogram-metres at sea-level in the latitude of Baltimore. If the unit of heat is the quantity of heat required to raise the temperature of a pound of water from 59° F. to 60° F., then the mechanical equivalent is 779.0 foot-pounds. If the unit of heat is the quantity of heat required to raise the temperature of one gram of water from 14.5° C. to 15.5° C., then the mechanical equivalent is 41,890,000 ergs. Numerous other experimenters have made determinations of the mechanical equivalent, both by the method followed by Joule and Rowland, and by other methods. Prominent among these is Griffiths, who heated the water in his calorimeter mainly by means of a known electrical current, traversing a known resistance, and hence giving out a known quantity of heat. Taking as a unit of heat the quantity of heat required to raise the temperature of a kilogram of water from 14.5° C. to 15.5° C., Griffiths found the mechanical equivalent to be 427.45 kilogram-metres at sea-level in the latitude of Greenwich. Rowland's value, when expressed in these same units and corrected to the latitude of Greenwich, is 427.0. For further details concerning the experimental determination of the mechanical equivalent, consult Preston, 'Theory of Heat'; and for numerous interesting illustrations of the first law of thermodynamics, consult Tyndall, 'Heat a Mode of Motion.'

The «second law of thermodynamics» is hard to explain in a limited space, or without the use of higher mathematics; and, as Rankine remarked, its exposition has been much neglected by the writers of popular works, so that «the consequence is that most of those who depend altogether on such works for their scientific information remain in ignorance, not only of the second law, but of the fact that there is a second law; and knowing the first law only, imagine that they know the whole principles of thermodynamics.» In its simplest form, the «second law» merely states that heat always tends to pass from a hotter body to a colder one. This fact is obvious enough in its simpler manifestations; for every housewife knows that to make the kettle boil she must put it on the stove and not in the refrigerator. It is not so evident, however, that there are no conditions whatever under which heat will pass of its own natural tendency from a lower temperature to a higher one. It is not evident at first thought, for example, that we cannot make a burning glass big enough to give a temperature, at its focus, which shall be higher than the temperature of the sun; yet we cannot do so, if the second law of thermodynamics is true, for the heat at the focus of the glass certainly comes from the sun, and if that focus were hotter than the sun, we should have a case in which heat is passing by its own natural radiative tendency from a cooler body (the sun) to a hotter one (the focus of the glass). The second law was first proposed, as a broad principle of nature, by Clausius; and although numerous distinguished mathematicians and physicists have questioned its validity from time to time, it is now recognized as a great, universal truth, applicable to all classes of phenomena, without exception, so long as we are dealing with large masses of matter. We cannot undertake, here, to discuss the seeming exceptions that occur in connection with particles microscopic or less in size. (See BROWNIAN MOVEMENT). It is indeed true that heat can be abstracted from a body and made to pass into a warmer one, and this is actually done on a commercial scale in cold storage plants and in the manufacture of artificial ice; but the point is that this feat cannot be accomplished without the expenditure of energy. We are to think of heat, in its tendency to pass from a higher temperature to a lower one, in much the same way as we think of water tending to run down hill. Water will not run up hill of its own accord, but it may be forced to pass from a lower level to a higher one by the expenditure of energy upon a pump or other equivalent device. The correctness of Clausius' hypothesis with regard to heat is substantiated by the fact that no case has yet been discovered in which it is demonstrably violated. On the other hand, many previously unknown phenomena of nature have been predicted by its aid, and in every instance subsequent experiment has borne out the prediction in every respect. For a short account of some of the better known objections that have been urged against the soundness of the "second law," consult the latter portion of Browne's translation of Clausius's 'Mechanical Theory of Heat.'

In studying the transformation of heat-energy into mechanical energy (or the reverse), it is customary to think of the conversion as being performed by a suitable type of heat-engine; for this conception helps to make the problem definite, so that the mind can readily grasp the principles involved. The imaginary engine is usually conceived to be perfect in construction, so as to run without friction and without losses by radiation or conduction. In fact, the material of which the engine is composed is assumed to be incapable of absorbing any heat at all. Some of its parts may, however, be assumed to be perfectly transparent to heat, and others to be absolutely opaque to it; and we may make such other extravagant assumptions as may be convenient for the discussion of the problem in hand, the only office of the imaginary engine being to assist the mind in the presentation and discussion of the essential facts, whatever those may be. These fictive engines are usually assumed, furthermore, to be "perfectly reversible," so that when, by the expenditure of mechanical power, they are forced to run backwards, all of the normal operations of the engine take place precisely as before, but in a contrary sense. If, for example, the engine, at some instant in its forward motion, absorbed a quantity Q of heat from an outside body whose temperature was T, then when the engine reaches the corresponding state in its reversed motion, it must give out this same quantity, Q, of heat, and must give it out again to the same body from which it originally abstracted it, and at the same temperature, T. An engine which fulfils all of these various conditions is called a "perfectly reversible engine"; or, more briefly, an "ideal engine."

Carnot's Theorem.— In 1824 Carnot gave a remarkable theorem (consult his 'Reflections on the Motive Power of Heat,' Thurston's translation), which may be stated in the following language: Of all the possible kinds of heat engine, which run by converting heat-energy into mechanical energy, and which take in their heat all at one given temperature and give out all that they do give out (if any) at another given temperature, there is none that is more efficient than the ideal, reversible engine; "efficiency" being defined as the fraction of the absorbed heat-energy that is converted into mechanical work. This theorem is of exceeding importance, as it holds true not only for the untold thousands of kinds of ideal engines that we might be able to think of at the present time, but also for any others that may depend upon principles of nature as yet undiscovered; always supposing that the two fundamental laws of thermodynamics, as stated above, are true. In Carnot's time, heat was believed to be a substance; and Carnot's proof of his theorem is based upon this view. After the newer conception of heat had been attained, however, Clausius proved that Carnot's theorem is capable of equally sound demonstration in accordance with the two thermodynamical laws now admitted. The proof is as follows: Let us assume that the theorem is false, and that there is some other engine, which we will designate as B, which is more efficient than some particular ideal reversible engine, A, which runs between the same two temperature limits. Let T_1 be the temperature at which both engines take in their heat, and let T_2 be the temperature at which each rejects such heat (if any) as it does not transform into work. Let H_1 and H_2, respectively, be the quantities of heat taken in and rejected, during a given time, by the reversible engine, A, and let H'_1 and H'_2 be the quantities taken in and rejected, respectively, by the other engine B. The quantities of heat that are transformed into work by A and B, respectively, are then $(H_1—H_2)$ and $(H'_1—H'_2)$; and the efficiencies are respectively $(H_1—H_2)/H_1$ and $(H'_1—H'_2)/H'_1$. The condition that we are assuming, in violation of the theorem, is that the efficiency of the engine B is greater than that of A; that is, $(H'_1-H'_2)/H'_1 > (H_1-H_2)/H_1$; or, what is the same thing, $H_1(H'_1-H'_2) > H'_1\ (H_1-H_2)$. Now suppose that the two engines are coupled together so that the engine B runs forward and drives the reversible engine, A, backward. Then A, owing to its reversibility, for every (H_1-H_2) units of mechanical work that it absorbs, takes in H_2 units of heat at the temperature T_2, and rejects H_1 units of heat at the higher temperature, T_1; while the other engine, B, for every $(H'_1-H'_2)$ units of mechanical work that it performs, takes in H'_1 units of heat at the higher temperature T_1, and rejects H'_2 at the lower temperature T_2. Now in the case supposed, where one of the engines drives the other one backward, the mechanical energy devoleped by the engine B is entirely absorbed by the reversed engine, A. Hence we have $(H'_1-H'_2) = (H_1-H_2)$; and this equation, taken in connection with the foregoing inequality, gives $H_1 > H'_1$. That is, the heat delivered by the doubled engine to the source whose temperature is T_1, is greater than the heat that is being withdrawn from that source; so that if we regard the doubled engine as a single machine, we have a case in which heat is passing, by its own natural tendency and without external compulsion, from a temperature T_2 to a higher temperature, T_1. But this is contrary to the second law of thermodynamics; and hence if that law is sound, it must be that no such engine as B exists. In other words, there is no engine which takes its heat all at a temperature T_1, and rejects what it does reject at a lower temperature T_2 which has a higher efficiency than the ideal reversible engine running between these same temperature limits. It will be observed that in case both of the engines are reversible, the foregoing proof can easily be made to show that neither one is more efficient than the other one. It follows, therefore, that all ideal reversible engines which take in no heat except at T_1, and reject none except at T_2, have the same identical efficiency; and this efficiency can, therefore, depend upon nothing but the two temperatures T_1 and T_2. In the language of mathematics, the efficiency of an ideal reversible engine which runs as here described is a "function" of the temperatures at which heat is absorbed and rejected, and of nothing else. In the foregoing demonstration it was assumed that all of the heat taken in by the engine B is either transformed into mechanical energy or rejected at the temperature T_2. If the engine B is of such a kind that this condition is not fulfilled, by reason of the engine losing some of its heat at temperatures intermediate to T_1 and T_2 (or by reason of any other imperfaction in design or construction), then the theorem is still true; for the assumption that we have made above is the one that is least favorable to the demonstration.

Absolute Temperature.— Let us consider an ideal, reversible engine, which in each unit of time takes in H_1 units of heat at the temperature T_1, and rejects H_2 units of heat at the temperature T_2. Then the efficiency of the engine is $(H_1-H_2)/H_1$; and this (as we have seen) must be equal to some function of T_1 and T_2. It will be more convenient, however, to write the efficiency in the form $1-(H_2/H_1)$; which is obviously permissible. Since this is a function of the two temperatures, so also is H_1/H_2; and we may write $H_1/H_2=f(T_1, T_2)$. Now H_2, being the heat rejected by the given engine at the temperature T_2, may be used again in a second ideal reversible engine, which we may assume to take its heat at T_2, and to reject what it does reject (if any) at some still lower temperature, T_3. The second engine, considered separately, would give a second equation entirely analogous to the one already written; and we should have $H_2/H_3=f\ (T_2, T_3)$. But we might consider the two engines, coupled together, to constitute a single ideal reversible engine, taking in a quantity H_1 of heat at T_1, and rejecting a quantity H_3 at the temperature T_3. From this point of view we could write $H_1/H_3= f\ (T_1, T_3)$. But if we multiply H_1/H_2 by H_2/H_3, we obtain H_1/H_3; and hence we see that the function f must be of such a nature that we have the identical relation

$$f\ (T_1, T_2).\ f\ (T_2, T_3)=f\ (T_1, T_3),$$

whatever the values of T_1, T_2 and T_3. Examination of this equation will show that the disappearance of T_2 by the multiplication of the two terms in the first member involves that the function f shall be of the form

$$f\ (T_1, T_2)=F(T_1)/F(T_2).$$

Hence we have the general relation

$$H_1/H_2=F(T_1)/F(T_2);$$

H_1 and H_2 being, respectively, the quantities of heat absorbed and emitted by any ideal reversible engine, at the temperatures T_1 and T_2; the engine being supposed to absorb no heat except at T_1, and to reject none except at T_2. The algebraic form of the function $F(T)$ will depend, evidently, upon the kind of thermometer that is used in defining the temperature T; but whatever the form of the function may be, its numerical value will always be the same for any fixed temperature, no matter what the nature of the thermometric scale may be, from which it is obtained. This follows from the fact that the last equation above must always hold true, and H_1 and H_2 are not dependent in any way upon any thermometric scale. The independence of the numerical value of $F(T)$ of all arbitrary thermometric scales suggested to Lord Kelvin the possibility of computing the numerical values of the function, and basing upon these values a new thermometric scale, which he called the "absolute scale," since its readings would be "absolute," in the sense of being independent of the properties of any particular kind of matter. Preliminary investigations of the quantities of heat absorbed and rejected by an ideal reversible engine in which the work is performed by the expansion of air indicated that the numerical values of the function $F(T)$ can be expressed in the form $F(T)=T+C+x$, when T is the temperature according to the normal, constant-volume air thermometer (see THERMOMETRY); C being a constant and x a small variable term, whose value, between the freezing and boiling points of water, never exceeds a very small fraction of a degree. For the details of the method by which the numerical values of the function $F(T)$ are evaluated, reference must be made to special works on thermodynamics, and to papers on the subject of absolute temperature. (See HEAT). It is sufficient, here, to say that by the application of the two fundamental principles of thermodynamics to the phenomena that occur when a mass of gas changes its state by an infinitesimal amount, it is possible to deduce a differential equation which, when integrated for the conditions that prevail in a constant-volume thermometer filled with the kind of gas under consideration, will give a finite relation between the scale of the gas thermometer and the "absolute scale." One of the most important terms in this differential equation relates to the change of internal energy experienced by a gas when the volume of the gas changes while the temperature remains constant. In order to evaluate this term, special experiments are necessary, in which the gas is caused to change its volume, while the temperature is constant. Joule and Kelvin were the first to devise an experiment capable of yielding accurate results of this character, and the work that they did along these lines more than half a century ago has never yet been adequately verified, although it constitutes the only secure basis of all that we know, to-day, about the numerical corrections that must be applied to the readings of a gas thermometer, in order to reduce those readings to the absolute scale. In their experiments, the gas was caused to expand through a porous plug, and the quantity of energy that must be added to it in order to prevent any change of temperature by this "free expansion" was determined by calculation. It is impossible to enter, in this place, upon the details of their work; but the writer of the present article has made a careful examination of the data given by Joule and Kelvin, and he finds that when the temperature is measured by the normal constant-volume hydrogen or nitrogen thermometer, in which the pressure at the freezing point of water is that due to one metre of mercury, and which is graduated according to the Centigrade scale so as to read 0° at the freezing point of water and 100° at the boiling point, (1) there must be a constant term of 273.10° added to the reading of the thermometer in order to obtain the reading of the instrument on the absolute scale, and also (2) a small variable term, whose values are given in the second and third columns of the accompanying table.

TEMPERATURE BY GAS THERMOMETER	Variable part of the correction to reduce to the absolute scale	
	Nitrogen thermometer	Hydrogen thermometer
0° C.	0.000°	0.000°
10°	— 0.003	+ 0.006
20°	— 0.006	+ 0.006
30°	— 0.007	+ 0.007
40°	— 0.008	+ 0.004
50°	— 0.008	0.000
60°	— 0.007	— 0.003
70°	— 0.006	— 0.006
80°	— 0.004	— 0.007
90°	— 0.002	— 0.005
100°	0.000	0.000

The corrections here given are different from those usually quoted, but it is believed that they are more accurate. In the case of the hydrogen thermometer, it will be observed that from 0° C. to 50° C. the corrections are positive, while from 50° C. to 100° C. they are negative. However improbable this change of sign may appear, it is certain that the differences between the readings of the hydrogen and nitrogen thermometers, as deduced from the corrections here given, correspond very faithfully with the actual differences as observed at the International Bureau of Weights and Measures at Paris. Owing to the smallness of the variable part of the correction, it is usualy, in writings upon engineering topics and upon thermodynamics generally, to take note only of the large constant term that is to be added, and to treat absolute temperature as though it were identical with the temperature as read from a constant-volume gas thermometer, save for the addition of the constant, 273.10° C. In other words, if t is the absolute temperature corresponding to a given reading T on the scale of a gas thermometer, it is customary to assume that $t=T+273.10°$, if the thermometer is graduated on the Centigrade plan, or $t=T+459.58°$, if the graduation is according to Fahrenheit.

Students of thermodynamics are often greatly confused by the introduction of the idea of «entropy»; and while this subject requires the higher mathematics for its adequate discussion, a few words may be given to it here. When a body whose state at any given instant is completely defined by two independent variables, undergoes any infinitesimal but reversible change on account of corresponding infinitesimal changes in the two defining variables, it will, in general, absorb or reject a certain infinitesimal amount of heat, and it is easy to form a differential equation of the first order and degree, which will express the quantity of heat that is absorbed; the expression being taken negative, if there is rejection of heat instead of absorption. We know, from the theory of differential equations, that the equation so formed can always be multiplied by some factor (the «integrating factor») which shall cause it to become an exact differential of some function of the variables whose differentials it contains; but, so far as pure mathematics is concerned, it is impossible to say, in advance, what that integrating factor will be, or what the nature of the function may prove to be, of which the modified expression is the exact differential. By the aid of the second law of thermodynamics, however, it may be shown that the reciprocal of the absolute temperature at which the infinitesimal transformation takes place is always an integrating factor of the differential equation in question. In other words, having written the differential expression for the quantity of heat absorbed by the body, we know that we only have to divide it by the absolute temperature of the body, in order to cause it to become the exact differential of some function of the variables. The function whose existence is thus indicated is called the «entropy» of the body, and in the study of thermodynamics this function is a very convenient thing, because its introduction simplifies the treatment of many problems. The main difficulty that students experience in connection with it is the difficulty of assigning to «entropy» any precise physical significance. It is probably better not to try to give any physical interpretation of this sort; for it is sufficient for many purposes merely to recognize the existence of the function, the very fact of its existence suggesting certain mathematical transformations which are exceedingly useful. The suggestion has sometimes been made, that it may prove to be possible to devise an instrument which shall enable us to measure the value of the entropy of a body directly, just as a thermometer measures the value of a temperature. If this could be done, the imagination of the student of thermodynamics would doubtless be greatly assisted; but it does not appear that the hope of discovering an instrument of this sort is at all well founded.

In studying the thermodynamic behavior of a body, the state of the body is defined by giving as many of its measurable attributes as may be necessary in order to fix the condition of the body absolutely. These measurable attributes are represented by letters, and are taken as independent variables. Then, by treating these independent variables by known mathematical methods, we can deduce certain conclusions with regard to the behavior of the body itself. Theoretically, there is no reason why the number of independent variables may not be as great as we please; but in all of the more important applications of thermodynamics it is found to be sufficient to take two independent variables. In the case of a gas, for example, it is usually sufficient to take two such variables, provided the gas is in a quiescent condition and homogeneous throughout. When the possibility of internal motions is admitted or the gas differs in composition or in other respects in its different parts, it is necessary to take more than two variables; but these cases will not be considered in the present article. (Gibbs, in his classical papers on the 'Equilibrium of Heterogeneous Substances,' published in the 'Transactions of the Connecticut Academy of Sciences' just previous to 1880, discussed many of the problems that arise when the composition of the substance under consideration departs from uniformity and homogeneity in any respect). Some latitude is permissible as to the variables that are selected for representing the state of the gas, but for the present we shall consider the state as being thoroughly defined when we know the pressure, P, that it exerts upon each unit of area of the wall of its containing vessel and also the volume, V, occupied by each unit of its mass. Other attributes of the gas may indeed vary, as well as P and V; but if P and V are really sufficient to define the state of the gas completely, then these other attributes that are capable of variation at the same time must all be expressible as functions of the two variables P and V. The temperature of the gas is one of the most notable physical attributes which is capable of variation; and it follows that there must be a relation connecting the temperature, T, with the variables P and V. This equation, which is called the "characteristic equation" or sometimes the "elastic equation," may be written, tentatively, in the general form $T=F(P, V)$. While we know that an equation of this nature must exist, we do not know the exact form of the function F for any actual substance. For gases, however, we know its approximate form, throughout certain ranges of the variables P and V. Robert Boyle showed that so long as the temperature of the gas is kept constant and the gas is not too highly compressed nor too near to its point of liquefaction, the volume varies very nearly as the reciprocal of the pressure, and Charles discovered (to express it in modern language) that so long as the pressure upon the gas remains constant, the volume is nearly proportional to the absolute temperature. Taking these two laws into account, it is evident that the form of the function F must be such that, for such values of the variables P and V as prevail under the conditions in which the laws of Boyle and Charles are nearly true, we must have

$$T=kPV, \text{ or } P=\frac{RT}{V};$$

T being the absolute temperature and k and R being constants whose values are to be determined by experiment. For many practical purposes, this relation between P, V and T is sufficiently exact. When the gas is highly compressed, however, or when it is near to the point of liquefaction, the foregoing equation is found to depart very materially from the facts as experimentally observed. Many attempts have been made to find a more general law connecting the temperature, pressure and volume, and such equations have been given by Rankine, Van der Waals, Clausius, Sarrau and other writers. As the equation of Van der Waals has been of special service and has figured to a great extent in the thermodynamical literature of recent times, it may be cited as an example of the attempts that have been made to find a superior form of elastic equation. The equation in question has the form

$$P=\frac{RT}{V-b}-\frac{a}{V^2},$$

where R, T, V and P have the same significance as before, and a and b are very small constants. If a and b are both zero, this equation reduces to the form previously given, and the same is true if V is very large indeed (that is, if the gas is very rare), since in that case the effects of the small constants a and b are negligible. If we assign to T any constant value that we please, we may, from Van der Waals' equation, trace all the possible relations that P and V can have, at this one temperature. That is, when a, b and R are known, and we have assigned a fixed arbitrary value to T, we may then select any number of values of V, and compute the value of P that corresponds to each one of them. If we plot the values so

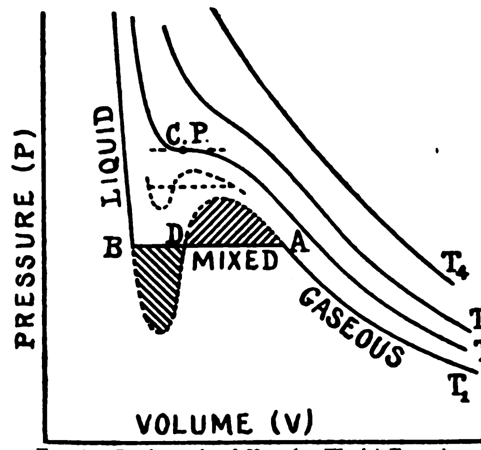

FIG. 1.— Isothermals of Van der Waals' Equation.

computed, by laying off horizontal distances to represent the values of V, and vertical distances to represent the corresponding values of P, we shall obtain a series of points representing the various states that the gas is capable of assuming, while T keeps its fixed value, and if we make the calculated points numerous enough, we may draw through them a curved line, which may be taken to represent the continuous series of states through which the gas passes, as the pressure is continuously varied, while the temperature remains constant. Such lines are called "isothermals," on account of the constancy of the temperature along them. Several such lines, as computed for as many different values of T from Van der Waals' equation, are shown in Fig. 1. If the temperature is high (as at T_4), the isothermal line may be indistinguishable in form from the corresponding line as computed from the elastic equation of Boyle and Charles. If, on the other hand, the temperature is sufficiently low, as is indicated at T_1, the isothermal line will have a very different shape. To trace the significance of this shape, let us begin at the right-hand end of the isothermal T_1, and see what happens when the pressure upon the gas is continuously increased. As the pressure grows greater, the volume of the gas diminishes; but there is no notable change of any other sort until a certain point A is reached. When this point is attained, any attempt to further increase the pressure merely results in the condensation of a part of the gas; the pressure remaining constant (as indicated by the horizontal line ADB) until, at B, the gas is entirely condensed into the liquid form. Further application of pressure then causes but a slight reduction of volume; a fact which is indicated by the steepness of the isothermal line above B. We have here described what actually happens when the gas is compressed along the isothermal T_1; but it must be noted that the plot of this isothermal from Van der Waals' equation does not give a straight part, ADB, but a reversed curve between A and B, as indicated by the dotted line. If we could actually make the gas follow this dotted line, we could cause it to pass from the gaseous condition into the liquid condition, without any discontinuity in state; that is, in such a manner that it would never be partly liquid and partly gaseous, and so that we should not be able to see when the conversion from one state to the other took place. It can be shown, however, that the states of the gas which correspond to the dotted part of the isothermal are essentially unstable, so that the attempt to make the gas follow the dotted portion of the theoretical isothermal is like trying to balance a pyramid upon its point. The line ADB which the gas actually follows in preference to the double loop, is in such a position that the areas of the two shaded loops are equal, as was first shown by Maxwell. A portion of the dotted loops in the immediate vicinity of A and B can be actually realized in the laboratory, by careful experiment; but the instability speedily becomes too marked to permit of the experiments being carried far. At temperatures intermediate between T_1 and T_4 the isothermals have a character intermediate between those shown for those temperatures. As we proceed upward from T_1, the loops on the isothermals grow less and less pronounced, as is indicated by the partial, dotted isothermal, and we presently arrive at one particular isothermal, T_3, where the loops just cease to exist. At any temperature higher than T_3 it is, therefore, impossible to liquefy the gas by the application of any pressure whatever, no matter how great. Hence the temperature T_3 is the «critical temperature» of the gas. (See CRITICAL POINT). There is one point on this critical isothermal (marked «$C. P.$»), at which the isothermal is precisely horizontal and where it also has a point of inflection; and this point corresponds to the critical point of the gas; its temperature being the critical temperature, its volume the critical volume and its pressure the critical pressure.

Although gases obey the characteristic equation of Boyle and Charles very closely when they are not too highly compressed and not too near to condensation, there is no gas which obeys it rigorously under all conditions. It is often convenient, however, to assume the existence of a gas of this sort, for the purpose of illustrating general principles, or of obtaining approximate solutions of thermodynamical problems; and the ideal (but non-existent) gas which fulfils the relation of Boyle and Charles absolutely and under all circumstances is commonly called a «perfect gas,» though «ideal gas» would appear to be a preferable name. In applying the conception of a perfect gas, it is customary to assume the further condition that when a gas of this sort changes its volume at constant temperature, the heat that it absorbs is exactly equivalent to the external work that the gas does, in expanding against the external pressure that the containing vessel exerts upon it. In other words, it is customary to assume that the perfect gas, in addition to obeying the laws of Boyle and Charles perfectly, is also so constituted that its internal energy depends upon nothing but the temperature of the gas. The characteristic equations of Van der Waals and others are decided improvements upon the equation of Boyle and Charles, and they represent, very well, the nature of the phenomena that occur in a gas in the vicinity of the critical point. None of them takes any account, however, of the fact that a body is capable of existing in the solid state, as well as in the liquid and gaseous states; and the first characteristic equation complete enough to take the solid state into account also, has yet to be proposed.

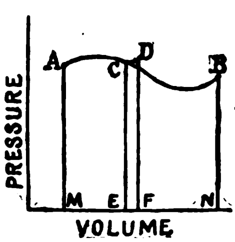

FIG. 2.

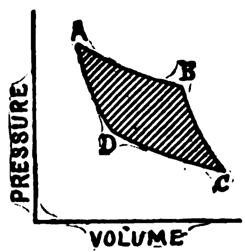

FIG. 3.

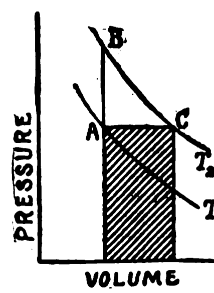

FIG. 4.

When a body passes from one condition of pressure and density to another, it either absorbs or emits heat, unless certain special conditions are fulfilled. To avoid circumlocution, we may speak of it as always «absorbing» heat; the emission of heat being considered to be merely a case of negative absorption. Suppose, for example, that a body is in the state corresponding to A, in Fig. 2; and for definiteness let us suppose that the body under consideration is a gas, although the reasoning will apply equally well to a liquid or to a homogeneous, isotropic solid. The height of A above the horizontal reference line then represents, on some convenient scale, the pressure to which each unit of the bounding surface of the gas is exposed; and the distance of A from the vertical reference line at the left corresponds, upon some other convenient scale, to the volume occupied by a unit mass of the gas. Now if the gas be caused to pass from the condition represented by A to that which is represented by B, by passing through all the intermediate conditions that are represented by the points that are intermediate to A and B on the line ACB, the gas is said to pass from the state A to the state B along the «path» ACB. In general a change of this sort will be accompanied by an absorption of heat; the heat which is absorbed being partly expended in increasing the internal energy of the gas, and partly in the performance of external work. It is a consequence of the first law of thermodynamics that the change in the internal energy of the gas is entirely independent of the shape of the path ACB, and depends only upon the positions of the points A and B. That portion of the absorbed heat which goes to increase the internal energy of the gas, therefore, depends upon nothing but the positions of A and B. The case is different, however, with that portion of the absorbed heat which is consumed in the performance of external work. Consider, for example, the state of the gas at the point C. The pressure upon the gas, per unit of area of the containing vessel, is represented by the vertical line CE; and when the volume of the gas increases by the slight amount EF, the external work that the gas does is represented by the product of the pressure and the increase in volume; that is, it is represented by the area of the little rectangle $CDFE$. We may regard the area $ACBNM$ as made up of an infinite number of infinitesimal rectangles, each of which is typified by the little rectangle that is shown; and hence it follows that the total quantity of external work done by the gas as it passes from the condition A to the condition B, along the path ACB, is represented by the area included between the curve ACB and the straight lines AM, MN and NB. Obviously this area depends upon the form of the path ACB; and hence the external work that is done by the gas also depends upon the form of that path, and so also does that part of the heat absorbed along ACB, which is consumed in performing this work.

When a gas (or other body) describes a *closed* path, such as is shown in Fig. 3, and returns finally to its original state, then the internal energy of the gas also returns to its original value; and the total quantity of heat that is absorbed by the gas during its passage around the closed path is therefore represented entirely by the external work that the gas does. That is, it is represented by the area of the closed path, as shown shaded in Fig. 3. A closed path of this sort is called a «cycle,» and the consideration of cycles of various kinds is very important in many branches of thermodynamical reasoning. If AB and DC, in Fig. 3, represent isothermal lines, and AD and BC represent adiabatic lines (that is, lines along which there is no absorption or rejection of heat by the gas), then the cycle $ABCDA$ is called a «Carnot cycle,» because it is the kind of a cycle that Carnot imagined his ideal, reversible engine to describe. (See Carnot's principle, enunciated in the earlier part of this article).

When a gas is heated from a temperature T_1 to another temperature T_2, the quantity of heat absorbed in the process will depend upon the precise way in which the passage from one of these temperatures to the other is effected. Thus let A, in Fig. 4, represent the initial state of the gas, and let the curved lines, T_1 and T_2, represent the isothermals corresponding to the temperatures T_1 and T_2. If we cause the gas to pass from the isothermal T_1 to the isothermal T_2 along the horizontal line AC, we are heating the gas while its pressure remains constant; and if we cause it to pass from T_1 to T_2 along the vertical line AB, we are heating it while its volume remains constant. If the difference in temperature between T_1 and T_2 is one degree, and the mass of the gas is (as we have already assumed) unity, then the quantity of heat absorbed along AB is the «specific heat at constant volume,» and the quantity absorbed along AC is the «specific heat at constant pressure.» That these two specific heats are really different will be evident from the fact (1) that the internal energy of the gas in the states B and C are not necessarily the same, unless the gas is a «perfect gas»; and also from the fact (2) that the heat that is absorbed along the path AC has to be partially expended in doing the external work represented by the shaded area; while along the path AB there is no external work done.

The fact that in an ideal reversible heat engine the efficiency does not depend at all upon the nature of the substance whose expansion does the work, is sometimes hard for the beginner in thermodynamical reasoning to understand, for the reason that objections occur to him which appear to controvert the principle, and to be themselves unanswerable. There is an answer, however, to every objection that can be urged. One of the commonest of the difficulties is this: In a steam engine, water is pumped into the boiler, and is then evaporated by the expenditure of a large amount of heat. The steam is next passed to the cylinder of the engine and expanded, after which it is turned into the condenser and re-converted into water. The quantity of heat which is expended upon the water in merely converting it into steam (and which is known as the «latent heat of vaporization») appears to be wasted in large measure, because the greater part of it is not converted into mechanical energy by the engine, but is merely rejected into the condenser. Engines have been designed and built, in which the water that is commonly used is replaced by some other liquid (such as ether or carbon disulphide) which has a much smaller latent heat of vaporization, in the belief that this apparently large source of loss could be avoided; but such engines have invariably proved disappointing, any trifling superiority that they may have shown from time to time being attributable to other causes than the smaller latent heat of vaporization of the working fluid. The reason for this is, that there is an intimate relation between the pressure of a saturated vapor at a given temperature, and the latent heat of vaporization of the liquid. This relation is sometimes known as the «second thermodynamic relation,» and sometimes as «Clapeyron's equation.» The elucidation of this matter requires a knowledge of the infinitesimal calculus, and reference must be made for it to the standard works on thermodynamics. Much of the practical experimental work that has been done upon the hot-air engine has probably been inspired by ignorance of the existence, or at least of the significance, of this «second thermodynamic relation.» See HEAT; SPECIFIC HEAT; THERMOMETER; THERMOMETRY; GASES, KINETIC THEORY OF; and other similar articles in this encyclopedia.

THERMO-ELECTRICITY. If an electrical circuit is constructed partly of one metal and partly of another, and one of the points of junction between the dissimilar metals is heated while the other is kept cool, a current of electricity will be caused to flow in the circuit. This fundamental fact was discovered by Seebeck in 1821. The electricity thus generated is not in any wise different from that which is generated by an ordinary galvanic battery; but on account of its mode of production it is called «thermo-electricity.» The electromotive force that is set up in a circuit under the circumstances here described is always quite small, and its intensity depends (1) upon the nature of the metals of which the circuit is composed, (2) upon the difference in temperature between the two junctions where the dissimilar metals come together and (3) upon the average temperature of these junctions. For the sake of definiteness, let the two metals of which the circuit is composed be designated by the letters X and Y. The phenomena of thermo-electricity may then be described in the following mathematical language: It is known from experiment that when the two metals X and Y are brought together so that their point of contact has the temperature T, an electromotive force exists between the two, which tends to send a current (say) from X into Y; and it is also known that the magnitude of this electromotive force can be expressed as a parabolic function of the temperature, T. Thus if E is the electromotive force in question, the facts of experiment can be adequately expressed by a relation of the form $E=a+bT+cT^2$; where a, b and c are constants whose values depend upon the natures of the metals X and Y. In the actual circuit there are necessarily two junctions across which electromotive forces of this character exist. Let the temperatures of these junctions be respectively T_1 and T_2. Then the foregoing formula shows that across the junction whose temperature is T_1 there is an electromotive force of intensity, $E_1=a+bT_1+cT^2_1$, tending to send a current from X into Y; and across the junction whose temperature is T_2 there is a similar electromotive force of intensity

$$E_2=a+bT_2+cT^2_2$$

also tending to send a current from X into Y. These electromotive forces being opposed to each other, so far as the production of a current around the circuit is concerned, the effective electromotive force around the circuit is the difference between E_1 and E_2; and if we denote this effective electromotive force by the letter F, we have

$$F=E_2-E_1=b\ (T_2-T_1)+c(T^2_2-T^2_1),$$

or

$$F=(T_2-T_1)\ [b+c(T_2+T_1)].$$

From this last equation it is evident that so long as the average temperature of the two junctions is constant (or, in other words, so long as T_2+T_1 is constant), the electromotive force will be proportional to the difference in temperature between the two junctions. But it is also evident that when the average temperature of the two junctions is such that the relation

$$b+c(T_2+T_1)=0$$

is fulfilled (or, in other words, when the average temperature of the two junctions is numerically equal to $-b/2c$), there will be no thermo-electromotive force in the circuit (and, therefore, no current), no matter what the difference in temperature between the two junctions may be. This average temperature, for which there is no thermo-electric effect in a circuit, has a definite value for every pair of metals, and is known as the «neutral temperature» for that pair. The values of the constants b and c, in the foregoing formulæ, could be determined experimentally, and recorded in tabular form for various pairs of metals. It is usual, however, to record the experimental data in a somewhat different manner, as we proceed to explain. If the average of the two temperatures T_1 and T_2 be denoted by T_0, then the formula for the effective electromotive force, F, may be written

$$F=(T_2-T_1)\ (b+2cT_0).$$

The constants b and c refer, it will be understood, to a particular *pair* of metals; but it is found that their values can be satisfactorily represented as the differences between constants which can be stated for the two metals separately. Thus b can be expressed in the form $b=B'-B''$ and $2c$ can be expressed in the form $2c=C'-C''$; B' and C' being constants whose values depend solely upon the metal X, and B'' and C'' being constants whose values depend, in a similar manner, solely upon the metal Y. The expression for the effective electromotive force F can, therefore, be written thus:

$$F=(T_2-T_1)\ [(B'-B'')\ +\ (C'-C'')\ T_0].$$

The values of the constants B and C for the different metals vary somewhat with the physical conditions of the metals; but the data given in the accompanying table will show the general nature of these constants, and will also suffice to represent, with some degree of approximation, the actual magnitude of the thermo-electric effects that may be expected from circuits composed of the metals there represented. In applying this table, temperatures are supposed to be expressed on the ordinary Centigrade scale, which defines the freezing point of water to be 0°, and the boiling point to be 100°; and the results are expressed in hundred-millionths of a volt, so that to reduce them to volts it is necessary to divide them by 100,000,000.

To illustrate the use of this table, let us compute the electromotive force of a circuit composed of iron and copper, when one of the junctions is kept at 0° C., and the other at 100° C. For iron we have $B=+1734$ and $C=-4.87$; and for copper we have $B=+136$ and $C=+0.95$. Hence we see that for this pair of metals $b=+1734-136=+1598$, and $2c=-4.87-0.95=-5.82$. The thermo-electromotive force in the circuit is therefore,

$$F=(T_2-T_1)\ \ (1598-5.82T_0).$$

But we have assumed that $T_2=100°$ and $T_1=$

0°; hence $T_2 - T_1 = 100$, and $T_0 = 50°$, and we have $F = 100(1598 - 5.82 \times 50) = 130{,}700$. Dividing this by 100,000,000 to reduce it to volts, the final conclusion is, that a thermo-electric couple of the kind described will give an electromotive force of about 0.00131 of a volt (in round numbers). To find the "neutral point" of an iron-copper couple, we merely have to set the expression $1598 - 5.82T_0$ equal to zero, and solve the equation for T_0. Proceeding in this manner, we find that the desired neutral temperature is 274° C.

THERMO-ELECTRIC CONSTANTS OF METALS.

METAL	B	C
Iron	+ 1734	— 4.87
Steel	+ 1139	— 3.28
Soft platinum	— 61	— 1.10
Hard platinum	+ 260	— 0.75
Magnesium	+ 244	— 0.95
German silver	— 1207	— 5.12
Zinc	+ 234	+ 2.40
Silver	+ 214	+ 1.50
Gold	+ 283	+ 1.02
Copper	+ 136	+ 0.95
Lead	0	0.00
Tin	— 43	+ 0.55
Aluminum	— 77	+ 0.39

Nickel is not included in the foregoing table, because its behavior is anomalous. From −18° C. to 175° C. its constants are $B = -2204$ and $C = -5.12$; but a short distance above 175° C. their values change profoundly, so that between 250° C. and 310° C. we have $B = -8449$ and $C = +24.1$. Above 340° C. we have, for this metal, the values $B = -307$ and $C = -5.12$. Antimony and bismuth are commonly used as the two metals in experimental thermo-electric circuits, since they yield an electromotive force which is larger than is obtainable under similar conditions by other metallic pairs. The thermo-electric constants of antimony and bismuth do not appear to have been determined with precision, however. When the average temperature of the two junctions (T_0) is about 20° C., the values of $B + CT_0$ are approximately as follows: Bismuth, pressed commercial wire, −9700; bismuth, pure pressed wire, −8900; bismuth crystal, axially, −6500; bismuth crystal, equatorially, −4500. Antimony, pressed commercial wire, +600; antimony, pure pressed wire, +280; antimony crystal, axially, +2260; antimony crystal, equatorially, +2640.

When a thermo-electric couple is generating an electrical current, heat is absorbed at the hot junction, and given out at the cold one. If an electric current is caused to flow across the junction of any two dissimilar metals, heat is either evolved or absorbed at the junction; and if an evolution of heat is observed when the current flows across from the metal X to the metal Y, there will be an absorption of heat when the current is made to flow from Y to X. This phenomenon, which was discovered by Peltier, is known as the "Peltier effect." Lord Kelvin showed that in a thermo-electric circuit the reversible heat effects are not confined to the junctions themselves. He showed, in fact, that when an electrical current is caused to flow through a wire that is locally heated by a gas flame or otherwise, the current tends to cause a displacement, along the length of the wire, of the point of maximum temperature. The effect may be illustrated by thinking of the wire as a tube conveying a stream of some real fluid; the fluid taking up more or less of the heat, and carrying it along in such a way as to shift the point at which the temperature is greatest. The analogy is imperfect, however, because in the case of electricity the heat travels with the current in some metals, and against it in others. This phenomenon (which is known as the "Thomson effect") has an important bearing upon the theory of thermo-electricity, because in a thermo-electrical circuit the temperature is necessarily variable from point to point, and, therefore, the "Thomson effect" may (and in fact does) modify the phenomena considerably. The effect is zero in lead, but in nearly every conductor it is quite sensible. The consequences of the "Thomson effect" are discussed in two papers in the first volume of Lord Kelvin's 'Mathematical and Physical Papers.'

When a circuit contains several thermo-electric couples, with their successive junctions alternately heated and cooled, the total electromotive force that is produced is sensibly equal to the sum of all the electromotive forces that the several couples would produce, if each existed separately. Advantage is taken of this fact in the instrument known as the "thermo-pile," which consists of a series of small bars of antimony and bismuth (often about 25 pairs altogether), disposed side by side so as to form an approximate cube and insulated from one another by strips of paper or other non-conductor. These bars are soldered together at the ends so that a current, in order to traverse the system, must pass back and forth through alternate bars of bismuth and of antimony; the passage of the current from bismuth into antimony being always effected (let us say) at the right hand end of the little pile of bars, while the passage from antimony into bismuth is always effected at the left hand end. The two free ends of the thermo-pile being connected by a wire, a current of electricity flows through the circuit so formed, when either of the surfaces containing the soldered junctions is warmed, while the opposite one is kept cool. This instrument is used to a considerable extent for the detection and even for the approximate estimation of radiant heat; the current that it produces and which is measured by a delicate galvanometer in the external part of the circuit being taken as the index of the amount of the radiation. (Consult Tyndall, 'Contributions to Molecular Physics in the Domain of Radiant Heat'). The thermo-pile was invented by Nobili, but it was so greatly improved by Melloni that it is commonly credited to him.

Many attempts have been made to construct a thermo-electric combination that would yield a current of electricity intense enough to be of commercial utility; but while such attempts have been partially successful, there is no great reason to suppose that thermo-electric generators will ever be of much practical value. The difficulties are partly structural and partly theoretical. In order to realize any considerable electromotive force, the number of elements must be large; and the experience heretofore has been that a complicated thermo-pile is not particularly durable. Even if this objection can be overcome, there remains the serious one that there are theoretical reasons, based upon thermodynamics (q.v.), for believing that the efficiency of the thermo-pile, as an instrument for converting heat energy into electrical energy, can never be high. In a particular case that was investigated by Lord Rayleigh, the maximum possible efficiency was found to be 6 per cent; and it is not likely that an efficiency materially greater than this will ever be actually attained with a thermo-pile that is large enough and durable enough to be of commercial value.

ALLAN D. RISTEEN,
Director of Technical Research, The Travelers Insurance Company, Hartford, Conn.

THERMOGRAPH (Greek, «heat-writing»), any form of self-registering thermometer (q.v.), by which an automatic record of variations of temperature is kept. Many different types of thermograph have been made, of which the following may be especially noted: (1) Photographic thermographs, in which the position of the mercury thread in an ordinary thermometer is photographed upon a moving sensitive film, either continuously or at short intervals of time; the moving sensitive film being actuated by clockwork, so that the time at which any given impression was made can be nicely determined. (2) Metallic-strip thermographs, in which a recording pen is actuated by a strip of metal composed of two substances of differing expansibility, riveted or soldered together. When a strip of this kind is heated, one of its sides expands more than the other, and the result is that the strip becomes curved by an amount which serves as a measure of the temperature to which the strip has been exposed. The pen which makes the record moves radially on a disc of paper which is caused to revolve at a steady rate by means of clockwork. (3) Electric-contact thermographs, in which a fine platinum wire is caused to descend, at intervals, into the open upper end of the capillary tube of a sensitive mercurial thermometer. When the wire touches the mercury column, it completes an electrical circuit, and by this means the position of the mercury thread in the thermometer is recorded. (4) The manometric thermograph, in which the pressure in a closed vessel filled with a gas is taken as the index of the temperature; the pressure being recorded automatically, and the temperature being afterward inferred from the recorded pressure, by means of a theoretical formula, or else by direct comparison of the instrument, at different temperatures, with a standard thermometer. (The pressure of an isolated mass of gas of this kind is known to be sensibly proportional to the absolute temperature of the gas, so long as the volume is kept constant).

THERMOMETER (Greek «heat-measurer»), an instrument for determining the temperatures of bodies. The general problem of thermometry is considered, in this encyclopedia, under the heading THERMOMETRY; and the present article will be devoted mainly to the consideration of the common mercury-in-glass form of the instrument, and to certain of its modifications. The mercury-in-glass thermometer depends for its action upon the fact that mercury expands about seven times as much as glass, for a given rise in temperature; so that when mercury is enclosed in a glass vessel, its apparent expansion is quite considerable. The mercury-in-glass thermometer consists essentially of four parts, these being (1) the mercury, (2) the spherical or cylindrical bulb of glass which contains it, (3) the fine tube which is attached to the bulb and which serves to make the expansion of the mercury evident, and (4) the graduated scale which is affixed to the capillary tube and from which the indications of the instrument are read. In the manufacture of thermometers which are intended for accurate work, the mercury is carefully purified by filtration through leather under pressure, and by subsequent distillation, and, in many cases, by chemical treatment also; and immediately before the mercury is placed in the thermometer it should be boiled so that it may be rendered free from moisture and from air. In the manufacture of the capillary stems of thermometers, some kind of glass which experience indicates to be adapted to this end is melted and the operator takes up a ball of it on the end of his blowpipe, blowing it out gradually and adding more glass to the mass from time to time. When the ball of molten glass has thus been brought to a convenient size, a second workman attaches his blowpipe to it also, and the two, still blowing, walk apart, so that the sphere of glass is drawn out into a very long and fine tube, which, when it has cooled, is cut into lengths and annealed. The calibre of each of these lengths is subsequently measured under the microscope, so that the instrument maker may know how large a bulb must be attached to each piece, in order that the degree-spaces on the finished thermometer may be of approximately the desired size. The bulb of the thermometer is usually made of a different kind of glass from the stem; and the process of making it consists simply in fusing to one end of the open stem a knob of special glass and then blowing it to size through the stem. In thermometers that are to be used for accurate scientific work, the bulbs should always be made of one of the three kinds of glass that are respectively known as «verre dur,» Jena 16^{III} and Jena 59^{III}. The first of these is a French glass, which has been demonstrated to be peculiarly adapted for use in thermometer bulbs, by the elaborate experiments made at the International Bureau of Weights and Measures, at Paris. The other two are made at Jena, Germany, and have been similarly proved to be adapted for use in accurate thermometers, by the experiments made at the Reichsanstalt, in Berlin. Since 1917 American glasses are manufactured that are well suited to the construction of accurate thermometers; but the problem to be solved is a difficult one and it will require much study and experiment. The stem and bulb of the thermometer being thus completed, the next step consists in cleaning them thoroughly on the inside. For this purpose they are washed out with hot nitric acid, with distilled water and with ether. They are then thoroughly dried, preferably by repeatedly exhausting them, while hot, with an air pump, and then filling them again with air that has been carefully dried. The next operation consists in filling the thermometer with pure mercury. In order to do this the bulb is heated until the air that it contains is partially expelled and the open end of the stem is then dipped beneath the mercury. As the bulb cools, the air remaining within it contracts and mercury rises through the stem until the bulb has become partially filled; this operation being repeated until the bulb is full. The instrument is next heated to a temperature considerably higher than the highest temperature to which it is to be exposed in use, the mercury that it contains becoming thereby so much expanded that it fills the entire stem and runs over at the top; and while the stem is still filled in this manner it is sealed off at the end by means of a blowpipe. In the higher grades of thermometers, a tiny pear-shaped bulb is left at the top of the stem, partly as a precaution against the destruction of the thermometer in case it is accidentally exposed to too high a temperature in its subsequent service and partly as an aid in the calibration of the stem. When such a pear-shaped bulb is provided, the stem may be sealed off at the end while the internal space is exhausted by means of an air pump, instead of while it is filled with mercury; or the tube may be filled, above the mercury column, with dry nitrogen or some other inert gas. The glass part of the instrument having been completed, it remains to affix the scale to the stem. In high grade thermometers, the scale is engraved upon the stem directly; but in the cheaper forms it is usually engraved or stamped upon a piece of metal or of wood, to which the thermometer is finally secured. Let us consider the high grade instruments first and the cheaper ones afterward. Instruments of the former class are graduated by finding, experimentally, two definite points upon the stem, corresponding to two known temperatures; the two known temperatures which are selected for this purpose being the boiling point and freezing point of water. When these two points are found, the space between them is divided into a certain number of equal parts, which are called degrees. In determining the position of the boiling point upon a thermometer, the instrument is placed in steam that is rising from water that is boiling freely under a barometric pressure equal to that which would be produced by a column of pure, ice-cold mercury, 760 millimeters high, at sea-level in latitude 45°. When the mercury column in the thermometer ceases rising and becomes stationary, the point opposite which it stands is marked upon the stem and is called the «boiling point.» If the barometric pressure under which the experiment is performed is not identically equal to the value assumed above, allowance must be made for that fact by the aid of the experiments of Regnault (or others) upon the variation of the boiling point of water per millimeter of change of barometric pressure. The boiling point having been marked upon the thermometer as here indicated, the instrument is then placed in a mixture of water and finely pulverized ice, as quickly as this can be safely done; and the point to which the mercury sinks is marked and called the «freezing point.» The distance, on the stem, between the boiling and freezing points, is then marked off, by means of a dividing engine, into as many equal spaces as there are degrees between the freezing and boiling points of water and (save for the affixing of numbers to the degree-marks) the thermometer is complete. It may be, of course, that the thermometer is to be divided into half degrees, or into tenths; but the operation is precisely the same, in this case, as it is when the division is to be made to degrees only.

We could evidently divide the space between the boiling point and the freezing point into as many equal «degrees» as we chose; for there is no reason, in the nature of things, why a «degree» could not have any one size, just as well as any other size. It is desirable, however, to have some uniform practice in this respect, and hence the manufacturers of thermometers invariably conform to one or the other of three standard systems. In France, and also for scientific work in nearly every country, it is customary to follow the plan introduced by Professor Celsius of Upsala, which consists in dividing the fundamental interval between the two fixed points into 100 equal parts, the freezing point being called «zero,» or 0°, and the boiling point 100°. This method of graduation is known as the «Centigrade» (or «hundred-degree») system. For general purposes in the United States and in England, it is far commoner to graduate thermometers according to the system introduced by Fahrenheit of Dantzig, about 1714. In this system the interval between the freezing and boiling points is divided into 180 equal spaces, or «degrees»; but the freezing point is here called 32° and the boiling point 212° $(32° + 180° = 212°)$. There has been much discussion as to the reason that Fahrenheit had for dividing the fundamental interval into 180 equal parts; but there can be no doubt but that his zero point was intended to represent the greatest cold that was known in his day, this being obtained by mixing salt and snow. By adopting this lowest temperature as his zero, he probably sought to avoid the use of negative temperatures; but in these days when temperatures several hundred degrees lower than his zero can be produced, the significance of the 32 is lost, and we now adhere to it simply from custom. The third thermometric system that has been used to a considerable extent is that due to Réaumur. In this system the fundamental interval is divided into 80 equal degrees, and the freezing and boiling points are marked 0° and 80°, respectively. This method of graduation is extensively used in Germany upon thermometers intended for household purposes; but for most other purposes in that country it has given way to the Centigrade system.

After a thermometer that is to be used for precise measurement has been made and graduated, it is subjected to certain experimental investigations, for the purpose of ascertaining the errors to which it may be liable. One of the most important of these investigations relates to the «calibration error,» which is due to such irregularities of calibre as the bore of the stem may possess. In order to determine the calibration errors, a thread of mercury of suitable length is detached temporarily from the column in the stem, by shaking the instrument. An expert in this kind of work can usually detach a thread of almost any length that he pleases, whether it be long or short. The instrument is then inclined so that the detached thread may be brought into various positions in the stem; and in certain of these positions its length is observed with great care. The volume of the thread being constant, it is plain that its length will be greater where the calibre of the tube is small than it will be where the calibre is relatively large. The details of the operation of determining the calibration errors of a thermometer are very involved; but the general plan consists in observing the lengths of detached threads of mercury at different points of the stem and then computing from these observed lengths, the relative areas of cross-section of the stem-calibre at various points. It is then possible to calculate a table of calibration corrections, by the aid of which it will be easy to correct any given reading of the instrument, so as to find what reading would have been obtained if the item had been of absolutely uniform calibre throughout.

Prominent among the other sources of error, there are four that merit special attention. (1) In the measurement of a temperature, the bulb of the thermometer is supposed to be fully exposed to that temperature; but since the mercury in the stem must be seen in order to be read, it often happens that the stem of an instrument is necessarily exposed to conditions of temperature that are materially different from those to which the bulb is subjected. Hence there is often a «stem error» to a thermometer, due to the fact that the mercury thread in the stem is colder (or hotter) than that in the bulb, and, therefore, shorter (or longer) than it really ought to be. The magnitude of this stem error will obviously vary with the conditions under which the thermometer is used. It is always uncertain in amount and hence it is customary, in well-executed scientific work, to design the apparatus that is to be used (including the thermometer itself), with special reference to the desirability of keeping the stem error as small as possible. (2) When the barometric pressure upon the bulb of the thermometer varies, the bulb yields elastically to these variations and often to an extent quite sufficient to influence the reading of the instrument by an amount that cannot be neglected. The error due to this cause can be determined and eliminated by means of the «external pressure coefficient,» which is obtained by subjecting the thermometer, at some fixed temperature, to a known change of external pressure and noting the alteration of the reading that this variation of pressure produces. (3) The pressure of the mercury upon the inner surface of the bulb may vary from several causes, one of which is the position of the thermometer itself. If the stem is in a vertical position, the bulb will be subjected to a pressure due to the height of the column of mercury in the stem; and when the thermometer is horizontal, this static pressure will be absent. In small thermometers the error due to this cause is unimportant; but in instruments of high precision, in which the stem may be several feet in length, it must receive due consideration. The constant which is used for correcting for this source of error and which is to be determined by experimenting with the thermometer in different positions but at the same constant temperature is called the «internal pressure coefficient.» (4) It is found that the glass of which a thermometer is composed exhibits certain anomalies in its expansion and contraction, when its temperature is altered. These result in an apparent variation in the position of the «zero point» of the thermometer, which is very troublesome when measurements of the highest precision are to be made. It is on account of this anomalous variation in the position of the zero point that the three kinds of glass mentioned in the earlier part of this article are recommended for the manufacture of the bulb; the variation of the zero having been studied in the case of these species of glass with great care. The phenomena as observed in the case of «verre dur» are thus described by Guillaume: «When a verre dur thermometer is quickly exposed to a temperature of 100° C., after having reposed for a considerable time at the ordinary temperature of the laboratory, its zero point falls with such rapidity that after an exposure of one minute at 100° C. the displacement is practically complete. If the thermometer is then placed in ice-water, its zero ascends, for the first few moments, at the rate of about 0.001° C. per minute; but this rate diminishes rapidly. When a thermometer is maintained at a constant temperature, its zero point rises little by little and the change can be traced plainly for several years. For thermometers of verre dur, the gradual rise at constant temperature amounts to about 0.001° C. per month when the thermometer is two years old; and at the end of four or five years the motion is found to have diminished to about 0.0002° C. per annum.» The ideal way of measuring a temperature, with a thermometer made of one of the three glasses mentioned above, is as follows: The thermometer is exposed to the temperature that is to be measured, and its zero point falls to a certain (presumably unknown) position. After the instrument has been read, it is introduced, as quickly as is consistent with its safety, into a mixture of water and pulverized ice. The mercury sinks at once and soon attains a stable position, which, on account of the slowness of the change of zero with falling temperature, is taken to be the zero corresponding to the higher temperature to which the instrument has been previously exposed. In accordance with this plan, the temperature to be measured is found by subtracting the subsequent reading in ice-water from the reading obtained at the temperature to be determined. The method here outlined, for eliminating the effect of variations in the zero point of a thermometer, is known as the «method of movable zeros,» and is now adopted at practically all of the centres of accurate thermometry except Kew, for temperatures between the freezing and boiling points. It is not yet possible, by any method of procedure, to determine temperatures more than a few degrees below the freezing point, or more than a hundred degrees (Centigrade) above the boiling point, by the aid of a mercury-in-glass thermometer, with a precision comparable with that which is attainable within the fundamental interval that lies between 0° C. and 100° C.

It is to be understood that in the foregoing discussion of the errors of the mercury-in-glass thermometer, we have been treating of the determination of temperatures to such a degree of precision that the final error is not to exceed (say) 0.005° C. No such elaborate care is required, if the only object of the measurement is to determine the temperature to the nearest degree, or half-degree.

Passing now to the consideration of the ordinary thermometers that are used about the household and by amateur meteorological observers, it may be pointed out, first, that in the manufacture of a thermometer that is to be sold at retail for (say) 50 cents, it is not commercially possible to engrave a special scale for each instrument. In making cheap thermometers it is customary to stamp out the scales in large numbers and then to blow the bulb of each instrument to such a size that the scale will be as nearly as practicable adapted to the finished thermometer. This can be done, by an experienced glass-worker, with greater accuracy than might be supposed; but it is evident that no high degree of precision can be attained in this way. The scale and the rest of the thermometer being adapted to each other as nearly as is commercially practicable, the thermometer is adjusted with respect to the scale by exposing it to some known temperature (say 70° F.) in the vicinity of the temperatures at which it is most likely to be used and then securing it in such a position that the point on the stem to which the mercury rises comes opposite the proper mark on the scale. Such a theremometer will give readings that are not greatly in error at temperatures near the one at which it is standardized; but at other temperatures any two such thermometers will necessarily diverge by an amount which depends upon the judgment and skill of the workmen who blew the bulbs and who endeavored to give them capacities adapted to the sizes of the degrees upon their respective graduated scales.

For further information concerning the methods that are used in precise thermometry, consult Guillaume, 'Thermometrie de Précision'; and for the historical aspect of the subject consult H. Carrington Bolton, 'Evolution of the Thermometer.' Consult, also, Preston, 'Theory of Heat.'

Gas Thermometer.—A thermometer in which the temperature is measured by the change of volume, or pressure, of a mass of gas enclosed in a glass envelope. The gases that are most commonly employed for this purpose are air, hydrogen and nitrogen; and thermometers containing these several gases are respectively called «air thermometers,» «hydrogen thermometers» and «nitrogen thermometers.» See THERMOMETRY.

Alcohol Thermometer.—A thermometer in which the temperature is indicated by the expansion of alcohol (instead of mercury); coloring matter of some kind being dissolved in the alcohol, so that the column of fluid in the stem of the instrument may be distinctly visible. Alcohol has a larger coefficient of expansion than mercury, and hence, for the same sizes of bulb and stem, the degrees are longer upon a thermometer containing it. Alcohol can also be used at temperatures that are low enough to destroy an ordinary thermometer, by the freezing of the mercury. No great degree of precision can be attained with the alcohol thermometer, however, partly because the liquid wets the glass and thereby causes the instrument to read too low when the temperature is falling, and partly for other reasons. For the measurement of temperatures approaching the freezing point of mercury (37.8° F. below zero) the International Bureau of Weights and Measures prefers a thermometer filled with toluene to one that is filled with alcohol; the toluene thermometer being apparently capable of yielding much more accurate results. Owing to the fact that alcohol boils at a much lower temperature than water, the alcohol thermometer can hardly be graduated by the method given for the mercury instrument, since exposure to a temperature of 212° F. would cause the alcohol to have a vapor pressure so high that the bulb would be likely to burst. These thermometers are, therefore, graduated, most commonly, by direct comparison with a standard mercury-in-glass instrument. The expansion of alcohol by heat is not strictly proportional to that of mercury and hence if the scale of the mercury thermometer is taken as the standard, the degree marks upon the alcohol thermometer will not be spaced at uniform intervals. These spaces are in fact smaller at low temperatures than at higher ones, as will be seen by examining any good alcohol thermometer that is adapted for observing a considerable range of temperature.

Maximum and Minimum Thermometers are thermometers which automatically record the highest or lowest temperatures to which they have been exposed during a given period. In the Rutherford maximum thermometer the capillary stem of the instrument is placed nearly horizontal and as the mercury rises it pushes before it a tiny index of iron or steel, placed within the tube; and the index, being left at the most extreme position attained by the mercury, indicates the highest temperature to which the instrument has been exposed. In the Rutherford minimum thermometer a similar index is used, but the thermometric column is here composed of alcohol and the index lies within the alcohol. When the temperature falls, the free end of the column of alcohol in the stem adheres to the index and drags it toward the bulb; but when the temperature rises again, the alcohol flows around the little index (which does not fill the capillary tube), and so leaves it in the position to which it had been drawn at the moment when the temperature was lowest. In both forms of thermometer the index is returned to a suitable position for making a new observation by the aid of a small magnet. In the Negretti and Zambra maximum thermometer the capillary tube is partially obstructed near the bulb so that although the mercury flows outward readily enough as the temperature rises, a fall of temperature at any moment causes the mercury thread in the stem to break at the obstruction, so that the maximum temperature to which the thermometer has been exposed can be read directly, in the usual manner. The broken thread can easily be returned to the partially empty bulb by jarring the instrument, or by whirling it sharply in a circle.

Clinical Thermometer.—A form of the Negretti and Zambra maximum thermometer, which is used by physicians for determining the temperature of the human body.

The graduation on these instruments is fine, so that the temperature can be read to the 10th of a degree or so; and the entire interval covered by the graduation rarely extends below 95° F., or above 115° F., the normal temperature of the body being about 98° F. In using the instrument, the bulb is placed under the patient's tongue or in the arm-pit.

Radiation Thermometer.—A form of thermometer designed to indicate the intensity of solar or terrestial radiation. The solar radiation instrument consists of a thermometer with a blackened bulb, the stem being sealed into an exhausted sphere of glass, so that the blackened bulb comes in the centre of the sphere. When sunlight is allowed to fall upon this thermometer and also upon a similar one with a bulb that is silvered and polished, the black bulb absorbs most of the radiant heat, while the polished one reflects most of it. The difference in the readings of the two instruments is assumed to indicate the intensity of the radiant energy falling upon them.

Upsetting Thermometer.—A form of thermometer provided with a constriction in the stem similar to that used with the Negretti and Zambra maximum thermometer, and so designed that when the instrument is inverted the mercury thread breaks at the constriction and runs down into the stem. These instruments are graduated so as to read correctly when they are held upside down. By upsetting a thermometer of this kind by means of clockwork, the temperature that prevails at any particular hour can be recorded.

Deep-Sea Thermometer.—An instrument commonly of the upsetting type, for observing temperature at various depths in the sea. It is enclosed in a very strong case, and is reversed at the depth at which the temperature is desired. At moderate depths the reversal is effected by sending a weight down along the sounding wire; but at greater depths the upsetting mechanism is usually actuated by a small propeller which is arranged so as to begin its rotation when the thermometer starts on its return to the surface of the sea.

Registering Thermometer.—Any thermometer which automatically records its own readings.

Dew-Point Thermometer.—A thermometer adapted to the determination of the temperature at which dew will be deposited from the air. The most accurate form of the instrument is that devised by Regnault. This consists of a pair of thin receptacles of polished silver, shaped somewhat like ordinary chemical test-tubes. A thermometer is placed in each of these, and one of the tubes is then partially filled with ether, or some other volatile liquid. When a current of air is passed through the ether by means of an aspirator, the rapid evaporation cools the silver tube and its contents (including the thermometer); and the observation consists in noting the temperature of the ether, when the polished exterior of the silver tube containing it is first dimmed by the deposition of dew. The second tube of silver, which is not cooled, assists the eye in judging when the dew is first deposited upon the other one; and the thermometer that the uncooled tube contains is used merely to record the temperature of the air at the time of the experiment.

Differential Thermometer.—An instrument for measuring or detecting differences of temperature, without reference to the absolute values of the temperatures that are compared. Sir John Leslie's form, as improved by Rumford, consists of a horizontal tube, turned upward at the two ends, and there provided with a pair of equal bulbs of considerable size. The bulbs are filled with air, and a small quantity of colored liquid is placed in the horizontal tube which joins them; the liquid serving to separate the air masses that the bulbs contain, and also as an index for reading the instrument. So long as the temperatures of the two bulbs remain equal, the pressure of the air will be the same in each, and the liquid index will not move. If one of the bulbs is warmed slightly more than the other one, however, the air that it contains expands and forces the liquid index toward the cooler bulb; the amount of this displacement indicating the difference in the temperatures of the bulbs. This form of differential thermometer is not used to any great extent at the present time, the thermo-pile (see THERMO-ELECTRICITY) and the platinum resistance thermometer (see THERMOMETRY) having almost entirely displaced it.

Wet Bulb Thermometer.—A thermometer whose bulb is covered with thin wet muslin, and which is used for determining the amount of moisture in the air. In practice, the wet bulb thermometer is used in connection with a similar thermometer having a dry bulb, the two being whirled through the air together, or having a current of air directed upon them by a fan, or otherwise. The evaporation of the moisture about the wet bulb causes that instrument to become cooler than the other one; and the difference in the readings of the two thermometers, when taken in connection with the reading of the dry one, enables the observer to determine the degree of saturation of the air at the time the experiment is made. Tables for this purpose are published by the Weather Bureau.

Weight Thermometer.—A thermometer consisting of a bulb provided with a capillary outlet in the place of the usual stem. In using this instrument, the bulb is first weighed while empty, and again when filled with ice-cold mercury. It is next heated to the boiling point of water, and the mercury which escapes from it on account of the expansion is collected and weighed. These data enable the observer to calculate the fraction of the original weight of ice-cold mercury that is lost upon heating the bulb to the boiling point. To determine any other temperature, he fills the bulb, as before, with ice-cold mercury, and then exposes it to the temperature that is to be measured (this temperature being assumed to be higher than the freezing point of water). Collecting the mercury that runs out of the bulb, and expressing its weight as a fraction of the weight of cold mercury that was present at the outset, he has only to compare the fraction so obtained with the fraction obtained in the first experiment, in order to be able to calculate, by a simple proportion, the temperature desired. The weight thermometer is not a convenient instrument to use, but it is simple in theory, and is free from certain of the errors to which ordinary thermometers are liable.

Metallic Thermometer.—An instrument in which temperature is determined by noting the change of form or of length that a metallic strip experiences when it is heated. In Bréguet's instrument, three thin strips composed respectively of platinum, gold and silver are rolled together into the form of a single ribbon, the gold being in the centre. The ribbon is then coiled into a spiral, with the silver on the concave side. When one end of such a spiral is fixed, a rise of temperature causes the spiral to partially unwind, owing to the fact that the coefficient of expansion of silver is greater than that of gold, while the coefficient of gold is also greater than that of platinum. The free end of the spiral is caused to actuate a pointer, by which the temperature is indicated.

Platinum Resistance Thermometer.—An instrument for determining temperature, by noting the variation of the electrical resistance of a wire or strip of platinum. (See THERMOMETRY).

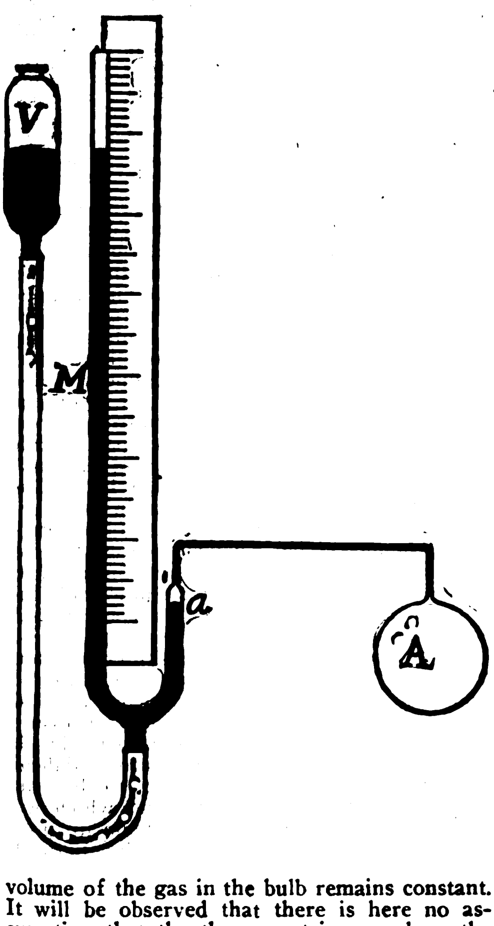
THERMOMETRIC ANALYSIS. See CHEMICAL ANALYSIS.

THERMOMETRY, the art of measuring temperatures. The «measurement» of temperature is quite a different thing from the measurement of a time, or a length, or a mass, and it consists merely in assigning to each temperature that may come up for consideration a definite place upon some sort of a numerical scale. The scale itself may be perfectly arbitrary, so that an interval of temperature upon one part of the scale cannot be said to be «equal,» in any physical sense, to an interval on some other part, even though the two are expressed by the same number of «degrees.» The chief essentials of a practical thermemetric scale are (1) that it shall be perfectly definite, so that when the same temperature is «measured» on several different occasions, the same identical result will be obtained each time, at least to a degree of approximation sufficient for the purposes for which the temperature is being determined; and (2) that it shall be possible for two or more different observers, provided with distinct instruments of measurement, to measure the same temperature, and obtain results that are identical, at least to the same degree of approximation as noted above. So long as these essential conditions are fulfilled, we may make use, for the purpose of establishing a thermometric scale, of any measurable property of matter, which varies in a determinate way with temperature; the «temperature,» in any such case, being defined as proportional to the atttribute that is measured, or to any continuous function of that attribute. We may, therefore, have as many different «scales» of temperature as we please, and any one of these will be just as defensible, and just as «correct,» as any other one, although no two of them will be in perfect agreement. In practice it is found that four particular kinds of thermometric scales are especially useful. These are based, respectively, upon (1) the expansion of some substance that is subjected to an unvarying pressure; (2) the increase in pressure of a gas which is kept rigorously constant in volume; (3) the variation of the electrical resistance of a conductor; and (4) the electromotive force of a thermo-electric couple (see THERMO-ELECTRICITY), one of whose junctions is kept at a constant temperature, while the other is exposed to the temperature that is to be measured. Of these four general methods, the first two have been longest and most commonly employed; and the particular instruments that have been most extensively used for putting them into practice are known respectively as the «mercury-in-glass thermometer» and as the «gas thermometer.» The mercury-in-glass instrument is described under THERMOMETER, and the gas thermometer is described in the present article, below.

The gas thermometer was probably the first form of thermometer to be constructed. The mercury-in-glass instrument followed, and for many years was used almost exclusively for the measurement of temperatures, doubtless on account of its simplicity and the ease with which it can be used. But as the science of thermometry developed, and increasing refinement in temperature determinations was demanded, it was found that the mercury-in-glass thermometer is liable to serious errors on account of the anomalous expansions and contractions of the glass envelope; errors which were of little or no importance when a determination of temperature to the nearest quarter of a degree or so was considered sufficiently accurate, but which were of paramount importance when it was proposed to determine a temperature to the hundredth or thousandth of a degree. The errors due to the cause in question can now be eliminated in large measure by making temperature determinations by the «movable zero» method (see THERMOMETER); but physicists nevertheless prefer to follow the lead of Regnault, who, in his celebrated 'Fourth Memoir' (1847), recommended the employment of the gas thermometer as the standard for the establishment of the temperature scale; and the gas thermometer is still the standard in all work of high precision. The great advantage of the gas thermometer consists in the fact that the coefficients of expansion of gases are many times greater than that of mercury, and the effects of anomalous changes of size in the glass bulb are of correspondingly less importance.

The gas thermometer is made in two general forms, according as it is desired to measure the temperature by the expansion of the gas at some constant pressure, or by the increase in the pressure of the gas at some constant volume. The latter plan being the one that is now by far the commoner in accurate work, we shall describe it first, and at some length.

The constant-volume gas thermometer is shown, in its essential features, in the accompanying illustration. It consists of a bulb, A, of considerable size, which is connected, by means of a capillary tube, with a mercury manometer, M. At a there is a mark upon the tube leading to the gas bulb, and care is taken, whenever an observation of any kind is made, to have the level of the mercury in the short arm of the manometer stand exactly at a, in order that the volume of the thermometric gas may always be rigorously the same. A movable reservoir of mercury, V, is connected with the column M for this purpose, by means of a flexible tube; so that by raising or lowering V the mercury in M may be brought to any desired level. Any gas that we please may be used in the bulb A, but hydrogen, nitrogen and air are the ones most commonly employed. In the filling of the bulb, the most elaborate precautions are taken, not only to have the gas that is used pure, but also, and more particularly, to have it perfectly dry. For this purpose the bulb is first exhausted by the aid of an air-pump, and is heated while in the exhausted condition, and allowed to stand for a time, so that any moisture that may adhere to the walls of the bulb may be driven off and removed. The bulb is then filled with gas that has been carefully dried by calcium chloride or other drying agents, and is then exhausted again and heated; the operations of exhausting and refilling being repeated several times, until there can be no doubt about the dryness and purity of the gas which is finally allowed to remain. Temperature, according to this instrument, is defined as being rigorously proportional to the pressure that prevails in the bulb A, so long as the



volume of the gas in the bulb remains constant. It will be observed that there is here no assumption that the thermometric gas obeys the laws of Boyle and Charles (see THERMODYNAMICS); the relation which has just been assumed being the *definition* of the term «temperature,» according to the constant-volume gas thermometer. If T be the temperature as thus defined, and P is the pressure prevailing within the bulb A, then we have, from the definition of temperature, $T = CP$, where C is a constant for the particular thermometer under consideration. (It is to be observed that P is the *total* pressure to which the gas in A is subjected. It includes not only the pressure that is read from the manometer M, but also that barometric pressure that prevails at the same time in the air of the laboratory; for this barometric pressure acts upon the top of the mercury column, and it is, therefore, to be added to the reading of the manometer M). To deduce the value of the constant C, we may subject the bulb A successively to the steam from boiling water, and to a mixture of ice and water, as described under THERMOMETER. The total pressure upon the gas in the bulb being noted in each case, let us suppose that it is P_0 at the freezing point, and P_{100} at the boiling point. Then the foregoing equation, when applied to these two cases, takes the following forms, respectively: $T_0 = CP_0$, $T_{100} = CP_{100}$; T_0 being the temperature of the freezing point according to the scale of this thermometer, and T_{100} being that of the boiling point. We may define either T_0 or T_{100} however we please, and then find the corresponding value of C; but it is desirable that the scale of the gas thermometer shall be as closely as possible like that of the ordinary mercury-in-glass instrument; and in order to fulfil this condition it is found to be best to subject the gas thermometer scale to the condition that the difference between T_0 and T_{100}, as determined by the gas thermometer, shall be numerically the same as the difference between the freezing and boiling points, on the ordinary mercury-in-glass scale. In other words, it is found to be best to have the average size of the degrees the same on the two instruments. In scientific work the Centigrade scale is used in practically every instance; and if we adopt it here, we shall have the relation $T_{100} - T_0 = 100°$, if the condition just mentioned is to be fulfilled. From this and the preceding equations we easily find that $C(P_{100} - P_0) = 100°$, or $C = 100/(P_{100} - P_0)$; so that when we know the values of P_{100} and P_0 by direct observation, we are prepared to determine C at once, and hence to calculate the gas-temperature, T, corresponding to any given pressure P, by means of the relation $T = CP$. It will be seen that the zero of the gas thermometer scale does not coincide with the freezing point of water, but that it is very much lower. The gas thermometer could not give $T = 0$, for example, *unless* $P = 0$; that is, not unless the temperature was so low as to cause the gaseous pressure to disappear altogether. The zero point from which the indications of the gas thermometer are counted, according to the formula given above, is called the «natural zero» of the instrument; and in order to be able to compare the gas scale with the scale of the ordinary mercury-in-glass thermometer, it becomes necessary to know what the temperature of freezing water is, as read from the gas scale. To determine this, we make use of the relation $T_0 = CP_0$. Substituting in this the value of C as already found, we find that $T_0 = 100P_0/(P_{100} - P_0)$. Now the quantity $(P_{100} - P_0)/P_0$ is known as the «coefficient of expansion at constant volume» for the gas. (The name is somewhat absurd, it is true, because there is no expansion at all, if there is no change of volume; and it would be more accurate to designate this fraction as the "coefficient of increase of pressure" at constant volume). It appears, therefore, that the temperature of melting ice, on the scale of the constant-volume gas thermometer, is numerically equal to 100 times the reciprocal of the coefficient of expansion of the gas at constant volume. Having found T_0, we have only to subtract it from every reading of the gas thermometer, in order to reduce that reading to its corresponding value as reckoned from the freezing point of water. If we call the values of $T - T_0$, as computed for any given gas thermometer, the "reduced readings" of that thermometer, then we find that the reduced readings of the nitrogen, hydrogen, air and carbon dioxide constant-volume thermometers are all nearly identical, and that they are all closely comparable with the readings of the ordinary mercury-in-glass thermometer. If two constant-volume gas thermometers be filled with the same gas in different states of density, then the reduced readings of the two are very nearly equal, but yet not necessarily identical.

The coefficients of expansion at constant volume of certain of the more important thermometric gases are given in Table 1, as deduced from a careful analysis of the data given by Chappuis, Regnault and numerous other experimenters of high standing. The "initial pressure" signifies the pressure on the gas in the thermometric bulb, when the bulb is surrounded by ice and water; this pressure being given as the most convenient way of fixing the density for which the coefficients were determined. Two coefficients are given for air at each initial pressure, because it appears to be

1.— Coefficients of Expansion at Constant Volume.

GAS	Initial pressure = 1,000 mm.		Initial pressure = 760 mm.	
	Coefficient of expansion	T_0	Coefficient of expansion	T_0
Hydrogen	0.0036624	273.04°	0.0036624	273.04°
Nitrogen	0.0036745	272.15	0.0036716	272.36
Carbon dioxide	0.0037258	268.40	0.0037106	269.50
Air	0.0036746	272.14	0.0036716	272.36
Air	0.0036720	272.33	0.0036697	272.50

impossible to decide, from the observations thus far made, which one of these values is most likely to be correct, the available measures falling into two general groups, one of which favors one of the foregoing values, while the second favors the other one. In Table 1 the values of T_0 are also given, for convenience of reference.

The International Committee of Weights and Measures, in consideration of the differences that exist even between the reduced readings of constant-volume gas thermometers, adopted the following standard scale for the measurement of temperature, calling it their "normal thermometric scale." The scale adopted is the Centigrade scale of the constant-volume hydrogen thermometer, in which the hydrogen has a density such that its pressure, at the freezing point of water, is equal to that due to a column of ice-cold mercury, one metre (1,000 mm.) high. The temperatures are understood to be "reduced," as described above, so that the thermometer reads 0° at the freezing point and 100° at the boiling point. The ideal scale would of course be the absolute thermodynamic scale (see Thermodynamics); but the corrections that are required in order to reduce gas thermometer readings to this scale are still too uncertain to be definitely adopted in precise thermometry.

2.— Comparative Readings of Constant-volume Gas Thermometers and the Mercury-verre Dur Scale ("Reduced" Temperatures).

Hydrogen	Nitrogen (or air)	Carbon dioxide	Mercury
− 10° C.	− 10.007°	− 10.032°	−10.077°
0	0.000	0.000	0.000
+ 10	+ 10.006	+ 10.025	+10.051
+ 20	+ 20.010	+ 20.043	+20.084
+ 30	+ 30.011	+ 30.054	+30.102
+ 40	+ 40.011	+ 40.059	+40.112
+ 50	+ 50.009	+ 50.059	+50.104
+ 60	+ 60.005	+ 60.053	+60.084
+ 70	+ 70.001	+ 70.044	....
+ 80	+ 79.998	+ 80.031	....
+ 90	+ 79.997	+ 90.016	....
+100	+100.000	+100.000	100.000

In Table 2 comparative readings are given, of the mercury-in-glass ("verre dur"; see Thermometer) scale, and the scales of the constant-volume hydrogen, nitrogen and carbon dioxide thermometers, in which the "initial pressures" are 1,000 millimetres of mercury. The significance of the table will be made plain by the following example: If all of these thermometers were exposed to a temperature at which the "reduced" reading of the hydrogen instrument was 30° C., then the nitrogen thermometer would read 30.011°, the carbon dioxide thermometer would read 30.054° and mercury-in-glass thermometer would read 30.102°. The readings given in the second column were obtained from experiments made upon the nitrogen thermometer; but Chappuis states that the reduced readings of the air thermometer and of the nitrogen thermometer are practically indistinguishable; and hence this column will serve for each of them.

In the constant-pressure gas thermometer, temperature is defined as proportional to the volume of a fixed mass of gas which is allowed to expand in such a manner that its pressure remains constant. Regnault experimented with thermometers of this class, and considered them to be distinctly inferior in accuracy to those in which the volume is constant, and which we have already described. This judgment pronounced by Regnault has met with the approval of nearly every subsequent authority upon experimental physics, and hence the constant-pressure gas thermometer has not been at all extensively used in practical work. Professor H. L. Callendar, in fact, is almost the only prominent advocate of the constant-pressure instrument at the present time. He claims that the constant-pressure gas thermometer is capable of yielding results even superior to those of the constant-volume thermometer; and he has devised a very ingenious form of the constant-pressure instrument, which certainly appears to overcome most of the objections that have been urged against it in the past. (Consult his paper entitled 'On a Practical Thermometric Standard,' in the *Philosophical Magazine,* for 1899, Vol. 48, page 519. Consult also, 'Proceedings of the Royal Society,' Vol: 50, 1892, page 247, and Preston, 'Theory of Heat'). To facilitate computations connected with the constant-pressure gas thermometer, we present, in Table 3, the coefficients of expansion of the principal thermometric gases at the constant pressure of 1,000 millimeters of mercury and also at 760 millimeters. These are obtained by a careful comparison of the best determinations that have yet been made.

3.— Coefficients of Expansion of Gases at Constant Pressure.

Gas	Pressure = 1000 mm.		Pressure = 760 mm.	
	Coefficient of expansion	T_0	Coefficient of expansion	T_0
Hydrogen.......	0.0036600	273.22°	0.0036606	273.18°
Nitrogen.......	0.0036731	272.25	0.0036707	272.43
Carbon dioxide..	0.0037422	267.22	0.0037247	268.48
Air...........	0.0036734	272.23	0.0036706	272.44

The coefficient of expansion of carbon dioxid at a constant pressure of 760 millimeters of mercury must be considered as still somewhat uncertain, though the value given in the table appears to be the best now attainable. The «natural zero» of the constant-pressure thermometer lies in about the same general region as the natural zero of the constant-volume instrument. The temperature of melting ice, as referred to the «natural zero» of the scales of the several constant-pressure gas thermometers, is given in Table 3, in the columns headed «T_0.» No extensive and accurate comparisons have yet been made between the constant-pressure and constant-volume thermometers, either for the same gas or for different ones.

In the platinum-resistance thermometer, temperature is defined as proportional to the electrical resistance of a coil of pure, annealed platinum wire. The «thermometer» itself consists of a coil of the wire, wound upon a sheet or strip of mica, and placed in one of the arms of a Wheatstone's bridge, so that its resistance may be accurately determined. It is usual to denote a temperature as defined by the platinum-resistance thermometer by the symbol «pt» («platinum temperature»). We have, therefore, $pt = CR$, where R is the observed resistance of the coil at the temperature denoted by pt and C is a constant whose value is to be determined. If R_0 and pt_0 and R_{100} and pt_{100} are the respective resistances and platinum-resistance temperatures at the freezing and boiling points of water, then we have, precisely as in the case of the constant-volume gas thermometer, $pt = 100\ R/(R_{100} - R_0)$, as the platinum-resistance temperature, as reckoned from the «natural zero» of the platinum-resistance thermometer. The «reduced platinum temperature,» obtained by subtracting pt_0 from the temperature pt as here computed, is the one that is commonly used, however; and Callendar and Harker and Chappuis have shown that the reduced platinum-temperature can be expressed in term of the reduced gas thermometer scale by means of a simple equation of the form:

$$pt = T + A.\frac{T}{100}\left\{\frac{T}{100} - 1\right\}$$

A being a constant whose value is to be determined experimentally. Callendar and Griffiths, for the purpose of determining A, recommend that the resistance of the platinum coil of the thermometer be observed at the temperature of boiling sulphur; the «reduced temperature» of this boiling point being, according to their experiments with the constant-pressure air thermometer, 444.53° C. (Eumorfopoulos states that the boiling point of sulphur on this scale is between 443.58° and 443.62° C. See 'Proceedings of the Royal Society,' 1908 A, 81, p. 339. Compare, also, Callendar and Moss, in the same publication, 1909 A, 83, p. 106). The platinum-resistance thermometer gives great promise of being a highly valuable instrument in the future. Indeed, it is so already; but it does not yet appear to be capable of determining the absolute values of temperatures closer than to 0.01° C. It may be used as a differential thermometer, however, so as to give results of a far higher order of accuracy. For this purpose two similar coils or strips of platinum are used, these being placed in two of the arms of a Wheatstone's bridge, so that the smallest departure from equality in their resistances can be observed. (See Resistance, Electrical). Langley's bolometer is an instrument of this sort. It is used to explore the solar spectrum, and consists of two strips of platinum foil, which are placed across the spectrum to be examined, with their edges toward the source of the light. The two strips are placed in the two arms of a sensitive Wheatstone's bridge, and so long as both the strips are exposed to radiation of the same intensity, the balance of the bridge is preserved. When one of the strips coincides with a Fraunhofer line, however, while the other is still exposed to the full radiative power of the source of light, the balance is destroyed, and the existence of the line is thereby demonstrated, even though the line be in the infra-red, where it is not visible to the eye.

Thermo-electric couples have been used to a considerable extent for the measurement of temperature, and Regnault experimented with them somewhat, but showed that they are distinctly inferior in accuracy to the other known methods of determining temperature. At exceedingly low temperatures, however, they are often of great value. Wroblewski, for example, made use of thermo-couples quite extensively for temperature measurements in his researches on the critical points of the gases which are liquefiable only at extremely low temperatures. The platinum resistance thermometer is more generally favored, however, for this purpose; though it cannot be used for temperatures too close to the absolute zero on account of the anomalous and sudden changes of resistance that occur in that region. (See Resistance, Electrical). At these extremely low temperatures the helium thermometer is still useful, however.

Consult Guillaume, 'Thermometrie de Précision,' and Preston, 'Theory of Heat.' See, also, the numerous scientific papers of Kamerlingh-Onnes relating to low-temperature research.

ALLAN D. RISTEEN,
Director Technical Research, The Travelers Insurance Company, Hartford, Conn.

THERMOPHONE, a resistance thermometer (see THERMOMETRY), in which the galvanometer that is most commonly employed is replaced by a telephone. Two coils of platinum wire, which are exposed to the respective temperatures that are to be compared, are introduced into two of the arms of a Wheatstone's bridge whose remaining arms contain known resistances. The telephone is placed in the cross-arm of the bridge. An alternating or pulsating current of low frequency is used in making the observation, and when the bridge is in balance, this fact is indicated by the silence of the telephone. See Warren and Whipple, 'The Thermophone,' in *The Technology Quarterly,* Vol. VIII, page 125.

THERMOPOLIS, Wyo., town and county-seat of Hot Springs County, on the Chicago, Burlington and Quincy Railroad, and on the west bank of the Bighorn River. It is noted for the large hot springs which issue along the river bank at this place. These springs are considered curative for rheumatism and similar ailments. They are protected as a State reservation. Pop. 1,500.

THERMOPYLÆ (Gk. θερμοπύλαι hot gates), in classical geography, a pass on the southeastern frontier of Æniania, Greece, leading from Thessaly into Locris, and on the route of the only good road from Thessaly to central Greece. It was situated between the range of Mount Œta and an inaccessible morass which bordered the Maliac Gulf; and in breadth it was a narrow tract of perhaps some 50 feet. Its name was derived from the presence of thermal springs. As the only means by which a hostile army might penetrate from northern into southern Greece, it held a peculiar strategic value in Grecian history. It is celebrated as the scene of the defense by Leonidas (q.v.) and the 300 Spartans against the vast host of Xerxes (q.v.) in August 480 B.C. The account of this battle given by Herodotus has been generally followed. Xerxes, ridiculing the numbers of the Hellenic defenders (5,200, not counting the Locrians, whose numbers are not known), sent against them the Medes and Cissians with instructions to take them prisoners and bring them before him. When, after a day's fighting, these were unsuccessful, the picked 10,000, called the «Immortals,» were sent forward; but, handicapped by the shortness of their spears, they were no match for the Hellenes, of whom few fell, while the Persian loss was on both days excessive. Xerxes was now in great perplexity, when Ephialtes, a Malian, came «to tell him of the pathway which led across the mountain to Thermopylæ.» This path ascended the gorge of the river Asopus, and the hill Anopæ; then passed over the crest of Œta and to the rear of Thermopylæ. The Persians arrived in the rear of Thermopylæ soon after mid-day of the third day. Tidings of their coming had already been brought to the Greeks by scouts and Persian deserters. Most of the Greeks withdrew, but the Spartans and the Thespians (700) remained, and the Thebans (400) were compelled to stay. Of the Spartans and Thespians, all fell; and of the Thebans, few escaped. To the complaint that the Persian arrows darkened the sky the Spartan Dieneces is said to have answered, «Good; then we shall fight in the shade.»

Through deposits from the Spercheius and other streams, great alterations have taken place at Thermopylæ, so that it is not now a pass but a swampy plain. Consult Schliemann, 'Untersuchungen der Thermopylen' (1883) and various standard histories of Greece. See also GREECE, ANCIENT — *History.*

THERMOPYLÆ OF AMERICA, a title applied to Fort Alamo, Texas. See ALAMO, THE.

THERMOSCOPE (Greek, «to show heat»), any instrument for indicating temperature. The term is commonly applied, however, to such instruments as indicate one temperature only, or a very limited number of temperatures; or to those which are used for indicating changes or difference of temperature, without giving the magnitude of these changes or differences. The forms that have been given to instruments of this kind are so manifold as to be almost past numeration. As a single illustration, the instrument may be cited, whose indications depend upon the melting points of alloys. An instrument or device of this sort contains buttons or wires of a number of alloys, whose several melting points are known; and in the observation of temperature by this method, the instrument is exposed to the temperature under examination, and a note is made of which of the alloys melt, and of which remain unmelted. If T_1 is the melting point of the least fusible of the alloys that have melted, and T_2 is the melting point of the most fusible of the alloys that have not melted, we can then assert that the temperature under consideration is higher than T_1, but lower than T_2. For many purposes in the arts, it is quite sufficient to know, in this manner, that a temperature is between certain limits. A thermoscope which can only indicate certain limits between which a temperature lies is called a «discontinuous thermoscope.» Continuous thermoscopes, which are capable of affording an actual measurement of any temperature within their range, are now commonly called «thermometers,» whether they resemble the ordinary mercury-in-glass thermometer or not. A thermoscope in which temperature is inferred by noting the electrical resistance of a coil of platinum wire, for example, is called a «platinum resistance thermometer.» See PYROMETER; THERMOMETER; and THERMOMETRY.

THERMOSTAT, a device in which the variation of heat is utilized to expand and contract a long strip of metal, so that its motion can be utilized to regulate a damper or to maintain approximately uniform steam pressure.

THERMOTAXIS, the regulation of the temperature of the body. The principal sources of animal heat are muscular exercise and the combustion of food, involving absorption of oxygen and liberation of carbon dioxide. Body temperature remains about normal under many trying circumstances through the balance maintained by the nervous system between its production and its dissipation. The chief avenues of dissipation are radiation from the surface of the body, the expired air and the excreta. Febrile action or fever is believed to be due to an overproduction of heat, to an underelimination or to both. The overproduction is believed to result from an increased combustion especially of albuminous substances of the body, with an increased discharge of carbon dioxide and the nitrogeneous wastes, urea, creatine and creatinine. When fever prevails the action of the heart is accelerated, the secretions of glands are impaired and the intricate process of metabolism is deranged. Heat-regulation, effected by reciprocal changes in heat-production and heat-dissipation and depending essentially upon the influence of cutaneous impulses and the temperature of the blood, is governed, it is generally believed, by two nerve-centres, one controlling heat-production, the other heat-dissipation.

THERMOTROPISM, a tendency toward warmth, exhibited in the reactions of animals. An example is found in the care with which ants move their eggs and larvæ from place to place in order to secure a proper and equable temperature for their welfare. Compare HELIOTROPISM, with which tendency this is somewhat confused.

THERMORPHA, or **ANOMODONTIA,** an order of extinct (Triassic and Perman) reptiles. «The dominant group among the earliest reptiles in each quarter of the globe where they have as yet been discovered,» say Woodward, «is directly intermediate in skeletal characters between the highest labyrinthodonts (*Mastododonsaurus* and its allies) and the lower mammals (*Monotremata*). Its members first received the name *Anomodontia* in allusion to the varied modifications of the dentition, so unusual among reptiles. They were afterward named *Theromorphia* or *Theromora* . . . in allusion to the many obvious resemblances in their skeleton to that of monotreme mammals.» These similarities are chiefly of the dentition, zygomatic arch, pelvis, cruro-tarsal joint, scapula and occasional doubling of the occipital condyle. The general shape of the skull is often closely mammalian, but its details show its unquestionable reptilian features. Three suborders are recognized — *Pareiosauria, Theriodontia* and *Anomodontia.*

The theromorphs were all land-reptiles with short, stout limbs and powerful jaws. Some were massive and of great size, like great alligators with turtle-like or even dog-like heads; others small and probably as agile as a weasel. They were the predatory beasts of their age, and were adapted in powers and characteristics to the pursuit of a large variety of animal prey. The most unreptile-like were those of the suborder *Theriodontia.*

It is a natural suggestion that the race of mammals, undoubtedly of reptilian origin, must have descended from this group, whose bones (numerous in the Triassic rocks of the western United States) show so many mammalian features; but thus far no direct connection can be shown. The dinosaurs, however, seem certainly to have descended from this stock. Consult Woodward, ‹Vertebrate Palæontology› (London 1898); Gadow, ‹Amphibia and Reptiles› (New York 1901), wherein many further references to details will be found.

THEROPODA, a sub-order of dinosaurs (q.v.).

THERSITES, thėr-sī'tēz, according to Homer, the ugliest man in the whole Grecian army that beleagured Troy. He was a malicious and slanderous brawler whom Ulysses publicly beat and brought to tears for his insulting attack on Aganon. He was eventually slain by Achilles for piercing with his spear the eye of the dead queen of the Amazons, Penthesilea, whom he had also spoken of with contumely.

THERY, Edmund, French writer on economics: b. Ragnac, France, 1854. He is a commander of the Legion of Honor, member of numerous societies interested in his line of work and has represented his government in various economic missions to several countries. His writings include ‹Europe et Etats-Unis d'Amérique› (1899); ‹La France economique et financière pendant le dernier quat de siècle› (1900); ‹La Banque de France de 1897 a 1909› (1910); ‹L'Europe économique› (1911); ‹Le regime actuel des chemins de fer en Russie› (1913), etc.

THESEUM, thē-sē'ŭm, or **THESEION,** thē-sē'ŏn, a temple in ancient Athens dedicated to the commemoration of Theseus and his exploits. It stood on an elevated site north of the Areopagus (q.v.) and in early Christian times was used as the church of Saint George of Cappadocia. Within its precincts Cimon is said to have deposited the bones of the hero which he had brought from the island of Scyros, but archæologists do not support this claim. The temple was begun 465 B.C. Many consider it to have been originally dedicated to Heracles or Hephæstus, but there is no reason to doubt that it is actually a Theseum. It was constructed of Pentelic marble in the purest Doric style and is technically to be described as an amphiprostyle, hexastyle peripteral temple, with pronaos, and opisthodomos or epinaos. The façade and rear pediment have each six columns; the sides 13 each; their height being about 30 feet. A fragment of the portico and the roof of the stella are still standing. There are also some noteworthy remains of the statuary with which the building was adorned by sculptors of the school of Phidias. On the metope are set forth the exploits of Theseus and Heracles and the frieze of the cella is also in part standing. The dimensions of the building are roughly to be estimated at 104 x 45½ feet. Consult Stuart and Revett ‹Antiquities of Athens› (London 1762–1816); Leake, ‹Topography of Athens› (London 1841); Dyer, ‹Ancient Athens, Its History, Topography and Remains› (London 1873).

THESEUS, thē'sūs or thē'sē-ŭs, in Greek legend, a king of Athens and national hero of Attica, son of Ægeus by Æthra, the daughter of Pittheus of Trœzen, in Peloponnesus. He was educated at Trœzen, at the house of Pittheus, and passed for the son of Poseidon (Neptune). When he came to years of maturity he was sent by his mother to his father, and a sword and sandals were given him by which he might make himself known to Ægeus (q.v.) in a private manner. On arriving at Athens he narrowly escaped being poisoned by Medea, the sorceress, but his father recognized the sword, and received Theseus as his successor on the throne. He next caught alive the wild Marathonian bull; but a much more important service was the slaying of the Minotaur and the freeing of Athens from the tribute of seven youths and seven maidens annually sent to Crete to be devoured by that monster. (See MINOTAUR). Fearing his son had perished while in Crete Ægeus destroyed himself; hence Theseus on his return succeeded his father as ruler of Athens. The Athenians were governed with mildness, and Theseus made new regulations and enacted new laws. The number of the inhabitants of Athens was increased: a court was instituted, which had the care of all civil affairs; and Theseus made the government democratic, while he reserved for himself only the command of the armies. To him also the Athenians ascribed the union of the towns of Attica into a single state, with Athens at the head, and the division of the people into the three classes of Eupatridæ, Geomori and Demiurgi (nobles, husbandmen and mechanics). Perhaps the most celebrated of the events in the career of Theseus after the slaying of the Minotaur was his war with the Amazons. He is said to have invaded their territory and carried off their queen, Antiope (according to another account, that with which the readers of Chaucer and Shakespeare are familiar, Hippolyta). The Amazons in their turn invaded Attica, and a battle was fought in the city of Athens itself. Theseus was victorious, and the Amazons driven out of Attica. He was absent from Athens on various expeditions, and when he returned the Athenians had forgotten his services. He retired to the court of Lycomedes, king of Scyros, who threw him down a deep precipice. In 469 B.C. his bones, as supposed, were found by Cimon in Scyros, and brought to Athens, where they received a magnificent burial. Statues and a temple (the Theseum, q.v.) were raised; and festivals and games were publicly instituted to commemorate his actions. A portion of the temple still remains standing. What shreds of history, if any, there may be in the accounts of Theseus cannot be ascertained. Consult Harrison, J. E., ‹Mythology and Monuments of Ancient Athens› (London 1890); Lübker, F., ‹Reallexikon des Klassischen Altertums› (Leipzig 1914); Schultz, A., ‹De Theseo› (Breslau 1874).

THESMOPHORIA, a pagan festival of ancient Greece. It was celebrated only by women, in honor of Demeter Thesmophoros («the lawgiver») as foundress of agriculture, and thereby of orderly social life and the marriage. At Athens the festival extended to three days, beginning with 24 October. On the first day there was a procession to the temple of Demeter at Halimos, southeast of the city; on the second a fast; and on the third day, called Kalligeneia («the bearer of a fair offspring»), general and often licentious indulgence.

THESMOTHETE, thĕs'mō-thēt (from a Greek word meaning lawgiver), one of the six inferior archons at Athens who presided at the election of the lower magistrates, received criminal informations, decided civil causes, took the votes at elections and performed other duties.

THESPESIUS, also called Claosaurus, a dinosaur whose fossil remains found in the upper Cretaceous strata in Wyoming, Montana and Colorado show it to have resembled the Iguanodon. It was upwards of 30 feet long and stood from 10 to 25 feet high. Like others of its species it was herbivorous and balanced its long forward body by its heavy tail. Complete sketches of the animal are found in the principal museums. (See DINOSAUR). Consult Marsh, O. C., ‹The reconstruction of the Cretaceous Dinosaur› (in *Transactions* of the Connecticut Academy of Sciences, Vol. XI, New Haven 1902).

THESPIS, Greek author. He was a native of Icaria, a deme of Attica, lived in the time of Solon, in the 6th century B.C., and is considered the inventor of tragedy, as he added to the dithyrambic choruses of the feats of Bacchus an actor, who, when the chorus was silent, generally recited a mythical story; and probably carried on dialogues with the leader of the chorus, appearing successively in different characters in a piece. This was a decided step toward the drama.

THESSALONIANS, Epistles to the. Authorship.— While Paul's authorship of the First Epistle to the Thessalonians has occasionally been questioned, the consensus of critical opinion is at the present time so nearly unanimous in favor of its genuineness that it seems needless to argue the question at all. The external evidence is strongly favorable; the style and vocabulary are admittedly Pauline; the doctrinal content, while not very full, is in harmony with Paul's teachings elsewhere; above all, in its whole tone and temper it is unmistakably and inimitably an outpouring of the very heart and soul of the great Apostle. As concerns the Second Epistle the case stands somewhat differently. Though the external evidence is even stronger than for the First Epistle, yet its Pauline authorship has been far more disputed. The difficulties which have been raised grow mainly out of its relation to the First Epistle, and practically reduce to three: (1) the resemblance in portions of the two letters, considered by some to be too close to permit us to think of the second as an independent composition; in answer to which it is said that this likeness covers no more than a third of the letter, and may easily be explained in any of many ways, as, for instance, that just before writing Paul might have glanced at a copy of his first letter; (2) the difference in tone and temper of the two letters, Paul seeming in the second more formal and less cordial and affectionate, a fact for which several explanations have been offered, as that if the first letter had failed helpfully to affect some of the Thessalonians, he might naturally speak in a more formal and distant way in his second letter, or, as Harnack has suggested, this letter may have been intended solely for the Jewish section of the church, while the other was for the main body of the church, which was Gentile in origin, and more loyal to Paul; and (3) the difference in the eschatological teaching, which, however, does not amount to a contradiction, but is to be regarded partly as a correction of a misunderstanding of the teaching in the first letter, which misunderstanding seems in spite of the correction still to continue in some circles, and partly is an addition of certain elements in Paul's doctrine of the Last Things which had not come out earlier, resulting in an apparent change of emphasis, but not in a real inconsistency. Certainly the difficulties in the way of explaining the letter as a forgery have been found greater than of accepting it as genuine, and consequently the later criticism seems decisively to favor the Pauline authorship of both Epistles.

Date and Place.— From the First Epistle itself in comparison with Acts it is easy to ascertain the date and place of composition. On his second great missionary journey, the second European city in which Paul worked was Thessalonica, the modern Saloniki. Here he established a church at once, but his very success caused him to be driven from the city after a stay possibly of only three weeks, almost certainly of only about as many months. From there Paul went to Greece, making a short stay at Athens and establishing himself for a year and a half at Corinth. It is plain that Timothy, who was sent back from Athens to visit, comfort and confirm the Thessalonian Church, rejoined Paul at Corinth with his report, and the first letter must have been written almost at once. According to some the second letter followed the first even without waiting for an answer and in any case the interval cannot have been long, a few weeks at most. The most common dating is in the spring of 51, but chronologists vary two or three years either way so far as the years to be assigned to the various events of Paul's work are concerned. These Epistles are accordingly among the very earliest New Testament books, only James and Galatians being considered by any to be earlier.

Conditions of Composition.— It is plain from 1 Thessalonians as well as from Acts that the reception of Paul and of his teaching at Thessalonica was peculiarly prompt and cordial. In a very short time a church was established, consisting partly of Jews, but mainly of proselytes and Gentiles, including some of the principal men and women of the city. Paul turned back to Thessalonica as a place where his work had been a peculiar delight, and the mutual affection of the Apostle and his converts must have been unusual. But his stay at the longest had been brief, and in spite of his plans and endeavors he had found it impossible to return, while at the same time he had reason to fear that misrepresentations were being circulated touching both his failure to revisit them and his purposes in his missionary work and his relations to his converts. From the report of his messenger Timothy, and possibly from a letter to Paul from the church, quotations from which some have thought they found embedded in this letter, it appeared that on the one hand a certain fanaticism showing itself in immorality and on the other hand a certain doctrinal and spiritual uncertainty had grown up in the Church. It was to remedy those conditions that Paul wrote his first letter. The second is a natural pendent to the first. It is usually held that Paul's letter mainly accomplished its purposes, but that either by the return of the messenger who carried it or by written response from the Thessalonians themselves, Paul learned that some disorders continued and that his teaching about the Last Things needed supplementing to correct misunderstandings, and thus arose the Second Epistle.

Contents.— These letters are peculiar in that two of Paul's fellow-workers, Silas and Timothy, are associated with him in the address (i, 1), though it is plain that in composition and in thought as well as in personal relations it is definitely his own letter. In 1 Thess., he first gives an explanation of his failure to return to them, adding an assurance of his strong affection for them and an assurance of his confidence in their affection for him and their continuing faith in Christ, all so put as to answer any misrepresentations of him and his work which might be current (i, 2–iii, 13). Then come various moral injunctions, first, to chastity, and then to brotherly love, with which is associated the duty of diligent labor (iv, 1–12). There follows the correction of the painful misunderstanding of some of the Christians as to their friends who had lately died, by the assurance that through their resurrection they would be at no disadvantage when Christ should return, and encouragement for all in reference to the same return (iv, 13–v, 11), and, finally, warnings against various disorders, couched in brief injunctions, and a few salutations (12–28). In the second letter, after a brief greeting (i, 1, 2), Paul gives utterance to a remarkable expression of thanksgiving and prayer (i, 3–12); then corrects the misunderstanding of what he had said in his first letter, assuring them that before the «Day of the Lord» there was much history to be made, including a great apostacy (ii, 1–12); a brief encouragement to fainthearted brethren follows (ii, 13–iii, 5), and warnings to the idle and dissolute (iii, 6–15), the Epistle ending with a word of explanation of how the Apostle added to his dictated letters a certificate in his own handwriting and the benediction with which he commonly closed his letters (iii, 16–18).

Professor of New Testament Interpretation, Colgate University.

THESSALONICA. See SALONICA.

THESSALY, thĕs'ạ-lĭ, or **THESSALIA,** the northeastern division of ancient Greece proper, bounded on the north by the Cambunian Mountains, separating it from Macedonia; on the west by the chains of Pindus and Tymphrestus, separating it from Epirus; on the south by Mount Œta, separating it from Ætolia, Doris and Locris; and on the east by the Ægean Sea. The rich plain enclosed between these mountains belongs almost entirely to one river basin, that of the Peneios (Salambria), which traverses it from west to east, and finds an outlet into the Thermaic Gulf through the vale of Tempe. It was especially famed for its fine breed of horses and its skilful horse-men. The name of Thessaly was derived from the Thessali, a Greek people who are said to have come into this land from the west, and who became the governing class in the country. Thessaly was broken up into separate states loosely united under a tagus, and long exerted no important influence on the affairs of Greece generally; but it rose for a brief period to a position of greater consequence when (about 375 B.C.) Jason of Pheræ, having been elected tagus, brought the whole of Thessaly completely under his power, and began to threaten the rest of Greece, but the confederacy was again weakened after his assassination in 370 B.C. Thessaly afterward became dependent on Macedonia, and finally was incorporated with the Roman Empire. In 1393, after the fall of the Byzantine Empire, Thessaly came, with the rest of the imperial dominions, into the hands of the Turks, and till recently formed a part of the Ottoman Empire. The greater portion of it was in 1881 incorporated in the kingdom of Greece. The Greco-Turkish War of 1897 was fought principally within the borders of Thessaly. Consult Baedeker, K., 'Greece' (4th English ed., Leipzig 1909); Kent, R. G., 'A History of Thessaly from the Earliest Historical Times to the Accession of Philip V of Macedon' (Lancaster, Pa., 1904); Leake, W. M., 'Travels in Northern Greece' (4 vols., London 1835); Philippson, A., 'Thessalien und Epirus' (Berlin 1897); Wace and Thompson, 'Prehistoric Thessaly' (Cambridge 1912).

THETFORD MINES, Canada, town in Megantic County, on the Quebec Central Railway, about 76 miles south of the city of Quebec. It is chiefly known for the deposits of asbestos in the neighborhood. There are numerous small industries. Pop. about 7,500.

THETIS, thē'tis, in Greek mythology, a daughter of Nereus and Doris, therefore one of the Nereids. Her nuptials with Peleus were celebrated on Mount Pelion, and were honored by the presence of all the gods except Eris or Discord, who was not invited, and who, to avenge the slight, threw in among the company the apple of discord. By Peleus she became the mother of Achilles (q.v.).

THEURGY, from the Greek *theourgia*, meaning divine work, and used among the ancients to signify supernatural agency in individual human affairs, or in the government of the world. Hence the act or art of invoking deities or spirits, or by their intervention conjuring up visions, interpreting dreams, receiving or explaining oracles, etc.; the power of obtaining from the gods, by means of certain observances, words, symbols or the like, a knowledge of the secrets which surpass the power of reason, to lay open the future, etc. The word also means that species of magic which more modern professors of the art allege to produce its effects by supernatural agency, as contradistinguished from natural magic. Also a system of supernatural knowledge or power believed by the Egyptian Platonists to have been divinely communicated to a hierarchy, and by them handed down from generation to generation.

THEURIET, Claude Andre, French poet and novelist: b. Marly-le-Roi, 8 Oct. 1833; d. 23 April 1907. He studied law in Paris, received his licentiate in 1857 and in that year entered the department of the Ministry of Finance. Soon, however, he turned his attention to literature. In 1896 he was elected a member of the French Academy, having received the *prix Vitet* in 1890. His poems include 'Le chemin des bois' (1867); 'Le Bleu et le noir' (1873); 'Nos oiseaux' (1886); and 'La ronde des saisons et des mois' (1891). He also published 'Jules Bastien-Lepage, l'homme et l'artiste' (1885), but is best known by his novels, among which are 'Nouvelles intrines' (1870); 'Mlle. Guignon' (1874); 'Channe dangereux' (1891); 'La Chanoinesse' (1893), etc. He was the author of some 60 works of fiction. He also wrote several dramas including 'Jean-Marie' (1871); 'Le maison des deux Barbeaux' (1885), and 'Jour d'été (1901).

THIAN-SHAN (tē-än'shän') **MOUNTAINS,** central Asia. See TYAN-SHAN.

THIAZOL DYESTUFFS. See COAL-TAR COLORS.

THIBAULT, Jacques Anatole France, critic and novelist: b. Paris, 16 April 1844. He is known wherever French is read and the Latin genius appreciated as ANATOLE FRANCE, and was called by Lemaître, one of the shrewdest of his contemporaries, «the ultimate flowering of the Latin genius.» Son of a Parisian bookseller, another «France» and a veteran of the body-guard of Charles X, Anatole grew up in the bookish atmosphere which he has conveyed marvelously into several of his stories as he has also his father's character. A Parisian of the Parisians, he was named officer of the Legion of Honor in 1895 and received into the Academy in 1896. For the rest the story of his life is in his writing. Besides early verses his well-nigh 50 volumes embrace charming books of autobiographic «truth and fiction» such as 'Le livre de mon ami' (1895), 'Pierre Nozaire' (1900) and 'Les désirs de Jean Sévier' (1912); books of philosophic criticism, themselves, as he openly professes, evidencing his own way of thinking in noting the ways of others, chief among them articles collected from *Le Temps* in five volumes of 'La vie litteraire' (1888–93) and 'Le génie latin' (1913); dramatic experiments, among which 'Thaïs' is best known; an extended controversial biography. 'La vie de Jeanne d'Arc' (1908); expressions of fervid patriotism in stress of war, such as 'Sur la voie glorieuse' (1915), and, finally and chiefly, a long series of books which in the guise of fiction express all the manifold phases of his political observations, his social aspirations and indignations, his philosophic speculations and the play of his recreative imagination in evoking the thought and life of a long out-lived past. This fiction, taken chronologically, gives the clue to the development of France out from the dilettant scepticism of Renan, through epicureanism, in its higher and also its lower sense, into an earnest, though still ironic, socialism, with occasional glints of fierce intolerance for obscurantists, reactionary or clerical. Outstanding among these books is first 'Le crime de Sylvestre Bonnard' (1881), his second novel, whose [illegible]ial sympathy with childhood and large-h[illegible]d irony have attracted writers of distinction, among them Lafcadio Hearn, to attempt its translation. 'Balthasar' (1900) and

'Thaïs' (1900), a mediæval and an early Christian study, show a curiously subtle "piety of imagination with impiety of thought." Nearer to his own mind were 'La Rotisserie de la Reine Pédauque' (1893) and 'Les opinions de Jérôme Coignard' (1893) in which the ascetic, epicurean and courtesan figures of Thaïs reappear in 18th century dress and an abbé becomes playful mouthpiece for the ironic expression of a scepticism more radical in France than any since Montaigne. Each book, without plot, is a chain of sparkling epigrams in which the laughing philosopher unmasks the pettinesses and inconsistencies of private and public morals and life. French politics are the unobtruded theme of four notable volumes of Histoire contemporaine, 'L'orme du mail' (1896); 'Le mannequin d'osier' (1897); 'L'anneau d'améthyste' (1899) and 'M. Bergeret à Paris' (1901), all jewels of graceful perversity. Then France's thought takes a more serious bent as he is drawn into the lists with Zola against militarist and religious reaction as revealed in the Dreyfus case. Of this good evidence is seen in 'Crainquebille' (1903); 'Les contes de Jacques Tournebioche' (1908) and the political satires 'L'Île des pingouins' (1908) and 'Les dieux ont soif' (1912) as well as in 'La vie de Jeanne d'Arc' (1908) and in 'Opinions sociales' (1902). All these books, whatever their form, are in effect criticism of contemporary life. He has himself said that he counts criticism as possibly the ultimate evolution of literary expression, well suited to a highly civilized society which is rich in old traditions, the last in date of all literary forms and destined to absorb all. All of them illustrate an idea of style which he has put admirably in 'Le jardin d'Epicure' (1894). "A simple style," he says, "is like white light; it is complex but does not seem so. In writing what appears a beautiful and pleasant simplicity is really the result of careful arrangement and strict economy in the use of the various parts of speech." In this art of hiding his art France is almost supreme. See LE CRIME DE SYLVESTRE BONNARD. Consult an English translation of 'Works' edited by Frederic Chapman (London 1908–19) already embracing 27 volumes. Of separate works there are many other versions. For criticism consult Michaut, G., 'Anatole France,' (Paris 1913), also works by Brandes, G. (London 1908), by George, W. L. (New York 1915), and Shanks, L. P. (Chicago 1919).

BENJAMIN W. WELLS.

THIBAUT, tē-bō, or **THEOBALD I,** king of Navarre: b. France, about 1200; d. 1253. He was educated at the court of Philip Augustus. As the Count of Champagne he is said to have been a lover of the queen of Louis VIII, whose death in 1226 Thibaut was suspected of having caused. He succeeded to the throne of Navarre on the death of his uncle, Sancho the Strong, in 1234. Going in 1239 to Palestine, he suffered defeat at Gaza. He left a reputation in literature as a trouvère whom even Petrarch and Dante, and other great poets praised. His poems, first published by Lévesque de la Ravallière (2 vols., Paris 1742), have appeared in several later editions. Consult Delbarre, 'Vie de Thibaut' (1850), and Lavisse, Ernest, 'Histoire de France' (Vol. III, part VI, Paris 1901).

THIBET, tĭ-bĕt'. See TIBET.

THIBODEAUX, tēb-ō-dō', La., town, parish-seat of Lafourche Parish, on Bayou Lafourche, and on the Southern Pacific Railroad, 47 miles west by south of New Orleans and 60 miles south by east of Baton Rouge. It is in an agricultural region in which the principal products are rice, sugarcane and cotton. The industries are connected chiefly with the cultivation and shipment of cotton, rice, sugarcane and vegetables. It contains foundries, canneries and ice plants. There are several private schools, among them Mount Carmel Academy, Thibodeaux College, and Guion Academy. Pop. 3,824.

THICKHEAD, a South American caterpillar-eating bird of the family *Capitonidæ*, so named because of the full-feathered and apparently excessive size of the head. The family is a large and handsome one, closely allied to the puff-birds, and sometimes united with them under the general term "barbet." In other parts of the world "thickhead" is applied to various other birds, especially in South Africa to the stonecurlew (*Œdicnemus*) of that region, translating the local Dutch name *dikkop*.

THIEF, one who steals or is guilty of theft; one who takes the goods or personal property of another without his knowledge or consent, and without any intention of returning them; one who deprives another of property secretly or without open force, as opposed to a robber, who uses open force or violence. A burglar is a thief who forces an entrance into a building.

THIEF RIVER FALLS, Minn., city, county-seat of Pennington County, on the Great Northern and the Minneapolis, Saint Paul and Sainte Marie railroads, about 50 miles northeast of Crookton on the Red Lake and Thief rivers. It lies in an agricultural section which raises much wheat, has a flour mill, foundry, sash and door factory and iron works. The notable buildings are the Carnegie library and the municipal auditorium. Pop. over 4,000.

THIERRY, tĭ-ĕr'ĭ (Fr. tē-ā-rē), **Amédée Simon Dominique,** French historian and politician: b. Blois, 2 Aug. 1797; d. Paris, 26 March 1873. As a young man he entered the service of the Minister of Marine, and in 1828 became professor of history at Besançon. His ideas being ultra-liberal, his course was suspended by the Minister of Public Instruction. In 1830 he became prefect of the department of Haute-Saône, and in 1838 returned to Paris, where he was appointed master of petitions addressed to the council of state. He held various other political appointments; but continued his historical investigations in the special field he had chosen: the origins of French national history; the early peoples and the neighboring races; and the conquest of the Gauls by the Romans. In 1841 he was elected a member of the Institute; in 1860 he became a senator, and in 1868 he received the cross of the Legion of Honor. His works include 'Histoire des Gaulois' (1828); 'Histoire de la Gaule sous l'administration romaine' (1840–47); 'Histoire d'Attila' (1856); 'Tableaux de l'empire romaine' (1862); Récits de l'histoire romaine au Ve siècle' (1860); 'Saint-Jérôme' (1867), and 'Chrysostome et Eudoxie' (1873).

THIERRY, Jacques Nicolas Augustin, French historian: b. Blois, 10 May 1795; d. Paris, 22 May 1856. He was educated in the Normal School at Paris in 1811, and in 1813 became teacher in a provincial school. The following year he quit this occupation and returned to Paris, where he embraced the socialistic views of Saint Simon, and became his secretary and his coadjutor in literary work, and in 1816 published a treatise of his own, ‹Des nations et de leurs rapports mutuels.› Perceiving the theoretical vagaries of his master, he separated from him in 1817, and became one of the conductors of the journal *Le Censeur Européen.* Shortly afterward he became a contributor to the *Courrier Français,* in which, in 1820, he published 10 letters on the history of France, which attracted attention. His celebrated work on the Norman conquest of England, ‹Histoire de la conquête de l'Angleterre par les Normands,› was published in 1825, and by the interest of the narrative, brilliance of style and novel mode of treating the subject, attained great success both in France and in England. From his close application to work M. Thierry became in the following year almost entirely blind, and at the same time was attacked by a nervous disorder, but still pursued his literary labors. An enlarged edition of the letters formerly written by him for the *Courrier* appeared in 1827, under the title of ‹Lettres sur l'histoire de la France.› In 1830 he was elected a member of the Academy of Inscriptions and in 1834 published ‹Dix ans d'Etudes historiques.› About this time he was entrusted by Guizot, then Minister of Public Instruction, with the editing of the ‹Recueil des monuments inédits de l'histoire du tiers-etat,› for the collection of documents relative to the history of France. To this publication he prefixed an ‹Essai sur l'histoire de la formation du tiers-etat,› separately published in 1853. In 1840 he published ‹Récits des temps métrovingiens,› which gained for him the Gobert prize of the Academy of Inscriptions. There exist translations of his chief works in English. There is a complete edition of his works (10 vols., 1856–60). Consult Valentin, ‹Augustin Thierry› (Paris 1895).

THIERS, tē-ār, **Louis Adolphe,** French statesman and historian: b. Marseilles, 15 April 1797; d. Saint Germain, Paris, 3 Sept. 1877. He studied law at Aix, and was admitted to the bar there in 1818. Desirous of a larger theatre for his ambition he went to Paris in 1821, and having got an appointment on the staff of the *Constitutionnel,* then the leading Parisian journal, he soon attracted attention by his articles in that paper. Journalism soon ceased, however, to supply sufficient stimulus to his active intellect, and he undertook his ‹Histoire de la Révolution française.› having as colleague Felix Bodin, whose name appeared with his in the first two volumes. The work was completed in 10 volumes in 1827. On the formation of the Polignac Cabinet, Thiers founded with Armand Carrel and Mignet, the *National,* whose first number appeared on 1 Jan. 1830. The new democratic organ exercised a decisive influence on public opinion, and the famous ordinances, the signal for the revolution of July, were now issued. Upon this Thiers counseled the issuing by the journalists of a revolutionary manifesto. It was signed by 43 names. To escape arrest Thiers fled, on the night of the 28th, to the neighborhood of Saint Denis, accompanied by Mignet and Armand Carrel. Louis-Philippe, becoming king of the French, Thiers was soon made councillor of state and attached to the department of finance. He was elected deputy for Aix, and after the death of Casimir Périer became Minister of the Interior in the Cabinet of Soult, October 1832. He next filled the offices of Minister of Commerce and Minister of Public Works and again became Minister of the Interior, but in consequence of differences with Soult and Gérard gave in his demission 11 Nov. 1834, but soon resumed office under Mortier. He again retired in February 1836, but a few days after returned to power as foreign minister and president of the council. These offices, after many vicissitudes, he again held in March 1840. Taking a strong interest in the Eastern question he declared in favor of Mehemet Ali of Egypt against Turkey; but neither the king nor the chambers wished to resort to extremities, and the policy of Thiers having received a grave check he retired from the Cabinet 29 Oct. 1840. He now devoted himself to historical pursuits, and his ‹Histoire du Consulat et de l'Empire,› begun in 1845, was completed in 1862, in 20 volumes. The revolution of February, 1848, found him prepared to accept the republic; and he was a member, first of the Constituent and then of the National Assembly. After the *coup d'état* of 1851 he was banished from France, but returned in August, 1852. After an absence of 12 years from public life he was chosen in the elections of 1863 deputy for the department of the Seine, and re-lected in 1869. In this position he regained much of his early popularity. He combated energetically the project of war against Prussia, because France was unprepared, and after the disaster of Sedan visited the courts of London, Vienna, Saint Petersburg and Florence to seek assistance against Prussia, but all that he could obtain was a promise that the four great powers would support the proposal of an armistice. Thiers accordingly proceeded to the headquarters of the king of Prussia at Versailles to open negotiations for peace. But he was unsuccessful, and Prussia proceeded to a war *à outrance.* On 17 Feb. 1871 he was elected chief of the executive power of the republic, and on the 21st opened negotiations with Bismarck, which resulted in the peace with Germany. On 31 August the title of president was bestowed upon him and his term of office fixed at three years. He resigned 24 May 1873, whereupon Marshal MacMahon was appointed president. When MacMahon began to put himself in opposition to the republic, Thiers acted in complete harmony with the republican chiefs of the two chambers, notably with M. Gambetta, to whom, on 3 Sept. 1877, he gave a meeting at Paris to read to him, and to several other politicians, a manifesto which he had just completed. But that very day he was attacked with congestion of the brain and died at night. Thiers was *par excellence* the representative of his country; a witty writer; and an accomplished debater. He was also genial, unselfish, large-hearted; and to establish the glory of France was the main secret of his measures and counsels.

Besides the works already named Thiers was the author of 'Histoire de la loi' (1826, English trans. 1859); 'De la propriété' (1848); 'L'Homme et la matière' (1875). Consult Atkinson, F. M., 'Memoirs of M. Thiers' (New York 1916); Belot. C., 'Le pouvoir exécutif sous le gouvernement de M. Thiers' (Bijon 1908); Le Goff, François, 'The Life of Louis Adolphe Thiers' (New York 1879); Hanotaux, G., 'Le gouvernment de M. Thiers' (Paris 1903); Marcère, E. de, 'L'Assemblée nationale de 1871' (ib. 1904); Simon, P. THIEVES' ISLANDS. See LADRONES.

THILLY, Frank, American writer and educator: b. Cincinnati, Ohio, 1865. He was educated in the Ohio University where he graduated in 1887, and completed his studies in Berlin and Heidelberg. For several years he devoted himself to teaching philosophy in Missouri University (1893–1904); psychology at Princeton (1904–06); philosophy at Cornell from 1906 on, finally becoming dean of the College of Arts. He edited the *International Journal of Ethics* (1909) and was president of the American Philosophical Society (1912). He is the author of 'Leibnitz' Controversy with Locke' (1891); 'Introduction to Ethics' (1900); 'The Proceeds of Inductive Inference' (1904); 'A History of Philosophy' (1914). He also has translated Weber's 'History of Philosophy' (1896); 'Poulsen's Introduction to Philosophy' (1885) and 'A System of Ethics' (1899).

THIMBLE, a small metallic sheath or cap used to protect the end of the finger in sewing. Seamstresses use a thimble having a rounded end. Those used by tailors are open at the end. In the manufacture of thimbles coin silver is mostly used, generally silver dollars, which are melted and cast into solid ingots. These are rolled into the required thickness, and cut by a stamp into discs of any required size. A solid metal bar the size of the inside of the intended thimble, moved by powerful machinery up and down in a bottomless mold of the size of the outside of the thimble, bends the circular discs into the thimble shape as fast as they can be placed under the descending bar. The work of brightening, polishing and decorating is done on a lathe. Thimbles are said to have been found at Herculaneum, and were used by the Chinese at a very early period. Their invention in Europe is traditionally ascribed to Nicholas van Benschoten, of Amsterdam, in the 17th century. In mechanics, the name thimble is applied to various fixtures, such as a tubular lining through which a bolt passes, etc.

THIMBLE-EYE, a fish, the chub-mackerel (q.v.).

THIMBLE RIG, or SHELL-GAME, a sleight-of-hand or gambling trick, performed by means of three thimbles and a pea or three nut shells and a small wooden tube or box. The pea being placed on a table and covered with one of the thimbles, the performer proceeds to shift the thimbles, covering the pea now with one, now with another, and offers to bet any bystander that no one can tell under which thimble the pea is. The person betting is seldom allowed to win, the pea being abstracted by sleight-of-hand. In the United States the trick is commonly known as the shell-game and is frequently played at race-track meetings, rural fairs and other gatherings.

THIONVILLE, tē-ôṅ-vēl, or **DIEDENHOFEN,** dē'dēn-hō-fĕn, Lorraine, an important railway centre. 18 miles north of Metz. It stands in a level plain on the Moselle River. Its manufactures comprise gloves, thread and nets; and there are sawmills and tanneries. Thionville is the seat of the Lorraine iron industry. There is some trade in corn, hemp, flax, fruit, vegetables, grain, wine and wood. An important fair is held annually. In the Franco-German War of 1870–71 Thionville was invested after the battle of Gravelotte, and after the fall of Metz it was besieged with vigor. On 25 Nov. 1870, it was occupied by the Germans. It suffered severely by the siege. It was restored to France under the terms of the armistice of 11 Nov. 1918 and confirmed by the Treaty of Paris of 1919. Pop. 14,184.

THIRD CENTURY. The central interest of this period lies in the fact that the Roman Empire at the climax of its power and extent, just when presumably it ought to be consolidating itself for a still greater future, began slowly but surely to crumble under the attacks of the barbarians. Toward the end of the century the Goths in Dacia gave the first hints of that power to defeat Roman armies which portended so clearly the fall of the empire. In the last decade the Saracens, a predatory Arab tribe, who are usually supposed to come into history much later than this, began to make themselves felt. Inspired by Mohammed and unified by religious fanaticism in the 7th century they were to prove more fatal to the empire than even the Goths. The success of the barbarians was favored by the disorder consequent on elections of emperors by the Prætorian guards. Septimius Severus (emperor 193–211) halted the barbarians for a while but Rome's decline and fall was inevitable. Severus reigned with vigor as became "the soldiers' emperor," defeating his competitors Niger and Albinus, but cruelly putting to death large numbers of the adherents of his rivals, thus further demoralizing the time. His reign came in the midst of a financial crisis for the empire during which the government resorted to debasement of the coinage to bolster up its credit. Severus was the first of Rome's rulers to lay the foundation of a great private fortune. As emperor he was an extremely hard worker, always at work by dawn, and devoted long hours every day to the duties of his position. On his return to Rome in 202 he was greeted with a popular reception but refused a triumph and in spite of his fortune always lived very modestly. Like Marcus Aurelius he attempted to found a dynasty and when he died at York (Britain), he bequeathed the empire to his two sons, Caracalla and Geta. Caracalla, having killed his brother, gave a frightful example of imperial misrule. Undoubtedly insane,— nothing else could account for his utter cruelty,— Gibbon terms him "a common enemy of mankind." During their father's lifetime the two sons had used the family fortune in racing and gaming, caring only to associate with gladiators and chariot drivers from the circus. To distract them Septimius planned the conquest of Caledonia and it was this that brought him to Britain, where he erected the wall known by his name between the Forth and the Clyde. After Caracalla had expended the family fortune he went to the greatest length of cruelty and injustice to secure more. One good result of his desire for money was the granting of Roman citizenship to all the provinces so as to secure the right to levy direct taxes and imposts on inheritances (215). In imitation of his father Caracalla visited the various provinces of the empire, but instead of benefiting from his stay, each in turn became the scene of his rapine and cruelties. Having heard that the citizens of Alexandria disapproved his mode of life he ordered a general massacre of the inhabitants. He was finally put to death by his soldiers in the East and was followed by a series of emperors in rapid succession, most of whom met violent deaths. Macrinus, who succeeded Caracalla, was put to death within a year by the soldiers. A feminine intrigue then seated Heliogabalus, an Oriental priest, on the throne. He was worse, if possible, than Caracalla and his name has become a byword for utter viciousness. After four years he was succeeded by Alexander Severus, who meant well and accomplished much, but the rule of Rome was now become a difficult task. He tried the expedient of paying an annual tribute to the Goths to keep them from molesting the empire. This token of weakness had, as might have been expected, exactly the opposite effect. Severus was murdered by a mutiny in the army (235) and was succeeded by Maximinus who bravely led his army against the Dacians and defeated them, but was assassinated by his own people near Aquilia the next year. Balbinus and Gordian reigned very briefly, though Gordian defeated the Persians under Sapor before meeting death from Philip the Arabian who succeeded him in 244.

In 248 Philip was succeeded by Decius who bitterly persecuted the Christians and was slain by the Goths who invaded the empire the following year. The Huns on the Caspian Sea come into history at this time as a new set of enemies for the empire. Emperors continued to succeed each other nearly every year — Gallus (251), Æmilianus (253), Valerian (254) who five years later was defeated, made prisoner and flayed alive by the Persians. Then came Gallienus and the era of the Thirty Tyrants, none of whom deserve particular mention.

The most interesting character of the 3d century is Zenobia, queen of Palmyra (died 274). Her husband, Odeanthus, had set himself up as ruler of Palmyra during the weakness of the empire in the time of the Thirty Tyrants, and she survived to continue his rule. Zenobia claimed to be a descendant from Cleopatra and her beauty was such that, if tradition be true, she far outrivaled the Egyptian queen. For a time during the disturbed state of the Roman Empire, she exercised sway over a large territory, boldly proclaimed herself Queen of the East and bade defiance to Rome. The ruins of Palmyra were among the first to be excavated and studied in modern times and this gave the town a special interest. The Arabs had for long told wonderful tales of a ruined city in the Syrian Desert, but their description was of remains so extensive and magnificent that it seemed that there must be Oriental exaggeration in their accounts. At the end of the 17th century, European travelers reached the site of Palmyra, however, and found that the Arabian stories minimized rather than exaggerated the truth. There was, for instance, a colonnade stretching almost a mile in length and many of the marble columns constituting it are still standing amid the sand of the desert.

Palmyra, as the inscribed monuments show, came into prominence about the beginning of the 2d century. Adrian took the city under his protection and on the occasion of his visit the name was changed to Adrianopolis. It was extremely prosperous a century later, its position between Parthia and Rome enabling it to trade with both. Under Caracalla, Palmyra received the *jus italicum* and became a Roman colony. After this, it was known as an important military post on the eastern confines. When the emperors in the 3d century led armies to the eastern frontiers, Palmyra was a favorite stopping place. Some of the citizens received even the honors of Roman senatorship and one of them, in the disturbed times after the middle of the 3d century, made himself ruler of the city and came to be recognized even by the Romans as having a certain independence. Odeanthus made himself extremely useful in the wars against the Persians and the Syrians and was rewarded by a tacit recognition at least of his domination over all the country from Armenia to Arabia. When absent on his expeditions, his wife, Zenobia, administered the government of Palmyra very successfully. Indeed, Aurelian, in one of his letters, ascribes to her the chief part in all her husband's successful career. She was an Arabian of dark beauty, black flashing eyes, pearly teeth and a strength which enabled her to accomplish marvels of physical endurance. She was as famous, however, for her intellectual talents as for her beauty. She knew a number of Eastern languages as well as Latin and Greek. Longinus, the famous Greek rhetorician whose Essay on the Sublime is so well known, had been her tutor in Greek. He had been invited to the court and remained faithful to her even in her misfortunes, suffering death for his fidelity.

Odeanthus was assassinated probably at the instigation of the Roman Emperor Gallienus, and Rome proceeded to subdue the Palmyrenes who had ventured defiantly to style their ruler "King of Kings and Restorer of the State." Zenobia, nothing daunted, and used to administrative emergency, took up the unequal contest with the Roman Empire. She held Egypt, Syria, Mesopotamia and Asia Minor as far as Ancyra. Other portions of the East were about to join her when the Roman army under Aurelian made its appearance and prevented further defections. In two great battles that were fought, Romans in Zenobia's forces bore the brunt of the losses. Summoned to surrender after the second defeat, she made light of her losses, saying that so far all who had fallen were Romans. Finally, she had to withdraw within the walls of Palmyra and Aurelian, in spite of the handicap of the desert, succeeded in maintaining the siege of the city. Finding further resistance hopeless, Zenobia attempted to escape, hoping to find a refuge in Persia, but betrayed by the influence of Roman gold she was captured. Then Palmyra capitulated. All the treasures of the city were seized but the inhabitants were spared. Zenobia was taken to Rome to grace the conqueror's triumph but after this, instead of being put to death, she was given a villa outside of the city of Rome where she lived peacefully, with her children till her death, making many friends among the Roman nobility of the time. It is probably to her taste that is due the construction of the beautiful architectural monuments of Palmyra which have made the city the subject of so much of interest, while her own life tinged it with romance.

The end of the 3d century, after a long period of anarchy, was occupied by the firm reign of Diocletian, a self-made man, the son of poor parents, who owed his advance to his military genius. He reigned for some 21 years (284–305) and then (see FOURTH CENTURY) resigned and retired to a pleasant country estate not far from Dioclea, his birthplace in Asia Minor. When in the midst of the critical times for the empire which followed his abdication, Maximilian, one of his successors, urged him to take up the imperial mantle again, he replied: «If you could but see the cabbages which I raise in my garden with my own hands, you would no longer talk to me of abandoning this happy spot for the Empire.» As might well be expected, the man who was capable of this could and did give the Roman Empire years of peace and prosperity, stained unfortunately by the persecution of the Christians, but that did not come until the beginning of the 4th century and under the influence of those who shared the empire with him.

While the 3d century produced no great authors a series of men wrote books that have attracted attention ever since. Plotinus (204–270), the well-known Neoplatonic philosopher who studied at Alexandria and afterward taught philosophy in Rome, wrote his 'Enneads' about the middle of the century. He was an eclectic, borrowing from many sources, and is a Neo-Aristotelian as well as a Platonist and deserves the name of Neo-philosopher. His disciple Porphyry (233–305) wrote a life of Plotinus and also of Pythagoras, but is best known for his treatise «Against the Christians,» which was answered by Eusebius at the beginning of the 4th century. It is known to us only from Jerome's commentary and other Christian criticisms. Longinus (210–273), the author of the essay 'On the Sublime' also belongs to this time and spent most of his mature life at the court of Zenobia in Palmyra. He was as we have said her chief counsellor and the instructor of her children but on the fall of Zenobia he was put to death as a traitor by the Emperor Aurelian. Jebb declared the essay 'On the Sublime' one of the best pieces of literary criticism in the Greek language. (See ON THE SUBLIME). Papinian, the greatest civil lawyer of antiquity, and Dio Cassius (155–230), the Greek historian of Rome, both flourished during the first quarter of the century. Dio's whole work in 80 books was in existence in the 10th century, only some 25 books XXVI to LX now remain nearly complete with but fragments of the others.

PRINCIPAL EVENTS OF THE THIRD CENTURY.

208. Septimus Severus invades Caledonia after conquest and establishment of military government in Britain.
211. Septimus Severus builds wall across Britain to exclude the Northern Picts.
217. Assassination of Caracalla.
222. Heliogabalus slain. Alexander Severus reigns.
226. Parthian Empire dissolved. Sassanian Persian Empire founded.
230. Death of Dio Cassius, the Greek historian of Rome.
235. Alexander Severus slain. Maximinus, a herdsman, becomes emperor.
249. Goths invade the Roman Empire, defeat and kill the emperor Decius.
259. The Persians take Valerian prisoner and flay him alive.
261. The Persians capture Antioch.
268. Germans invade Italy. Claudius defeats the Goths. Persians invade Asia Minor. Odeanthus and Zenobia revolt.
270. Death of Plotinus, Neoplatonic philosopher, author of the 'Enneads.'
272. War with Zenobia, queen of the East.
273. Longinus, philosopher and counsellor to Zenobia put to death by Aurelian.
274. Aurelian subdues Zenobia; yields Daria to the Goths.
284. Diocletian and Maximinus joint emperors. The second Roman embassy reaches China.
287. The Celts or Franks settle on the left bank of the Rhine.
292. Galerius and Constantius become coadjutors to Diocletian and Maximinus. The Roman empire divided into four parts.
297. Siege of Alexandria.

THIRD RAIL. See ELECTRICAL TERMS.

THIRD-RAIL SYSTEM, in electric railway construction, a method of supplying trains on an electric railway with current sent through a conductor located on the track and termed a third rail. Being the first electric system for handling heavy traffic, it possesses unusual interest. In starting a train of five cars by electricity, from 500 to 1,200 amperes are required.

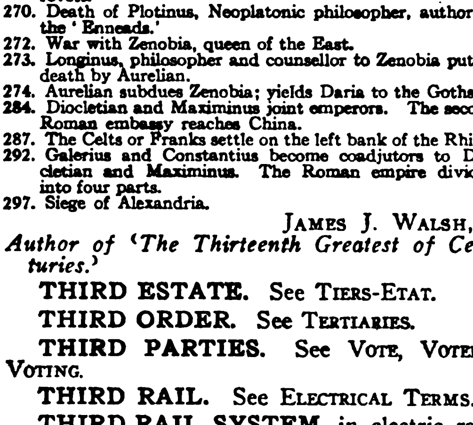

FIG. 1.— Diagram showing typical load carried at power house of Metropolitan Elevated Railway, Chicago, for 24 hours.

If such currents were passed through a trolley wheel, very excessive arcing would be caused, due to the fact that the wheel touches the wire at only one point. The contact surface is not sufficient to carry this current, and burning of the wheel and trolley wire would result. With a sliding shoe, however, instead of a single point of contact, there is a surface about six inches long by two inches wide, and two of these in use at once under normal conditions. The third-rail system differs from the ordinary trolley road only in detail, the principle of operation being similar. These details, however, are such as to make possible the application of electric traction to heavier trains than has been found practicable with the overhead trolley, and the system has thus broadened the field for the application of electricity to railway work, so as to bring it into successful competition with steam for the heaviest classes of service. The reasons for its general adoption on elevated roads were on account of the advantages peculiar to electric traction itself, namely:

1. Reduction in cost of power for handling trains.
2. Increase in passenger handling capacity.
3. A service more attractive to the public generally.

The reduction in the cost of power is obtained largely from the generation of power in a single central steam plant, instead of a great number of smaller plants, as with the steam locomotive system. On this point of economy the fuel bill is one of the large items in the operation of a railroad. With steam locomotives, such as were formerly used on the Chicago elevated roads, the only fuel available cost in the neighborhood of $3.50 to $5.50 per ton, whereas, in the modern power house, designed for electric railway systems, coal ranging from $1.25 to $1.75 a ton was burned with entire success during the period of low prices for coal. When to this is added the enormous loss in radiation from a large number of steam locomotives, exposed as they are in running over the line of the road, and we compare this with the relatively small loss experienced with a well-constructed stationary boiler plant, it is not surprising that the cost for coal per car mile on the electric railways in Chicago is about one-third the cost per car mile with steam locomotives. The comparison is particularly favorable in Chicago on account of the ability to obtain a very cheap grade of coal directly from the Illinois and Indiana coal fields. In New York and other eastern cities, this difference is not so great, as coal delivered at those points is necessarily higher in price on account of larger freight charges. Besides the saving in the coal bill, there is a further gain by the use of large compound-condensing engine units. These large steam units having a comparatively steady load, develop power with a very much lower steam consumption than the small engines of a locomotive with their constant starting and stopping, and consequent cooling of cylinders, etc. Another item in which a considerable saving is made is in the cost of repairs and renewals to the motor equipment as compared with locomotives.

The second advantage — increase in capacity for handling passengers — is due, first, to the fact that with electric motors a much higher rate of acceleration can be obtained in starting trains, thereby increasing the average speed over a given line of road. The trains can also be handled with so much greater accuracy and precision that a much shorter interval is perfectly safe, all of these directly contributing to the end of greater capacity.

The third item — service more attractive to the public generally — is proved by the facts of the absence of smoke and steam, and the great reduction in noise, these being especially important in systems passing through the heart of a large city, as is the case with elevated roads. In regard to the use of the third-rail system on interurban roads, the same general considerations apply as to the economy of operation, except that, trains being less frequent, the economy in the power generation is not so great an item. There is another field for the third-rail electric railway system, which has been developed by the New York, New Haven and Hartford steam road, and that is the use of light trains for suburban and interurban service on many of their branch lines.

One of the most difficult problems in equipping an electric railway system is the proportioning of the total capacity of a power house to the number of cars run, and the subdivision of this total capacity into proper-sized units. In order to determine these points, it is necessary to be able to estimate the maximum loads that will have to be carried during the rush hours and the minimum loads during midday and midnight. The maximum load does not always depend upon the total number of trains run, as on some lines more than half of these trains will be running light in one direction in order to carry the crowds back on their return or vice versa. In subdividing the total capacity of a power house, it is desirable to have a single unit which will carry the minimum light load with reasonable economy. The load on a power house operating in connection with an elevated railway system varies not only from a maximum during rush hours to a minimum during off hours, but also momentarily during the starting and stopping of trains, these fluctuations being most violent when the least number of

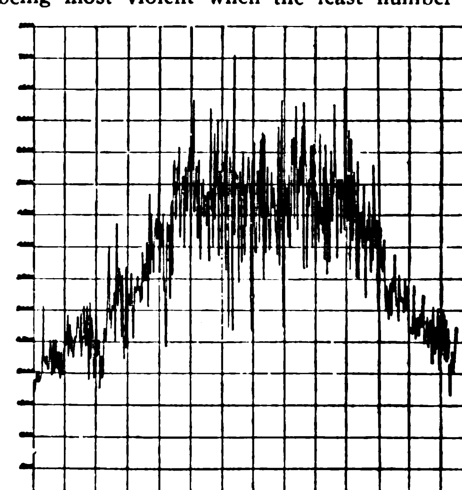

FIG. 2.— Diagram showing fluctuations in the consumption of electrical energy on the Metropolitan Elevated Railway, Chicago, at short intervals from 5 A.M. to 9:30 A.M., ranging from 1,700 to 7,000 amperes.

trains are in service. Under the worst conditions, this rate will vary from 300 amperes to 4,000 in 15 seconds, or the reverse. It is necessary, therefore, that all parts of the engine should be especially heavy, particularly the flywheel, in order that sudden changes in the load should not interfere with the proper regulation of the engine speed.

The accompanying diagram, Fig. 1, shows a typical load curve at the power-house. Curve A is that of the trains in service. Curve B shows the additional amount of energy for heating the cars, with heaters only partly turned on during the rush hours; while curve C gives the total load with heaters turned on full during the rush hours. The high peaks of the curve occur at the rush hours of travel.

The second diagram, Fig. 2, shows the violent fluctuations in the demand for electrical energy for operating the trains.

In the third-rail system the use of the ordinary track rail for the conductor was largely a matter of convenience in the first case, as rails were the easiest form of steel to obtain in reasonable lengths, and their shape was such as to lend themselves to the various requirements of attaching bonds, angle bars and insulating supports. The value of an ordinary commercial steel rail as an electric conductor, as compared with copper, is about 10 or 12 to 1, with of course the additional disadvantage against the rail of the necessity of the frequent bonding, the rails usually coming in 30-foot lengths. To offset this lower carrying capacity, however, compare rails at $17 per ton with copper at $360 per ton, and it can be seen that one can afford to put in the larger amount of steel required for a given electrical capacity and still have a good margin in favor of the rails. A commercial 80-pound track rail has a carrying capacity about equal to an 800,000 centimeter copper cable. In purchasing the contact rails for the extension of a western railway line, they were made of steel of a special chemical composition, having a higher electrical carrying capacity than the ordinary commercial steel rail. The composition was obtained after a series of experiments conducted for the Manhattan Railway in New York, with a view to getting the best possible conductor with a composition of steel that could be successfully rolled into rails. The use of this composition results in a steel rail so soft as to be unfit for ordinary railway service, but the conductivity is raised so that, compared with copper, the ratio is about 8 to 1, as against 12 to 1 for ordinary commercial steel rails.

THIRLMERE, thėrl-mēr, England, a long and narrow lake in the mountains of Cumberland County, in the centre of the Lake District, northwest of Mount Helvellyn, between Derwentwater and Grasmere. It is three miles long by a quarter of a mile wide. The city of Manchester bought and converted it into a reservoir for its water supply, and the system, begun in 1886, was completed in 1894 at enormous expense.

THIRLWALL, thėrl'wâl, **Connop,** English prelate and historian: b. Stepney, Middlesex, 11 Jan. 1797; d. Bath, 27 July 1875. He was educated at the Charter-house and at Trinity College, Cambridge, where he obtained a Fellowship. He afterward studied for the law and was called to the bar in 1825. Having exchanged the law for the church he was ordained in 1828, and some years after received the living of Kirby Underdale, in Yorkshire. Here he added to his pastoral duties a variety of literary labors. The first of his works, published by himself (his father had previously issued a number of essays and poems written by him in extreme youth), was a translation of Schleiermacher's 'Gospel of Saint Luke,' to which he prefixed an introduction. This work appeared anonymously in 1825. His next work was a translation of the first two volumes of Niebuhr's 'History of Rome,' with Archdeacon Hare (1828–31). Then followed the work to which he chiefly owes his reputation, his 'History of Greece,' the first edition of which appeared in Lardner's 'Cabinet Cyclopædia,' in eight volumes, between 1835 and 1844. It was well received, and before the appearance of Grote's history (the first two volumes of which were published in 1846) was without a rival in the English language. Grote himself praises it for the learning, sagacity and candor it displays, and said that if it had appeared a few years earlier he should probably never have conceived the design of his own work. In 1840 Thirlwall was presented by Lord Melbourne to the Welsh bishopric of Saint David's, which he resigned a little more than a year before his death. He was for a time one of the editors of the Cambridge 'Philological Museum,' and during the closing years of his life was a member of the committee for the revision of the Old Testament. He was one of the bishops who spoke and voted for Gladstone's bill for the disestablishment of the Irish Church. Consult Perowne, 'Remains, Literary and Theological, of Connop Thirlwall' (London 1877–80); Thirlwall, 'Essays, Speeches, and Sermons' (1880); Stanley, 'Thirlwall's Letters to a Friend' (London 1882); Morgan, 'Four Biographical Sketches' (1892); Clark, 'Old Friends at Cambridge and Elsewhere' (1900).

THIRST, a craving for water or other drink. As appetite shows a need for the introduction of food into the system, so thirst is a sensation indicating the necessity of an increased supply of water. This sensation is referred to the throat, yet it is not a purely local feeling, but an index of the wants of the tissues at large, for thirst cannot be allayed unless the water swallowed reaches the stomach, is absorbed and carried into the blood. Thirst may also be relieved by the direct introduction of water into blood-vessels or by rectal injections of it, or by its absorption through the skin. How long the demands of thirst may be successfully withstood cannot be stated definitely, since human beings as well as the lower animals differ among themselves, and under varying circumstances of climate, etc., as to the degree of tolerance. Certain it is that of all substances a regular supply of water is most essential to the maintenance of life. If deprived of it for even 8 or 10 hours, greater inconvenience, pain and debility are suffered by an individual than from an equal deprivation of solid food. As thirst is but the expression of a dearth of water in the tissues, any condition which causes a more rapid elimination of water than usual will increase thirst. Such is the effect of severe muscular exercise, especially, for example, the exertion in a heated atmosphere habitual with stokers, iron-puddlers, etc. Thirst is also increased by certain articles of food, excess of salt or sugar, for example: in febrile disorders; in severe diarrhœas and hæmorrhages; in diabetes; in acute gastritis; in polyuria; in certain forms of hysteria, etc.

For allaying thirst nothing is so grateful as pure cool water, sipped a little at a time. Sweet drinks are not as effective in relieving thirst; but the vegetable acids in oranges, lemons, grapes, limes, etc., have a tendency to allay thirst, and to lessen the desire for large quantities of fluid, since the acid provokes an increased flow of saliva. Toast-water, small pieces of ice, effervescent drinks and dilute phosphoric acid alone or combined with a little aromatic bitter are also of value. In fever, cleansing the mouth, and swabbing it with glycerine, borax and water is of more service sometimes than drinking large quantities of water.

THIRTEENTH AMENDMENT. See Constitution of the United States; Constitutional Amendments, History of.

THIRTEENTH CENTURY. John Fiske in 'The Beginnings of New England' terms this period «The glorious thirteenth century» . . . «a wonderful time, but after all less memorable as the culmination of mediæval empire and mediæval church than as the dawning of the new era in which we live to-day.» John Morley said, «I want to know what men thought and did in the thirteenth century — because the thirteenth century is at the root of what men do in the nineteenth century.» Freeman 'The Norman Conquest' calls it «The age of wonders . . . which wrought the body politic of England into a shape which left future ages nothing to do but to improve in detail.» Frederick Harrison in 'A Survey of the Thirteenth Century' declared «Of all the epochs of effort after a new life that of the age of Aquinas, Roger Bacon, Saint Francis, Saint Louis, Giotto and Dante is the most spiritual, the most really instructive, and indeed the most truly philosophical.» It would be hard to find a group of men so different in character, ways of looking at things and individual intellectuality, so concordant in their estimate of an important period of history as these expressions indicate, but similar appreciation might be quoted from Macaulay, Green, Bishop Stubbs, Carlyle, Walter Scott and many others.

The century has been hailed by many as the greatest in the history of humanity. Nothing shows more clearly the recent change in estimation of the Middle Ages than this. No phase of human achievement in the intellectual and artistic side of man is lacking in this age; many are represented by products that surpass all others. In painting and sculpture, in architecture, in the minor arts and crafts, in literature, in philosophy, in education, in social work, even in the building of hospitals and the care of the ailing, and most surprising of all in medical education and surgery, there was a wonderful accomplishment at this time, the history of which was concealed from us until comparatively recent years by an exaggeration of interest in classical antiquity and in the Renaissance. Just in proportion as we have become deeply interested once more in art, architecture, the arts and crafts, in sculpture and handsome public buildings, in the home and the city beautiful, we have learned to realize how many of the ideals we are striving for now were accomplished marvelously in this late mediæval century. Generations which themselves had lost or impaired these higher interests, affected to condemn this old time. It was grouped among the «Dark Ages,» though we now know it to have been in John Fiske's expression one of the «Bright Ages.»

The central interest of the century and its greatest triumph was the Gothic cathedrals. In England and France particularly, but also in Germany and Italy there arose in the early part of the century some of the most beautiful edifices ever built by man. The generations solved the architectural engineering problems of these huge constructions with absolute success. The decoration of them made a universal appeal and for sheer beauty and suitability has never been excelled. The sculpture on the façade of many of these Gothic cathedrals as at Amiens, Chartres, Rheims, is among the greatest plastic work in the history of art. The figure of Christ over the main door at Amiens has been declared the most beautiful presentation of the human form divine ever made. Every phase of cathedral decoration took on the perfection of its sculpture. The carved stone work, the hammered iron of the gates and grilles, the very hinges and latches of the doors, the brass and bronze work in connection with the altar, the bells, the stained glass, all approached perfection so closely that they have been objects of deep admiration ever since whenever men have been profoundly interested in the arts and crafts. The stained glass has never been excelled and is still an object of almost reverential respect, some of it unapproachable in its beauty.

All the fittings and furnishings of the cathedral, even the least obtrusive, partook of the same surpassing qualities. Dark corners were not left unfinished for it was the house of God. Every detail was the object of loving devotion. The needlework of the time is probably the best in history. The cope of Ascoli (*circa* 1280) is looked upon as the most beautiful ever made. The church vestments and hangings were charmingly worked. The precious vessels for the altar were gems of the metal workers' art, of exquisite line and form, delicately finished and appropriately set with jewels. The Mass books, as well as the Books of Hours, used by the educated worshippers, were so beautifully illuminated that they have been marvels ever since and command high prices in the auction-rooms. Manifestly, there was nothing that the people of the time wanted to do well which they did not accomplish with a marvelous perfection. Their domestic and municipal furnishings partook of the same excellence. The very utensils in the kitchen were beautiful as well as useful and the combination of the two qualities in ordinary life has been declared the criterion of culture in the hearts of a people.

The historic life of the century centres around the cathedrals very much as their social life centred around it in the cities and towns. Their education came into existence as the development of cathedral schools and these were usually placed under the rectorship of the chancellor of the cathedral. The *studia generalia,* as the universities were called because they provided education in so many different subjects, grew into their modern form during the courses of the century. At the beginning a few cities, Salerno, Montpelier, Bologna and Paris and one or two others, had rather important schools of special subjects around which various faculties gradually gathered. By the end of the century there were some 20 important universities in our modern sense of the word with large undergraduate departments and as a rule the three graduate departments of theology, law and medicine. The course of study for undergraduates was summed up by Huxley in his inaugural address as rector of Aberdeen University: "I doubt if the curriculum of any modern university shows so clear and generous a comprehension of what is meant by culture as this old *trivium* and *quadrivium*." The seven liberal arts, as the *trivium* and *quadrivium* were also called, constituted the undergraduate university studies of grammar, logic and rhetoric, geometry, astronomy, theology and music.

All of these subjects were treated from a scientific standpoint and these were really scientific universities. The study of the classics as the basis ot undergraduate education did not come in until the Renaissance time. Hence Huxley's candid admiration for these old-time universities so that he did not hesitate to say that "their work brought them face to face with all the leading aspects of the many-sided mind of man." The philosophical teaching particularly anticipated many modern ideas. Matter and form as the explanation of the composition of matter resembles the modern physical chemistry theory that all matter consists of an underlying substratum the same in everything and differentiated into various substances by the dynamic elements which enter into it. The scholastics taught that matter and force could be annihilated by the power that brought them to existence, but not destroyed by any human agency, thus anticipating the modern experimental demonstration of the indestructibility of matter and the conservation of energy. They faced the ethical problems of mankind, especially those which concern social relations, exactly in the same spirit which the modern world, after a rather long interval of failure to recognize human rights as superior to those of property, has come around to again. In writing on capital and labor for our time Pope Leo XIII quoted the ethics of Saint Thomas Aquinas, drawn up more than six centuries before.

The numbers in attendance at the universities at the end of this century were probably larger in proportion to the population of the various countries than at any time in the history of education down to our own day. The universities of Bologna and of Paris had, during the last quarter of the century, more students than any university of modern times. Oxford and Cambridge were more numerously attended than at any time afterward. Some of the students were boys of 12 or 13 but graduation was earlier than with us as it is still in most foreign countries. On the other hand many mature students remained at the university for years listening to a favorite professor or working up some special theme. The literary output of the universities in philosophy and theology as well as from the graduate departments generally was extensive. Original work was encouraged, though it was the subject of severe criticism. Groups at various universities were engaged in encyclopedic research and publication. A series of *summas* of knowledge in general and of special departments was made.

The discipline of the immense numbers of students represented a problem which was solved by sharing disciplinary regulation with students committees chosen by the Nations, that is, the organizations of the students from particular parts of Europe in attendance at the university. The Nations were fraternal unions which helped the student when he first came to the university to orient himself and get settled for his university work. They protected students against impositions and furnished information with regard to courses and professors. Many of the features of modern life at our universities were thus anticipated. Initiations accompanied by hazing were common practices and the Nations provided recreation of various kinds. On the other hand when students were ailing or when remittances from home were delayed by the vicissitudes of the times, help was provided and students were tided over crises in their affairs. A number of abuses crept into university life through these organizations and conflicts between town and gown are noted before the end of the 13th century, but it was later in the historv of universities that these became so intolerable as to demand correction. In the early history of the universities the students were as important a factor at least as the faculty and new universities were often founded by the withdrawal of dissatisfied students to some other town.

The graduate schools were the most important departments of the universities. In theology, Saint Thomas of Aquin or Aquinas has been an authority ever since and the contributions which he made to philosophy have been the subject of enduring interest. There was a magnificent development of law throughout the various countries and a corresponding evolution of the teaching of law. Canon law particularly was taught with a scientific thoroughness unequalled before and unsurpassed since. It became the basis of all European law. The medical schools are, however, the special surprise for our time. Early in the century the Emperor Frederick II made a law for the Two Sicilies requiring students of medicine to spend some three years at the university preliminary to their medical studies, and then four years at medicine, followed by a year of practice with a physician before they were allowed to practise for themselves. That is a modern standard re-established but recently after a long interreguum. Salerno, the first university medical school, set the example in teaching and insisted on the employment of the natural means of cure, fresh air, water, diet, exercise and occupation and diversion of mind. These are all emphasized in the famous *Regimen Sanitatis Salernitanum*, issued at Salerno about the beginning of the century and published in some 300 editions since the invention of printing. It was the most read popular book on medicine for centuries, republished many times even in the last century. The textbooks in surgery extant from this time have been a revelation. The surgery of the four masters of Salerno who collaborated in the work quite after the modern fashion of textbook writing is surprising in its anticipation of modern surgery. We have, besides, the book of Theodoric of Lucca and of Bruno of Longoburgo as well as of William of Salicet, Lanfranc and Mondeville. In these, anæsthesia,— through mandrake and opium,— antisepsis by the use of strong wine — they boasted of union by first intention — and a great many of the operations, especially a whole series of intra-abdominal and intracranial operations, as well as many instruments and modes of treatment considered to be modern are described. In the large, very well-planned hospitals of the time, with finely organized nursing, many operations undreamt of in the intervening centuries until our generation were successfully accomplished, not merely as emergency interventions, but to save suffering and prolong life.

The names of the teachers in these graduate schools, Albertus Magnus, Thomas Aquinas, Roger Bacon, Bonaventure, Duns Scotus and Alexander of Hales, are probably better known than any group of teachers in history. Instead of losing prestige in the course of time they have gained repute in recent years with increase of interest in the mediæval period. Albertus Magnus is the only scholar in history with whose name the adjective great has become incorporated as if it were a family name. He was a man of the widest interests, intent on testing all knowledge carefully. Humboldt pointed out how much he knew about physical geography, physics, climatology and the physiology of plants. Meyer the historian of botany declared "No botanist who lived before Albertus could be compared with him unless Theophrastus with whom he was not acquainted, and after him none has studied plants so profoundly until the time of Conrad Gesner and Cæsalpino." Albert discussed scientifically the Milky Way and its significance, the irregularities in the moon's surface, lunar rainbows, various kinds of refraction and many other problems supposed to be modern. His great pupil Aquinas, adopting Aristotle, laid down the metaphysical principles which are now coming to be recognized as fundamental ideas in the physical and social sciences. Hence a great revival of study of his works. Even more immediately interesting than these to the modern world is Roger Bacon, the international celebration of whose 700th birthday attracted so much attention at Oxford in June 1914. Bacon probably invented gunpowder, suggested that explosives might be used for motor purposes,— boats running without oars or sails and carriages without horses,— discussed the theory of lenses, declared that mathematics and experiment were the two important factors for advance in science; anticipated modern ideas as to Biblical revision, insisted on the value of Greek and Hebrew for education, declared that light travels with appreciable velocity and spoke with assurance of aviation. It is clearer than ever now why the people of his time called him *Doctor Admirabilis,* the admirable teacher.

A feature of 13th century education most interesting for our time is the feminine education of the period. At Salerno in southern Italy women were encouraged to study even medicine during the 12th century and the department of women's diseases was in their charge. We have many licenses to practise medicine in the Two Siciles granted to women at that time still extant. At Bologna at the end of the 12th century the daughter of Irnerius the great teacher of law became an instructor in the law school. All of the Italian universities had women teachers on their staff. The unfortunate Héloïse and Abelard incident at Paris seems to have given a serious setback to feminine education in the universities of the west of Europe, but in Italy the custom established in the 13th continued, and there have been women professors at the Italian universities every century since.

The literature of the century is the proof of the intellectual quality of the time, for it was not only great but widely read. Its value will be best recognized from the fact that probably well-read people know the works of the 13th century better than of any other, except their own, though they are often not quite conscious of the fact, not having noted the dates. The enduring work of the time begins with the Arthur legends put into fine literary form by Walter Map or Mapes, just as the century begins. To him we owe Lancelot. "Like Paris, handsome, and like Hector, brave," but with a fault that makes him even more appealing, so that probably he is the most interesting character of fiction ever created. Then came the ballads of the Cid in Spain, followed by the Nibelungenlied with the Meistersingers and Minnesingers and then the Troubadours and Trouvêres with the Romance of the Rose and Renard the Fox in what we call France, and, finally, the Trovatori in Italy, culminating in Dante who, the greatest of the Trovatori, was just ready to write what has often been proclaimed the greatest poem of all literature, as the century closed. Such other writers as Villehardouin, Joinville, Matthew of Paris, the earliest encyclopedists, Vincent of Beauvais, Thomas of Cantimprato, Bartholomew the Englishman, and such works as that of William of Durandus and Jacobus de Voragine of the Golden Legend, are perennially interesting. The century has also the greatest of the Latin hymns, the 'Dies Iræ,' the 'Stabat Mater,' the marvelously beautiful religious poetry of Saint Francis himself, of Saint Thomas Aquinas, of Bernard of Morlaix and of Saint Bonaventure.

The century saw the publication of what must be considered the first of encyclopedias. Vincent of Beauvais, under the patronage of Louis IX, with the aid of a great many young assistants of the Dominican Order whose expenses were generously defrayed by the king, was enabled to gather an immense amount of information for his time. In spite of the difficulty of hand transcription, his work extends to over 50 of our volumes octavo. The matter is well chosen and of wide interest, and the surprise is how many things supposed to be much more modern in human knowledge are to be found in Vincent. Pagel declared "the reading of the work easily becomes absorbing."

The century provided a magnificent series of contributions by explorers to the knowledge of the world at that time. Travelers in the Near and the Far East told the stories of how other people lived and their books still extant demonstrate what excellent observers they were. The greatest of these explorers was Marco Polo, whose name was for so long a by-word for credulity and tendency to exaggeration, who proves now, like Herodotus, to have had a basis of real truth for all that he told. He visited the Christian kingdom of Abyssinia as well as China and nearly all the world between. He told of Burmah, of Siam, of Cochin China, of Japan, of Java, of Ceylon and India and he had heard interesting accounts of the coast of Zanzibar and distant Madagascar and at the opposite end of the world of Siberia and the shores of the Arctic Ocean. Colonel Yule, a modern authority on the literature of travel, can scarcely find words to praise Polo enough. There were many other famous travelers whose works have come down to us from the century and are republished in recent years. Friar John of Carpini went on a mission to the Tatar emperor of the time, across the Ural Mountains and River, past the northern part of the Caspian Sea, across the Jaxartes, along the Dzungarian lakes to the Imperial camp near the Orkhon River. Friar William of Rubruk or Rubruquis, the account of whose travels was printed by Hakluyt in his collection of voyages at the end of the 16th century, went even further. Some of his observations, as for instance on Chinese writing, are surprising enough, but he has many details of Asiatic nature, ethnography, manners, morals, commercial customs, that were true to life. Friar Oderic a little later traveled through India and then through China to Nankin and Peking, reached the Great Wall, entered Tibet and appears to have visited Lhasa. Sir John Mandeville (15th century) borrowed much from him, as well as from the Præmonstratensian monk Hayton. Most of the men who thus wandered in distant lands were graduates of the universities of the time and while they were credulous with regard to what they heard, very much as Herodotus himself, they could be absolutely depended on for information with regard to things which they themselves had seen.

Besides the intellectual education which came in the cathedral schools and their developments at the universities there was a great phase of popular education along artistic lines which was initiated in the midst of the building of the cathedrals. Most of the beautiful things in the great Gothic churches were made by workmen of the little mediæval towns in which they were built. None of these had more than a few thousand and probably did not average 10,000 inhabitants. Somehow artistic artisans to do all the beautiful work demanded were found and there was the popular taste to appreciate and the diffusion of liberal education to patronize and encourage the making of such beautiful things. There are receipted bills for the payment to village blacksmiths and village carpenters, for iron and woodwork, which we now rank as artistic masterpieces. Practically all the decorations and fittings of their cathedrals were executed by the townsmen themselves and even their bells and stained glass were made at home, not brought from a distance. Transportation difficulties threw them back on themselves and compelled technical developments while transportation facilities in our time have had an opposite effect. To secure the making of such beautiful things there had to be a skilled and well-trained group of artisans. There has probably never been a time when the arts and crafts, in our modern sense of that term, have been so appreciated and cultivated. In this culture the working classes were probably the most important factor. Technical training was provided by the guilds. Boys were apprenticed to trades and crafts of various kinds, and after four or five years of training became journeymen and traveled from place to place to learn the secrets and customs of their craft in the various regions. After two or three years of this on the presentation and acceptance of an example of their work called a masterpiece — this is where this old English word comes from — they were admitted as master workmen into the guild. This represented a degree in technics. The guild training was practically a technical school and as the guilds existed everywhere opportunities for arts and crafts education abounded. Any growing youth who had taste or talent for any form of artistic work could easily secure the opportunity for its development and then, more important still, obtain the chance to do his work in conditions where encouragement and appreciation would come to him. In England at the end of the Middle Ages there were 30,000 guilds (Toulmin Smith), the county of Norfolk alone having 900, the small town of Wymondham having 11 still known by name. One of them possessed a guild hall. All the guilds of the town are said to have been "well endowed with lands and tenements." In Bury Saint Edmunds, Suffolk, there were 23 guilds; Boston, Lincolnshire, had 14 of which the titles and particulars are known and London had a large number. The guild had increased in number greatly from the 13th century but there is definite evidence that most of the important guilds in existence in England at the end of the 15th century had been in existence for several hundred years. During this time they had accumulated very large amounts of money and invested funds of various kinds, not so much from the fees paid by their members as from bequests of various kinds made to them because it was felt that they were doing great good work. Unfortunately it was this accumulation of money that led to their legal destruction, though a few of the London guilds which were spared in the time of Henry VIII on the plea that they were trading or secular associations and not religious organizations have at the present time an income of over $50,000 per year each. The old guilds were trades unions, social clubs, insurance societies, civic organizations, popular entertainment committees, but withal religious sodalities enforcing fulfilment of religious duties yet not permitting the clergy to hold office or dominate policy.

The social history of the time is its most interesting feature for our era. The beginning of the period saw the rise of the two great mendicant orders, the Begging Friars, the Franciscans and Dominicans. A world so deeply intent on commerce as to give rise to Hansa and the great Italian commercial cities was afforded the example of two large bodies of men who took voluntary poverty for their lot so as to be free to do better things in life.

The coming of the Friars in such an age produced a deep impression. Saint Francis is one of the most lovable men of all history. A young man who, during convalescence from a severe illness, learns in Dean Stanley's words that «the world looks very different when viewed from the horizontal,» gets up from it, resolved that the fascination of trifles shall not obscure the good things of life. He proceeded to forget all about himself and his personal interests and found that all the world began to think of him. He got so close to the heart of nature that it is not surprising that we have legends that the birds and the fishes, and even the wolf of Gubbio harkened to him. He gathered around him a group of men forever famous for their absolute simplicity of life and for their refusal to let selfish motives rule them in any way. Such a life might seem too ideal to have any practical influence over mankind, and, above all, too mystical to make any appeal except to a mediæval world, yet literally dozens of lives of Saint Francis have been written in our very busy practical age. Probably never since his own time has there been so many people, and above all so many whose opinion is of value, ready to proclaim Saint Francis one of the most wonderful characters of humanity as in our era of crowded interests. The love for Lady Poverty of the «little poor man of God,» as he loved to call himself, has appealed to all religious and poetic souls ever since. No wonder that Dante has made such a brave figure of him in the 'Divine Comedy,' and placed beside him as equal in influence and power the great founder of the Dominicans.

The development of hospitals in the 13th century has been the subject of much study in the modern time. Virchow particularly has shown that there was probably scarcely a town of 5,000 inhabitants or more in Germany which did not have a hospital. He attributes this great development, more marked even in other countries than in Germany, to Pope Innocent III who founded «the hospital of the Santo Spirito by the old bridge across the Tiber and blessed and dedicated it as the future centre of a universal humanitarian organization.» Pope Innocent summoned Guy of Montpelier to Rome, having heard that he was in charge of the best organized hospital of the time, built Santo Spirito under his direction and then when bishops come to Rome, as they had at regular intervals, he commended the hospital of Santo Spirito to their study and recommended, where it was virtually a command, that there should be a hospital as far as possible like that, according to conditions in each locality, in every diocese in the world. Many of these hospitals were beautifully built. Municipalities constructed them for their citizens and they were public buildings, part of the scheme of the city beautiful which so many mediæval cities cherished. In smaller places hospitals were often built by the nobility and Virchow has called attention to the number of them constructed under the patronage of the family to which Saint Elizabeth of Hungary belonged. Her hospital at Marburg not far from where the beautiful church erected in her honor a few years after her death now stands, was a model for others. The hospital in Siena, added to (14th century) in memory of Saint Catherine, was another centre of charitable influence. The sister of Saint Louis of France, Marguerite of Bourgogne, built a beautiful hospital at Tonnerre, which Viollet le Duc has figured in his 'Dictionary of Architecture.' This shows how well these hospitals solved the problems of hospital construction which we have realized again in the modern time. There was a fine organization of nursing in these hospitals under the care of religious orders of men and women, especially the Augustinians. How well their work was done can be best appreciated from the great development of surgery which took place at this time, for good surgery is impossible without good hospitals and good nursing. Portions of many of these hospitals remain as evidence for what they were.

With a notable development of social service during the century and the opportunity afforded for feminine education, it is not surprising that the names of a series of women of this time are well known, indeed their prestige has been growing constantly in this last generation just in proportion as similar opportunities are afforded in this century. Saint Elizabeth of Hungary is probably the most famous and the beautiful cathedral erected in her honor at Marburg within a few years after her death, one of the handsomest monuments ever raised to a woman, is the testimony of her generation to their affectionate regard for the «dear Mrs. Saint Elizabeth» (Frau Heilige Elisabeth) as they quaintly called her because she was just a wife and the mother of four children who, though she died at 24, had found time to do great good work for the poor around her. Queen Blanche of Castile, the mother of Saint Louis of France, was another wonderful mother of the time. Her great son attributed all that he was to his mother's training. She was an administrator of high ability who lifted France out of a period of threatened anarchy to preserve his kingdom for her boy, and yet declared that she would rather see him dead at her feet than know that he had committed a mortal sin. The great women of the time came not only on thrones but also among the middle classes. Another mother of the time whose name is recalled in veneration was the wife of a London tradesman, Mabel Rich, whose son, Saint Edmund of Canterbury, one of the most sterling characters of the time, a scholarly churchman, made archbishop, went into exile rather than submit to a tyrant king. Edmund tells how the poor around his mother's home in London blessed her for her charity and was quite frank that he owed nearly everything in life to her. Another distinguished Englishwoman whose name has come down to us from this time is Isabella, the famous Countess of Arundel. She did not hesitate to admonish even the king himself, Henry III, when he was violating the liberties of England. Matthew Paris says that with a dignity which was more than that of woman she reminded the king that many times he had extorted money from his subjects and not kept his word and the rights of Englishmen were written down and he was violating them. With the revival of interest in Saint Francis there has come a parallel rebirth of admiration for Saint Clare of Assisi who at the age of 17 left home to have Saint Francis teach her how to live a life that would not be wasted in worldliness. Her mother and sister, who had opposed her vocation originally, joined her in the second order of Franciscans in a few years.

The military and political events of the century have a special significance because as a rule their influence still lives. The Crusades came to an end, the fourth under Boniface, Marquis of Montferrat (1222), the fifth led by King Andrew II (1228), the sixth (1248) and the seventh and last (1270), under Louis IX of France. The Children's Crusade (1212) was one of the sad interludes of an enthusiasm which went beyond reason. Most of the many thousands of children crusaders perished miserably or were sold into slavery by designing leaders. In 1230 the Teutonic Knights in a crusade against the pagan tribes of the Baltic region established themselves in Prussia and laid the foundation of what at the Reformation, through the ambition of a grand master, was to become a duchy, the beginning of modern Prussia. In 1282, Rudolph of Hapsburg, a Swiss noble, elected emperor in the first election held after the reform of the Imperial Electorate and the creation of seven electors, conferred on his sons the duchies of Austria and laid the foundation of the Hapsburg dynasty. All during the century the kings of Aragon were extending their sway over the Spanish Peninsula and the Balearic Islands (1230). After the Sicilian Vespers, a massacre of the French in Sicily by the Sicilians, so-called from its commencement at vespers on Easter Monday (1282), the kingdom of Sicily passed to them. Less than 20 years before (1265) the French under the House of Anjou had ascended the throne of. the Two Sicilies. In 1235 the duchy of Brunswick was formed under the House of Guelph. Five centuries afterward, when reigning in Hanover, the Guelphs were to succeed to the throne of England (George I) where they still reign. The century saw the rise of Florence in importance, the decline of the republic of Pisa, the increase of Venice in power under an aristocracy which became hereditary toward the end of the period and the enfranchisement of the serfs at Bologna. The closing year of the century Pope Boniface VIII proclaimed the first jubilee and the crowds who flocked to Rome to celebrate it were so large that they could not cross the bridge to the Vatican until the rule of the road of keeping to the right was proclaimed, the first time in history there is mention of it.

Everywhere political events were occurring destined to far-reaching significance. Edward I of England to whom the contest between Robert Bruce and John Baliol for the crown of Scotland had been referred as umpire, conferred it upon Baliol on condition that he should receive it as a vassal of England. The Scotch refused to acknowledge any such dependence, for Scotland, to which Magnus of Norway (1266) had ceded the Hebrides, felt its nationality at stake. Baliol was dethroned and fled to Edward who attempted to enforce his rights. William Wallace, the famous hero of Scottish popular poetry, led an insurrection that was joined by Sir William Douglas and Robert Bruce who gathered round them most of the Scots. They were defeated by Edward at Falkirk (1299), but Robert Bruce was proclaimed king and succeeded in maintaining himself until the defeat of Edward II at the great battle of Bannockburn (1306) settled him firmly on the throne.

The foundation of the Ottoman or Turkish Empire (1299) under Othman I in Bithynia led to the consolidation of Mohammedan power to the serious disturbance of Europe. The Turks are historically relatives of the Mongols who had already created the splendid empire of the Seljuks and who from the 11th to the 13th century governed the greater part of the caliphs' dominions in Asia and thus prepared the way for the Ottomans, their successors. The nucleus of their empire was formed in Asia Minor toward the end of the century under Er-Toghrul. Osman or Othman or Ottoman, his son, is looked upon as the founder of the empire.

The century saw the career of the best ruler of all time, Louis IX of France, or Saint Louis as he came to be called. It has been said of him, «Of all the rulers of men of whom we have record in history, he probably took his duties the most seriously with most regard for others and least for himself and his family.» The watchword of his rule was justice, though he made it the aim of his life that men should have justice and education, and when for any misfortune they needed it — charity. For an unjust judge there was short shrift. The old tree at Versailles under which he used to hear the causes of the poor who appealed to him stood for many centuries the living reminder of Louis' efforts to make the dispensing of justice equal to all men. Voltaire, unsympathetic in so many ways, said of him, «Louis IX appeared to be a prince destined to reform Europe if she could have been reformed, to render France triumphant and civilized and to be in all things a pattern for men. A far-reaching policy was combined with strict justice and he is perhaps the only sovereign who is entitled to this praise; prudent and firm in counsel, intrepid without rashness in his wars, he was as compassionate as if he had always been unhappy. No man could have carried virtue further.» Guizot, the French statesman and historian, so little appealed to by the mediæval, said «The world has seen more profound politicians on the throne, greater generals, men of more mighty and brilliant intellect, princes that have exercised more powerful influence over later generations; but it has never seen such a king as this Saint Louis, never seen a man possessing sovereign power and yet not contracting the vices and passions which attend it, displaying upon the throne in such a high degree every human virtue, purified and ennobled by Christian faith. He was an ideal man, king and Christian, an isolated figure without any peer among his successors or contemporaries.» His reign is the history of France for nearly 50 years (1226–70). He influenced not alone France but the other peoples of his time deeply. He was chosen as the umpire in disputes in foreign countries.

Louis' instructions to his son, so emphatic of justice as the great law among men, his deep interest in education, his foundation of the Sorbonne, his beneficence to the University of Paris, his encouragement of art and architecture, La Sainte Chapelle is his monument, as well as his scholarly patronage of men of letters in friendly intercourse, all stamp him as one of the most broad-minded of men.

Two great Spanish monarchs deserve to be mentioned beside Saint Louis. They are Ferdinand (1200–52), the Saint, king of Castile and Leon, whose mother, Berengaria, was the sister of Blanche of Castile, the mother of Saint Louis. To him is due the collection of translations in the vernacular of the *Forum Judicum* or Code of Visigothic laws, which is one of the oldest specimens of Castillian prose extant and the foundation of Spanish jurisprudence. His son, Alfonso X (1221–84) the Wise, is also known as the astronomer because of the Alfonsine tables, a series of astronomical observations compiled by his direction, but better known as the author of the code *Las Siete Partidas,* the basis of modern Spanish law. Ticknor ('History of Spanish Literature') declared that Alfonso «first made Castilian a national language by causing the Bible to be translated into it and by requiring it to be used in all legal proceedings.» Under these two great monarchs, Spanish literature began its magnificent course, the ballads of the Cid and of Bernardo del Carpio becoming the common property of the people.

Surprisingly enough one phase of political history outside of Europe in the century is as important as anything in Europe. Genghis Khan founded the Mogul or Mongol Empire. He was a Tartar (Tatar) chieftain, by name, Temuchin, who on the death of his father succeeded to the Mongol throne at the age of 13 (1175). The chiefs who owed him allegiance were turbulent and restless, and had been restrained by the iron rule of his father. They refused to submit to a mere boy, but Temuchin's mother had the courage and vigor to repress many of them and keep them to their allegiance until Temuchin showed before long that he could rule them himself. He soon extended his sway over neighboring chiefs and in 1206 proclaimed himself emperor, invaded northern China and securing firm footing within the Great Wall soon conquered most of the country. He then turned westward, defeated the Mohammedans who had beheaded his envoys, overwhelming an immense army of nearly half a million, of whom 160,000 were left dead on the field. Pressing westward he besieged Bokhara, capturing it and Samarcand, and then Merv, all of which were sacked and burned. Astrakan was taken, the Russians defeated and Great Bulgaria ravaged. His troops conquered more of India and most of China, so that this one-time chief of a petty Mongol tribe «lived to see his armies victorious from the China Sea to the banks of the Dnieper; and though the empire which he created ultimately dwindled away in the hands of his degenerate descendants, leaving not a wrack behind, we have in the presence of the Turks in Europe a consequence of his rule, since it was the advance of his armies which drove their Osmanli ancestors from their original home in northern Asia and thus led to their invasion of Bithynia under Othman and finally their advance into Europe under Amurath I.»

Representative government developed during the century parallel with other achievements. Magna Charta was signed in 1215; the concluding sentence of chapter 1 runs: «We have also granted to all free men of our kingdom, for us and for our heirs forever; all the underwritten liberties to be had and held by them and their heirs of us and our heirs forever.» Whatever the original intention, this became eventually a grant to all free Englishmen. In 1257 the Provisions of Oxford under King Henry III established the stated recurrence of the great national council of Parliament. In 1265 the Knights of the Shire and the representatives of the townspeople who formed later the House of Commons were admitted to Parliament, while those personally summoned to attend by the king from the great nobles formed the House of Lords. Beginning with 1295, under Edward I, the attendance of the town members became regular, making Parliament really representative of the country. In the meantime, Bracton's 'Digest of the English Common Law' (1282) secured the legal rights of Englishmen of all classes, and forms the basis of law down to our own time in all English-speaking countries.

Nothing of all the accomplishment of the century probably possesses livelier interest for our commercial age than their organization of business in spite of what must have seemed insuperable difficulties to less enterprising times. Trade combinations and municipal affiliations as well as commerce facilities among distant, different peoples were rendered possible and even easy. Some even of the most modern developments of international intercourse were anticipated. Miss Zimmern ('The Hanseatic League,' Stories of the Nations Series) said: «There is scarcely a more remarkable chapter in history than that which deals with the trading alliance or association known as the Hanseatic League. The league has long since passed away, having served its time and fulfilled its purpose. The needs and circumstances of mankind have changed and new methods and new instruments have been devised for carrying on the commerce of the world. Yet, if the league has disappeared, the beneficial results of its action survive to Europe, though they have become so completely a part of our daily life that we accept them as matters of course, and do not stop to inquire into their origin.»

The condition of the great mass of people as the result of the growth of genuine democracy in this period is particularly interesting for our time. Good authorities have declared it the happiest century of human existence. More men and women than probably at any other time enjoyed the blessedness of having found their work and that work eminently satisfying, because it represented an interest of the mind or soul rather than the body. Artistic power and the art impulse were never so widespread, and triumphs of arts and crafts work were made even in very small towns. As for those without special talent the manual workers, Thorold Rogers, in his 'Economic Interpretation of History,' says: «On the whole there were none of those extremes of poverty and wealth which have excited the astonishment of philanthropists and the indignation of working men. The age, it is true, had its discontents . . . but of poverty that perishes unheeded, of willingness to do honest work and a lack of opportunity, there was little or none.»

Wages were very low, according to our standards and money values, but the necessaries of life were proportionately cheap, and the ratio between wages and prices is the all-important consideration. The social improvement which marked the 13th century led to the fixing by statute in the time of Edward III in the early 14th century of the minimum wage of four pence a day and set maximum prices for necessaries of life. A pair of hand-made shoes was four pence, a fat goose two and one-half pence, a fat sheep a shilling and two pence, and a stall-fed ox only 24 shillings. Needless to say this ratio between wages and prices secured the workman against want. An act of Parliament in the 14th century names «beef, pork, mutton and veal as the food of the poorer sort.» Holidays were frequent. Besides the Sundays there were some 35 holy days during the year on which no work was done, and Saturday afternoon was free after the vesper hour, 2 P.M., as also the vigils of all first-class feasts. Standish O'Grady declared this abundance of leisure a source of the greatness of the time. Twice in the world's history, in the 5th century B.C. in Greece and the 13th century A.D., men have spent one-third of their time in leisure in preparation for and in celebration of religious mysteries. In both periods they had the time and the energy to create artistic and intellectual monuments which the world will never willingly let die.

PRINCIPAL EVENTS OF THE THIRTEENTH CENTURY.

1202. The Fourth Crusade led by Boniface, Marquis of Montferrat.
1204. Conquest of Normandy. Constantinople is besieged and taken by the French and Venetians. Baldwin, Count of Flanders, elected emperor of the East. Seat of the Greek empire removed to Nicæa.
1206. Genghis Khan, the Mongol emperor, begins his career of conquest, extending his expeditions from China to Bulgaria.
1208. Pope Innocent III lays an interdict on England. The Albigensian Crusade.
1209. The Inquisition instituted at Avignon to check heresy.
1212. Defeat of the Saracens at Tolosa, Spain. Contests between Moors and Christians arouse the spirit of chivalry. Goths divide into three kingdoms, Castile, Aragon and Portugal. The ill-starred Children's Crusade.
1214. The liberties of Oxford University confirmed by papal authority.
1215. General revolt against the king of England. John I of England forced to sign Magna Charta. Rise of trade guilds and labor unions.
1220. Venice becomes independent. Golden period of commerce. Cities of Venice, Genoa and Pisa furnish ships for the Crusades. Architecture, fine arts and the industries flourish throughout western Europe.
1226. Louis IX, afterward known as Saint Louis, ascends the throne of France. Saint Francis of Assisi, founder of the Franciscan Order, dies.
1227. Death of Genghis Khan.
1228. The Fifth Crusade led by King Andrew II.
1230. Teutonic knights establish themselves in Prussia
1231. Saint Elizabeth of Hungary dies.
1236. Tatars invade Russia.
1245. Alexander of Hales, the "Irrefragable Doctor" of English theology, dies.
1248. Saint Louis IX of France leads the Sixth Crusade.
1252. Death of Ferdinand the Saint, king of Castile and Leon.
1253. The Jews are expelled from France.
1257. The Provisions of Oxford formulated.
1260. Michael Palæologus founds a family of distinguished Eastern emperors.
1261. Recovers Constantinople from Western domination.
1262. The Barons' War in England.
1263. Sir John de Baliol founds Baliol College, Oxford.
1264. Vincent of Beauvais, the encyclopedist of the Middle Ages, dies.
1265. Henry III of England reigns. Deputies of the Commons first summoned to Parliament. The kingdom of the Two Sicilies comes under French domination.
1268. The Mongol-Tatars invade China.
1270. The Seventh and last Crusade. Death of Saint Louis of France.
1271. Marco Polo's travels extend the knowledge of the world.
1272. Edward I crowned king of England.
1274. Saint Thomas of Aquinas, "Prince of Scholastics," dies.
1280. Albertus Magnus, the "Doctor Universalis" of German philosophy, dies.
1280. The Mongol-Tatars conquer China, overthrow the Southern Sung dynasty and establish the dynasty of Yuen. Under Kublai Khan, grandson of Genghis, the grand canal of China is dug.
1282. The Sicilian Vespers. Massacre of the French in Sicily. Conquest of Wales by the English.
1284. Death of Alfonso X, the Wise, of Spain.
1285. Philip IV reigns in France.
1290. The Jews are expelled from England.
1294. Roger Bacon, the "Doctor Admirabilis" of English science, dies.
1295. The English Parliament is organized.
1297. Edward I takes the coronation chair and the records of Scotland to London.
1299. Scotch defeat at Falkirk. The Ottoman or Turkish Empire founded.

JAMES J. WALSH,
Author of 'The Thirteenth Greatest of Centuries.'

THIRTY-NINE ARTICLES, The. See ARTICLES, THE THIRTY-NINE.

THIRTY TYRANTS, (1) a body of Athenian aristocrats, headed by Critias and Theramenes, who undertook to administer the affairs of Athens at the close of the Peloponnesian War, 404 B.C. They put to death their opponents, and set a Spartan garrison in the Acropolis. Later Thrasybulus led the exiled citizens against Athens, defeated the forces of the Thirty, and slew Critias. Democratic government was restored and soon afterward recognized by Sparta. (2) The Thirty Tyrants of Rome were a band of revolutionists who tried to secure the Imperial power during the reigns of Valerian and Gallienus (qq. v.).

THIRTY YEARS' WAR, so called because it lasted from 1618 to 1648, was at first a struggle between Protestants and Roman Catholics, north Germany supporting the former, and southern Germany, with Austria at its head, the latter cause. It gave the Swedes an opportunity to extend their dominion south of the Baltic, it reduced the resources and weakened the power of Austria, and it gained for the northern states of Germany the breathing space needed to develop independent existence. Few wars, however, have been more calamitous in their general effect on the mass of the people and the happiness and progress of mankind. Apart from the horrors which attended the capture of Magdeburg, and other barbarous scenes of the struggle, it reduced the peasantry and most of the townspeople to abject misery; it may be said to have effaced for a time literature and art in Germany, and it magnified the system of petty principalities, since partly effaced as a result of the Napoleonic wars, but still a powerful obstacle in the way of complete German progress.

On the one side were Austria, nearly all the Roman Catholic princes of Germany, and Spain; on the other side were, at different times, the Protestant powers and France. The occasion of this war is to be found in the fact that Germany had been distracted ever since the Reformation by the mutual jealousy of Roman Catholics, Lutherans and Calvinists, which led the Protestant princes to form the Evangelical Union in 1608, against which the Roman Catholic League was formed the following year. Certain concessions had been made to the Protestants of Bohemia by the Emperor Rudolph II (1609), but these were withdrawn by his successor Matthias in 1614, and four years afterward the Bohemian Protestants were in rebellion. Thus began the first part of the long war, the part that is known as the Bohemian War. The Protestant Bohemians were led by the Count of Thurn, and the Union sent an auxiliary corps into Bohemia, under the command of the brave Ernest, count of Mansfeld. Their leaders drove the imperial troops from Bohemia, invaded the archduchy of Austria, and advanced to the gates of Vienna, but unfavorable weather and want of resources compelled the invaders to retreat. Soon after, Ferdinand, with the title of Ferdinand II, was chosen emperor (28 Aug. 1619). He had borne the title of king of Bohemia since the resignation of his cousin Matthias in 1617. The Bohemians, knowing his hostility to Protestantism, had already declared his title to the Bohemian crown void, and offered it to the elector palatine, Frederick V, the head of the Protestant Union, and husband of Elizabeth, daughter of James I of England. Frederick accepted the crown, but he was ill fitted to cope with the difficulties before him, and the great victory of the troops of the League (8 Nov. 1620), under Maximilian of Bavaria, on the Weissenberg (White Mountain), near Prague, which was followed by the flight of the new king, put an end to the Bohemian rebellion, and crushed the Protestant cause in that quarter. Frederick was put under the ban of the empire, his territory was taken from him and bestowed on Maximilian of Bavaria.

Ferdinand had now a favorable opportunity of concluding a peace on moderate terms. But his unsparing treatment of the conquered, and the reactionary proceedings against the Protestants generally, all of whom had been expelled from Bohemia, at last roused the determined opposition of the Protestant princes, who sought and obtained foreign assistance. Aided by supplies of money from England, and by a body of troops from Holland, Count Mansfeld, Christian of Brunswick, and the Margrave of Baden again took the field, and they were joined by Christian IV of Denmark. Mansfeld was defeated by the imperial general Wallenstein at Dessau (25 April 1626), and after a difficult march through Hungary to the lower Danube, died in Bosnia on 30 November in the same year. Meanwhile Christian of Brunswick had also died, and Christian of Denmark had been defeated by Tilly at Lutter am Barenberg (27 Aug. 1626) and compelled to withdraw to his own territory. The allies of Denmark, the dukes of Mecklenburg, were now obliged to flee from their territories, which were taken possession by Wallenstein with the consent of the emperor. Holstein, Schleswig and Jutland also soon fell into the hands of the imperial troops. Pomerania and Brandenburg had detachments forced upon them by Wallenstein. The power of the emperor extended to the Baltic, and to secure this power an attempt was made to seize all the important towns on the coast. Straslund alone made serious resistance, and during a ten-weeks' siege, which was carried on with furious energy (May to July 1628), it baffled all the attacks of Wallenstein, who was at last forced to retreat with great loss. This check thwarted the plans of Wallenstein, and led to a short interruption of the war. In the peace of Lübeck (12 May 1629) Christian of Denmark received back all the territories belonging to him that had been occupied and devastated by the imperial troops, on the condition of promising to interfere no more in the affairs of Germany.

Austria was once more victorious; but the greater its victory the more complete was to be the triumph of the Roman Catholic Church. With this object the emperor issued the Edict of Restitution, in virtue of which all the ecclesiastical foundations and other church property that had been confiscated for the behoof of Protestants since the religious peace of Passau (1552) were to be restored to the Roman Church, and the Calvinists were to be excluded from the benefits of that peace. This ordinance, which threatened to take a large number of bishoprics, and almost all the abbeys and other ecclesiastical foundations of north Germany, out of the hands of those who then held them, filled all Protestant Germany with alarm and prolonged the war. Many princes and towns refused to obey it, and the emperor was obliged, in order to give effect to it, to keep his forces in the field. But these forces did not long remain under the command of Wallenstein. At a meeting of the Electoral College of the empire in August 1630, Ferdinand found it expedient to yield to the general demand for his deposition, and the supreme command of the imperial armies was given to Tilly, who thereupon marched against Magdeburg, which had refused to carry out the edict.

In the meantime a new belligerent appeared on the scene, one whose exploits form the most interesting episode of the whole war. This was Gustavus Adolphus, king of Sweden, who landed on the coast of Pomerania on 24 June 1630. The inducements which led him to mix himself up with the struggle were the desire of protecting Protestantism in Germany, that of establishing the power of Sweden on the coast of the Baltic and that of checking the advance of the power of Austria in north Germany. For this last reason he had the secret support of the French minister Richelieu, who was jealous of the growing power of the house of Hapsburg. Gustavus Adolphus was generally hailed by the inhabitants of the Protestant states of Germany as their deliverer, but the Protestant princes did not extend to him so eager a welcome. Fearing the revenge of the emperor they for the most part refused his offered alliance, and at the diet of Leipzig resolved to maintain a neutral attitude. The old Duke of Pomerania, whose territory had been terribly devastated by the imperial troops, had at once opened his land to him, but the electors of Brandenburg and Saxony refused him a passage through their territories, and while the time was consumed in negotiations the town of Magdeburg, after repeated assaults, was taken and destroyed (20 May 1631). Tilly now threatened Saxony, and the elector, John George I, hastened to conclude, in his own defense, the alliance which he refused in the interests of the Protestant cause. On 17 September (O. S. 7 September) the forces of Tilly and Gustavus Adolphus met at Breitenfeld, close to Leipzig, when the former were completely defeated. Tilly retreated to the south while the Swedish king advanced to the Main and Rhine. Before the end of winter the latter had made himself master of the bishopric of Würzburg and the greater part of the Lower Palatinate, as well as of the towns on the Rhine. In the spring of 1632 he marched by way of Nuremberg to the

Lech, on the banks of which Tilly had taken up a strong position. On 15 April 1632 this position was forced by the Swedes and Tilly was mortally wounded during the engagement. After placing a garrison in Augsburg, Gustavus Adolphus, accompanied by the former Elector Palatine, Frederic V, advanced as far as Munich, the Bavarian capital. Meantime the emperor had in his distress again turned to Wallenstein and induced him by entreaties and great concessions to undertake to levy and command a new army. After a successful operation against the Saxons, Wallenstein joined the Bavarian troops in Bohemia and marched with them into Franconia, where the Swedes had posted themselves strongly not far from Nuremberg. On arriving there Wallenstein took up another strong position in the neighborhood and fortified a camp. Here the two armies lay for months facing each other without coming to a pitched battle; until at last Gustavus found that the resources of the neighborhood were exhausted and resolved to venture upon an attack on the enemy's camp. But in spite of the bravery of the assailants, the attack, again and again renewed, was always repulsed. Gustavus Adolphus was obliged to give up the hope of success in his attempt and soon after he led his troops into Saxony. Thither Wallenstein followed him, and on 16 Nov. (O. S. 6 Nov.) 1632, a battle was fought at Lützen, near Leipzig, in which Wallenstein was defeated, but in which the victorious Swedes lost their king and leader.

After the death of Gustavus Adolphus the direction of the war was assumed by the Swedish Chancellor Axel Oxenstierna, who, in the first place, got the Protestant princes and towns of the Franconian, Swabian and the two Rhenish circles of the Germanic empire to promise in the Heilbronn Convention to uphold the Swedes until the victory of the Protestant cause should be secure. The principal generals who acted under him were Bernhard von Weimar and the Swedish general Horn. France furnished supplies of money. Bavaria was laid waste by the Swedes, who since the death of their king carried on the war in as barbarous a manner as the Imperial troops, who were now quartered in Silesia. In this province and in Bohemia Wallenstein lingered without exhibiting any of the energy that was demanded of him by the imperial court. This slackness, together with other circumstances, caused him to be suspected of entering into treasonable negotiations with the enemy, and Ferdinand ultimately deposed him and placed him under the ban of the empire, in consequence of which he was murdered by some of his own officers (25 Feb. 1634). After this the imperial army moved into Bavaria, and on 6 Sept. 1634, gained a complete victory over Bernhard von Weimar at Nördlingen. Several German princes, the principal of whom was the Elector of Saxony, who had never been well inclined to the Swedes, now thought it convenient to conclude separate peaces with the emperor, and the people generally began to cherish the hope of soon seeing the termination of the war. The separate peace with Saxony, the peace of Prague, was concluded 30 May 1635, and in it Saxony received the whole of Lusatia as a hereditary possession, while the emperor virtually gave up the edict of restitution.

The hopes raised among the people of Germany by this and other separate peaces were far from being confirmed. Germany itself was almost unanimous in desiring peace, but the Swedes thought it to their interest to continue the war in order not to lose the advantages they had gained, and France now determined to take a more active part in the war, with the view of abasing the house of Hapsburg and extending the French frontier to the Rhine. Richelieu promised to the Swedes important aid in money and troops, and the war was renewed with greater vigor than had been shown since the death of Gustavus Adolphus. The Swedish general Banér conquered and rendered desolate Saxony and Thuringia (1636); Bernhard von Weimar took Rheinfelden, Freiburg and Breisach (1638), and formed the scheme of creating for himself an independent principality on both banks of the Rhine, but was stopped short in his career by death in July 1639. In the midst of these events the emperor had died (February 1637), and had been followed by his son Ferdinand III, a man of milder and less energetic temper than his father, but as firmly attached to the Catholic faith, and equally inclined to force it on his subjects.

In the autumn of 1640 the new emperor assembled a diet at Ratisbon to deliberate over the best method of conducting the war, and while this council was sitting, Banér, who had for the last few years been constantly engaged in the east of Germany, conceived the audacious plan of leaving his winter quarters and taking the whole council, along with the emperor, prisoners (January 1641). A sudden thaw prevented the execution of this scheme by melting the ice on which he had hoped to cross the rivers. Banér died during the retreat. He was succeeded in the command of the Swedish army by Torstenson, the ablest of the generals who proceeded from the school of Gustavus Adolphus. Although generally confined by the gout to a sedan chair, he astonished the world by the rapidity of his movements. He vanquished the imperial armies near Leipzig (Breitenfeld 1642), advanced into Moravia with the intention of penetrating into Austria and attacking the emperor in his capital, then suddenly appeared in Schleswig and Holstein and put to flight Christian IV of Denmark, who had lately allied himself with the emperor and brought an army into the field (1643). Later (August 1645), Wrangel, another Swedish general, forced Christian to accept a disadvantageous peace. After his victory over Christian IV, Torstenson again turned south, and having destroyed two imperial armies, one under Gallas and the other under Hatzfeld and Götz, in conjunction with Rakoczy, prince of Transylvania, once more threatened Vienna (1645). But the emperor was again delivered from the danger. The withdrawal of Rakoczy obliged Torstenson to give up his design; and in the following year, worn out by disease, he resigned his command, which was taken up by Wrangel. Meantime the French had been operating on the Rhine and in the west of Germany. After the death of Bernhard von Weimar they had taken his army into their pay. At the head of this army Guébriant obtained several successes, but toward the close of 1643 suffered a severe defeat in which his army was in great part destroyed. He himself was mortally wounded soon after. In the following year neither of the French generals Enghien and Turenne was able to gain any considerable advantage; but on 3 Aug. 1645, the Austrian general Mercy was defeated at Allersheim, near Nördlingen, after which the junction of the French and Swedes was inevitable. Late in the summer of 1646 their united armies advanced through Swabia and Bavaria, and in the armistice of Ulm (March 1647) compelled Maximilian of Bavaria to fall away from the emperor. In the following year further successes were gained and Wrangel was on the point of uniting his forces with those of the other Swedish general Königsmark who had penetrated into Bohemia, when the news reached the armies that the Peace of Westphalia, which had been negotiating for five years at Münster and Osnabrück, was concluded. By a singular coincidence it happened that the last blow of the war was struck at the place where the war originated, Prague. Königsmark had taken one part of the town and was preparing to attack the other when he was stopped by the news of peace. Bibliography.—'Cambridge Modern History' (Vol. IV, New York 1906); Gardinier, S. R., 'Thirty Years' War' (London 1874); Ward, A. W., 'Thirty Years' War' (1869) and German works by Barthold, Gindely, Schiller and others.

THISBE. See PYRAMUS AND THISBE.

THISTLE, a composite plant of the genera *Carduus, Cirsium, Centaurea, Onopordon* or *Sonchus.* Other related plants are the golden thistle or Spanish oyster-plant (*Scolymus hispanicus*) whose roots are used as a vegetable like salsify and parsnip, which they resemble somewhat closely in flavor; globe-thistles (*Echinops*), often planted in shrubberies and herbaceous borders for their striking effects; blessed thistle (*Cnicus benedictus*) a hardy annual herb useful for rockeries and wild gardens, but commonly regarded as a weed in the Mediterranean region where it is native, and in California where it has escaped cultivation; and the milk-thistle, also called blessed or holy thistle (see SILYBUM), often grown in European gardens for its edible roots, leaves and heads and also for its ornamental qualities. Several plants of other families have sometimes been called thistle from their apparent resemblance to true thistles. The best known of these are probably the blue thistle (*Echium vulgare*) of the *Boraginaceæ,* and the fuller's or clothier's teasel (*Dipsacus fullonum*) and its few related species of the family *Dipsacaceæ.*

Among the best known genera the following species are probably most widely recognized. The Scotch or cotton thistle (*Onopordon acanthium*) is a biennial occasionally grown in America and sometimes seen wild in the Eastern States. It has cottony white spiny foliage and large solitary terminal heads of pale purple flowers. The plants are often six feet tall and are planted in front of dark colored shrubbery. They seem unlikely to prove troublesome as weeds in America. Some of its other popular names are Queen Mary's, silver, Argentine, oat, asses' and down thistle. The Scottish emblem seems more likely to be really the stemless thistle (*Cirsium acaule*) which is common in Scotland. The so-called Canada thistle (*Cirsium arvense*) is a native of Europe. It has become a troublesome weed in fields where methods of cultivation and rotation are faulty, spreading both by its seeds and its perennial creeping root-stocks, every fragment of which is capable of propagating a new plant. Prevention of leaf formation by persistent cultivation is a sure remedy as well as a safeguard. The plant is a slender herb about three feet tall and has numerous small purplish pink flower heads. The bull thistle (*C. lanceolatum*) and the yellow thistle (*C. horridulum*) are also well-known relatives found along roadsides and in fields, especially pastures. The pasture thistle (*Cirsium odoratum*) is found in similar places. The star thistle (*Centaurea calcitrapa,* etc.) bears a resemblance to the blessed thistle. Several related species, notably the corn flower, blue bottle, bachelor's button or bluet (*C. cyanus*) and the dusty miller (*C. cineraria*) are popular garden plants. Three species of sow thistles — the common (*Sonchus oleraceus*), the field (*S. arvensis*) and the spiny leaved (*S. asper*) — are well-known weeds in the United States and the Carline thistle (*Carlina vulgaris*) plays a similar rôle upon poor soils in Europe. The last was so named because tradition says that Charlemagne used its roots medicinally.

THISTLE, Order of the. See ORDERS, ROYAL.

THISTLE-BIRD, the American goldfinch (q.v.).

THISTLE CROWN, the name of a gold coin of James VI of Scotland, of the value of 97.3 cents. It bore on the obverse a rose and on the reverse a thistle, both crowned.

THISTLEWOOD, Arthur, English conspirator: b. Tupholm, Lincolnshire, 1770; d. London, 1 May 1820. He is said to have imbibed anarchistic doctrines from the writings of Paine and from a visit to France before the fall of Robespierre. He entered the army in 1798 and rose to the rank of a lieutenant. After various misfortunes, both natural and the result of gambling and dissipation, he became an active member of the society formed by Thomas Spence, which aimed at revolutionizing all social institutions. He attempted to organize a revolution in 1816 which failed through the efforts of informers, and in 1817 was indicted for treason, but escaped conviction. In 1818–19 he suffered a year's imprisonment for a threatened breach of the peace. After his release he became the principal agent in the memorable Cato Street conspiracy (so called from the meeting-place of the conspirators in London), the object of which was to murder several of the members of the administration at a cabinet dinner, attack either Coutts's or Child's bank, seize the Tower and Mansion House and set up a provisional government. The day selected for carrying out the plot was that fixed for the funeral of George III at Windsor, when all the military would be out of London to take part in the funeral procession. This absurd scheme was betrayed by a man who was ostensibly one of the conspirators and the deepest in Thistlewood's confidence. The projectors were arrested just as they were about to proceed to the execution of their purpose 23 Feb. 1820. Being tried and condemned as a traitor, Thistlewood, with four of his coadjutors, was hanged and decapitated.

THISTLEWOOD CONSPIRACY. See CATO STREET CONSPIRACY; THISTLEWOOD, ARTHUR.

THIVÆ, thē'vē. See THEBES, GREECE.

THOBURN, Isabella, American missionary and educator: b. near Saint Clairsville, Ohio, 29 March 1840; d. Lucknow, India, 1 Sept. 1901. She came of Scotch-Irish parentage. She was educated in the Wheeling Female Seminary, supplemented by a year in the study of art at the Cincinnati Academy of Design. After teaching in the public schools for several years, she spent a year as an instructor in a private school at New Castle, Pa., and, in 1866, became preceptress of the Western Reserve Seminary at West Farmington, Ohio. In 1869, at the organization of the Woman's Foreign Missionary Society of the Methodist Episcopal Church, she was selected as its first missionary, being assigned to work in India, whither her brother, James M. Thoburn (q.v.), had gone 10 years before. In April 1870 she organized a school for native girls at Lucknow with but six pupils and herself as the only teacher. She also engaged in evangelistic, Sunday school and zenana work. The grade of the school thus established was gradually raised as its attendance increased until a full high school course was offered. In response to a demand for still more advanced courses of instruction, classes in the lower collegiate grades were offered in 1887 and, in 1895, after having complied with the rigid requirements of the British Indian government, it was granted a charter as the Lucknow Woman's College. Climatic conditions, which seriously impaired her health, necessitated several extended furloughs, the years 1880–82, 1886–90 and 1899–1900 being spent in America, though they were years filled with activity in behalf of the cause to which her life had been devoted. The name of the Lucknow Woman's College was subsequently changed to that of the Isabella Thoburn Woman's College. Consult Thoburn, Bishop J. M., 'Life of Isabella Thoburn.'

THOBURN, James Mills, American Methodist Episcopal bishop: b. Saint Clairsville, Ohio, 7 March 1836. He was graduated at Allegheny College, Meadville, Pa., in 1857, and soon after entered the ministry. In 1859 he was sent as a missionary to India and until 1908, when he retired, was identified with work in that region. He was elected bishop of India and Malaysia in 1888 and was for six years the editor of the *Indian Witness*. His writings include 'Missionary Addresses' (1887); 'India and Malaysia' (1893); 'The Deaconess and Her Vocation' (1893); 'Christless Nations' (1895); 'The Church of Pentecost' (1901); 'Life of Isabella Thoburn' (1903) and 'The Christian Conquest of India.'

THOBURN, Joseph, American soldier: b. Carrickfergus, Ireland, 29 April 1825; d. Cedar Creek, 19 Oct. 1864. In August following his parents emigrated to America, settling on a farm in Belmont County, Ohio. His education was obtained in the primitive rural schools of the period, supplemented by diligent private study. He became a teacher in the public schools at the age of 17 and later, having advanced to the principalship of a village school, he began the study of medicine. He was graduated from Starling Medical College, Columbus, Ohio, in 1850. After a term as an interne in hospital service, he located for the practice of his profession at Wheelling, (West) Va. At the outbreak of the Civil War he was commissioned surgeon of the first regiment raised in Virginia for the Union service. At the battle of Philippi, its colonel (Benjamin F. Kelley) was seriously wounded and, the other field officers not being available for duty, the command of the regiment devolved upon the surgeon, who continued to act in that capacity until the expiration of its 100-day term of service. When the regiment reenlisted for three years he was commissioned as its colonel. After a year of service as a regimental commander, he was assigned to the command of the Fourth Brigade, Second Division, Third Army Corps, Army of the Potomac, but had to be given an extended leave on account of a severe wound. He was with his regiment throughout the spring and summer of 1862, later being transferred to the Department of West Virginia, where he was again assigned to the command of a brigade. In May 1864 he took part in the disastrous Lynchburg raid. On 22 July 1864 he was assigned to the command of the First Division of the Department of the Kanawha (later known as the Army of West Virginia and also as the Eighth Army Corps), in which capacity he participated in most of the active movements of the Shenandoah campaign, including the battles of Kernstown, Opequan and Fisher's Hill. In the disposition of the forces at Cedar Creek by Gen. Horatio G. Wright (in the absence of General Sheridan) Colonel Thoburn's division was placed in a peculiarly exposed position, over his protest. In the surprise attack with which the battle of Cedar Creek began (19 Oct. 1864), his command was driven from its camp in utter rout at dawn and, while striving to rally his men for defensive action, he fell mortally wounded. A commission as brigadier-general of volunteers was made out to him the day of his death. His remains were buried with full military honors at Wheeling. Consult 'Official Records of the Union and Confederate Armies' (Series I, Vols. 12, 25, 27, 29, 33, 37, 43, 51) and Pond, George E., 'Personal Memoirs of General Philip H. Sheridan' and 'The Shenandoah Campaign.'

THOBURN, Joseph Bradfield, American writer: b. Bellaire, Ohio, 8 Aug. 1866. In 1871 his parents removed to Marion County, Kan., where he was reared on a farm and attended the public schools. He learned the printer's trade and did some newspaper work, after which he entered the Kansas Agricultural College from which he was graduated in 1893. In 1899 he removed to Oklahoma City, where he engaged in newspaper work. He served as secretary of the Oklahoma Territorial Board of Agriculture from December 1902 until July 1905. Since 1907 he has devoted himself largely to the work of research and writing along the lines of local and western history.

From 1913 to 1917 he was connected with the University of Oklahoma as a specialist in research, field-work and collections in local history and anthropology. During this time he did considerable work in the way of excavating prehistoric earth-works, cave dwellings, tumuli, etc., in Oklahoma. In the course of these investigations he secured positive evidence that the natural mounds, so called, which are so abundant in the region immediately west of the lower half of the valley of the Mississippi, the origin of which had long been a subject of dispute among scientists, are of human origin, each tumulus, so far as examined, proving to be the ruin of a timber-framed, dome-shaped, earth-covered human habitation. He has been in the service of the Oklahoma Historical Society since July 1917, being engaged in research, field collections and editorial work. He is the author of a comprehensive history of Oklahoma, published in 1916.

THOLEN, tō'lĕn, Netherlands, an island in the province of Zeeland, north of the Ooster Schelde and 21 miles northwest of Antwerp, contains 47 square miles. It is protected by dikes. The soil is productive and the principal products are wheat, rye, barley, oats, flax, madder, beans and potatoes. Tholen is also the name of the chief town. Pop. 3,254.

THOM, tŏm, **James,** Scottish sculptor: b. Ayrshire, Scotland, 1799; d. New York, 17 April 1850. He was by trade a stonemason and suddenly leaped into notice by his group 'Tam o' Shanter and Souter Johnny,' cut in the sandstone on which he was accustomed to work. This group now forms part of the Burns monument at Doon, near Ayr. It was first exhibited in Edinburgh (1828) and by its success the sculptor was led to move to London, but in 1837 sailed for the United States, where his genius found at last a liberal recognition. Among his best known works is 'Old Mortality' now in Laurel Hill Cemetery, Philadelphia, of which he was induced to make many replicas.

THOMA, tō'ma, **Ludwig,** German satiric novelist and dramatist: b. Oberammergau, 21 Jan. 1867. He attended gymnasia at Munich and Landshut, the Forestry School at Aschaffenburg, and, in order to study law, the universities of Munich and Erlangen, thus obtaining his entire education in Bavaria. For a short time he practised law at Dachau, later at Munich (1897–98), soon relinquishing this career for that of literature. The general tone of his literary work is well indicated by the fact that he has been connected with the humorous and oppositional weekly *Simplicissimus* (q.v.) at Munich, as editor, since 1899. *März,* a more serious periodical (bi-monthly), has also for a time been under his editorship. The cartoons and quips of *Simplicissimus* were one of the mainstays of the German liberals in their fight with the Imperial Government, and it was one of the great disappointments of 1914 to behold the paper assume a more and more chauvinistic attitude after the events of August in that year, supporting the predatory and imperialistic policy of the German government where resistance would have been the proper attitude of a liberal organ. Thoma's own policy presented a similar change: caught in the great wave of chauvinism which the government had efficiently launched, he took part in the patriotic shouting, and incidentally engaged in polemic correspondence with a number of American writers, including George Haven Putnam, who published some of the interchanges of views in American newspapers. But Thoma is too critical and subtle a man to become a chauvinist of the worst type. In his literary work his opposition is directed chiefly against petty social prejudices and, in the political field, to the Roman Catholic Church; in the latter respect he resembles Anzengruber (q.v.) and Rosegger (q.v.), both of whom, like Thoma, bitterly attack the abuses of the petty clergy, not from a Protestant standpoint, but from the usual hostile position of the laity in Catholic countries. The most notable satires on the clergy are the short story 'Der heilige Hies' (Munich 1904), and the bitter novel 'Andreas Vöst' (ib. 1905, 13th ed., 1910). His three best plays, which are very popular on the German stage, are 'Die Lokalbahn,' a comedy (1902); 'Moral,' comedy (1909), and 'Magdalena,' a popular tragedy ('Volksstück,' 1912). Each has as its theme one of the deficiencies of provincial life. 'Die Lokalbahn' pictures the officious bustle of gossiping town officials, who never achieve any results; 'Moral' reveals the low morality of a group of persons who have joined a society for moral uplift in order to be the more effectively cloaked from each other; 'Magdalena' is the story of a girl's gradual shifting from a love-life that is frank and unselfish, and which, therefore, meets with no disapproval from the villagers, to one that is governed by considerations of money, thus causing her ostracism and death. No man has better depicted the life of the small peasant and country townsman in Bavaria than has Thoma.

Other works are 'Agricola' (1897); 'Assessor Karlchen' (1900); 'Witwen' and 'Die Medaille,' comedies (1901); 'Hochzeit,' short stories (1901); 'Grobheiten,' poems (1901); 'Die Wilderer,' short story (1903); 'Lausbubengeschichten,' burlesques of child life (1904; 25th 1,000, 1907); 'Peter Schlemihl' (1906); 'Tanta Frieda' (like 'Lausbubengeschichten,' 1906; 30th ed., 1910); 'Kleinstadtgeschichten' (1908); 'Erster Klasse,' comedy (1910); Lottchens Geburtstag,' a comedy (1911); 'Der Wittiber,' a novel (1911); 'Josef Filsers Briefwechsel,' a satire (1912); 'Das Säuglingsheim,' burlesque (1913). In the 'German Classics' (Vol. XIX, New York 1914), appears a translation of 'Der heilige Hies' (Matt the Holy).

JACOB WITTMER HARTMANN.

THOMAS, Saint, also called **DIDYMUS** (*Tomas* being the Aramaic; *Didymus,* the Greek word signifying "twin"), one of the Twelve Apostles known as THE DOUBTER. He is said to have been a native of Antioch, the twin brother of a sister Lysias, children of Diophanes and Rhoa. Eusebius implies that he was a stepbrother of Jesus and that his real name was Judas. The scene in the Gospel, in which the doubts were at last dissipated, that Thomas had expressed with great vehemence as to the fact of the resurrection, is the chief of the three occasions on which he is prominent (consult John xx, 24–29; Luke xxiv, 36–49). After the crucifixion of Christ it fell to the lot of Saint Thomas to proselytize India, and tradition relates with great circumstantiality that he hesitated to travel there until Jesus appeared to him in a vision and ordered him to go to Gondophares, the Indo-Parthian King, who ruled over the Kabul Valley and the Punjab, and to build him a palace. Saint Thomas accordingly went to India, and converted and baptized the King Gundaphoras or Gondophares whose name is known to archæologists through many inscriptions and coins as reigning from A.D. 21 to 52 at Peshawar on the Indus. Later traditions state that Thomas went farther south and east than the Punjab; founded the Church of the Christians of Saint Thomas in Malabar, and was martyred on Mount Saint Thomas near Madras. (See CHRISTIANS OF SAINT THOMAS). In Ceylon, Saint Thomas shares with Buddha the honor of the footprint on Adam's Peak, reputed as left on his ascension into heaven. His remains were transferred to Edessa where Chrysostom mentions his grave as one of the four genuine tombs of the apostles, the other three being those of Peter, Paul and John. An apocryphal, 'Gospel of Thomas,' is published in Tischendorf's 'Evangelia Apocrypha.' In his 'Zoological Mythology' (1872), Gubernatis states that in the Middle Ages the Germans of Westphalia made the ass the symbol of Thomas the incredulous apostle to apply to all unbelievers and for a long time, even among German youth, the boy who was last to enter school on Saint 'Thomas' day was called the "ass Thomas." See APOCRYPHA.

THOMAS, Albert Ellsworth, American dramatist: b. Chester, Mass., 18 Sept. 1872. He was graduated at Brown University in 1894, and took his A.M. degree in 1895, becoming a newspaper writer directly afterward. He was employed on leading New York papers, including the *Tribune, Post, Times* and *Sun* between the years 1895 and 1909, when he became a dramatic writer and also published a novel 'Cynthia's Rebellion' (1904). His plays include 'Her Husband's Wife' (1910); 'The Divorce Fund' (1911); 'Little Boy Blue' (1911); 'The Big Idea' (1914), etc.

THOMAS, tō-mä, **Ambroise Charles Louis,** French musical composer: b. Metz, 5 Aug. 1811; d. Paris, 12 Feb. 1896. He studied in the Paris Conservatoire, and in 1832 gained the Grand Prix de Rome, which enabled him to continue his studies in Italy. Returning to France he began to write for the Opéra Comique, his first opera being 'La double Echelle' (1837). Among his early operas may be cited also 'Betty' (1846); 'Le Caïd' (1849), and opera bouffe; and 'Le Roman d' Elvire' (1860). He is best remembered, however, by the more serious works of his later years, 'Mignon' (1866); 'Hamlet' (1868), and 'Françoise de Rimini' (1882). He was appointed professor of composition at the Paris Conservatoire in 1852, and in 1871 succeeded Auber as director. His non-operatic works include a 'Messe Solennelle' (1857), a 'Marche Religieuse' (1865), cantatas, and chamber music.

THOMAS AQUINAS. See AQUINAS, THOMAS.

THOMAS, Arthur Goring, English composer: b. Ralton Park, Sussex, 20 Nov. 1850; d, 20 March 1892. He studied at Haileybury College and his musical education was received at Paris, and at the Royal Academy of Music. His opera, 'The Light of the Harem,' was given with acceptance while he was still a student at the academy. In 1883 his second opera 'Esmeralda' was produced at Drury Lane Theatre and was warmly received. In 1885 followed 'Nadeshda' and 'The Golden Web,' the latter being completed by S. P. Waddington and produced at Liverpool in 1893. Besides his operas he composed 'The Sun Worshippers,' a choral ode, 'Out of the Deep,' and 'The Swan and the Skylark,' both cantatas, the latter one being finished by Sir C. V. Stanford. He is commemorated by the Goring Thomas scholarship at the Royal Academy of Music.

THOMAS, Augustus, American playwright: b. Saint Louis, Mo., 8 Jan. 1859. He was a special writer and illustrator on Saint Louis, Kansas City and New York newspapers, and became editor and proprietor of the Kansas City *Mirror* in 1889. He soon left the field of journalism and became a playwright. He is the author of the popular dramas, 'Arizona,' 'In Mizzoura,' 'The Burglar,' 'The Man Upstairs,' 'On the Quiet,' 'The Earl of Pawtucket,' 'The Other Girl,' 'Mrs. Leffingwell's Boots,' 'The Education of Mr. Pipp,' 'Jim Delancey,' 'The Embassy Ball,' 'The Witching Hour,' 'The Harvest Moon,' 'As a Man Thinks,' 'Indian Summer,' 'That Overcoat,' 'The Hoosier Doctor,' 'The Rio Grande,' 'The Copperhead,' etc. He is a member of the American Academy of Arts and Letters and of the National Institute of Arts and Letters, of which he became president in 1914, and from which he received a gold medal for his services to the drama. In 1914 he received the degree of A.M. from Williams College.

THOMAS, Becket. See BECKET, THOMAS.

THOMAS, Calvin, American college professor: b. near Lapeer, Mich., 28 Oct. 1854; d. New York, 4 Nov. 1919. He was graduated at the University of Michigan in 1874, taking his A.B. degree the same year and the degree of LL.D. in 1904. He taught Latin and Greek at the Grand Rapids High School for a while, after which he studied philology at Leipzig in 1877–78. Following this course he devoted himself to the teaching of German, and was professor of that language at Columbia University. He edited a number of the standard German classics for school and college use and wrote extensively on philological subjects for educational and literary publications, besides assisting in the compilation of the New Standard Dictionary. In 1909 he edited an 'Anthology of German literature.'

THOMAS, Charles Spaulding, American lawyer and politician: b. Darien, Ga., Dec. 6, 1849. He removed his family to Michigan in his youth, and was educated in the State university, taking his LL.D. there 1871. He practised law in Colorado, and was chairman of the Democratic national convention at Kansas in 1900. From 1899–1901 he was governor of Colorado, and in 1913 was chosen United States Senator to fill the unexpired term of Charles J. Hughes, deceased. He was reelected for the term 1915–21.

THOMAS, Cyrus, American archæologist and entomologist: b. Kingsport, Tenn., 27 July 1825; d. 1910. He was admitted to the bar in

1851 and practised law for several years, finally entering the Lutheran ministry in 1864. He was naturalist on the United States Geological Survey 1869–74, and professor of natural sciences in the Southern Illinois Normal University 1874–77. He was State entomologist of Illinois 1875–82, and in 1882 he became ethnologist in the United States bureau of ethnology in charge of mound explorations. Of special interest in this latter line are his 'Study of the Manuscript Troano' (1882); 'Notes on Certain Maya and Mexican Manuscripts' (1884); 'Mound Exploration' (1888); 'Prehistoric Works East of the Rocky Mountains'; 'Indians of North America in Historic Times' (with W. J. McGee 1903).

THOMAS, Edith Matilda, American poet: b. Chatham, Ohio, 12 Aug. 1854. She was educated at the State Normal School, Geneva, Ohio. Much of her verse is distinctly above the average, displaying not only very subtle feeling, but great delicacy of expression. She contributed to many periodicals and published in book form 'A New Year's Masque, etc.' (1885); 'The Round Year' (1886); 'Lyrics and Sonnets' (1887); 'The Inverted Torch' (1890); 'Fair Shadow Land' (1893); 'In Sunshine Land' (1895); 'In the Young World' (1895); 'A Winter Swallow and Other Verse' (1896); 'The Dancers' (1903); 'Cassia and Other Verse' (1905); 'The Guest at the Gate' (verse, 1909); 'The White Messenger'; 'The Flower from the Ashes' (1915).

THOMAS, George Henry, American soldier: b. Southampton County, Va., 31 July 1816; d. San Francisco, Cal., 28 March 1870. On his father's side he was of Welsh and English ancestry. His mother was of Huguenot descent. He received this early education at Southampton Academy, near his home, and soon after his graduation was appointed to a cadetship at the West Point Military Academy, by the Hon. John Y. Mason, member of Congress from the Southampton district. He was graduated at West Point in 1840, standing 12th in a class of 42 members, W. T. Sherman being sixth. He was a thoughtful and industrious student at the academy, a characteristic that followed him throughout his later military career. In 1840 he was appointed lieutenant in the Third artillery. He served in the war against the Seminoles in Florida, and later in the Mexican War, and was brevetted captain and major for meritorious services at Monterey and Buena Vista. He was instructor at the Military Academy in 1851–54. In 1852 he was united in marriage with Miss Frances Kellogg of Troy, N. Y. He was commissioned major of the Second cavalry in 1855, and for some years saw duty on the western frontier, and engaged in campaigning against hostile Indians.

Upon the breaking out of the Civil War he espoused the cause of the Union, and was appointed brigadier-general of United States Volunteers. It has been stated that early in 1861, during the period of suspense and uncertainty that preceded the war, he was vacillating in his loyalty to the government, and that he applied for services in the Southern army; but this is not true, as is clearly shown by the facts presented by his biographers, Van Horne, Piatt and Coppee. In June 1861, he was assigned to the command of General Patterson, with the United States forces in the Valley of Virginia, but was soon transferred to the west, and was placed in command of the first division of the Union army in Kentucky. On 19–20 Jan. 1862, he won the first important victory gained by the government forces in the west, signally defeating the Confederates under General Zollicoffer, at the battle of Mill Springs (q.v.), in Kentucky, and was promoted to the rank of major-general of volunteers and thanked by President Lincoln in a complimentary order. At the battle of Stone River (q.v.), near Murfreesboro, his command held the centre of the Union line, where he gave additional evidences of his abilities as a commander, and of his staying qualities as a fighter. At the battle of Chickamauga (q.v.), in September 1863, Thomas commanded the 14th corps composed of three divisions of Rosecrans' army, and at the crisis of the engagement on 20 September he held the left of the general line, and successfully resisted the repeated attacks of the Confederates. About noon the right wing of the army, weakened by the withdrawal of troops to protect Thomas' left flank, gave way before the assaults of Hood and Longstreet. The right of the army was routed, but Thomas reformed his troops on Snodgrass Hill, and with the aid of reinforcements brought forward by General Gordon Granger, and other detachments, checked the onslaught of the victorious Confedrates, repelled their repeated attacks, and held the position until nightfall, when he safely withdrew his forces to Rossville. His defense of Snodgrass Hill was one of the most dramatic events and one of the most deadly struggles of the Civil War. He fairly won the title of the «Rock of Chickamauga,» by which he is so well known.

In the engagement of November 1863, in front of Chattanooga (q.v.), General Thomas' forces stormed the heights of Missionary Ridge and drove General Bragg's army from its strong position on the crest, gaining a complete victory over the Confederates. In the campaign against Atlanta (q.v.) in 1864 Thomas was second in command to General W. T. Sherman, and ably co-operated with that great soldier in accomplishing the brilliant series of successes achieved by the Union army. When General Sherman left Atlanta and marched with his army through Georgia to the sea, General Thomas took command of the Federal forces remaining in Georgia, Alabama and Tennessee, and prepared to meet the Confederate forces under General Hood, then threatening an advance into Tennessee. General Thomas then began the concentration of his forces at Nashville (q.v.). His troops under Schofield and Stanley stayed Hood's advance at Franklin, Tenn., and inflicted terrible losses upon the Confederates, but Hood soon appeared before Nashville and threatened to attack the city. General Thomas was now reinforced by Gen. A. J. Smith's command from Missouri, and a large force of cavalry under Gen. J. H. Wilson. Time was needed for equipping the cavalry and reorganizing the troops. Severe winter weather had set in, and the hills about Nashville were covered with ice and sleet — thus delaying military operations. Meantime the authorities at Washington became impatient at the delay, and ordered Thomas to attack Hood. General Thomas explained and remonstrated, and took due time for preparation. Orders were issued finally relieving Thomas from the command, but before they could be executed he attacked Hood's army and gained one of the most complete and brilliant victories of the war, routing and almost dispersing Hood's forces. General Thomas, by these results, fully vindicated his judgment against all criticism, and received the thanks of the President and Congress for his splendid victory. He was also commissioned a major-general in the regular army.

At the close of the war he was in command of the Department of the Cumberland at Nashville, and was most useful in reorganizing and sustaining the civil laws and government in Tennessee and the adjacent States. His high personal character, executive ability and good judgment were instrumental in establishing peace and good order throughout that section. General Thomas must be credited with a very high order of military ability, and a most honorable place in the history of the Civil War. He made no serious military mistakes, and can be charged with no defeats.

After the closing of the war he was assigned to the command of the Military Division of the Pacific, with headquarters at San Francisco, where he died. His wife survived him but a few years. They had no children. Consult Coppée, Henry, 'Life of General Thomas' (New York 1893); Bradford, Gamaliel, 'Union Portraits' (Boston 1916); Van Horne, T. B., 'Life of Major-General G. H. Thomas' (New York 1882).

THOMAS, George Housman, English illustrator and engraver: b. 7 Dec. 1824; d. Boulogne, France, 21 July 1868. He began life as an apprentice to a wood engraver, and practised that art in Paris, but gave the greater part of his time to book illustration, in which he became very proficient. He lived in the United States in 1846–47, and made designs for banknotes. After his return to England he became draftsman on the *Illustrated London News*. His notable pictures are 'The Queen Giving Medals to Crimean Heroes,' and 'The Queen and Prince Albert at Aldershot.'

THOMAS, Isaiah, American printer and bookseller: b. Boston, 19 Jan. 1749; d. Worcester, 4 April 1831. He was apprenticed to Zachariah Fowles, a Boston printer, with whom he established the *Massachusetts Spy*, of which he soon became sole proprietor. So bold were his Whig editorials that in 1771 he was summoned to appear for alleged sedition. He refused, and the attorney-general, when ordered to prosecute, failed to obtain a bill of indictment from the grand jury. After participation in the skirmish at Lexington, he continued the publication of the *Spy* at Worcester, where it thereafter appeared with the exception of a brief period in 1776–77. In 1788 he opened a bookshop in Boston, with branches in various parts of the United States. Among his publications were the *Massachusetts Magazine* (8 vols., 1789–95); a folio Bible (1791); and several editions of Watts' 'Psalms and Hymns.' He was the founder (1812), first president, and most liberal patron of the American Antiquarian Society. He published a 'History of Printing' (1810), which contains much valuable material. This was reprinted in 1874 by the Antiquarian Society. Consult Lincoln, 'History of Worcester' (1837); Thomas, B. F., 'Memoir of Isaiah Thomas' (Boston 1874); Hill (in Antiquarian Society 'Transactions,' Vols. IX and X, Worcester 1909).

THOMAS, Jesse Burgess, American Baptist clergyman: b. Edwardsville, Ill., 29 July 1832; d. 7 June 1915. He was graduated from Kenyon College in 1850, and practised law in Chicago 1857–62. He was pastor of the First Baptist Church, Brooklyn, 1864–69, of the Michigan Avenue Baptist Church, Chicago, 1869–74, and from 1874–88 was pastor of the First Church, San Francisco. From 1888 he was professor of church history at the Newton Theological Seminary. He published 'The Old Bible and the New Science'; 'The Mould of Doctrine,' etc.

THOMAS, John, American physician and soldier: b. Marshfield, Mass., 1725; d. Chambly, province of Quebec, 22 June 1776. He was sent as surgeon to the army in Nova Scotia in 1746; was on the medical staff of General Shirley's regiment in 1747; but secured an appointment as lieutenant in 1759. In 1760, while commanding a regiment under Amherst, he was engaged in operations against the French at Lake Champlain and at Montreal. He was a delegate to the Massachusetts provincial congress 1774–75 and having, during the Revolution raised a regiment of volunteers, was appointed brigadier-general. He took part in the siege of Boston; forced the British to evacuate Dorchester; and participated in the Canadian campaign.

THOMAS, John Jacob, American writer on agricultural topics and authority on horticulture: b. near Lake Cayuga, 1810; d. 1895. He became widely known for editorial work and was a recognized authority on farm topics. His best known publication is 'The American Fruit Culturist' (1845), the twenty-first edition of which was reprinted in 1909. He also issued a book on 'Farm Implements and Machinery' (1869) and a work on 'Rural Affairs' (9 vols., 1855–81); writings greatly valued in his day.

THOMAS, Joseph, American lexicographer: b. Cayuga County, N. Y., 23 Sept. 1811; d. Philadelphia, 24 Dec. 1891. He was educated at Rensselaer Polytechnic Institute, Troy, N. Y., and at Yale, was graduated in medicine at Philadelphia, and engaged in practice there. He was in India in 1857–58, where he made a study of Oriental languages and later spent four months in Egypt in the study of Arabic. He was subsequently professor of Latin and Greek at Haverford College, Pennsylvania. He was associate editor with Thomas Baldwin of 'A Pronouncing Gazetteer' (1845), which was revised and published as 'A Complete Pronouncing Gazetteer or Geographical Dictionary of the World' (1855); 'A New and Complete Gazetteer of the United States' (1854), etc. He also wrote 'A First Book of Etymology' (1851–52); 'Travels in Egypt and Palestine' (1853); 'A Comprehensive Medical Dictionary' (1864; rev. ed., 1886); 'Universal Pronouncing Dictionary of Biography and Mythology' (1870–71; 3d ed., rev., 1905); and other works.

He contributed the pronouncing vocabulary of proper names to ‘Webster's Unabridged Dictionary.’

THOMAS, Kempis. See KEMPIS, THOMAS À.

THOMAS, Lorenzo, American soldier: b. Newcastle, Del., 26 Oct. 1804; d. Washington, D. C., 2 March 1875. He was graduated from the United States Military Academy in 1823. At the organization of the Adjutant-General's Department he received a major's commission and served as chief of staff of the army in Florida (1839–40) and in the same capacity on the staff of General Butler during the Mexican War. In 1861 he became brigadier-general and adjutant-general of the army and was retired from active service in 1869. He was named Secretary of War by President Johnson in 1868, but did not take office because of the refusal of Stanton to vacate.

THOMAS, Martha Carey, American woman educator and writer: b. Baltimore, Ohio, 2 Jan. 1857. She was educated at Cornell University, where she was graduated in 1877; studied in Johns Hopkins and Leipzig and took the Ph.D. degree at the University of Zürich in 1883. The Western University of Pennsylvania and Brown University have conferred on her the honorary degree of LL.D. She taught English branches in Bryn Mawr College of which she was chosen president in 1895. She also was elected a trustee of Cornell University. She has published ‘Sir Gawayne and the Green Knight’ (1883); ‘The Education of Women’ (1900), and many articles on the higher education of women contributed to standard magazines. Mrs. Mary Garret, a benefactress of Bryn Mawr, left her for educational uses $15,000,000.

THOMAS, Seth, American manufacturer: b. Plymouth Hollow (now Thomaston), Conn., 1 Dec. 1816; d. there, 28 April 1888. He was the son of Seth Thomas (1786–1859), in whose honor Thomaston was named and who began the manufacture of metal-movement clocks. The son greatly enlarged the business, introducing his clocks throughout the world. He manufactured all sorts of timepieces.

THOMAS, Theodore, American musician: b. Esens, East Friesland, 11 Oct. 1835; d. Chicago, Ill., 4 Jan. 1905. He played the violin in public at the age of six and when only 10 made his first public appearance in New York. In his early concert and operatic engagements he appeared with Jenny Lind, Sontag, Grisi and Mario. During 1855–69 he was associated with Mosenthal, Bergmann, Matzka, Bergner and William Mason in successive seasons of chamber-music concerts. In 1864, having organized the orchestra which long went under his name, he began his symphony concerts in New York. These were continued, excepting the interval from 1869 to 1872, until 1878, when he went to Cincinnati to become director of the College of Music. With an orchestra, sometimes of 40 and later enlarged to 60 pieces, he visited the large cities of the East and West, giving concerts of both popular and classical music and did much for the development of musical taste. With his name were associated the biennial musical festivals held in Cincinnati from 1873 to 1898. Festivals of a similar character were held under his direction in Chicago in 1882 and 1884 and in New York in 1882. As early as 1862 he was appointed conductor of the Brooklyn Philharmonic Society; when the New York Philharmonic Society was organized he was chosen its leader, and both positions he retained until 1891 when he made his residence in Chicago and became leader of the permanent orchestra in that city. In 1893 he was appointed musical director of the World's Columbian Exposition. Consult Thomas, Rose Fay, ‘Our Mountain Garden’ (New York 1904; new ed., 1915) and Upton, G. P. (editor), ‘Theodore Thomas: A Musical Autobiography’ (2 vols., Chicago 1905).

THOMAS, Theodore Gaillard, American physician: b. Edisto Island, S. C., 21 Nov. 1831. He was educated at Charleston College and was graduated as a physician in 1852, speedily moving to New York where he served in Bellevue Hospital and became professor of diseases of women in The College of Physicians and Surgeons. He also was surgeon to the Women's Hospital and consulting physician to the Children's Hospital and to Saint Mary's Hospital of Brooklyn. He was a distinguished gynæcologist and president of the American Society of Gynæcologists; honorary member of the London Obstetrical Society and corresponding secretary of the Obstetrical Society of Berlin. He performed the first ovarian operation in the United States and published an account of it in 1870. His work on the ‘Diseases of Women’ (Philadelphia 1868) ran into six editions and was translated into the five modern languages, including the Chinese.

THOMAS, William Henry Griffith, English theologian: b. England, 1861. He was educated at King's College, London, and Christ Church, Oxford, and was ordained a priest of the Church of England in 1885. From 1896–1905 he was vicar of Saint Paul's, London; principal of Wyckliffe Hall, Oxford, 1905–10; was appointed professor of Old Testament theology in Wyckliffe College, Toronto, 1910. He is author of ‘Methods of Biblical Study’ (1902); ‘A Commentary on Genesis’ (3 vols., 1907–08); ‘The Power of Peace’ (1908); ‘Christianity in Christ’ (1909); ‘A Commentary on Romans’ (3 vols., 1911–12); ‘Work of the Ministry’ (1911); ‘The Prayers of Saint Paul’ (1914), etc.

THOMAS, William Widgery, American Ambassador: b. Portland, Me., 26 Aug. 1839. He was graduated at Bowdoin College in 1860 and in 1862 became bearer of dispatches for the government of the United States. He carried a treaty to Turkey; became vice-consul-general at Constantinople and subsequently was appointed acting consul at Galatz, Moldavia, and war-consul at Gothenburg, Sweden. In 1865 he resigned and in the following year was admitted to the Maine bar. In 1869 Mr. Thomas was made commissioner of public lands for the State of Maine and in 1870–73 served as State commissioner of immigration. In 1870 he visited Sweden, returning to America with 51 Swedish colonists and settling them in northern Maine, founding the colony of New Sweden. In 1883–85 Mr. Thomas was Minister Resident of the United States to Sweden and Norway and in 1889–94 and 1897–1905 was Envoy Extraordinary and Minister Plenipotentiary to Sweden and Norway. In 1873–75 he was member of the Maine house of representatives and of the State senate in 1879. He is a public orator of note and has taken part in many celebrations in Sweden and at home; secured Swedish participation in the Louisiana Purchase Exposition of 1904. He has published 'Sweden and the Swedes' (2 vols., 1891); translation of Victor Rydberg's 'The Last Athenian' (1869), and is corresponding member of the Royal Swedish Academy for Literature, History and Antiquities.

THOMAS, W. Va., city, situated in the Fairfax district of Tucker County, near the summits of the Allegheny Mountains and on the Western Maryland Railroad. Mining is the chief industry. The local bank has resources amounting to $500,000. The value of taxable property within the city limits is $1,000,000. The educational establishments include graded and high schools. The city has a modern fire department with motor equipment and has over one mile of brick pavement. The annual receipts and expenses average approximately $11,000. Pop. 3,500.

THOMAS, Gospel of, one of the New Testament apocryphal books written in the early half of the 2d century. It treats of the boyhood of Jesus and represents him as performing miracles; it was used by the Gnostics, and probably in its original form was much more strongly Gnostic in doctrine than now, having been subject to an orthodox revision. The book in its present form is fragmentary. There is a Latin translation and a Syriac version with English translation was published in 1875. See APOCRYPHA.

THOMAS OF CELANO, religious poet: b. Celano in the Abruzzi about 1200; d. about 1255. He was among the earliest followers of Saint Francis d'Assisi, and in 1221 was warden of the Minorite houses of Worms, Mayence and Cologne and provincial of the order for Germany. He returned to Assisi in 1230. There is much reason for thinking that he was the author of 'Dies Ira, Dies Illa' (q.v.). He also wrote the two sequences, 'Fregit Victor Virtualis'; and 'Sanctitatis Nova Signa.' Consult Lisco, 'Dies Iræ, Hymnus auf das Weltgericht' (1844).

THOMAS OF LONDON. See BECKET, THOMAS À.

THOMAS THE RHYMER. See RHYMER, THOMAS.

THOMASIUS, tō-mä'zē-oos, **Christian**, German philosopher and jurist: b. Leipzig, 1 Jan. 1655; d. Halle, Germany, 23 Sept. 1728. He was educated at Frankfort-on-the-Oder, and became professor of law at Leipzig in 1684. In 1687 he substituted the German language for Latin in his lectures, and in the following year established a scientific magazine published in German. The caustic wit with which he criticized educational methods and religious topics of the day, together with his advance views, on theology in particular, aroused a storm of opposition, and he was forced to leave Leipzig. He went first to Berlin and thence to Halle in 1690, where he became one of the founders of the university, in which from 1694 until his death he was professor of jurisprudence. He was among the first to break away from traditional pedantry and mediæval terminology, introduced improved methods of study into various departments of learning and as a jurist took a firm stand against trial and torture for witchcraft. He wrote 'History of Wisdom and Folly' (3 vols., 1693); 'Thoughts and Reminiscences' (1723–26), and other important works. Consult works concerning him by Luden (1805); Wagner (Berlin 1872); Nicoladini (ib. 1888); Kayser (Hamburg 1900); also White, A. D., 'Seven Great Statesmen in the Warfare of Humanity with Unreason' (New York 1910).

THOMASIUS, Gottfried, German theological writer: b. Egenhausen, Württemberg, 1802; d. 1875. He was educated at Halle and Berlin and occupied the chair of theology at Erlangen University from 1842 until he died. He is author of 'Origines' (1837); 'Christi Person und Werke' (1852–61; 3d ed., 1886–88); 'Christlichen Dogmengeschichte' (1874–76; 2d ed., 1886–89) and various similar works. Consult von Stahlin, 'Löhe, Thomasius, Harless' (Leipzig 1887).

THOMASTON, Conn., town in Litchfield County, on the New York, New Haven and Hartford Railroad, 10 miles north of Waterbury on the Naugatuck River. It was built up by the noted clockmaker, Seth Thomas, who removed there in 1813 and established his business. The great clock for Independence Hall, Philadelphia, was made there in 1876. The town has clock and watch factories, a brass rolling mill and cutlery manufactures. Pop. about 4,500.

THOMASVILLE, tŏm'as-vĭl, Ga., town and county-seat of Thomas County, on the Atlanta, Birmingham and Atlantic, the Florida Central and the Atlantic Coast Line railroads; about 10 miles from the Florida boundary and 55 miles south of Albany. It is in an agricultural and stock-raising region. The chief industrial establishments are cotton compresses, cigar factories and creameries. There is a large trade in cotton, pine, tobacco, wool, fruit, vegetables and grain. A branch of the State University, called the South Georgia Agricultural and Mechanical College, is located here. Other educational institutions are the Young's College for Women, founded in 1869, opened in 1871; the Vashti Industrial School for girls, supported by the Women's Home Missionary Society of the Methodist Episcopal Church, South; a normal school for negroes; the graded schools and a public library. Thomasville was settled in the 19th century and received its present charter in 1889. Pop. 6,727.

THOMASVILLE, N. C., city in Davison County on the Southern and the Carolina and Yadkin railroads, 22 miles southeast of Greensboro. A Baptist orphanage is located here. The city has cotton mills, machine shops and furniture and woodworking factories and is growing. Pop. about 4,000.

THOMISM, tō'mĭzm, one of the two great schools of scholasticism, the other being Scotism (q.v.). It derived its name from its founder, Saint Thomas Aquinas, the great Dominican doctor; while Thomism and Scotism are both scholastic in their fundamentals they differ in various conclusions and corollaries chiefly as follows: (1) on the nature of universals; (2) the principle of individuation; (3) the manner in which grace acts on the human will; (4) the proof of immortality of the soul; (5) freedom from original sin in the case of the mother of Christ; (6) the effects of the merits of the Incarnation; (7) certain points on the mode of the efficacy of the sacraments; (8) whether an action may be morally indifferent; (9) on the question of toleration. See AQUINAS, THOMAS.

THOMPSON, Augustus Charles, American Congregational clergyman: b. Goshen, Conn., 30 April 1812; d. 1901. He was educated at Yale University, at Hartford Theological Seminary and at the University of Berlin. His ordination as a Congregational pastor at Roxbury, Mass., took place 27 July 1842. With the Rev. Dr. Rufus Anderson he visited India in 1854 with a deputation from the American Board of Missions and was delegate to the London Missionary Conference in 1878. He lectured on Foreign Missions at Andover Theological Seminary (1877–80), at Boston University (1882) and at Hartford Theological Seminary (1885–86). He is author of numerous memorials including those of Mrs. A. J. Waters (1854); H. M. Mill (1856) and Rev. Dr. Anderson (1880). His larger publications include 'Moravian Missions' (1882); 'Foreign Missions' (1889); 'Protestant Missions' (1894), and 'The Eliot Memorial' (1900). He also published translations in the Marathi and Tamil tongues.

THOMPSON, Benjamin, COUNT RUMFORD, American physicist: b. North Woburn, Mass., 26 March 1753; d. Auteuil, near Paris, 21 Aug. 1814. He entered a Salem counting-house in 1766, later was made major of New Hampshire militia by the English governor, Wentworth, but, charged with being a Tory, fled to Boston, where he was associated with the British officers. He went to England in 1776 as bearer of certain dispatches, and as a reward for his services obtained a situation in the Foreign Office under Lord George Germain. He became Under-Secretary for the Colonies in 1780, and was shortly afterward appointed lieutenant-colonel of the King's American dragoons. Returning to England in 1783, he retired on half-pay. In 1784 he was knighted and went to the Continent. Through the recommendation of the Prince of Zweibrücken (afterward king of Bavaria) he entered into the service of the reigning elector-palatine and Duke of Bavaria, where he effected many important and useful reforms in both the civil and military departments of the state, the latter of which he practically reorganized. As the reward of his success he received from the sovereign of Bavaria various orders of knighthood, was made a lieutenant-general and created count of the Holy Roman Empire, choosing the title Count Rumford from the name of his wife's native town (now Concord, N. H.). He left Bavaria in 1795, and returned to England, where he employed himself in making experiments on the nature and application of heat and on other subjects of economical and philosophical research. He clearly recognized that heat is a mode of motion, and that by a given amount of mechanical work a definite amount of heat may be produced. Among the objects which engaged his attention was the search for a remedy for smoky chimneys, which at that time formed one of the greatest nuisances in the country; and he succeeded in discovering the principles upon which fireplaces and chimneys have since been constructed. He likewise suggested the plan and assisted in the foundation of the Royal Institution, which led to other establishments of a similar description. In 1804 he removed to Paris, where he took up his residence; and, his wife being dead, he married the widow of the celebrated Lavoisier; but the union proved unfortunate and a separation ere long took place. Count Rumford then retired to a country house at Auteuil, about four miles from Paris, and there devoted his time to the embellishment of his domain and to the cultivation of chemistry and experimental philosophy. His investigations respecting the strength of materials and the force of gunpowder led to considerable improvements in artillery, and he also made discoveries in connection with light and illumination. Count Rumford was by no means a man of extensive learning, but he was familiar with the discoveries and improvements of contemporary science, and the industry and perseverance with which he pursued his inquiries enabled him to make some considerable additions to the knowledge of chemistry and practical philosophy. He was the founder and first recipient of the Rumford medal of the Royal Society, and also founder of the Rumford medal of the American Academy of Arts and Sciences, and of the Rumford professorship in Harvard University. His complete works, with a memoir by George E. Ellis, were published by the American Academy of Arts and Sciences (Boston 1870–75). Consult also Slosson, E. E., in 'Leading American Men of Science' (ed. by D. S. Jordan, New York 1910).

THOMPSON, Charles Miner, American editor and author: b. Montpelier, Vt., 24 March 1864. Following his graduation from Harvard in 1886 he became literary editor of the *Boston Advertiser* (1887–90); associate editor of the *Youth's Companion* (1890–1911) and later a part owner and the editor of that journal. He is noted as a writer of stories for boys. His publications include 'The Nimble Dollar' (1895); 'The Calico Cat' (1908); 'An Army Mule' (1910).

THOMPSON, Daniel Greenleaf, American lawyer, psychological and sociological writer: b. Montpelier, Vt., 9 Feb. 1850; d. New York, 10 July 1897. He was graduated from Amherst and was admitted to the bar in New York in 1872 but devoted himself chiefly to sociological work. Amherst conferred on him the Ph.D. degree in 1894. He became noted as a controversial writer and is known chiefly for 'A System of Psychology' (2 vols., 1884); 'Religious Sentiments of the Human Mind' (1888); 'Social Progress' (1889); 'The Philosophy of Fiction in Literature' (1890), and 'Politics in a Democracy' (1893). The latter publication was translated into the Dutch language.

THOMPSON, Daniel Pierce, American author, lecturer, lawyer and politician: b. Charlestown, Mass., 1 Oct 1795; d. Montpelier, Vt., 6 June 1868. He was educated at Middlebury College, where he was graduated in 1820. He began life as a private tutor in Virginia where he studied law and was admitted to the bar in 1823. He settled in Montpelier the following year, held various judicial offices from that time to 1835 when he was authorized by the legislature to compile the laws of Vermont from 1824 to 1834 (1835) and was elected secretary of state (1853–55). He edited the *Green Mountain Freeman* (1849–56) and proved a voluminous writer. His publications include 'The Advocates of Timothy Peacock, Esq.' (1835), a satire on the Anti-Masonic agitation; 'May Martin or the Money Diggers' (1835), a prize story afterward reprinted in London; 'The Green Mountain Boys' (1840); 'The Rangers' (1857); 'Tales of the Green Mountains' (1852); 'Gant Gurley or the Trapper of Lake Umbagog' (1857); 'The Doomed Chief' (1860), founded on the story of King Philip, and other tales based on Revolutionary stories. He left an unfinished novel, 'The Honest Lawyer.'

THOMPSON, David, Canadian explorer: b. London, 30 April 1770; d. Longueuil, 16 Feb. 1857. He was educated at Christ Hospital School and at Oxford. When but 19 he came to America and took service with the Hudson Bay Company in 1789, beginning work as an explorer in the Great Lakes country. In 1798 he discovered Turtle Lake, one of the sources of the Mississippi; in 1807 he crossed the Rocky Mountains and explored the Columbia River. From 1816–26 he was surveying for the Canadian-United States Boundary Commission. His greatest work aside from his surveys was a map of the Canadian Northwest made in 1814. The last years of his life were spent near Longueuil where he died.

THOMPSON, Denman, American actor: b. near Girard, Pa., 1833; d. 1911. His youth was passed in Swanzy, N. H., and he made his debut in Lowell, Mass., in 1852 in the 'French Spy,' in which he played a small part. His success was made in 'Joshua Whitcomb' in 1875, and his greatest popularity won in the 'Old Homestead,' in which he introduced again the character of "Josh Whitcomb" in country life. This had a run of four seasons in New York alone and its success caused Thompson to tour the country. Consult McKay and Wingate, 'Famous American Actors of Today' (New York 1896).

THOMPSON, Sir Edward Maunde, English palæographist and bibliographer: b. Jamaica, 4 May 1840. He was educated at Rugby and University College, Oxford, was appointed assistant in the British Museum in 1861, assistant-keeper of manuscripts in 1871, in 1878 keeper of manuscripts and Egerton librarian, and from 1888 until 1909 he was principal librarian and secretary. In 1898 his official title as a servant of the British Museum was changed to director and principal librarian. He was Sandars reader in bibliography, Cambridge (1895–96; 1905–06). He was knighted in 1895. For the 'Rolls Series' he has edited 'Chronicon Angliæ, 1328–1388' (1874); 'Chronicon Galfridi le Baker de Swynebroke' (1889), and 'Adæ Murimuth Continuatio Chronicorum' together with 'Robertus de Avesbury de Gestis Mirabilibus Regis Edwardi Tertii' (1889); for the Camden Society, 'Letters of Humphrey Prideaux' (1875) and 'Correspondence of the Family of Hatton' (1878); for the Hakluyt Society, 'Diary of Richard Cocks in Japan' (1883); for the Royal Society of Literature, 'Chronicon Adæ de Usk' (1876); and for the Hellenic Society, with Sir R. C. Jebb, a facsimile of the 'Laurentian Sophocles' (1885). In 1893 appeared his 'Handbook of Greek and Latin Palæography.' He has also written 'An Introduction to Greek and Latin Palœography' (1912); 'Shakespeare Handwriting' (1916).

THOMPSON, Elizabeth Rowell, American philanthropist: b. Lyndon, Vt., 21 Feb. 1821; d. Littleton, N. H., 20 July 1899. She was married to Thomas Thompson, a Boston millionaire, in 1845, and during his life engaged with him in philanthropic work. On his death in 1869 she inherited the entire income from his estate, and continued her charitable labors. She was an advocate of temperance reform, wrote a tract, 'Figures of Hell,' which was widely read, and contributed large sums for the furtherance of the cause. She gave $10,000 for an investigation of yellow fever in the South, and purchased and presented to Congress Carpenter's painting, 'Signing of the Emancipation Proclamation by President Lincoln in the Presence of his Cabinet.' She invested more than $100,000 in establishing heads of families in business, founded the town of Long Mont, Kan., and gave to each colonist 640 acres of land and $300. She contributed to the purchase of the Vassar College telescope, and was a generous benefactor of the American Association for the Advancement of Science, of which she was made the first patron. She was stricken with paralysis in 1888 and was afterward unable to continue her philanthropic work. In 1891 she was pronounced insane by a Kansas City jury, and a curator was appointed to the charge of her property in Missouri. She left an estate appraised at $400,000 with no public bequests.

THOMPSON, Francis, English poet: b. Ashton, Lancashire, 1860; d. London, 13 Nov. 1907. He was the son of a Lancashire physician, was educated at Ushaw Roman Catholic College, near Durham, and studied medicine at Owens College, Manchester. He took no interest in medicine, and turning his attention to literary work he went to London. Here after a struggle with poverty and hardship for some five years his work was brought to the attention of Alice Meynell (q.v.) through whose assistance and that of her husband, Wilfred Meynell, Thompson soon achieved reputation as a poet, and his fame steadily increased. Truly an ascetic, he stood alone among contemporary poets both for purity of thought and beauty of expression. He contributed to the critical reviews and published 'Poems' (1893); 'Sister Songs' (1895), and 'New Poems' (1897). Of his prose works, published posthumously, may be mentioned 'Life of Saint Ignatius Loyola' (1909); 'A Renegade Poet, and Other Essays' (1910); 'Life of John Baptist de la Galle' (1911). Consult his 'Works' (3 vols., New York 1913); also Beacock, G. A., 'Francis Thompson' (Marburg 1912); Meynell, E., 'Life of Francis Thompson' (New York 1913); Rooker, K., 'Francis Thompson' (London 1913).

THOMPSON, George, English reformer: b. Liverpool, England, 18 June 1804; d. 7 Oct. 1878. He acquired notoriety during the anti-slavery agitation by lecturing in the British Colonies. His subsequent tour in the United States produced great excitement and caused President Jackson to denounce him in a message to Congress. He was a friend of Garrison, Whittier and others in the anti-slavery movement and visited America several times. His influence aided materially in preventing the recognition of the South by Great Britain during the Civil War. He also took a prominent part in the Anti-corn Law League and the British India Association to secure better government for India; was a member of the British Parliamentary Reform Association, and was elected member of Parliament 1847–52.

THOMPSON, Sir **Henry,** English surgeon: b. Framlingham, Suffolk, 6 Aug. 1820; d. London, 18 April 1904. He was educated at University College, London, and was awarded the Jacksonian prize in 1852 for an essay on 'The Pathology and Treatment of Stricture of the Urethra,' and again in 1860 for an essay on 'The Healthy and Morbid Anatomy of the Prostate Gland.' In 1853 he became assistant surgeon to University College Hospital, surgeon 10 years later, professor of clinical surgery in 1866, and consulting surgeon in 1847. In 1884 he was professor of pathology and surgery to the Royal College of Surgeons. He received numerous honors from foreign countries, was knighted in 1867, and created a baronet in 1899. His works treat mostly of the urinary organs and their diseases, of cremation, and of diet. Among them may be mentioned 'Clinical Lectures on Diseases of the Urinary Organs' (8th ed., 1888); 'The Preventive Treatment of Calculus Disease' (1888); 'Tumors of the Bladder' (1884); 'Cremation, or the Treatment of the Body after Death' (1874); 'Modern Cremation, its History and Practice' (4th ed., 1901), in which he advocates the substitution of cremation for the present method of sepulture; 'On Food and Feeding' (11th ed., 1901). He was also an artist of note, a pupil of Alma Tadema and others, and exhibited pictures at the Royal Academy, the Salon and elsewhere.

THOMPSON, Jacob, American politician: b. Caswell County, N. C., 15 May 1810; d. Memphis, Tenn., 24 March 1885. He was graduated at the University of North Carolina in 1831, admitted to the bar in 1834 and engaged in law practice in Chickasaw County, Miss., in 1835. He was a member of Congress in 1839–51, and opposed the Compromise of 1850 as not sufficiently favorable to the South. He was appointed Secretary of the Interior by President Buchanan in 1857, and in December 1860, while still holding that office, he was appointed a commissioner from Mississippi to urge upon North Carolina the adoption of a secession ordinance. In January 1861 he resigned from the Cabinet in consequence of the action of President Buchanan in sending reinforcements to Fort Sumpter, which he declared to be a violation of an understanding with the Cabinet that the order should not be given without the knowledge of that body. He took an active part in the subsequent secession movement, was governor of Mississippi in 1862–64 and later served as aide to General Beauregard and inspector-general for the Department of Mississippi. He was Confederate commissioner to Canada in 1864, and a promoter of the plan to seize Chicago and release the prisoners at Camp Douglas near that city. He was accused of being the instigator of plots to burn various Northern cities, also of complicity in the assassination of President Lincoln. A price was put upon his head and he fled to Europe. He returned to the United States, but was not brought to trial.

THOMPSON, James Maurice, American author: b. Fairfield, Ind., 9 Sept. 1844; d. 15 Feb. 1901. He was educated in Georgia, and served in the Confederate army during the Civil War. Afterward he settled in Indiana and practised law and civil engineering at Crawfordsville. Out-door life was his passion, and from 1885 to 1889 he was State geologist of Indiana and chief of the Department of Natural History. In 1890 he joined the staff of the New York *Independent.* His books are the records and observations of a nature-lover rather than a scientist, the product of his trips to the lake and swamp regions of Florida and Louisiana and to the hills of Alabama, Mississippi and Georgia. He was expert with the bow and arrow, with which he hunted instead of a gun. He wrote 'The Witchery of Archery' (1878); 'His Second Campaign' (1882); 'By-Ways and Bird Notes' (1885); 'The Boy's Book of Sport' (1886); 'Sylvan Secrets' (1887); 'Poems' (1892); 'The Ocala Boy' (1895); 'My Winter Garden' (1900); 'Alice of Old Vincennes' (1900).

THOMPSON, Sir **John David Sparrow,** Canadian jurist and for some time Premier of the Dominion: b. Halifax, 10 Nov. 1844; d. Windsor, England, 12 Dec. 1894. His father, who had come from Waterford, Ireland, held the office of queen's printer. Thompson was educated at the common school, Halifax, and was called to the bar in that city in 1865. He joined the Roman Catholic Church in 1871. After holding several municipal offices, he was elected to the Nova Scotia assembly for Antigonish (1877). His success at the bar earned him the dignity of queen's counsel in 1879. He was attorney-general in 1878 and premier of the province in 1879. After the defeat of his government in the same year Thompson was made a judge of the Supreme Court of Nova Scotia. This position he resigned to accept the portfolio of Minister of Justice in Sir John A. Macdonald's Cabinet (1885), entering the Dominion Parliament as member for Antigonish. He remained Minister of Justice until 1892, distinguishing himself by his oratorical power and his untiring industry. In 1887 he visited Washington as one of the commissioners on the fisheries question. The honor of knighthood was conferred on him in August 1888. Sir John again visited Washington as one of the representatives of his government in the unsuccessful reciprocity negotiations of 1891 and 1892. He is understood to have been offered the position of Premier on the death of Sir John A. Macdonald (1891), but preferred to remain as Minister of Justice under the leadership of Sir J. J. C. Abbott. On the retirement of the latter (December 1892) Sir John Thompson became Prime Minister. His incessant Parliamentary labors rapidly undermined his health and brought about his death under singularly tragic circumstances. Visiting England in 1894 to be sworn in as a member of the privy council, he expired suddenly of syncope almost immediately after the ceremony. Consult Hopkins, 'Life and Work of the Rt. Hon. Sir John Thompson' (Toronto 1895).

THOMPSON, John Reuben, American journalist and poet: b. Richmond, Va., 23 Oct.

1823; d. 30 Oct. 1873. He was graduated from the University of Virginia in 1844; practised law in Richmond in 1847, but soon entered on a literary career and for 12 years edited the *Southern Literary Messenger* to which Donald G. Mitchell contributed his 'Reveries of a Bachelor.' Ill health caused his removal to Augusta, Ga., where in 1859 he edited the *Field and Fireside* magazine. Driven to London by events of the Civil War he actively defended the Confederacy in contributions to English magazines. At the close of the war he returned to America and became editor of the New York *Evening Post*. He was author of several poems which were popular at the time.

THOMPSON, Joseph Parrish, American clergyman and Oriental scholar: b. Philadelphia, 7 Aug. 1819; d. Berlin, Germany, 20 Sept. 1879. He was graduated at Yale 1838, studied theology at Andover and Yale seminaries (1839–40) and was ordained Congregational minister the latter year. He became pastor in New Haven (1840–45); New York, Broadway Tabernacle (1845–71). He lectured on Egyptology at Andover in 1871. In 1872 he assisted in establishing *The Independent*; Harvard gave him the degree of D.D. in 1856; The University of New York the degree of Ph.D. in 1857. He pursued his Oriental studies in Berlin (1872–79) and died there. He published several memoirs, including those of Timothy Dwight and David Hale. Also 'Lectures to Young Men' (1846); 'Egypt Past and Present' (1856); 'Genesis and Geology' (1869); 'Church and State in the United States' (1874); 'The United States as a Nation' (1877); 'The Workman: His False and His True Friends' (1879). His political and social essays were collected and published under the title of 'American Comments on European Questions' (1884).

THOMPSON, Launt, American sculptor: b. Abbeyleix, Ireland, 8 Feb. 1833; d. Middletown, N. Y., 26 Sept. 1894. He arrived in the United States 1847, and began his study of sculpture under Erastus Dow Palmer in Albany. In 1857 he removed to New York where he opened a studio; he became an associate of the Academy of Design in 1859; an academician in 1862 and vice-president in 1874. He traveled extensively, visiting Rome (1867–68); and being again in Italy (1875–87), residing the greater part of the time in Florence. His works include 'Elaine' (a bust); 'Morning Glory' (a medallion), and portrait of Gen. John A. Dix; statues of Napoleon (Metropolitan Museum, New York 1867); Abraham Pierson (Yale 1874) and of Winfield Scott (Washington, D. C.); portrait busts of William C. Bryant, Edwin Booth as Hamlet, Charles L. Elliott, etc.

THOMPSON, Mortimer M., American journalist and humorist: b. Riga, N. Y., 2 Sept. 1832; d. New York, 25 June 1875. He was educated at the University of Michigan, was for a time connected with the stage, settled in New York in 1852 and shortly after began writing there for the press. He subsequently became a popular lecturer and continued humorous contributions to the weekly newspapers. His books, written under the pseudonym of "Q. K. Philander Doesticks, P.B." ("Queer Kritter, Philander Doesticks, Perfect Brick"), include 'Doesticks — What he Says' (1855); 'Plu-ri-bus-tah' (1856), a travesty of Longfellow's 'Hiawatha'; 'Nothing to Say' (1857), and others.

THOMPSON, Richard Wigginton, American lawyer: b. Culpeper County, Va., 9 June 1809; d. Terre Haute, Ind., 9 Feb. 1900. He was admitted to the bar of Lawrence County, Ind.., in 1834. He served in both houses of the State legislature, and in 1840 was elected to Congress. He declined an appointment as Minister to Austria in 1849, and later the post of solicitor-general of the Land Office, which President Fillmore offered him. In 1867 he became judge of the Fifth Indiana Circuit Court, and in 1877–81 was Secretary of the Navy. He resigned this post before the completion of his term in order to become chairman of the American committee of the Panama Canal Company. He published 'The Papacy and the Civil Power' (1877); 'History of the Protective Tariff' (1888); 'Footprints of the Jesuits' (1894) and 'Recollections of Sixteen Presidents, from Washington to Lincoln' (1894).

THOMPSON, Robert Ellis, American educator: b. near Lurgan, Ireland, 5 April 1844. He was graduated at the University of Pennsylvania in 1865 and from 1868 to 1892 held successively in that institution professorships in Latin and mathematics, social science, history and English literature. He has held lectureships at Harvard, Yale and Princeton Theological Seminary, and has contributed editorially to the *Penn Monthly*, the *American*, the *Irish World* and the *Sunday School Times*. In 1874 he was ordained to the Presbyterian ministry. Since 1894 he has been principal of the Central High School of Philadelphia. His publications include 'Social Science and National Economy' (1875); 'De Civitate Dei'; 'The Divine Order of Human Society' (1891), being his Stone lectures at Princeton; 'History of the Presbyterian Churches of America' (1895); 'Protection to Home Industry' (1885), being his Harvard lectures; 'The Hand of God in American History' (1902); 'The Historic Episcopate' (1910) and 'The History of the Dwelling House and its Future' (1914). He has edited Duffield's 'Latin Hymn-writers and Their Hymns' (1889); 'Political Economy for High Schools' (1895); 'The Apostles as Everyday Men' (1912).

THOMPSON, Silvanus Phillips, English physicist: b. York, 19 June 1851; d. 1916. He was educated at Bootham School, York, at Flounders' Institute, Pontefract, and at the Royal School of Mines. In 1876–85 he held the professorship of experimental physics at University College, Bristol, and in 1885 became principal and professor of physics in the City and Guilds Technical College, Finsbury. He was president of the Physical Society; of the Institution of Electrical Engineers and of the Röntgen Society. His works include 'Elementary Lessons in Electricity and Magnetism' (1881; rev. ed., 1915); 'Dynamo-Electric Machinery' (1886; 7th ed., 1904); 'Light, Visible and Invisible' (1897; 2d ed., 1910); 'Michael Faraday' (1898); 'The Life of Lord Kelvin' (1910).

THOMPSON, Smith, American jurist: b. Stanford, N. Y., 17 Jan. 1768; d. Poughkeepsie, N. Y., 13 Dec. 1843. He was graduated at Princeton in 1788, admitted to the bar in 1792 and several years later established a law practice in New York. He was chosen to the legislature in 1800, was associate justice of the State Supreme Court in 1802–14, chief justice in 1814–18. In 1818 he became Secretary of the Navy under President Monroe, and from 1823 until his death was a justice of the Supreme Court of the United States.

THOMPSON, Vance, American journalist and playwright: b. 17 April 1863. He was graduated at Princeton in 1883, studied in Germany and was a dramatic critic in New York in 1890–97 His dramas include ‘In Old Japan,’ ‘The Dresden Shepherdess,’ ‘Florian's Dream,’ etc.; and among his books are ‘French Portraits: Being Appreciations of the Writers of Young France’ (1900); ‘Diplomatic Mysteries’ (1905); ‘The Spinners of Life’; ‘Life and Letters of Ethelbert Nevin’ (1913); ‘The Night Watchman and Other Poems’ (1914); ‘The Ego Book’ (1914); ‘Eat and Grow Thin’ (1914); ‘Drink and be Sober’ (1915); ‘The Carnival of Destiny’ (1916); ‘The Peace Girl’ (a romantic comedy drama) (1916); ‘Woman’ (1917).

THOMPSON, Waddy, American lawyer: b. Pickensville, S. C., 8 Sept. 1798; d. Tallahassee, Fla., 23 Nov. 1868. He was graduated at the South Carolina College in 1814, admitted to the bar in 1819 and in 1826–30 served in the State legislature. He became solicitor of the Western Circuit in 1830, was elected brigadier-general of militia at the time of the Nullification excitement and in 1835–41 was a Whig member of Congress. In 1840 he was chairman of the Committee on Military Affairs. He was appointed Minister to Mexico in 1842, and while on this mission concluded two important treaties and procured the liberation of more than 200 Texan prisoners. He published ‘Recollections of Mexico’ (1846).

THOMPSON, William, American Revolutionary soldier: b. Ireland, about 1725; d. near Carlisle, Pa., 4 Sept. 1781. He served as captain of militia in the French and Indian War (1759–60) and was made colonel of eight Pennsylvania companies in June 1775. The following year he took the same rank in the Continental Army and later became brigadier-general. He relieved Gen. Charles Lee at New York and in April led 14 regiments to Canada to re-enforce General Thomas, during whose illness he commanded until General Sullivan arrived. By the latter's orders he led an unsuccessful attack on the British at Trois Rivières on 6 June and was captured but immediately paroled.

THOMPSON, William Hale, American mayor: b. Boston, Mass., 14 May 1869. In infancy he was removed by his parents to Chicago, where he was educated in the public schools. He spent five seasons on the ranches of the Standard Cattle Company in Colorado, Montana and Wyoming; was for three years manager of a cattle ranch in Nebraska. Since his father's death Mr. Thompson has managed the real estate interests left by his father and other real estate interests of his own. In 1900–02 he served as alderman from the second ward of Chicago; in 1902–04 was county commissioner of Cook County and in 1915–19 was mayor of Chicago.

THOMPSON, William Howard, American lawyer and legislator: b. Crawfordsville, Ind., 14 Oct. 1871. The family moved to Kansas while he was a child and he was educated at the Seneca Normal School. He studied law with his father and was admitted to the Kansas bar in 1894. He was clerk of the Court of Appeals (1906–13) and was elected United States senator in 1913. In 1916 he served as delegate to the Democratic National Convention.

THOMPSON, William Tappan, American newspaperman and humorist: b. Ravenna, Ohio, 31 Aug. 1812; d. Savannah, Ga., 24 March 1882. He lived for a time in Philadelphia where he worked on the *Chronicle*; afterward was secretary to James D. Westcott while Territorial governor of Florida, and studied law under his charge. He became assistant editor of *The State Rights Sentinel*, was a volunteer in the Seminole War (1835–36), and established *The Mirror* in Augusta, Ga., afterward merged with *The Family Companion*. Thereafter he was attached to several papers and won reputation as a humorist by the «Major Jones Letters» written for *The Miscellany* which he established in Madison. He was associated with Park Benjamin in publishing at Baltimore; served on the staff of Governor Brown in the Civil War, and also as a Confederate volunteer. In 1887 he sat in the Constitutional Convention of his State. His many publications were popular and were collected and issued by his daughter after his death. He wrote several successful plays, including a dramatization of the ‘Vicar of Wakefield.’

THOMPSON, Wordsworth, American artist: b. Baltimore, Md., 27 May 1840; d. Summit, N. J., 28 Aug. 1896. He began to sketch soldiers and battle scenes in 1861, and his work proved popular with the newspapers. He went to Paris and studied in the École des Beaux Arts, and exhibited ‘The Morelands of Au-Fargi’ in the Salon of 1865. In 1868 he settled in New York, but made several trips abroad at later intervals. His painting, ‘Desolation’ (1875), won him an associate membership in the National Academy. In 1877 he became a full-fledged academician; in 1878 he was made a member of the Society of American Artists; in 1879 he won a gold medal at the Paris Exposition. Among his noted paintings are ‘Annapolis in 1776’ (owned by the Buffalo Fine Arts Academy); ‘Passing the Outpost’ (owned by the Union League Club, New York); ‘The Parting Guest’ (owned by the New York Historical Society); ‘A Midsummer Day on Long Island’; ‘A May Day on Fifth Avenue,’ etc.

THOMPSON, Conn., town in Windham County, on the French and Quinebaug rivers, and on the New York, New Haven and Hartford Railroad. Within the town limits are the villages of Grosvenor Dale, North Grosvenor Dale, New Boston, Thompson, East Thompson, West Thompson, Wilsonville, Mechanicsville and Quinebaug. It is in an agricultural region. The chief manufacturing establishments are cotton and woolen mills, flour and grist mill, planing mills, a boot and shoe factory and machine shops. Thompson was originally a part of Killingly, but became a parish in 1728, and in 1785 was incorporated as a town. Pop. 4,804.

THOMPSON INDIANS. See SALISHAN.

THOMPSON'S STATION, Battle of. After the battle of Stone River (q.v.) the Confederate cavalry were active on Rosecrans' flanks and rear, and late in February 1863 Gen. Earl Van Dorn, with over 6,000 men, crossed the Tennessee River at Florence and marched northward to Columbia, on Duck River, threatening Franklin, about 28 miles nearly west of Murfreesboro. On 4 March General Rosecrans ordered a general reconnoissance in front of his lines to ascertain the Confederate strength and, if possible, the enemy's intention. One of these reconnoitering columns was sent from Franklin. It was under command of Col. John Coburn and consisted of his brigade — 33d and 85th Indiana, 19th Michigan and 22d Wisconsin — the 124th Ohio, 600 cavalry under Col. T. J. Jordan and Aleshire's Ohio battery of six guns; in all 2,837 officers and men. A train of 101 wagons accompanied the expedition, 80 of which were to collect forage. Coburn was instructed to advance the first day to Spring Hill, where he was to halt for the night of the 4th, and next day divide his force, sending part of it to Rally Hill, on the left, to meet a co-operating cavalry column from Murfreesboro, and the other part toward Columbia, each to return to Spring Hill at night, unless the detachment at Rally Hill should be joined by the cavalry expected from Murfreesboro. Colonel Jordan, with the cavalry and battery, led the advance and when three miles out of Franklin met Gen. W. H. Jackson's cavalry division of two brigades and King's battery moving north. Both parties formed for battle, Aleshire opened with his guns, King's guns replied, the skirmishers became engaged, and after a brisk engagement of an hour Jackson withdrew toward Spring Hill and Coburn went into camp four miles south of Franklin. One of Aleshire's guns had been disabled and with the forage train of 80 wagons, half of them loaded, was sent back to Franklin. Van Dorn had started from Columbia that morning with the five brigades of Gens. N. B. Forrest, W. T. Martin, G. B. Cosby, F. C. Armstrong and Col. J. W. Whitfield, 6,000 men and 12 guns, and when Jackson with the two brigades of Armstrong and Whitfield fell back after the engagement, Van Dorn formed line at Thompson's Station, nine miles south of Franklin, and awaited Coburn's advance. Jackson's division was posted on a range of hills crossing the Franklin pike, with King's battery on the extreme left and Forrest's brigade, with a battery, was on Jackson's right. On the morning of the 5th Coburn advanced cautiously and on nearing Thompson's Station Jordan charged with his cavalry, drove a small Confederate force from the station and seized a range of hills near it. Coburn followed with the infantry to near the station, when, on entering a pass, with hills on either side, he was arrested by shells from the Confederate artillery on his right and left, enfilading his line. It was necessary to dislodge King's battery on his right and he formed his line for the attack; Aleshire's guns on opposite sides of the turnpike and railroad which ran close to each other, the guns supported by the cavalry, and the 33d and 85th Indiana advanced down the hill against King's battery, when suddenly the Confederate guns ceased firing and from behind a stone wall Whitfield's brigade, reinforced by a regiment of Armstrong's, opened a fire that drove the two regiments back up the hill. Whitfield followed, and when nearing the summit he was charged and driven back, made a stand behind the depot of Thompson's Station and with the assistance of two of King's guns compelled Coburn's men to fall back beyond the hill. At about the same time Coburn was informed that about 1,000 cavalry had been discovered on the left and he resolved to retreat; but it was first necessary to check the Confederate advance. The movement in retreat was to be covered by the battery and the cavalry, but when Jordan saw the signs of a movement in retreat and the probability of being cut off by Forrest's cavalry on the left, he ordered the wagon train and its guard to the rear, to be followed by the battery, Jordan following the battery after a slight resistance to Forrest. Meanwhile Armstrong and Whitfield had been ordered to assault Coburn's left and Forrest to reach his rear. Armstrong, Whitfield and part of Forrest charged, and after a fierce struggle for the crest of the hill were again driven from it with great loss. Again the Confederates charged; Coburn was forced back; Forrest, with two regiments, gaining his rear, charged him; and after a few volleys at close quarters Coburn surrendered. His loss, as officially reported, was 48 killed, 247 wounded and 1,151 captured or missing. Van Dorn's loss was 56 killed, 289 wounded and 12 missing. Meanwhile other columns had pushed out from Murfreesboro and driven other bodies of Confederate cavalry across Duck River and Gen. Gordon Granger, commanding the reserve corps of Rosecrans' army, upon hearing of Coburn's defeat, strengthened Franklin and concentrated a column at that place to move upon Van Dorn, at Spring Hill and Thompson's Station. Granger moved on the 9th, attacked and drove Armstrong's cavalry brigade from Thompson's Station and advanced to Spring Hill, Van Dorn having fallen back during the day to recross Duck River at Columbia. On the next day Granger's cavalry pushed Armstrong across Rutherford's Creek near Columbia; and Van Dorn's main body recrossed Duck River. Pursuit was suspended and on the 11th the various commands engaged in the general reconnoissance returned to their former positions. Consult 'Official Records' (Vol. XXIII); Van Horne, 'History of the Army of the Cumberland' (Vol. I); Wyeth, 'Life of Gen. N. B. Forrest.'

E. A. CARMAN.

THOMSON, tŏm'sŏn, Charles, American patriot: b. Maghera, County Derry, Ireland, 29 Nov. 1729; d. Lower Merion, Pa., 16 Aug. 1824. He came to America in 1740, was educated in the academy at Thunder Hill, Md., and became a teacher in the Friends' Academy, Newcastle, Del., afterward taught in Philadelphia, and then engaged in business in that city. He acted as commissioner among the Indians and in 1756 was adopted into the Delaware tribe as the «Truth Teller.» From the first he ardently espoused the cause of the colonies, and in 1774 was made secretary of the Continental Congress, a post he occupied until 1789. Upon Washington's election to the Presidency he was sent to Mount Vernon to inform him of the event. He then retired from public life and afterward occupied himself with literary labors.

He published 'An Enquiry into the Causes of the Alienation of the Delaware and Shawanese Indians' (1759); 'The Holy Bible, containing the Old and New Covenant, translated from the Greek [the Old Covenant from the Septuagint]' (1808), and 'A Synopsis of the Four Evangelists' (1815). Consult Harley, 'The Life of Charles Thomson' (1900).

THOMSON, Sir Charles Wyville, Scottish naturalist: b. Bonsyde, Linlithgow, 5 March 1830; d. there, 10 March 1882. He was educated at the University of Edinburgh, where he took the medical course and showed great ability in botany and natural history. He was appointed lecturer on botany in King's College, Aberdeen, in 1850 and professor at Marischal College in 1851. He filled the chair of natural history in Queen's College, Cork, in 1853 and in 1854 went to Queen's College, Belfast, as professor of mineralogy and geology. In 1860 he was transferred to the chair of natural science in the same college and in 1868 became in addition professor of botany in the Royal College of Science at Dublin. He returned to Scotland in 1870 to become professor of natural history in the University of Edinburgh. He took an active part in the scientific investigation of the British seas by the *Lightning* and *Porcupine* expeditions and published 'The Depth of the Sea' (1873). He was appointed in 1872 chief of the scientific staff of the *Challenger* Expedition (q.v.), and on its return in 1876 was knighted. In 'The Voyage of the Challenger: the Atlantic' (1877) he gave a general account of part of the investigations carried out on the famous voyage.

THOMSON, Edward, American Methodist Episcopal bishop: b. Portsea, England, 12 Oct. 1810; d. Wheeling, W. Va., 22 March 1870. He came to the United States in 1819, was graduated in medicine at the University of Pennsylvania in 1829 and practised in Jeromeville and Wooster, Ohio. In 1832 he united with the Methodist Church and in the following year was admitted into the Ohio Conference. He was pastor of a church in Detroit, Mich., in 1836 and in 1838–43 was principal of the Norwalk Seminary. He was the first president of the Ohio Wesleyan University at Delaware, in 1846–60, and in 1864 he was elected bishop, in which office he continued until his death. He edited the *Ladies' Repository* at Cincinnati 1844–46, the *Christian Advocate and Journal*, New York 1860–64, made a missionary tour of the world and published 'Moral and Religious Essays' (1856); 'Sketches, Biographical and Incidental' (1856); 'Our Oriental Missions' (1870); 'Evidences of Revealed Religion' (1872), and other works.

THOMSON, Edward William, American civil engineer and author: b. Toronto, Ont., 12 Feb. 1849. He was educated in Trinity College Grammar School and by his own exertions. When but 16 he enlisted and served (1864–65) in the Third and Fourth Pennsylvania regiments; and in the Queen's Own Rifles in 1866. He became a political writer on the *Toronto Globe* (1879–91); was editor of the *Youth's Companion*, Boston (1891–1901), afterward becoming a special writer on Canadian politics. He was also the traveling correspondent of the *Evening Transcript*, Boston. His published works include 'Old Man Savarin' (1895), 'Between Earth and Sky' (1897), 'Aucassin and Nicolette' (1895, versified from the translation); 'When Lincoln Died, and other poems' (1909), etc.

THOMSON, Elihu, American inventor and electrician: b. Manchester, England, 29 March 1853. In 1858 he came to the United States, was educated in the public schools in Philadelphia and from 1870 to 1880 was professor of chemistry and mechanics in the Central High School there. After a visit to the Paris Exposition in 1878 he became interested in the subject of lighting by electricity and his experiments, carried on with the aid of E. J. Houston, resulted in patents secured in 1878 and 1879. The following year he became electrician to the American Electric Company, afterward known as the Thomson-Houston Electric Company. This, by consolidation with the Edison Company in 1892, became the General Electric Company, the largest plant for producing electrical machinery in the world. His patented inventions in electrical appliances number over 600 and many of them have come into universal use. Among these are the three-coil armature for dynamos and motors; the induction-coil system of distribution; the induction motor; the constant-current regulator for arc-lighting dynamos; the process of welding metals by electricity; the magnetic blow-out for switches and fuses and the electric meter for direct and alternating currents. Since 1892, when the General Electric Company established its plant in Lynn, Mass., he has resided there, retaining his connection as consulting electrical engineer. In 1889 he became president of the American Institute of Electrical Engineers, and in 1890 received from the Paris commission half the prize of 10,000 francs for his meter. He was decorated in 1889 for electrical inventions by the French government as Officer et Chavalier de la legion d'Honneur; given the honorary degrees of A.M., Yale, D.Sc., Harvard and Ph.D., Tufts; has received many medals and awards, among which is the Rumford Medal, and was awarded Grand Prix at Paris expositions of 1889 and 1900. He is past president of the American Institute of Electrical Engineers, Fellow of American Academy of Arts and Sciences, member of the Institution of Civil Engineers, London, the American Chemical Society, the American Physical Society, the National Academy of Sciences and of many other societies, and was official United States delegate to Chamber of Delegates, Electrical Congress, in 1893 at Chicago. He has been for many years a Fellow of the American Association for the Advancement of Science, serving as vice-president at the Columbus meeting, Section B, Physics; and has been vice-president of the American Physical Society. He was president of the International Electrical Congress at Saint Louis in 1904 and also president of the Chamber of Official Delegates at the said Congress. He was elected honorary member of the Institution of Electrical Engineers of Great Britain in 1904. In 1909 he was elected president of the International Electrotechnical Commission, succeeding the late Lord Kelvin in that capacity upon the decease of the latter. Professor Thomson was the first recipient of the Edison medal and also received the award of the Eliott Cresson gold medal by the Franklin Institute, Philadelphia, for his electrical work. Among the most notable of his papers prepared for scientific societies are that on 'Electric Welding,' read before the Boston Society of Arts in 1886, and one prepared for the American Institute of Electrical Engineers in 1887, on 'Novel Phenomena of Alternating Currents.'

THOMSON, Frank, American engineer and railroad president: b. Chambersburg, Pa., 5 July 1841; d. Merion, Pa., 5 June 1899. As a student he acquired a thorough practical and scientific knowledge of mechanical engineering, so that when he quit the shops of the Pennsylvania Railroad at Altoona, he was able to build a locomotive. As chief assistant to the Assistant Secretary of War he constructed roads and bridges and superintended the transportation of troops during the Civil War; after which he was appointed superintendent of the eastern division of the Philadelphia and Erie Railroad. He re-entered the service of the Pennsylvania Railroad in 1873 and as superintendent of the eastern system constructed the excellent road-bed and introduced the standard track. From 1897 until his death he was president of the company.

THOMSON, George, Scottish song collector: b. Limekilns, Scotland, 4 March 1757; d. Leith, Scotland, 18 Feb. 1851. He was educated at Banff and in 1780 removed to Edinburgh where he became junior clerk to the board of trustees for the Encouragement of Arts and Manufactures. He was subsequently promoted to be chief clerk, an office he held until his retirement in 1839. In 1792 he conceived the plan of making a complete collection of Scottish airs, secured the services of such well-known authors as Campbell, Scott and Burns to supply words for the melodies where necessary and since there was neither prelude nor coda to the songs he engaged Pleyel, Haydn, Beethoven, Mozart and others of note to remedy the deficiency and also to compose accompaniments for them. The results of his labors were published as follows: Scottish airs (6 vols., 1793–1841); Welsh (3 vols., 1809–14), and Irish (2 vols., 1814–16).

THOMSON, James, Scottish poet: b. Ednam, Roxburghshire, 11 Sept. 1700; d. Richmond, Surrey, 27 Aug. 1748. He was educated at the University of Edinburgh in 1715 and at first intended to enter the ministry, but in 1725 went to London to devote himself to literature. His poem on 'Winter' was published in the following year, in 1727 it was followed by 'Summer,' 'Spring' appeared in 1728 and in 1730 the series was completed and published as 'The Seasons.' It was very successful and was followed by his play 'Sophonisba,' produced at Drury Lane in 1730. For two years he was on the Continent as traveling tutor to the son of Charles Talbot, afterward Lord Chancellor, and on the death of his pupil in 1733 was appointed by the young man's father to a sinecure office with a salary of £300 a year. He published a patriotic poem entitled 'Liberty' (1734–36), included in 1736 in the volume with 'Sophonisba' and 'Britannia.' His famous song, 'Rule Britannia,' formed part of 'The Masque of Alfred' (1740), written by him with his friend, David Mallet, to music composed by Dr. Arne. In 1744 Lord Lyttelton conferred upon him the sinecure office of surveyor-general of the Leeward Islands, worth £300 a year. In the same year he issued a new edition of 'The Seasons' with extensive additions and alterations, and in 1748 appeared 'The Castle of Indolence: An Allegorical Poem,' a fine imitation of Spenser. He was buried in the parish church of Richmond. Among his works not already mentioned are 'Agamemnon' (1738), a play; 'Edward and Eleanora' (1739), a play which was published but rejected by the censor; 'Tancred and Sigismunda,' a tragedy (1745), his most successful play, and 'Coriolanus' (1749), a posthumously acted play. 'The Seasons' marks the dawn of a new era in English poetry, an era characterized by a departure from the formation and artificiality of Pope and his school in favor of simplicity and truthfulness to nature. The impulse gathered strength in Gray and Cowper, and reached its fullest expression in Wordsworth. The work found warm admirers in France and other countries and is still read. A good recent edition of Thomson's works is the 'Aldine' (1897) by Tovey. (See SEASONS, THE). Consult Morel, L., 'James Thomson, sa Vie et ses Œuvres' (Paris 1895); 'Life' in Tovey's edition; Bayne, 'Thomson' ('Famous Scots Series,' 1898); Macaulay, G. C., 'James Thomson' (New York 1908).

THOMSON, James, British professor of engineering: b. Belfast, 16 Feb. 1822; d. Glasgow, 8 May 1892. He was a brother of William Thomson, Lord Kelvin, and was graduated from the University of Glasgow in 1839. In 1851 he settled at Belfast as civil engineer and in 1857 became Crown professor of civil engineering at Queen's College. Here he remained unil 1873, when he was called to the similar chair at Glasgow. In early life he was devoted to various inventive purposes, his first being a mechanism for feathering the floats of steamer paddles. More practical was his invention in 1850 of a «vortex water-wheel,» and later of a jet-pump used in draining lowlands, a centrifugal pump and improvements in turbines and in the action of blowing-fans. For many years he was engaged in investigations of the plasticity of ice, his first contribution to the subject (1848) being a paper communicated to the Royal Society of Edinburgh on 'The Effect of Pressure in Lowering the Freezing-point of Water.' The most important of his contributions to this subject dealt with «crystallization and liquefaction as influenced by stresses tending to change of form in crystals.» He also published researches on currents of atmospheric circulation; on the flow of water in rivers and on the jointed prismatic structure seen at the Giants' Causeway. Failure of eyesight caused him to resign his chair in 1889.

THOMSON, James, Scottish poet: b. Port-Glasgow, 23 Nov. 1834; d. London, 3 June 1882. He was trained at Chelsea for the calling of army schoolmaster and after teaching at various regimental centres was discharged from the army with several others for a breach of discipline in 1862. He had gained the friendship of Charles Bradlaugh (q.v.) and contributed to his *National Reformer* over the signature B. V. In 1872 he was in Colorado as agent of a mining company and in the following year went to Spain as a war correspondent for the New York *World*. In 1874 (March to May) he contributed to the *National Reformer* his most famous poem, 'The City of Dreadful Night' (printed in book form, with other poems, 1880), a finished, sombre work, in which his gloomy temperament clearly shows itself. His other publications include 'Vane's Story, Weddah and Om-el-Bonain and other Poems' (1881); 'Essays and Phantasies' (1881); 'A Voice from the Nile and other Poems' (1884); 'Satires and Profanities' (1884), and 'Poems, Essays and Fragments' (1892). His 'Poetical Works' were issued in two volumes in 1895 and a volume of 'Biographical and Critical Studies' appeared in 1896. (See CITY OF DREADFUL NIGHT, THE). Consult the 'Life' by Salt (1889; rev. ed., 1898); also Ward, 'English Poets' (2d ed., Vol. IV, 1883).

THOMSON, John, Scottish painter: b. Dailly, Ayrshire, 1 Sept. 1778; d. Duddingston, 30 Oct. 1840. He studied for the ministry in Glasgow University for a year, in 1793 entered the University of Edinburgh and on his father's death in 1799 succeeded him as minister of his native parish. In 1805 he was presented to the parish of Duddingston, near Edinburgh, and here he rapidly acquired fame as a landscape-painter and developed a close friendship with Sir Walter Scott. His pictures were much in demand and he exhibited frequently in Edinburgh. On the foundation of the Scottish Academy in 1830 he was elected an honorary member, after declining ordinary membership. Many of his pictures are in the National Gallery of Scotland, but a considerable number are hung in private collections. Among the former are 'Bruce's Castle of Turnberry'; 'Ravensheugh Castle'; 'Scene on the Clyde'; 'The Trossachs'; 'Aberlady Bay,' and 'Trees on the Bank of a Stream.' The National Gallery in London contains 'Loch an Eilan' and the South Kensington Museum has a water-color of 'Duddingston Loch.' He felt throughout his artistic life the want of early and systematic training, but he holds a distinct place in the history and development of British art, as the first painter to grasp and express the wildness and power of Scottish scenery. Consult Baird, 'John Thomson' (1895).

THOMSON, Joseph, Scottish explorer in Africa: b. Penpont, Dumfriesshire, 14 Feb. 1858; d. London, 3 Aug. 1895. He was educated at the University of Edinburgh and there distinguished himself so highly that he was appointed in 1878 geologist and naturalist to the exploring expedition sent out to East Central Africa by the Royal Geographical Society under the command of Alexander Keith Johnston. When Johnston died, 28 June 1879, Thomson assumed the leadership of the party and conducted it to Lake Tanganyika and near the head-waters of the Kongo. A mutiny of his followers prevented him from proceeding farther and he returned by way of Lake Leopold, reaching the coast 10 July 1880. In 1882 he set out on a great journey from the east coast of Africa to Victoria Nyanza. This was undertaken on behalf of the Royal Geographical Society and during it he visited Kilimanjaro and Mount Kenia and proceeded through the country of the Masai by way of Lakes Naivasha and Baringo to Victoria Nyanza. In 1885 he was awarded the founder's medal of the Royal Geographical Society and in the same year traveled in Nigeria on behalf of the National Africa Company in order to conclude treaties with the kings of Sokoto and Gando. In 1888 he explored the Atlas Mountains in Morocco and in 1890–91 traveled on behalf of the British South Africa Company in the territory of the Central Africa Protectorate. His travels are described in his works 'To the Central African Lakes and Back: the narrative of the Royal Geographical Society's East Central African Expedition, 1878–80' (1881); 'Through Masai Land: a Journey of Exploration Among the Snowclad Volcanic Mountains and Strange Tribes of Eastern Equatorial Africa' (1885); 'Travels in the Atlas and Southern Morocco: a Narrative of Exploration' (1889). He also wrote a work on 'Mungo Park and the Niger' (1890) and a novel 'Ulu,' with Miss Harris-Smith. Consult 'Life' by J. B. Thomson (1896).

THOMSON, SIR Joseph John, English physicist: b. Manchester, 18 Dec. 1856. He was educated at Owens College, Manchester, and at Trinity College, Cambridge; was lecturer at Trinity in 1883 and since 1884 has been professor of experimental physics at Cambridge. His researches and lectures tend far toward establishing the theory of ions. He has also been an active member of the Society for Psychical Research. He has published 'A Treatise on the 'Motion of Vortex Rings' (1884); 'Recent Researches in Electricity and Magnetism' (1892); 'Elements of the Mathematical Theory of Electricity and Magnetism' (1895); 'Conduction of Electricity through Gases' (1903); 'Corpuscular Theory of Matter' (1907); 'Thermochemistry' (1915), etc. In 1906 he received the Nobel prize in physics and in 1908 he was knighted.

THOMSON, Thomas, Scottish antiquary, elder brother of Rev. John Thomas, the painter: b. Dailly, Ayrshire, 10 Nov. 1768; d. Edinburgh, 2 Oct. 1852. He was graduated from Glasgow University in 1789 and adopting law as his profession, went to Edinburgh and was admitted an advocate in 1793. He acquired a large practice, but gradually devoted himself more and more to the study of legal antiquities. In 1832 he succeeded Sir Walter Scott, who was one of his close friends, as president of the Bannatyne Club. Among his numerous publications are 'The Acts of the Parliament of Scotland, 1424–1707' (10 vols., 1814–24); 'Registrum Magni Sigilli Regum Scotorum, 1306–1424' (1814); 'The Acts of the Lords Auditors of Causes and Complaints, 1466–94' (1839), and 'Acts of the Lords of Council in Civil Causes, 1478–95' (1839); 'Forms of Process in the Court of Session during the Earlier Periods, with the later variations' (1839); 'Chamberlain Rolls' (3 vols., 1817 and 1845); 'Memoirs of Sir George Mackenzie' (1821). Consult 'Memoir' (1854) by Cosmo Innes.

THOMSON, Thomas, British chemist: b. Crieff, 12 April 1773; d. near Holy Loch, 2 July 1852. He was educated at Crieff, Stirling and the University of Saint Andrews, and in 1799 graduated M.D. at Edinburgh. He edited the supplement to the third edition of the 'Encyclopædia Britannica,' to which he contributed the articles 'Chemistry,' 'Mineralogy' and ‹Vegetable, Animal and Dyeing Substances.› In the article ‹Mineralogy› he used the system of symbolic representation, but it is incorrect to describe him as the introducer of this auxiliary of chemical science. In 1800 on the completion of the ‹Encyclopædia,› he began a course of lectures on chemistry, which he continued till 1811, opening, in addition, a laboratory for practical instruction in chemistry, about the first institution of the kind in Great Britain. In 1802 he published the first edition of his ‹System of Chemistry,› which obtained rapid success both in Great Britain and on the Continent. In 1810 he published his ‹Elements of Chemistry.› His ‹History of the Royal Society› appeared in 1812. In 1813 he went to London and began there a scientific journal, the *Annals of Philosophy,* which he continued to edit till the end of 1820. The lectureship in chemistry in the University of Glasgow was conferred on him in 1817, the office being shortly afterward raised to a professorship, and he himself created regius professor of chemistry in 1818. His work on the atomic theory was published in two volumes in 1825, under the title of ‹Attempt to Establish the First Principles of Chemistry by Experiment.› The accuracy of the work was severely criticized by the Swedish chemist Berzelius. Thomson discovered a large number of chemical compounds, such as hyposulphurous acid, chlorochromic acid and a great variety of salts. In 1830–31 he published his ‹History of Chemistry,› and in 1836 appeared his ‹Outlines of Mineralogy and Geology.› In 1846 he retired from his professional duties.

THOMSON, William, English archbishop: b. Whitehaven, 11 Feb. 1819; d. York, 25 Dec. 1890. He was educated at Queen's College, Oxford, of which he was successively Fellow, tutor and head. Ordained deacon in 1842, he was curate at Saint Nicholas, Guildford and Cuddesdon, near Oxford, 1842–47, when he was made tutor of his college, of which he became provost in 1855. In 1861 he edited a series of essays by various writers under the title ‹Aids to Faith,› intended as a counterblast to ‹Essays and Reviews›; and in that year was appointed bishop of Gloucester and Bristol. In February 1863 he became archbishop of York. He was the author of ‹An Outline of the Necessary Laws of Thought› (1842); ‹The Atoning Work of Christ, viewed in Relation to some Current Theories› (1853); ‹Crime and its Excuses› (in Oxford Essays, 1855); ‹Life in the Light of God's Word›; ‹Limits of Philosophical Inquiry›; ‹Design in Nature›; and a series of essays entitled ‹Word, Work and Will.›

THOMSON, William, 1st Lord Kelvin, British mathematician and physicist: b. Belfast, 26 June 1824; d. Glasgow, Scotland, 17 Dec. 1907. He was graduated from Cambridge in 1845, and in 1841 published a paper ‹On the Uniform Motion of Heat in Homogeneous Solid Bodies, and in Connection with the Mathematical Theory of Electricity,› contributed to the *Cambridge Mathematical Journal.* In 1845 he became first editor of the *Cambridge and Dublin Mathematical Journal,* a post which he held for seven years. He was appointed professor of natural philosophy in the University of Glasgow in 1846, and occupied this position for 53 years, till his resignation in 1899. His jubilee as a professor was celebrated in 1896 by many brilliant university functions and distinguished men of science came from many countries to do him honor. Lord Kelvin's contributions to physical science and its applications are very numerous. In all the domains of dynamics, sound, light, heat, magnetism and electricity there are achievements to his credit. The form in which the mariner's compass is now generally employed was patented by him in 1876, and the siphon recorder used in connection with almost all submarine cables was introduced by him in 1867. His extremely delicate mirror galvanometer was also originally invented for the purposes of submarine telegraphy, and in this connection his automatic curb sender is also worthy of notice. His quadrant and absolute electrometers are well known to the student of electrostatics, and his portable electrometer and water-dropping apparatus are of great use in practical meteorology. He published important papers on the theory of magnetism, and the theory of electric images with the associated method of electric inversions is due to him. Lord Kelvin was the first to direct the attention of scientific men to Sadi Carnot's pioneer work in thermodynamics, and it is mainly to his researches and those of Rankine and Clausius that we owe the present advanced condition of that science. The absolute scale of temperature based on the second law of thermodynamics was first proposed by Lord Kelvin. In the building up of the great modern doctrine of the conservation of energy Lord Kelvin took an important part, and the portion of that doctrine known as the dissipation of energy is almost entirely due to him. He also propounded a modified atomic theory in which the atoms are conceived as vortices, and he threw much light on such questions as the age of the earth, cosmic evolutions and geological time. Lord Kelvin, then William Thomson, was associated as electrician with the company which undertook the laying of an Atlantic cable in 1857, and was largely responsible for the success which ultimately crowned this pioneer effort of submarine telegraphy in 1866. He might, indeed, be called the first electrical engineer. He was knighted in 1866, and in 1892 was raised to the peerage as Baron Kelvin of Netherall, Largs, Ayrshire. He was president of the Royal Society from 1890 to 1895, and was awarded the Copley and Royal medals. In 1871 he presided over the meetings of the British Association at Edinburgh. He was Rede lecturer at Cambridge in 1866 and was many times elected president of the Royal Society of Edinburgh. He was awarded the Prix Poncelet by the Institute of France in 1874, and the Helmholtz medal by Germany in 1892. He received so many honors that there is not space to enumerate them. Perhaps the most notable was the jubilee celebration of his professorship at Glasgow University in 1896. The gathering was attended by 2,500 distinguished guests; the ceremonies and jubilation lasted three days. The Grand Cross of the Royal Victorian Order was conferred on him. The city officials joined in the event, cable companies all over the world sent congratulations and a message was sent from the university half around the world, via Newfoundland, New York, San Francisco, New Orleans, Washington and back to London and Glasgow, being received by Lord Kevlin in seven and one-half minutes. Lord Kelvin's most important published work is the well-known 'Treatise on Natural Philosophy' (Part I, 1867; new ed., 1879), written with Professor Tait. An abridged edition has also been published. His other works are 'Papers on Electrostatics and Magnetism' (1873); 'Mathematical and Physical Papers' (1882, 1884, 1890); 'Popular Lectures and Addresses,' and articles in the 9th edition of the 'Encyclopædia Britannica,' some of which have been also published separately. He visited the United States in 1884, in 1892 and again in 1902. Consult his 'Life' by Andrew Gray (1908), and by Thompson, S. P., (1910).

THOMSONITE, one of the zeolite family of minerals ($H_{10}(Na_2,Ca)_5Al_{10}Si_{10}O_{40}$). It usually occurs in columnar forms or radiated concretions of snow-white color; less frequently in distinct orthorhombic crystals (comptonite). It is a hydrous silicate of aluminum, sodium and calcium. It is found filling cavities in igneous rocks in Scotland, the Faroe Islands, Nova Scotia, at Golden in Colorado, and elsewhere. Much so-called thomsonite, including the pebbles of Grand Marais, Minnesota, is mesolite.

THOR, thôr or tôr, in Norse mythology, the god of thunder, son of Odin by Jörd (the earth). He was represented as a powerful man in the prime of life, with a red beard, girt with his girdle of strength, and armed with his mighty hammer Miölnir («the smasher»). He was the foe of the giant demons, and friendly to man. Some have thought him identical with Jupiter; others identify him with the Anglo-Saxon, Thonar. Sacrifices were offered up to him under oaks. Thursday has its name from him. Consult Uhland, 'Der Mythus vom Thor' (1868).

THORACIC DUCT, a vertical canal lying in front of the spine, and receiving the terminations of the lacteal and lymphatic vessels. It is the receptacle for the materials which go to renovate the blood, these materials being derived from the digestion of food and from the elaborated products of the lymphatic glands. From the thoracic duct the chyle or nutrient matter is poured directly into the current of the circulation, the duct opening into the great veins (internal jugular and subclavian veins) lying at the root of the neck on the left side. A second and smaller lymphatic or thoracic duct lies on the right side of the body, and receives the contents of the lymphatics of the right arm and right side of the head. The chief thoracic duct is dilated at its lower extremity, at the junction of the loins and back, into the receptaculum chyli. The contents of the thoracic duct contain the elements of the blood already elaborated.

THORAH, tō'ra, or **TORAH,** in Hebrew literature, a definite commandment laid down by recognized authority. When used with the definite article the word refers specifically to the Mosaic law, that is the Pentateuch; and often to the Ten Commandments.

THORAX, that part of the trunk in higher vertebrates between the neck and abdomen containing the heart, lungs and other viscera, enclosed by the ribs, sternum and thoracic vertebræ. Sometimes the term is restricted to the bony structure that forms the chest. The term is also applied to those segments of the body in *Arthropoda* which lie between the head and the abdomen. Thus in insects there are three segments forming the thorax, named, respectively, the prothorax, mesothorax and metathorax. The prothorax bears the first pair of legs, the mesothorax the second pair of legs and first pair of wings, while the metathorax bears the third pair of legs and second pair of wings. In crustaceans and spiders the head and chest segments are united together to form a single mass, named the cephalothorax. In man and higher vertebrates the thorax is formed by the sternum or breast-bone in part and by the ribs and spine, laterally and behind. In mammals alone is the thorax and its cavity completely shut off from the cavity of the abdomen by a complete diaphragm or midriff. See ANATOMY; OSTEOLOGY, HUMAN; TORSO.

THOREAU, thō'rō, **Henry David,** American «poet-naturalist»: b. Concord, Mass., 12 July 1817; d. there, 6 May 1862. He was graduated at Harvard in 1837 and began in that year the copious journal with which in 1850–60 he filled 30 manuscript volumes, did some teaching at Concord and on Staten Island, N. Y., appeared occasionally as a lyceum lecturer in Concord and other New England towns that chanced to call him, and, until his death, practised at intervals and with great skill his art of pencil-manufacture, making, Emerson said, as good an article as the best English. In 1839 he took the excursion recorded in 'A Week on the Concord and Merrimac Rivers,' which was published in 1849 in an edition of 1,000; the return of 700 as unsalable (1853) afforded him the humorous boast that he had now a fair-sized library all of his own writing. In the course of the voyage there are many phases for speculation and opinion, the result being less a narrative than a collection of essays and discussions. Chiefly for the preparation of this work, but also to undertake an experiment in simplicity of living, and to have opportunity for his observation of wild nature, he lived alone, in a house built by himself, from July 1845 to September 1847, at Walden Pond, not far from Concord village. There, too, he wrote several of his papers and gathered material for his 'Walden, or Life in the Woods' (1854), the best known and probably the most nearly classic of his books. After this episode, which some folk professed to think very odd, «he preferred,» says Emerson, «short work,» building boats, grafting, surveying and other odd jobs, writing meanwhile for current periodicals. In 1846, 1853 and 1857 he went to the Maine woods, and his accounts, partially printed in magazines in his lifetime, were posthumously collected in book form, constituting what is perhaps, after 'Walden,' his most interesting work. Other jaunts to Cape Cod (1849) and Canada (1850) were also described. The titles of these posthumous volumes are 'Excursions' (1863); 'The Maine Woods' (1864); 'Cape Cod' (1865); 'Early Spring in Massachusetts' (1881); 'Summer' (1884); 'Winter' (1888);

Henry D. Thoreau.

'Autumn' (1892); 'Miscellanies' (1894); 'The First and Last Journeys of Thoreau, lately discovered among his unpublished Journals and Manuscripts,' edited by Sanborn (Boston 1905). He refused in 1841 to pay taxes to a government concerned in slavery and war, and was jailed for a few hours. He was said to have aided the escape of fugitive slaves when at Walden. At any rate he sounded the bell to announce Emerson's first anti-slavery address at Concord, and on 30 Oct. 1859 made there a bold public defense of John Brown, later repeated in Boston. As a scientist, it is said that he made few discoveries. His exact knowledge in this domain, however, was gained at first hand; his works abound in interesting observation and fragments of natural history; notwithstanding that when he came to report nature he seems to have valued it largely for what it interpreted to him. He was much of a poet, but lacked metrical facility, and wrote little. Some of his work in verse, such as 'Smoke,' which Emerson thought finer than anything of Simonides, is of a high order. In prose, despite exaggerations and other rhetorical defects, he attained greater certainty of expression. Throughout his writings there is a tonic quality which may in part arise from what John Burroughs, the chief later representative of the school of literary naturalists which Thoreau inaugurated, calls his «stimulating contrariness.» The 20th century has brought a greater appreciation of Thoreau, especially of his prose works, which now appear destined to outlive those of his contemporaries. (See WALDEN). There is a 'Riverside' complete edition (1893); an edition of the 'Letters' by Sanborn (1894). A complete edition appeared in 1906. Consult also Channing, W. E., 'Thoreau, the Poet-Naturalist' (1873; new ed., 1902); Sanborn's 'Life' ('American Men of Letters Series,' 1882); the 'Lives' by Page (1877) and Salt (1890; 1896); Japp, A. H., 'Thoreau: His Life and Aims' (Boston 1877); Marble, A. R., 'Thoreau: His Home, Friends and Books' (New York 1902); More, P. E., 'Shelburne Essays, First and Fifth Series' (New York 1907–08); Payne, W. M., 'Leading American Essayists' (New York 1910); Rickett, A., 'The Vagabond in Literature' (New York 1906); Sanborn, Frank B., 'A Life of Henry D. Thoreau' (New York 1916); Torrey, Bradford, 'Friends on the Shelf' (Boston 1906); an essay by Burroughs in 'Literary Values' (1903), and also lives of Emerson, A. Bronson Alcott and Hawthorne.

THORIANITE, a mineral consisting chiefly of thorium and uranium oxides, about 71 per cent of the former and 12 per cent of the latter, occurs at Norris, Madison County, Mont.

THORITE, a rare but important mineral found almost exclusively in Norway. Theoretically it is an anhydrous thorium silicate, $ThSiO_4$, but all analyses show the presence of considerable water and more or less uranium, lead and iron. The variety orangite, which is of a bright orange to lemon-yellow color, is the richest known thorium ore, containing by analysis 71.65 per cent of thoria. Uranothorite has a dark reddish-brown color and contains 9 to 10 per cent of uranium sesquioxide. Thorite proper is black or very dark brown. It crystallizes in tetragonal crystals isomorphous with zircon, the usual habit being a square prism terminated by a square pyramid. Prismatic cleavage is distinct and the fracture is conchoidal. Its hardness is 4.5 to 5, and the specific gravity ranges from 4.2 in some uranothorite to 5.4 in some orangite. It is transparent in thin splinters to nearly opaque in large or altered masses. Its lustre is resinous, streak yellow to dark brown. Thorite was formerly one of the chief sources of supply of the rare earth thoria and is still of much value for that purpose, though its use has been supplanted.

THORIUM, one of the most valuable of the rare elements. It was discovered by Berzelius in a Swedish mineral and called by him «thorium» after the ancient Swedish god Thor. Found in the minerals thorite, orangite, euxenite, aureite and in monazite sand. This latter substance is found in considerable quantity in Brazil and in North Carolina and is one of the most valuable sources of thorium and of a number of other rare elements related to it. Thorium, symbol Th, atomic weight 232, is a grayish metallic element that can be separated in an elementary condition by heating the chloride, $ThCl_4$, with metallic potassium or sodium. It is soluble in mineral acids and burns brilliantly to the oxide ThO_2, thoria, when heated in the air. This oxide is the most important compound of thorium as it is used together with the oxides of certain other rare elements to form the «mantles» for the Welsbach incandescent gas lights. See MINERAL PRODUCTION OF THE UNITED STATES.

THORN, tōrn, Germany, in Prussia, in the province of West Prussia, on the Vistula, 51 miles southwest of Marienbad. It is an important stronghold, the head of the eighth Prussian fortress district, a railway junction, surrounded by detached forts, and has withstood many sieges, the last being in 1915. It dates from 1231, and its principal buildings comprise the ancient castle, town-house and other gabled and handsome edifices; there is also a statue to Copernicus, who was born there. It was taken from Poland by Prussia in 1793. Its manufactures include machinery, castings, soap and a special gingerbread. There is considerable trade in corn and timber, besides wood, linen, hides, bark and ashes. An important conference was held in 1645 to reconcile Protestant and Catholic differences, presided over by German and Polish churchmen, but was far from meeting with success. Pop. 46,227.

THORN-APPLE. See DATURA.

THORNDIKE, Edward Lee, American psychologist: b. Williamsburg, Mass., 31 Aug. 1874. He was educated at Wesleyan University (A.B., 1895), Harvard (A.B., 1896), Columbia (Ph.D., 1898), and taught in the Western Reserve University (1898–99). He became instructor in psychology in Columbia University (1899–1904) and has been professor there since the latter year. He is author of 'Educational Psychology' (1903); 'Mental and Social Measurements' (1904); 'Animal Intelligence' (1911); 'The Original Nature of Man' (1913); 'The Psychology of Learning' (1914), and many monographs on similar subjects.

THORNE, Joseph, American inventor: b. Marlborough, N. Y., 17 Feb. 1826; d. Sing Sing, N. Y., 4 May 1897. He served through the

Mexican War. Becoming an engineer he associated himself with Elias Howe while the latter was perfecting his sewing-machine. Afterward he was connected with the Singer Company and later established a factory in Scotland. He invented a typewriter, a sewing machine and a typesetting and distributing machine, which bear his name. This last machine was developed in Hartford, Conn. See COMPOSING MACHINES.

THORNHEADED WORMS, or **ACANTHOCEPHALA,** a group of parasitic roundworms (q.v.) of the genus *Echinorhynchus,* having the proboscis armed with a circle of hooks.

THORNHILL, SIR **James,** English painter: b. Melcombe Regis, 1676; d. Thornhill, Dorset, 13 May 1734. Queen Anne appointed him her sergeant-painter and he was much engaged in the decoration of palaces and public buildings, in which his chief works are to be found. Among his best efforts may be mentioned the dome of Saint Paul's, Great Hall at Greenwich Hospital and some rooms at Hampton Court. He also painted the altar-pieces at All Souls and Queen's colleges, Oxford. His forte was in the treatment of allegorical subjects. He was confirmed in his position sergeant-painter by King George I in 1720 and knighted in the same year. Hogarth clandestinely married Thornhill's daughter in 1729, and always expressed great admiration for that painter's works which show invention, even genius, although living critics have not confirmed the favorable verdict of George I and his contemporaries.

THORNS AND SPINES IN PLANTS, acute-pointed projections from the trunks, branches or twigs of plants. A thorn arises from the wood of which it is an outgrowth, whereas a prickle or spine is an outgrowth of the bark and can be removed when the bark is peeled off. The raspberry and the rose are good examples of prickle-covered plants; the hawthorn and some wild plums of plants covered with thorns. Prickles and spines are believed to be useful to the plants which bear them, either as protections against the browsing of animals, as auxiliaries in climbing, holding their position, etc.; thorns are considered to be abortive branches, a deduction based upon the facts that in nature they often bear leaves, and under domestication may develop into branches. Various hawthorns exhibit the former phenomenon and the apple and pear the latter.

THORNTON, SIR **Edward,** English diplomat: b. London, 13 July 1817; d. there, 26 Jan. 1906. He was educated at King's College, London, and at Cambridge University and in 1842 was appointed attaché at Turin. He was engaged in important diplomatic missions to Mexico and the South American states in 1845–65, and in 1865–67 was Minister to Brazil. In 1867 he was appointed Minister to the United States, served on the commission to adjust the Alabama Claims in 1871 and was arbitrator in the commission on the United States and Mexican claims in 1873. He became Ambassador to Russia in 1881, to Turkey in 1884 and in 1887 retired from the diplomatic service.

THORNTON, John Wingate, American author: b. Saco, Me., 12 Aug. 1818; d. Scarboro, Me., 6 June 1878. He took his LL.B. degree at Harvard in 1840; was admitted to the bar and practised in Boston. The honorary A.M. degree was conferred on him bv Bowdoin College in 1860. He was the founder of the New England Genealogical Society and was vice-president of the American Static Association. His published works chiefly include genealogical memoirs of distinguished men and families, including a 'Life of John Bowles,' 'Ancient Pemaquid,' 'Pulpits of the American Revolution' (1860) and the 'Historical Relations of New England to the English Commonwealth' (1874) Consult 'Memoirs of John Wingate Thornton' (Boston 1879).

THORNTON, Matthew, American legislator, signer of the Declaration of Independence: b. Ireland, 1714; d. Newburyport, Mass., 24 June 1803. He came with his parents to America in 1717, lived for a time at Wiscasset, Me., removed to Worcester, Mass., and there received his education. Entering the profession of medicine, he practised at Londonderry, N. H., and in the Louisburg expedition under Sir William Pepperell (1745) served as surgeon. He presided over the provincial convention of 1775; in 1776 became a delegate to the Continental Congress; and although he did not take his seat until November, and had not been elected when the Declaration of Independence was adopted, he was granted the special privilege of signing it. He had already been chief justice of the Court of Common Pleas in New Hampshire when in 1776 he was made a judge of the Supreme Court, and this office he held until 1782.

THORNTON, William, American architect and physician: b. Tortola, West Indies, 1762; d. Washington, D. C.,1827. He was educated as a physician and resided for a number of years in Philadelphia where he was well known for his scientific attainments and was a member of the American Philosophical Society. He was a skilled architect and designed the Philadelphia Library building. Later he removed to Washington and planned the Capitol, of which he partly supervised the construction. He was the first commissioner of public buildings at the national capital and also was first Commissioner of the patent office, to which he was named in 1802. He wrote 'Cadmus or the Elements of Written Language' (Philadelphia 1913).

THORNWELL, James Henley, American educator: b. Marlborough District, S. C., 9 Dec. 1812; d. Charlotte, S. C., 1 Aug. 1862. He was graduated in 1831 from the South Carolina College and studied law but declined to practise and finally was ordained by the Bethel Presbytery in 1834 and became pastor of the Lancaster Court House congregation. He was professor of logic, *belles lettres* and metaphysics in the South Carolina College (1837–39), pastor at Columbus, S. C. (1840), returning to the college as professor of literature (1842–52). In 1841 he visited Europe. He served as president of the South Carolina College (1852–55). He was author of a number of works treating of theological subjects and his writings, edited by Rev. J. B. Adger were published in 1874. Consult Palmer, Ben, 'Life and Letters' (Richmond 1875).

THORNYCROFT, Sir **John Isaac,** English engineer and naval architect: b. Rome, Italy, 1 Feb. 1843. He was graduated from the engineering department of Glasgow University and studied shipbuilding at Govan on the Clyde. He became a builder of torpedo boats and has constructed many such boats for English and other European governments. He is the inventor of the turbine-propeller for use in shallow-draft vessels; and was knighted in 1902.

THORNYCROFT, William Hamo, English sculptor: b. London, 9 March 1850. He received his education at University College School, London, and entered the Royal Academy schools in 1869. He first exhibited at the Academy in 1871 and in the same year went to Italy. He gained a gold medal from the Academy in 1875 for a group representing 'A Warrior Bearing a Wounded Youth From the Field of Battle' and in 1880 he completed his 'Artemis' for the Duke of Westminster. He became R.A. in 1888. He was made an honorary member of the Royal Academy of Munich in 1889 and he received a *médaille d'honneur* at the Paris Exhibition of 1900. His principal works include, in addition to those mentioned, 'Teucer' (1881), now in the Tate Gallery; 'The Mower' (1884); a memorial of the poet Gray (1885) at Pembroke College, Cambridge; a bust of S. T. Coleridge (1885), in Westminster Abbey; 'The Sower' (1886); the National Memorial to General Gordon in Trafalgar Square, London; 'Medea' (1888); a statue of John Bright (1890) in Rochdale; 'The Bather' (1898); 'Lot's Wife'; and many monumental statues, including those of Queen Victoria, Archbishop Thomson (York Minster) and W. E. Gladstone (1902). The style of this sculptor shows a return from pictorial realism toward the severity of Greek idealism. His monumental statues, the best of which is that of Gordon, are some of the noblest in English art, and his heroic figures, such as 'Teucer,' are instinct with life, while exhibiting something of the purity of line and classic grace which belong to the Periclean age of sculpture.

THORODDSEN, thôr'ŏd-sĕn, **Thorvald,** Icelandic physicist: b. Flatey, Breidifjord, West Iceland, 6 June 1855. He was educated at the College of Reykjavik and the University of Copenhagen and was a teacher at the first-named institution, 1885–95. Since the last-named date he has resided in Copenhagen, spending his summers in Iceland, and has made a geological survey of the entire island. Among his publications are 'History of Icelandic Geography' (1892–1902); 'Geological Map of Iceland' (1901); 'Earthquakes in Iceland' (1899); 'History of Icelandic Volcanoes' (1882).

THOROGUMMITE, a rare mineral found only in Lano County, Tex. It is essentially a hydrated thoro-silicate of uranium, containing also ceria, yttria, lead, etc. It is regarded as made up of three molecules of thorite, linked with one of uranic oxide. It is highly valuable as an ore of uranium and thorium. It occurs massive or in crude crystals resembling thorite in form. Its color is dull yellowish-brown; hardness, 4 to 4.5; specific gravity, 4.43 to 4.54.

THOROLD, Canada, town in the province of Ontario, on the Grand Trunk Railroad (Welland branch) and the Niagara, Saint Catherine and Toronto Electric Railway, 26 miles northwest of Buffalo, N. Y. It has four churches, several big flouring mills, a foundry, cement, woodworking and paper mills, knitting, printing and publishing establishments, telegraph offices and ample hotels, a bank and a public library. Pop. about 2,500.

THOROUGHWORT. See Eupatorium.

THORPE, thôrp, **Francis Newton,** American author and jurist: b. Swampscott, Mass., 16 April 1857. He was educated at Lake Shore Seminary, at Syracuse University (Ph.D., 1883; LL.D., 1907). He was Fellow and professor of American constitutional history of the University of Pennsylvania (1885–98) and University of Pennsylvania Law School (1885–86); has been professor of political science and constitutional law, University of Pittsburgh, since 1910. Mr. Thorpe is author of 'The Story of the Constitution' (1891); 'A Constitutional History of the American People, 1776–1850' (2 vols., 1898); 'The Constitutional History of the United States, 1765–1895' (3 vols., 1901); 'A Social and Industrial History of the American People' (1901); 'A History of the United States for Schools' (1902); 'A Short Constitutional History of the United States' (1904); 'The Civil War: The National View' (1906); 'History: The Career of Man on the Earth' (1909); 'The Government of the People of the United States' (1889); 'A Course in Civil Government' (1894); 'The Government of Pennsylvania' (1894); 'The Constitution of the United States With Bibliography for Students of Political Science' (1894); 'The Statesmanship of Andrew Jackson' (1909); 'The Federal and State Constitutions, Colonial Charters and Other Organic Laws of the States, Territories and Colonies Now or Heretofore Forming the United States of America' (7 vols., published by Act of Congress, 1909); 'Benjamin Franklin and the University of Pennsylvania' (1893); 'Franklin's Influence in American Education' (1903); 'The Home and the Household' (1910); 'Business' (1910); 'William Pepper, M.D., LL.D., Provost of the University of Pennsylvania' (1904); 'William Hickling Prescott' (in 'Studies of Great Authors,' 1899); 'The Spoils of Empire' (1903); 'The Divining Rod' (1905); 'An American Fruit-Farm: Its Selection and Management for Pleasure and for Profit' (1915); 'The Essentials of American Constitutional Law' (1917), etc.

THORPE, Rosa Hartwick, American author: b. Mishawaka, Ind., 18 July 1850. She was graduated from the high school, Litchfield, Mich., in 1868, and was married to E. C. Thorpe in 1871. She is widely known by her poem 'Curfew Shall not Ring To-night.' She has published among other works 'Fred's Dark Days' (1881); 'The Year's Best Days' (1889); 'Ringing Ballads' (1887); 'Sweet Song Stories' (1898).

THORWALDSEN, tôr'wâld-sĕn, **Albert Bartholomew (Bertel),** Danish sculptor: b. Copenhagen, 19 Nov. 1770; d. there, 24 March 1844. His father, an Icelander, was employed in the royal dockyard at Copenhagen in cutting figure-heads for vessels, and little Thorwaldsen's first employment was in helping his father. In his 11th year he entered the Academy of Arts, where he gained in 1793, along with a medal, the privilege of studying three years abroad. He resolved to visit Rome, where he arrived in November 1797, and under the inspiration of Canova and Carstens the painter devoted himself to reproducing that ideal beauty of ancient statuary, which became ever after the one object of his artistic life. It was not until 1803 that he became at all widely known. He had finished a model of Jason without finding a purchaser, when the well-known and wealthy Thomas Hope called at his studio and arranged with him to have it executed in marble. The fortune of its designer was now made. Commissions flowed rapidly in upon him, new creations from his hand followed in quick succession and his abilities as a sculptor became everywhere recognized. In 1819 he returned to Denmark, and his journey through Germany and his reception at Copenhagen bore the appearance of a triumph. His first works in this city were the busts of the king and queen. He was next employed by the commissioners for the rebuilding of the Fruekirke or church of Our Lady, to design the decorations for the same, which now form its main ornament. In 1820 he returned to Rome, visiting on his way Berlin, Dresden, Warsaw and Vienna, and receiving numerous orders for works. He remained at Rome till 1838, when he undertook another journey to Copenhagen, being principally moved to this step by the contemplated establishment in that city of a museum of his works and art treasures. His return was a true national festival, both for Copenhagen and the whole of Denmark. With the exception of a short visit to Rome the remainder of his life was spent in the Danish capital, and he both took a vivid interest in the establishment of the Thorwaldsen Museum (q.v.) and enriched it by important contributions. Consult Thiele, ‹Thorwaldsen's Biographie› (1856); Plon, ‹Thorwaldsen sa Vie et ses Œuvres› (1867); both of these works have been translated into English; Hammerich, ‹Thorwaldsen und seine Kunst› (1876).

THORWALDSEN MUSEUM, a building and art collection at Copenhagen raised from funds left by the sculptor Thorwaldsen. The building was constructed after a plan furnished by the architect Bindesböll, and is purely Greek in style. In contains the models and works bequeathed by the sculptor to his native city, which comprise 80 statues from his hand; three long alto-relievos and 130 busts. In the centre of the building is the highly decorated tomb of Thorwaldsen. The museum was opened in 1846.

THOTH, thŏth or tōt, an Egyptian deity identified by the Greeks with Hermes. He was originally the moon-god, and the invention of letters, arts and sciences was attributed to him. The ibis was sacred to him and he is represented with the head of that bird, and with the tau cross in his hand. The dog-headed ape is also one of his attributes, and he is frequently depicted with a dog's head. There were 42 sacred books bearing his name, which were under the guardianship of the Egyptian priests. These books he is said to have composed; and he accordingly appears in the monuments with tables and stylus. He has been identified with the Greek Hermes. See HERMES TRISMEGISTUS.

THOTHMES, thŏth'mēz or tōt'mēz (son of Thoth); the name of four Egyptian kings. Under Thothmes I, Egypt saw its darkest days come to end with the expulsion of the Hyksos, and the revival of truly national art and civilization and of national power. The era of foreign invasion, with the consequent enrichment of the royal treasury, began. Ethiopia was made a tributary state, and eastward the limits of Egyptian power were pushed as far as to the Euphrates. At his death Thothmes I was succeeded by Thothmes II, his eldest son, with Hatasu, his daughter, and Thothmes III, his younger son, as coregents. Thothmes II beautified Thebes, but his reign was brief and insignificant. Thothmes III was the Alexander of Egyptian history. After the death of Hatasu he entered upon that series of wars which comprised 14 campaigns, in the course of which he subdued Palestine, Syria, Mesopotamia in part, and large tracts of territory between the Euphrates and the Mediterranean. The names of the cities he took, including Megiddo and Tyre, are inscribed in his triumphant self-eulogy on the walls of Karnak. He added extensively to the architectural glories of Thebes. As Hatasu, the Semiramis of Egypt, erased the name of the Thothmes II, her half-brother, from his monument at Karnak, so was her name erased with the record of her campaigns, during which she appeared in male attire, from the recording inscriptions by Thothmes III. He reigned from 1503 to 1449 B.C. He was succeeded by Amenhotep II at whose death Thothmes IV began his reign. The latter waged war in Ethiopia, Syria and Phœnicia, but his career was without national or political significance. Consult Breasted, J. H., ‹History of the Ancient Egyptians› (New York 1908).

THOU, too, **Jacques Auguste de** (in Latin, THUANUS), French magistrate and historian: b. Paris, 8 Oct. 1553; d. 7 May 1617. On the revolt of Paris, produced by the violence of the League, he adhered to Henry III, and after the assassination of the Duke of Guise, was principally instrumental in reconciling Henry with the king of Navarre. In 1595 he succeeded his uncle as chief justice, and immediately registered in anticipation of the Edict of Nantes, which he assisted in preparing, the Edict of Saint Germains in favor of the Protestants. In the regency of Mary de Medici he was appointed one of the directors-general of finance, and otherwise employed in nice and difficult matters, in which he was conspicuous for integrity and ability. His greatest literary labor was the composition in Latin of a voluminous ‹Historia sui Temporis,› of which the first part appeared in 1604. When finished it consisted of 138 books, comprising events from 1545 to 1607. It is remarkable for its general impartiality. To this he added ‹Commentaries,› or memoirs of his own life, composed in the same spirit. The most complete edition of the history is that published in London in 1733, by Buckley, in seven volumes. Consult Collinson, ‹Life of Thuanus, with some Account of his Writings› (1807).

THOUGHT, a cognitive relation other than that of direct awareness, born by the mind either toward an object which is believed to exist, or toward a so-called "abstract object," such as a universal, concerning which the question of existence has no meaning. This latter feature distinguishes thought from imagination in the narrower sense which is directed toward objects capable of existence, without involving any belief in their existence. Since it differs from mere presentation, the thought-relation, so far as it furnishes us with any knowledge of its objects, furnishes us with what Bertrand Russell calls knowledge by description — knowledge that is, which may be expressed by propositions. On this account thought can be conveyed by language, for language, though totally unable to transmit an immediate presentation, is well adapted as a vehicle for the relations between presentations, as embodied in propositions. This intimate association between thought and language leads to the nominalist identification of the two, which possesses all the defects inherent in every form of nominalism (q.v.). A more vicious form of this nominalism pervades a large part of the modern psychology of reasoning and consists in the recognition in the mental life of nothing but particulars. The fundamental method of psychology is, of course, introspection. Now, the psychologist receives his training in introspection in the domain of the senses. Here introspection means for the most part the formation of an inventory of the sense-data constituting a given experience. The psychologist consequently acquires the tendency to consider the analysis of consciousness complete when all the mental states of the level of sense-data are checked off and tagged. When he approaches an act of thought, or the consciousness of a universal, or any similar experience, he is likely to find such mental states as he is accustomed to examine, entirely absent, except for a few vague residual organic or kinæsthetic sensations and verbal images. He, therefore, identifies these with the thought-consciousness or universal-consciousness and either concludes that these forms of consciousness add to the mind no constituent elements not already found in sensation, memory, imagination and feeling, or postulates the existence of some substantive mental state not involving images or emotions. Unable to explain how such a barren mental state can be so pregnant with meaning, he has recourse to such unexplanatory phrases as "conscious attitudes." The true reason for the ability of a vague picture of a particular triangle to convey the entire meaning of triangularity, or for power of a verbal image of the law of gravitation to symbolize the law itself, is that the mind is a structure and no structure is exhausted by its inventory.

There is no doubt on earth that whether the consistency or the correspondence theory of truth be valid, a necessary condition of true thinking is that the pattern of thought should agree with the pattern of things. Now, if two patterns agree, we do not have the relations of the parts of one pattern symbolized by the parts of the other, but precisely by the relations between those parts. Accordingly, it is only reasonable to suppose that relations are conveyed in the mind, not by items, but by relations; that qualities are conveyed by qualities; that facts are conveyed by facts. The muscular strain in the orbits that may be the only substantive state in my mind when I think of a certain mathematical theorem is not my consciousness of that theorem, but merely a sort of a mental chalk-mark with which I make myself aware of my reference to the theorem. To call my true consciousness of the theorem either imageful or imageless involves a gross confusion of categories. (See LOGIC; MEANING; PSYCHOLOGY). Consult James, W., 'Principles of Psychology' (New York 1890); Messer, A., 'Empfindung und Denken' (Leipzig 1908); 'Psychologie' (Stuttgart 1904); Ogden, R. M., 'Introduction to General Psychology' (New York 1910); Titchener, E. B., 'Experimental Psychology of the Thought-Processes' (New York 1909).

THOUGHT TRANSFERENCE. See TELEPATHY.

THOUSAND ISLANDS, a group of islands in the Saint Lawrence River (q.v.), near Lake Ontario. For about 40 miles east of Ontario the Saint Lawrence has a width of three to seven miles and here there are about seven large and 1,600 small islands. The belt of Laurentian gneiss which extends from the Adirondacks in New York into Canada is here crossed by the Saint Lawrence River. The crystalline rock and glacial deposit forming the river bed presents an uneven surface; some of the points being above the water form islands. A large number of the islands belong to Canada, the others to the State of New York. Handsome summer residences have been erected on many of the islands and large hotels furnish accommodations for the many city people who visit the place each summer.

THOUSAND AND ONE NIGHTS, The. See ARABIAN NIGHTS, THE.

THRACE, thrās, anciently a part of the Balkan Peninsula, whose territory was somewhat indefinite, but which comprised the region north of Macedonia, including Scythia. Its territory was understood differently at different times by the ancients, but was later limited to the country between the northern boundary of Macedonia and the Danube and that which lies between the Black Sea, the Bosporus, the Propontis and the Hellespont, the Ægean Sea and the Strymon River. The Balkans divided it into two parts — the Romans recognized only the southern division as Thrace. The land was inhabited by wild tribes, abounded in mines, had fertile lands and produced celebrated horses. The chief mountains were the Hæmus (Balkan), Rhodope and Pangæus. The largest river, the Hebrus or Maritza. The chief towns, Abdera where Democritus was born; Sestos and Byzantium. The mythological founders of Greek poetry, music and philosophy are supposed to have come from Thrace. The Thracians were classed as barbarians up to about 475 B.C., when Xerxes invaded the country and introduced some Eastern customs. His rule was short, but Philip of Macedon in the 4th century occupied a portion of the territory, and in 133 B.C. it came under the power of Rome. Native kings maintained a nominal rule, however, for several centuries. About 335 A.D.

Constantine sent a colony of Sarmatians to Thrace and continued to colonize the country. A few years later Thrace was overrun by the Goths and later by Attila and his Huns. In the following centuries a Bulgarian population developed, and about 1450 the country came under Turkish rule. For modern history see BULGARIA; BALKAN PENINSULA; SERBIA.

The Thracians can hardly be regarded as a distinct race, being a mixed people much confused with the Illyrians. The early tribes were low in morals and addicted to phallic worship. Their dialects were closely allied to the Greek. The native deities were Ares, Bendis and Dionysius. See ILLYRIA.

THRASHER, one of the large, thrush-like wrens of the American genus *Harporhynchus*, of which the familiar Eastern species is the brown thrasher (*H. rufus*), one of the most pleasing of American migratory birds. It is about 10 to 12 inches in length, slender, with a long bill and tail, rufous upper parts and a cream-white breast sharply marked with arrow-shaped streaks. A frequenter of orchard and shade-trees, it is as likely to make its nest on the ground or upon bush-piles near the house as at the edge of the woods, and its oblong pepper-and-salt sprinkled eggs are familiar to every country boy. The thrasher in spring utters a highly varied song, so brilliant and full of startling phrases of melody and apparent mimicry that it fairly rivals the performance of the mocking-bird itself. While it eats some grain, it is tolerated because it is destructive to various grasshoppers, worms and bugs. The genus contains several other well-marked and interesting species of the West and Southwest. Consult Coues, ‘Birds of the Southwest’ (Washington 1879); Forbush, E. H., ‘Useful Birds’ (Boston 1913) and ornithologies of the United States generally.

THRASYBULUS, thrăs-ĭ-bū'lŭs, Athenian general and democratic leader: d. about 390 B.C. He was a friend of Alcibiades, whose recall from exile he obtained. In 411 B.C. he commanded a galley in the fleet at Samos, joined in the opposition to the oligarchy of the Four Hundred and exacted an oath from the Athenians in the fleet to uphold democratic government. At the battle of Cynossema he commanded the right wing and secured the victory by a sudden attack upon the Peloponnesians. In 407 B.C., with a fleet of 30 ships, he reduced most of the revolted cities on the coast of Thrace to submission and about the same time was with Alcibiades elected one of the new generals. Banished on the establishment of the Thirty Tyrants, he seized, with the aid of some Thebans, the fortress of Phyle and with an increased force occupied the Piræus. After the accession of the Ten he was defeated by Lysander and Libys, but, together with all who had joined him, was saved from punishment by the contrivance of Pausanias. In 395 B.C. he led an army to the assistance of the Thebans, then menaced by Sparta, and five years later was sent with 40 ships to aid the Rhodians against Teleutias, restored the Athenian interest in Byzantium, secured several new alliances and reduced Methymna and other towns in Lesbos. Afterward sailing south, he anchored in the Eurymedon, near Aspendus in Pamphylia, when the inhabitants, exasperated by some act of his soldiers, fell upon him in the night and killed him.

THREAD. The filaments of fibrous substances spun out for weaving are in a general sense called threads, the specific name of such filaments being yarn. Thread in a specific sense consists of two or more filaments of yarn twisted together for greater strength; when the filaments do not exceed two this is called doubling and the manufacturing process is doubling and twisting. Doubled yarn or thread is used in some sorts of weaving, especially in that called bobbin net, but its principal use is for sewing. When manufactured for this purpose it is specifically known as sewing thread. A large proportion of sewing thread is simply doubled yarn and the processes of yarn doubling and of the manufacture of sewing thread are substantially the same, but thread for sewing purposes often requires to be stronger and firmer in texture than doubled yarn and then three, four and six strands of yarn of fineness proportioned to the thickness of the thread required are used to produce it. The manufacture of sewing thread in the United States is very extensive. The chief seat of the cotton thread manufacture in Scotland is Paisley; in England, Manchester. Linen thread is manufactured largely in Ireland. Cotton was first used in the manufacture of sewing thread at Pawtucket, R. I., by Samuel Salter in 1794. Flax had always been used everywhere, but as Mrs. Salter was spinning cotton she noticed the fineness of the fibre and at once conceived that it would make smooth thread. The idea was put into practice. The operation of «spinning» cotton is really making thread for weaving. A loose cotton called a «roving» is drawn out into a filament or yarn and twisted and wound on bobbins that later go to the weaving machine. See COTTON MANUFACTURES IN THE UNITED STATES.

THREADCELLS. See NEMATOCYSTS.

THREADNEEDLE STREET, London, England, the short thoroughfare faced by the Bank of England, which is proverbially called «The Old Lady of Threadneedle Street.» The name is supposed to be derived from the three needles on the coat-of-arms of the Needlemakers' Guild.

THREADWORM, a common name often used for any of the Nematoda (q.v.). It is distinctly inappropriate when applied to the thick fleshy species like Ascaris and belongs properly to filiform nematodes, especially the Filariidæ. In medical usage the term ordinarily designates the pinworm (Oxyuris) or the whipworm (Trichuris), common intestinal parasites of man. See ROUNDWORMS.

THREAT is defined in law as a menace of destruction or injury to the lives or property of those against whom it is made and may be the subject of a civil action for damages or frequently an equitable action may be maintained to restrain threats and intimidations. One who is induced by threats to enter into an agreement, pay money or do any other act, which in itself is lawful, may by proper means avoid the consequences of such act, same having been performed under duress. One who threatens to do another a bodily harm or to take the life of another may be required to give bond to keep the peace; to threaten a court, or anyone under its immediate protection, is punishable; and in some jurisdictions to obtain a pecuniary advantage by threat is a punishable offense, as is also a threat to accuse one of a crime for the purpose of obtaining money. In many of the United States the offense of sending threatening letters for the purpose of obtaining money is punishable and it is contrary to the postal laws of the United States to send upon the outside of any mailable matter any printed or written threatening language and one is punishable who assists knowingly in forwarding threatening letters. See BLACKMAIL; CORRUPT PRACTICES ACTS.

THREE-COLOR PROCESS. See COLOR PRINTING; PRINTING; ENGRAVINGS.

THREE FATES, The. See NORNS.

THREE HOURS' AGONY, or THREE HOURS' SERVICE, a devotion practised on Good Friday, from noon till 3 o'clock in the Roman Catholic and some Protestant Episcopal churches in commemoration of the Passion. It was introduced by Father Messia, S.J., of Lima, about 1730, and reached Rome in 1738. It was introduced into the English Church about 1865 and was rendered legal by the Act of Uniformity Amendment Act (1872), which permits additional services, consisting of any prayers from the Liturgy or Bible, with address or sermon and hymns.

THREE KINGS, the men who came from the East to adore the Infant Jesus (Matt. ii, 1–12). They are probably called kings from Psalm lxxii, 10, which verse is used in the services of Epiphany. They brought offerings of gold, frankincense and myrrh and according to tradition their names were Gaspar, Melchior and Balthasar. On their return to the East they received baptism. The Empress Helena is said to have brought their bones to Constantinople, whence they were removed to Milan, and afterward to Cologne. In the chapel of the Three Kings, built by the Emperor Maximilian (1459–1519), in Cologne Cathedral, are exhibited their crowns and the shrine is supposed to contain their relics.

THREE-MILE LIMIT. See INTERNATIONAL LAW.

THREE MUSKETEERS, The. If a vote were taken in Europe and America as to the best historical romance ever penned there can be little doubt that it would favor 'The Three Musketeers' ('Les trois Mousquetaires') of Alexandre Dumas. Published in 1844, just three decades after 'Waverley,' this work exemplified Scott's theory of the historical novel to perfection. It focussed interest upon certain minor figures whose fate was linked with that of famous personages and great movements of a bygone day. Unlike the fictions of Scott, however, it freely ordered and changed the facts of history, implying the romancer's emancipation from actuality and his right to shape his story at will so long as it should reflect in general the spirit of the time represented. Dumas had read the 'Mémoires de M. d'Artagnan,' by Gatien Courtilz de Sandras (Cologne, 1701–02). His imagination, thus incited, played over the period of Richelieu's ascendancy, and with unflagging verve and brilliance he described what might have happened to a more courageous and chivalrous d'Artagnan caught in the counter-currents of amorous and political intrigue in 1628.

The plot turns upon the enmity between the queen of Louis XIII and his Minister, Richelieu. The latter seeks to control the queen through his knowledge of her love for Buckingham, attested by her bestowal upon the English lord of certain diamonds, the gift of her husband. Richelieu, for his own ends, arouses the jealousy of the king, who demands that the queen wear the diamonds at a state ball. It behooves the queen, therefore, to recover the gems in all haste, and the difficult mission is undertaken by d'Artagnan and his gallant friends, the three guardsmen. After encountering well-nigh insuperable obstacles d'Artagnan succeeds, but he incurs the enmity of Richelieu's most dangerous agent, Milady Clarik. He falls enamored of her, yet escapes her toils — assassination and poison — only to learn that she is the cardinal's emissary sent to England to threaten Buckingham with exposure unless he will cease his efforts to aid the besieged Huguenots of La Rochelle. D'Artagnan and the musketeers, thereupon, thwart Milady, who, languishing in prison, ere long prevails upon her Puritan jailer to release her and to achieve the murder of Buckingham. Then she contrives to poison d'Artagnan's sweetheart, but, pursued by the avenging guardsmen, is overtaken and adjudged to suffer death for her many crimes. Richelieu, secretly pleased to be relieved of so wicked an ally, pardons d'Artagnan and commissions him a lieutenant of the musketeers.

From first to last, the romance moves at a rapid pace in a world of passion and daring, of hot blood and ready swords, of intrigue and revenge, of jaunty heroism, of splendid loyalty and of dauntless love and friendship. It kicks up its heels, too, now and then, in the mood of rollicking humor. For all its departures from historic fact, it paints in vivid colors a living picture of France in the 17th century. Especially memorable are its portraits. Though Milady prove the villain of melodrama in petticoats, she is far from being a mere lay figure; and Buckingham, Richelieu, the queen, even the lackeys of d'Artagnan and the musketeers, above all these gallant gentlemen themselves, are vital creations. D'Artagnan, the impetuous and generous Gascon, is well matched by his friends, the shrewd and dainty Aramis, the boastful and dandified Porthos, and the melancholy Athos. It is small wonder that the four should have enthralled the minds of readers of every race and clime, and that Dumas, yielding to popular demand, should have continued their adventures in 'Twenty Years After' (1845) and the 'Vicomte de Bragelonne' (1848–50). These sequels and 'The Three Musketeers' are discussed in monographs on Dumas, in French, by Glinel (1884), de Bury (1885), Parigot (1902) and Lecomte (1904), and in English by Fitzgerald (1873), Spurr (1902) and Davidson (1902). The relation of Dumas to Scott is made clear in Louis Maigron's 'Roman historique en France' (1898).

FRANK W. CHANDLER.

THREE-PHASE SYSTEM. See Electrical Terms.

THREE RIVERS, Canada, city, port of entry and county-seat of Saint Maurice County, Quebec, on the north bank of the Saint Lawrence River at its junction with the Saint Maurice, 90 miles below Montreal, 66 miles above Quebec, and on the Canadian Pacific, and connected by ferry with the Grand Trunk Railway. By the French generally named Trois Rivieres. It has a large export trade in lumber and wood-pulp, the Shawanegan and other falls of the Saint Maurice being extensively utilized as water power for these industries; a large iron works, and important manufactures of foundry products and machinery, and other manufactures. The Roman Catholic cathedral is an imposing structure; other handsome buildings are the bishop's palace, the college and several convents, schools, and churches. The city is lighted by gas and electric lights and has hotels, banks and semi-weekly and weekly newspapers. Three Rivers was founded by Champlain in 1634, and a battle was fought here, 8 June 1776, between the Americans and British. The former were outnumbered and defeated. Pop. 13,691.

THREE RIVERS, Mich., manufacturing town in Saint Joseph County, on the Michigan Central Railroad, and at the junction of the Saint Joseph, Portage and Rocky rivers. It has car-building shops, railroad-supply factories, manufactures marine engines, knit goods, tools and paper pulp, and has foundries and brass and machine shops. There is a handsome Carnegie library. Pop. about 5,000.

THREE-WIRE SYSTEM. See Electrical Terms.

THREMMATOLOGY. A term proposed by Ray Lancaster (from the Greek *thremma,* a nursling) to cover the principles and practices connected with the improvement of domesticated animals and plants. It is distinct from evolution in general in that its ultimate purpose is utilitarian. The breeder is interested in definite results, whereas nature is supposed to be indifferent to everything but the «survival of the fittest.» The purpose then in thremmatology is not to make the creature «fit» the conditions of life, but rather to bring both the creature and conditions to harmonize with the highest needs and purposes of man.

This brings to the surface in thremmatology, as a question of prime importance, one that is curious rather than otherwise in evolution, namely: Can the conditions of life be employed directly to influence deviation in the desired direction independently of selection; in other words, can individual modification become hereditary, or as the expression goes in general evolution, are acquired characters inherited?

All students agree that the development of individuals is strongly modified by the conditions of life, that is, the environment. Out in nature if these modifications are not inherited it implies only a little more work for selection, and the final result is the same whether they are inherited or not. The answer to the question is interesting, therefore, rather than vital so long as the study is confined to general evolution; but in thremmatology the answer involves a vital principle because the breeder, especially of animals, cannot afford unlimited selection. All the animals represent money, and the owner is interested in getting results with a minimum destruction of values. He is interested, too, in securing improvements as rapidly as possible, because time is money, and man cannot afford the «countless ages» of nature. If, therefore, individual modifications are inherited, even to the slightest degree, the effect is rapidly cumulative, much time is gained and the necessity for selection is largely reduced,— both important considerations from a business standpoint. Upon the answer to this question will depend the kind of soil and climate employed in plant breeding, the daily care, the shelter, the amount and character of feed provided for breeding animals, as well as the matter of exercise and training where speed or intelligence are involved. That these are important in the development of the individual all are agreed, but it is also necessary that they be provided for breeding stock for the sake of the offspring?

Evolutionists in general are interested primarily in form, while the thremmatologist is concerned very largely, if not mainly, with function. The size or shape of the cow is of less importance than her ability to convert large amounts of feed into milk and do it economically. This faculty depends directly upon the functional ability of a very limited portion of the body and not so much upon the general form. The ability of the horse to attain high speed depends not only upon his conformation but quite as much upon the «quality» of his motor parts, whether active or sluggish, and the mental make-up, whether well balanced or erratic. Functional activity is, therefore, of much more interest in thremmatology than in general evolution, and functional variation is recognized as one of the principal opportunities for improvement.

The systematic study of thremmatology involves the following topics:

1. A working knowledge of the ordinary theories and concepts of general evolution.
2. The kinds of variation; namely, qualitative, relating merely to size; meristic, relating to pattern; and functional, relating to organic activities.
3. Continuous variation in which all values are presented for selection, and discontinuous variation in which some values seldom or never occur, as in the case of sports, in polymorphism and as it is involved in the idea of orthogenesis.
4. The causes of variation, first, as between different individuals of the same generation; second, as between different individuals of the same parentage but of different generations; third, as between different individuals of the same parentage and the same generation, as with twins, litters, etc., without regard to parentage; fourth, as between succeeding generations of the same species, representing deviation of the race; fifth, modifications in the individual during its development plainly due to the conditions of life, rather than to heredity. These different uses of the term variation should be kept distinctly in mind, and even then it is better to use the word «deviation» for the fourth, and «modification» for the fifth form of what is usually called variation. These causes will drop into two groups; first, selective mating, raising

questions touching the basis of selection; second, the environment, raising all questions of the effect of the conditions of life, acclimatization and the inheritance of modifications or acquired characters.

5. Statistical studies of heredity in order to construct the array, eliminate chance, determine the skew, study the laws of regression and progression and the relative influence of parents.

6. Correlation, as determined by correlation tables, and useful as indexes of valuable characters.

7. The practical selection of breeders accompanied by a full appreciation of the financial considerations involved, and the relation between performance and breeding powers as exhibited by livestock records.

8. The testing of sires as a final basis of selection.

9. The importance of selecting for prolific strains, among both animals and plants, and the advantages of vigor and longevity.

10. The disturbing effect of fashion, and the best methods of meeting its demands in breeding without sacrificing real quality.

It is important in the study of this phase of evolution that the breeder have in mind fairly comprehensive ideas of general evolution; that he be not a blind adherent of any peculiar dogma, and that he free his mind from a mass of traditions that serve only to cloud the judgment and deter progress. For example it has been held as a general principle that inbreeding is necessarily fatal to fecundity and to vigor; yet wheat, one of our most vigorous and prolific crops, is systematically inbred. One of the first lessons the breeder should learn, therefore, is that what is true of one species is not necessarily true of all species.

What has been accomplished by way of improvement, and it is much, has been gained almost exclusively by selection, and under disadvantageous circumstances. For example, among plants increase is so rapid as to compel sweeping selections merely for reduction of numbers, not affording opportunity for as good a basis of judgment as if more space and time were at hand. In this way some of the best things are lost. On the other hand among animals numbers are too few for the best selection and the oft-repeated attempt «to establish a small herd of high-class animals» has been as often a failure for the reason that numbers are too few to afford material for proper selection even to maintain the initial standard, to say nothing of improvement.

The well-nigh universal practice of using young sires is fatal to the most rapid progress, for in such cases the selection has been made before full development. Thus some of the worst specimens are accepted because prepossessing at an early age and many of the best are discarded which if given time to fully mature would prove their right to exist.

The practice among the better breeders today is tending toward larger numbers, better conditions of life, the selection of more mature animals, followed by an actual breeding test resulting in older sires, emphasis of those «points» that have their basis in utility, and withal an ideal standard that, once adopted, is changed but slowly, if at all.

As would be expected the most rapid progress has been made in those breeds or varieties of animals and plants in which practically all the individuals can be put to the performance test. For example, it is comparatively easy to get a record from a cow or a speed horse and to know what the one can do at the pail or the other on the track. On the other hand it is impossible to put the meat animals to the actual test without sacrificing the individual as a breeder. Accordingly breeders of beef cattle, swine and other meat-producing animals have been working somewhat in the dark and to relieve the situation many have felt obliged to sacrifice on the block some of their best bred animals in order to test their standards of selection and verify their methods of breeding.

The improvement of animals and plants is a difficult and often a money-losing enterprise, but it is fascinating because of what is possible. By breeding, the sugar content of beets has been increased from 3 or 4 per cent to 12 and even 20 or more per cent. Corn has been bred richer in nitrogen than is wheat, and its oil content is raised or lowered at will. So far as is known any character may be substantially improved and the upper limit of improvement has never yet been reached with any animal or plant.

Many plants, and some animals, have received little attention at the hands of the breeder, and have either become extinct or else exist among us with little or no improvement, except such as has naturally followed upon better general conditions. Conspicuous examples are clover and alfalfa among legumes; timothy and other non-grain producing grasses; asparagus, salsify and many other vegetables and most shade and ornamental trees.

Cats breed without attention and their variations do not, therefore, become fixed. The American bison was allowed to become extinct, not because he would not have become useful if carefully bred, but because he was too near like common cattle to repay the trouble of domestication. In the same way the common hen prevented the domestication of the prairie chicken, but fortunately no real rival stood in the way of that truly American bird, the turkey.

Thus has thremmatology lost much valuable material, but notwithstanding this there is yet at hand awaiting the attention of the master much that is full of undeveloped possibilities, and with the development of our knowledge of the principles underlying heredity and variation great improvements in methods of breeding may be confidently expected.

EUGENE DAVENPORT,
Dean of the College of Agriculture, University of Illinois.

THRESHER SHARK, or FOX SHARK, a well-known shark (*Alopias vulpes*), with a short conical snout and less formidable jaws than the white shark. The upper lobe of the tail fin is very elongated, being nearly equal in length to the rest of the body, and is used as a weapon by which this shark is able to kill or disable many fishes in a school, when he rushes into the midst of the crowd and lays about him. Tail included, the thresher attains a length of 13 feet. It inhabits the Atlantic and the Mediterranean.

THRESHING MACHINES. See FARM MACHINERY.

THRIFT, a stemless fleshy herb (*Statice armeria*) of the seacoasts of the world. It has tufted rosettes of linear leaves with no perceptible difference between blade and petiole and white, pink or purple five-parted flowers, with clawed petals. These blossoms are nearly or quite sessile in compact heads terminating an almost naked scape, and are subtended by brown, dry bracts, the two lowest reflexed, and partly united into a sheath. Thrift is otherwise known as sea-pink or lady's cushion, and is occasionally cultivated for flower-borders.

THRING, Edward, English schoolmaster and author: b. Alford, Somersetshire, 29 Nov. 1821; d. 22 Oct. 1887. He was educated at Eton and King's College, Cambridge, and after taking holy orders and serving as curate at Gloucester and elsewhere, in 1853 was appointed head master of Uppingham School. From an institution run down in efficiency and reputation he made it one of the healthiest, best equipped and flourishing public schools of England. No schoolmaster since Arnold was more successful in imprinting on the characters of his pupils a high ideal of duty as the great end of life. His own earnestness and honesty, his firm discipline and stern denunciation of cowardice and wrong gave character and reputation to the school. Among his published works are 'Thoughts on Life Science' (1869); 'The Theory and Practice of Teaching' (1883); 'Uppingham Sermons' (1886); 'Poems and Translations' (1887); and 'Uppingham and School Songs and Borth Lyrics' (1887). Consult Parkin, 'A Memory of Edward Thring' (1898); Skrine, 'Uppingham by the Sea' (1878).

THRIPS, a genus of minute insects, order *Hemiptera*, suborder *Homoptera*, closely allied to the *Aphides*. They are extremely agile and seem to leap rather than fly, whence the common name "leaf-hopper." They live on flowers, plants and under the bark of trees. *T. cerealium* is a common species, scarcely a line in length or in extent of wing, residing in the spathes and husks of cereals, especially wheat, to which it is most injurious.

THROAT, the front of the neck, including the structures below the chin and above the collarbone, and also, by an extended usage, the passage from the mouth to the stomach (fauces, pharynx and œsophagus), and the passage from the mouth to the lungs (larynx and trachea or windpipe), these being the passages for food and breath. The throat and its various structures are subject to many diseases, some of which are among the most difficult with which medicine has to deal. See NOSE AND THROAT, DISEASES OF.

THROMBOSIS, the formation or development of a thrombus (q.v.) in the heart, blood-vessels, lymphatics or other ducts. It is essentially the coagulation of fibrinogen and is usually induced by some condition which retards the flow of the blood, lymph, etc., such as roughness or other structural change in the lining membrane of a vessel or the presence of some foreign body or some alteration in the constitution of the blood, lymph, etc. In the heart and arteries it seldom occurs unless their lining membranes are roughened or their muscular tone is so much impaired that the blood is not forcibly and readily propelled onward. It is most frequent in veins, where the circulation is naturally slow, and it rarely occurs in capillaries. The thrombi formed may shrink and dry into leather-like masses or calcify, forming phleboliths (in veins) or soften and be absorbed or suppurate; or they may organize, as after the ligaturing of an artery. Some of the causes of thrombosis are: wounds and other injuries, inflammation (see PHLEBITIS; PHLEGMASIA), pressure on a vessel, failure of the propelling power of the heart, as in cases of marasmus and exhausting diseases and bacterial infection of the blood. The symptoms of thrombosis are those of the arrest of the circulation and differ according to the vessel affected. They include passive hyperæmia, venous dilatation, swelling of adjacent parts, gangrene, anasarca of an extremity, etc. The treatment varies according to the seat of the affection. See PATHOLOGY.

THROMBUS, *in anatomy*, a plug or clot formed in a vessel and partially or totally closing it. If it remains at its place of origin it is called a primary thrombus; if it has grown beyond its original limits it is a propagated thrombus; carried by the blood-current from a distant blood vessel and forced into a smaller one, obstructing the circulation, it becomes an embolus. A thrombus consists of coagulated fibrin entangling in its meshes red and white blood-corpuscles or of coagulated lymph, in lymphatics, and the term has been applied (milk thrombus), to an accumulation of curdled milk in a lactiferous tube. Thrombi are designated by various names according to their color, causation, shape, etc. Thus a white thrombus is one which contains no pigment or is composed chiefly of leucocytes; red, one colored by red blood; traumatic, one which results from an injury; infective, one occurring as the result of septic or bacterial poisoning; annular, one which has an opening through its centre, the circumference being attached to the wall of the vessel; and laminated or mixed, one whose substance is disposed in layers, which may differ in material. Thrombi, if small and remaining at the point of origin, may do little or no harm, but they are liable to be swept away and to become dangerous emboli. If they block up the lumen of a vessel they give rise to pain and swelling and to loss of function in parts of the body more or less remote. See THROMBOSIS.

THRONE, a chair of state or superior seat occupied by a sovereign, bishop or other dignitary. The modern throne is usually a decorated arm-chair of great size, raised on a dais and covered with a canopy, more or less ornamented. Anciently the throne was very elaborate; was made of marble, decorated with precious stones, and was frequently supported by pillars or figures representing beasts or men.

THROOP, Enos Thompson, American jurist, governor and diplomat: b. Johnstown, N. Y., 21 Aug. 1784; d. Auburn, N. Y., 1 Nov. 1874. He studied law at Albany and while there began a life-long friendship with Martin Van Buren. He took up practice of law at Auburn in 1807 where he soon entered public life as postmaster and county clerk. He was elected member of Congress in 1814 and in 1823 appointed circuit judge. It fell to his lot to try the Morgan abduction case and his service on the bench gave general satisfaction. Yielding to urgent request, he resigned to allow his name to be placed on the State ticket with Van Buren in 1828 and on the latter's becoming Secretary of State to President Jackson in March 1829, Throop became governor and was re-elected the following year. He served as naval officer at the port of New York, 1833–38, when he was sent by President Van Buren as chargé-d'affaires to the kingdom of the Two Sicilies (Naples). Relieved from this post on the election of Harrison, he spent two years at Paris and then returned home to private life. From 1847 to 1857 he brought a farm of 800 acres at Kalamazoo, Mich., to high cultivation. In the latter year he retired from activity to his former residence, Willowbrook, Auburn, N. Y., where with his nephew, E. T. Throop Martin, and family he shared the friendship of Secretary Seward and entertained such prominent visitors as Washington Irving, Jenny Lind and members of the diplomatic corps at Washington.

THROOP, Montgomery Hunt, American jurist: b. Auburn, N. Y., 26 Jan. 1827; d. Albany, N. Y., 11 Sept. 1892. He was educated at Hobart College in 1846; was admitted to the bar in 1848 and practised in Utica with his uncle, Ward Hunt (1854–56), and with Roscoe Conkling (1856–64). He removed to New York City in 1864; was appointed commissioner to revise the State statutes (1870); was chairman of the commission to revise the Code of Civil Procedure (1877) and removed to Albany in 1880 to devote himself to the publication of law books. He published 'The Future; a Political Essay' (1864); 'The Validity of Verbal Arguments' (1870); 'The New York Justices Manual' (1880); 'Digest of Decisions of the Supreme Judicial Court of Massachusetts' (1887); 'Revised Statutes of New York State' (1888).

THROOP, Pa., borough in Lackawanna County, near Scranton, and served by the New York, Ontario and Western and the Delaware, Lackawanna and Western railroads. Coal-mining is the chief industry and there is also a silk mill in operation. Pop. 5,133.

THROOP (troop) **POLYTECHNIC INSTITUTE,** located at Pasadena, Cal. It was founded in 1891 by Amos G. Throop to provide a liberal and practical education for both sexes. It is entirely non-sectarian, the charter providing that a majority of the trustees «shall not belong to any one religious denomination.» Its organization comprises five schools: (1) the grammar school; (2) the academy; (3) the commercial school; (4) the normal school; (5) the college. The academy offers three courses, classical, literary and scientific; and the college three courses, chemistry, electrical engineering and natural science, all leading to the degree of B.S. Some studies in each course are required, and some elective. Throughout the grammar and high school grades manual training is a regular part of the curriculum; instruction is given in wood carving, sloyd, carpentering, forging, machine-shop work, clay modeling, mechanical and free-hand drawing, sewing and domestic science. The commercial school provides a two years' course; and the normal school three two years' courses in manual training, domestic economy, free-hand drawing and designing, all of which include psychology, pedagogy and history of education. There is also a summer school of art and manual training, designed mainly for teachers; work done in this school is credited toward a normal diploma. The institute (1904) occupies two buildings, Polytechnic Hall and East Hall. The library in 1917 contained 7,000 volumes; and the Pasadena Public Library is also open to students. The productive funds amounted to $600,000, the students numbered 154 and the instructors 38.

THROSTLE, a Scotch name, like «mavis», for the British song-thrush (q.v.).

THRUSH, a bird of the passerine family *Turdidæ,* a family which contains some of the most familiar and attractive birds, and most of the best songsters of the world. They are characteristically but not entirely migratory. A few are only five or six inches in length, but the American robin (q.v.), eight inches is a typical form; and most of them are elegant in form and pleasingly but not gaudily colored. The thrushes are divisible into five subfamilies. The thrushes proper (*Turdinæ*) are represented by such familiar forms as the American bluebird, robin, woodthrush, shy northern hermit and olive-backed thrushes, noted for their richly melodious songs, the English blackbird, song-thrush, missel-thrush and fieldfare, besides the nightingale, robin-redbreast, hedgesparrow and many related forms in other parts of the world, most of which are elsewhere described under their names. Three American thrushes of this group call for brief mention, namely, the hermit thrush (*Hylocichla pallasii*), which is migrant through the Eastern States, breeding in the far north, and is noted for its grand song, which has been said to express «serene religious beatitude»; the olive-back or Swainson's thrush (*Hylocichla ustulata*), distinguished by the olive tint of its upper parts, and also a sweet-voiced emigrant; and the tawny thrush (see VEERY). In all of these the young are spotted, although the adults may be uniformly colored.

The second subfamily is composed of the genera *Myiodectes* and *Cichlopsis.* The third contains the Old World warblers (*Sylviinæ*), fantails, kinglets (qq.v.) and the like; the fourth (*Polioptilinæ*), the gnat-catchers (q.v.); and the fifth (*Miminæ*), the mocking-birds, thrashers (qq.v.) and related forms, many of which seem to imitate other birds, composing their own songs out of a medley of other notes, although the report of this tendency has usually been exaggerated; this last subfamily is by the most modern ornithologists separated from the thrushes and put with the wrens. Consult Evans, 'Birds' (New York 1901).

THRUSH, a form of parasitic stomatitis, due to the presence in the mouth of the thrush-fungus, white-moutte or sprue. (See MOUTH). The disease usually occurs in infants, but may appear later in life, even in old age, in association with some severe acute illness or some wasting disease, as pulmonary tuberculosis. The patches of thrush (technically aphthæ) are most commonly found on the dorsum and edges of the tongue, on the hard palate and on the inside of the lips and cheeks, and resemble curdled milk. Although the fungus may enter and even be formed in a healthy mouth, it will not flourish there. Inflammation or other abnormal condition of the mucous surface, and acid secretions, cause it to grow and develop. Thrush may be propagated by contagion, and in some institutions is at times almost endemic. It may be conveyed from one babe to another through an infected nipple of a nurse, or by means of infected spoons, feeding-bottles, teats, etc. Usually the mucous membrane of the mouth underlying the fungous patches is of a bright or livid red, but when the system of the patient is much deteriorated, and the mycelium has penetrated deeply, shallow ulcerations may result. Sometimes the fungus of thrush is found in diphtheritic membranes. Any doubt as to the nature of white patches in the mouth should be settled by a microscopic examination.

Of itself thrush is not dangerous, but it is usually significant of a deteriorated state of health. Occurring in apparently healthy children, it lasts but a few days; in children having gastro-intestinal catarrh and diarrhœa, and who are much debilitated, it may last for weeks, fresh spots appearing as others vanish. The redness and excoriation around the anus and adjacent skin of infants so affected is vulgarly regarded as an indication that the «thrush has run through the patient,» and if the mouth condition has improved it is considered a favorable sign. While the thrush-fungus has been found in the œsophagus, and even lower in the alimentary canal, there is no reason to believe that it is the cause of the redness and excoriation above referred to, which are rather due to a superficial dermatitis resulting from an excess of starchy food and a vitiated blood state.

Strict attention to diet is necessary in treatment; diminish the amount of sugar and starchy food, and give milk and lime-water. The mouth must be kept clean, and the chance of acidity diminished by dilute alkaline fluids, such as limewater or Vichy. A solution of borax and glycerine, or of sulphite of sodium, should be frequently sprayed upon the patches or applied with the finger, covered with soft cloth. The general health is to be maintained by tonics, hygienic measures and relief of debilitating ailments.

THRUSH, ***in veterinary surgery,*** a diseased condition of the frog of the horse's foot appearing as a severe and acute inflammation, which usually proceeds to ulceration, and which is accompanied by a fetid discharge. It is most frequently seen in horses of unsound constitution, and especially appears in stables where drainage and cleanliness are deficient. The best application for it is mineral tar. Calomel dressing is to be substituted for the tar in severe and intractable cases, and ulcerated and loose parts of the frog are to be carefully removed. Consult 'Report on Diseases of the Horse' (United States Bureau of Animal Industry, Washington 1911).

THRUST FAULT. See FAULT.

THRUSTON, Lucy Meacham, American novelist: b. King and Queen County, Va., 29 March 1862. She was graduated from the Maryland State Normal School in 1880, and was married to Julius Thruston in 1887. She has published 'Mistress Brent' (1901); 'A Girl of Virginia' (1902); 'Jack and His Island' (1902); 'Where the Tide Comes In' (1904); 'Called to the Field' (1906); 'Jenifer' (1907); 'The Heavens of the Unexpected' (1910).

THUCYDIDES, thū-sĭd'ĭ-dēz, Greek historian: b. Attica, about 460 B.C.; d. about 400 B.C. His father's name was Olorus, his mother's Hegesipyle. He possessed gold mines in Thrace opposite the island of Thasos, and was in consequence one of the richest and most influential men in Thrace. In 431 B.C. the Peloponnesian War, which forms the subject of his work, was begun. In 430 the plague broke out in Athens. Thucydides took it, but recovered, and in 424 B.C. commanded a squadron of seven ships at Thasos. The Spartan general Brasidas besieged Amphipolis, and Eucles, who commanded in that important post, sent to Thucydides for aid. Thucydides made all haste in preparing to answer the summons, and seems to have used his private means to forward his equipment, but Brasidas, apprehensive of the approaching relief, offered favorable terms to Eucles, which were accepted, and Thucydides only arrived the day after the surrender. Yet he was in time to save Eion from falling into the hands of the enemies. Whether this transaction led to the banishment of Thucydides, or whether he exiled himself to escape death as its probable consequence, is not known; but from this time he became an exile, and the duration of his exile, according to his own account, was 20 years. Before the conclusion of this term the war terminated (404 B.C.), and all political exiles were permitted to return. Thucydides returned to Athens in the following year; and met a violent death a year or two later, but at what exact time, and whether in Thrace or Athens, is not known. During his exile he remained close to the theatre of the war, of which he was a diligent observer, and as he could not remain in the Athenian dominion he may have passed this period of his life, or the greater part of it, within the domains of the Spartan alliance. It is also probable that he visited Sicily and southern Italy. His history consists of eight books, the last of which differs from the others in containing none of the political speeches which form so striking a feature of the rest, and is also generally supposed to be inferior to them in style. Hence it has been thought by various critics to be the work of a different author, of Xenophon, of Theopompus, or of a daughter of Thucydides; but it is more probable that it is the author's own without his final revision. The history is incomplete, the 8th book stopping abruptly in the middle of the 21st year of the war. As a historian Thucydides holds the foremost place. He was painstaking and indefatigable in collecting and sifting facts, brief and terse in narrating them. His style is full of dignity and replete with condensed meaning. It is, however, sometimes harsh and obscure from over-condensation. He is unsurpassed in the power of analyzing character and action, of tracing events to their causes, of appreciating the motives of individual agents and of combining in their just relations all the threads of the tangled web of history, and his work has been styled the «Statesman's Handbook.» It is to the superiority and impartiality of his judgment that he owed the power of producing a work which should be, as he himself said, a possession for posterity. Among the most valuable editions of Thucydides are those of Bekker (3 vols., Berlin 1821); Classen (8 vols., Berlin 1862–78); Poppo (1821–38); and Stahl (1873–74). There are English translations by Dale (Bohn Classical Library), and Benjamin Jowett (with introduction and historical notes, 2 vols., London 1881; Boston 1883). Consult Bury, J. B., 'Ancient Greek Historians' (New York 1909); Cornford, F. M., 'Thucydides Mythohistoricus' (ib. 1907); Grundy, G. B., 'Thucydides and the History of his Age' (London 1911), also standard histories of Greece.

THUGS, or **THAGS,** a vast fraternity of murderers that formerly existed in India until the British government undertook to crush it out in the early '30 of the 19th century. The practitioners of Thuggee claimed to be a religious sect devoted to the goddess Kali, or Deve or Bhowanee, as she was indifferently called. Composed of Mohammedans and Hindus — mostly the former — the Thugs combined robbery with assassination; they strangled their victims and interred the bodies. They operated in companies of from two to 200, with scouts, «inveiglers,» apprentices and professional stranglers. Some believe that the organization dates back to the days of Alexander or even Xerxes; but more probably it originated with the wild camp-followers and plunderers who followed the Moslem armies of conquest. The craft was hereditary; its followers were divided into Burkas, or persons fully instructed in the art, and Kuboolas, or novices. They were first employed as scouts, then as Sextons, then as shumseeas or holders of hands, and lastly as Bhurtotes or Burkas. The novice became a cheyla or disciple to a high priest of the cult, a gooroo, who conferred the rank or ordination upon the qualified student. The Thugs traveled along the roads as traders or pilgrims, or as Sepoys seeking or returning from service. Sometimes one of their number figured as a rajah with a large retinue of followers. Scouts gathered information about travelers, and «inveiglers» wormed themselves into the confidence of their intended victims. The crimes were usually committed when all were encamped, and two Thugs were appointed to each person to be murdered. Occasions have been known where as many as 60 persons were strangled in one party. The rules of the Thugs forbade the killing of women, fakirs, musicians, dancers, sweepers, oil-vendors, carpenters, blacksmiths, maimed and leprous persons, and Ganges water-carriers. Despite the prohibitions, however, women were frequently strangled. They did not murder white people on account of investigations accompanied by punishment that would surely result. This circumstance accounts for the fact that, although Thuggee was known to exist in the 16th century, it was not partially unravelled till about 1812. At that time there were at least 10,000 Thugs plying their hideous trade; some 30,000 natives vanished annually, leaving no trace behind. In the midst of this reign of terror a savior suddenly appeared in the person of Captain (afterward Maj.-Gen. Sir William) Sleeman, a junior official in the service of the East India Company. He began Thug-hunting in 1830, with the title of «General Superintendent of Operations against Thuggee,» conferred on him by Lord William Bentinck. An Irishman, Molony, had captured a roving band of 115 Thugs in 1823, while another gang was seized in 1826. Within five years Sleeman had thousands of them in prison; 20 Thugs confessed to him that they had participated in 5,120 murders; one, Buhram, who had been a strangler for 40 years, had 931 murders to his discredit; Ramzan had 604, and Futty Khan 508. Sleeman broke the back of the organization. Up to October 1835 no fewer than 1,562 Thugs had been committed; 382 were hanged and 986 transported or imprisoned for life. As a sect they no longer exist, though isolated cases still occur. Consult the annual 'Reports on the working of the Thagi and Dakaiti Department of the Indian Government,' from 1860; 'Ramaseeana: a Vocabulary of the peculiar language used by the Thugs' (Calcutta 1836); *Quarterly Review,* January 1857 and October 1901; Hutton's 'Thugs and Dacoits' (London 1857); Meadows-Taylor, 'Confessions of a Thug' (London 1879); Sleeman, Sir W., 'The Thugs or Phansigars of India' (Philadelphia 1839); and the same author's 'Report on the Depredations committed by the Thug Gangs of Upper and Central India' (Calcutta 1840) and 'Rambles and Recollections of an Indian Official' (London 1844; new ed., August 1915); Sue, Eugene, 'The Wandering Jew' (1844–45).

HENRI F. KLEIN,
Editorial Staff of The Americana.

THULE, thū'lē (Greek, Θούλη), a name given by the ancients to an island or group of islands in the ocean to the northwest of Europe. It was thought to be the northernmost inhabited region of the earth. It is believed to have been the Shetland Islands, though some have identified it with Iceland, and others with both Norway and Jutland. The term «ultima Thule» was used by the Romans whenever reference was made to the farthest distant unknown land.

THULITE, a rose-pink variety of the mineral xoisite (q.v.).

THULSTRUP, Thure de, American artist: b. Sweden, 1848. Graduated from the National Military Academy at Stockholm, he entered the Swedish army in 1865; served in the Franco-Prussian War and was present at both battles of Lyons. He served also in Algeria as an officer in the French army. After studying drawing in Paris he went to Canada, later coming to the United States. In 1872 he joined the staff of the *Graphic* as illustrator; was connected with the Frank Leslie publishing house in the same capacity from 1876 to 1880; when he entered the employ of Harper Brothers. He is especially well known as a military and historical illustrator.

THUMANN, too'män, **Paul,** German painter: b. Tschacksdorf, Brandenburg, 5 Oct. 1834; d. 1908. He was a student in the Academy of Berlin from 1853 to 1855 and subsequently worked under Julius Hubner in Dresden till the year 1860. At Weimar he studied with Ferdinand Pauwels and in 1866 was appointed professor in the art school of that city. From 1875 to 1887 he filled the duties of professor in the Art Academy of Berlin. He was mainly occupied in the illustration of Auerbach's 'Kalender'; Goethe's 'Dichtung und Wahrheit'; Tennyson's 'Enoch Arden'; Chamisso's works; and Heine's 'Buch der Lieder,' etc. His success in this work was due to the powerful drawing, thoughtfulness, and genuine feeling which characterized his style; yet latterly he lapsed into a certain sickly sentimentality and frivolity of treatment which injured the reputation won by his early productions. Among his paintings the best are five canvases which illustrate the life of Luther, executed for the castle of Wartburg; 'The Wedding of Luther'; 'The Return of Hermann from the Battle of Teutoburg Forest'; and 'The Three Fates.'

THUN, toon, Switzerland, (1) a lake in the canton of Bern, 10 miles long by two miles broad. Its surface is over 1,800 feet above sea-level and its greatest depth 712 feet. It forms the outlet of the Aar, which leaves it at the northwest. The lake is enclosed by gentle slopes, covered with villas and orchards, except beyond Sigriswyl, where the north bank is more precipitous. The scenery is idyllic. Fish are plentiful, especially eels, carp, pike, etc. Steamers run from Thun to Interlaken, and an old road follows the coast toward the south, a new one toward the north. The important towns along the banks are Oberhofen (health resort), Spiez and Simmerthal. The first steamer on the lake was launched in 1835. (2) The town of Thun in the canton of Bern is one mile distant, and is the station for travelers touring the Bernese Oberland. It is the principal military arsenal of Switzerland and here is located a military institution for army officers. The noteworthy buildings are the Gothic church and the old 12th century castle. The manufacture of bricks and pottery forms the main industry. Thun was the capital of the canton of Oberland of the Helvetian Republic (1798–1802). Pop. 7,885.

THUNDER. See LIGHTNING AND LIGHTNING-RODS.

THUNDER-BIRD, an imaginary bird occurring in the mythology of races of low culture, and personifying thunder or its cause. Among the Caribs, Brazilians, Algonkins and various other North American Indians and among the Karens of Siam, the South African Bechuanas and Basutos, and other aborigines, there are legends of a flapping or flashing thunder-bird, which seem to translate into myth the thought of thunder and lightning descending from the upper regions of the air, the home of the eagle and the vulture.

THUNDER CLOUD, Mohawk Indian chief and army scout: b. Caughnioga, Canada, about 1856; d. Rochester, N. Y., 1916. He became noted during the Indian troubles (1872–76) and rendered valuable assistance to the United States army, being one of those who helped to capture Chief Red Cloud. In civil life he became celebrated as an artist's model and posed for the leading painters of Indians and Indian scenes. Frederick Remington used him frequently and he appears in various historical groups in the capitol at Saint Paul, Minn., the work of Millet and others. His head appears on the gold coin of the United States for which Victor Brenner selected his profile.

THUNDERBOLT, The, a comedy in four acts, by Sir Arthur Wing Pinero, represents the mature work of one of the most skilful of contemporary English dramatists. In it he discards most of the theatrical conventions which constitute the common stock in trade of the playwright's craft and which he knows how to use with consummate ease and dexterity. He himself modestly describes 'The Thunderbolt' as «an episode in the history of a provincial family.» We are introduced in the first act into a family conclave of the Mortimores. Edward, the only member who has achieved wealth, lies dead upstairs. He was a bachelor and although he had been estranged from his brothers and sister for many years, they are his «next of kin» and presumably his heirs, for, to their delighted surprise, he has apparently left no will nor made any provision whatever for the young woman who is known to be his daughter and whom he has educated and supported lavishly and affectionately. The reactions of the various members of the family to this situation as it develops are portrayed with a ruthless truth and simplicity which remind one rather of Balzac than of the author of 'Sweet Lavender,' 'The Magistrate' and 'The Second Mrs. Tanqueray.' One feels the influence of the conversational play of Shaw and Granville Barker but in 'The Thunderbolt' it is real talk of quite ordinary people, always forwarding the movement of the drama, never halting it for philosophical discussion or brilliant monologue. Pinero is so enamored of his new realistic method that he sacrifices to it the opportunity of an effective «curtain» in the third act. The family is again in council and the thunderbolt has fallen; there *was* a will leaving everything to the daughter, Helen. Thaddeus, having just been forced to confess that it was his wife, not himself, who had found and destroyed this will, flings out of the room with a frantic but futile appeal to the family and the lawyers: «Oh, my God, let me get her away! . . . Don't you harm a hair of her head! Don't you touch her! She's been a good wife to me!» Instead of ending the scene on this poignant note, Pinero makes us linger to watch the exasperated family quarrel and lament over the money they see slipping through their greedy fingers. But greedy and selfish and petty as they are, they are very human, and James' frank statement in the last act of what the money really means to them reconciles one to the solution by which they all get a share, although Helen's magnanimity is perhaps the least natural thing in the play. She is not a very appealing heroine and all the other characters are people one would avoid if possible in real life. There is no love interest, no sex problem, no fun, and but little action. In view of the lack of these elements of popular appeal it is not surprising that 'The Thunderbolt' has not been one of Pinero's conspicuous successes on the stage but to the real lover of the drama and to the student of life, it is his most important play. It was first

produced in London in 1908 and was presented at the New Theatre, New York, in 1910.
GRACE R. ROBINSON.

THUNDERING LEGION. See LEGION, THE THUNDERING.

THÜNEN, tu'nen, **Johann Heinrich von,** German economist: b. Oldenburg, 1783; d. 1850. He received a thorough education in agriculture and also studied at Göttingen. In 1810 he bought an estate in Mecklenburg-Schwerin, which he developed into a model farm. He is known now principally for the economic views expressed in 'Der isolirte Staat in Beziehung auf Landwirtschaft und Nationalökonomie' (3 vols., 1826–63). In this work he sets down simple premises in regard to wages and land, production, markets, etc. His law of wages has found favor among more recent economists. Consult Palgrave, 'Dictionary of Political Economy' (3 vols., London 1899); and Schumacher, H., 'J. H. von Thünen, ein Forscherleben' (2d ed., Rostock 1883).

THURBER, George, American naturalist and writer: b. Providence, R. I., 2 Sept. 1821; d. Passaic, N. J., 2 April 1890. He was educated at the classical and engineering school at Providence; he became a pharmacist and a lecturer on chemistry, finally securing an appointment (1850) with the commission to settle the boundary between the United States and Mexico. He made an important collection of plants and on his return to Providence was given the degree of A.M. by Brown University. He secured an appointment in the Assay Office in New York, lectured on botany in Cooper Institute and on botany and materia medica in The New York College of Pharmacy. Later he occupied the chair of botany and horticulture in the Michigan College of Agriculture but returned again to New York and to lecture at the College of Pharmacy and finally became editor of the *American Agriculturist* for 24 years. In 1880 he visited Europe. He was life member of the Royal Horticultural Society, life member of the American Pomological Society, an active member of the New York Academy of Sciences and corresponding member of the Philadelphia Academy. His collection of Western plants is in the Gray Herbarium at Harvard.

THURGAU, toor'gow, Switzerland, a canton at the northeast, with an area of 381 square miles. Unlike most Swiss cantons it has no high elevations, but a diversified surface, most of which is productive. It belongs to the Rhine Basin and is chiefly watered by the Thur and affluents. There are extensive forests, and the arable lands yield a limited amount of grain and potatoes and grapes — fruit is abundant. Stock-raising and dairying are also carried on. Manufactures consist of linen and hempen cloth, ribbons, lace, hosiery, muslin, buttons and wooden articles. There is considerable trade, owing partly to Lake Constance and the Rhine on its borders. The canton was organized in 1798, although it had been in possession of the Swiss from 1460. For nearly 200 years prior to that time it belonged to the house of Hapsburg. The capital is Fravenfeld. Pop. of canton 140,540. See SWITZERLAND.

THURIBLE. See CENSER.

THURIFER, in Roman Catholic Church services, the attendant at High Mass, Solemn Vespers and Benediction, who uses the thurible, either by simply waving it to and fro or for incensing the clergy, choir and congregation, and who at certain times presents it to the officiating priest that he may incense the altar or the Host. Strictly speaking, the office of thurifer belongs to the acolyte, the highest of the four Minor Orders, but all the functions of the acolyte are now freely performed by laymen.

THURINGERWALD, tü'ring-ĕr-vält, or **FOREST OF THURINGIA,** Germany, a series of mountain ranges centrally located, extending from the Werra near Eisenach southward as far as the valley of the Rodach. The ramifications toward the southeast and the west connect it with the Frankenwald and the Rhön Mountains. The highest elevations are found in the Grosser Beerberg (3,228 feet), and the Schneekopf (3,201 feet), west of Zelle. The entire mountain range is covered to its summit with evergreens and leafy trees and its slopes and valleys present charming landscape and views. The principal streams are the Gera, Wipper, Ilm and Schwarza, flowing into the Unstrut and Saale; the Rodach, Haslach, Steinach and Itz; and the Werra with its affluents — the Hörsel and Leine. There are rich deposits of iron, copper, cobalt, lead and, in the neighborhood of Friedrichroda, alabaster. The valleys and slopes are the scene of an active industry, including porcelain factories, glass-works, wooden manufactures, especially toys, slate, meerschaum and other pipes, firearms and celebrated pottery. Thüringerwald is much frequented by tourists, and the transportation and other facilities are unsurpassed.

THURINGIA, Germany, territorial name still borne by that part of Upper Saxony generally bounded by the Werra, the Saale and the Harz Mountains, though it has no longer any political significance. It was once a much more extensive territory. The name was derived from the Thuringian tribe which occupied it in the 5th century. Much of its area is covered by the Thüringerwald (q.v.). Erfurt is the largest city. The region has had a chequered history, falling in turn to Thuringian, Frank and Carlovingian. It was in turn a kingdom, duchy and mark. (See SAXE-WEIMAR). Consult Devrient, Ernst, 'Thüringische Geschichte' (Leipzig 1907); Knockenhauer, Thomas, 'Geschichte Thüringens in der karolingischen und sächsischen Zeit' (Gotha 1863); 'Geschichte Thüringens zur Zeit des ersten Landgrafenhauses' (ib. 1871).

THURLOE, John, English statesman: b. Essex County, 12 June 1616; d. London, 21 Feb. 1668. He studied law, was admitted to Lincoln's Inn in 1647 and was appointed to a government post in 1648. He took no part in the political events leading to the king's death. On 29 March 1652 he was appointed Secretary to the Council of State under Cromwell; and was also given control of the intelligence department, which duties he performed so remarkably well that it was said that the enemies of the Protector made no move without detection by Thurloe or his assistants. He stood high in Cromwell's regard and enjoyed his confidence to a greater extent than any other adviser. He served in the Parliaments of 1654 and 1656, and was reappointed Secretary of Cromwell's Council of State in 1657. He became chancellor of Glasgow University in 1658. He supported Richard Cromwell's succession after the death of Oliver Cromwell, sat in the Parliament of 1659, continued prominent in government affairs and in 1660 was reappointed Secretary of the Council of State. After the Restoration he was arrested on a charge of high treason 15 May 1660, but was freed subject to attending the secretaries of state whenever they should require his services. His correspondence is in the Bodleian Library, Oxford, and is an important source of historical information. A part of it was published with a biographical sketch by T. Birch (1742).

THURLOW, thėr'lō, **Edward**, Lord, English lord-chancellor: b. Bracon Ash, Norfolk, 9 Dec. 1731; d. Brighton, Sussex, 12 Sept. 1806. He was educated at Caius College, Cambridge, subsequently entered the Middle Temple and in 1754 was called to the bar. In 1761 he attained the rank of king's counsel, and was employed to prepare the evidence for the appeal in the great Douglas cause, which, however, did not come on for hearing in the House of Lords until 1769. In 1768 he was returned as member of Parliament for Tamworth, and became a constant supporter of Lord North's administration. In 1770 he was made solicitor-general, and Attorney-General in 1771. In 1778 he was appointed lord-chancellor, and raised to the peerage as Baron Thurlow. The personal favor of the king retained him in office during the Rockingham administration, whose measures he actively opposed, but he was compelled to resign on the dissolution of the ministry in 1783. He was still considered the confidential adviser of the king, and on the dissolution of the coalition ministry at the close of the year the great seal was restored to him by Pitt. In 1788 the king's illness rendered it necessary to consider the contingency of a regency and Pitt suspected Thurlow of intriguing with the Prince of Wales. Thurlow then began publicly to oppose the measures of his colleagues, particularly Pitt's scheme for maintaining the sinking-fund, in the House of Lords, whereupon Pitt demanded his dismissal, to which the king at once agreed. Consult Campbell, 'Lives of the Chancellors'; Foss, 'Judges of England' (London 1848-64).

THURMAN, thėr'man, **Allen Granbery**, American lawyer and politician: b. Lynchburg, Va., 13 Nov. 1813; d. Columbus, Ohio, 12 Dec. 1895. He was brought, in childhood, to Chillicothe, Ohio, and there received an academic education. After teaching for a time he studied law in the office of his uncle, William Allen (q.v.); in 1835 was admitted to the bar and forming a partnership with his uncle soon attained success as a practising lawyer. At the same time that he began his legal career he became active in politics as a member of the Democratic party, but held no political office until 1844, when he was elected to Congress. He was one of the earnest supporters of the administration in the conduct of the Mexican War; though a Democrat and opposed to any change in the Missouri Compromise (q.v.), he, with the most of the Northern Democrats, voted for the Wilmot Proviso (q.v.), and replied to Southern criticism of this act in a speech stating, forcibly, the reasons of the North for opposing the extension of slave territory. At the close of his Congressional term he resumed the practice of law, and in 1851 was elected one of the judges of the Ohio Supreme Court; here his learned and able decisions won him wide reputation as a jurist. When his term of office expired in 1856 he again took up the practice of his profession, this time in Columbus. He took no active part in politics until 1867, when he was nominated by the Democrats as governor of Ohio; he conductd a vigorous campaign, and though defeated by a small plurality, the Democratic party carried the legislature. In the next year he was elected to the United States Senate and re-elected in 1874. His ability in debate won him immediate recognition, and he was appointed a member of the Judiciary Committee, and became the leader of his party in the Senate; during his last term he was elected president pro tem. He favored a liberal policy of reconstruction, introduced the so-called Thurman Bill compelling the Pacific Railroad to comply with the conditions of their franchise, and succeeded in effecting the passage of this bill against a powerful opposition. In 1876 he was a member of the Electoral Commission (q.v.), and steadfastly supported the claims of Tilden. He was a candidate for the Democratic Presidential nomination in 1876, 1880 and 1884; in 1881 he was appointed a member of the Paris Monetary Conference. In 1888 he was the Democratic nominee for Vice-President and took active part in the campaign; after the defeat of his party in that year, he retired from political life. Consult Hensel and Parker, 'Lives and Public Services of Grover Cleveland and Allen G. Thurman' (Philadelphia 1892).

THURN, Henry Matthias, Count, Bohemian Protestant military leader: b. 1580; 28 Jan. 1640. He served in the Turkish War and for his services was made Burgrave of Karlstein, Bohemia, by Emperor Rudolph I; he was deprived of his estates, however, after he was named one of the Thirty Defenders of the Faith by the Bohemian estates. He was the leader of the Bohemian Protestant insurgents at the beginning of the Thirty Years' War in 1618; invaded Austria and unsuccessfully besieged Vienna in 1619; and was decisively defeated at White Hill in 1620. He afterward served in the Swedish army; and in 1632 fought under Wallenstein at the defeat of Lützen.

THURSDAY, the fifth day of the week, so called from the old Teutonic god of thunder, Thor, the northern Jupiter. The German name Donnerstag is of similar origin; and Thor, Donner, are equivalent to English thunder. Ascension-day is often called Holy Thursday.

THURSDAY ISLAND, Queensland, a small island in Torres Strait, 30 miles from Cape York. It has an excellent harbor, Port Kennedy, which is a port of call and trade depot. Pop. about 2,000.

THURSTON, John Mellen, American statesman; b. Montpelier, Vt., 21 Aug 1847; d. Omaha, Neb., 9 Aug. 1916. His parents took him to Wisconsin, where he was educated in the public schools. He received his education at Wayland Academy at Beaver Dam, Wis., and in 1869 was admitted to the bar. Soon afterward he went to Omaha, Neb., where he spent most of his life. About 1873 he was a member of the city council and was city attorney in 1874–77. In 1875 he was elected to the Nebraska legislature as a Republican and was a presidential elector in 1880. Soon afterward he became counsel for the Union Pacific Railroad. In 1893 the Republican caucus nominated him for United States Senator, but he did not go to Washington until 1895. He remained until 1901. He seconded the nomination of William McKinley for President in 1896, vacating the chair at that convention to do it. From 1889 to 1891 he was president of the Presidential Republican League. In 1901 he became a commissioner of the Saint Louis Exposition.

THURSTON, Robert Henry, American engineer and educator: b. Providence, R. I., 25 Oct. 1839; d. Ithaca, N. Y., 25 Oct. 1903. He was graduated from Brown University in 1859, and received his mechanical training in his father's engine-building shops. In 1861 he joined the engineer corps of the navy, served during the Civil War, was twice promoted, and in 1865 was appointed assistant professor of natural philosophy at the United States Naval Academy. In 1872 he resigned his commission in the navy, and accepted the professorship of mechanical engineering at the Stevens Institute of Technology. He was appointed a member of the United States scientific commission to the Vienna Exhibition in 1873; and in 1885 became the director of Sibley College, the engineering department of Cornell University, and university professor of mechanical engineering. The excellence of the Sibley College curriculum is largely due to his ability as an organizer, and his administration made the college one of the foremost engineering schools of the country. As an inventor he was known for his magnesium burning lamps, army and navy signal apparatus, various forms of testing machines for iron and other metals, and an engine-governor and other improvements on the steam-engine. In scientific research his most noteworthy work was done in investigating the commercial economy of the steam-engine, and in determining the useful qualities of various alloys. His contributions to engineering and scientific literature are also of value, being marked by a clearness of statement unusual in technical writing. The more important of his publications are 'Materials of Engineering' (3 vols., 1884; new ed., 1907–10); 'Manual of the Steam Engine' (1890–1902); 'Manual of Steam Boilers' (1888–1901); 'Engine and Boiler Trials' (1890–1903); 'History of the Steam Engine' (1878–1902). Others are 'Friction and Lubrication' (1884); 'Materials of Construction' (1890–1900); 'Stationary Steam Engines' (1885); 'Friction and Lost Work in Machinery and Mill Work' (1885–1903); 'Heat as a Form of Energy' (1890); 'Life of Robert Fulton' (1891) and numerous scientific papers. Consult Durand, W. F., 'Robert Henry Thurston' (Washington 1904).

THUSNELDA, wife of Arminius (q.v.), chief of the Cherusci, a German tribe which drove the Romans from the Elbe and the Weser in 9 A.D. In 14 A.D. the Roman legions again penetrated the German interior, and Thusnelda was taken captive to Rome by the Roman conqueror, Germanicus Cæsar (q.v.).

THWAITES, thwāts, **Reuben Gold,** American historian and editor: b. Dorchester, Mass., 15 May 1853; d. 1913. He was educated at the high school of his native town and in 1874–75 took a postgraduate course at Yale. From 1876 to 1886 he was managing editor of the Wisconsin *State Journal.* He published 'Down Historic Waterways' (1888; rev. ed. 1902); 'The Story of Wisconsin' (1890); 'The Colonies, 1492–1750' (1891); 'Afloat on the Ohio' (1897); 'Daniel Boone' (1902); 'Father Marquette' (1902); 'Brief History of Rocky Mountain Exploration' (1904); 'France in America' (1905); 'School History of the United States' (1912). He also edited 'The Jesuit Relations' (73 vols. 1896–1901); 'Original Journals of Lewis and Clark' (7 vols., 1905); 'Early Western Travels, 1748–1846' (32 vols., 1904–07), and other works. Consult Turner, F. J., 'Reuben Gold Thwaites' (Madison, Wis., 1914).

THWING, twĭng, **Charles Franklin,** American college president: b. New Sharon, Me., 9 Nov. 1853. He was graduated at Harvard in 1876, and at Andover Theological Seminary in 1879; received the honorary degees of S.T.D., from Chicago Theological Seminary in 1889, LL.D., from Marietta College in 1894, from Illinois College in 1894, from Waynesburgh College in 1901, from Washington and Jefferson College in 1902, and from Kenyon College in 1910; was ordained Congregational minister in 1879; was pastor of North Avenue Congregational Church in Cambridge, Mass., 1879–86, of Plymouth Church in Minneapolis, 1886–90, and president of Western Reserve University and Adelbert College since 1890. He is associate editor of *Bibliotheca Sacra* since 1884, secretary of the Carnegie Foundation for the Advancement of Teaching, and president of the Intercollegiate Peace Association. President Thwing is the author of 'American Colleges: Their Students and Work' (1878); 'The Reading of Books' (1883); 'The Working Church' (1894); 'Within College Walls' (1894); 'The College Woman' (1894); 'The American College in American Life' (1900); 'College Administration' (1900); 'The Best Life' (1900); 'The Choice of a College' (1901); 'God in His World' (1902); 'The Youth's Dream of Life' (1902); 'If I were a College Student' (1902); 'A Liberal Education and a Liberal Faith' (1903); 'College Training and the Business Man' (1906); 'Higher Education in America, A History' (1906); 'Education in the Far East' (1909); 'History of Education in the United States since the Civil War' (1910); 'Universities of the World' (1911); 'Letters from a Father to His Son entering College' (1912); 'Letters from a Father to His Daughter entering College' (1913); 'The Co-Ordinate System in the Higher Education' (1913); 'The Family: An Historical and Social Study' (1886 in collaboration with Carrie Butler Thwing, revised 1913); 'Education according to Some Modern Masters' (1916) and contributions to magazines.

THYESTES, thī-ĕs'tēz. See ATREUS.

THYLACINE, an Anglicization of the generic term *Thylacinus* given to the predatory marsupial called Tasmanian or zebra wolf, and described under DASYURE (q.v.).

THYME, one of the species of the labiate genus *Thymus,* small, shrubby, perennial herbs of the Old World, cultivated on account of their aromatic foliage as flavoring herbs, or for ornament. *T. vulgaris,* an erect, or somewhat decumbent plant, from one to two feet high, has sessile linear-lanceolate leaves with revolute margins. The pale-lilac flowers are small, and in interrupted spikes at the ends of the branches. Thyme has a very strong and pungent odor, and was formerly employed for seasoning. It is a favorite food of bees, and that of the Grecian hills produced the famous honey of Mount Hymettus. Another thyme, sometimes grown as a culinary herb, but more often to cover rock-work and waste places, is the creeping thyme or mother-of-thyme (*T. serpylliformis*). Its internodes are short, so that the plant is very leafy, and it grows in dense, broad tufts. One of its varieties (*citriodorus*), is the lemon-scented thyme. Oil of thyme is distilled from these plants, especially in France, where they are very abundant, and may be used in perfumery instead of the oil of origanum, and is of utility in veterinary practice. Thymol is a solid, acrid stearoptene obtained from this oil, and is used, chiefly externally in alcoholic solution, for a stimulant and powerful antiseptic in the treatment of wounds and sores. Other labiates called thyme, from their aroma, are *Calamintha acinos,* and *C. nepeta,* the basil thyme, and *C. clinopodium,* the horse-thyme. The cat-thyme is the herb-mastic, or *Teucrium marum,* a powerful sternutatory, useful for its scent. Virginian thyme is *Koellia virginiana.*

THYME OIL, a volatile oil obtained by distilling the leaves and flowering tops of *Thymus vulgaris,* or garden thyme, with water. Colorless when pure, sparingly soluble in water, easily so in alcohol. It contains two hydrocarbons pinene, $C_{10}H_{16}$, and cymene, $C_{10}H_{14}$, as well as a phenol-like body thymol. Used in liniments and dressings as a stimulant and antiseptic.

THYMOL, *in chemistry,* $C_{10}H_{14}O$, a colorless crystalline compound obtained from the oil of thyme, horse mint, etc. Often called thyme camphor. Its chemical nature is analogous to that of phenol, or carbolic acid, though it has but little of the caustic properties of that body. It crystallizes in plates, is almost insoluble in water, soluble in alcohol, melts at 44° C., and is very easily attacked by many chemical agents. It has a very strong odor and is used as an antiseptic and disinfectant. Iodine and caustic potash convert it into di-iodo-thymol, which is the well-known antiseptic aristol.

THYMUS GLAND, one of the ductless glands, existing as a temporary organ, developed to its full size about the end of the second year of life and decreasing in size after that period. At puberty it almost or wholly disappears. At its full development it appears to consist of two lobes or halves, situated in the middle line, and placed partly in the neck, extending from the cartilage of the fourth rib upward as high as the inferior edge or border of the thyroid gland (q.v.). It is covered in front by the breastbone, and by the sternohyoid and sternothyroid muscles. It rests upon the pericardium or heartsac, and lies on the neck on the front and sides of the trachea or windpipe. This gland is of a pink-gray color, exhibits a lobulated appearance, and is of soft consistence. Its weight at birth is about half an ounce. Its microscopic structure exhibits a composition of lobules, each lobule being formed of regularly disposed masses of what is termed lymphoid tissue, consisting of a meshwork of exceedingly delicate connective tissue, the meshes being crowded with round cells identical with the white corpuscles of the blood and lymph corpuscles. The functions of this gland are still undetermined. It is placed in the same category as the thyroid gland and spleen; and the most probable theory as to its use is that which assigns to it the work of elaborating the elements of the blood, especially in the earlier years of life. It is generally believed to exert a strong influence on growth and development. It is employed in organotherapy (q.v.). The well-known 'sweatbread' is the thymus gland of a calf or lamb.

THYRIDOPTERYX, a genus of foliage-destroying insects. See BAGWORM.

THYROID GLAND, a structure having no outlet or duct, and classified with the spleen, thymus gland and suprarenal capsules under the general name of ductless glands. In man the thyroid gland is situated at the upper part of the trachea or windpipe and consists of two halves or lobes, placed one on each side of the windpipe, and united by a narrow bridge of substance — the isthmus of the gland. It is covered in front by the muscles of the neck and its sides lie in contact with the common carotid artery. Its under surfaces embrace the windpipe and larynx. This gland is of a reddish color. It is larger in women than in men, and weighs, on an average, about one and one-half ounces. It may become enormously enlarged, as in goitre. Its structure consists of numerous small shut sacs, surrounded by a network of capillary blood-vessels. Each vesicle or shut sac is lined internally by a single layer of columnar cells, and is filled with a glairy mucoid substance. The blood-vessels of the gland are derived from the superior and inferior thyroid arteries and its nerves come from the pneumogastric and sympathetic trunks. The use of this gland is not quite clear, but is generally held to be the production of a secretion which has a great influence on alimentation. Its business is connected with the maintenance of a proper quality of blood, either by the removal of certain effete substances from the blood, or by the addition of certain elements to it. Its complete extirpation or atrophy is attended with disease. The thyroid gland of the sheep is used in the treatment of myxœdema, the complication resulting from the loss of function of the gland.

THYROID GLAND, Diseases of. Several varieties of enlargement have been noticed in the thyroid and are generally grouped under the general term goitre (q.v.). Myxœdema is the condition resulting when the gland ceases to function either because of atrophy or of the excision of the organ. The thyroid gland of the sheep is used in the preparation of an extract which is efficacious in the relief of this condition. See CRETINISM; SECRETIONS, INTERNAL; THYROID GLAND.

THYRSE, thẽrs, a form of inflorescence consisting of a compact panicle in which the middle pedicels are the longest, giving the whole an ovate shape. The primary pedicels are centripetal, and the secondary centrifugal. The horse-chestnut and lilac furnish examples.

THYSANURA, an order of neuropteroid insects. See BRISTLETAILS.

TIAHUANACO, tē-ä-wä-nä'kō, Bolivia, the ruins of a prehistoric city, near the south shore of Lake Titicaca, in lat. 16° 42′ S., long. 68° 42′ W., about 40 miles west of La Paz city. The ruins stand on an eminence 12,930 feet above sea-level, which, from the water marks around it, seems to have been formerly an island in Lake Titicaca. The level of the lake, however, is now 135 feet lower, and its shores two miles distant. This fact, in conjunction with others, warrants the belief that these remains antedate any others known in America; they indicate a different and higher order of art than was found to exist at the time of the Spanish conquest, in any other part of that Continent. The ancient Peruvians had but the vaguest traditions concerning them, believing that the structures of which they are the remains were raised in remote ages, by giants, in a single night. The chroniclers of the Spanish conquest have described them, and their accounts do not differ materially from those of modern travelers. They are in a state of extreme dilapidation. Some of the structures seem to have been built on a pyramidal plan, and to have covered several acres; but the most remarkable features still remaining are monolithic doorways, pillars and statutes of stone, elaborately sculptored in a style wholly different from any other remains of art yet found in America. One of these doorways is 10 feet high, 13 feet broad, with an opening six feet four inches by three feet two inches, the whole cut from a single stone. Its east front has a cornice in the centre of which is a human figure of strange form, crowned with rays, interspersed with serpents with crested heads. On each side of this figure are three rows of square compartments, filled with human and other figures, of apparently symbolic design. The statues are broken, so that it is difficult to state their original dimensions; but these may be inferred from the size of the head of one, which is four feet in length and of proportionate width. The whole neighborhood is strewn with vast blocks of stone elaborately wrought, some of which measure three feet in length by 18 feet in width, and six feet in thickness. Some of these stones have been found to weigh as much as 400 tons and were transported many miles. No mortar was used in the masonry; stones grooved and tongued were held together with clamps and bronze pins. Dressing and carving of stones was done with stone and bronze tools. On some of the islands of Lake Titicaca are other monuments, of great extent, but of true Peruvian type, apparently the remains of temples destroyed on the arrival of the Spaniards. Those of the island of Coati, however, have many features in common with the ruins of Tiahuanaco, and probably belong to the same epoch, and are to be ascribed to the same unknown and mysterious people who preceded the Peruvians, as the Tulhuatecas or Toltecs did the Aztecs. Not far distant from the ancient site stands the present town of the same name, largely built from stones taken from the old ruins. Consult Stübel and Uhle, 'Die Ruinenstätte von Tiahuanaco' (Breslau 1892).

TIARA, the crown of the Pope, a cylindrical diadem with three crowns and a pointed top surmounted by a mound and a cross of gold, which the Pope wears as a symbol of sovereignty. It is placed upon the Pope's head at his coronation by the second cardinal deacon, with the words, «Receive the tiara adorned with three crowns, and know that thou art Father of princes and kings, Ruler of the world and Vicar of our Saviour, Jesus Christ.» The tiara is not worn upon purely spiritual occasions, the Pope then wearing the mitre of a bishop. The first crown is said to have been added to the mitre by Nicholas I (858–867) as a symbol of uniting the princely crown with it; the second crown was added by Boniface VIII (1294–1303); and the third, first appears on the monument of Benedict XII (1334–42).

TIBALDI, tē-bäl'dē, **Pellegrino,** Italian painter and architect: b. Bologna, 1527; d. Milan, 1598. In 1547 he commenced his profound study of Michelangelo at Rome and painted for Cardinal Poggi, in his palace at Bologna, the 'History of Ulysses.' When Caracci saw these pictures, in which the style of Michelangelo appeared in a softened and refined form he pronounced Tibaldi *il Michelangelo Riformato* — an improved version of Michelangelo. He also decorated the chapel of Saint James for the Augustinians. Among his architectural works are the palace of Cardinal Borromeo at Pavia (1562); the Church of Saint Fidelis at Milan, and the new façade of the cathedral in that city. He likewise furnished Philip II who had summond him to Spain in 1586, with the plan for the Escorial, and painted the ceiling of the library in that palace. Consult Gurlitt, 'Der Barockstil in Italien' (Stuttgart 1887); Zanotti, 'Le pitture di Pellegrino Tibaldi' (Venice 1756).

TIBER, tī'bẽr (Italian, *Tevere*), Italy, a river rising in the Apennines of Tuscany, in central Italy, about 11 miles north of Pieve San Stefano, some 4,000 feet above sea-level. It is one of the largest and most celebrated rivers of the country, has a winding course, flows 244 miles and empties into the Mediterranean, passing many noted cities on its way to the sea, which enters by two branches — the Fiumicino and Fiumara. It is navigable for small craft as far as the mouth of the Nera, a distance of about 90 miles, but for small steamers only as far as Rome where it attains a breadth of about 250 feet. Its principal tributaries are the Nera and Paglia, which also receive their own affluents. The upper course is precipitous and the mountain streams which supply its water are the cause of its frequent overflow and consequent inundations. The chief cities on its route are Perugia, Orvieto, Ostia and Rome. The swift current carries along a vast amount of sediment from which condition arose the name «yellow Tiber,» *flavus*

Tiberis, alluded to by Virgil. Consult Smith, S. A., 'The Tiber and its Tributaries' (London 1877).

TIBERIAS, tĭ-bē'rĭ-as, **Sea of.** See GALILEE, SEA OF.

TIBERIUS, tī-bē'rĭ-ŭs **(TIBERIUS CLAUDIUS NERO CÆSAR),** Roman emperor, son of Tiberius Claudius Nero, and Livia Drusilla, who was afterward married to the Emperor Augustus: b. 16 Nov. 42 B.C.; d. Misenum, 31 March 37 A.D. Brought up in the imperial household, Tiberius had by his conquests in Germany and Gaul gained the confidence of Augustus, by whom he was made a Roman consul. In 11 A.D. he was compelled, in order to retain the favor of Augustus, to divorce his wife, Vipsania Agrippina, and to marry Julia, the emperor's daughter, and in 14 A.D., shortly before the death of the emperor, he was formally adopted as his heir. According to Tacitus, the reign of Tiberius, although marked by cruelty and infamy which could have been possible to only the most profligate and dissolute of men, was rendered less tyrannous than might have been expected, by the strict maintenance of justice in matters of taxation and at times by a certain respect for the privileges of the Senate, and the rights of the common people, a course to be commended in a period of absolute despotism. The atrocious disregard of human life and liberty wherever his own private interests were at stake could, however, scarcely have been equaled. It was in this reign that the crime of «læsa majestas» was established. Consult Jerome, T. S., 'The Tacitean Tiberius' (in 'Classical Philology,' Vol. VII, Chicago 1912); Mommsen, 'The Roman Provinces from Augustus to Diocletian' (1886); Schiller, H., 'Geschichte der römischen Kaizerzeit' (Gotha 1883); Tarver, J. C., 'Tiberius the Tyrant' (New York 1902).

TIBERIUS CONSTANTINE (TIBERIUS II), emperor of Byzantium: b. Thrace; d. Byzantium, 582 A.D. He was brought up by the Emperor Justin II whom he succeeded on the throne of the Eastern Empire in 578. It was during his reign that the great influx of Huns and Slavs in the north and east, and that of the Lombards in the west, began seriously to threaten the Roman empire.

TIBET, tĭb'ĕt or tĭ-bĕt, or **THIBET,** a country of central Asia, under Chinese suzerainty, lying between latitude 28° and 36° N., and between long. 79° and 103° E. It is bounded on the north by East (Chinese) Turkestan, on the east by China proper, on the south by British India, Bhutan and Nepal and on the west by the Indian state of Kashmir. The area is estimated at about 463,200 square miles. Tibet forms the most extensive and loftiest plateau region in the world. It is structurally a complex of faulted mountains whose intervening valleys have been filled up with detritus, converting them into plains whose general level lies from 10,000 to 17,000 feet above the sea, while the mountains tower almost as high again above them. The main Himalaya range runs along the southwestern boundary and the Karakoram with its outrunners traverses the western part of the country. These ranges have numerous peaks between 20,000 and 29,000 feet in height. On the northern boundary runs the Kuen-Lun Range, sending numerous spurs and offshots into the plateau. The eastern half of Tibet is traversed by a system of more or less parallel ranges with a southeast trend. The enclosed plains in western and northern Tibet form closed drainage basins, very poorly watered, and containing salt lakes. The eastern longitudinal valleys are drained by the headwaters of the Yang-tse-kiang, Hoang-ho and Salwin rivers and in the south, along the northern base of the Himalayas, run the Indus to the west and the Brahmaputra to the east. The climate is excessively dry, with great and sudden fluctuations in temperature, and severe cold and biting north winds in winter. The vegetation is scanty and characteristic of desert and alpine regions. There are green meadows only along the streams and in the eastern mountains are forests of birch, poplar and coniferous trees. Wild animals are very numerous along the watered regions and antelopes, yak oxen and wild asses are characteristic of the steppes.

The inhabitants, who number about 2,000,000, are of a semi-civilized Mongolian race somewhat akin to the Burmese. In the north they are nomadic, but in the south they are settled in substantial houses of stone or sun-dried brick, and cultivate the soil along the river valleys. The industries are not important, but there is a considerable trade with China, and wool, furs, musk, gold, borax and salt are exported. The language of the people is similar to the Chinese, but has taken on polysyllabic characters. A considerable amount of literature, mainly religious, has been accumulated, and printing has been practised for centuries. The prevailing religion is Buddhism, of the form known as Lamaism. The priesthood is exceedingly numerous and the government is a theocracy. At its head is the Grand Lama or Dalai Lama, who resides at Lhasa (q.v.), the capital, and who claims to be the head of the Buddhist world. This priest government has enforced a strict exclusion of non-Buddhist foreigners, particularly from the capital. A Chinese resident was permanently stationed at Lhasa. Russian diplomatic influence seemed to have gained a foothold in Tibet when, in 1903, the British Indian government took the occasion of the non-compliance of the Tibetans with the terms of the treaties of 1890 and 1893, governing frontier trade relations, to send a military expedition across the boundary. The avowed purpose was to negotiate with the Tibetan government, but the latter declined to negotiate and the British column pushed on toward Lhasa. On 31 March 1904 at Guru where the Tibetans had built a wall across the highway to oppose the advance, 1,500 of their soldiers were flanked and effectively enclosed in a circle. An attempt to disperse them, and make them retire without firing on them, was met by the Tibetan general wounding a Sikh by a pistol shot which was the signal for a general onslaught by the Tibetans. A terrible magazine rifle fire, and the bringing into action of a mountain battery resulted in the slaughter of about 400 of their soldiers, the British subsequently occupying their camp. The advance also met with serious opposition at the Karo-la, and at Gyantse jong or castle, where for a time they were besieged by thousands of Tibetans. The expedition eventually reached Lhasa; after long negotiations, ended only by the threat of enforcing compliance, Colonel Younghusband concluded a treaty which was afterward censured by the Indian government as in excess of his instruction. Protest from the Chinese government led to the Anglo-Chinese convention in 1906, whereby British evacuation of Chumbi Valley was secured and China, as Suzerain power of Tibet, paid an indemnity of 2,500,000 rupees. The agreement entered into between the two countries at this time was further strengthened by the conclusion of trade regulations between India and Tibet (1908). At the time of the Chinese Revolution in 1911 the Tibetans expelled the Chinese garrison, and an expedition subsequently sent out from Szechuan and Yunnan was withdrawn because of Great Britain's disapproval. In 1912 the British government outlined its attitude toward the Tibetan question, in accordance with the provisions of the treaty of 1906, objecting to Chinese assertion of sovereignty over Tibet. A tripartite conference was opened at Simla in 1913, but was dissolved without reaching any satisfactory agreement. Since that time Great Britain has declined to reopen negotiations. Consult Coales, O., 'Eastern Tibet' (in *Geographical Journal*, April 1919); Gerard, F., 'Tibet: The Country and its Inhabitants' (tr. from French, London 1904); Landon, P., 'Lhasa: The Tibet Expedition, 1903–04' (2d ed., London 1906); Lansdell, H., 'Chinese Central Asia' (2 vols., London 1893); Rijnhart, S. C., 'With the Tibetans in Tent and Temple' (London 1901); Younghusband, F. E., 'India and Tibet' (London 1910).

TIBET DOG, or **TIBET MASTIFF,** a breed of dogs about the size of a Newfoundland dog, but with a head resembling that of the mastiff, and having the flews large and pendent. The color is usually deep black, with a bright brown spot over each eye; the hair is long and the tail bushy and well curled. This variety is extremely savage, and has been known from classic times, when it was employed by the Romans, especially under the emperors, in the games of the circus.

TIBIA. See ANATOMY; OSTEOLOGY, HUMAN.

TIBULLUS, Albius, Roman poet: b. about 54; d. about 19 B.C. He belonged to the equestrian order, and was on intimate terms with Messala (q.v.), whom in 31 he accompanied in a campaign in Aquitanian Gaul. He set out with him thence to the East also, but was forced through ill-health to land and be left behind at Corcyra. Henceforth he lived on his estate, between Tibur and Præneste. Horace was warmly attached to him and addresses to him one of his epistles, in which he credits his friend with the possession of a tender heart, beauty, wealth, good health and good taste in enjoying life. There are four books of elegies under his name, but the third and a part of the fourth are spurious. These poems are among the most perfect of their kind which have come down to us from classical antiquity. The elegies of Tibullus are characterized by agreeable simplicity and tender feeling, and are free from the insipid prolixity into which Ovid frequently falls. The chief editions are those of Bährens (Leipzig 1878); and Hiller (ib. 1885); Lachmann (1829); Müller (ib. 1885); Postgate (1906). There is a translation by Cranstoun (1872). Consult Duff, J. W., 'A Literary History of Rome' (New York 1909); Sellar, W. Y., 'Horace and the Elegiac Poets' (Oxford 1892); Teuffel, W. S., 'Geschichte der römischen Literatur' (Vol. II, 3d ed., Munich 1911).

TIBURON, tē-boo-rōn, Mexico, an island in the Gulf of California, situated in the upper part of the gulf, 230 miles from the mouth of the Colorado River, and separated from the coast of Sonora by a channel from two to five miles wide. It is 30 miles long and from 10 to 20 miles wide, and covered with grass and desert vegetation. It is inhabited by the Ceris or Seris Indians, who have been left almost wholly to themselves by the Mexican government, and still live in a primitive state of nature. They are warlike and feared by the neighboring tribes on the mainland; use poisoned arrows, and are said to practise cannibalism.

TIC-DOULOUREUX, tĭk'doo-loo-rē'. See FACIAL NEURALGIA; NEURALGIA.

TICAO, tē-kow', Philippines, one of the islands of Masbate province, lying northeast of Masbate Island, and southwest of Sorsogón, Luzon, area 140 square miles; with dependent islands 149 square miles. It is long and narrow, extending 23 miles from northwest to southeast, and narrowing gradually from a width of eight miles in the north to the southern point Cape San Rafael; the surface is rugged with many small mountain groups, and single peaks; the highest elevation in the northwest is 1,525 feet. The west coast is steep and rugged, the east coast indented by several small bays. Hemp, rice, sugarcane, cotton and chocolate are raised in small quantities; and gold is obtained from the river sands. The more important occupations of the people are stock-raising, weaving, fishing and hunting. Pop. 10,183.

TICHBORNE (tĭch'bôrn) **TRIAL,** a famous English lawsuit in which was contested the validity of the claim of one Thomas Castro that he was Roger Charles Tichborne, heir of the Tichborne estates. Roger Charles, the eldest son of Sir Alfred Joseph Tichborne, died at sea in 1854 and upon the death of the second son, in 1866, the youngest was acknowledged heir. But Lady Tichborne was not satisfied that her eldest son was really dead, and so she advertised for him. Castro, a butcher from Wagga Wagga, Australia, also known as Arthur Orton, of Wapping, came forward and claimed to be Roger, the rightful heir. He was accepted by Lady Tichborne, who, however, died before his suit to recover the estate began. The trial lasted 103 days and was ended by Castro being non-suited, 6 March 1872. He was arrested and charged with perjury and a trial of 188 days followed, a verdict of guilty being found 28 Feb. 1874. Castro was sentenced to 14 years' imprisonment with hard labor. He was discharged on a ticket-of-leave in 1884, confessed his imposture in 1895, and died in poverty and oblivion in 1898. The second trial, which was the longest in the history of the English courts, cost £55,315. Consult 'The Tichborne Romance' (Manchester 1871).

TICINO, tē-chē'nō (German *Tessin*), Switzerland, a canton situated on the southern frontier of the republic, and bounded on the east, south and west by Italy. Area, 1,088 square miles. The Saint Gotthard group of the Lepontine Alps forms the northern and the Adula Alps the eastern boundary. Ramifications of these fill up the canton, but are cut by the valley of the Ticino River. The latter drains practically the whole canton, and empties into Lake Maggiore, which extends some distance across the southern boundary. The canton thus belongs to the basin of the Po. The upper mountain regions are rocky, but the southern part of the canton is very fertile, producing grain, fruits and grapes. Large numbers of goats are raised in the mountains. The principal mining industries are granite and marble quarrying. Commerce and manufactures are unimportant, although there is a considerable tourist traffic over the Saint Gotthard Railroad, which traverses the canton. The capital is Bellinzona (q.v.). In 1803 the canton of Ticino was formed by the union of the cantons of Bellinzona and Lugano, formerly part of the Helvetian Republic, and it was received as a full member of the Swiss Confederation. Pop. 158,556. See SWITZERLAND.

TICINO (German and French, *Tessin*), river of Switzerland and northern Italy, rising on Mount Saint Gotthard, and flowing in a general southeast direction, first as a rapid torrent through the canton of Ticino, then through Lake Maggiore, and finally as a clear, navigable stream on the boundary between Piėdmont and Lombardy. After passing Pavia it joins the Po. Length, exclusive of Lake Maggiore, 108 miles.

TICKELL, Thomas, English poet: b. Bridekirk, Cumberland, 1686; d. Bath, Somerset, 23 April 1740. He was educated at Queen's College, Oxford, a fellowship of which he held 1710–26. He was the friend of Addison, who introduced him both into the world of letters and public life, and on becoming in 1717 secretary of state made Tickell under-secretary. He held the office of secretary to the Lords Justices of Ireland from about 1724 till his death. He translated the first book of the 'Iliad, about the time of the appearance of the first part of Pope's 'Homer.' Addison declared that Tickell's version was the best, while Pope professed to believe it the work of Addison himself and wrote in reply the famous satire on Atticus. But without doubt Tickell made his own translation, which Addison corrected. Tickell's longest poem is 'Kensington Gardens' (1722); his most popular, the ballad of 'Colin and Lucy'; while his finest is the elegy to Addison prefixed to his edition of Addison's works (1721). Consult Johnson, Samuel, 'Lives of the Poets' (Oxford 1905).

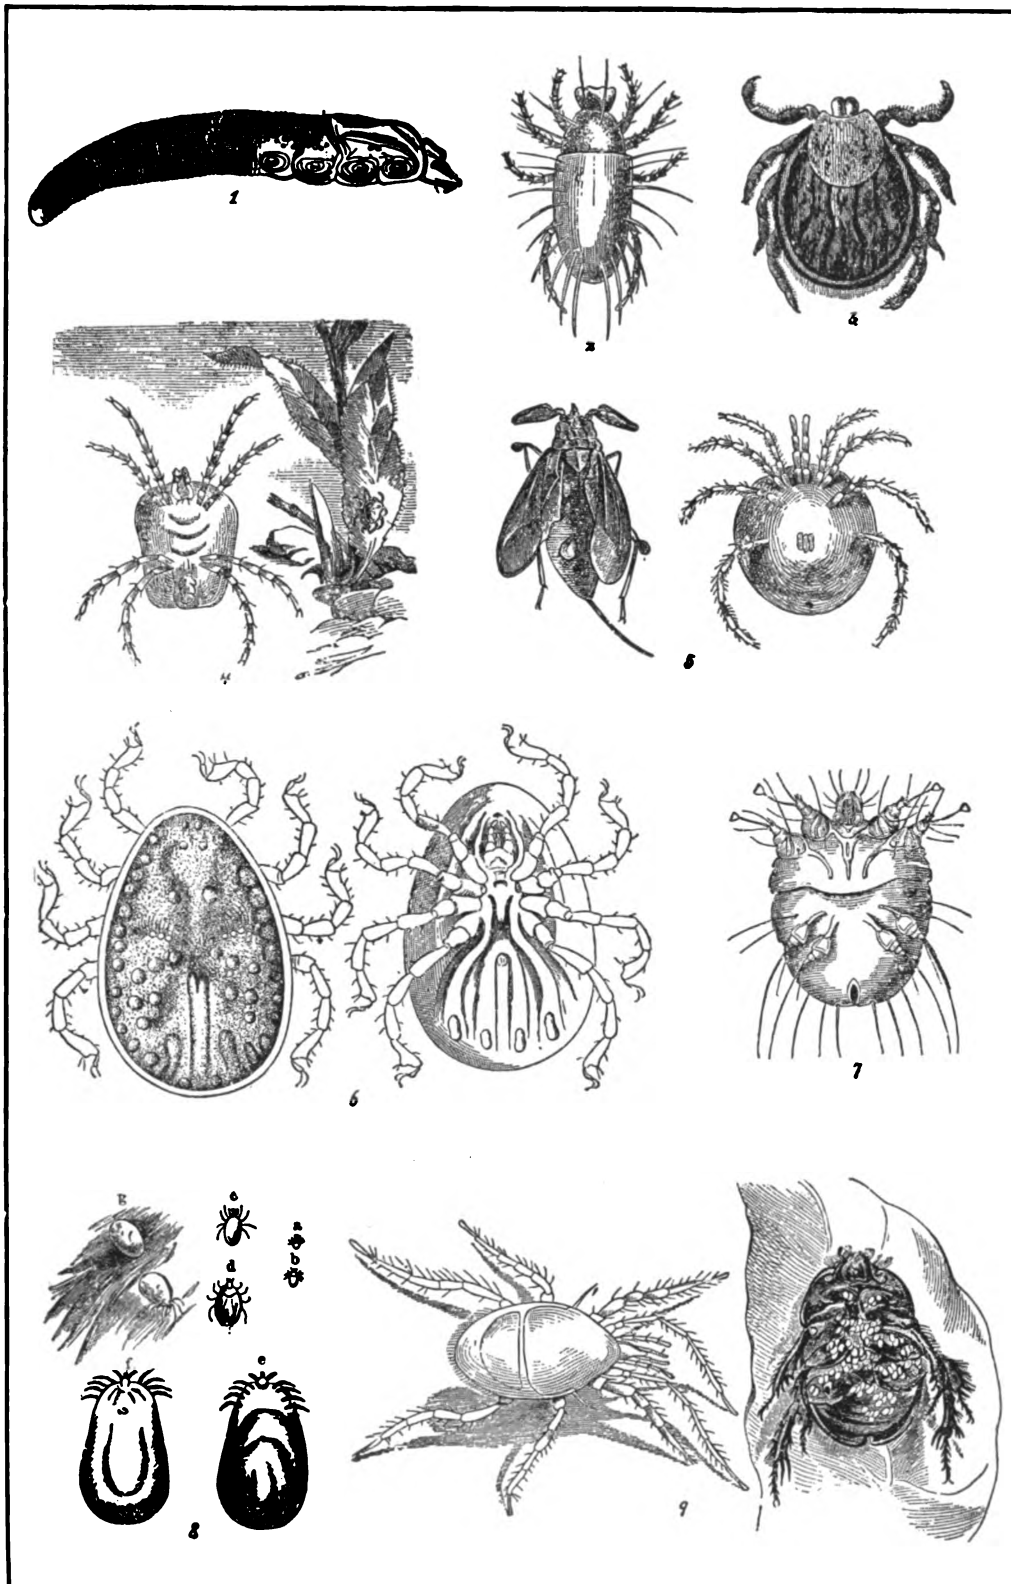
TICKET-OF-LEAVE, a written license granted by the English government, whereby a penal convict was given his liberty for good behavior before the expiration of his sentence. It originated in the permit granted to prisoners transferred to the colonies, but it came into domestic use in England after 1840, when the colonies refused to receive more convicts. Certain restrictions were imposed on the recipient, requiring that he report to the police at stated intervals until his term expired, that he should not make change of address without notifying the police, etc. The system was much abused and it was said that in 1856, 2,666 convicts were thus liberated. The number of crimes committed increased and the necessity for more stringent measures led to the adoption of the mark system, under which only those convicts, sentenced for terms of more than two years and whose marks for good behavior and industry showed that they were entitled to it, were granted the license. The effectiveness of such a system is greatly increased by the co-operation of many charitable organizations which use every possible means to re-establish the ex-convict and to enable him to lead an honest, industrious life.

TICKNOR, Francis Orrey, American physician and poet: b. Baldwin County, Ga., 1822; d. near Columbus, Ga., 1874. He studied medicine and engaged in practice near Columbus. His verse, particularly that concerning the Civil War, was highly popular throughout the South. Several of his poems are in Stedman's 'Anthology,' and after his death his verses were collected and published with a biographical sketch by P. H. Hayne, 'Virginians of the Valley, and Other Poems' (1879).

TICKNOR, George, American historian: b. Boston, 1 Aug. 1791; d. there, 26 Jan. 1871. He was graduated at Dartmouth in 1807, and was admitted to the bar in 1813, but never adopted the law as an active profession. He lived in Europe 1815–19 for the purpose of pursuing his studies, and on his return was appointed to the Smith professorship of modern languages and literature in Harvard. In 1835 he resigned his professorship, and for the next three years traveled in Europe. On his return he devoted himself to writing a 'History of Spanish Literature,' published in 1849, in three volumes, a corrected and enlarged edition appearing in 1863. Its value was at once recognized by scholars and it was translated into Spanish, French and German. He produced in 1863 a 'Memoir of Prescott,' the historian. He also wrote 'Outline of the Principal Events in the Life of General Lafayette' (1825); 'Remarks on Changes lately Proposed or Adopted in Harvard University' (1825); 'Remarks on the Life and Writings of Daniel Webster' (1831); 'Lecture on the Best Methods of Teaching the Living Languages' (1832). Consult Hillard, George S., and Ticknor, Mrs. Anna and Ticknor, Anna Eliot, 'Life, Letters and Journals of George Ticknor' (2 vols., 1876), critical ed., by Ferris Greenlet (1909).

TICKS AND MITES, small arthropods usually considered to be an order (*Acarida*) of the class *Arachnida* (q.v.). They have the regions of the body the most completely coalesced of any articulated animals, for not only are the head and thorax more or less united to form a cephalothorax, but the latter is continuous with the abdomen, often without the slightest indication of the line of union, and except in a few cases the abdomen is entirely unsegmented. The mouth-parts usually form a piercing and suctorial proboscis composed of the cheliceræ and pedipalpi, the latter being made up in part of a jointed, usually tactile palpus, while the cheliceræ may be stiliform and un-

TICKS AND MITES



1 Follicle Mite or "Blackhead" (Demodex homonis)
2 Cheese Mite (Tyroglyphus siro)
3 Tick (Ixodes reduvius)
4 Scarlet Mites (Trombidium holosericeum)
5 Water Mite (Atax spinipes)
6 Pigeon Tick (Argas reflexus)
7 Itch Mite (Sarcoptes hominis)
8 Tick (Ixodes ricinus)
9 A Beetle Mite (Gamasus coleoptratorum) at the left shown enlarged; at the right, devouring a beetle

jointed or two-jointed and clawed or chelate. Typically the mature forms or imagoes have four pairs of walking legs of from five to eight joints terminated by variously arranged claws, stalked or sessile suckers or pads; but the legs may be variously modified, reduced to mere tubercles, to two pairs or disappear altogether in some parasitic forms. Respiration is effected by means of simple or branched tracheæ opening by from one to three pairs of stigmatæ at the bases of the legs, or by means of a pair of air-sacs opening at the base of the proboscis or on the back or, in the absence of all special respiratory organs, may be purely integumentary. The alimentary canal is commonly a spacious sac which may be forked or much branched. In most cases there is no blood-vascular system. The sexes are separated, the generative ducts open on the base of the abdomen, and fertilization is accomplished through copulation. A few are parthenogenetic and sexual dimorphism is frequent. They are oviparous, ovo-viviparous or viviparous. The larvæ frequently differ greatly from the imagoes in appearance and habits and almost always have three pairs of legs. After a few molts, usually two, they form nymphs or pupæ which also may be very different, and after a single molt metamorphose into the mature form or imago.

Mites and ticks are found in all parts of the world and under every variety of environment. Many are parasitic either temporarily or permanently, and on both animals and plants, a few are commensals in ants' nests, etc., others are predaceous, and seize and suck the juices from weaker animals, some live in decaying vegetable substances, many in damp earth, in moss or under the bark of trees, many are aquatic either in fresh water or the sea, and some of the marine forms descend to great depths. While most of the members of this order have no direct relation to human affairs, many affect our interests in important and manifold ways. Some, like the itch-mites, are the cause of annoying diseases of man and animals, some like the cattle ticks are the bearers of disease-producing parasites, some are seriously destructive to our crops or to manufactured food-products, etc.; and many are beneficial as destroyers of harmful insects and their eggs. Owing to their great powers of reproduction and their tenacity of life, the harmful species are difficult to combat, preparations of sulphur and lime or powerful insecticides applied directly to the colonies being the most effective remedies. The number of known species already amounts to thousands, although the smaller mites have been little studied outside of Europe. They vary in size from the microscopic mites to the large cattle ticks about an inch in length. Differing greatly not only in habits and appearance but also in structure, the *Acarida* are divided by systematists into numerous families and subfamilies, of which a few representatives may be mentioned.

The *Oribatidæ* is an extensive family of 20 genera and 200 to 300 species of free-living forms with hard skins and robust bodies and usually three pairs of stalked stigmatæ and simple tracheæ. They are mostly vegetable feeders, never parasitic and with the exception of a few aquatic forms lives in damp earth under leaves, bark, etc.

The *Gamasidæ* are somewhat similar, with rounded bodies and a hard skin, but have only a single pair of stigmatæ at the base of the second pair of legs. The blood system is well developed. They often swarm on the under side of rove-beetles, carrion-beetles and other insects and some are parasitic on bats and birds; 35 genera and perhaps 200 species are already known.

The *Ixodidæ* are the ticks, large blood-sucking species, with ovoid bodies and leathery skin capable of great extension. They are temporary parasites of vertebrates, chiefly of birds and mammals. As a rule the eggs are deposited in the ground; the newly hatched larvæ have three pairs of long clawed legs with which they attach themselves to a host, insert the beak and suck the fluids. When ready to slough they may drop off, seek concealment until the skin is changed, when the same maneuver is repeated. After passing the larval and nymphal states the imagoes live among herbage and shrubbery and upon opportunity again attach themselves, but usually in pairs, to some warm-blooded host, inserting the strong beak and drawing blood while copulation takes place. The fertilized female becomes greatly distended, often to a spherical form, drops off and deposits her eggs, often to the number of 20,000 to 30,000. The large cattle-tick (*Boophilus bovis*) of the western ranges, now known to be the intermediate host of the parasite of Texas fever and a great scourge to cattle and other animals, is an example. Others are the wood-tick (*Ixodes unipunctata*), so common in New England, and certain European species, one a parasite of poultry and introduced into the United States, as the related dove-tick also has been.

The *Hydrachnidæ* are the attractive and familiar water-mites, another large group of 40 genera and about 500 species. The adults, remarkable for their sexual dimorphism and brilliant colors, suck the juices of small crustaceans while the young are parasitic on aquatic insects and mussels. The brilliant scarlet eggs of some species are frequently found attached to aquatic plants and stones in a mass of jelly. A related family containing mostly marine predaceous forms is the *Halacaridæ*. An allied family is the *Trombidiidæ*, including the scarlet mites and the red spiders so well known to horticulturists. A very common one is *Tetrarhynchus telearius*, which spins a web on the under side of leaves and is very destructive to plants during hot dry weather. Others cause great damage to orange and lemon groves. The young are parasitic on insects.

The disgusting itch-mites form a family (*Sarcoptidæ*) of short, rounded forms which lack eyes, tracheæ and stigmatæ altogether. They are microscopic and burrow in the skin of various animals, causing the diseases known as itch and mange, which are very difficult to eradicate but usually yield to persistent applications of sulphur washes. No less than 68 genera and 550 species parasitic on mammals, birds and insects have been described. (See Itch). Sheep-scab and mange in various domestic animals are caused by related mites of the genera *Psoroptes* and *Symbiotes*. They all have the feet wonderfully provided with adhesive organs in the form of hooks, bristles and sucking cups. Closely allied are the *Tyroglyphidæ*, comprising perhaps 50 species of minute forms with biting jaws. They are chiefly remarkable for their great reproductive capacity and the enormous numbers in which they occur in slowly decomposing vegetable substances, etc. Here belong the cheese-mites (*Tyroglyphus siro* and *T. longior*) which are cultivated and sown in certain cheeses in order to give them an appearance of maturity and an acid flavor. Many similar species infest stored grain, dried fruits, etc., and some, like *Aleurobius* and *Rhizoglyphus*, destroy living roots, bulbs and grains. Another one abounds in unrefined sugars.

Two strictly parasitic families in which the body has become elongated and worm-like and otherwise degenerate are *Demodicidæ* and *Eriophydidæ*. The former live in the hair follicles and skin glands of man and domesticated animals. *Demodex folliculorum* sometimes causes the «blackheads» which appear about the human nose; similar species infest the pig, dog, sheep, ox and other animals. That of the ox sometimes so perforates the skin that it has little value for leather. In these forms the legs are very small and degenerated and one pair may be lost. The second family is that of the gall-mites which have but two pairs of legs, the posterior being sometimes represented by bristles. They form galls in the buds and leaves of plants whose juices they suck. Most of the species are confined to a particular species of plant, so that the 235 which have been described are probably but a small representation of those actually in existence. Some are parasitic in the galls made by others, recalling the inquilines among the gall flies.

TICONDEROGA, tī-kŏn-dē-rō'gạ, N. Y., village, Essex County, on the stream which is the outlet of Lake George, and on the Delaware and Hudson and the Rutland railroads, about 95 miles north by east of Albany, and a short distance from lakes Champlain and George. In the vicinity are rich deposits of crystalline graphite, the chief source of the supply in the United States. The village is in an agricultural region. The good water power is utilized to some extent for manufacturing. The chief manufactures are lumber products, wood pulp, paper and dairy products.

The history of Ticonderoga and vicinity begins with the early settlement of Vermont and northern New York. In 1755 a fort was built here, by the French. They called it Fort Carillon, on account of the caroling or chiming of the waters. The value of the site, near the head of Lake Champlain and at the entrance to Lake George which, with a short portage, formed a waterway to the Hudson, was recognized by both the French and English. Two years after the erection of Fort Carillon it was garrisoned by a force of 9,000 men under Montcalm. Wishing to extend the power secured by so advantageous a position, Montcalm attacked and captured Fort William Henry on Lake George. In July the following year General Abercrombie attempted to capture Fort Carillon, and although he had a force of 15,000, he was unsuccessful; his loss was about 2,000. In 1759 another and successful effort was made to wrest the fort from the French; General Amherst with a force of 12,000 captured both Carillon and Crown Point. After the beginning of the Revolutionary War, the whole region bordering on Lake Champlain, Lake George and the Hudson River became a battle ground. On 10 May 1775, a small force of Americans, less than 100 in number and known as «Green Mountain Boys,» under Ethan Allen (q.v.), demanded the British commander to surrender «in the name of the Great Jehovah and the Continental Congress!» and thus, despite the fact that Allen held no commission and also that the Continental Congress had not yet convened, captured the fort, then called Ticonderoga. Burgoyne's plan of campaign included regaining this fort, and on 30 June 1777 he endeavored to capture the Americans, but failed. On 5 July of the same year, he made another attempt and this time succeeded. Later other engagements took place here and in the vicinity, but the English kept possession until after the surrender of Burgoyne. In 1780 an English force occupied the fort for a short time. At the close of the wars with England the fort ceased to be of importance, and as it was not occupied it soon became a ruin. Near the village stands a part of the gray stone walls of the old fort. Many tourists visit the village each year, and it has some note as a summer resort. Pop. 2,918.

TICONDEROGA, Expedition Against, an incident in the American Revolutionary War. See Allen, Ethan; Ticonderoga.

TICPOLONGA, the name in Ceylon of Russell's viper (*Daboia russellii*) common in the south of India, Ceylon and Burma. See Russell's Viper.

TICS, spasmodic contractions of muscles, especially those which occur in the muscles of the face. Such affections are characterized by painful muscular twitching. The term tic, as referring to facial spasm, is especially applied to tic-douloureux. See Facial Neuralgia.

TICUNA, te-koo'nä, or **TUCUNA,** too-koo'nä, a tribe of aboriginal Indians found in the forests of Brazil and Peru, around the confluence of the Javary and Marañon or Upper Amazon. They are of slender but good physique, have dark skins, and live in a state of nature, their sole adornments being feather armlets and monkey teeth necklets. They live by fishing and hunting, and are distinguished for their honesty and straightforward dealings. Their birth, death and other ceremonials and customs are interesting. Early in the 18th century the Jesuits established missions among these people. Consult Chamberlain, A. F., in 'Journal de la Société des Américanistes de Paris' (Vol. VII, Paris 1910).

TIDE-MILL, a water-mill so constructed as to utilize the action of the tide. This is usually accomplished by one of two methods. The first consists of shutting off the water in a reservoir at flood tide, its escape through a race-way giving the motion to the mill. In such tide-mills the return of the tide through the sluice may also be utilized. The other and less expensive method involves the placing of a horizontal wheel in the water to be turned by the current either in ebb or flow. The motion of this mill is not uniform; it attains its greatest velocity at half tide and is suspended entirely at the turn of the tide; but with exception of this suspension a uniform velocity can be obtained through the use of regulative machinery. The old London tide-mills, in use in the river Thames, were built on a platform which was entirely afloat, water-wheel, mill-room and all. Tide-mills have never attained any great success owing to the inconvenience of so irregular a motive power. But in recently projected mills an attempt is made to obviate this difficulty by the use of an ingeniously constructed tidal-motor.

TIDEMAND, Adolph, Norwegian painter: b. Mandal, 1814; d. Christiania, 1876. He studied at Copenhagen and at Düsseldorf under Schadow, afterward going to Munich and Rome. Among his works are the large historical compositions 'Gustavus Vasa Addressing the Dalecarlians' and 'Devotional Meeting of the Haugainer,' and many genre subjects, such as the cycle of 10 pictures illustrating 'Norwegian Peasant Life'; 'Grandmother's Bridal Crown,' and 'The Wolf Hunter's Tale.' He was for many years painter to the king.

TIDES. 1. Introductory.— Persons living along the seashore are familiar with a semi-daily rising and falling of the waters, which, although generally amounting to only a few feet, often suffices to cover and bare by turns wide stretches of the sea-shore. Without tide tables, or any knowledge of the moon's position, the approximate time of the tide can be foretold from its observed time of occurrence on a previous day, by allowing 50 minutes for its daily retardation. Toward and after the time of Cæsar, the Romans were well acquainted with ocean tides as the writings of Cæsar, Seneca, Pliny the Elder, Claudianus, and others clearly show. By referring the tides to the attraction of the moon and sun, Newton took the first important step in their explanation. Since his time important investigations of the laws of the tides have been made by Laplace, Airy, Kelvin, G. H. Darwin, H. Poincaré and many others.

2. Definitions, etc.— The tide is the periodic rising and falling of oceanic and other large bodies of water, due mainly to the attraction of the moon and sun as the earth rotates upon its axis. Remarkable stages of the water level at a given place, whether due to earthquakes, gales or other causes which probably have no definite law of recurrence, although popularly known as "tidal waves," cannot be regarded as belonging to tidal phenomena. The rising and falling is accompanied by, and depends upon, lateral or horizontal movements of the waters called tidal currents or tidal streams or the flow and ebb. Their periodic character distinguishes them from ordinary ocean currents. The tide rises until it reaches a maximum height called high water and then falls until it reaches a minimum height called low water. The difference in height between a high and a low water is called a range of tide. At most ports two high waters and two low waters occur each lunar day. The average length of a lunar day is 24 hours 50 minutes 28 seconds. The interval of time between the transit of the moon across the meridian and the occurrence of high or low water is called a lunitidal interval. The average value of the high-water lunitidal interval at any seaport is sometimes called the corrected establishment to distinguish it from the high-water lunitidal interval on the days of new and full moon, which is known as the establishment, or the vulgar establishment, of the port.

At the times of new and full moon the tidal forces of the moon and sun act in the same direction, whereas at first and last quarters they oppose each other. When they unite their forces we have spring tides, characterized by large ranges of the tide; when they are opposed, neap tides, having small ranges. The spring and neap tides usually occur soon after the corresponding phases of the moon. The interval is called the retard or age of the tide, or age of the phase inequality, and is usually less than 60 hours. The lunitidal intervals have their mean values at the times of spring and neap tides; the tides occur a fraction of an hour earlier between spring and neap tides, and later between neap and springs. Other things being equal, the range of tide is greater than usual by about one-sixth part when the moon is near perigee and about as much less than usual when near apogee. An increase or decrease of about one-tenth part of the range occurs when the moon is near the equator or near its point of extreme declination, respectively.

Diurnal inequalities among the four tides of a day are due to the presence of a diurnal wave or partial tide, whose period is approximately 24 hours. The cause of this wave lies in the fact that if the moon is north or south of the equator, its tidal forces are somewhat different both in magnitude and in direction when two times half a lunar day apart are compared.

3. The Tidal Forces.— All particles of the earth (the seas included) will continue to occupy positions fixed relatively to one another if no other forces are impressed upon them than the following: The earth's attraction; its centrifugal force of axial rotation; and a force acting upon all of its particles alike, for example, the centrifugal force due to the revolution of the earth about the centre of gravity of earth and moon. If an extraneous force does not act upon all particles alike, then motions will be set up in the yielding parts. The attraction of the moon upon a given particle (near the surface, say) is along a line drawn (at any given instant) from the particle to the moon's centre; its intensity, which is inversely proportional to the square of the distance, and its local direction (that is, direction with respect to the earth's surface) continually change as the earth rotates upon its axis. The attraction of the moon upon a particle at the earth's centre (or upon the earth as a whole) is along a line drawn from the earth's centre to that of the moon; it is independent of the earth's axial rotation. Because the action of the moon upon the surface particle differs from its action upon the particle at the earth's centre there results a tendency to produce motion relatively to the earth's centre. A consideration of this tendency will enable us to answer the question why there should be two high waters each lunar day, instead of only one high water. In a single sentence, the reason is that the moon attracts the waters on the hemisphere facing the moon more powerfully than it does the earth; but attracts the earth in general more powerfully than it does the waters on the farther side of the earth. The difference between the action of the moon at any point of the ocean and its action on the centre of the earth is the tide-producing force at the specified point. It is not difficult to show that, to higher powers of the small quantity a/r, the vertical and horizontal components of the moon's tide-producing force are very nearly $\frac{M}{E}\frac{a^3}{r^3}g\,(3\cos^2\theta - 1)$ and $\frac{3}{2}\frac{M}{E}\frac{a^3}{r^3}\,g\sin 2\theta$ respectively, where M denotes the mass of the moon, E that of the earth, g the force of gravity, a the mean radius of the earth, r the distance between centres of earth and moon, and θ the zenith distance of the moon corrected for parallax. The numerical value of $\frac{M}{E}\;\frac{a^3}{r^3}$, when r has its mean value, is 0.000000056; and so the vertical force has a range of 0.000000168g, as has also the horizontal force. The solar tidal force is 46 per cent that of the lunar. The tides are mainly due to the horizontal component of the forces. These are the forces which deflect a plumb line, although by an amount so small that it can hardly be measured. The deviation, in case of the moon, amounts to only 0."017 either way from the mean vertical. For a sufficiently deep body of water extending 163 nautical miles along the equator the range of tide at either end will be one inch.

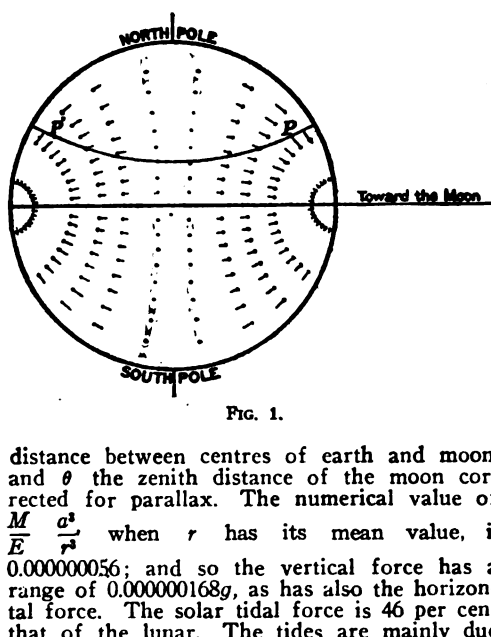

Fig. 1.

The system of arrows in Figs. 1, 2, 3 are intended to represent the horizontal component of the moon's tide-producing force at various places on the earth's surface. The arrows located upon the same small circle are supposed to be of equal length, and all arrows are supposed to lie in a system of great circles which meet in a point directly under the moon and, of course, in the antipodal point. At these two points and along a great circle midway between them the length of the arrows is zero; in other words, the force vanishes. The system of arrows is fixed with respect to the moon, and so sweeps over the surface of the earth as the moon performs her apparent daily revolution. The system shifts somewhat when the moon is north or south of the equator. At any point P on the earth's surface, the moon being upon the equator, the horizontal forces are equal in magnitude and direction to the horizontal forces at P', a point upon the same parallel of latitude as P, but 180° distant in longitude; or, what amounts to the same thing, they repeat themselves at any given point P every half lunar day, or 12h. 25m. 14s. on an average. But when the moon is not upon the equator, the forces are generally not the same at P and P', either in magnitude or in direction, and so do not exactly repeat themselves every half lunar day. This alternation of the forces gives rise to a diurnal inequality in the tides. It will be noticed that for places situated upon either side of the equator, the forces have, when the moon is upon the equator, a meridional component directed from the poles toward the equator, and

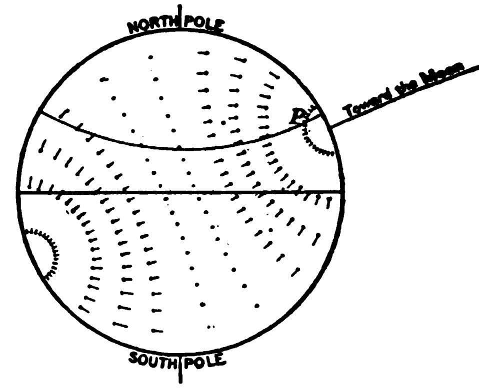

Fig. 2.

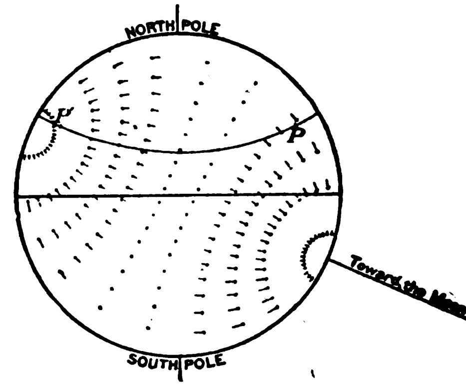

Fig. 3.

that this component nowhere points from the equator toward the poles; consequently the existence of the moon causes the water (half-tide level) at the equator to be higher than it would otherwise have been. The moon's movement in declination, therefore, causes a fortnightly fluctuation in half-tide level. Similarly the sun produces a semi-annual fluctuation.

4. Real Equilibrium Tides.— If in the case of any body of water, its free period be several times smaller than the period of the tidal forces, say less than three or four hours, the surface will at every instant be normal to the plumb line as disturbed by these forces. In particular, consider the mean lunar semi-diurnal tide of a deep lake situated in north latitude. Upon referring to Fig. 4 it may be inferred that high water will occur at a point south of the no-tide point when the moon is on meridian; at a point west of the no-tide point at 3 o'clock, lunar time; at a point north of it, at 6 o'clock; at a point east of it, at 9 o'clock. The no-tide point is the centre of gravity of the surface. This theory nearly explains the tides found in Lake Superior and the semi-diurnal tide in the eastern portion of the Mediterranean Sea; it partially explains the semi-diurnal tides in the Gulf of Mexico and the Caribbean Sea, and the diurnal tides in the Atlantic Ocean east of the United States.

5. Hypothetical Equilibrium Tides.— If a spherical body like the earth were entirely covered by an ocean so deep that its free period of oscillation would be several times smaller than the period of the tidal forces, the tidal forces of the moon would cause the surface of the ocean to assume the form of an ellipsoid of revolution with the longer axis pointing toward the moon's centre. For any zenith distance θ of the moon the height of the tide above the undisturbed spherical surface becomes $\frac{1}{2}\frac{M}{E}\frac{a^3}{r^3}\frac{a}{1-\frac{3}{5}\sigma/\delta e}(3\cos^2\theta-1)$ where σ denotes the density of the water and δe that of the earth. The numerical value of $\frac{M}{E}\frac{a^4}{r^3}$ is 1.17 feet. The corresponding value for the sun is 0.54 foot. If the $\sigma/\delta e = 0$, the range of the hypothetical lunar tide becomes 1.8 feet; if $\sigma/\delta e = 1$, the range becomes 4.4 feet. In case of the earth $\sigma/\delta e = \frac{2}{11}$.

The hypothetical tide just described can be easily calculated for any time and place and is known as the uncorrected equilibrium tide. It bears no resemblance to the actual tide of our oceans.

6. Some Dynamical Questions Involved in the Subject.— Because the requirements for equilibrium tides are seldom found in the oceans, their waters must be treated as aggregates of heavy particles performing some kind of oscillatory motion. A progressive free wave in a canal has as its velocity of propagation $\sqrt{gh}$ and for the maximum velocity of the water particles $A\sqrt{\frac{g}{h}}$ where h denotes the undisturbed depth of the water and A the amplitude of the vertical movement. The longest or fundamental period of free oscillation of a rectangular area or sheet of water is

$$\text{period} = \frac{\text{twice length of sheet}}{\sqrt{gh}}.$$

Sheets tapered or sharpened at the ends oscillate more rapidly than do rectangular ones of the same length, while sheets narrowed at the middle or broadened at the ends oscillate less rapidly. The free oscillations of a given body of water can often be approximately determined by comparing with a more simple body whose motion is known. The given body need not have a strictly uniform depth nor be completely surrounded by land.

The general equations of motion for matter upon a rotating sphere show that a moving particle of unit mass is deflected or accelerated relatively to the earth's surface, toward the right in north latitude, toward the left in south latitude, as if by a force whose numerical value is velocity $\times 0.0001458$ sin (latitude), the velocity being expressed in feet per second and the force in poundals (Ferrel's law). This divided by g or 32.1722 gives the transverse slope which a river, or strait through which there is a current, will assume on account of the deflecting force of the earth's rotation.

7. Hypothetical Dynamical Tides.— The case of an equatorial canal encircling the earth is simple and instructive, although bearing no resemblance to any existing tidal body. If the depth of the water be greater than 67,000 feet, high water will occur when the moon is on meridian (above or below the horizon); if less than 67,000 feet, low water will occur when the moon is on meridian. For the depth 67,000 feet the range of tide will become very large. If this depth be greatly increased, the range will approach its equilibrium value, which is 1.8 feet for the lunar tide; if this depth be greatly diminished, the range will approach the value 0.000,026 h, h denoting the depth. In the latter case the amplitude of the horizontal displacement will be 137 feet. For the depth of 10,000 feet the range of tide is 0.31 foot and the amplitude of the horizontal displacement 161 feet; for the depth of 20,000 feet the corresponding quantities are 0.74 foot and 196 feet, respectively. If friction proportional to the velocity be introduced, the effect will be to displace the crests of the lunar and solar wave with reference to the moon and sun, but by unequal amounts. To this has been attributed the age of the tide.

8. Partial Explanation of Ocean Tides.— From §§ 3, 4 an idea of the magnitude of the equilibrium tide can be obtained. It represents the direct effect of the action of the moon upon the waters where the body is so small and deep that its motion can be ignored. In a larger body whose free period is quite different from that of the tidal forces it is reasonable to suppose that tides even smaller than the equilibrium tides will be raised. In § 7 this was found to be the case for an equatorial canal of moderate depth encircling the earth. Again, if a canal, bounded at each end, be so shallow that a wave-length (λ) extends through only a few degrees of a great circle, then even if its length approximates to λ the tides are obviously small because the tidal forces act very nearly alike on both halves, while the particles move in opposite directions in the two halves. Results like these contrasted with those obtained from observing the tides of the oceans lead to the belief that, as a rule, the ocean tides as we know them are so great that they can be produced only by successive actions of the tidal forces upon oscillating systems each having, as free period, approximately the period of the forces, and each perfect enough to preserve the general character of its motion during several such periods were the forces to cease their action.

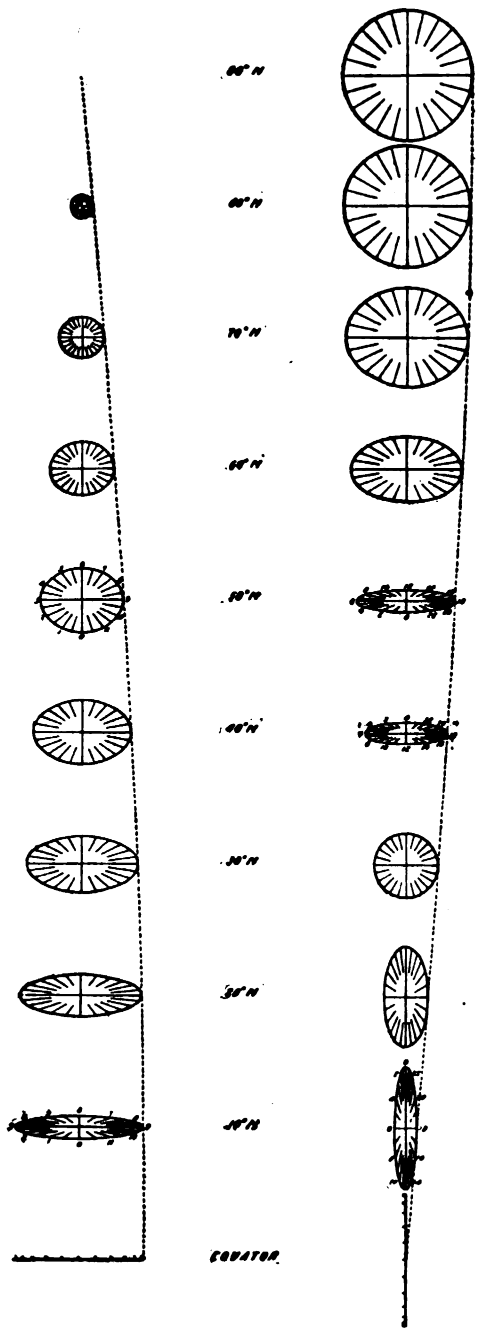

FIG. 4.— Semi-diurnal and Diurnal Tidal Forces.

That oscillations according to one of the free periods may persist for a long time can be seen in the case of some seiches; for, although probably started by a meteorological disturbance and sustained by no periodic force, yet in some harbors, straits, or bays they execute a large number of oscillations before dying out, and their periods are fairly constant in such cases. If a suitable harbor can continue to oscillate for possibly a day or two because of the inertia of the water, it is clear that an oscillation can be sustained in a large body, like a portion of one of the oceans, by a very small periodic force provided that the free period of the body is nearly equal to the period of the forces and that the boundaries are such that no great amount of energy is carried away by progressive waves or otherwise.

Suppose the oceans by reason of their depths and the configuration of shore lines to contain several. such systems whose free periods are nearly the periods of the tidal forces. These systems generally consist of still more simple sheets having like periods and which may be styled «areas.» The times of tide can be found by means of the following rule:

If to the particles of water in a given oscillating system, each area of uniform depth, and wherein the resistances are proportional to the velocities of the particles, a series of simple harmonic forces having for period the free period of the body of water be applied, and a permanent state established, then must the time of elongation be simultaneous with the time when the virtual work of the external periodic forces upon the system becomes zero.

The forces in various parts of the system and at various times or hours are those of Fig. 4. projected upon the lines of motion of the particles. The virtual displacements are the same at each assumed hour, but differ in different parts of the system.

9. Cotidal Lines.—Although the cotidal lines in the ocean are generally real and distinct, they seldom indicate the progression of a wave at the rate due to depth; such progressions, however, exist in many shallow arms of the sea, particularly in tidal rivers. Because the principal ocean tides are due chiefly to stationary oscillations, as has just been pointed out, we may expect to find extensive regions characterized throughout by nearly simultaneous tides. For that portion of the Atlantic Coast of America extending from Rhode Island to the Bahamas and Haiti, high water occurs almost simultaneously. The same is true for southeastern Alaska and the Gulf of Alaska; for the Pacific Coast of Central America, and for the eastern coast of the Philippines. The time of tide changes but little along the Atlantic Coast of Morocco and Portugal. In localities like these the rise and fall amounts to several feet even off shore and in deep water.

The Arctic Ocean is characterized by progressive tides of small range derived from the Atlantic Ocean.

In the oceans, in certain arms of the sea, and in certain lakes are to be found a considerable number of no-tide points due to various causes. From a point of this kind radiate all cotidal lines belonging to a tidal period; and so these lines, or the tide which they represent, are there said to be «amphidromic.»

Excluding lakes and seas not communicating tidally with the ocean, and considering only the semi-daily tides, about 25 no-tide points can be enumerated; a large percentage of these are to be found in straits and sounds.

A lake whose longest free period of oscillation is several times less than the period of the tidal forces will experience equilibrium tides and possess a no-tide point situated at the centre of gravity of the surface of the lake. The sequence of the cotidal lines about the point will be the same as that of the tidal forces. (Fig. 4). For semi-daily tides the numbers will increase in the clockwise or counter-clockwise sense according as the point lies in north or south latitude.

In a strait or sound a nodal line is reduced to a no-tide point through the deflecting force described in § 6; around such a point the sequence of the tide is the reverse of that of the forces. If a no-tide point is due to the overlapping of two systems, the sequence depends upon the tidal hours of the systems.

10. Peculiarities of Tides.—The distance between the Antarctic Continent and Australia being more nearly equal to the half length of a solar wave than of a lunar, causes the solar wave to be comparatively large along the southern coast of Australia. The same is true, but in a lesser degree, for the region between the Antarctic Continent and South Africa. The distance from the Antarctic Continent to the Atlantic Coast of the United States being a little more than one and one-half lunar wave-lengths causes the ratio of the solar to the lunar wave to be comparatively small along this coast. If the ocean oscillate differently for different constituents, we can readily see reasons for considerable differences of epoch and so for remarkable «ages» of the tides.

If a tidal river be so shallow that the range of tide is a considerable fraction of the depth, ordinary wave-like oscillations of the water are no longer possible. The result is that as the wave progresses, the duration of the rise will be shortened and that of the fall lengthened. An extreme case results in a phenomenon called a *bore* — an advancing wall of water, which may be several feet in height, flowing up the bed of a river. A bore (q.v.) occurs in the Petitcodiac River, an affluent of the Bay of Fundy, its height at Moncton being three or four feet. Bores occur in several of the rivers of India, in several of western Europe, in the Amazon River, in the Tsien-tang Kiang and in Turnagain Arm, Alaska. Various other peculiarities in the shape of the wave are due to the shallowness of the water. A much contracted entrance to a bay not only reduces the range within, but alters the shape of the wave.

On the other hand, the range may increase as the tide passes up a funnel-shaped bay or estuary, and especially may this be the case when the bay has a large stationary oscillation related to the waters outside. The Bay of Fundy has at its head a spring range of nearly 50 feet, which fact depends upon both of these circumstances. But the large tides in Bristol Channel, England, and in Bristol Bay, Alaska, are due chiefly to the contracting and shoaling of these bodies.

As a rule strong tidal currents occur in straits, tidal rivers, over shoals, and off capes.

Along the open coast and in the ocean at large, tidal currents generally set successively in all directions, the motion being elliptically harmonic or nearly so. This horizontal motion having two degrees of freedom is much harder to specify than is the tide, or motion defined by the rise and fall of the surface. Points at which the velocity ellipses or hydographs become circles may be styled «circular points.»

11. Tides in the Earth's Crust.— By these are meant the rise and fall experienced by the surface of the apparently solid earth due primarily to the tide-producing forces of the moon and sun acting upon the earth's crust and all matter within.

With the exception of § 5, we have made no mention of the attraction of the tidally disturbed waters upon themselves because the density of water is only 2/11 that of the «solid» earth, and the depth of the ocean is but a small fraction of the earth's radius. In the production of body tides not only is the direct disturbing action of the tidal forces involved, but also the attraction of the matter, however, disturbed upon itself.

Let a_g denote the rise and fall of the ocean's surface as measured from the earth's centre and expressed in terms of the earth's radius, a_e the rise and fall of the surface of the «solid» earth similarly measured; then the actually observed rise and fall of the waters surface relatively to the land is $a_g - a_e = m$. The value of a_e is required. From theoretical considerations of the direct and indirect effect of the tidal forces,

$$a_e = k_e a_g = \frac{k_e a}{1 - k_c k_e}$$

where a denotes the range of the equilibrium tide in an ocean of small density covering the earth, due to the direct action of the tidal forces; k_e and k_c are two moduli depending respectively upon the elasticity and internal constitution of the earth; $k_e a$ denotes the range of the deformation in the surface of the «solid» earth due to the direct action of the tidal forces.

Assuming that the day has not altered in length since the earth was in a fluid state, or when $k_e = 1$, we have observed ellipticity of meridian $= \frac{1}{1-k_e} x$ ellipticity due directly to diurnal rotation. That is,

$$\frac{1}{297} = \frac{1}{1-k_c} \cdot \frac{1}{578};$$

whence $k_c = 0.486.1$

The value of k_e can be determined by comparing the observed period of the movement of the axis of figure about the axis of rotation with the period of free precession (or 305 sidereal days) obtained upon the assumption of a rigid earth.

Another determination of k_e is obtained by comparing the observed range of the monthly or fortnightly tide with the equilibrium range due to the direct action of the tidal forces. This ratio or m/a is found to be about ⅔. Daily or semi-daily tides in a deep lake or in a buried pipe also give a determination of m/a. The actual deviation of the vertical from its mean position, due to the daily or semi-daily tidal forces, and obtained by means of a horizontal pendulum, gives, upon comparison with the direct theoretical deviation, another determination of the ratio m/a. If k_c be taken as 0.5, and m as ⅔, then by the above equation,

$k_e = 0.5$ and $a_e = \frac{2}{3} a$; that is, the actual rise and fall of the surface of the «solid» earth is about $\frac{2}{3}$ of the rise and fall of the surface of an ocean of small density surrounding a rigid sphere. If the latter be 1.8 feet (§ 5), the former will be about 1.2 feet. [This mode of treatment is due to Ch. Lallemand.]

12. Observation of Tides.— The height of the tide, or water surface, at any given time can be directly observed upon a graduated fixed staff if the water be tolerably smooth. A long box fixed in a vertical position, having a small opening near the lower end, and usually supplied with a float, enables one to observe during stormy weather as well. In some instances only the times and heights of the high and low waters are observed and recorded. But a more satisfactory record is obtained by reading the gauge at regular intervals one hour or one-half hour apart.

Automatic or self-registering gauges are usually constructed for drawing a continuous curve. Such a gauge consists of a float and box, a time-piece, and some form of recording apparatus. The record from an automatic gauge can be procured with comparatively little trouble; it shows clearly the peculiarities of the tide; and it furnishes material for a thorough analysis or discussion.

The velocities and directions of tidal streams are usually ascertained by aid of a float and line or some form of current-metre. Such observations are attended with considerable difficulty because they must generally be made at some distance off shore.

13. Analysis of Observations.— If only the high and low waters are to be treated, they are first referred to the moon's transit for obtaining lunitidal intervals. The ranges of tide are found at the same time. The intervals and the heights or the ranges are next classified according to certain astronomical arguments for the purpose of bringing out the corresponding tidal inequalities.

The harmonic analysis rests upon Laplace's principle of forced oscillations, namely:

The state of any system of bodies, in which the primitive conditions of the motion have disappeared through the resistances which the motion encounters, is coperiodic with the forces acting on the system.

Here is the clue to what oscillations ought to be found in the tidal wave; for, there ought to be an oscillation corresponding to each term of the causes producing the tide. Such terms follow from the development of the tide producing potentials of the moon and sun. Their arguments and «speeds» involve simple combinations of the mean longitudes and mean motions of the local meridian projected on the celestial sphere, the moon, the sun, the equinox, the lunar perigee, the solar perigee, and the moon's node. There are three principal classes of terms: semi-diurnal, diurnal and long-period.

If for a sufficiently long time the observation curve be read and summed with reference to any constituent or component defined by its «speed,» the effects of the other components will gradually disappear and the final sums will pertain only to the one sought (including, of course, its harmonics). To avoid reading the curve with reference to each component, the tabulation according to mean solar time is made to serve for all. This is done by distributing the (solar) hourly heights among the component hours as nearly as possible. Tables showing the proper distribution of hourly heights as well as blank forms into which the heights are to be copied have been used quite extensively. For about 30 years perforated sheets, known as stencils, have been used for pointing out which hourly heights of the tabulation go with the various hours of the component sought. These enable one to dispense with the labor involved in copying into the various forms. Some years ago a set of movable scales or strips was devised upon which the hourly heights are copied once for all summations. Several machines have been devised or constructed for facilitating the work of analysis, but they have not yet come into actual use.

Through the 24 partial sums or means finally obtained for a given component (and its harmonics) imagine a curve to be drawn. It may be represented by a Fourier series whose coefficients and initial phases can be found without difficulty. Then by taking the initial phases from the proper astronomical arguments for that time, the required epochs will be obtained.

14. Prediction of Tides.— At most ports the time of tide can be roughly predicted by adding to the time of the moon's transit, upper or lower, the average value of the lunitidal interval or «establishment» for the port. Where the diurnal wave is not large, the height of high water above mean sea-level is roughly equal to half of the mean range of tide; the low water is as much below this plane or datum.

Where great refinement is desired, the process just referred to involves much labor, and can best be carried out after a tolerably complete harmonic analysis has been made. This done we have only to add together a series of cosine terms for obtaining the height of the surface of the sea at any given time. But the number of these terms is so great that such a computation would soon become laborious, since it must be made for many assumed times in each day's predictions. Several predicting instruments have been designed or constructed. Generally speaking, the object of such an instrument or machine is to produce simple harmonic motions of suitable periods, phase and amplitude and to combine the results into one compound wave, or perhaps into two compound waves. The simplest form may be described thus: Upon one or more shafts, driven by hand or by clockwork, are fixed a number of wheels which mesh into other wheels, causing the latter (or wheels moved by them) to revolve with angular velocities having given ratios to the angular velocities of the shafts. These ratios are taken, as nearly as possible, proportional to the speeds of particular tidal components. Rigidly connected to these wheels are cranks carrying pulleys, or pins working in slots and which impart to vertical rods carrying pulleys rectilineal harmonic motions. At one end of the machine a chain or flexible wire is made fast; thence it is laid alternately over and under the pulleys. Near the other end of the chain or wire is attached a marking point which, when moved transversely to the line of motion of the paper roll, traces the tidal curve. It is evident that the machine continually sums a series of cosine terms.

If the instrument include a set of cranks at right angles to those giving the tide curve, together with pulleys and a summation chain or wire, the movement of a point on the chain (taking the place of the tracing point) across a fixed line or mark, corresponding to mean sea-level, will show the time when a high or low water occurs.

The original and simplest form of instrument is that due to Kelvin. The one designed by Ferrel is somewhat complicated, inasmuch as it separates out the principal lunar component. It was used in the office of the United States Coast and Geodetic Survey for about 30 years. Its chief advantage consists in indicating upon its face the times and heights of the tides. The office has recently completed and put in operation a machine which besides tracing a curve, as does Kelvin's indicates upon its face the times and heights of the tides,— the times becoming known through the additional mechanism just described.

Annual.— Tide Tables issued by the governments of Great Britain, France, Germany, the United States and other countries.

ROLLIN A. HARRIS,
Author of 'Manual of Tides.'

TIDEWATER, arms of the sea, bays, creeks and rivers where the tide ebbs and flows are public, and all persons may use the same for the purpose of navigation and fishing, unless restrained by law; in such waters the tide must actually ebb and flow. It is the rise and fall of the water, and not the proportion of salt water to fresh that determines whether or not the particular portion of a stream is within tidewater; the same determination applies to small streams as well as large ones. Open sea is the property of all nations; the rights and privileges therein, if any, being restricted to a specified distance from the shore — generally three miles. In the United States the titles to tidewaters and lands are vested in the States abutting thereon, or of its citizens, but are subject, however, to the constitutional rights of the United States. The Congress of the United States, under its power to regulate commerce, has the control of all navigable waters, and for such purposes they are the public property of the nation and subject to legislation; the test of navigability being whether or no the waters form a continued highway over which commerce may be carried on.

At various bathing beaches where the ocean frontage has become very valuable, private parties and owners of bathing pavilions often occupy the region between high and low water, and shut out or try to shut the public therefrom. This they have no right to do. Neither has any municipality a right to construct a bridge over a tidewater stream so as to obstruct navigation, which is the right of the public. The mariner also has the right to land wherever the shore connects with a public highway. Owners of land or a tidal shore have a right to build a pier or wharf for convenience in landing and embarking, but they must allow passage along the tide line, and must not block navigation. The right of fishing in tidal waters cannot be stopped by any adjacent landowner, though it is subject to local enactment for the protection of fish. Oyster beds often lie in tidal waters, and have been the subject of much dispute. See RIPARIAN RIGHTS.

TIECK, Johann Ludwig, German dramatist and novelist of the Romantic School, known also under the pseudonyms, PETER LEBRECHT and GOTTLIEB FÄRBER: b. Berlin, 31 May 1773; d. Berlin, 28 April 1853. He was of lowly origin, his father being a poor ropemaker. From 1782 to 1792 he attended the Friedrichswerder Gymnasium in his native city, coming under the influence of teachers with literary inclinations (Rambach, A. F. Bernhardi), and beginning a friendship with Wackenroder that was to last until the latter's death. His wish to become an actor was denied by his parents, and he was obliged to go to the University of Halle (1792) to study theology and philology, and to the University of Göttingen (1792–95), where he took up modern philology and literature. In 1797 he wrote cheap stories for the apostle of enlightenment at Berlin, Nicolai, and, during a short stay in Hamburg, made the acquaintance of Klopstock and Schröder, and became engaged to Miss Alberti (d. 1837), whom he married the following year. He became thoroughly well acquainted with all the members of the early romantic school in Germany, in 1798–1800, while living in the university town of Jena (the two Schlegels, Novalis, Fichte, Brentano, Gries), as well as with Goethe and Schiller, who were living at Weimar, a short walk from Jena. For 15 years, beginning 1802, Tieck and his wife lived, with few interruptions, on the Ziebingen estate (near Frankfort on the Oder) of his intimate friend, Wilhelm von Burgsdorff (really the property of the latter's uncle, Count Finkenstein). He traveled in Italy (1804–06) with his sister Sofie (1755–1833), who had married Bernhardi, and in various libraries on this journey he became acquainted with important manuscripts of mediæval German poems ('Nibelungenlied,' 'König Rother,' etc.). In 1819 he settled in Dresden, where he became (1825) manager of the Court Theatre, with the title of *Hofrat.* The last years of his life were spent chiefly at Berlin, to which city he was called (1840) by King Frederick William IV of Prussia, who greatly admired his work, and who granted him an annual pension of 3,000 thalers. Together with Friedrich Schlegel (q.v.) and August Wilhelm Schlegel (q.v.), Tieck was the founder of the Romantic School in Germany, and while he was not the most profound or original writer of this movement, he certainly was its most versatile member. His connection with C. A. Nicolai did not last long, and Tieck's first independent venture in literature was the romance of wild adventure, 'William Lovell' (Berlin 1795–96), an imitation of Réstif de la Bretonne (q.v.). In 1797, in his 'Volksmärchen,' appeared the satirical comedy 'Der gestiefelte Kater' ("Puss in Boots"), an outrageous and ingenious burlesque on the taste of the Berlin public in dramatic literature, which is not unlike some of the comedies of George Bernard Shaw. But Tieck's romantic productions begin with his collaboration with Wackenroder on the 'Herzensergiessungen eines kunstliebenden Klosterbruders' (1797) and 'Franz Sternbalds Wanderungen' (1799), romances of artistic journeys through Germany, which first opened the eyes of Germans to the beauties of the architecture and the spirit of the Middle Ages; also 'Phantasien über die Kunst' (Hamburg 1799), in which the same views are expressed in the form of criticism. His art demands are best embodied in a number of plays appearing from 1799 to 1804 ('Prinz Zerbino,' 'Der blonde Eckbert,' 'Genoveva,' 'Melusine,' 'Kaiser Octavianus'), in which Tieck consciously pursues a tendency new in literature, namely, the emphasis on feeling, longing and mood, and the attempt to bring about a different attitude toward art as well as toward the past (particularly the Middle Ages). Tieck had considerable literary scholarship, aside from his productive work, and he was the editor of a number of old German poems and the translator of 'Don Quixote' and Shakespeare (in the latter task he was aided by August Wilhelm Schlegel and by his own daughter Dorothea, 1799–1841). In the creative field his best work is in three departments: fantastic plays, 'Phantasus' (Berlin 1812–16); his poems (Dresden 1821–23); and his short stories (*novellen*), whose literary influence is by no means limited to their own day. The best of the latter are 'Der Aufruhr in den Cevennen' (first published, Berlin 1826); 'Der Gelehrte' (1828); 'Der Hexensabbath' (1832); 'Die Vogelscheuche' (1835), and 'Des Lebens Ueberfluss' (1839). He was less successful in his long two-volume novel, 'Vittoria Accorombona' (Breslau 1840). For editions of his works consult 'Novellen' (7 vols., Berlin 1823–28); 'Gesammelte Novellen' (14 vols., Berlin 1835–42); 'Ausgewählte Werke' (Stuttgart 1886–88); 'Ausgewählte Werke,' with biography, by Witkowski (Stuttgart 1903); 'Tiecks Werke, Auswahl' (6 vols., Berlin 1908); Tieck's correspondence with various persons (Raumer, Solger, Bernhardi) has also been published in separate editions. Translations of 'Puss in Boots,' 'Fair Eckbert,' and 'The Elves' are given in 'German Classics' (Vol. IV, New York 1913). Consult also Köpke, Rudolf, 'Ludwig Tieck' (2 vols., Leipzig 1855); Hoffmann, J. L., 'Ludwig Tieck' (Nürnberg 1856); Kaiser, Oskar, 'Der Dualismus Tiecks als Dramatiker und Dramaturg' (Leipzig 1885); Fischer, L. H., 'Aus Berlins Vergangenheit' (Berlin 1891); Danton, H. G., 'The Nature Sense in the Poetry of Ludwig Tieck' (New York 1906); Marchard, L., 'Les deux sources du Sternbald' (in *Revue germanique*, Vol. II, p. 522); Hemmer, H., 'Die Anfänge Ludwig Tiecks' (Strassburg 1908).

JACOB WITTMER HARTMANN.

TIED ISLANDS. See SHORE LINE.

TIEDEMANN, tē'dĕ-män, **Christopher Gustavus,** American legal writer: b. Charleston, S. C., 16 July 1857; d. Buffalo, N. Y., 25 Aug. 1903. He was graduated from the College of Charleston in 1876 and from Columbia Law School in 1879 and was professor of law for 10 years in the University of Missouri and six in New York University. From May 1902 he had been dean of the Buffalo Law School. Among his publications are 'The Law of Real Property' (1883); 'Limitations of Police Power' (1889); 'The Unwritten Constitution of the United States' (1890); 'State and Federal Control of Persons and Property' (1900).

TIEDEMANN, Diedrich, German philosopher: b. Bremerworde, 3 April 1748; d. Marburg, 24 Sept. 1803. He was professor of philosophy in the University of Marburg from 1776 and published 'Researches on the Origin of Languages' (1772); 'System of the Stoic Philosophy' (1777); 'The First Philosophers of Greece' (1780); 'Origin of the Magic Arts' (1787); 'Spirit of Speculative Philosophy from Thales to Berkeley' (1790–97), his principal work; 'Theætetus; or, Human Knowledge' (1794).

TIEDGE, tēd'gĕ, **Christoph August,** German poet: b. Gardelegen, Prussia, 14 Dec. 1752; d. Dresden, Saxony, 8 March 1841. He enjoys distinction as the author of 'Urania,' a lyric-didactic poem (1800), and 'Mirror for Women.' He also wrote 'Wanderings through Life's Market,' and 'Elegies.' His admirers have been many, and his poetry has sometimes been compared with that of Cowper. The year following his death the Tiedge Foundation was established for the purpose of assisting poets and artists or their widows and children, and also for the care of the poet's grave. Consult Kern, 'Beiträge zu einer Charakteristik des Dichters Tiedge' (Berlin 1896).

TIEFLAND. See MARTA OF THE LOWLANDS.

TIEGHEM, tē-gäṅ, **Philippe-Eduard Léon van,** French botanist: b. Bailleul, 19 April 1839; d. Paris, 30 April 1914. He was maitre de conferences at l'École Normale (1864); member of the Academy of Sciences (1877); professor of botany at the Museum (1879); professor of the Institute National Agronomique (1900). He greatly advanced the knowledge of the anatomy of the vegetable kingdom and proposed a new classification of the vegetable world. He established divisions among the Phanerogamia according to the character of the ovule. He wrote 'Traité de botanique' (Paris 1891); 'Elements de botanique' (Paris 1898), besides numerous works on his studies of myxomycetes, ascomycetes, bacteria, fermentation, etc. His articles are numerous in the *Journal de Botanique* and *Annales des Sciences Naturelles*.

TIELE, tē'lĕ, **Cornelis Petrus,** Dutch writer on comparative religion: b. Leyden, 16 Dec. 1830; d. there, 14 Jan. 1902. He was educated at Leyden and Amsterdam, in 1853 became pastor of the Remonstrant congregation at Moordrecht, and in 1856 removed to Rotterdam, where he became closely associated with Albert Réville (q.v.), whose liberalism in theological matters he fully shared. He was director of the Remonstrant theological seminary at Leyden from 1873 till his death, and during 1877–1901 held the professorship of the history and philosophy of religion in the University of Leyden, a chair specially created for him. In 1896–98 he delivered the Gifford lectures in the University of Edinburgh, published as 'Elements of the Science of Religion' (2 vols., 1897–99). He was one of the pioneers in the study of comparative and historical religion, and among his chief works are 'The Religion of Zoroaster' (1864); 'Comparative History of the Egyptian and Semitic Religions' (1869–72); 'History of Religion in Antiquity' (1892–96; 2d ed., 1901); 'Western Asia in the Light of Most Recent Discovery' (1894). Consult Jordan, L. H., 'Comparative Religion' (New York 1905).

TIEMANNITE, native mercuric selenide. It is a gray, metallic mineral of high specific gravity, 8.2 to 8.5; and a hardness of 2.5. It occurs massive with chalcopyrite in the Harz Mountains in Germany, and in choice isometric-tetrahedral crystals at Marysvale, Utah.

TIENTSIN, tē-ĕn'tsĕn', China, a city and treaty port in the province of Chili, situated on the Peiho River, 70 miles by water from its mouth in the Gulf of Pechili. The old city is a square surrounded by walls and ditches and traversed by broad, straight streets. Two miles to the south lies the European quarter. Tientsin is southeast of Peking with which it is connected by rail and also with the Manchurian Railroad. It is the river port of the capital, although large vessels cannot ascend the river. Its position at the northern terminus of the Grand Imperial Canal, however, makes it one of the principal trade centres of the empire. The total volume of imports amounted (1916) to about $59,017,093, of which more than one-third represented imports from foreign countries; exports totaled $34,097,085. Tientsin was besieged by a detachment of Taiping rebels in 1853. The Taiping army was on the way to Peking, and the defeat at Tientsin saved the capital from attack. In June 1900, during the Boxer troubles, Tientsin was occupied, after severe fighting, by the allied troops. Pop. estimated at 800,000. See CHINA.

TIEPOLO, tē-ā'pō-lō, **Giovanni Battista**, («IL TIEPOLETTO»), Italian painter: b. San Piero di Castello, near Venice, 5 April 1696; d. Madrid, 22 March 1770. He was a pupil of Gregory Lazzarini and followed as closely as he could in the footsteps of Paul Veronese, whose style he reproduced in numerous wall and ceiling pictures. Many churches and palaces of Venice were decorated by his hand. In 1750 he was summoned to Würzburg, where for three years he worked in the archbishop's palace on the wall paintings in fresco 'Olympus,' 'Four Quarters of the Earth,' and 'Life of Frederick Barbarossa.' In 1754 he returned to Venice as director of the Art Academy. In 1763 King Charles III summoned him to Spain to decorate the royal palace. Here he painted 'Smithy of Vulcan,' 'Apotheosis of Spain' and the ceiling frescoes 'Spain and her Provinces.' He was the last great master of the Venetian school. His coloring was superb, and his designs spiritual and expressive even when the drawing was incorrect. Among Tiepolo's easel pictures may be named 'Christ in the Garden'; 'Adoration of the Kings' (Imperial Gallery, Vienna); 'After the Bath' (Berlin Museum); 'Immaculate Conception' (Vicenza and Madrid). Many of his altar pieces are in the churches of Venice. A few of his paintings are in the Metropolitan Museum, New York. Consult Chennevières, H. de, 'Les Tiepolo' (Paris 1898); Gheltof, Urbanide, 'Tiepolo in Ispagna' (Venice 1881); Molmenti, P. G., 'G. B. Tiepolo' (Milan 1910); 'Masters in Art' (Vol. VI, Boston 1907).

TIERNAN, Frances Fisher («CHRISTIAN REID»), American novelist: b. Salisbury, N. C., 5 July 1846. Among her many works are 'Valerie Aylmer' (1870); 'Morton House' (1871); 'Nina's Atonement' (1873); 'A Daughter of Bohemia' (1873); 'A Question of Honor' (1875); 'The Land of the Sky,' a volume of travel (1875); 'Bonny Kate' (1878); 'Hearts of Steel' (1882); 'Miss Churchill' (1887); 'Philip's Restitution' (1888); 'Armine' (1884); 'The Land of the Sun' (1894); 'The Picture of Las Cruces' (1895); 'The Man of the Family' (1898); 'Weighed in the Balance' (1901); 'A Daughter of the Sierra' (1903); 'Princess Nadino' (1908); 'The Light of the Vision' (1912); 'The Daughter of a Star' (1913); 'A Far-Away Princess' (1914); 'The Secret Bequest' (1915). In 1909 Mrs. Tiernan was awarded the Lætare Medal by the University of Notre Dame.

TIERRA DEL FUEGO, tē-ĕr'rā dĕl fwā'-gō, an archipelago at the extreme south of South America, separated from the mainland by the Strait of Magellan which forms its boundary on the north and northwest, while the Atlantic Ocean bounds it on the east and the Pacific Ocean on the southwest; total area about 19,299 square miles. Politically, it is divided into two parts, each of which will be briefly described. (1) The western part, the area of which is 11,000 square miles, belongs to Chile and is included in the extensive Chilean territory of Magallanes, whose capital, the little town of Punta Arenas, stands on the western (mainland) shores of the strait, and is a port of call for steamships of some European and Australian lines (Hamburg to Callao, etc.). The lands belong to the state. (2) The eastern part, area 8,299 square miles and population about 1,000 whites and several thousand Indians, belongs to Argentina and forms a territory of that republic, its capital being Ushuaia. Of this region about 1,000,000 acres have passed into private ownership and only a small proportion is rented. In the north there are fertile valleys and roads connecting the villages lead through Chilean territory to ports on the southern coast of the Strait of Magellan. The interior is mountainous or hilly, but well adapted to stock-raising. «The climate of this region,» it is said, «though cold, is not severe, inasmuch as the mean temperature, maximum and minimum, as taken during several years, is $+ 5°$ C. and $— 10°$ C., respectively. Calm days are frequent in winter. Rain increases in the autumn, and in the summer dry winds from the southwest and west prevail, and occasionally are of terrific force.» (Consult 'Argentine Republic: a Geographical Sketch,' issued by the International Bureau of

American Republics, Washington 1903). There are no navigable rivers, but many streams of moderate size and a number of lagoons. The oldest and in some respects still the most interesting description of the region of the famous strait (of which both shores are now held by Chile) is that one written by Anthony Pigafetta, who accompanied Magellan and told of what they saw in October 1520, mentioning the characteristic storms, the «very great and high mountains covered with snow» surrounding the strait, and finally saying: «In it we found at every half league a good port and place for anchoring, good waters, wood all of cedar and fish like sardines, missiglioni, and a very sweet herb named appio (celery). There is also some of the same kind which is bitter. This herb grows near the springs and from not finding anything else we ate of it for several days. I think that there is not in the world a more beautiful country or a better strait than this one.» Pigafetta's sketch map of Magellan's Strait proves that he regarded Tierra del Fuego as a great southern continent stretching toward the antarctic pole. Consult Lord Stanley of Alderley, 'The First Voyage Round the World,' printed for the Hakluyt Society.

TIERS-ETAT, tē-ăr-zā-tā, the third estate, a name early given in France to the free bourgeoisie, to distinguish them from the nobility and the clergy, the other two estates. The three estates together formed the états-generaux or States-General, a legislative body which might be compared to the English Parliament. The third estate became famous in the political upheaval in France at the end of the 18th century, when, in the last States-General, it claimed power equal to that of both of the other orders. In 1789 it assumed the name of the National Assembly, and by its subsequent assumption of supreme power consummated the French Revolution. See France — History from Revolution to Empire.

TIETJENS, tĕt'yĕns, or **TITIENS, Therese Johanna Alexandra,** German soprano singer of Hungarian descent: b. Hamburg, 17 July 1831; d. London, England, 3 Oct. 1877. She made her début in her native city as Lucrezia in the opera of 'Lucrezia Borgia' in 1849, and her after career was one of great success, as she not only possessed a voice of great power and purity, but was an actress of much ability likewise. She made her home in London after 1858. In 1875 she visited the United States singing in 'Don Giovanni' and other grand operas.

TIFFANY, Charles Comfort, American Protestant Episcopal clergyman: b. Baltimore, Md., 1829; d. 20 Aug. 1907. He was educated at Dickinson College, Andover Theological Seminary and the universities of Halle, Heidelberg and Berlin and took orders in the Episcopal Church in 1866. He was rector of the Church of the Atonement, New York, 1874–80, and of Zion Church there, 1880–90. He was archdeacon of New York (1893–1902). He published 'Expression in Church Architecture'; 'Modern Atheism'; 'History of the Protestant Church' (1895); 'The Prayer Book and the Christian Life' (1897).

TIFFANY, Charles Lewis, American manufacturer: b. Killingly, Conn., 15 Feb. 1812; d. New York, 18 Feb. 1902. In 1837 he began his business career in New York, where in partnership with John B. Young he opened a stationer's store, to which were added Chinese and Japanese works of art and later French jewelry. The business founded on borrowed capital of $1,000 grew rapidly, the jewelry trade soon becoming the most important. In 1848 the firm began to deal exclusively in jewels, bronzes and other articles of virtu, and to manufacture gold and silver ware. The same year when the value of the diamond was so depreciated because of the unsettled conditions in Europe, Tiffany instructed his partner, at the time being in France, to buy as many diamonds as he could. Through this venture the reputation of the house among leading diamond merchants was established. In 1851 the name became Tiffany and Company, and the firm was incorporated in 1868. Changing conditions from time to time necessitated removals farther uptown, until the business was located at the present site in 1905. Mr. Tiffany was known as the chief diamond merchant in the United States, and established branch houses, also well known in London and Paris. The standard for sterling silver, 0.925 fine, now recognized throughout the entire country, was adopted by him in 1851. He was a liberal patron of the fine arts.

TIFFANY, Louis Comfort, American artist and decorator; b. New York City, 18 Feb. 1848. In early life he evinced a strong inclination toward the fine arts; hence his parents wisely gratified his tastes and educated him for an artist. He first studied with George Inness and Samuel Coleman in New York, then with Léon Bailly in Paris. He spent five years in Europe and the Orient, and besides working in water colors and oils, devoted much of his time to the study of the decorative arts. He became interested in glass and its possibilities in the early 70's and revived the mosaic theory in the construction of colored glass windows. Believing that work executed upon this principle would give the best artistic results, but finding that the glass in the markets did not have the range of color and texture necessary to carry out his ideas, he began a series of experiments through existing glass houses, but as these failed to grasp his thoughts he established works of his own. He succeeded in producing not only many of the finest effects that were obtained in the past, but also discovered new formulas by which he could make glass unlimited in its range of color and texture. With this glass, which is known as «Tiffany favrile glass» he has not only made windows of great beauty, but also vases and different objects of artistic interest which at once commanded the admiration of the world. In 1878 he organized a company under the title of Louis C. Tiffany and Associated Artists, for the purpose of promoting the decorative arts in America and particularly the developing the making of colored-glass windows. This was the foundation of the business. The glass blowing branch was first established as the Stourbridge Glass Company, and subsequently the Tiffany Furnaces. The general manufacturing and merchandising began under the name of the Tiffany

Glass Company, which in the development and broadening of its business became the Tiffany Glass and Decorating Company and the Allied Arts Company which are now more generally known as the Tiffany Studios. One of his most notable works in mosaic is the Chancel of the Crypt in the Cathedral of Saint John the Divine in New York, executed in glass mosaisc and semi-precious stones. Another recent example is the interior decoration of the new Madison Square Presbyterian Church in New York. But while there are hundreds of churches with Tiffany windows and many of them entirely decorated by his artists, ecclesiastical work is only one of the many branches of his varied artistic achievements. In domestic decorative work his two dwellings, the city home at Madison avenue and 72d street, New York, and «Laurelton,» his country house at Oyster Bay, L. I., are varied examples of his individuality and taste. Many of the most notable residences, university halls, hotels, theatres and other buildings in New York, Boston, Chicago and other large centres have been decorated by his art workers. Louis C. Tiffany is perhaps more widely known through his work in glass, mosaics and interior decorations, as these naturally appeal to the popular taste and attract attention by their exposure to public view. His genius, however, has not been restricted even to these varied fields, but he has constantly sought employment wherever artistic feeling could give expression. His studies in chemistry and his exhaustive laboratory work revealed new possibilities beyond the realms of glass. He has worked successfully in tapestry, rugs and other materials, pottery, metallic lustres, enamels and in later years he has given much thought to art jewelry and silverware, all of which, however, have not weaned him from his early love of the brush. He was from the first, and is to-day, a painter and works with his brush not only in his studios in town and country, but also on his annual trips abroad. After one of his winter sojourns in Egypt he brought home in 1906 over 23 water colors which he executed while sailing in his dahabiah on the Nile. His water colors and pictures in oil are frequently seen in the galleries of the art clubs and at other exhibitions. Among his principal canvases are 'Dock Scene' (1869); 'Spring' (1874); 'Wading at Seabright, N. J.' (1876); 'Street Scene in Tangiers' (1876); 'Study of Quimper, Brittany' (1877); 'Duane Street, New York' (1878); 'In the Fields at Irvington, N. Y.' (1879); 'The Cobblers at Boufarick' (1888); 'Feeding the Flamingoes' (1888); 'Church in Morlaix, Brittany' (1890); 'Market Day at Nuremberg' (1892); 'Street Scene in Algiers' (1895); 'Algerian Shops' (1895). Mr. Tiffany is art director of the Tiffany Studios, president and art director of the Tiffany Furnaces and vice-president and art director of Tiffany and Company, the jewelry house founded by his father. He was made a member of the Water-Color Society in 1870, an associate of the National Academy of Design in 1871 and an academician in 1880. He is also a member of the Society of American Artists, the Architectural League, the New York Society of Fine Arts, the Société Nationale des Beaux Arts of Paris and the Imperial Art Society of Japan. In 1900 he received a gold medal and the decoration of Chevalier of the Legion of Honor from the French government, in 1901 a gold medal at the Dresden Exposition, in 1902 a special diploma from the Turin Exposition and in 1903 Yale University conferred upon him the degree of A.M. In addition to these honors and decorations the art work, notably in glass, made under his direction received numerous awards at international expositions. Consult 'The Art Work of Louis C. Tiffany' (Garden City, N. Y., 1914).

TIFFANYITE. Certain bluish or bluish-white diamonds, principally from Brazil, although a few have been found in India and South Africa, phosphoresce for a considerable time after having been exposed to bright sunlight, electric light, or other brilliant rays. This property results from the inclusion in the diamond of a hydrocarbon or a rare earth, and for this class of diamonds the New York Academy of Sciences (1890) has given it the name «tiffanyite.»

TIFFIN, Edward, American physician, preacher and politician: b. Carlisle, England, 19 June 1776; d. Chillicothe, Ohio, 9 Aug. 1829. About 1786 he went to Charlestown, Va., and in 1789 was graduated in medicine at the University of Pennsylvania. Three years later he became a local preacher in the Methodist Church, likewise studying law and continuing the practice of medicine. About 1797 he removed to Chillicothe, in what was then the Northwest Territory, was elected to the Territorial legislature and in 1799 was speaker. He was chosen president of the convention which framed the State constitution (1802), and became first governor (1803–07) of Ohio. The town of Tiffin in that State was named for him. He arrested the Burr-Blennerhassett expedition in 1805. (See BLENNERHASSETT, HARMAN; BURR, AARON). He was a United States senator in 1807–09, resigned in the latter year to assume the speakership of the Ohio legislature. He was the first commissioner of the General Land Office (1812), and at the burning of the National Capitol by the British in 1814 saved the papers from destruction. In 1815 he was made surveyor-general of the Northwest Territory and continued in that office almost until the end of his life.

TIFFIN, Ohio, city, county-seat of Seneca County, on the Sandusky River and on the Baltimore and Ohio, the Pennsylvania and the Cleveland, Cincinnati, Chicago and Saint Louis railroads, about 80 miles north by west of Columbus, the State capital and 40 miles southeast of Toledo. It was settled in 1817 by Erastus Bowe, and incorporated in 1835. In 1836 it was chartered as a city. It is the commercial and industrial centre for a large portion of the country, in which are many fine farms. In the vicinity of Tiffin are deposits of clay and glass-sand. The chief manufacturing establishments of the city are machine shops, glass works, potteries, wagon and carriage works, motor truck works, glove and mitten works, candy factories, breweries, iron works, planing mills, emery-wheel works, flour mills and furniture factory. There are about 5,000 employees in the city's manufactories. The principal public buildings are the county courthouse, the municipal buildings, the churches and schools. There are 16 churches, representing 10 denominations, and

Saint Francis Hospital and Home. The educational institutions are Heidelberg University (Reformed), opened in 1850 (nearly 650 students in 1915), Ursuline College, public and parish schools and two libraries. Tiffin is the location of the national home of the Junior Order of United American Mechanics, containing about 400 children. The four banks have a combined capital of $500,000; the annual business done through the banks amounts to over $3,000,000. The government is administered under a board of public safety, board of public service and council of seven members elected by wards and at large. Pop. 14,256.

TIFLIS, tĭf'lēs', Russia, the capital of the government of Tiflis in the general government of Caucasia (see TRANSCAUCASIA), situated at the southern base of the Caucasus about midway between the Black and the Caspian seas. It is picturesquely built on terraces rising from the valley of the Kur, and surrounded by orchards and vineyards. Some walls and towers of the old fortifications remain, and there are several parks and a botanical garden. Among the numerous churches the most interesting is the cathedral of Zion, dating in part from the 5th century. Other notable buildings are the palace of the governor-general, the Caucasian museum and library. The educational institutions include nearly a dozen high schools, besides numerous technical schools, one of the foremost of which is the finely equipped school of commerce. The chief industries are the manufacture of leather, oil, silk, woolens, carpets and tobacco. There is also a cotton-mill and several breweries and distilleries. Commerce has declined somewhat, though the city is connected by rail with both the Black and the Caspian Sea. Pop. 327,800.

TIGER, the largest and most admirable of the cats (*Felis tigris*). In size and power it surpasses the lion, as it does in beauty, and expresses the highest type of feline structure. (See FELIDÆ). The ground color of the body is a bright tawny yellow, bearing black stripes running at right angles with the general axis of the body and limbs. The under parts and inner aspect of the limbs are white, as also are the throat and chest. On these white parts the stripes are lighter, and gradually merge into the white color. The tail is not tufted at its extremity, and is usually of lighter hue than the body, with dark rings. White or albino varieties of the tiger have been found, as also black ones. The maximum length, including the tail, is about 11 feet, and the largest weigh about 500 pounds. The tiger attains its full development in India, the Bengal variety being the largest and most typical; but it also occurs in southern Siberia, Turkestan, Persia, Java, Sumatra, China and Japan, encountering a range of climate from tropical to sub-arctic conditions. In habits these animals are far more active and agile than the lion, and exhibit a large amount of fierce cunning. They generally select the neighborhood of water-courses as their habitat, and spring upon the animals that approach to drink, then drag them to a more retired spot to be devoured. The march of the animal through the thick brushwood of the jungles in which it lives is noiseless and stealthy, and it appears rather to avoid than to court danger, although, when brought to bay, no animal presents a fiercer front than the tiger. Where deer, antelopes and wild hogs are abundant, domestic animals are comparatively safe, but otherwise the tiger is ready enough to prey on the latter. When pressed by hunger or enfeebled by age and incapable of dealing with larger prey, like buffaloes, the tiger prowls around villages, and, having once tasted human flesh, becomes a confirmed cattle-lifter and man-eater, sometimes causing the temporary abandonment of a large district by the terror-stricken inhabitants; and in several historic instances districts of country in southern India, Indo-China and the adjacent islands have been deserted premanently because so infested with tigers harbored by neighboring swamps and jungles. The number of persons killed by tigers each year in India averages about 930, mostly in Bengal, Madras, Central Provinces, Assam and Burma. About 32,000 head of cattle are also killed annually in India by tigers.

The natives destroy tigers by traps, pitfalls, spring-guns and poisoned arrows, but the orthodox method of keeping down their numbers as pursued by Europeans is to employ natives to beat the bush while the game, when started, is shot by the sportsmen seated on elephants. The sport is exciting, but dangerous; for a wounded tiger has been known to spring on an elephant and to inflict serious wounds on the driver and occupants of the howdah, before it could be dispatched. A safer and more common method is to tether a live goat, or otherwise set a bait in a place where a tiger may be expected, then erect a platform on poles or in a tree near by, and await the animal's approach on a night when moon or stars shed light enough to enable the watcher to shoot his prey.

These great cats have always been kept in captivity by Oriental rulers, and now and then have been completely tamed. They have been a feature of every menagerie and animal trainer's show since such collections began to be formed, and as they readily breed in captivity the supply will easily be maintained. Consult Baker, 'Wild Beasts and their Ways' (London 1890); Blanford, 'Mammals of India' (ib. 1888); Lydekker, R. 'The Game Animals of India' (ib. 1907); Porter, 'Wild Beasts' (New York 1894), and books on sport and travel in India and the East Indies.

TIGER-BEETLE, a beetle of the family *Cicindelidæ,* in which the head is wider than the thorax, and the terminal hook of the maxillary jaws is jointed at its base. This insect is swift and active, and preys upon other insects. It is very often found in sandy places and the larvæ live in straight deep burrows in the ground. The color varies, corresponding as a rule to the general coloring of the surroundings. This beetle is more common in the tropics. Over 1,500 species are known, less than 100 of which have been found in the United States. Some species are wingless. See plate accompanying the article INSECTS.

TIGER-CAT, a name of not very definite signification, sometimes given to those animals of the family *Felidæ* which are of medium size, and somewhat resemble the tiger in form or markings, such as the chati, margay, serval, etc. In America the ocelot (q.v.) is most often meant. The marbled tiger-cat is a small beautifully variegated species (*Felis marmorata*) of the eastern Himalayan region.

TIGER-EYE, a semi-precious, chatoyant stone, of blue, yellow or brown color, which exhibits a charming change of colors when revolved. It is a silicious pseudomorph after crocidolite. The original mineral is changed by infiltration of silica and when accompanied by the oxidation of its iron its blue color is altered to yellow or brown. It is extensively cut into watch charms, cuff buttons and many fancy articles which are largely sold at many tourist resorts, often, though fraudulently, as of local origin, the mineral being found only in Griqualand, South Africa. See CROCIDOLITE.

TIGER-FLOWER, a Mexican plant (*Tigridia pavonia*) of the iris family, frequently cultivated for the brilliance and oddity of its flowers. These are solitary, terminal and cup-shaped in the centre, but have a wide-spreading limb, formed by the three obovate clawed segments of the perianth, which are the largest, and are brilliant red at the outer edge, shading to yellow, spotted with reds and purples at the base. The three inner segments are fiddle-shaped. The flowers are fugacious, lasting only a day, but there is a long succession of them. There are many varieties of these Tigridias, in which the hues of the corollas range through various shades of yellow to white. The stem is about a foot high, slightly zigzag and branched; and it bears a few alternate distant leaves, the greater number of the leaves being radical and sword-shaped. The tunicated corms need to be lifted into a dry place out of reach of frost during the winter, as they are not hardy in the northern United States. Tigridias are propagated by seeds or offsets. There are other species of the genus, which are not so handsome or conspicuous as *T. pavonia;* some of them have bluish flowers.

TIGER LAKE. See NAHUEL-HUAPI.

TIGER-LILY. See LILY.

TIGER-MOTH, one of the large moths of the genus *Arctia,* the caterpillars of which are known as «woolly bears» because of their heavy covering of black and brown hairs.

TIGER SHARKS, a shark (*Stegostoma tigrinum*) common in the Indian Ocean. The full-grown fish, from 10 to 15 feet long, frequent the open sea. The color is a yellowish-brown, with black or dark brown transverse bands or spots.

TIGER-SNAKE, a large blackish, yellow marked elapine poisonous serpent (*Notechis sculatus*), widely disseminated in Australia and Tasmania, and very numerous.

TIGHE, tī, **Mary** (BLACHFORD), Irish poet: b. Dublin, 9 Oct. 1772; d. Woodstock, County Kilkenny, 24 March 1810. She was married to her cousin, Henry Tighe, in 1793. Though her poem, 'Psyche, or the Legend of Love,' was privately printed (1805), it was only after her death that her complete writings were published. The first edition was in 1811, and they have been several times reprinted. The 'Psyche' is written in the Spenserian stanza and is founded on the story of Cupid and Psyche as narrated in 'The Golden Ass' of Apuleius. Her other poems are chiefly of a religious cast. It is probably as the subject of Moore's lyric, «I saw thy form in youthful pride,» and of Mrs. Hemans' 'Grave of a Poetess,' that Mrs. Tighe will be longest remembered.

TIGRANES (tĭg-rā'nēz) **I,** king of Armenia, 96 to 55 B.C. A descendant of Artaxias, the founder of the Armenian kingdom, he brought under his rule large accessions of territory in Syria and Mesopotamia, and in 83 B.C. had acquired most of the provinces of Syria from the Euphrates to the sea. By his marriage with the daughter of Mithridates, king of Pontus, he formed an alliance with that monarch disastrous to the smaller kingdoms of Asia Minor. He invaded Cappadocia in 78 and completely subjugated its inhabitants. Other wars followed and Tigranes became the mightiest king in Asia. He built the new capital, Tigranocerta, whither he transplanted the inhabitants of many captive places, including Cappadocia, Syria and Cilicia. His possessions were wrested from him by the Roman general Lucullus, but were nearly all recovered by Tigranes, only to be lost again to Pompey in 66. In the final defeat of Tigranes, Pompey was aided by the rebel son of the Armenian king, who claimed the provinces of Gordyene and Sophene for himself. Tigranes was able to retain only Armenia proper, for which he was obliged to pay Pompey an enormous sum and to subsidize the entire Roman troops under him. Tigranes was succeeded by his second son, Artavastes. Consult Reinach, T., 'Mithridate Eupator roi de Pont' (Paris 1890).

TIGRIS, tī'grĭs, Asia, an important river which rises near the Euphrates (q.v.) from two sources. The western and chief branch rises near Kharput, and under the name of Dejleh or Shatt, flows southeast. After passing Diarbekir it receives the eastern branch, flows past Mosul and Bagdad and joins the Euphrates at Kurna; together they form the Shattel-Arab and thus enter the Persian Gulf. The stream waters the ancient Nineveh, and separates Assyria from Mesopotamia on its way to Bagdad. It is only navigable for small boats and its entire length is 1,150 miles. Keleks, or large rafts, supported by inflated skins, are much in use for the transportation of freight. The chief tributaries are the Greater and Lesser Zab and the Diyala. The biblical name of the river is Hiddekel.

TILDEN, Douglas, American sculptor: b. Chico, Butte County, Cal., 1 May 1860. He lost his hearing in early life and was graduated from the State Institution for the Deaf in Berkeley, Cal. (1879). Taking up the study of sculpture in 1887 at the National Academy of Design, New York, and later abroad, he was appointed a member of the jury on sculpture at the World's Columbian Exposition in Chicago. He was elected a member of the National Sculpture Society, the New York Art Club, the San Francisco Art Association, etc., and was professor of sculpture at the Mark Hopkins Art Institute (1894–1900). His works include 'Base-Ball Player'; 'Tired Boxer'; 'Indian Bear Hunt'; 'Football Players,' etc.

TILDEN, Samuel Jones, American lawyer and statesman: b. New Lebanon, N. Y., 9 Feb. 1814; d. Greystone on the Hudson, near Yonkers, N. Y., 4 Aug. 1886. He was educated at Yale and at New York University, being graduated from the latter in 1837. He then studied law and was admitted to the bar in 1841. He attained the first rank in his profession, being particularly successful in reorganizing corporations involved in litigation, and amassing one of the largest fortunes ever gained in the practice of law. While a student in college, he had taken an active part in politics, writing and speaking in favor of Martin Van Buren's policy; in 1845 was elected to the New York State legislature and was a member of a special committee to consider the settlement of anti-rent troubles, his report on the subject forming the basis of subsequent legislation. In 1846 he was a member of the State constitutional convention and in 1848 was one of the delegates of the Free Soil faction of the Democratic party to the National Convention, but his political activity then slackened until after the Civil War. During the war, however, he was several times consulted by President Lincoln; he believed that the war, once begun, must be carried through by the Federal government, but opposed some acts of the administration as unconstitutional. In 1866 he was made chairman of the Democratic State committee and in 1867 was a member of the State constitutional convention. As chairman of the State committee he took a leading part in the overthrow of the Tweed Ring, opposing their delegates in the State conventions and being active in collecting evidence against their leaders and bringing them to prosecution; in 1872, having been elected to the State legislature, he was the leader in the impeachment of two of the Tweed judges. (See TAMMANY SOCIETY; TWEED, W. M.). In 1873 he resigned as chairman of the State committee; but in 1874 was nominated and elected Governor of New York. His administration was notable for his successful exposure of the «canal ring,» an association made up of persons who obtained contracts for canal work which they never fulfilled, but for which they were paid, and their political supporters. Governor Tilden employed a skilled engineer to examine their work and then surprised the legislature by a wholly unexpected special message setting forth in detail the fraudulent methods of the «ring.» This served as a direct appeal to the people; and so aroused public opinion that the legislature was forced to authorize the governor to appoint a canal commission. The reports of this commission resulted in a marked diminution in the appropriation for canals and the indictment of several officials for defrauding the State. In 1876 Tilden was the Democratic nominee for President of the United States, and received the largest popular vote, but lacked one electoral vote necessary for his election. As the electoral votes from several States were contested on account of alleged fraud, the matter was referred to a special Electoral Commission, which decided in favor of the Republican candidate, Rutherford B. Hayes. (See ELECTORAL COMMISSION). Popular excitement had run high and many Democrats still claimed Tilden's election, but he urged his supporters quietly to accept the decision of the commission. In 1880 and 1884 his party again wished to nominate him for the Presidency, but each time he declined the nomination. He bequeathed the most of his fortune to establish a public library in New York; but the will was contested by the heirs and only a part of the bequest came into the city's possession. (See TILDEN FOUNDATION). Consult 'Writings and Speeches of Samuel J. Tilden' (ed. by John Bigelow, 2 vols., New York 1885); 'Letters and Literary Memorials of Samuel J. Tilden' (ed. by John Bigelow, 2 vols., ib. 1908); Bigelow, J., 'Life of Samuel J. Tilden' (2 vols., ib. 1895); Haworth, 'Disputed Presidential Election of 1876' (Cleveland 1906).

TILDEN, (SIR) William Augustus, English scientist: b. London, 15 Aug. 1842. He was a graduate of various schools and of the Royal College of Chemistry; in 1864 became demonstrator of the Pharmaceutical Society; from 1872–80 science master at Clifton College; professor of chemistry, Mason College, Birmingham, 1880–94; president of the Institute of Chemistry, 1891–94; treasurer of the Chemical Society, 1899–1903 and president, 1903–05; professor of chemistry, Royal College of Science, London, 1894–1909, and dean of the college 1905; emeritus professor in the Imperial College of Science and Technology from 1909. In 1908 he was awarded the Humphrey Davy medal of the Royal Society. He published numerous scientific papers and in book form 'Introduction to Chemical Philosophy' (1876); 'Practical Chemistry' (1880); 'Hints on Teaching Chemistry' (1895); 'A Manual of Chemistry' (1896); 'A Short History of the Progress of Scientific Chemistry' (1899); 'The Elements' (1910); 'Chemical Discovery and Invention in the Twentieth Century' (1917) and 'Sir William Ramsay' (1918).

TILDEN FOUNDATION, The, one of the integral components of the New York Public Library Fund. By the will of Samuel J. Tilden (q.v.) the bulk of his property was left for the establishment of the Tilden Trust, to found a free public library and reading room in New York. This will was contested in a long suit in the courts and was broken in 1891, the property being decreed to the heirs. Mrs. William B. Hazard, one of the latter, was entitled by this decision to half of the estate, but she relinquished about $2,000,000 of her portion in order that Tilden's wishes might be carried out to some extent. In 1895 an agreement was reached whereby the trustees of the Tilden Trust Fund, the Astor Library and the Lenox Library agreed to unite their properties, forming a single «New York Public Library — Astor, Lenox and Tilden Foundations.» The city of New York subsequently agreed to erect on the site of the old reservoir, in Bryant Park, 40th to 42d streets on Fifth avenue, a handsome and spacious structure for these great libraries. The work was begun in June 1899 and completed in May 1911. See also LIBRARIES.

TILEFISH, a large oceanic fish (*Lopholatilus chameleonticeps*), allied to the cods, and belonging to the family *Malacanthidæ*, represented by the blanquilla and other well-known food-fishes of the Pacific Coast. It weighs from 10 to 40 pounds and is big-headed and brilliantly colored, with a curious triangular fatty protuberance on the top of the head in advance of the long low dorsal fin. Its flesh is excellent and it is caught in the same manner as are cod. The curious story of this fish is thus sketched by Lucas: «This fish, belonging to a tropical family having its headquarters in the Gulf of Mexico, was discovered in 1879 in moderately deep water to the southward of Massachusetts and on the edge of the Gulf Stream, where it was taken in considerable numbers. In the spring of 1882 vessels arriving at New York reported having passed through great numbers of dead and dying fishes, the water being thickly dotted with them for miles. From samples brought in, it was found that the majority of these were tilefish, while from the reports of various vessels it was shown that the area covered by dead fish amounted to somewhere between 5,000 and 7,500 square miles, and the total number of dead was estimated at not far from a billion. This enormous and widespread destruction is believed to have been caused by an unwonted duration of northerly and easterly winds, which drove the cold arctic current inshore and southward, chilling the warm belt in which the tilefish resided and killing all in that locality. It was thought possible that the entire race might have been destroyed, but, while none were taken for many years, in 1899 and 1900 a number were caught, showing that the species was beginning to reoccupy the waters from which it had been driven years before.» Consult Lucas, 'Animals of the Past' (New York 1902) and 'Reports' and 'Bulletins' of the United States Fish Commission, especially for 1884 and 1899.

TILES are stone, metal or composition slabs for use in covering a roof to keep out the water. Since the most common material is baked clay, and this same clay is used to form drain pipe, the word tile has been extended in meaning to cover clay pipes termed drain-tile. This same baked clay is often colored and fused on one side, giving it a glazed finish often of great beauty. Such colored and glazed tiles are used for interior walls, dados, floors, mantles, etc. Drainage tiles are made of native clay and usually glazed inside. Each tile has at one end an extended rim which overlaps the small end of the tile next to it, thus forming a continuous pipe. Roofing tiles take the form either of flat shingle or slate-like slabs or of pantiles. A section through a pantile shows a horizontal-like curve, one side of the tile being concave and the other convex — the latter curve fitting over the concave curve of the next tile, and so on. In this manner there is no opening left open to the weather. The same principle is often applied to the flat tiles and to ridge tiles, which bear on one edge a semi-circular convex lip, and on the other a concave one. Ridge tiles are made in angles to fit and cap the ridge-pole of a roof, to turn corners and to ornament projections. Roof tiles are glazed or dull, according to the maker's fancy, and are used in varieties of colors. Modern taste seems to prefer either highly glazed saffron or terra-cotta pantiles, or else dark dull flat ones. But during the Renaissance and until recent years highly colored glazed roof tiles either in the flat or corrugated style were in large demand throughout southern and central Europe. Fine examples of decorative roofs are preserved from the Middle Ages, a notable instance being the roof ot Saint Stephen's Cathedral in Vienna. Such tiles are often enameled and are thus rendered waterproof. Slate, marble and metal roof-tiles are occasionally employed.

Interior tiles are made in great varieties of shapes and sizes, colors and materials, ranging from fine brick-clay tiles to those of enameled and painted porcelain. They are used for pavements, flooring and revetments to walls. Old houses in the south of Europe were commonly paved with red brick-tiles baked hard and sometimes glazed. The method of decoration usually employed was to inlay clays of different colors in the bodies of the tiles, producing designs often of great beauty. Enameled tiles were used in the 15th and 16th centuries for the pavings of interiors of importance, such as chapels, chambers of honor, etc. These thin, enameled tiles broke easily and only a few examples are to-day preserved in the cathedrals and castles of France and Italy. The use of tiles for wall revetments and for dados was not general during these periods but has grown in recent years. Modern wall tiles are usually painted or glazed and are of various fine clays, not infrequently of porcelain. Large wall spaces are covered with painted tiles in pictorial or decorative composition, the work of Théodore Deck affording some fine examples. Tiles with slightly raised figures are also used, the style having been borrowed from the Persians who are masters of their manufacture. A recent effective use of colored clay tiles may be seen in the subway stations in New York, where especially pleasing effects have been inexpensively produced by the judicious selection and blending of colors. Modern usage does not follow the example of the Middle Ages in the employment of carved and leaded marble tiles. In these latter the variously shaped slabs of stone were incised with intricate and elaborate designs and the incisions filled with lead or colored compositions and sometimes with fine mosaic work. Consult Church, W. A., 'Patterns of Inlaid Tiles,' etc. (1845); Herdtle, H., 'Vorlagen für das polychrome Dachornament' (1885); Jones, Owen, 'Designs in Mosaic and Tessellated Pavements,' etc. (1842); Monceaux, Henri, 'Les carrelages historiés du moyen-âge et de la renaissance,' etc. (1887); Wallis, Henry, 'Italian Ceramic Art,' etc. (1902) and the papers of Ricardo, H. R., on 'Architect's Use of Enameled Tiles' (in *The Architectural Review* for 1902, Vol. XI).

TILGHMAN, tĭl'man, **Mathew**, American patriot: b. Queen Anne County, Md., 17 Feb. 1718; d. Talbot County, Md., 4 May 1790. He was a member of the Maryland assembly in 1751 and as a magistrate and prominent member of Talbot County was a member of the committee which drew up the Maryland protest to the Stamp Act. In 1774 he was made president of the Provincial Congress or Convention which controlled the affairs of the colony until its statehood, and in 1777 represented Talbot County in the Provincial Senate. He was a delegate to the Continental Congress, 1775–77 and was throughout the entire pre-Revolutionary period a staunch defender of the cause of independence and an able advocate of civil rights.

TILGHMAN, Tench, American soldier, nephew of M. Tilghman (q.v.): b. Talbot County, Md., 25 Dec. 1744; d. Baltimore, Md., 18 April 1786. His career as a merchant in Philadelphia was interrupted by the Revolution. He joined the Continental army at the outbreak of the war and was one of the officers sent to confer with the Six Nations. In

1776 he was appointed aide-de-camp to Washington, in which position he continued to the close of the war and in this capacity was entrusted with the bearing of the surrender of Cornwallis to Congress on 19 Oct. 1781. In May 1781 he was made lieutenant-colonel to take rank from 1 April 1777. At the close of the war he settled in Baltimore, where he again took up a mercantile life. Consult ‹Memoir of Tench Tilghman› (Albany 1876).

TILIACEÆ, a family of trees, the lindens, with some shrubs and a few herbs, mostly indigenous to the tropics, especially in South America and Asia. A few are natives of the north temperate zone. The chief genus is *Tilia*, characterized by alternate, simple leaves; solitary or variously grouped axillary flowers with four or five sepals and petals, numerous stamens with two-celled anthers; and several-celled capsules or drupes. One of the most striking peculiarities of the family is the abundance of mucilaginous substances in various parts of the plants, particularly in the young twigs, inner bark and buds. On this account several species are valued for stock-food. Many of the species are noted for their tough fibrous bast, often used for making cordage, bagging and even fine fabrics, as in the case of jute. Some species furnish edible fruits, for instance, *Grewia denticulata*, which yields large quantities of acid drupes about half an inch in diameter. The linden and the basswood are particularly useful trees in the cool temperate zone, where they are employed for timber, street and park planting and as forage for bees, their abundant nectar furnishing one of the finest grades of honey. See LINDEN; CORCHORUS; FIBRE; JUTE; LIME.

TILL, a heterogeneous mixture of clay, boulders, sand, gravel and rock flour, covering generally the surface of the rocks in the glaciated region. It represents the ground moraine of the great Pleistocene ice sheet, which finally slid over it and compacted it more or less firmly. It sometimes rises locally in compressed dome-shaped eminences known as drumlins. Till or boulder clay is unstratified, in contrast to glacio-fluvial deposits, or modified drift. Till that has become consolidated is known as tillite. See GLACIAL PERIOD; DRIFT.

TILL EULENSPIEGEL. In ‹Till Eulenspiegel› Friedrich Lienhard exemplifies his favorite method of treating, with manifest application to his own time, an old genuinely German subject conceived in a way that is no less novel than poetic. The work is in three parts. The first, ‹Eulenspiegels Ausfahrt› («Eulenspiegel's Departure»), and the third, ‹Eulenspiegels Heimkehr› («Eulenspiegel's Return Home»), were brought out together in 1896; the second, ‹Der Fremde› («The Stranger,» 1900), is an episode capable — as is also the first part — of separate representation.

The traditional coarse and rascally practical joker of the 15th century (see EULENSPIEGEL) is transformed in Lienhard's drama into an idealist. He is no hero; he lacks the poise of a humorist, he has too much sentiment to be a cynic; knowing the worth of life, he rebels against pettiness and narrowness, but he has no other weapon than somewhat hollow laughter, and no other plan of campaign than somewhat boorish mischief-making. The transformation is not unlike that of the 16th century Faust at the hands of Goethe; but the scope of Lienhard's subject is naturally narrow in comparison with Goethe's and the setting of his action is more specifically historical. There is a melancholy suggestiveness in the fact that Lienhard's Till meets his end in the Peasants' Revolt, and in the further fact that Lienhard dignifies him with the approval of Hans Sachs — giving, as it were, to the individualist who, in a contemptible time, could find no better place than that of court fool, the sanction of the Nuremberg shoemaker's optimistic faith in social regeneration.

That Hans Sachs should be brought into this action at all is enough to indicate that Lienhard was less concerned for the probability of his plot than for its atmosphere. If it is probable that in Eulenspiegel's community there should be so sane and resolute a peasant girl as Gertrude, to whom he is sincerely devoted, it is improbable that his love for her should not have sufficed to steady him. As the «stranger» of the episode he finds — meanwhile oblivious of Gertrude — a kindred spirit in the daughter of an innkeeper. But when a wager has carried him from an artful pretense to the point of realizing this spiritual kinship, he seems to see no incongruity in abandoning the girl to the commonplace lover whom she has promised to marry, in case she loses the bet. However, neither the plot nor the farcical comedy, of which there is no lack, gives this work its chief significance. The modernized Eulenspiegel is a Diogenes. It is hardly his fault if, in his search for an honest man, he does not even find himself.

WILLIAM G. HOWARD.

TILLAGE. See AGRICULTURE IN THE UNITED STATES.

TILLETT, Benjamin, English labor leader: b. Bristol, 1859. He was employed in coal pits and brickyards from the age of eight years, went to sea at 12 and served in the navy for two years after he was 17, being then invalided out of the service. He later became a tea cooper and in 1887 was one of the organizers of the Tea Cooper's and General Laborers Association. He was also associated with the organization of the Dock, Wharf and General Workers' Union of Great Britain and Ireland and became its secretary. He was one of the leaders of the Great Dock Strike of 1888; for many years an alderman of the London County Council, and was several times an unsuccessful candidate for Parliament. He was a loyal worker for maximum production during the European War and was one of the labor leaders sent to visit the Western battle front. Author of ‹Trades Unions and Socialism› (1894); ‹History of the London Transport Workers' Strike, 1911› (1912).

TILLETT, Wilbur Fisk, American Methodist theologian: b. Henderson, N. C., 25 Aug. 1854. He was graduated from Randolph-Macon College in 1877 and from Princeton Theological Seminary in 1880. He held a pastorate at Danville, Va., 1880–82 and has been professor of systematic theology at Vanderbilt University since 1884 and vice-chancellor there from 1886. He has published ‹Our Hymns and Their Authors› (1889); ‹Discussions in Theology›

(1890); 'Personal Salvation' (1902); 'The Doctrines of Methodism' (1903); 'A Statement of the Faith of Worldwide Methodism' (1906); 'Hymns and Hymn Writers of the Church' (with C. S. Nutter, 1911).

TILLEULENSPIEGEL, tĭl'oi"lĕn-spē-gĕl, a series of stories collected and first published in Low Dutch, in the year 1483. See EULENSPIEGEL; TILL EULENSPIEGEL.

TILLITE, a rock consisting of a heterogeneous or non-stratified mixture of boulders and sand, supposed to have been glacial till originally. The name was applied by Davis to beds in the South African Permian succession believed to have been of glacial origin. Shantum tillite is a member of Roxburg Conglomerate in eastern Massachusetts of Carboniferous, possibly Permian, age. See TILL.

TILLMAN, Benjamin Ryan, American legislator: b. Edgefield County, S. C., 11 Aug. 1847; d. Washington, D. C., 3 July 1918. He received his education at Bethany Academy, entered the Confederate army on the outbreak of the Civil War, but was obliged to forego active service owing to a severe illness. The close of the war found him undertaking the management of his mother's farm in the back country, a farmer in spirit and life. During the troubled days of Reconstruction he played his part in the reprisals of the whites. In the '80's a curious political situation developed in South Carolina, which finally landed Tillman in the governorship. The aftermath of war and the persistence of caste lines put a widening gulf between the aristocrats of the seaboard plain and the back country people of the mountains. With the overturning of the Republican domination the patrician class began to resume once more oligarchic rule of the State. There were mutterings of discontent among the mountaineers and farmers in the backwater districts. As champion of the latter Tillman suddenly found himself thrust forward. In 1890 in the most bitter campaign in the State's history he was elected governor. From the day of his inauguration to the end of his second term South Carolina was a constant ferment. The one incident of his rule that stands out among all the other turbulent affairs was his promulgation of the famous dispensary law and the events following it. This law gave sheriffs and constables the power to enter stores and private houses and to seize any liquors found there which did not bear the stamp of the State. Riots occurred; Tillman ordered out the militia; some companies refusing to obey this summons were publicly degraded, and conditions bordering on anarchy existed, but the law stayed and the governor was triumphant. Tillman soon became a national figure. He took a prominent part in the State Constitutional Convention of 1895, which set an educational qualification for the franchise, and by his violent attitude against the negro he became the object of attack by Northern sentimentalists. He was a bitter opponent of Cleveland; his speeches against the latter gaining him the name of «Pitchfork Ben.» In the national Democratic conventions of 1896, 1900 and 1904 Tillman was the stormy petrel who raged at all who opposed his views. In 1894 he was elected to the United States Senate and was re-elected in 1900, 1906 and 1912. His terms in the Senate were marked chiefly by the quarrels he had. Cleveland he had hated and it was not in the realm of possibility that he and Roosevelt could be other than enemies and enemies they frankly were during Roosevelt's incumbency of the Presidency. In his later years Tillman became less and less the bugaboo in the eyes of the people who had at first opposed him with all of the bitterness of caste and class. As he broadened into a national figure and in the Senate fought the fight of the whole South with untiring vigor, he came first to be tolerated, then respected by all the people of his State. The closing years of his life found him chairman of the Senate Committee on Naval Affairs, perhaps the second most important governing body in the country, and as such he worked incessantly for the building up of the navy. He advocated a greater navy, government armor-making plants, etc., and warned manufacturers that the government would force them to act fairly. He supported his friend, Secretary Daniels, maintaining in public and private that Daniels was a misunderstood, much underestimated man who would prove his worth in time.

TILLMAN, Samuel Escue, American soldier and author: b. near Shelbyville, Tenn., 2 Oct. 1847. He was graduated from West Point in 1869, and assigned to frontier duty. In the following year he was called to West Point as assistant professor of chemistry, and was later appointed professor of mineralogy and geology. He continued to teach in the Military Academy for many years, being retired by operation of law on 2 Oct. 1911. In 1874–75 he served as a member of the United States expedition to Tasmania to witness the transit of Venus. He was recalled to active duty on 6 June 1917 and assigned to duty as superintendent of the United States Military Academy. He is the author of 'Essential Principles of Chemistry' (1884); 'Elementary Mineralogy' (1894); 'Elementary Lessons in Heat' (1889); 'Descriptive General Chemistry' (1899); 'Important Minerals and Rocks' (1900), and other textbooks.

TILLODONTIA, a group of extinct mammals, chiefly of the North American Eocene rocks. They were large plantigrade, five-toed land animals, whose skeleton presents characters intermediate between those of *Carnivora* and *Rodentia*. The brain is small and slightly furrowed. The dentition was complete and marked by large, rodent-like incisors. A prominent genus was *Tillotherium*. See RODENTIA.

TILLOTSON, tĭl'ŏt-sŏn, **John,** English prelate, archbishop of Canterbury: b. Sowerby, Yorkshire, October 1630; d. 22 Nov. 1694. His father, a strict Calvinist, brought up his son in the same principles. He was graduated at Cambridge and elected a Fellow of Clare Hall in 1651. In 1666 appeared his 'Rule of Faith,' a reply to a work by John Sergeant, an English clergyman, who had become a convert to the Catholic faith. In 1670 he became prebendary of Canterbury. When Charles II, in 1672, issued a declaration for liberty of conscience for the purpose of favoring the Roman Catholics, he preached strongly against it, but was, nevertheless, advanced to the deanery of Canterbury, and three years after (1675) presented to a prebend in Saint Paul's. On the accomplishment of the revolution he was taken into favor by King William, and in 1689 he was appointed dean of Saint Paul's. On the suspension of Archbishop Sancroft as a non-juror he was appointed to exercise the archiepiscopal jurisdiction, and in 1691 accepted the archbishopric itself. He had previously formed an abortive scheme for the comprehension of the Presbyterians within the Church, and had also failed in another design for forming a new book of homilies. When, therefore, he accepted the primacy, a large party assailed him with great animosity. He bore these attacks in silence, and even prevented some prosecutions for libel against him, directed by the Crown. He was also charged with Socinianism; in answer to which he republished four of his sermons on the ‹Incarnation and Divinity of Our Saviour.› The only class to whom he did not show a mild and tolerant spirit was the Roman Catholics, toward whom he had a strong aversion. Tillotson's sermons were for half a century the most popular of that class of compositions in the English language but have since fallen into neglect and even disesteem. In other respects than that of style they are generally commended for benignity of spirit rather than depth or richness of thought. An edition of his sermons was published by his chaplain, Dr. Ralph Barker (14 vols., London 1695–1704). Consult also Birch, Thomas, ‹Life› (London 1752).

TILLY, tĭl'ĭ (Fr. tē-yē), **Johann Tserklaes**, COUNT OF, Bavarian commander: b. Castle Tilly, Brabant, near Belgium, February 1559; d. Ingolstadt, Bavaria, 30 April 1632. He received a strict Jesuit education, but preferring life in the army he became a soldier of fortune in the service of Spain, and later in that of Austria, after which he attached himself permanently to the Bavarian army, and under the banner of its king, the head of the Catholic League, entered upon the Thirty Years' War. His first signal victory was that of White Mountain, 6 Nov. 1620, when he defeated the Protestants in Bohemia. He was victorious over Christian of Brunswick at Höchst (1622) and Stadtlohn (1623), thus gaining the title of Count of the Empire. In 1626 he compelled Christian of Denmark, who had joined the Protestant forces in Saxony, to retire into his own domain. In 1630 he was made commander of the Imperial army and in 1631 won the famous battle of Magdeburg against Gustavus Augustus of Sweden and the Saxon Protestants. In the following September the Bavarian troops were, however, completely routed by the Swedes at Breitenfeld, and in the engagement upon the river Lech, April 1652, Tilly, who had been victorious in 36 battles in the religious wars of Germany, was mortally wounded. Consult Klopp, O., ‹Tilly in Dreissigjährigen Krieg› (Stuttgart 1861); Villermont, ‹Tilly, ou La Guerre de trente ans› (Tournay 1859); Wittich, K., ‹Magdeburg, Gustav Adolf und Tilly› (Berlin 1874).

TILSIT, Germany, a town in East Prussia, at the confluence of the Memel or Niemen, and the Tilse, 65 miles northeast of Königsberg. Its principal buildings are the gymnasium, realschool, churches, theatre, barracks, castle ruins and benevolent institutions. The chief manufactures are iron castings, machinery, paper, soap, glass, oils, snuff, chemicals, cloth, cheese and leather. The eel and salmon fisheries are important, as well as the large stock-markets. At Tilsit the famous peace ending the Russian-French-Prussian War was concluded (1807), by various concessions, changes of territorial government, Napoleon largely dictating the terms. In the early days of the European War in 1914 Tilsit was taken by the Russians, but later abandoned. See WAR, EUROPEAN. Pop. 40,000.

TILTON, Theodore, American journalist: b. New York, 2 Oct. 1835; d. Paris, France, 25 May 1907. He was graduated from the College of the City of New York in 1855 and became a journalist on the New York *Observer*. In 1856 he joined the editorial staff of the *Independent*, and in 1863 became its editor-in-chief. In 1871 he became an editor of the Brooklyn *Union*, but shortly after established a weekly periodical, the *Golden Age*, which he discontinued in 1874. In 1874 he caused great consternation in Plymouth Church, Brooklyn, and a sensation throughout the country, by accusing the Rev. Henry Ward Beecher of criminal intimacy with his wife. The trial which resulted in the disagreement of the jury, covered a period of six months. After 1883 he lived abroad. He was the author of several volumes of verse, ‹The Sexton's Tale and Other Poems› (1867); Thou and I› (1880); ‹Swabian Stories› (1882); ‹The Chameleon's Dish› (1883); ‹Heart's Ease› (1894); a novel, entitled ‹Tempest-Tossed› (1873); ‹The Fading of the Mayflower: A Poem› (1906).

TIMARU, a New Zealand town on South Island in Geraldine County, on the east coast, 100 miles by rail southwest of Churchtown. It is an important railroad centre, being situated at the very junction of the Fairlie line. The principal exports are flour, wool and frozen meats. Timaru has a fine harbor. Pop. about 6,424.

TIMBER AND STONE LAW. On 3 June 1878 Congress passed the Timber and Stone Law which with certain amendatory acts is now in force. Under this law all unreserved unappropriated, non-mineral surveyed public lands within the public land States which are chiefly valuable for the timber or stone thereon and unfit for cultivation at the date of sale, may be sold at their appraised value but in no case less than $2.50 per acre. One timber and stone entry may be made for not more than 160 acres (a) by any person who is a citizen of the United States or who has declared his intention to become such citizen, if he is not under 21 years of age and has not already exhausted his right by reason of a former application for an entry under this act or has not already acquired title to or is not claiming under the other public lands laws any other lands which with the land for which he applies would aggregate more than 320 acres or (b) by an association of such persons or (c) by a corporation each of whose stockholders is so qualified. Provision is made for a careful appraisement of the value of the timber and stone on the land in question and the applicant must make payment in accordance with such appraisal.

TIMBREL, a musical instrument much resembling a tambourine (q.v.), has been in use since the earliest times. It is mentioned in the first book of the Old Testament (Ex. xv, 20), and seems to have been known to all ancient peoples. It is also known as the tabor, tabret, tambor, etc., and its form varies from the bottle-shaped drum of Egypt or the long narrow drum of Provence, to the modern tambourine of Spain.

TIMBUKTU, tĭm-bŭk'too (also spelled Tombouction and Timbuctoo), French Sudan, a celebrated trading station situated on the great bend of the Niger River, on the southern border of the Sahara, in lat. 16° 43′ N., and long. 2° 57′ W. The city lies in a desert region about nine miles from the banks of the river, and 800 feet above sea-level. It measures three miles in circumference, and consists of adobe houses without windows. In the centre are three large mosques, and on the northern outskirts two forts. The commerce by caravans across the Sahara was formerly enormous, is still considerable and again increasing, being estimated at $4,000,000 annually. The trade is chiefly salt, fabrics, hardware, ostrich feathers rubber, cotton, tobacco, sugar and gold. Recent excavations have disclosed ancient Egyptian architecture pointing to a prehistoric foundation. The modern city was founded toward the end of the 11th century, and became known to Europeans in 1353. Owing to its former difficulty of access Timbuktu was long an object of curiosity for travelers. The sultan of Morocco captured the city and adjacent territory in 1590, deposing the native Songhoi rulers. After a time the Moroccan rule was thrown off, and various tribes controlled the city until the French took possession of it in 1893. A telegraph line connects with Algeria. A French military territory has its headquarters there. Pop. (1917) about 16,000, almost all Mohammedans. Consult Dubois, 'Timbuctoo, the Mysterious' (1896); Lady Lugard, 'A Tropical Dependency' (London 1905).

TIMBY, Theodore Ruggles, American inventor: b. Dover, Dutchess County, N. Y., 5 April 1822; d. Brooklyn, N. Y., 1909. He «was an inventor from childhood,» says Parton, and at 16 invented the floating dry dock. Among his other inventions are those of floating batteries of iron and steel for coast-defense; a method of sighting and firing heavy guns by electricity, patented in 1862 at Washington, afterward adopted by the United States government, and now used in all leading countries; the American turbine wheel; the first portable barometer; the process of printing terrestrial globes in colors; and a process for quickly ripening coffee. He was the first to advocate the modern use of iron in the construction of warships, and his most famous invention is the revolving turret which was first introduced in the original *Monitor* (see MONITOR, THE; MONITOR AND MERRIMAC), and has since been adopted in naval architecture throughout the world. This invention, through official neglect and other failure to recognize and proclaim Timby's contribution to the national defenses that gave victory in «the battle upon which hinged the fate of the Civil War,» has been wrongly ascribed to John Ericsson (q.v.), chief engineer of the *Monitor*. But the true history of the case shows that as early as 1841 Timby exhibited at the War Department a model and plans of a revolving battery, to be made of iron, the idea of which was suggested to him when first he observed the circular form of Castle William on Governor's Island, New York harbor. In 1843 he is said to have filed his preliminary specification of the model and plans in the United States Patent Office, and Caleb Cushing the same year sent a duplicate model to China. (See illustration under MONITOR). The published records of the office reveal patent No. 3,673 sealed to Theodore R. Timby of Cato, N. Y., in 1844 for an improved waterwheel, also patent 4,845, 10 Nov. 1846, for its further improvement, and this is recorded as expired in 1861. On 31 Dec. 1844 a patent was granted to John Ericsson for propelling ships. But there is no record of the revolving floating or coastal battery by either inventor. It is interesting to note, however, that 11 Aug. 1841 a patent was granted to Prosper Martin of Philadelphia, Pa., for floating batteries; and 11 Oct. 1841 to Daniel Fitzgerald, New York, for submarine gunboats. Timby, from 1851 to 1861, is said to have urged the importance of the revolving floating battery on Emperor Napoleon III. Meanwhile, having developed improvements in his invention, the outbreak of the Civil War was his opportunity, and on 8 July 1862 patents Nos. 35,846 and 35,847 were granted to Theodore R. Timby of Worcester, Mass., for (a) revolving battery tower, (b) discharging guns in revolving tower by electricity, and (c) No. 36,593, 30 Sept. 1862 improved revolving battery tower. Incidentally in 1862–63 he received patents for portable warming apparatus; for mercurial barometers; for solar time globe and solar timepieces. The only records of patents to John Ericsson around these dates are three in 1863 comprising (a) instruments for taking soundings; (b) port-stopper for vessels of war; (c) operating gun carriages. Under his revolving battery tower and related patents, Timby entered into an agreement with the builders of the *Monitor*, including Ericsson as supervising engineer, for its use in the construction of that vessel, and received therefor $5,000. He also received $5,000 royalty for each of the two subsequent vessels built by that company. Although this American inventor received no compensation and no official recognition of his services to the country, his claims were not officially disputed. His invention of the revolving turret, as well as of the «Timby system» of coast-defense adopted by many nations, has been acknowledged by military and naval authorities at home; the legislature of New York passed (1890) a concurrent resolution declaring it to be the «duty of Congress to make such investigation . . . as shall do ample justice in the premises and vindicate the genius that contributed so largely in rescuing the country from a grave peril during the darkest days of its existence»; and influences were brought to bear on Congress and elsewhere to secure full acknowledgment of his patent rights and remuneration for his work from the United States government. Bills to this end were introduced in the national Senate in 1893 by the senators from New York, but apparently without result. An interesting applicable commentary on such conditions may be found in the report of Charles M. Keller, examiner of patents for the year 1844 (Doc. No. 78, p. 507):

«It is a matter of surprise that society at large which has been and must continue to be so much benefited by inventions and the progress of the useful arts should pay so little attention to this subject. The fruits of the labors of inventors are enjoyed and recognized by the world at large, but the authors of all these benefits pass through the world unnoticed, and in most cases unrewarded. It is to be regretted that literary men do not turn their attention to the progress of the useful, and, with the pen of fancy, add ornament and beauty to the solid edifice. Mr. Timby received patents for a mole and tower system of defense (1880); a subterranean system of defense (1881); and a revolving tower and shield system (1884). In his later years he was a resident of Brooklyn, N. Y., where he occupied himself with various literary and other avocations, being especially interested in scientific and philosophical pursuits. Among his writings is a volume entitled ‹Lighted Lore for Gentle Folk› (1902), which contains his reflections on a variety of subjects. Consult New York *Herald* and New York Evening *Post*, 7 June 1843; *Harper's Monthly*, January 1863, pp. 241–248; ‹American Annual Cyclopædia,› 1864, «Revolving Turrents,» pp. 719–723; Todd, ‹Nuts for Boys to Crack› (1866), p. 166; Parton, ‹The People's Book of Biography — Lives of the Most Interesting Persons of All Ages and Countries,› containing a sketch of Timby and an account of his connection with the *Monitor;* King, «Theodore R. Timby» (in *Successful Americans*, January 1902); *American Shipbuilder*, 23 Oct. 1902, «A Half-forgotten Hero»; and Memorial of the Patriotic League of the Revolution to the 57th Congress, presented by Virginia Chandler Titcomb, 1902.

JOHN H. CLIFFORD,
C. LEONARD-STUART,
Editorial Staff of The Americana.

TIME, that dimension of the world which we express in terms of before and after. Our experience of time is in general analogous with our experiences of space (q.v.), but it has certain important differences from the latter. These reside primarily in the fact that whereas it is customary for us to think only of the physical order of things in spatial terms, the temporal sequence pervades mind and matter alike. For this reason many philosophers who have treated of space as something secondary and derived have assigned to time a very fundamental status. This has been especially the case among such idealists as Berkeley. In Leibnitz's philosophy time appears as the backgound, so to speak, of the pre-established harmony between the monads, while space is merely the confused perception of their logical relations. Royce, like most of the Absolutist disciples of Hegel, holds a view of time which makes it prior to all finite minds, forming their natural environment, as it were, while for the Absolute Experience it is merely a phase of mental content. Bergson considers time the only true dimension of Being, when this is perceived in the truest manner by intuition, while he considers space as an artificial intellectualization of the time process.

These views of the nature of time are opposed to those which assimilate it to space. Kant, for example, makes time the form of the internal sense and space the form of the external sense. The time of the natural scientist has always partaken of the nature of space and now partakes of this nature more than ever, for it is considered by the advocates of the theory of relativity (q.v.) that a moving body carries with it a temporal system entirely different from that of the world with reference to which it is at rest and that the true units of both time and space are neither points nor moments, but moments-in-the-history-of-a-point. The grand problem in the philosophy of time consists in the harmonization of these physical time theories with the apparent differences between time and space.

The first step toward the closing of this breach is the analysis of our experience of time. This has been done with great care by William James (q.v.) in his ‹Principles of Psychology.› He finds that within a definite, limited interval of duration, known as the specious present, there is a direct perception of the temporal relations. After an event has passed beyond the specious present, it can only enter into consciousness by reproductive memory. As James says, «The object of memory is only an object imagined in the past to which the emotion of belief adheres.» One might add in the same way that our cognition of the future is only cognition by anticipation and that the object of anticipation is only an object imagined in the future to which the emotion of belief adheres.

We thus see from James' account that our temporal experience is divided into three qualitatively distinct intervals: the remembered past, the perceived specious present and the anticipated future. By means of this tripartite division, we are able to orient our present selves in the temporal stream of our own experience. However, we do not merely have at our disposal the temporal order generated by our present experience, but the memory of the temporal orders of past experiences, and the expectation of the temporal orders of future experiences. These temporal orders are themselves subject to a correlation and a temporal arrangement, for two temporal orders not too remote from one another will possess in common certain items by which they may be compared and the order of their specious presents be determined. As a consequence, it is possible to construct a secondary temporal order of the immediately given temporal orders of our experience and it results directly from this that we can construct a temporal arrangement of our specious presents and their contents. We thus see how it is possible for time to have its roots in experience and yet to be a dimension in which experiences and their contents are arranged.

Now, it has been shown in the article on space that the ease with which space undergoes scientific manipulation is due to the fact that the space of science is a construction from the spatial data of our experience which is largely determined by considerations of scientific convenience. As we have just seen, the fact that experiences are arranged in time does not prevent the stuff from which time is made from being of the nature of experience-data. There is consequently no obstacle to a treatment of this material in a manner entirely parallel to the physical treatment of space, or to the combination of time-data with space-data and other empirical data into a single universe which is not separable into purely spatial and purely temporal dimensions, as in the case of the theory of relativity. Of course, the time of science, like the space of science, is a construction which is largely arbitrary and so in a sense a fiction, but there is reason to believe that the time of the unscientific man, of Bergson himself, owes its homogeneity, its unique, definite direction of flow, its continuity, to more or less unconscious acts of construction which differ in degree, not in nature, from those of the scientist. There is no reason to believe that our time data, taken raw, unordered, unschematized, indicate of themselves a single series into which all events fit in a definite order; indeed, there is good reason to believe that the laws which we unquestioningly associate with time are outlined only in the vaguest way in our definite temporal experiences.

Before leaving the subject of the philosophy of time, a word or two must be said concerning the Zenonian paradoxes. These have to do with the flying arrow, which cannot remain where it is, nor be where it is not, and with Archiles, who, though the swiftest of men, cannot catch up with the slow tortoise except by occupying an infinity of positions, and with other similar matters. In fact, though these paradoxes seem to deal with space and time, they deal with the properties of infinite assemblages (see ASSEMBLAGES, GENERAL THEORY OF) and dense series and were in truth unanswerable until the recent thoroughgoing mathematical treatment of these matters, though they have now been completely solved. (For a more detailed treatment of these paradoxes see ZENO OF ELEA). Here it is only necessary to state that Bergson mistakenly regards these difficulties as insurmountable on an intellectualistic view of time and that James turns them to use in proving his theory that time is discontinuous.

W., 'Our Knowledge of the External World as a Field for Scientific Method in Philosophy' (Chicago 1914).

TIME, Measurement of. All our measures of time depend primarily upon the motion of the earth upon its axis and around the sun. The first motion enables us to count off the successive days; the other the successive years. The measurement of time thus becomes a most important branch of practical astronomy in the affairs of men. It falls into two distinct classes, the determination of the years and that of the days or fractions of a day. Other units of time than this may be regarded as subsidiary. Centuries are determined by the count of years; weeks and months by a count of days; hours, minutes and seconds by dividing the day into fractions.

The primary object of a measure of time is the expression or determination of the moment or date of any event. This is expressed by the period of time elapsed since some standard moment or epoch. Long intervals, expressed in years, are measured from some great epoch, chosen by a nation — in all Christian nations the birth of Christ is taken for this purpose. The general subject of measuring or expressing long intervals of time is treated in our article Chronology (q.v.). The present article deals mainly with fractions of a day, or with what is commonly called the "time of day."

To express the time of day we must have a moment at which we consider the day to begin and from which we count the hours and minutes. The natural moment for this purpose is that when the sun crosses the meridian, because it can be more easily observed than any other phenomenon growing out of the earth's rotation. This moment is actually taken as the beginning of the day by astronomers on shore and, to a large extent, by navigators at sea. The latter usage grew out of the fact that at noon the navigator determines the latitude of his ship. But, to express the moment of an event, navigators are now beginning to count from midnight, as landsmen habitually do. The Jews formerly considered the day to begin at sunset and the practice in ancient times was to divide the 24 hours into two parts, the day and the night. Each of these parts was divided into 12 hours. Thus men had the first, second and third hour of the night, etc., and the corresponding hours of the day, as we see in the Bible. Owing to the inequality in the length of the day at different seasons of the year, the hours thus employed were of unequal length. In an age when the modern clock was unknown and there was no accurate instrument for measuring time in universal use, this inequality was of little importance. But when an accurate measure was once obtained, a more uniform measure of the hours became necessary. For obvious reasons midnight became the most convenient time to begin the day of 24 hours. Thus arose the system of setting the clocks at 12 when the sun crosses the meridian, beginning a new day 12 hours later when the clock marks midnight and dividing the hours into A.M. and P.M. This system was adopted without change until the introduction of railways showed its defects and made a slight modification necessary.

The first inconvenience felt from the system arose from the fact that the intervals between successive noons, as indicated by the passage of the sun across the meridian, are not equal. To show the nature and effect of the inequality, let us suppose a perfect clock so regulated as to go always at the same rate and to be set at noon on 1 January of any year at the moment when the sun crosses the meridian and to be so exactly regulated as to again show noon on 1 January of the year following. It will be found that, during the month of January, the clock will continually gain on the sun at a rate of 28 seconds a day at the beginning of the month, which rate will continually diminish to eight seconds at the end of the month and will change to a losing rate about the middle of February. The effect of the accumulation will be that, at the latter date, the clock will be found to be more than 10 minutes ahead of noon when the sun crosses the meridian. Then it will begin to fall back for several months until, in May, it will be seven minutes slower than the sun. Then it will forge ahead again and again fall behind until, when January again comes around, it will once more coincide with the sun.

This inequality between the moments of the sun's successive transits over the meridian is due to two causes; the obliquity of the ecliptic and the eccentricity of the earth's orbit. If, instead of using the sun, we measured time by the apparent diurnal motion of the stars, no inequality would be noticeable. The effect of the eccentricity is that the sun seems to move forward among the stars more rapidly in the winter months than in those of summer. And the effect of the obliquity of the ecliptic is a still larger inequality, going through its cycle of changes twice in a year.

So long as an error of modern fractions of an hour was of no importance, people in general had no occasion to trouble themselves with this inequality; but when time had to be measured to a minute, it became intolerable, and the system of mean time had to be introduced. The latter is defined by the going of a perfect clock in the manner already supposed, and so set that, in the average of the whole year, it shall be as much ahead of the sun as behind it. The greatest difference between the clock and the sun will then be about 16 minutes, which difference occurs in one direction early in November, and in the other about the middle of February. The difference is called the *equation of time* and is given for each day in the household almanac, thus enabling the household clock to be set by the sun. Some such system as this is now used in all civilized countries where exact time is of importance.

Besides true solar time and mean solar time, a species of time of great importance to the astronomer is sidereal time. Sidereal time is measured by the stars, or rather by the daily motion of that point in the equator from which the true right ascension of the stars is reckoned, called the vernal equinox. Two successive upper transits of the vernal equinox over the same meridian determine a sidereal day, which is nearly 3 minutes and 36 seconds shorter than a mean solar day, but divided, like it, into 24 hours. About 21 March are sidereal and mean times agree; the former gains on the latter an entire day in the year. The sidereal day commences at the instant the vernal equinox makes its upper transit, and, therefore, changes in 12 months through the entire 24 hours. The hours are counted from 0 to 24.

Time may be determined by observations on the sun or stars with a sextant, or an altazimuth for rough purposes, or with a transit adjusted to the meridian, for refined work. With the last instrument a chronograph is frequently used for recording the observations. The telescope usually has from 5 to 11 equidistant lines ruled on glass (or spider lines), which are placed in the common focus of the eye-piece and object glass, the centre line being adjusted to the optical axis of the telescope and set in the meridian. When ready for observations, the observer sets the telescope at the proper angle to observe the passage of the star across the meridian,and records on the chronograph the transit over each line by interrupting the circuit with an observing key held in the hand and electrically connected with the chronograph, on which a break-circuit chronometer is making a continuous record. The chronograph sheet is read by means of a scale.

A relation which was of little immediate importance in former generations, but which became very important when railways began to run, was that of the relation of time to longitude. We readily see that, as the earth revolves, the various meridians on its surface are brought into line with the sun. Another way of conceiving the case is to think of noon as continually traveling around the earth from east to west. The rate of motion is one hour for every 15 degrees of longitude. What is true of noon is true of any other hour of the day. Any such hour is about three hours crossing the continent from the Atlantic Coast to San Francisco. The result of this is that if a passenger with a good watch travels westward, he will find his watch continually ahead of the time at the places he reaches. Of course the opposite effect is produced when he travels east. Before 1883 this relation of time was productive of endless confusion on railways everywhere. Conductors could not be changing their watches every minute as they traveled east or west, and thus every railroad had to adopt some meridian as that by which it kept its time. There were, therefore, almost as many meridians as railroads, and passengers frequently missed their trains by not knowing what time to go by.

In 1883 was introduced our present zone system, which is now used over almost the entire country, and is rapidly being introduced into Europe. This system consists in dividing the country into zones by meridians of longitude, 15 degrees, or one hour apart. The central meridians of the zones used in the United States and Canada are those of 60 degrees west of Greenwich, 75 degrees, 90 degrees, 105 degrees and 120 degrees, known respectively as Colonial or Atlantic, Eastern, Central Mountain and Pacific time. The lines dividing one zone from the next are arranged, as nearly as convenient, to run about midway between these meridians. Within each zone one and the same time is used.

The result of this system is that, so long as a traveler journeys only within a single zone he finds the time to be everywhere the same. But when he crosses the line from one zone to the next, the time suddenly changes by one hour. In traveling from New York to San Francisco he crosses three of the zone lines, so that, on arriving at his destination, the time will be three hours slower than in New York.

It should be carefully understood that in this system of expressing time, which we now use throughout almost our entire country, the time actually used is not the true time of day, as indicated by the sun, except on the standard meridians. It does not correspond to sunrise or sunset, as given in the almanacs. At midway points, Cincinnati, for example, the time used is necessarily in error by almost half an hour in one direction or the other. But the inconvenience thus arising is very slight. Consequently, if any one determines his time by the passage of the sun across the meridian, he must correct it according to his longitude, from his standard meridian, in order to obtain the stand-

ard time. The inconvenience thus arising is very small compared with the advantages of the uniformity to which the system gives rise.

Similar systems are in use in all European countries except Ireland, Holland, Russia and Greece, which retain the time of their capitals, except in the case of the Russian railroads, which take their time from Pulkova. All other European countries take their time from meridians differing by an integral multiple of 15° or 7½° from that of Greenwich. This is in accordance with the method of reckoning time for international purposes, agreed to by the International Conference held at Washington, D. C., in 1883. Universal time is reckoned from mean noon, the day commencing at midnight, and divided into 24 (instead of into two portions of 12) hours each. Local time will still be used for local purposes; but the method of fixing it will be changed. Since the earth is divided into 360° and the day in 24 hours every 15° will represent the difference of an hour in time. If the earth be divided into 24 equal parts, at every 15th meridian, and if the local mean noon of such meridians be adopted as the standard noon of all places 7½° each side of it, it will follow that when it is noon at Greenwich and at all places within 7½° of Greenwich, it will be 11 o'clock by local (but still noon by universal) time for all places between 7½° and 22½° west of Greenwich, and 13 o'clock by local (but still noon by universal) time for all places between 7½° and 22½° east of Greenwich, and so on throughout the world. Universal time will be the same universally, and local time will differ from it only by even hours, instead of by the various odd minutes by which local standards differ from each other at the present time; while in no case will the difference between standard noon and absolute noon at any place exceed half an hour, since a difference of 7½ degrees of longitude equals a difference of half an hour in time.

Time Signals.— Many observatories send out time signals either daily, hourly or sometimes continuously every second, or every other second, to various parts of the country for the purpose of giving accurate time to all sorts of industries. They are sent out over the telegraph lines, the wires being permanently run into the observatories for the purpose, and the signals are generally sent automatically by a distributing clock which is kept as near the exact time as possible. An electric current passes through the clock and is broken or closed regularly by a toothed wheel on the second hand arbor of the clock. Perhaps the best known set of time signals is that sent out by the Naval Observatory at Washington. It is as follows: three or four minutes before noon, whenever the telegraph companies switch in the loops to the observatory, the clock begins to send out make-circuit signals every second over the various lines, the minutes being indicated by leaving out the seconds 55, 56, 57, 58 and 59 in each, and the half minutes by leaving out the 29th second of each. The click following such a one-second gap then always indicates the beginning of a half-minute and the first following a gap of five seconds indicates the beginning of a minute, except at the exact noon. Just before this there is a gap of 10 seconds, and then exactly at noon the circuit closes and remains closed for just a whole second, the beginning of the marks indicating exact noon. The closing for a whole second is in order to make sure that that particular mark goes through all the telegraph lines, for this particular signal is made to do a great many things at different places, such as the dropping of time balls, and it is more important that this particular second be distinctly sent than any of the others. After the break at the close of the noon signal the telegraph companies quickly switch out the loops to the observatory, and the lines immediately resume their normal work. In the city of Washington this particular noon signal drops a time ball on the top of the State, War and Navy Department Building, and it also automatically corrects, by setting forward or back exactly to 0 hours 0 minutes 0 seconds, all the clocks in the department buildings of the government, no matter how much they may have gained or lost since the preceding noon.

In recent years an artifical regulation of time consists in arbitrarily setting forward all public clocks by the amount of one hour on the first of May of each year, the hour being again dropped in the month of October. The principal advantage of this proceeding is that during the summer months the time of artificial lighting is lessened, with a consequent large aggregate saving in expenditure. Up to the year 1916, this regulation had been adopted in England, Germany, France, Austria, Holland, Denmark, Norway, Italy and Portugal. It was adopted as a war measure in the United States in 1918–19, but was repealed in the latter year.

TIMGAD, Algeria, the ancient Roman city THAMUGADI, in the department of Constantine, near Lambèze, about 25 miles southeast of Batna on the Philippeville-Biskra Railroad, is approached through a valley bounded by the Aures Mountains and stands on the northern fringe of the African Desert. It was a fortified frontier town at the junction of six roads, and was founded in 100 A.D. by Lucius Munatius Gallus. It flourished for three centuries and then underwent various vicissitudes, owing to native insurrections and the incursions of the Vandals, in 535 being partially destroyed. Four years later, under the Byzantine general Solomon, it was restored and had another period of prosperity until the Arab invasion of 646, when the Christian governor, Gregory of Timgad, was defeated and killed, the town being subsequently abandoned, falling into ruins and gradually becoming buried beneath the desert sands. Recent excavations undertaken by the French government have revealed ruins, which for beauty, architecture and magnificent extent have gained for Timgad the title of the «African Pompeii.» Nearly the whole of the city has been laid bare (see illustrations) and exhibits the usual Roman platting, two main streets, the Decumanus Maximus extending east and west and the Cardo Maximus intersecting at right angles, upon and around which the city was built. The principal buildings are on the main streets and among the prominent civic features are the magnificent triumphal arch of Trajan, the Forum (seating 3,500), with the theatre, basilica, library and other buildings surrounding it, the temple of Jupiter Capitolinus, statues of the Roman emperors, a Byzantine fort, the Christian basilica and cathedral erected by Gregory, the governor already mentioned, houses and stores, markets and annexes, thermæ and latrinæ. The arch of Trajan, the finest Roman construction of its kind in northern Africa and the dominating attraction of Timgad, bears an inscription which translated reads:

"The Emperor Cæsar Nerva Trajan Augustus Germanius, son of the divine Nerva, sovereign pontiff, four times tribune, three times consul, father of his country, founded the Marcian colony, Trajan of Thamugadi, by the help of the third Augustus Legion, Lucius Munatius Gallus being the legal imperial proprietor."

The epigraphic wealth of the city is considerable, including inscriptions to early Christians, showing that they were persecuted and underwent martyrdom, while others bear such historical names as Novatus, a member of the Council of Carthage in 258; Sextus in 320; Faustinius, opponent of Gaudentius the Donatist, in 411, and Secundus, bishop of Numidia, exiled by Huneric in 484. Consult Ballu, A., 'Guide Illustré de Timgad' (Paris 1911).

TIMOLEON, tĭ-mō'lē-ŏn, Grecian commander and liberator of Sicily: b. Corinth, about 400 to 395 B.C.; d. Syracuse, 337 B.C. He was accused of having caused the death of his brother, Timophanes, the head of the state, and is said to have exiled himself from Corinth for 20 years in consequence. Little is known of his life until he entered the service of the Greek cities of Sicily in the effort to expel their Carthaginian invaders, an undertaking in which he met with signal success. In 343 he drove Dionysius from Syracuse and in 339, with only 12,000 men, met and conquered a force of 70,000 Carthaginians and allies under Hasdrubal and Hamilcar, at the Crimissus. Thereafter he secured a treaty by which the Carthaginians were confined to the territory east of the Halycus. In the cities thus freed from their enemy, he restored democratic government, and was looked upon as the defender of their liberties. In Syracuse he not only restored ancient rights, but gave its citizens a new and yet more liberal constitution. Consult Plutarch's 'Lives.'

TIMON, tī'mōn, Athenian misanthrope: b. near Athens. He flourished in the later part of the 5th century B.C., and the ingratitude of his friends so greatly embittered him that he retired into solitude. His name has become proverbial as descriptive of a misanthrope. He formed the subject of a famous dialogue by Lucian and his story is familiar through Shakespeare's tragedy.

TIMON OF ATHENS. Very little has yet been discovered concerning 'Timon of Athens.' There is no record of any early performance or any edition other than the strangely imperfect one in the folio of 1623. On the evidence of style the play is dated about 1607 and thus referred to the same period as the three other tragedies with which it has most in common, 'King Lear,' 'Antony and Cleopatra' and 'Coriolanus.' It is generally agreed that the best parts of Timon are not only Shakespeare's but must be counted among his highest achievements in poetry — "poetry," as a recent writer has said, "coming short of 'Lear,' perhaps in poignancy of diction and certainly in pathos of situation, but surpassing even 'Lear' or 'Coriolanus' in the sheer force of that emotion which, in different forms, is common to the three plays" (Wright). On the other hand, many of the un-Shakespearean scenes are of almost unaccountable poorness, by no means justifying Masefield's verdict that they were written by "a man of genius, a skilled writer for the stage, and of a marked personality." The best supported modern view is that something over half the play is by Shakespeare and the rest the unintelligent addition of an unknown reviser. Fleay thought that the Shakespearean fragment was hastily expanded in 1623 for the express purpose of making it fill a gap in the Folio volume, caused by the decision to remove 'Troilus and Cressida' from the number of tragedies. One of the sources is certainly the brief account of Timon in Plutarch's 'Life of Mark Antony,' whence Shakespeare derived most of his material for 'Antony and Cleopatra.' This may have been supplemented by a similar, but much longer narrative in Painter's 'Palace of Pleasure.' The introduction of incidents not found in either of the foregoing works seems to establish the use also of an anonymous earlier Timon play (a comedy), and perhaps of Lucian's dialogue of Timon. There are yet unsolved difficulties about explaining how the last two writings became known to Shakespeare, for the Timon comedy seems neither to have been printed in Shakespeare's day nor to have been acted in London, whereas Lucian's dialogue was not accessible in English. In 1678 the Restoration dramatist, Thomas Shadwell, brought out a revision of 'Timon of Athens,' of which he boasted, "I have made it into a play." The claim may be allowed, for Shadwell's play had reasonable success and there exists no positive proof that 'Timon of Athens' had ever been acted previously. A later adaptation, made by Richard Cumberland in 1768, was acted by Garrick in 1771. Cumberland omitted large portions of the original, added the character of Evanthe, Timon's daughter, romanticized that of her lover, Alcibiades, and much lightened the gloom of the play's close. This piece was a failure. Horace Walpole remarked sardonically that Cumberland's alteration was "marvellously well done, for he has caught the manner and diction of the original so exactly, that I think it is full as bad a play as it was before he corrected it." The best recent discussion of 'Timon of Athens' is by E. H. Wright ('The Authorship of Timon of Athens,' 1910).

TUCKER BROOKE.

TIMOR, tē-mōr', an island of the Malay Archipelago, the most eastern and largest of the Lesser Sunda Islands, 700 miles southeast of Borneo and 500 miles west by south of Papua or New Guinea; length, 300 miles; width, 60 miles; area, 12,450 square miles. Coasts are steep and generally difficult of access on account of coral reefs; the island is traversed by a mountain chain everywhere giving evidence of volcanic origin; one peak, Mount Atlas, is over 12,000 feet; the interior is very little known. The vegetation is less luxuriant and less varied than in the other islands of the East Indies. The coast lands are cultivated to some extent, the northern part of the island being more favorable to agriculture than the southern. Coffee, rice, sugar and cocoanuts are grown, but mostly for domestic use; some coffee is exported, also sandalwood, wax, trepang and tortoise shell. Horses, ponies and cattle are raised and a few exported. There is considerable mineral wealth, but it has not been developed. The people are mainly Papuan, with Malayan, Polynesian and Negrito mixture, with a few Chinese, who control the trade. Many of the people are savage, being classed as «headhunters.» The island politically is divided between Portugal and Holland, the northern part (7,350 square miles) being Portuguese, the southern part (5,120 square miles), Dutch. This division was first made by treaty in 1859, and the boundaries and relationship of the two countries more exactly defined by another treaty in 1893. In 1908 another treaty was ratified and some territory exchanged between these governments. The Dutch capital is Kupang (9,000 pop.), the Portuguese Dilli (3,000 pop.). The Portuguese population of the island (1915) was 378,000; the Dutch between 200,000 and 300,000; but only a few hundred of these are Europeans.

TIMORLAUT, tē-mōr'lowt, also called TENIMBAR, a group of islands of the Malay Archipelago, lying about 300 miles east by north of Timor Island and 150 miles west by south of the Aru Islands, all being southwest of New Guinea. The group consists of Yamdena (or Timerlaut), 1,151 square miles in area, Selaru, Larat, Vordat, Molu and Maro and a number of small uninhabited islands, with a total area of over 2,000 square miles. The larger islands are hilly, the maximum elevation being 820 feet; the others are low and flat, of coral formation. Agriculture is carried on in a primitive fashion; some cattle are raised; turtle fishing is an industry of some importance, and turtle and trepang are exported. The population is estimated at 20,000, mostly Papuans.

TIMOTHEUS, Athenian general: b. about the end of the 5th century; d. Chalcis in Eubœa, about 354 B.C. In 378 he was made commander of the fleet sent out by the Athenian Confederacy to gain the alliance of the Peloponnesian cities and of those along the coast of Laconia, and defeated a Spartan fleet in 375. Peace having been declared with Sparta, he was recalled to Athens. In 372, having been sent to the coast of Asia Minor to aid the satrap of Phrygia, he secured the island of Samos, and by the further acquisition of Sestus and Crithote gained for Athens the control of the Hellespont. In 356 he was appointed, with Chares and Iphicrates, to the command of an expedition against Byzantium, but, refusing to engage in a battle in what he deemed an unpropitious moment, he was accused by Chares of causing the Athenian defeat, and was deposed from power.

TIMOTHEUS, tĭ-mō'thē ŭs, Greek dithyrambic poet: d. 357 B.C. He was the most famous lyric poet of his day. An ancient Greek manuscript of about 100 lines of his 'Nomos,' discovered at Abusir, in Egypt, in 1902, is believed to be the oldest Greek writing in existence, and is thought to have been copied in the 3d century B.C. It is in the Attic poetic dialect, display originality in metre and recounts the defeat of the Persians at Salamis. Timotheus was also remarkable as a musician, improving his instrument, the cithera, and displaying a knowledge of harmonic principles. A collection of the fragments of his poems are to be found in Bergk's 'Poetæ Lyrici Græci.' Consult also Smyth, H. W., 'Greek Melic Poets' (New York 1900); Wright, W. C., 'Short History of Greek Literature' (New York 1907).

TIMOTHY, a disciple of Saint Paul: b. in Lycaonia, Asia Minor, probably at Lystra, of a Gentile father and Jewish mother. His father's name is unknown; his mother's was Eunice, his grandmother's Lois. By his mother and grandmother he was early made familiar with the Old Testament Scriptures, and it seems likely that by them also he was first instructed in the Christian faith, which they had probably been won over to on Saint Paul's first missionary visit to Lystra, while Timothy was still very young. When Saint Paul, along with Silas, visited Lystra on his second missionary journey, seven years after the first, Timothy became an active fellow-worker with the apostle, and he accompanied him and Silas in the further course of their mission. Timothy accompanied Paul to Philippi and Berœa; but he is not mentioned as being with Paul at Thessalonica, which the apostle visited after Philippi and before Berœa. He was then left in the last mentioned city alone, but rejoined Paul at Athens, from which city he was sent back to Thessalonica. After remaining there some time he once more joined his master at Corinth. No further mention is made of Timothy till at least five years later, when he is found with Paul at Ephesus on his third missionary journey. From Ephesus he was sent along with Erastus into Macedonia and Achaia to prepare the churches there for the visit that Paul himself was meditating (Acts xix, 22). Timothy met the apostle again in Macedonia, and was among those who preceded him on his journey to Jerusalem. We lose sight of him for the next two or three years; but he appears at Rome with Paul at the time when the epistles to the Colossians, Philippians and Philemon were written. From the third verse of the first chapter of the first epistle to Timothy we learn that Timothy was on one occasion left at Ephesus when Paul went into Macedonia, and it is supposed that this was after Paul had been released from the confinement in which he was placed when he was sent to Rome from Jerusalem. Tradition makes Timothy the first bishop of Ephesus. He is said to have been martyred in the reign of Domitian or Nerva.

TIMOTHY AND TITUS, Epistles to. Pastoral Epistles.—The two letters which purport to have been written by the Apostle Paul to his young friend and assistant Timothy and the letter which in the same way purports to have been written to his fellow-worker Titus are commonly called from the nature of their contents the «Pastoral Epistles.» They sustain so many resemblances to each other that it is simplest and most helpful to treat them as a group, as, indeed, is commonly done.

Arguments as to Paul's Authorship.— Before touching on their contents and significance, it is best to take up the much debated problem of their authorship. External evidence in favor of Paul's having written them, consisting of quotations and citations by name, is abundant from the earliest times, going back, in fact, to Polycarp and Ignatius (before 120), if not to Clement of Rome (95). The one case of rejection, that by Marcion, is plausibly explained on the ground of antagonism to the doctrines taught. This strong attestation caused them to be unhesitatingly accepted as from Paul down to about the beginning of the last century, but since that time scarcely any point in New Testament criticism has been more constantly and strenuously disputed, and at present there is no point on which critics who deserve consideration are more evenly divided. (1) The first objection to be noted is that these letters cannot be from Paul's pen because the circumstances implied do not agree with the conditions otherwise known to have existed at any time in the apostle's life. It is admitted on all sides that there is no period described in Acts into which these letters fit, but the latest criticism, under the influence of Harnack, holds that Acts was written before the end of Paul's imprisonment at Rome and, if so, it is as legitimate to hold that he was released as that he was put to death soon after the time reached in the story of Acts. This release is rendered plausible by the facts that there was no charge against him on which he could have been fairly condemned (cf. Acts xxvi, 32); that Paul certainly not only hoped but expected release (Phil. i, 25; Philemon 22); and that what ancient tradition exists on the subject is to the effect that he visited Spain as he earlier intended, which would imply release from his first imprisonment. The question of the genuineness of these letters must be settled apart from this point. (2) Another argument against the Pauline authorship is that the vocabulary, the formation of the sentences and the way in which they are related to each other vary irreconcilably from Paul's acknowledged writings. A difference on these points must certainly be recognized, but when we consider the difference in the topics discussed, the lapse of time, which, if not more than five years since the composition of Philippians, might have brought many new circumstances to influence language, and the possible freedom with which Paul's amanuensis may have reproduced what he gave out, it is held by many critics of acuteness and standing that the differences may be harmonized with Pauline authorship. It is interesting to note in this relation that it has lately been urged that the language and style of the «Pastorals» approach in many points those of Luke and that, as it is said in 2 Timothy that he was Paul's only companion when that letter was written, it is presumable that he put that letter on paper, and if so, almost certainly the other two, a fact which would go far to explain the differences under consideration. It is also to be taken into account that the peculiarities of vocabulary and style are equally, if not more, difficult to explain on the theory that the letters were fabricated in direct imitation of Paul's genuine letters, since such a literary artist would naturally have avoided such striking deviations from Paul's previous usage as are recognized to exist. (3) It is also urged that the doctrinal content of these Epistles is inconsistent with Paul's teaching in other letters, and it should be recognized that a difference at least in the form of presentation of truth actually exists. But when it is taken into account that the opponents of Pauline authorship commonly hold that these letters were written by a «Paulinist,» probably by a disciple who felt that he was merely reproducing his master's ideas, it must also be recognized, as it generally is, that no doctrinal contradiction or essential inconsistency exists between the two types of teaching. When the variations in Paul's presentation of his theological views in his acknowledged Epistles, as in 1 Thessalonians, Galatians, 1 Corinthians and Colossians, are taken into account, it should equally be recognized that in the circumstances presupposed in these Epistles Paul might have given the teaching which stands in them. (4) It is also insisted that the conditions which are implied as existing in the churches, alike as to heresies and as to church government, require a later date than can fall in the lifetime of Paul. But it is answered that the government of the churches is by no means so advanced as is sometimes asserted, and that there is no ground for denying that this stage of ecclesiastical development and also such a prevalence of error as is implied, might have been reached by the year 65. (5) It is also objected that the tone of these letters is more formal and distant than it is in the other Epistles, though they were sent to churches; that directions are given to Timothy which are unnatural, as in relation to affairs at Ephesus when Paul had himself just been on the ground, as is implied in 1 Timothy, or when he urges his leaving his work immediately, as in 2 Timothy, and that it is inconceivable that Paul should have addressed Timothy as a youth and a weakling. In answer it is argued that the letters, especially 1 Timothy and Titus, were in reality «open letters,» intended to be read to the churches at Ephesus and in Crete; that 1 Timothy i, 3 does not imply that Paul had himself been lately at Ephesus; that as Timothy might be unavoidably delayed in leaving at Paul's request, directions might well be given to apply in case of such hindrance; that it is not unnatural that Paul, who years before had called himself «the aged,» should still think of Timothy as a youth, it being a not uncommon characteristic of elderly men to think of men of the next generation as more youthful than they really are; and that it is by no means unreasonable to hold that Timothy may have needed the strengthening and heartening of the appeals in these letters, as Paul the strong may personally have been especially drawn to him by the very traits which would show as weakness when he had to live his own independent life as a church leader. It is also to be noted that almost every one of these points tells as strongly against the supposition of fabrication, since a fabricator would naturally avoid these difficulties, and, in particular, would not have inserted anything which might seem to reflect discreditably upon Timothy.

Critical Conclusion.— So far as the above contentions are concerned, it may reasonably be held that neither side has advanced decisive arguments, but that, while the character of the letters does not demonstrate Paul's authorship, on the other hand, the letters have not been proved to be by another hand. Perhaps it should also be remarked that many critics who do not accept Pauline authorship for the letters as they now stand find themselves obliged to recognize that many of the historical notices, especially in 2 Timothy, are genuinely Pauline. Various attempts have been made to show how these fragments could have been woven into documents otherwise fabricated, but thus far all attempts to give a plausible explanation of such an unparalleled literary phenomenon have failed, and it is to be recognized that, in view of the acknowledged relationship of these letters to each other, any attestation of one, as this of 2 Timothy, in some sense attests them all. In the end the decision of the problem of the genuineness of these letters will probably be found to depend on the weight to be given to their acceptance and attestation by the early Church, and it may be said to be true to-day as it was in the time of the Muratorian Fragment (perhaps 175): «An Epistle to Titus and two to Timothy, written out of personal feeling and regard, are still honored in the respect of the Catholic Church in the arrangement of ecclesiastical discipline.»

Occasion and Order of Epistles.— If not Pauline, critics hold that these letters were worked up to confirm the traditional views of the Church against errorists of the author's own time, many holding that 2 Timothy was first composed on the basis of genuinely Pauline memoranda, so to speak, and on this theory, although much later dates have sometimes been suggested, they could hardly have been written after 100 or before 80, while the place of composition would be absolutely indefinite. If accepted as written by Paul, all is much clearer. 1 Timothy was written to Timothy at Ephesus to strengthen him in his position as representative of Paul in the superintendency of the churches, probably in 65 or 66; Titus was written presumably soon after to Titus, who was in Crete in a position similar to Timothy's, to advise and confirm him in his work; and 2 Timothy was sent perhaps in 67 from the prison in Rome where Paul lay chained and facing death not remotely, to express to Timothy his thoughts in view of this situation, and to urge him to come to Rome as soon as possible.

Value.— If these epistles are not genuine Pauline letters, they yet have a certain value as testifying to the conditions in the Church during the last decades of the 1st century in regard to both erroneous thought and needed methods of administration. If genuine, they have a much greater value still as setting forth the last thoughts of the great Apostle in reference to dangerous errors of the time and the importance of both right thinking and right living, and, above all, his thoughts in view of death, constituting what we might call his last will and testament for the benefit, not of Timothy alone, but of the Church universal.

TIMOTHY. See Grasses in the United States.

TIMROD, Henry, American poet: b. Charleston, S. C., 8 Dec. 1829; d. Columbia, S. C., 6 Oct. 1867. After study at the University of Georgia and some legal education, he was for a time a tutor, at the outbreak of the Civil War became war correspondent of the Charleston *Mercury,* and in 1864 was made assistant editor of the *South Carolinian* at Columbia. The destruction of Columbia by Sherman was the ruin of his occupation, and his subsequent career was unfortunate. Just previous to the war-time, Timrod and P. H. Hayne (q.v.) were brilliant members of that Southern literary coterie in which W. G. Simms was the most prominent. In 1860 a small volume of his poems appeared, but with little recognition. Done under unfavorable conditions, Timrod's poetry has many excellent qualities, and in some cases attains real elevation. Among his best pieces are 'At Magnolia Cemetery'; 'Charleston' and 'The Cotton Boll.' A memorial to him was placed in Washington square, Charleston, in 1901. His verse was collected and published, with a biographical sketch, by Hayne in 1873. An edition, with memoir, in 1899, was followed in 1901 by the so-called memorial edition.

TIMUQUOMAN FAMILY, a group of American Indians formerly occupying central and northern Florida. In 1527 — when first known to the Spaniards — these Indians had some 50 settlements along the Saint John's River. There were five original tribes speaking as many dialects. Wars of other tribes and the inroads of the English from Carolina gradually reduced the tribes in numbers, and they fled to Volusia County, at the headwater of the Saint John's. The territory thus abandoned was afterward occupied by the Seminoles (q.v.).

TIMUR, tē-moor' **(TIMUR BEG, TIMUR LENG, TAMERLANE,** the latter a corruption of Timur Leng, «Timur the Lame»), Mongol conqueror: b. Kesh, near Samarcand, about 1336; d. Otrar, 17 Feb. 1405. He was a descendant of Genghis Khan and became chief of his tribe in 1370, having previously reigned jointly for some years with his brother-in-law, Hussien, of whom he became jealous and whom he put to death, after defeating him in a short civil war. He established a firm government in his dominions and then embarked on his career of conquest. He subdued Persia and the whole of central Asia from the Great Wall of China to Moscow, and in 1398 invaded India, which he mastered from the Indus to the mouth of the Ganges. His cruelty knew no bounds. On one occasion, it is recorded, he massacred 100,000 prisoners, while on the banks of the Ganges he was called by the emperor of the East and other princes to aid in repelling the Turks under Bajazet. He wrested Syria from the Mamelukes on his return journey, overran the sultan's dominions with his vast army and on 20 June 1402 met Bajazet on the plain of Angora, routed his immense army and took him prisoner. In 1404 he began preparations for an expedition into China, and early in 1405 began the advance which was stopped by his death. Timur, however, was not a mere barbarian. He was an able administrator, with many statesmanlike traits, a patron of science and art and is also reputed to have been an author, though on dubious evidence. Consult Howorth, 'History of the Mongols'; Jean de Bec, 'Tamburlain' (1586; Eng. trans., 1595); Malcolm, 'History of Persia.'

TIN, a hard, white, ductile metal, obtained by smelting tin-stone or cassiterite — so-called from the Cassiterides, islands from which it was first brought into European markets. Tin appears to have been known in the time of Moses; and at a somewhat later period in Jewish history it was brought by the ships of Tarshish from the islands east of the Persian Gulf. The Phœnicians traded largely in the tin ores of Cornwall, which was then, as now, celebrated for its mineral wealth. The mountains which separate Galicia from Portugal were also very productive of tin in ancient times, and still continue unexhausted. The mountains between Saxony and Bohemia have been wrought as tin mines for several centuries and still continue productive. Mines of it occur in the Peninsula of Malacca, in India, in Chile, in Mexico, in Peru, etc. Large deposits of tin-stone have been discovered in Queensland, New South Wales and Tasmania.

Tin-stone.— Tin-stone or tin dioxide (SnO_2) is the only ore used for obtaining metallic tin. Its chemical composition is oxygen 21.4 per cent, tin 78.6 per cent. It is found disseminated throughout the alluvium of valleys or in lode at considerable depths beneath the surface; the former deposits yield what is called stream-tin, while from the latter mine-tin is obtained. The first process to which the ore is subjected is grinding. The ground ore is then washed, which removes the impurities; for the specific gravity is so high that it is easy to wash away the earthy matter, and even some of the foreign metallic ores with which it is often mingled. But there are other bodies so nearly of the same specific gravity of the tin ore that they cannot be thus removed. The ore is then roasted in a reverberatory furnace, whereby most of the sulphur and arsenic are expelled. The ore, thus freed as much as possible from foreign matter, is mixed with from 15 to 20 per cent of its weight of pulverized anthracite coal and a small proportion of flux, generally limestone, and heated strongly in a reverberatory furnace, so as to bring the whole into the state of fusion which is kept up with gradually increasing temperature for about eight hours. The lime unites with the earthy matters still mixed with the ore and flows with them into a liquid slag, while the coal reduces the oxide of tin to the metallic state. The reduced tin falls by its own weight to the bottom, and is, at the end of about eight hours, let out by tapping a hole in the furnace which had been filled with clay.

Refining Process.— The tin thus obtained is still very impure; it contains generally iron, copper, arsenic and tungsten. In order to purify it the blocks of tin are placed in a reverberatory furnace and moderately heated to the point where the tin melts and flows into the refining basins, while the greater part of the foreign metals remains in the solid state. The molten tin in the refining basins is then stirred with poles of green wood, whence gases are given off, and the metal is maintained in a state of artificial ebullition. The upper parts of the contents of the basin are oxidized and removed from the surface, while the greater part of the foreign metals collects at the bottom. The metal is allowed to partially cool, during which process it separates into zones, the upper part consisting of nearly pure tin, while the under is so impure that it must be returned to the furnace and again melted. The upper layer of tin is removed into molds, containing each about three hundredweight, in which it is allowed to solidify; it is then sent into the market as block-tin, the purest specimens being called refined tin.

Characteristics.— Tin, when pure, has a fine white color like silver but with a slightly bluish hue, and when newly melted its brilliancy is great. It has a slightly disagreeable taste, and emits a peculiar smell when rubbed. Its hardness is between that of gold and lead. Specific gravity, 7.28. It is very malleable; tin leaf, or tin-foil as it is called, is about one one-thousandth part of an inch thick; and it might be beaten out into leaves as thin again, if such were wanted for the purposes of art. Its ductility and tenacity are much inferior to those of most of the metals known in early times; a bar of tin a quarter of an inch in diameter will not support a greater weight than 294 pounds. Tin is very flexible and produces, while bending, a remarkable creaking noise, known as the «cry of tin.» It melts at about 460° F. When cooled slowly it may be obtained crystallized in the form of a rhombodial prism. By washing the surface of a mass of tin with warm dilute aqua regina it becomes covered with a number of crystals, which, from their unequal action upon light, give an appearance to the metal somewhat resembling that of watered silk. After a short exposure to the air tin loses its lustre and assumes a grayish-black color, but undergoes no further alteration. Neither is it sensibly altered by being kept under water. When cooled to 54° below zero it undergoes a transformation into what is called «gray tin.» In this form it is very brittle and has lost all its metallic properties. When tin is melted in an open vessel its surface becomes very soon covered with a gray powder, which is an oxide of the metal. If the heat be continued the color of the powder gradually changes, and at last it becomes yellow.

Tin Ores.— These are but two in number, tin ore and tin pyrites, known respectively by the technical names of cassiterite and stannite. The first of these occurs crystallized, and in a great variety of forms, which may all be derived from an octahedron with a square base, the angle over the apex being 112° 10′. The majority of the crystals have the general figure of a right square prism, with four-sided pyramids at each extremity. They occur often in twin form, the twin crystals forming an elbow. The cleavages take place parallel with the sides of this prism and with both its diagonals. The crystals may be cleaved also parallel to the sides of the above-named octahedron, but with difficulty. The prisms are sometimes vertically streaked. Lustre adamantine; color various shades of white, gray, yellow, red, brown and black; streak pale gray, in some varieties pale brown; semi-transparent, sometimes almost transparent, and in others opaque; brittle; hardness six to seven, about that of feldspar, specific gravity, 6.96. Tin ore presents itself in a great variety of compound or macled crystals. It also occurs reniform, rarely in botryoidal shapes, and massive, with a granular or columnar composition, the individuals being strongly connected and the fracture uneven. The wood-tin of the Cornish mines is a mere variety of tin ore. It is so-called because of its resemblance to a cross section of the trunk of a tree, with the concentric rings of annual growth. In color it is dark reddish to brown. The following ingredients were found in specimens of crystallized, massive and wood-tin ore:—

	Crystallized	Massive	Wood-tin
Oxide of tin........	99.00	95.00	85.14
Oxide of iron......	0.25	5.00	13.42
Silica.............	0.75	0.00	1.03

In its greatest purity cassiterite contains nothing but oxide of tin. Alone it does not melt before the blowpipe, but is reducible when in contact with charcoal. It occurs disseminated through granite, also in beds and veins, in lode mines. It also occurs in the beds and alluvial deposits of streams in the form of rolled pebbles and is extracted in this shape as «stream-tin» by placer works and dredges. The variety called wood-tin has hitherto been found only in these repositories, but is occasionally found in pockets in rock formations. Tin pyrites ($Cu_2S.FeS.SnS$), the other ore of tin, occurs massive, with a granular composition; fracture uneven, imperfectly conchoidal; lustre metallic; color steel-gray, inclining to yellow; streak black; opaque; brittle; hardness about that of fluor-spar; specific gravity, 4.35. Before the blowpipe sulphur is driven off and the mineral melts into a blackish scoria, without yielding a metallic button. It is soluble in nitro-muriatic acid, with precipitation of part of the sulphur. It contains from 14 to 30 per cent of tin. It is found at Saint Agnes in Cornwall, in Saxony and in Bolivia and in Virginia, Idaho and Montana in the United States.

Production.— The world's production of tin in the calendar year 1916 amounted to 135,-360 short tons. Of this total, 49,130 tons (about 36 per cent) came from the Federated Malay States; 23,500 tons from Bolivia; 14,-000 tons from Banca, Dutch East Indies; 9,400 tons from Siam; 8,400 tons from China; 5,980 tons from Australia; 5,680 tons from Nigeria; 5,500 tons from Billiton and Singkep, Dutch East Indies; 5,260 tons from Cornwall, England; 4,900 tons from the British Protected Malay States; 2,100 tons from the Union of South Africa; and 1,500 tons from all other countries. About 33,000 tons were lode tin — from Bolivia, Cornwall, South Africa and Australia — and the remainder from placer workings. The total is 10,870 tons less than for 1913, just preceding the war. Incomplete figures indicate that the output for 1917 is about 2,000 tons more than for 1916, in spite of the serious decrease of nearly 5,000 tons from the Federated Malay States; a condition resulting from an increase of 5,800 tons in the output of Bolivia. Although the complete blockade of Germany left that nation's usual consumption, amounting to 21,000 tons annually, free upon the market, the price of tin rose enormously during 1917 — from 44.19 cents per pound in January to 85.35 cents per pound in December. These figures are to be compared with an average price of about 44 cents per pound for the years immediately preceding the war. During the first years of the conflict the price fell below 31 cents.

The contribution of the United States to the 1916 total was about 140 short tons, derived almost entirely from Alaska, and chiefly the product of dredges operating in the York district, in the western part of the Seward Peninsula. The output of this district was 162 tons of «stream tin» estimated to average 60 per cent of metallic tin. Nearly two-thirds of the whole Alaskan output was sent to Singapore to be smelted and refined. The United States output for 1917 was but 90 tons. Nearly all of the production is from placer workings, the one lode mine worked being the Lost River mine, in Alaska. The other tin producing localities in the United States are in Lander and Humboldt counties, Nevada; the Black Hills in Pennington County, South Dakota; near Lincolnton in North Carolina; near Gaffney, South Carolina; and in the Franklin Mountains, north of El Paso, Texas. In all of these localities the ore is cassiterite. This ore has been found in small quantities also in the Temescal Mountains of California, near Corona — a deposit which produced 135 tons of tin in 1890–91; in Virginia, in Rockbridge and Nelson counties; in Washington, at Silver Hill, near Spokane; in Maine, at Winslow, and several other localities; and in New Hampshire, at Jackson. Wood-tin has been found in the gold-bearing gravel of Panther Creek, Idaho; and in the Big Prickly Pear Creek district of Montana. There was in 1916 but one smelter in the United States handling tin ores, the plant of the American Smelting and Refining Company at Perth Amboy, N. J. Its capacity is about 14,000 tons of tin per year and it works almost solely upon Bolivian concentrates. Before the war a large percentage of the Bolivian tin concentrates was sent to Germany for smelting. With the cessation of this service a large smelting plant was built in Chile and another plant erected in the United States.

In 1917 there was imported into the United States for consumption a total of 77,866 short tons of metallic tin, having an aggregate value of $68,603,439. Thus it appears that the United States consumed nearly 57 per cent of the entire world's output of tin for the year.

Uses.— The principal use of tin in the United States is in the production of tin-plate for the manufacture of tinware and of terne-plate for roofing and building purposes. In terne-plate the tin used to plate the iron sheets carries a percentage of lead. Tin is used also in the manufacture of cheap mirrors, the «silvering» compound consisting of an amalgam of tin and mercury. It is also used largely in the technical arts in various alloys; as in Britannia metal, type metal, solder, pewter, bell metal and several bronzes.

TIN-MOUTH, a fish. See CRAPPIE.

TIN PLATE, Manufacture of. The manufacture of tin plate was probably begun in Bohemia, about the beginning of the 16th century, and was first attempted in England about 1670. The early crude methods consisted of the simple expedient of dipping the plates of iron into a vat of molten tin and allowing the surplus metal to drain off. In 1865 Mr. Morewood, of South Wales, England, invented a machine which gave tin plate manufacture its start, greatly reducing the cost of production. At the surface of the pot he placed a pair of steel rods which seized the plate as it came up and rolled off the superfluous tin; thus leaving the coating of the plate smooth and even. Since then many improvements have been made in the methods of manufacture, making the product more serviceable and reducing materially the manufacturing expenses. The modern method is as follows:

After the bars of steel have reached the rolling mill they are first cut into accurate lengths, then placed in the sheet-mill furnace, brought to a cherry-red heat, taken out in pairs and given three or four passes through roughing rolls, each bar being fed through sidewise and rolled singly. After cooling they are again heated, placed one upon the other, and in pairs are again rolled. The doubler then grasps the plates at one end with a pair of large tongs and brings the two ends together. The loose ends are then shorn off square, and the fold is flattened by means of a powerful press, thus making four thicknesses or plates, one end of each being free, the other still forming the bend. The plates are again heated, passed through the roughing rolls, taken by the doubler, opened back to the bend, and once more doubled. The first bend is snipped off when the ends are squared, thus making one free end for each sheet in the pack. This is done to prevent buckling and to insure a perfect finished plate. They are then heated for the fourth time, passed two or three times more through the finishing rolls and are then ready for the pickler.

After the sheets have been separated and examined for possible flaws, they are sent to the black pickler, where they are immersed in a strong solution of acid and hot water to remove all dirt, after which they are rinsed and allowed to drain. All perfect plates, in order to make them sufficiently soft for general use, are sent to the annealing furnace, which opens the pores and toughens the plate. After being heated there thoroughly for a period of about 12 hours the plates are cooled off and carried to the cold rolls through which they are passed singly. The re-squarer then trims the four edges and restacks the plates in the annealing box; they are again annealed and put into the white pickler, in which the acid solution is much weaker than in the first bath.

Having been pickled and rinsed, the plates are placed in water boshes; immersed in a bath of melted palm-oil; placed in a pot containing molten tin and lead; and finally dipped into another pot of tin of lower temperature than the previous one. From the tinning pot they are put into the grease pot, the thickness of the coating being determined by the length of time they remain therein. After cooling they are cleaned by passing through bran and dust. This completes the process and the plates are ready for the market.

According to the census of 1905 there were in the United States 36 establishments engaged in the manufacture of tin plate, employing $10,813,239 capital and 4,847 persons; paying $2,383,070 for wages and $31,375,714 for materials; and having an aggregate output valued at $35,283,360. The business has largely increased since, and the present method of figuring the production is by boxes. Of these the production in 1914 was 20,271,683, 1915 22,925,437, 1916 26,979,994 and 1917 32,898,597. The tremendous increase, due to war orders, cannot be maintained unless there is an increase in the production of tin, which is not expected.

Consult Louis, H., 'Metallurgy of Tin' (1911); Schnabel, C., 'Handbook of Metallurgy' (2d ed., 2 vols., London 1905–07).

TIN WEDDING. See WEDDING ANNIVERSARIES.

TINAMOU, a South American game-bird, the *Crypturi*, called «partridge» by European colonists because of its superficial likeness to those birds, but structurally occupying a distinct place, the determination of which has greatly puzzled ornithologists. The view now prevails that they are a «very distinct group of birds, which though not to be removed from the *Carinatæ* present so much resemblance to the *Ratitæ* as to indicate them to be the bond of union between those two great divisions. Many genera and species are known in southern South America and two or three forms extend northward into Mexico. They vary in size from that of a quail to a guinea hen. The head is small, neck slender, bill elongated and plumage close and inconspicuous, usually brownish or bluish, with few ornamental markings. The wings are short and rounded, and the tail so short and soft as in some species to appear absent altogether. Some of them inhabit forests and others more open country, and show very little skill or courage in avoiding the gun or escaping capture. Their flesh is delicious. They nest upon the ground and lay very remarkable eggs, since the shell «looks as if it were of highly burnished metal or glazed porcelain, presenting also various colors, which seem to be constant in the particular species, from pale primrose to sage-green, or light indigo, or from chocolate brown to pink-orange.» The fact that the male alone incubates the eggs is one of many ratite characteristics of this antique and curious group of birds. Consult Newton, 'Dictionary of Birds' (New York 1896) wherein will be found many references to special authorities.

TINCAL, or TINKAL, a common trade name for borax (q.v.) in the crude state.

TINCKER, Mary Agnes, American novelist: b. Ellsworth, Me., 18 July 1833. In her earlier days she taught in a Roman Catholic parochial school and from 1873 to 1887 lived in Italy. Her best known novel is 'Signor Monaldini's Niece' (1878); others are 'By the Tiber' (1881); 'The Jewel in the Lotus' (1884); 'Aurora' (1885); 'Autumn Leaves' (1898).

TINCTURE, *in pharmacy,* an alcoholic solution of some medicinal substance, prepared by digestion, maceration or percolation. It may be a solution of some chemical element as iodine, of some single chemical compound as chloride of iron, or a solution of that part of some plant which will dissolve in the solvent used: example, tincture of cinchona bark. Simple tinctures are those obtained from a single drug, compound tinctures from many. The solvents (*menstrua*) are various; pure alcohol, mixtures of alcohol and water or of alcohol and ether, alcoholic solutions containing ammonia, etc.

TINDAL, Matthew, English controversialist: b. Beer Ferris, in Devonshire, about 1653; d. 16 Aug. 1733. He was graduated from Lincoln College, Oxford, in 1676, in 1678 was elected a Fellow of All Souls' College, and afterward became a Doctor of Civil Law, and an advocate of Doctor's Commons. In the reign of James II he turned Roman Catholic, but in 1688 returned to the Church of England. He published several pieces, political and theological, among which were a 'Letter to the Clergymen of the two Universities, on the subject of the Trinity and Athanasian Creed,' and a treatise, 'The Rights of the Christian Church asserted against Priests' (1706). This work excited a sensation among the high church clergy, who attacked it with great vigor. Tindal published two defenses of it, which the House of Commons ordered to be burned by the common hangman, with the original treatise. In 1730 he published his 'Christianity as Old as the Creation, or the Gospel a Republication of the Religion of Nature,' in which his object was to show that there cannot be any revelation distinct from the internal revelation of the law of nature in the hearts of mankind. This deistical or rationalist work — by which his name is chiefly known — received a great many answers.

TINDALL, or TYNDALE, William, English reformer and translator of the Bible: b. near Welsh borders, about 1490; d. Vilvoorden, Belgium, 6 Aug. 1536. He entered the University of Oxford in 1510, and was graduated in 1512. He subsequently went to Cambridge, where he resided till 1521, and about this latter date became tutor to the children of Sir John Walsh, a landed gentleman in Gloucestershire. He preached with great acceptance in the neighborhood, but soon got into trouble owing to his unorthodox views. In 1523 he went to London, where he came under the influence of Luther's teaching. It was at this time that he began his translation of the New Testament, but finding it unsafe to carry out such a work in England, he went to Hamburg in 1524, and immediately afterward to Luther at Wittenberg, where he remained till April 1525. During this time he was proceeding with his translation, with the assistance of one William Roy, and the printing of it was begun at Cologne in 1525. A Roman Catholic clergyman, John Cochlæus, came to know of this, and obtained an injunction ordering the stoppage of the work, whereupon Tindall went to Worms and had the work printed there. It was smuggled into England in 1526, and at once Archbishop Warham and Bishop Tunstall took the lead in seizing and burning copies. Attempts were also made to get hold of Tindall, but he fled to Marburg, where he enjoyed the protection of the landgrave of Hesse. Here he became a Zwinglian in his attitude on the Eucharist, and published some of his most important original works, including The Parable of the Wicked Mammon' (1528); 'The Obedience of a Christian Man,' and 'How Christian Rulers Ought to Govern' (1528), and 'The Practyse of Prelates' (1530). He also engaged in a vigorous polemic with Sir Thomas More. From Marburg he went to the Netherlands, and for several years resided in Antwerp, but toward 1533 left the city for a time, owing to Henry VIII's efforts to seize him. In 1535 he was captured at Antwerp by the imperial officers, assisted by an English Roman Catholic student named Phillips who professed to adopt his reforming opinions. He was lodged in the state prison at Vilvoorden, near Brussels, and despite some efforts to save him, made by Cromwell and others, he was tried for heresy, condemned, degraded from holy orders, then strangled and his body burned. A fragment of the interrupted Cologne print of his New Testament translation is in the British Museum, and there are two extant copies of the first edition of his complete New Testament (1525), one (practically complete) in the Baptist College, Bristol, the other (incomplete) in Saint Paul's Cathedral. A revised edition was issued by him at Antwerp in 1534, and a further revision in the following year. His translation of the Pentateuch appeared at Marburg in 1529–30, and that of Jonah at Antwerp in 1531; a copy of each is in the British Museum. Tindall's translation is of much importance in the history of the English style and English literature, and formed the basis, as far as it went, of the Authorized Version of nearly a century later. There is an edition of Tindall's original works by the Parker Society (3 vols.; 1848–50). Consult Demaus, 'Life of William Tindall' (1886); Price, I. M., 'Ancestry of Our English Bible' (Phila. 1907).

TINDER, a dry substance that readily ignites from a spark; before the introduction of friction matches, it was in common use as a means of starting a fire. It consisted usually of charred linen which caught the spark from a flint and steel; since the tinder did not flame, the fire was started by touching a match dipped in sulphur to the ignited tinder. Tinder-boxes were boxes in which tinder was kept ready for use; they were usually provided with a flint and steel, the latter often fastened to the cover of the box in such a manner that the flint when struck against it sent sparks into the tinder within. «German tinder» or amadou consisted of the more solid portions of certain fungi, mainly tree-growing polyfores, prepared by boiling in water and drying. Sometimes saltpetre, or even a little gunpowder, is added. Amadou has been used to stop bleeding and also in surgery as a support and for pressure and protection. «Spanish tinder» was a stuff prepared from the pubescence of the flower-heads, stems and leaves of globe-thistle. The use of the word tinder has been extended to denote any substance easily inflammable.

TINEIDÆ, a family of moths, prominently represented by several small species whose caterpillars are destructive to woolen fabrics, furs and various stored products. See CLOTHES-

MOTH; FLOUR AND MEAL INSECTS; GRAIN INSECTS; MOTHS, etc.

TINGLEY, Katherine, American theosophist: b. Newburyport, Mass., 6 July 1852. She married P. B. Tingley in 1889. She was for some years an assistant to W. Q. Judge, who with H. P. Blavatsky were active in establishing theosophy as a philosophy and religion and on his death she founded, 18 Feb. 1898, a new branch called the Universal Brotherhood and Theosophical Society, which has branches in many cities and countries and headquarters at Point Loma, Cal. She has edited *Century Path* for a number of years and has written 'The Mysteries of the Heart Doctrine' (1902); 'Nosegay of Everlastings' (1913); 'Theosophy and Some of the Vital Problems of the Day' (1915). See THEOSOPHY.

TINOCERAS, tĭ-nŏs'ē-ras, a genus of mammals now extinct, found in the Eocene of Wyoming (Bridger beds) and representing the order *Dinocerata*. The individuals were all large, some of them nearly equaling the elephants, and differed little from, if, indeed, they were not identical with, *Uintatherium.*

TINOS, tē'nōs, or **TENOS,** tē'nŏs, Greece. an island in the monarchy of the Cyclades, immediately southeast of Andros. It is 18 miles long by eight miles broad and has an area of 81 square miles. It is traversed by high mountains, the terraced slopes of which yield wine, wheat, melons, figs, etc. Marble and silk goods are the chief exports. Tenos or Hagios Nikolaos, the chief town, on the south coast, is the see of a Roman Catholic bishop, has two Roman Catholic churches and a small harbor. North of the town is the white marble church of Penagia Evangelistria, a famous pilgrim resort. Excavations in 1902 on the site of ancient Tenos revealed remains of the temple of Poseidon. Tenos was prominent in the wars with the Persians and during the Greek Revolution 1821–27. Pop. 12,000.

TINTERN ABBEY, England, a ruin of unrivaled beauty in Monmouthshire, on the Wye, eight miles south of Monmouth. It was founded in 1131 by the Cistercian monks — the church in 1287. It is well preserved and is a noble specimen of the transition from Early English to the Decorated. The open work of the windows is one of its chief beauties. Under Henry VIII the abbey was dismantled and its lands bestowed upon the earl of Worcester.

TINTERN ABBEY, 'Lines Composed a Few Miles above Tintern Abbey, on Revisiting the Banks of the Wye during a Tour, July 13, 1798' a reflective poem in 159 lines of blank-verse, by William Wordsworth, was composed in 1798, and was published that same year in the famous volume entitled 'Lyrical Ballads.' The clumsy title has long since been shortened by the public to 'Tintern Abbey'— in itself misleading, since the poem has nothing to do with the abbey, which is used simply to identify the landscape that serves as a basis for the poet's reflections. Wordsworth had visited the region alone and on foot in 1793; upon his second visit, five years later, he recalls the first and compares his feeling for nature at that time with what it is now. His theme in general is the inter-relation between nature and the spirit of man, each as an interpreter and revealer of the other: the contemplation of nature gives an insight into the invisible world that comprehends both nature and man; nature has the power to throw light upon the mystery of human life; she can console and sustain; man's own emotional experiences, in turn, reveal and interpret nature. Primarily reflective, 'Tintern Abbey' is at the same time intensely subjective, and hence is almost as lyrical in essence as Wordsworth's so-called 'Ode on Immortality,' with the ideas of which it has so much in common. The two in both thought and style are Wordsworth's greatest poems; each complements the other; and taken together they form the *locus classicus* of the Wordsworthian faith and doctrine. The Platonism that informs the 'Ode,' though less fundamental to 'Tintern Abbey,' yet colors the latter throughout.

The poet distinguishes three successive periods in his attitude toward nature: his first, and merely animal delight, grows into a sensuous appreciation of natural beauty, and this in turn finally develops into a moral and contemplative attitude and brings the «philosophic mind» that identifies nature, man and God (compare 'The Prelude,' Book VIII, lines 340–356). Perhaps none of the ideas in the poem, taken singly, was new to the world; but certainly never before had they been fused into a whole and stated with such impressiveness and splendor as the utterance of one great personality. The style of the poem, though it undeniably drops toward the end in the poet's address to his sister, is in the main superb. Here is Wordsworth's «grand manner,» as in the 'Ode,' no less appropriate and perfect in its way than the beautiful simplicity of his 'Michael' (q.v.). No other of his poems contains so many of his most felicitous lines, such as

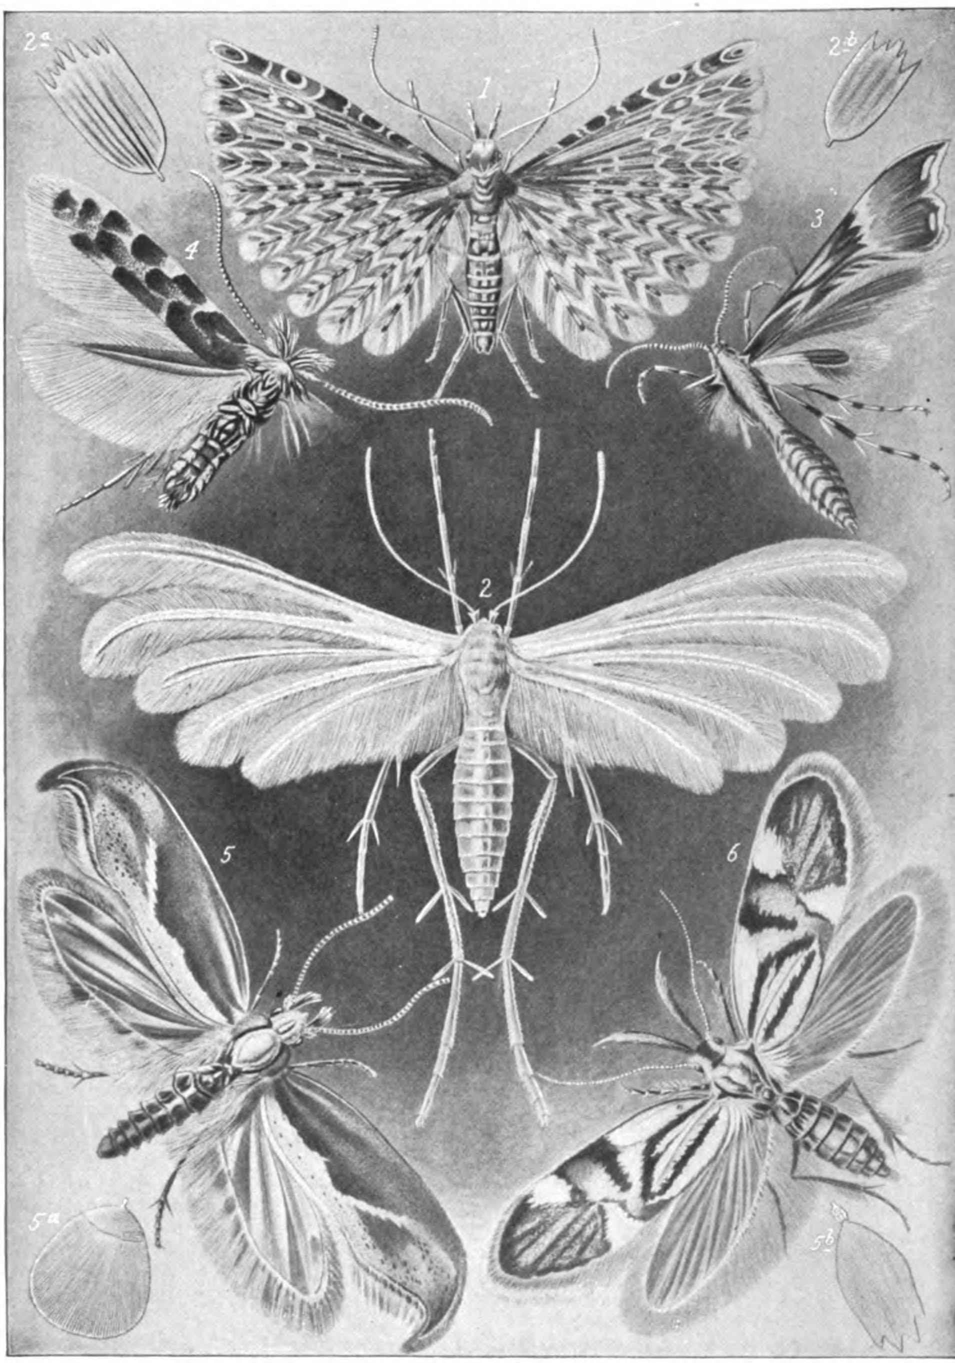
"the still, sad music of humanity",
"the little, nameless, unremembered acts of kindness and of love",
"nature never did betray the heart that loved her".

Its faith in the entire beneficence of nature is of course the obvious weakness of the poem considered philosophically. How far 19th century theories and discoveries have invalidated its teaching cannot be discussed here. It is doubtful whether the average reader is at all affected by Wordsworth's failure to see the other side of nature, by his lack of scientific vision. Here he speaks simply as a seer; and the passage in which he declares his sense of the Power «whose dwelling is the light of setting suns» is perhaps as moving and sublime as any in the whole range of English poetry, as incomparable, at least in style, as anything in Shakespeare or Shelley. Whether considered as the self-revealing utterance of a great personality, or as the statement of a doctrine that has immensely influenced the course of modern poetic thought, or simply as an example of magnificent diction, 'Tintern Abbey' has a permanent place among the supreme achievements of modern poetry.

MARION TUCKER.

TINTORETTO, tēn-tō-ret'tō, **Jacopo Robusti,** son of a dyer (Italian, *tintore*), whence his usual surname, Italian painter: b. Venice, 16 Sept. 1518; d. there, 31 May 1594. He was a pupil of Titian, but was soon dismissed by his master, perhaps through fear of rivalry. He thereupon worked without a master, taking as

TINEID MOTHS (much magnified)



1, 2, 3 Feathered Moths 4, 5, 6 Common Moths Other figures are details of the scales

his ideal in painting a union of the design of Michelangelo with the coloring of Titian. He painted with such extraordinary facility and rapidity as to gain the epithet «Il Furioso.» Annibale Carracci said that he was sometimes equal to Titian, often inferior to Tintoretto. He treated Scripture subjects in a perfectly naturalistic spirit, but at times this became decidedly coarse. Ruskin estimates Tintoretto very highly, and places him among the supreme painters. The greater number of his works are to be found in his native city, and of these the following may be named: In the Palace of the Doges: 'Paradise,' the largest oil-painting in the world, with a very large number of figures; 'The Delivery of the Doge's Insignia to Niccolò da Ponte'; 'Recapture of Zara'; 'Forge of Vulcan'; 'Mercury with the Graces'; 'Minerva driving back Mars'; 'Descent from the Cross'; etc. In the Academy: 'Saint Mark descending to the Rescue of a Condemned Christian Slave'; 'Adoration of the Kings'; etc. In the church of Madonna dell' Orto: 'The Last Judgment'; 'Adoration of the Golden Calf'; 'Miracle of Saint Agnes,' and 'Presentation in the Temple.' The Uffizi gallery at Florence contains some of his works, including 'Abraham's Sacrifice' and a 'Marriage at Cana'; and the Pitti Palace contains among others, a 'Descent from the Cross'; 'Vulcan with Venus and Cupid,' and a 'Madonna.' The Prado Museum at Madrid is rich in works by Tintoretto, among them being many portraits; and others are to be seen in the National Gallery at London ('Saint George Destroying the Dragon'; 'Christ Washing the Feet of His Disciples'), Berlin, Dresden, Vienna, Paris, etc. Consult Ruskin, 'Stones of Venice'; 'Modern Painters'; etc.; Osler, 'Tintoretto' (1879); Stearns, 'Jacopo Robusti' (1895); and the 'Lives' by Bonsusan (1907) and Philipps (1911).

TINWORTH, George, English sculptor: b. London, England, 5 Nov. 1843. He was the son of a wheelwright and in his father's shop began the practice of wood carving. In 1861 he took lessons in an art school at Lambeth and in 1864 entered the Royal Academy schools. After exhibiting figures and groups of figures at the Royal Academy, he obtained an appointment in the Doulton art pottery (1867). The productions by which he became famous were mainly terra-cotta panels with groups of figures in high relief illustrating scenes from sacred history, which combine originality of design, with dramatic effectiveness and devout feeling. His most important work is the reredos in York Minster, with 28 terra-cotta panels.

TIONONTAIC, an American Indian tribe formerly residing near Nottawasaga Bay, Ontario, Canada. When first discovered by the French in 1616, they were called the Tobacco Nation, from their large fields of tobacco. In 1670, the remnants of the tribe joined the Wyandottes (q.v.).

TIPPECANOE, a nickname of Gen. William Henry Harrison, given to him on account of his victory in the battle of Tippecanoe (q.v.). In the presidential campaign of 1840, which resulted in the election of Harrison and Tyler, «Tippecanoe and Tyler too» was the party war-cry of the Whigs.

TIPPECANOE, Battle of, fought 7 Nov. 1811 near the site of the present village of Battle Ground, on the Tippecanoe River, in Tippecanoe County, Ind., between about 900 Americans under William Henry Harrison (q.v.), who was then governor of the Territory of Indiana and a force of Indians nominally under «the Prophet,» brother of Tecumseh (q.v.), but actually commanded by three chiefs, Stone Eater, White Loon and Winnemac. The Indians were estimated by Harrison at about 6,000, but were probably much less in number. Harrison encamped on the night of 6 November near the Indian village on the Tippecanoe River and while his men were asleep in the early morning of the 7th the Indians fell upon them with great fury and were only defeated and driven from the field after several hours of desperate fighting, in which the whites lost about 185 in killed and wounded, the loss of the Indians being unknown, though they left 40 dead on the field. The village was found on the 8th deserted and was burned by Harrison's men. For reasons of prudence Harrison then fell back to Vincennes. Consult Pirtle, 'The Battle of Tippecanoe' (1900), No. 15 of the «Filson Club Publications.»

TIPPERARY, tĭp-ĕ-rā'rĭ, Ireland, a town and the county-seat of the famous county of Tipperary in Munster. The town is situated 42 miles northwest of Cork and 110 miles southwest of Dublin. It has a large grammar school, several religious schools and butter and provision markets.

TIPPLE, Ezra Squier, American Methodist Episcopal clergyman: b. Camden, N. Y., 23 Jan. 1861. He was graduated at Syracuse University in 1884, took his Ph.D. there in 1886 and was graduated at Drew Theological Seminary in 1887. He served as a pastor in New York in 1887–1905, when he became professor of practical theology at Drew Theological Seminary. Since 1912 he has been president of that institution. He is a trustee of Syracuse University and is author of 'The Heart of Asbury's Journal' (1905); 'The Life of Freeborn Garrettson' (1910); 'Francis Asbury' (1916); 'The Drew Theological Seminary, 1867–1917' (1917), etc.

TIPPOO (or TIPU) SAHIB, tĭ-poo' sä'-hĭb, sultan of Mysore: b. 19 Nov. 1749; d. Seringapatam, Mysore, 4 May 1799. He was the son of Hyder Ali Khan, whom he succeeded in 1782. During the operations of the English troops under General Mathews in Malabar, he checked the advance of the British at Bednor, April 1783 and temporarily wrested Mangalore from its western invaders. In the following autumn he was compelled to surrender this province to Great Britain. In 1784 he was forced to sign a treaty of peace; but, continuing to intrigue, war was declared against him in 1790 and in 1791 he was defeated by Lord Cornwallis and obliged to surrender half of his domain and to pay 33,000,000 rupees to his English conquerors. In 1799 he was suspected of an alliance with France and again defeated by the British and their allies, the Mahrattas. He was killed while fighting in this campaign. Consult Bowring, 'Haider Ali and Tipu Sultan' (1893).

TIPTON, England, town in Staffordshire, situated six miles northwest of Birmingham. It has coal and iron mines, iron foundries, steam boiler and structural iron works, red and white-lead factories, cement works and brick-yards. Pop. about 32,000.

TIPULIDÆ, the family of craneflies (q.v.).

TIRABOSCHI, tē-rä-bŏs'kē, **Girolamo,** Italian literary historian: b. Bergamo, 28 Dec. 1731; d. Modena, 3 July 1794. He was educated by the Jesuits, afterward joining their order and was for many years a professor in the University of Milan. He was a scholar of note, his greatest work being the 'Storia della Letteratura Italiana' (1772–93) in 13 volumes. He also published 'Biblioteca Modenese' (6 vols., 1781–86), and 'Memorie storiche modenesi' (1793–94). He was librarian to Francis III, duke of Modena, from 1770.

TIRAILLEUR, tĭ-rä-lyėr, a skirmisher, sharpshooter; the title was first employed by the French in 1792, to denote light-armed troops thrown out from the main body to do skirmish work, feel the enemy, cover the movement of the main body, etc.

TIRASPOL, tē-räs-poly', Russia, a river-port in the government of Cherson, on the Dniester, 60 miles northwest of Odessa. It possesses five churches, two synagogues and a state bank. One of its chief attractions is its gardens. The principal industries are tobacco-raising and fruit culture. There are four factories and some trade is carried on.

TIRE, the outer band placed around the felloes of a wheel, made in various forms, for several purposes. The common tire for a wooden-carriage wheel is made of iron or steel and serves the double purpose of holding together the parts of the wheel and resisting wear in traversing the ground. The continuous steel tire is an American invention and consists of a flat hoop of steel usually of the same width and formed so to fit tightly over the felloes; it is expanded by heating and put on in a heated condition; upon cooling it shrinks and tightly compresses the wheel. It is further secured by sunk-bolts through the felloes. The wire wheel made on a suspension principle, as in the bicycle, has a steel felloe with a concave outer surface for holding a rubber tire or a pneumatice tire. These have been highly developed in the bicycle (q.v.) and the automobile (q.v.); car wheels and locomotive wheels of cast iron or cast steel have usually tires of tough wrought steel shrunk on, so that the wearing surface may be as durable as possible. See RUBBER TIRES.

TIREBUCK, William Edwards, English novelist: b. Liverpool, 1854. He was for some years a writer on the staff of the Liverpool *Mail* and the Yorkshire *Post*, but in 1888 retired from newspaper life and devoted himself to writing fiction. His best-known novels include 'Saint Margaret' (1888); 'Dorrie' (1891) and 'Miss Grace of All Souls' (1895). He is also the author of an estimate of 'Dante Gabriel Rosetti' (1882) and of a later work entitled 'Great Minds in Art' (1888), etc.

TIRESIAS, tī-rē'sĭ-ạs, according to Greek mythology, a soothsayer of Thebes, reputed to have been struck blind either because he had revealed to men things which they ought not to know, or because he had seen Athene bathing. Athene conferred upon him the power to understand the language of birds, while Zeus gave him the gift of prophecy and long life. Tennyson has a poem on the subject of 'Tiresias' (1885), who also figures in many Greek legends.

TIRLEMONT (Flemish, *Thienen* or *Tienen*), Belgium, town in the province of Brabant, on the Geete River, 11 miles southeast of Louvain and 29 miles east of Brussels. There are two churches dating from the 12th century, Notre Dame du Lac and that of Saint Germain. Saint Germain has a fine altar-piece by Wappers. The town was taken by the Duke of Marlborough in 1705; on 16 March 1793 it was the scene of a victory by the French over the Austrians, and in the European War it was occupied by the Germans soon after the outbreak of the war in 1914, remaining in their hands until the armistice. Industries include brewing and the manufacture of leather, woolens, soap and engines. Pop. 17,581.

TIRPITZ, Alfred von, German admiral: b. Kustrin, 1849. Graduating from the Marine Academy when only 17 years of age, he advanced rapidly, and in 1896 was State Secretary of the Navy and in 1898 Minister of State of Prussia. In 1911 came his promotion to the post of Lord High Admiral. He took great interest in the development of the submarine and had immense faith in this arm of the navy. He is credited with having organized and planned the submarine blockade of the British Isles in 1915–16. When he carried his policy to the extent of sinking unarmed vessels, culminating in the torpedoing of the *Lusitania* (q.v.), he aroused such indignation in neutral countries that the unwisdom of the policy was apparent and his resignation was arranged for, though the assigned reason was his illness. See WAR, EUROPEAN.

TIRYNS, tĭ'rĭnz, Greece, in Argolis, 10 miles southeast of Mycenæ, an ancient city on a rocky height which formed the Acropolis; beneath which another city extended along the plain. The town was destroyed 468 B.C. Much of the citadel and of the cyclopean walls with their pointed gates are still standing, together with some interior passages or galleries of similar construction. The excavations conducted by Schliemann in 1884–85 resulted in the discovery of a magnificent palace, comprising various buildings and approached by a peristyle. The complete arrangement of public halls and private apartments is apparent. Consult Schliemann, 'Tiryns' (1886); Perrot and Chipiez, 'Histoire de l'Art dans l'Antiquité' (Vol. VI, 1894) and Baedeker's 'Greece.'

TISCHBEIN, tĭsh-bīn, **Johann Friedrich August,** German painter: b. Maestricht, 1750; d. Heidelberg, 1812. He studied with Johann Heinrich Tischbein and in Paris and Italy. After serving as court painter in Waldeck he became director of the Leipzig Academy in 1800. He painted many noteworthy portraits, including nine of the princes and princesses of Orange-Nassau (Amsterdam) and that of Schiller, which he finished in 1804.

TISCHBEIN, Johann Heinrich, German painter: b. Haina, 3 Oct. 1722; d. Cassel, 22

Aug. 1789. He studied under the court painter Freese in his native town and under Boucher, Van Loo and Watteau in Paris. He entered the studio of Piazzetta in Venice 1748, returned to Cassel in 1751, was made court painter to the landgrave and in 1776 became director of the New Academy. He painted numerous portraits and historical pictures, which, although not possessing great strength, were considered among the best produced in Germany at that period. Among them may be mentioned 'Lessing' (1760); 'Count Waldner von Freundstein' (1761); 'Augustus and Cleopatra' (1769), and 'Belisarius' (1786).

TISCHBEIN, Johann Heinrich Wilhelm, German painter and etcher, called «the Neapolitan»: b. Haina, 15 Feb. 1751; d. Eutin, 26 July 1829. He was a nephew of Johann Heinrich Tischbein and the most famous of the Tischbein family. He studied under his uncle and other relatives and in Hamburg, Bremen and Holland. Goethe assisted him in going to Italy and in 1787 the two went together to Naples, where Tischbein enjoyed the patronage of Sir William Hamilton and from 1789 to 1799 was director of the Academy. In 1809 he became court painter to the Duke of Oldenburg. The 43 'Idyls' celebrated in Goethe's verse were painted by Tischbein at Eutin. To different publications he contributed over 150 etchings and engravings and his paintings include 'Conradin of Swabia Hearing his Sentence' (1784); 'An Italian Landscape' (1819); a portrait of Goethe, and a portrait of the artist himself. Consult Michel, 'Etude biographique sur les Tischbeins' (1881).

TISCHENDORF, tĭsh'ĕn-dŏrf, **Konstantin von,** German biblical critic: b. Lengenfeld, Saxony, 18 Jan. 1815; d. Leipzig, 7 Dec. 1874. He was educated at Leipzig, where he qualified as a lecturer in 1840. In the latter year he went to Paris and deciphered the 'Codex Ephræmi' and soon afterward he began to travel extensively in Europe, Egypt, Sinai and Palestine in search of biblical manuscripts. In 1844 he saved from the flames in the Convent of Saint Catharine on Mount Sinai a valuable manuscript of the Old Testament, but failed to get possession of more than a part of it. This part he published in facsimile in 1846 as the 'Codex Friderico-Augustanus,' so named in honor of his patron, the king of Saxony. He was appointed in 1845 extraordinary professor, in 1850 ordinary honorary professor and in 1859 ordinary professor of theology and biblical palæography at Leipzig. He again visited the East in 1853 and in 1859 he made a third visit at the cost of the Russian government. On the third journey to Sinai he brought back the rest of his 'Codex Friderico-Augustanus,' better known as the 'Codex Sinaiticus,' the oldest Greek manuscript of the Bible, containing the entire New Testament and the Epistle of Barnabas, besides much of the Old Testament. (See CODEX SINAITICUS). A magnificent facsimile edition was published in four volumes at Saint Petersburg in 1862. In 1869 Tischendorf was ennobled by the emperor. Among his contributions to the textual criticsm of the New and the Greek Old Testament are 10 editions between 1843 and 1870, the largest being 'Monumenta Sacra Inedita: Nova Collectio' (1855–70). He issued several editions of the Greek New Testament, of which the eighth critical edition (two vols., 1864–72) is of great importance. In his 'Novum Testamentum Triglottum' (1854) he printed together his Greek text, the Latin of Jerome and the German of Luther. His 'Synopsis Evangelica' (5th ed. 1854) should also be mentioned in connection with this part of his work. He edited the Septuagint with critical appendix (1850; 7th ed. 1887) and on the New Testament apocrypha and pseudepigrapha published 'De Evangeliorum Apocryphorum, Origine et Usu' (1851); 'Acta Apostolorum Apocrypha' (1851); 'Evangelia Apocrypha' (1853); and 'Apocalypses Apocryphæ' (1866). 'In wann wurden unsere Evangelien verfasst?' (1865; Eng. trans.) he shows a strongly conservative tendency. He described his travels in the works 'Reise in den Orient' (1845–46) and 'Aus dem Heiligen Lande' (1862).

TISHRI, a month in the Jewish calendar. the first of the civil year and the seventh of the ecclesiastical. It corresponds to portions of our September and October and contains the Jewish Day of Atonement as well as the Feast of Tabernacles. It is frequently mentioned in the Old Testament and in 1 Kings xiii, 2 it is related that «. . . all the men of Israel assembled themselves unto King Solomon at the feast in the month Ethanim, which is the seventh month»; the term Ethanim, used instead of Tishri, signifies streaming rivers, the result of the September floods. The name tishri occurs in the Palmyrene inscriptions and, therefore, was probably not confined to the Jews.

TISSANDIER, tē-sän-dē-ā, **Gaston,** French aeronaut: b. Paris, France, 21 Nov. 1843. He was the inventor of a dirigible balloon in which he made an ascent of five and one-third miles, from Paris in 1875; he alone surviving of the members of the aeronautic experiment. Besides his written contributions to the subject of aeronautics he has contributed to the 'Library of Wonders' series, well-known volumes on the subjects of light, water, coal and fossils.

TISSERAND, François Félix, French astronomer: b. Nuits-Saint-Georges, Côte-d'Or, 15 Jan. 1845; d. Paris, 20 Oct. 1896. He was educated at the École Normale Supérieure and in 1866 he became adjunct professor at the Paris Observatory. He took his doctor's degree in 1868 with a thesis which was a brilliant extension of the scope of the method of Delaunay. He went to Malacca to observe the solar eclipse of 18 Aug. 1868 and in 1873 became director of the *Observatory* at Toulouse. He was a member of the French expeditions observing the transit of Venus, in Japan, in 1874 and in Martinique in 1882. He was elected to the Academy of Sciences in 1878; in 1883 became professor of celestial mechanics at the Sorbonne; and in 1892 was appointed director of the Paris Observatory. He made many valuable investigations in the field of celestial mechanics and wrote brilliantly on the subject. The results of his own labors and that of others in this field are set forth with masterly grasp and simplicity in his 'Traité de mecanique celeste' (4 vols., 1886–96). He revised Lalande's catalogue and was editor of the *Bulletin Astronomique.*

TISSOT, tē-sō, **Claude Joseph,** French philosopher: b. Fourgs (Doubs), 26 Nov. 1801; d. Dijon, 7 Oct. 1876. He translated the larger part of Kant's writings into French. Among his original works are 'Of the Beautiful, Especially in Literature' (1830); 'Short History of Philosophy' (1840); 'The Mania of Suicide and of Revolt' (1840); 'Parceling of the Land and Division of Property' (1842); 'Principles of Morality' (1866); 'Catholicism and Public Instruction' (1874); 'Insanity Considered Especially in its Relations to Normal Psychology' (1876).

TISSOT, James, French painter: b. Nantes, 15 Oct. 1836; d. Abbey of Bouillon, 8 Aug. 1902. He was a pupil of Ingres, studied in London under Seymour Haden, and attracted attention by his brilliant pictures of fashionable women, actresses and grisettes, as in his 'Promenade in the Snow' (1859). His series of etchings 'Parisian Women' was very popular. He suddenly changed his whole artistic aim in life under the stress of a sudden bereavement and went to Palestine (1890) where he studied for six years the scenery and buildings and rural activities of the Holy Land for the purpose of producing a set of pictures illustrating the life of Christ. These paintings were subsequently reproduced by Lemercier in Paris under the title 'La vie de notre Seigneur Jésus-Christ'; and a parallel publication of them has been issued in this country. The original drawings and paintings, 540 in all, are now in the Brooklyn Institute of Art. Just before his death he began his paintings illustrating the Old Testament.

TISSUE, *in biology,* a group of similar cells in an animal body (or a plant) which form a definite fabric, having the same origin and discharging the same function. Tissues are classified according to their structure when completely developed, in accordance with their functions, or with reference to their mode or origin. A common classification of animal tissues includes cellular tissue, connective tissue (q.v.), epithelial tissue (see EPITHELIUM), muscular tissue (see MUSCULAR SYSTEM, DEVELOPMENT OF), nerve-tissue (see NERVOUS SYSTEM, EVOLUTION OF THE), etc. Fatty tissue consists of a meshwork of white fibrous tissue in which fat-cells are imbedded. It is found beneath the skin, around various internal organs, in the marrow of bones, and elsewhere, and is both protective and heat-retaining in its function. Mucous tissue is merely a stage in the development of ordinary connective tissue. Adenoid tissue, found in the glands, consists of a network of very delicate connective tissue, in which white cells of various sizes are entangled. The cartilage (q.v.) or gristle of the joints is one of the primary animal tissues. See ANATOMY, COMPARATIVE; PLANTS, STRUCTURE OF; BONE; CARTILAGE; HISTOLOGY; PARENCHYMA.

TISSUE PAPER. See PAPER; PAPER INDUSTRY IN AMERICA.

TISZA, tĭs'ŏ, **Koloman Borosjeno von,** Hungarian statesman: b. Grosswardein, 16 Dec. 1830; d. Budapest, Hungary, 23 March 1902. He was educated for the law, but entered the civil service in 1848, and took a prominent part in educational affairs. Although not at first identified with the revolutionary movement, the attempt of Austria to control ecclesiastical matters in Hungary in 1859 brought him forward as the leader of the party which stood for Protestant autonomy. In 1860 he was elected to the Hungarian Parliament, where he opposed the conciliatory measures offered by the imperial government in the proposal to relinquish absolute authority and to yield the right of representation to the Magyar provinces, and stood resolutely and persistently for independence. In 1861 he succeeded Count Telsky as the leader of the Constitutional party. He was subsequently instrumental in uniting the moderate Radicals with the Liberal party, but was at all times opposed to the socialistic and agrarian demands of the revolutionists. In 1875 he was appointed Minister of the Interior, and some months later became Prime Minister. He resigned his office in 1890, but continued until his death to direct the affairs of his party and to control legislation.

TISZA, Stephan, COUNT, Hungarian statesman: b. Budapest, 1861; d. 31 Oct. 1918. He was educated at the universities of Berlin, Heidelberg and Vienna and was appointed to a post in the Hungarian Ministry of the Interior in 1882. He was elected to the Hungarian Parliament in 1886, and was conspicuous for his strong support of close relations with Austria. He was Premier and Minister of the Interior in 1903–06, losing his seat in Parliament at the same time that his ministry fell. He was again appointed Premier 10 June 1913, and occupied that office at the outbreak of the European War in 1914. He was thoroughly in sympathy with the war and was regarded as one of its chief authors. Growing dissatisfaction with the continuation of the war, and overwhelming demands for suffrage and other reforms which Tisza was unwilling to grant resulted in efforts to bring about the fall of his Cabinet in 1917, and he resigned 13 May 1917. In 1918 he was assassinated.

TITANIA, according to Ovid, a name of Latona, a daughter of the Titan Coius. Shakespeare in 'Midsummer Night's Dream,' gives the name to the wife of Oberon.

TITANIFEROUS IRON ORES are chiefly varieties of the minerals ilmenite, hematite and magnetite. Ilmenite (q.v.) is often called titanic iron ore and is richer in titanium than either of the others. The value of these ores for both iron and titanium, which was long questioned, seems at last to be established. The remarkable attraction of titanium for nitrogen suggests its use in freeing iron and steel of blow-holes, while titanium steel is known to possess remarkable toughness and tensile strength. Much excellent work has been done by Rossi in pointing out the merits of titanium steel and in developing processes for the reduction of titaniferous iron ores. The most important known occurrences of these ores are in Norway, Quebec and the Adirondack Mountains, in each of which regions there are beds of vast extent. These occurrences have been exhaustively described in papers by F. J. Pope and J. T. Kemp.

TITANITE, a mineral occurring in mono clinic crystals, often wedge-shaped and twinned, having the composition of calcium silico-titanate. Its lustre is adamantine to resinous; hardness, 5 to 5.5; specific gravity about 3.5. Parting is often prominent, while prismatic cleavage is less distinct. Its colors vary greatly. Dark brown to black crystals, sometimes several inches in diameter, occur mostly in limestone in Saint Lawrence County, New York, and in Canada. The variety sphene is usually bright green or golden yellow, and often occurs in gneiss or chloritic schists in transparent or translucent twin crystals. Owing to the high refractive and dispersive power of such crystals, gems of rare beauty and inferior to none but the diamond in their play of colors, may be cut from them, though they lack durability owing to their low degree of hardness. The finest of these gem sphenes are from Switzerland, the Tyrol, Delaware County, Pennsylvania and Tilly Foster, New York.

TITANIUM. See ELECTRO-CHEMICAL INDUSTRIES; MINERAL PRODUCTION OF THE UNITED STATES.

TITANOSAURUS, a genus of huge sauropodous dinosaurs. See DINOSAURIA.

TITANOTHERIUM. See BRONTOTHERIUM.

TITANS, tī'tạnz, *in Greek mythology,* six sons and six daughters of Uranus and Ge, namely Oceanus, Koius, Krelius, Hyperion, Iapetus and Kronus; Theia, Rhea, Themis, Mnemosyne, Phœbe and Tethys. Uranus having banished to Tartarus the Hekatoncheires ("the hundred-handed") and the Cyclops, Gaia called the Titans to avenge their brothers. They rose and freed them, deposed Uranus, and set Kronus in his place. Kronus and the Titans were in their turn put down by the sons of Kronus and Rhea, named the Olympii, with Zeus at their head, but not till after a long struggle, in which Zeus brought to his aid the Cyclops and Hekatoncheires, whom Kronus had again imprisoned in Tartarus. Zeus quelled the Titans with the lightning given him by the Cyclops, hurled them to Tartarus, placing them under the care of the Hekatoncheires. This struggle, called the Titanomachia, was regarded as symbolic of the conflict of reason and order with the rude forces of nature. Consult Mayer, 'Die Giganten und Titanen in der antiken Sage und Kunst' (1887).

TITCHENER, tĭch'ĕn-ẽr, **Edward Bradford,** American psychologist: b. Chichester, England, 11 Jan. 1867. He was graduated from Oxford in 1890, and afterward studied in Leipzig. He returned to Oxford as extension lecturer in biology, but was called to Cornell University, Ithaca, N. Y., in 1892, as assistant professor of psychology, and in 1895 became Sage professor of psychology there. His writings include 'A Primer of Psychology' (1898); 'Experimental Psychology' (1901); 'Text Book of Psychology' (1910); 'A Beginner's Psychology' (1915). He is also editor of the *American Journal of Psychology.*

TITE, SIR **William,** British architect: b. London, Feb. 1798; d. 23 April 1873. He shared in the work of rebuilding the body of Saint-Dunstan-in-the-East in 1817–20; was engaged in building the Scottish Church in Regent square in 1827–28; and was one of the designers of the London and Westminster Bank, Lothbury, in 1838. He rebuilt the Royal Exchange in 1841–44, a work which is considered his greatest achievement as an architect. He designed the earlier English railways stations as well as those on the line from Havre to Paris, France. He planned the Woking Cemetery in 1853–54; was a member of Parliament from 1855 until his death; and was knighted in 1869. Author of 'A Catalogue and Description of the Antiquities Found in the Excavations for the Royal Exchange' (1848).

TITHES, taxes, either voluntary or compulsory, consisting of one-tenth of the income taxed. Usually tithes were one-tenth of the annual profit of the land and were paid for purposes of church support. The custom is of extreme antiquity. In Genesis xiv, 20, Abraham allows a tenth of the spoils taken from four kings to their victor. Moses allowed tithes for the support of the Levites and for service in the temple (Lev. xxvii, and Num. xviii). In 778 Charlemagne commanded tithes to be collected within all the portions of the old Roman empire over which he ruled; this was for the support of the Christian Church. These tithes were by him allotted to four different uses: one part was for the maintenance of the edifice of the church, and the other three, severally, for the support of the bishop, the clergy and the poor. Ecclesiastical tithes were always more or less oppressive in their operation, being unevenly imposed, but after their introduction into Great Britain they were systematized. They were first enjoined in England in 786 and in 794. Offa, king of Mercia, gave the Church all the tithes of his kingdom, and this law was subsequently made general for all England by Ethelwulf. When dioceses were divided into parishes the tithes of each parish were allotted to its minister, at first by common consent, but afterward, about 1200, by the law of the land in England. The custom of paying tithes became established in Germany and France about the same time, the 9th century, and in the Scandinavian countries in the 11th century. At first the payment of the tax was always in kind, that is, in grain, livestock, wool, etc., and such tithes were known under three heads, namely, prædial, or those which arise immediately from the soil, as grain, fruits and wood; mixed, or those consisting of natural products but nurtured by the care of man, as calves, lambs, eggs, cheeses, wool, etc.; and personal, or those arising from the profits of personal industry as in the pursuit of some profession, or some trade of livelihood. With regard to their value tithes were divided into great and small; great tithes being grain and wood, and belonging to the rector, and small tithes being the other prædial tithes with the mixed and the personal tithes, and belonging to the vicar.

Tithes proved a source of great trouble in every country in which they were collected and a constant cause of bickering between the clergy and the people. They have, therefore, been abandoned in nearly all countries except England, where they are still retained. There they have been the cause of constant friction between the people on the one hand and the officers of the law and the clergy on the other. Under Henry VIII, the owners of certain great estates were relieved of the duty and this increased the feeling of the tithe-payers that their burden was an unjust one. In three-fourths of Ireland it was found impossible to collect tithes, for long periods at a time, and the enforcement of the law, especially in cases of non-members of the Church, was not infrequently accompanied by riot and revolt. Finally, an act of commutation was passed by which tithes were assessed in money, the value being based on the average price of corn for a preceding term of years. The matter has been the subject of much legislation by Parliament, which has generally established in lieu of the old system a fixed money rent charge payable annually. Consult Clarke, H. W., 'History of Tithes' (1891); Degge, S., 'The Parson's Counsellor with the Law of Tithes' (1820), and Selden, J., 'History of Tithes' (1618).

TITHING, an old English subdivision of the population. It consisted of a company of about 10 households, one of the integral parts of a hundred (see SHIRE), who were regarded as a distinct political division for some purposes of police and civil regulation. At its head was the tithing-man, who was directly responsible to the officers of the Crown, the several members of the tithing being bound for the peaceable behavior of each other. The institution of the tithing has passed away, the tithing-man has evolved into the police constable, but in some parts of England British conservatism still preserves the name and the corresponding territorial distinction.

TITHING MAN. See TOWN AND TOWN MEETINGS.

TITHONUS, tĭ-thō'nŭs, a son or nephew of Laomedon, king of Troy. He was beloved of Eos (Aurora, Morning), who induced Zeus to make him immortal. Her prayer was granted but she had neglected to ask for perpetual youth, and in time her lover took on all the signs of extreme age. Tithonus prayed to the gods to be relieved of this «cruel immortality» and was metamorphosed into a grasshopper. Tennyson has written a remarkable poem, 'Tithonus,' on this mythological incident.

TITIAN (TIZIANO VECELLI), the greatest painter of the Venetian school and one of the world's greatest painters: b. Pieve in Cadore, a district in the Venetian or Carnic Alps, 1477; d. Venice, 27 Aug. 1576. He was the son of Gregorio di Conte Vecelli, a descendant of an ancient family and a man of some note in his province. It was the custom of this family to follow arms or the law, but young Titian showed such genius for art that at the age of nine or 10 he was sent to Venice to learn painting. He studied under Gentile Bellini and afterward with Giovanni Bellini and then attached himself to Giorgione, who was the idol of the day. Master and pupil worked together on the outside frescoes for the new Fondaco dei Tedeschi, the exchange of the German merchants in Venice. After Giorgione's sudden death by the plague in 1510, Titian completed several of his master's works. Titian's pictures of this period show much similarity to Giorgione's and are often referred to as «Giorgionesque Titians.» One of the most famous is 'Sacred and Profane Love' (in the Borghese Gallery in Rome), about which so much has been written. To this period also belong the 'Virgin and Child' (Vienna Gallery), popularly called 'La Zingarella'; the Bishop of Paphos, or 'Baffo' (Antwerp Gallery); 'Saint Mark' (in the Salute, Venice); the 'Three Ages' (Bridgewater Gallery, England); 'Madonna of the Cherries' (Vienna Gallery); 'Daughter of Herodias' (Doria Gallery, Rome); 'Christ with the Tribute Money' (Dresden Gallery); and 'Noli me Tangere' (National Gallery, London).

In 1511 Titian went to Padua to paint a series of frescoes in the Senola di S. Angelo and returned to Venice in 1513, where he became superintendent of government works and was ordered to complete the paintings left unfinished by Giovanni Bellini in the Hall of the Great Council of the Doge's Palace. Here he painted the portraits of five successive Doges. In 1514 he was invited to the Court of Alfonso, Duke of Ferrara, for whom he painted many charming works, including the 'Worship of Venus' and the 'Bacchanel,' with Ariadne dozing over her wine-cup (both in the Prado, Madrid), and the superb 'Bacchus and Ariadne' (in the National Gallery, London). At Ferrara he formed a friendship with Ariosto and Aretino, whose portraits he painted. In 1516, while painting these delightfully decorative and pagan triumphs of Bacchus and Venus, he began work on the 'Assunte,' or 'Assumption of the Virgin,' for the church of S. Marie Gloriosa dei Frari, Venice (now in the Venice Academy). This was finished in 1518 and created a sensation, for it was considered the most astonishing performance in color on a grand scale that had as yet been executed. The same gallery now preserves the famous 'Presentation of the Virgin,' a large and much restored picture, and one of Titian's masterpieces of masterpieces. In 1526 he completed the 'Pesaro Madonna,' on which he had worked for seven years. This is still in the church of the Frari and represents the Madonna enthroned with adoring saints, including Saint George, and members of the aristocratic Pesaro family beneath the group. The 'Cornaro Family,' belonging to the Duke of Northumberland, is a work of the same general character. The 'Entombment of Christ' (in the Louvre) is another early work, and 'Christ Crowned with Thorns' (also in the Louvre) still shows the influence of Giorgione.

In 1525 Titian married. Nothing is known about his wife, who died in 1530, leaving three children, one the infant Lavinia, of whom Titian painted so many beautiful portraits. Titian now removed to a fine house in the Biri Grande, a fashionable suburb of Venice, where he had beautiful gardens sweeping down to the sea. Here he had his sister do the honors of his establishment and here he entertained lavishly and charmingly. In 1532 he painted a portrait of Charles V, the emperor, in Bologna, and was, in consequence, created a Count Palatine and a Knight of the Golden Spur. His two sons were also made nobles of the empire — a most unusual honor for a painter. From this time onward Titian enjoyed a worldly success greater than that any other painters ever had accorded to them, with the exception of Raphael, Michelangelo and Rubens. In 1540 D'Avalos, Marquis del Vasto, gave him a pension and Charles V an annuity of 2,000 crowns (afterward doubled) on the treasury of Milan. When visiting Rome in 1546 he was given the freedom of the city. In 1550 he painted the famous portrait of Philip II of Spain, which helped his suit for the hand of Queen Mary of England. Notwithstanding the many statements that Titian visited Spain, modern authorities affirm that he never was there. He traveled much in Italy and went to Augsburg and was at the Council of Trent in 1555. In 1565 he went to Cadore to design decorations for the church at Pieve, his native town. He spent most of his life, however, in Venice, where he worked until the last moments of his life. Vasari saw him with brushes in hand painting furiously. Titian was, according to most authorities, 99 when he died of the plague, then raging in Venice. Vasari gives his birth as 1480, but Titian, writing to Philip II in 1571, said he was 95. He was buried in the church of the Frari near his famous painting, the 'Madonna di Casa Pesaro.' Canova's monument now marks his grave. His son, Oragio, died of the plague a few days after Titian. He, too, was a painter, but overshadowed by his father's greatness. In the confusion and riotous days of the plague Titian's splendid villa was entered and plundered by thieves. Titian's last painting was a 'Pieta,' which was finished by Palma Giovine. Although Titian lived in grand style and had many orders, he seems to have had much trouble in collecting his payments; for his correspondence is full of appeals to his debtors. He gave splendid entertainments and attracted the most brilliant men of the age. It is related that when Henri III of France passed through Venice on his way from Poland to take the French throne, he called on Titian with his suite of noblemen and that the painter presented him as a gift with all the pictures of which he inquired the price.

Even allowing for the abnormal length of his professional career, Titian's prolific faculty is amazing. More than a thousand pictures in European and American galleries are attributed to Titian. Of these 250 are spurious or doubtful. The largest collection (41 works) is in the Prado, Madrid. The Uffizi has 18; the Pitti, 16; Naples Museum, seven; the Venice Academy, eight; the Louvre, 18 and the National Gallery, London, six. Some critics accord the famous 'Concert' in the Louvre, which has long been considered a Giorgione, to Titian.

«Titian was a man of correct features and handsome person,» writes William M. Rossetti, «with an uncommon air of penetrating observation and self-possessed composure — a Venetian presence worthy to pair with any of those most potent, grave and reserved signors, whom his brush has transmitted to posterity. He was highly distinguished, courteous and winning in society, personally unassuming and a fine speaker, enjoying (as is said by Vasari, who saw him in the spring of 1566) health and prosperity unequaled. He was not a man of universal genius or varied faculty and accomplished like Leonardo da Vinci and Michelangelo: his one great and supreme endowment was that of painting. Titian may properly be regarded as the greatest manipulator of paint in relation to color, tone, luminosity, richness, texture, softness, surface and harmony and with a view to the production of a pictorial whole converging to the eye, a true, dignified and beautiful impression of its general subject matter and of the objects of sense which form its constituent parts. In this sense Titian has never been deposed from his sovereignty in painting. Titian's pictures abound with memories of his home country and of the region which led from the hill summits of Cadore to the Queen City of the Adriatic. He was almost the first great painter to exhibit an appreciation of mountains, mainly those of a turretted type, as exemplified in the Dolomites. Indeed he gave to landscape a new and original vitality, expressing the quality of the objects of nature and their control over the sentiments and imagination with a force that had never been before approached. The earliest Italian picture expressly designated as 'landscape' was one which Titian sent in 1552 to Philip II. Naturally a good deal of attention has been given by artists, connoisseurs and experts to probing the secret of how Titian managed to obtain such extraordinary results in color and surface. His figures were put in with the brush dipped in a brown solution and then altered and worked up as his intention developed. In his earlier pictures the gamut of color rests mainly upon red and green; in the later ones upon deep yellow and blue. The pigments which he used were nothing unusual; indeed they were both few and common. Palma Giovine records that Vecelli would set pictures aside for months and afterward examining them as if they were his mortal enemies would set to work upon them like a man possessed. Also that he left many pictures in progress at the same time, turning from one to the other, and that in his final operations he worked far more with the finger than with the brush.» Titian seems to have taken Palma Vecchio as his model for softness and Giorgione as his model for richness. He distanced all his predecessors in the study of color as applied to draperies.

Titian excelled in every style. The 'Assumption of the Virgin' is ranked as one of the world's greatest pictures and the 'Entombment of Christ,' the 'Christ Crowned with Thorns' (Louvre), the 'Ecce Homo' (Vienna Gallery), in which Aretino posed for Pilate, the 'Supper at Emmaus' (Louvre), 'Saint Mark' (Salute, Venice), the 'Presentation in the Temple,' 'Christ in the Garden' (Madrid), 'Noli me Tangere' (London) and 'Saint Jerome' (Barera, Milan) attest his power in religious subjects. An exuberant fancy and dash characterizes his delightful mythological production such as 'Bacchus and Ariadne' (National Gallery), 'Bacchenal' and 'Worship of Venus,' 'Diana and Actaeon,' 'Callisto,' 'Jupiter and Antiope,' 'Europa,' 'Venus' (Pondo), 'Venus and Cupid' (Florence), 'Danae' and 'Venus and Adonis' painted for Philip II, 'Venus Anadyomene' (Bridgewater Gallery), the 'Madonna of the Cherries' (Vienna) and the 'Madonna of the Rabbit' or 'Madonna del Consiglio' (Louvre) prove that his 'Virgin and Child' can stand comparison with any other great master in Italian art. As a portrait painter Titian is unequaled. According to Vasari «There has scarcely been a noble of high rank, scarcely a prince or lady of great name, whose portrait has not been taken by Titian.» His list of famous men and women is long. Perhaps at the very top stands the unknown 'Man with the Glove' (Louvre), young, handsome and charming. Many times was the Duchess of Urbino painted, the most famous being the 'Bella' in the Uffizi, Florence. Many times also his daughter, Lavinia, smiles down the centuries. Sometimes she is holding a dish of fruit (Berlin), sometimes a jeweled casket (Lord Cowper) and sometimes a fan (Dresden). The Uffizi contains four superb studies: Catarina Cornaro, Queen of Cyprus, Sandovino, Francesco, Duke of Urbino and Eleanora, the Duchess of Urbino. Charles V on horseback at the battle of Muhlberg, now in the Prado, Madrid, shows for all ages what kind of man the emperor was. Titian painted three portraits of himself: one in early life (Vienna), one in middle age (Berlin) and one in old age (Prado, Madrid). Francis I (Louvre), though a great portrait, was not painted from life, for Titian never saw this sovereign. The famous work in the Louvre called 'Titian and his Mistress' represents Alphonso, Duke of Ferrara and his wife Laura di Dianti. Pope Paul III was another fine subject. The great 'Trinity' or 'Last Judgment,' in which Charles V appears, was so loved by the emperor that he had it in his room during his last illness and kept his eyes fastened on it till the last. Titian also painted one great historical work in 1539, 'The Battle of Cadore' representing the moment when the Venetian captain, facing the enemy, dashed into the rushing stream with men and horses. All are represented life size. This picture perished by fire in 1577 and is only known to-day by Fontana's engraving and a sketch by Titian in the Uffizi.

"Titian," writes Kugler, "was born in grand Alpine scenery amidst a sturdy and vigorous race; and it is in the combination of these antecedents with the gorgeous color and stately forms of Venetian life that we trace that breadth of qualities so conducive to the development of art in which he takes precedence of every other painter. Two forms of nature especially courted his pencil — landscape and portraiture; and in each he revealed to the world treasures of truth and poetry not worked out before. For Titian is not only the painter of humanity in its largest distinctions — in the beauty of woman, the dignity of man and the artlessness of childhood — but he is especially the delineator of all those under every aspect of the high born and the affluently placed classes of society. Sir Joshua Reynolds says of him whatever he touched by a kind of magic he invested with grandeur and importance. The intellectual, the noble, the splendid, the well-formed, the well-fed, the well-dressed were the mutual subjects of his art. His type accordingly of Christ, John the Baptist and the Magdalen — characters in whom the pride of life and the abnegation of self are incompatible qualities — cannot satisfy those who look for the realization of a sacred idea. Titian can, therefore, hardly rank as a painter of religious feeling except in his earliest works when he was still under the influence of Giorgione."

Esther Singleton.

TITICACA, tē-tē-kä'kä, the largest lake in South America and one of the most remarkable on the globe, situated on the southeastern boundary of Peru, its eastern shores belonging to Bolivia. It is about 130 miles long and 30 miles wide through most of its length, though 43 miles at one point. It lies at an altitude of 12,635 feet, in a large plateau basin between the two main cordilleras of the Andes. It is of irregular shape, and contains several islands. Copacabana Peninsular almost cuts it in two at the southeast extremity. The greatest depth is 720 feet. Its surplus water is discharged southward by the river Desaguadero, which flows into Lake Aullagas, and thence disappears in the Salinas Grandes, so that the water of the lake does not reach the ocean. Lake Titicaca was formerly much larger than now, and is still decreasing in area. There are geologic evidences that it formerly discharged into the Amazon watershed, in the eastern side of the Cordillera Real. In spite of the high altitude the shores are inhabited, and steamers ply on its waters. The largest island in the lake also bears the name Titicaca. Puno is the largest town on its shores. The locality was the seat of a prehistoric civilization of great interest, and the islands and the regions around the lake contain some of the most interesting architectural remains of ancient Peru.

TITLARK, a small lark-like bird of the family *Motacillidæ*, many species of which inhabit most parts of the world in every variety of region, some being migratory, others permanent residents. The nest is made upon the ground, or dry grass and stalks, lined with finer plants and hair, and the eggs are four to six. The American titlark (*Anthus rubescens*) is six and one-half inches long and 11 in wing extent; olive brown above, each feather darkest in the middle; beneath yellowish brown, the sides of the neck spotted longitudinally with dark brown; round eyes and superciliary stripe yellowish; central tail feathers like back, the others blackish brown, the external one mostly white and a white spot at the end of the second; primaries edged with whitish, and the other quills with pale brownish; bill and feet black. It is very generally distributed over North America, extending to the Pacific and to Greenland, and is accidental in Europe. The flight is exceedingly easy and graceful; it occurs in flocks of tens or hundreds, running fast on the ground, vibrating the tail whenever it stops, not squatting like the larks, but moving the body on the upper joints of the legs. It is found in the fields, on the prairies, along rivers, and on the seashore; the notes are clear and sharp tweets, the last much prolonged; it breeds in the East only north of the Saint Lawrence River, and especially in the coastal districts of Labrador; but in the Rocky Mountain region spends the summer much farther south, but at cool elevations. This bird is very similar to the *A. obscurus* and *spinoletta* of Europe, though the latter has a longer bill and less slender tarsi and toes, and has no yellowish superciliary stripe; the outer tail feathers are not white, and the spots are less distinct below. Among the European species the most extensively distributed is the meadow titlark or pipit (*A. pratensis*), which is a favorite field-bird in Great Britain. The tree-pipit or titlark (*A. arboreus*) is another favorite. Both are kept as cage-birds. Consult general works, and Coues, 'Birds of the Northwest' (Washington 1874).

TITLE-DEED, a paper, or one of several papers, written or printed, or partly written and partly printed, describing a property in detail, and through what ownership or authority it came into the present custody, by virtue of which a person claims ownership or title. The term is often used in the plural to denote the several muniments of title turned over by the grantor on delivering the property to the grantee or his agent and in this sense title-deeds are any documents containing evidence of the title or any part of the title to real estate or other property so granted. Every owner of property is supposed to have his own title-deeds, but the modern system of registering real estate transfers requires an official copy of the title-deeds to be entered in the office of the registrar or of whatever public agent assumes the duties of registrar, and there be open to the public inspection.

TITLE INSURANCE is effected in countries having public offices for the record of titles to real estate through the agency of title guaranty companies. This business has assumed importance in the United States where the system is most fully developed. In this country law requires all transfers of real estate, all mortgages, wills, judgments, etc., to be entered in official registers open to public inspection. In the larger cities these records soon became so voluminous that the matter of verifying title became a cumbersome affair callfng for the prolonged services of expert realty lawyers. Moreover such research was attended with long delay and with great expense; yet this had to be repeated every time a fresh transfer or mortgage took place, since the vendee or mortgagee was not apt to accept the property without assurance of its being unencumbered and sound in title. Finally in 1876 a Philadelphia company was organized to guarantee titles, and the plan proved so successful that companies have since been organized in nearly every large city in the country. The plan of operation of these companies calls for large capital, for in order to be independent of the clumsy and sometimes inaccurate methods of public record offices the title insurance companies form their own records of real estate titles in the locality in which they operate, and must maintain for this purpose a large staff of expert title examiners. On account of the size of its force a well-equipped company can make the first examination and guaranty of a title in less than a week, whereas from one to three months was sometimes required by the practising attorneys. The fee required in this first instance is usually about the same as that charged by a reliable lawyer, or, in case of a long examination, about one-half per cent of the value of the property negotiated; but it has the added advantage of guaranteeing against loss if there is any inaccuracy of the search. After a property has been once examined and its title guaranteed, the noting of future transactions affecting it is a simple matter, and subsequent guaranties are issued upon short notice and for a small fee.

TITLE TO PROPERTY. See REALTY.

TITLE REGISTRATION, a system of public records under which titles to real property are recorded in public offices for the purpose of expediting the process of transfer and of giving legal notice to claims of ownership to lands so entered. In England the registration of titles is of comparatively recent introduction, the system being due to the land transfer acts of 1875, under which it was first successfully practised. The office of record in that country is conducted by a registrar appointed by the lord chancellor, who also fixes the fees for the various services of the office. These fees, paid in the form of stamps, provide the emoluments of office from which the registrar draws his pay. Under the act of 1875 the registrar must approve of the title submitted and in case of a sale the vendor must make affidavit that he has produced all the deeds, wills and other instruments of title as well as all the evidences of encumbrances on the land, in order that the registrar can make a fair entry. When once a title is registered no adverse title will acquire any advantage by length of possession, but any person claiming an adverse interest can lodge a caution of that fact and be entitled to notice of all further transactions on the property. When the registered land is sold the name of the transferee is entered on the register and he is issued a certificate of title. The law is not compulsory in England, but is being gradually adopted because of its advantages over the old system.

In the United States it early became customary to register titles, mortgages and notices of transfer of interest, encumbrances, etc., in public offices, usually in the office of the county clerk of the court. This officer has no judicial or discretionary powers and is empowered only to register official copies of deeds, mortgages, agreements, etc. In place of the issuance of a certificate the clerk notes on the original or a duplicate deed that a true copy has been entered on the official register and this copy becomes legal notice of claim of title to all the world. The clerk of the court, who is a county officer in the United States, and elected, not appointed, frequently delegates this part of his work to an appointed assistant known as the registrar of deeds. Between the parties of a conveyance the recording or non-recording of the instrument is of no moment, but conveyances made after the first is recorded are void, and any conveyance not recorded is void as against a subsequent conveyance to a bona fide purchase from the person in whose favor a recorded conveyance has been executed. State regulations, however, usually govern the matter of registration in regard to its effect as constructive notice. For the «Australian system» of national land registration, see TORRENS SYSTEM.

TITLES, words or phrases bestowed on individuals as a mark of distinction, rank or dignity, and in some cases implying office or vocation. Titles may be official, honorary, civil, military, temporal or ecclesiastical. The use of titles is as old as civilization and seems to have arisen from titles bestowed for some public service, and only later to have been bestowed in virtue of the dignity of the office or employment of the recipient, and even later to have become hereditary. As used by the Greeks and Romans, however, titles conformed to the first and the last customs — they were bestowed for service and were hereditary. Later, Roman offices carried their titles with them irrespctive of the merits of the holders, for example, the names Cæsar and Augustus, and the phrase *pater patriæ*, all of which came to be applied to the imperial throne regardless of the character of the occupant.

Titles to-day in existence in Europe are interesting relics of the feudal period. First came the titles of count and duke. Counts (*comites*, companions) were the followers of the feudal lords and the dukes (*dux*, leader), the military leaders.

Placed at the head of provinces, their rôles were the same, to administer their territory, defend it against depredations and forays from without, and to organize and lead its man-power in the military service of the overlord when the latter went forth to battle. Later came the appellation marquis to denote those in charge of the «marches,» marshes, usually on the frontiers or border lands. Under the count came his lieutenants with the title of viscounts. As regards the title baron, which signifies man *par excellence*, it was at first applied only to the higher feudal personages, the great tenants-in-chief of the Crown. The knight was he who had received an order of chivalry or knighthood, and so on through the several grades of feudal society.

Among modern rulers the titles king and emperor with the feminines and in the case of the late Russian Empire that of tsar, are the titles of supreme heads of government. The title king harks back to a period when its bearer bore it by right of *kinship* as the head of his tribe. The later *rex* and its derivatives in the Romance languages denotes a ruler. And the word emperor, which is used in the same sense, originally denoted the ruler of an empire or a confederation of several states, each of which had a king at its head. In this respect the word was advisedly applied to William II, late emperor of Germany. Meanwhile it had become customary to add to the titles signifying the office, honorary qualifying titles. Henry IV of England was called «Grace»; Edward IV, «Most High and Mighty Prince»; Henry VII, «Highness»; and Henry VIII, «Majesty.» This latter title was universally adopted by the sovereigns of Europe, and was subsequently subjected to further qualification, as in the case of James I, who was called «His Sacred Majesty of England,» and was formally addressed as «James, by the Grace of God, King of Great Britain, France and Ireland, Defender of the Faith,» etc. Catholic rulers, meanwhile, had assumed such titles as «Catholic» for Spain, «Most Faithful» for Portugal, etc. The present ruler of Great Britain receives the title, «George V, by the Grace of God, of the United Kingdom of Great Britain and Ireland and of the British Dominions beyond the Seas King, Defender of the Faith, Emperor of India,» etc. The eldest son of the British sovereign is styled the Prince of Wales, and the eldest daughter the Princess Royal; the other sons and daughters are styled prince and princess, and all, together with the children of the sons of the reigning sovereign, are addressed as Royal Highness. The five orders of nobility in Britain are distinguished by the titles of honor — duke marquis, earl, viscount and baron. These nobles have several titles, granted by district patents, in their progressive steps in the peerage. A duke may thus be a marquis, an earl, a viscount, and a baron. One of the inferior titles is permitted as a matter of social dignity to be assumed by the eldest son. Thus the eldest son of the Duke of Sutherland takes the courtesy title, as it is called, of Marquis of Stafford. Courtesy titles do not raise their bearers above the rank of commoners, and consequently the eldest sons of peers are eligible for election as members of the House of Commons. The lowest hereditary title is that of baronet, which, besides its name, which is placed after the name and surname of its bearer, entitles him to the prefix Sir. The dignity of knighthood is not hereditary. The titles of esquire and master (Mr.) are now given indiscriminately to nearly all classes of persons. The Continental titles of prince, duke, marquis, count, viscount and baron often differ considerably from the corresponding titles in England. Thus in England the title prince is confined to members of the royal family; Austria has, or had, archdukes but no dukes, Russia had only grand dukes.

It is an axiom that hereditary titles lose their value in proportion as they become common. In England this latter danger is obviated by the rule of primogeniture which insures that there shall be but one bearer of a title in a generation, while in France all the sons receive titles, the eldest the highest title, for instance, that of duke, the second son, a marquisate, and so on. In Mohammedan lands the only hereditary title is that of sherif, except in the ruling houses. Pasha and bey, at first purely military titles, are now conferred on civilians, but are not hereditary. Japan had a system of titles closely resembling that of Europe, and like the latter, based on her old feudal system. China, under the empire, ennobled the ancestors of the person to be honored and usually made the title hereditary for a stated number of generations. The Turkish sultan is style *padishah* (lord king) and as head of Islam he is «the Commander of the Faithful.» The ruling houses of India have a graduated system of titles closely akin to that of Europe. The Pope of Rome is distinguished by the title «His Holiness,» and addressed as «Your Holiness»; cardinals by the title «His Eminence»; bishops as «Monsignor,» and in England as «My Lord.» The title of bishops is «The Lord Bishop of ——,» of archbishops «The Most Reverend the Lord Archbishop of ——,» deans are addressed as «Very Reverend,» and archdeacons as «Venerable.» All clergymen and ministers of the Christian and Jewish faiths are now generally styled «Reverend.»

Titles in the United States.— Hereditary titles and other titles of nobility are forbidden by the Federal Constitution and the citizen of another country who bears such a title when he becomes a citizen of the United States must relinquish his title. Various offices of dignity and trust carry with them certain forms of address, but these forms of address pertain to the offices alone, and the holders of these offices have no claims to the prescribed form of address after their terms of service have expired. The President, governors of States, and ministers of foreign nations are addressed, and spoken of, as your or his «Excellency,» save in the case of speaking to the President, who should be addressed as «Mr. President.» The vice-president, members of the Cabinet and members of Congress, heads of departments, assistant secretaries, comptrollers and auditors of the treasury, clerks of the Senate and House of Representatives, State senators, law judges, mayors of cities, etc., are entitled «Honorable.» Military, naval, ecclesiastical and other professional dignities are distinguished by the titles common to the English-speaking peoples of the world. Consult the 'Almanach de Gotha'; 'Burke's Peerage'; Cokayne, G. E., 'Complete Peerage' (new ed., 1910); Phillips, Walter Alison, 'Titles of Honor' (in 'Encyclopedia Britannica,' Vol. XXVI, Cambridge 1911).

TITLES OF HONOR. See ORDERS (ROYAL) AND DECORATIONS; TITLES.

TITMARSH, M. A., or Michael Angelo, a pseudonym employed by Thackeray when contributing his 'Paris Sketch Book,' 'Yellowplush Papers,' etc., to *Fraser's Magazine.*

TITMOUSE, one of the diminutive birds of the subfamily *Parinæ,* family *Paridæ,* which are among the most interesting of passerine birds. There are more than 75 known species, ranging widely over most parts of the world except Australia, but most abundant in the temperate and colder regions of the northern hemisphere. None of them are really migratory, though they roam widely during the winter in search of food, nor are they gregarious, though in this particular also stress of weather frequently causes them to gather in flocks, often with other small birds,—as redpolls, finches, etc. They are not songsters, though most of them have characteristic, and frequently musical, call notes, and during the breeding season they sing after a fashion, rather weakly. They are very active, restless, familiar birds, usually showing little fear of man and oftentimes coming about houses in their continual search for food. They eat everything from seeds to the eggs and young of other birds. The nesting habits are varied, but they lay numerous eggs and raise two or more broods each season. The plumage is never brilliant, though occasionally striking, but is most frequently plain, though very tasteful.

Structurally the titmice, aside from their small size, are hard to distinguish from the jays. to which birds their habits also ally them in many ways. The bill is short and stout, straight and unnotched, and there are no rictal bristles, but the base is covered by tufts of bristly feathers, directed forward, entirely concealing the nostrils. The feet are stout, with scutellate tarsi and short toes. The wing is rounded, with 10 primaries, of which the first is exceedingly short. The tail as long as or longer than the wing is composed of 12 feathers, and usually rounded or graduated. The plumage of the body, long, soft and loose.

Of the 75 species of titmice, one-fifth occur in America all of these having been taken within the limits of the United States. About two-thirds of all the species belong in the genus *Parus,* and the same proportion holds among our American forms. The most abundant and familiar of our species is the black-capped titmouse (*P. atricapillus*), widely distributed and known everywhere as the chickadee. The typical form ranges in eastern America from typical form ranges in eastern, but closely allied sub-species, or species, occupy practically all the rest of the Continent. The general color is ashy-gray, the back with a brownish tinge, the under parts white, or nearly so; the crown, nape, chin and throat black, with the cheeks white. In size, the various forms range from four and one-half to five and one-half inches, of which the tail is about half. The chickadee is a very active, tireless little bird, retiring to the woods and swamps during the summer, but in winter very abundant in our villages and parks and about houses. It can easily be attracted to any spot where food is provided, and if unmolested by cats or otherwise will soon become very familiar. Although it eats bread and crumbs and other articles of a vegetarian's diet, its tastes are carnivorous and it is especially fond of «meat-on-the-bone.» When foraging for themselves, chickadees eat an enormous number of insects and thus justify their existence, if that were necessary. As a matter of fact chickadees are so familiar, so daintily clothed, so cheerful even in the severest weather, and so courageous, and their usual call note «chick-a-dee-dee,» is so pleasing, none of our birds is more universally loved and enjoyed. In the spring, when the mating begins, the chickadee has another note, a plaintive, though not drawled, «pe-we.» The nest is a mass of moss, feathers, wool, plant down, etc., placed in a hole in a stump, tree or fence post, usually not far from the ground. The eggs are five to eight in number in each of the two broods, and are white, spotted with reddish-brown. The chickadee of the South Atlantic States (*P. carolinensis*) is said to have notes quite different from the northern species. In the southeastern United States, ranging north to New Jersey, but rarely further, is another very abundant titmouse, quite different from the chickadee in both color and form, known as the tufted titmouse (*Parus bicolor*). It is a gray bird, with a black forehead, and a conspicuous crest, an inch longer than the chickadee and not so attractive. The notes are not so attractive as those of the chickadee and become monotonous; the most common rendering in words is «peto, peto, peto,» but it also has other calls. The tufted titmouse is not so familiar or confiding as the chickadee and is distinctly a woodland bird, seldom seen about houses. It is not shy and is readily approached, while the prominent crest makes it easy to recognize. The nesting habits and the eggs are similar to those of the chickadee, but the latter are considerably larger. A tufted titmouse occurring in the valley of the Rio

Grande (*Parus atricristatus*) is notable for its glossy black crest, while the bridled titmouse (*P. wollueberi*) is a related species occurring in the southwestern United States, and is remarkable for the very conspicuous black and white markings on the head. Besides several other interesting species of *Parus,* the southwestern United States is the home of four or five very small titmice, belonging to the genera *Psaltriparus* and *Auriparus.* The former are called «bush-tits» and though very plainly colored with black, brown and plumbeous, their very small size, four inches or even less, and their large, woven, pensile nests, with lateral entrance, make them an interesting group. The gold tit (*Auriparus flaviceps*) is of about the same size, but is notable for the rich yellow head, the other upper parts being ashy and lower parts whitish. These little birds build great globular nests of twigs, in the bushes, lining them with down and feathers. The eggs are pale bluish speckled with brown.

Of the tits of the Old World, seven species occur in Great Britain, but one of them, the crested tit (*Parus cristatus*), is only an accidental visitor. The great tit (*P. major*) is the largest European species, though only about the size of our tufted titmouse. The general color is yellowish and gray, with white cheeks and black head and throat. The blue tit (*P. cœruleus*) and the cole tit (*P. ater*) are the commonest of the English species. The former has the top of the head light blue and a bluish cast to the rest of the plumage. It is the species usually called «tom-tit.» The azure tit (*P. cyanus*) of Siberia, which is sky-blue and white, and the large Japanese tit (*P. varius*), which is handsomely marked with chestnut, will serve as examples of the more brightly colored titmice. The long-tailed tits of the genus *Ægithalos* are remarkable not merely for their excessively long tails but because they build very elaborate cozy nests, which are purse-shaped and hang free or are attached along one side to the trunk of a tree. The eggs are very numerous, as many as 20 having been found in one nest.

Consult in addition to standard ornithologies, Coues, 'Birds of the Northwest' (Washington 1874); and 'Birds of the Colorado Valley' (Washington 1887), and Evans, A. H., 'Birds' (in 'Cambridge Natural History,' Vol. IX, New York 1900).

TITTLEBAT TITMOUSE, the name of a London shop clerk who figures as the hero of «Ten Thousand a Year,» a novel by Samuel Warren (q.v.).

TITULAR BISHOP, an episcopal title in the Roman Catholic Church substituted by Pope Leo XIII for the older one of bishop *in partibus infidelium.*

TITULAR CHURCH, a name given to the parish churches of Rome, as distinct from the patriarchal churches, which belong to the Pope, and from the oratories. Each titular church is under a cardinal priest, has a district assigned to it, and a font for baptism in case of necessity.

TITUS, companion and well-loved friend of Saint Paul. He was converted by the apostle (Tit. i, 4), at Antioch 50 or 51 A.D., and in the same year accompanied him to Jerusalem, and was present at that first council which recognized Gentile converts as part of the Church, and exempted them from the burden of the Mosaic ritual (cf. Acts xv, 1 — 35 with Gal. ii, 1-3). Paul soon afterward carried out the liberty thus accorded by refusing to require Titus, a Greek, to be circumcised (Gal. ii, 3-5). Titus was subsequently with Paul at Ephesus (56), whence the former was sent on a special mission to the Corinthians, carrying with him Paul's second epistle to that church (2 Cor. viii, 6, 22, 23; xii, 18). When Titus returned (57 A.D.) he found the apostle in Macedonia (2 Cor. vii, 5-6, 13-15). Subsequently (65 or 66 A.D.) he was left in Crete to arrange the affairs of the Church and «ordain elders in every city» (Tit. i, 5). Returning thence to Rome he was dispatched by Paul (66 or 67) to Dalmatia (2 Tim. iv, 10). Titus returned to his work in Crete, and died at an advanced age. See also TITUS, EPISTLE TO.

TITUS, Flavius Sabinus Vespasianus, Roman emperor: b. 40 A.D.; d. Reate, 13 Sept. 81 A.D. He was the son of Vespasian, whom he succeeded as emperor in 79 A.D., and was brought up at the court of Nero with his friend Britannicus, whom he accompanied in his wars in Germany and Britain. Later he commanded a legion in the war of Vespasian against the Jews, conducting the campaign in Judæa in 69 in the place of his father, who was then called to the imperial throne. At the end of a long and cruel siege Jerusalem was taken by Titus 8 Sept. 70. Titus returned to Rome in 71, where he was rewarded with the title of Cæsar and given a part in the government of the empire. He early manifested the qualities of a humane and able ruler and he became the idol of the Roman people. The Colosseum, begun by Vespasian, was completed under his direction, and the public baths named in his honor, and other institutions for the public benefit were established by him

TITUS, Epistle to, one of the epistles of Saint Paul, stated to have been written to Titus, as bishop over the Cretans, from Nicopolis in Macedonia. It is known as one of the «Pastoral Epistles,» because devoted chiefly to admonitions on the subject of pastoral duties. In this epistle Saint Paul describes what a bishop ought to be, and applies severe language to certain of the Cretans. This, and the two epistles to Timothy, have been subjected to much discussion. See TIMOTHY AND TITUS, EPISTLES TO.

TITUS ANDRONICUS. Several plays of the Shakespeare canon preserve a mystery due to almost total absence of external evidence; in the case of 'Andronicus' the tantalizing uncertainty arises from the existence of an unusually large mass of data. Shakespeare's substantial concern in the tragedy is avouched by the double testimony of Meres, who in 1598 lists 'Titus Andronicus' among Shakespeare's tragedies, and of Hemmings and Condell, who in 1623 included the play in the Shakespeare Folio. On the other hand, three quarto editions are anonymous, and though this is natural enough in the case of the first (1594), it is surprising that the publishers of the 1600 and 1611 quartos should not have mentioned Shakespeare's then popular name. Moreover, a large majority of the best critics have been strong in their conviction that the marks of Shakespeare's mind are not evident in the plot, the characterization, or the language of this play. There is little of the unevenness here which one finds in works written by inferior authors and revised by Shakespeare; in versification as in dramatic power this tragedy is pretty consistent throughout, and it bears much more affinity to the work of Kyd or Peele than to Shakespeare's. The problem is complicated by references to what may conceivably have been earlier versions of our play. A drama called 'Titus and Vespacia' (Vespasian?) was acted for the first time, 11 April 1592. We cannot positively determine whether this was an old form of 'Titus Andronicus' or, as the title more naturally suggests, a quite unrelated work on the subject of two historical Roman emperors. Another work, called by Henslowe 'Titus and Andronicus' or 'Andronicus,' was put on the stage as a new work in January 1594, by the Earl of Sussex's company and revived in June of the same year by the Lord Admiral's and Lord Chamberlain's (the last Shakespeare's company). On 6 Feb. 1594, 'A Noble Roman History of Titus Andronicus' was licensed to John Danter, and in the same year our play, called 'The Most Lamentable Roman Tragedy of Titus Andronicus,' was printed by Danter for Edward White and Thomas Millington. The subsequent quarto editions in 1600 and 1611 were printed for White, and all three were sold at the same shop. Without entering into fuller discussion of this evidence and of other entries in the Stationers' Register, it may be said that the records seem to establish the identity of Henslowe's 'Titus and Andronicus' with our play as printed in 1594. (The contrary conclusions of Prof. G. P. Baker, *Publications of Modern Language Association* 66–76, 1901, have been invalidated by the discovery in 1905 of the 1594 quarto). If we eliminate Henslowe's earlier 'Titus and Vespacia' as probably unrelated, there seems little reason to believe that any version of 'Titus Andronicus' existed in Shakespeare's lifetime which differed essentially from that we possess. Danter licensed 'Titus Andronicus' for publication (6 Feb. 1594) on the same day on which Sussex's company is last recorded as acting it, and his manuscript, printed later in the year, would seem to be that which they acted. We have no reason to believe that Shakespeare revised any plays either for this company or for Pembroke's company, which is said also to have performed the piece. The text of the play in the Shakespeare Folio of 1623 must, on the other hand, be that acted by the Lord Chamberlain's company in June, 1594, or later. Since the differences between these versions, however, are relatively quite unimportant (Act III, sc. ii is added in the Folio), it appears as likely on bibliographical as on stylistic grounds that Shakespeare had no more than a slight part in the play.

No direct source for 'Titus Andronicus' has been discovered. Its relation to two later continental works, 'Aran en Titus' (Aaron and Titus) by the Dutch poet Jan Vos (printed 1641) and a German play of Titus Andronicus and the arrogant empress (ca. 1620), has been learnedly discussed by H. De W. Fuller (*Publications Modern Language Association* 1–65, 1901); but it seems probable that these foreign works, as well as another German play of which traces exist, are based upon perversions of the extant 'Titus Andronicus' text, as disseminated by traveling English actors, and not, as Fuller argues, upon two hypothetical earlier English plays. Early 17th century allusions to 'Titus Andronicus,' though not very numerous, are such as to prove that the play was popular with the masses of the public. Later, John Downes, writing of the performances of Sir William Davenant's company after the Restoration, mentions 'Titus Andronicus' among several others which "being old plays, were acted but now and then; yet being well performed were very satisfactory to the town." In 1687 Edward Ravenscroft published an adaptation 'Titus Andronicus, or the Rape of Lavinia. Acted at the Theatre Royal,' with a preface containing some important remarks concerning the old play. Among the more unconventional modern theories regarding the authorship of 'Titus Andronicus' may be noted Grosart's argument that it was written by Greene, 'Englische Studien' (1896); J. M. Robertson's that it is essentially Peele's 'Did Shakespeare write Titus Andronicus' (1905), and an ill-considered recent hypothesis of H. D. Gray that the play was originally by Shakespeare, revised by Greene and Peele, 'Flügel Memorial Volume' (1916).

TUCKER BROOKE.

TITUSVILLE, Pa., city in Crawford County, on Oil Creek and on the Pennsylvania and the New York Central railroads, 100 miles north of Pittsburgh and 50 miles southeast of Erie, Pa. The city is on a plain which slopes slightly toward the south and east. The natural drainage is supplemented by an excellent system of sewerage. The water is obtained from artesian wells. The broad streets are largely paved and tree-lined. Electric trolley lines traverse the principal streets. The manufacturing industries consist of one of the largest iron works in the country, a high grade steel works, machine shops and foundries, large oil refineries, paraffine works, large branch of the American radiator works, large branch of the Bethlehem Steel Company, chemical works, planing mills, specialty works, cutlery works and an electric light and power plant. The output consists of iron, car tanks, steam engines and boilers, forgings, oil well machinery and fittings, gasoline engines, refined oils, gasoline, etc. There are large oil fields in the vicinity and the first well sunk for petroleum was drilled just outside of the city limits in the summer of 1859, striking oil on 27 August of that year. There are three banks consisting of a national bank, a commercial bank and a trust company. One of the finest banking buildings in the State was erected in 1918. Among other public buildings are 12 large edifices and two halls for religious services, a high school with a four-year course, four graded public schools and a kindergarten, all under one superintendent; Saint Joseph's Academy, kindergarten and parish school. The city has also an excellent library, "Benson Memorial Library," an excellent Young Men's Christian Association and Young Women's Christian Association and the Titusville Hospital. Titusville was first settled in 1796, becoming a borough in 1847 and chartered as a city in 1866. The town was laid out in streets in 1809. It suffered great damage from flood and fire 5 June 1892 which destroyed one-third of the city with a loss of 60 lives. The city owns and operates the waterworks and one of the electric light plants. The government is vested in the mayor and five commissioners, the mayor being elected for four years and the commissioners for two years. The majority of the people are native born, the predominating foreign element consisting of Scandinavians, Irish and Germans. Pop. 8,550.

TIUI, tē-wĕ', or **TIVI,** tē'vē, Philippines, pueblo, province of Albay: on Lagano Bay, on the northeast coast, 23 miles north by west from the pueblo of Albay. It is the centre of a hemp growing region, and exports hemp by way of Tabaco. It is especially celebrated for its thermal springs of iron and sulphur waters with medicinal properties, which are visited by large numbers of natives. Pop, about 11,000.

TIUMEÑ, tyoo-mĕny', Russia, in Siberia, government of Tobolsk, 120 miles southwest of Tobolsk, on the Tura River. It is an important centre of trade, lying on several commercial routes, with railroad communication. It has a large technical school. Its principal manufactures are leather, soap, candles, carpets, pottery and woolen goods. These articles are exported to China, the Kirghiz steppe, Bokhara and everywhere in Siberia. The Tiumeñ and woven carpets are especially renowned. In Tieumeñ was located a famous exile prison. Pop. about 35,000.

TIVERTON, R. I., town in Newport County, on Narragansett Bay, near Fall River, Mass., and on the New York, New Haven and Hartford Railroad. There are cotton manufactories and oyster and fishing industries. Pop. 4,032.

TIVOLI, tē'vō-lē, Italy, in the province and district of Rome, on the Teverone or Aniene, 16 miles northeast of the capital. Its position on a rocky height overlooking the river is extremely picturesque. Tivoli commands a fine view of Rome and the Campagna. It contains a fine modern cathedral which contrasts sadly with the other town buildings. Its antiquities are numerous and interesting, and include a temple of the Tiburtine sybil, temple of Vesta, villa of Hadrian, etc. The artificial cascades formed by the Teverone constitute an interesting feature of the landscape and supply power for the electric lighting of Rome, and for various factories. The old Latin name was Tibur, important in the Latin Confederation. It became subject to Rome in 338 B.C. The population of the commune is about 15,000. Consult Baedecker's ‹Central Italy and Rome.›

TLAPALLAN, the mythical home of the Toltecs, and the land from which came their great culture god, Quetzalcoatl, and to which he returned when his mission on earth was done. See QUETZALCOATL; MEXICO — MYTHOLOGY; CHOLULA.

TLAXCALA, tläs-kä'lä, or **TLASCALA,** Mexico, the smallest state in the republic, situated between the states of Puebla, Hidalgo and Mexico. Area, 1,534 square miles. The capital, Tlaxcala, located about 60 miles east of Mexico City, was in ancient time a large city, but its 1919 population is only 2,800. It has a bishop's palace and a statehouse that retains much of their former grandeur. The holy well of Ocotlan, in the suburbs, is covered by a costly and imposing sanctuary. The state lies within the plateau region, and its surface is broken by high mountains. The principal occupations are agriculture and some manufacture of cloth, though iron and silver are found in the mountains. Tlaxcala was at the time of the Discovery, a powerful native state which had maintained its independence of the Aztecs. It became an ally of Cortes and retained its own government for a time under the Spaniards. Pop. about 192,000, almost all Indians.

TLEMCÉN, tlĕm-sĕn', Algeria, in the province of Oran, 70 miles southwest of the city of Oran, and 30 miles from the Mediterranean. It is a walled town with nine gates, and is divided into three sections, namely, the citadel and military establishment; the business portion, containing the residences of foreigners; and the native section. The town stands on a mountain slope at an elevation of 2,500 feet, amid olive-groves and vineyards. It has 32 mosques, Protestant and Catholic churches, a museum and Jewish synagogue. The manufactures comprise textiles, carpets and leather articles, burnooses, etc. Trade is important, especially with Morocco. It is a historic city, some of the mosques dating from the 11th century. At the height of its prosperity, in the 13th and 14th centuries, it is reputed to have had 125,000 population. Pop. 39,874.

TLINKET, or **TLINKIT,** a group of tribes which constitute a distinct linguistic stock known as Kolushan. They inhabit the coast and islands of southern Alaska. Previous to the advent of the white men their houses were rudely constructed, and their trade carried on with neighboring tribes. The exchange of slaves was carried on extensively, and they were treated by their masters with the greatest cruelty. They have greatly diminished of late years, till there now remain but about 5,000, a large number of them being employed in the canning industry.

TO A SKYLARK. Shelley's ‹Skylark,› perhaps the most famous of English lyrics, was written at Leghorn, Italy, and published with ‹Prometheus Unbound› in 1820. It is composed of 21 five-line stanzas, each of which ends with a long line that represents the brief pause of the bird on the wing as it prepares for yet higher flight. Mrs. Shelley says: «In the spring we spent a week or two at Leghorn, borrowing the house of some friends who were absent on a journey to England. It was on a beautiful summer evening while wandering among the lanes, whose myrtle hedges were the bowers of the fireflies, that we heard the carolling of the skylark, which inspired one of the most beautiful of his poems.» This exquisite lyric has been used in generations of school «readers» and «selections,» but even such familiar handling has not served to tarnish the peculiar qualities in which it still remains matchless and unapproachable. Shelley's skylark, unlike Wordsworth's, loses itself in the empyrean; it is a spirit not a bird, an embodied voice, an aspiration. It is beside the mark to urge that the poem has «the defects of its qualities»; for, from the standpoint of what the poet meant to do, it has no defects. It is a perfect work of art, having a worthy purpose which it perfectly attains. The poem pursues the flight and the song of the bird swiftly up to the blue; four exquisite similes liken the lark to the poet, to the maiden, to the glow-worm and to the rose; the song of the bird sings itself in the heart of the poet; at the end comes the pathos of the infinite and unsatisfied desire never absent from Shelley's nature lyrics. The criticism of almost a century has applied to the 'Skylark' the epithets which have long since become banal but which seem inevitable: it is melodious, exquisite, ethereal, ecstatic. As such it is unsurpassed and is probably unsurpassable. Wordsworth's 'Skylark' represents a more human point of view; Keats' 'Ode to a Nightingale,' an equally consummate achievement of a different kind.

MARION TUCKER.

TOAD, an amphibian of the anourous family *Bufonidæ* or some related family in the series *Arcifera*, in allusion to the structure of the shoulder girdle. The *Bufonidæ* present the following distinctive features: The tongue is well developed, fixed to the front of the mouth, and has the hind end free. The result of this arrangement is that it can be filliped by means of appropriate muscles with the greatest speed and precision, and thus serves these usually totally toothless animals in the capture of insects which adhere to this mucous-coated organ. Teeth are always absent from the jaws, but may be present on the vomer in a few foreign genera. The hind toes are more or less webbed, the front toes webless and the ends of the toes are neither clawed nor furnished with adhesive discs. In all cases the vertebræ are procœlous or have their bodies hollowed in front, the transverse processes of the sacrum are expanded and ribs are absent. This family is an extensive one of about 15 genera and 100 species and is cosmopolitan, but is especially well represented in tropical America. The species differ considerably in habits, most of them being terrestrial burrowers, but some are aquatic, others arboreal.

Within the United States, *Bufo* is the only genus, being represented by 9 or 10 species, most of which belong to the southwestern United States and Mexico. The common eastern toad (*B. lentiginosus*) is found in one or other of its sub-species throughout the eastern United States and Canada. The familiar roughness and wartiness of the skin of toads is due to the presence of glands and, especially on the head, to bony deposits. They are chiefly terrestrial and nocturnal, and feed upon insects of which they destroy large numbers. Toads visit the water in March or April, their breeding season, for the purpose of depositing their eggs, which are in long strings and are fertilized by the male upon their extrusion. During the mating season the males are very noisy at night and so pugnacious that they sometimes kill one another in their encounters. Development takes place rapidly and the tadpole-stage is passed in three or four months, when the young toads leave the water in multitudes. The popular repugnance to these perfectly harmless animals has no doubt arisen from their unprepossessing aspect and outward appearance. No venom or poison apparatus of any kind exists in these creatures; and save that the secretions of the skin may be of acrid or irritant nature when brought in contact with cut or exposed surfaces, they are utterly harmless to man. There is a swelling above the eyes covered with pores and large, thick and prominent enlargements behind the eyes which secrete an acrid fluid, which protects these animals from the attack of carnivorous mammals. They also swell up with air when attacked by snakes. When handled, toads frequently eject urine from the vent, but the widespread belief that the contact of this fluid with the skin produces warts is utterly unfounded. Toads are extremely tenacious of life and can exist a long time without food; their hibernation in mud, cracks and holes has probably given rise to the stories of their being found in places where they must have existed for centuries without food and air. These stories, however, have no foundation in fact, for Dr. Buckland proved, by direct experiment, that no toad can live for two years if deprived of food and air. Another common belief that toads are often rained down is probably to be explained by the fact that great numbers of young toads frequently leave, during showers of rain, the vicinity of pools in which their larval life was spent. Toads are really extremely interesting animals, and much entertainment can be derived from their observation.

Among foreign toads are the great *Bufo agua*, large enough to fill a quart measure, of the West Indies and South America; the green toad (*B. viridis*) of Europe, noted for its change of color; the long-tongued toad (*Rhinophrynus dorsalis*) of Mexico, which feeds on termites; the European fire-toad (*Bombinator igneus*), so called from its brilliant red under parts and belonging to the family *Discoglossidæ;* and the remarkable Surinam toads, which are tongueless and carry the young in little cavities on the back. The last belongs to the distinct family *Pipidæ*. The spade-foot toad (q.v.) and the tree-toads or tree-frogs (q.v.) belong respectively to the families *Scaphiopidæ* and *Hylidæ*. Many of the toads have remarkable and interesting breeding habits, for accounts of which reference must be made to works of herpetology. Consult Boulanger, E. G., 'Reptiles and Batrachians' (New York 1914); Cope, E. D., 'Batrachia of North America' (Washington 1889); Boulenger, G. A., 'Tailless Betrachia' (London 1892); Dickerson, M. C., 'The Frog Book' (New York 1914); Gadow, 'Amphibia and Reptiles' (New York and London 1901); Kirkland, 'Habits, Food and Economic Value of the American Toad' (in Bull. 6, Hatch Exper. Sta., Amherst, Mass., 1897); Sampson, 'American Naturalist' (1900).

TOAD-FLAX, a common roadside weed (*Linaria linaria*) belonging to the family *Scrophulariaceæ*. It somewhat resembles a snap-dragon, but is smooth and has many linear leaves, either alternate or opposite and verticillate on the lower portions of the stem, and very pale green. The stem is prolonged by a terminal bracted densely flowered raceme. The blossoms are pale yellow with a short spur, a two-lipped corolla, the lower lip spreading and three-lobed, with a base so enlarged as nearly to close the throat with an orange-colored palate. This combination of orange and yellow has given rise to the name «butter-and-eggs.» It is also called ramstead. The plant has been naturalized from Europe and is rather pretty, but it is very tenacious and very difficult to eradicate.

A native toad-flax is *L. canadensis*, a slender plant, with blue flowers and with a tendency toward oppositeness. The Kenilworth ivy (*Cymbalaria cymbalaria*) is also called ivy-leafed toad-flax and is a glabrous trailing perennial, with reniform-orbicular leaves and bluish flowers. *L. triornithophora*, a European plant, is peculiar for its purple, long-spurred flowers blooming in whorls of three and resembling birds, which has suggested the Latin name, «three-birds» toad-flax. The American bastard toad-flax (*Comandra umbellata*) is a delicate, pale green, smooth plant of the sandal-wood family, with greenish white or purplish, campanulate corollas and oblong leaves quite unlike the *Linaria*. In England *Thesium linophyllum*, with leaves like those of toad-flax, is known by the same name as *Comandra*.

TOADFISH, any fish of the genus *Batrachus*, so called from the large head, wide gape and generally toad-like appearance. The common toad-fish (*B. tau*) is from eight inches to a foot long, light brown marbled with black. There are about 12 species, dwelling principally in tropical and sub-tropical seas.

TOADSTONE, (1) *in geology*, an old English name for certain amygdaloidal basaltic rocks occurring in Cumberland, England. The name is also applied to a mottled, apparently spherulitic felsite, found near Boston. (2) Fragments of rocks or precious stones, resembling toads either in color or form, also fossils of various kinds, supposed to possess special therapeutic virtues. Such objects were for many centuries highly prized in Europe, being worn as rings or amulets.

TOADSTOOLS, properly fungi of the family *Agaricaceæ*, which includes the edible mushrooms. See FUNGI.

TOASPERN, Otto, American artist: b. Brooklyn, N. Y., 26 March 1863. He was graduated at the Royal Academy of Fine Arts, Munich (1888); was the pupil of N. Gysis and P. Nauen; and became an instructor in the National Academy of Design, New York. He is best known as an illustrator of *Life; Ladies' Home Journal; Century; Harper's* and several leading European periodicals.

TOAST, originally bread dried or scorched before the fire. In the 16th century it became the fashion in England to add toasted bread to drinks. From this habit the term toast came to be applied to a drink of honor proposed to some person or sentiment during the course or at the conclusion of a meal. The growth of social drinking in the 17th century greatly increased the custom of toasting, and it became common to toast not only the reigning monarchs, the hosts and the flag, but each person of the assembled company, absent friends and numerous sentiments. Finally the term came to denote not only the drink but the person or sentiment toasted, and in this dual sense the word is used to-day. Toasts are properly drunk standing, and it is the modern custom to have some person present reply to the sentiment proposed in an appropriate speech. Consult Chamber's 'Book of Days' and Valpy's 'History of Toasting' (1881).

TOBACCO, the common name applied (1) to plants of the genus Nicotiana, of which there are a large number of species, and (2) to the dried leaves of these plants prepared in various ways for smoking, chewing or snuffing. Originating in America, the use of tobacco has been extended into practically all parts of the world and, indeed, it has come to be incomparably the most generally used of all narcotics. It appears that the name tobacco was derived from the word *tabaco*, originally employed by the natives of Haiti to designate the tube used by them in smoking or taking snuff and adopted by the Spaniards as the name of the product most generally used in smoking; although other products than true tobacco were taken by the natives in the form of snuff. The habit-forming properties or narcotic effects of tobacco are due to its content of nicotine and related alkaloids.

The tobacco plant belongs to the family of Solanaceæ and is thus related to the tomato, potato, eggplant, red pepper and jimson weed. There are some 50 or more species of Nicotiana but only two of these, *N. tabacum* and *N. rustica*, are of economic importance. The Indians of western North America, however, held *N. quadrivalvis* in high esteem for smoking purposes. Also, *N. sylvestris, N. alata* and a few others are used to some extent for ornamental purposes. Additional well-known species are *glauca, longiflora, glutinosa, trigonophylla*. Nearly all species of Nicotiana are native to America, but *N. suavolens* appears to be indigenous to Australia. All of the more important commercial types of tobacco are produced from *N. tabacum*. This is a coarse, rank-growing annual, reaching three to six feet or more in height. The leaves are simple, alternately arranged on the stem, very large but quite varied in size, ovate to lanceolate in shape, entire or with wavy margin, petiolated or sessile and decurrent. The number of leaves varies markedly in the different varieties but is not much affected by differences of environment. The green portions of the plant are covered with soft hairs either branched or single stalked, some of which are capitate and glandular, secreting a viscid, gummy substance. Stomata occur on both surfaces of the leaf. The inflorescence is a terminal panicle producing large flowers ranging in color from deep red through various shades of pink to white, a light pink being the more common color. Under favorable conditions flowering branches also develop from buds borne in the leaf-axils. The calyx of the flower is bell-shaped, four or five-cleft. The corolla tube is funnel-shaped with spreading and pointed lobes. The blossom is normally self-fertilized. The five stamens are attached to the base of the corolla tube. The stigma is capitate. The capsule is two to four-valved, bearing a very large number of seed. The seed are small, there being 300,000 to 400,000 in an ounce. There are numerous distinctive varieties of *N. tabacum* and of the leading commercial varieties there are many sub-varieties or local strains bearing distinctive names but usually differing among themselves only in minor details. In some instances, however, important commercial types of tobacco are produced from mixtures of distinct sorts designated collectively by the type name rather than by distinctive varietal names. This is notably true of Cuban and Turkish tobaccos. *N. rustica* is an annual with a much branched stem and large, ovate leaves with petiole. The corolla tube of the blossom is cylindrical with rounded lobes and is greenish yellow in color. The seed are about three times the size of those of *tabacum*. *Rustica* is decidedly earlier in maturing than is *tabacum*. It is not grown commercially in America but is extensively cultivated in India and in certain sections of Asia Minor and Russia, and to some extent in other European countries.

History.— Tobacco was widely used by the Indians at the time of the discovery of America by Columbus and relics of the Mound Builders show that pipe smoking was a very ancient custom among the aborigines. On landing in the West Indies in 1492 members of Columbus' crew observed that the natives smoked rolls of dried tobacco leaves. When the Spaniards landed in Mexico in 1519 they found the natives cultivating tobacco with care and skill. It was believed by them to possess great curative powers for such diseases as bronchitis, asthma and rheumatism. Other aromatic materials such as liquidambar were frequently mixed with tobacco for smoking purposes. The natives of the Orinoco forests of Venezuela understood the use of tobacco and the preparation and use of tobacco by the natives of Brazil are described in detail by André Thevet who visited that region in 1555. For smoking, the dried leaves were rolled into a small cylinder enclosed in a leaf of corn or palm. Similarly, when Cartier discovered what is now Canada he found the Indians drying tobacco leaves in the sun. The powdered leaves were smoked in pipes made of stone or wood. Early explorers traveling through the interior of the country found the habit of smoking very general among the aborigines from the Great Lakes to the Gulf of Mexico. The pipe of peace carried by the Indian tribes, which was an elaborately carved and decorated object, was smoked in common by those attending grand councils and was held very sacred. The tobacco cultivated by the Indians of North America to the east of the Mississippi was *N. rustica* while in Central and South America *N. tabacum* was the species principally grown. It has already been made clear that the American aborigines used tobacco in the form of cigars and for pipe smoking and, moreover, it is recorded that chewing the leaf was practised in some sections, while in South America the manufacture of snuff had reached a perfection which in some respects has never been surpassed. Thus, the American Indians had evolved methods of cultivating tobacco and preparing it in all forms which are now used. Finally, it is stated that a great North American tribe which dwelt near Lake Huron engaged in the cultivation of tobacco on a commercial scale, the product being sold to other tribes. According to early authorities, the Spaniards began the culture of tobacco in Haiti prior to 1535. Shortly afterward it was extended to the island of Trinidad whose product soon became famous in Europe. Tobacco culture was soon developed on a large scale in the West Indies and in Venezuela and Brazil. At least four distinct varieties of *N. tabacum* were grown, viz.: (1) A large broad-leaf type; (2) a long narrow-leaf «Ox-tongue» form; (3) a type resembling (2) but with broader leaves; (4) a type with very small leaves. Thus, prior to the settlement of Jamestown, the Spaniards and Portuguese had developed an important trade in tobacco between Europe and the West Indies and South America. John Rolfe began the culture of tobacco at Jamestown in 1612 from seed brought from South America or the West Indies and in 1619 20,000 pounds were shipped to England. The growing of tobacco in Maryland began about 1631 and soon became an important enterprise. These two States have continued to grow tobacco in large quantities up to the present day. The Virginia colonists at first grew the crop on the bottom lands of the tide-water region. As the settlers moved further inland, however, it was found that the more elevated and somewhat heavier soils produced tobacco better suited to trade requirements. Overproduction of tobacco soon became a serious menace to the welfare of the colonists and an inspection service was established in order to prevent the export of damaged or inferior leaf. Attempts were made also to limit the acreage grown but with indifferent success. It appears that the growers learned at a very early date the influence of the soil and the cultural and curing methods on the character of leaf tobacco produced. Thus, the selection of suitable soils, the proper spacing of the plants in the field, use of certain methods of manuring and following definite practices of topping, «suckering,» harvesting and curing came to be recognized in the first few decades of practical culture as being of fundamental importance. In the main, present-day cultural methods, therefore, differ from those of the early colonists in details rather than in fundamental principles. The exports of tobacco from Virginia had reached 18,000,000 pounds in 1700, and about 40,000,000 pounds in 1750 while at the outbreak of the Revolution the combined exports of Virginia and Maryland amounted to 100,000,000 pounds. Prior to the Revolutionary War the production of tobacco in the other colonies was not of much importance, but during the past century there was an enormous expansion in total production in the United States. New centres of production were developed and the crop as a whole became differentiated into a number of distinctive types. After the close of the Revolution pioneer settlers from Virginia and Maryland carried the culture of tobacco into Tennessee, Kentucky, Missouri and Ohio. The tobacco produced in western Kentucky and Tennessee, however, found its way to market through New Orleans while the product of eastern Ohio was sent to Baltimore. Missouri at one time became a leading tobacco-producing State although in recent years the production has fallen off to a nominal figure. During the first quarter of the last century the culture of cigar leaf tobacco began to assume importance in the Connecticut Valley and by the middle of the century the cigar tobacco districts of the Miami Valley of Ohio, the Gadsden area in Florida and the New York areas had become established. Next came the development of the Lancaster, Pa., district and, beginning about 1870, the culture of cigar leaf developed very rapidly in southern Wisconsin. As tobacco culture in Virginia was pushed forward onto the gray lands of the south central border counties and into North Carolina a lighter and finer-textured product was obtained. About 1825 began the use of charcoal in curing which had the effect of further improving the quality of the light-colored leaf and subsequently the charcoal was replaced by a system of flues for leading out of the barn the smoke from the fuel used in curing. In this manner began the development of the vast bright flue-cured tobacco industry. During the latter part of the century this industry spread into eastern North Carolina and South Carolina. Tobacco culture had been introduced into the Blue Grass region of Kentucky at an early date but the discovery of the White Burley variety in Brown County, Ohio, in 1864 revolutionized the industry in central Kentucky and southern Ohio and the Burley type soon came to be produced in enormous quantities. The outstanding event of the past quarter century in the industry is the development in the Connecticut Valley and in western Florida of the shade-grown cigar wrapper leaf industry, a very intensive and highly specialized agricultural enterprise. Turning to the introduction of tobacco into foreign countries, it appears that the plant was first grown in France in 1556 by André Thevet from seed taken back by him on his return from Brazil. The plant attracted little attention, however, till introduced and exploited at the royal court by Jean Nicot, Ambassador to Portugal, whose name became immortalized in the generic name of tobacco, *Nicotiana*. Tobacco also was first grown in Portugal and in Spain at about this time, and almost immediately was introduced into Belgium, the Netherlands and Rome. Upon his return to England from Virginia in 1585 Sir Richard Grenville introduced pipe smoking as practised by the Indians. For a full half century after its introduction into Europe tobacco was used almost exclusively as a medicinal agent and it was generally believed to possess wonderful curative properties. During the first half of the 17th century however, indulgence in tobacco became very general in most of Europe although in some instances strenuous efforts were made by the authorities to prevent its use. Amsterdam and Rotterdam became at the outset the leading distributing centres for American-grown tobacco. The culture and the use of tobacco were introduced into India, Persia and other Asiatic countries early in the 17th century.

Commercial Types of Tobacco.— The differentiation of leaf tobacco into types has reference primarily to the different uses of the leaf in manufacture. A further distinction is frequently made as to the district or locality in which the product is grown. In the United States there are eight important commercial types of tobacco, viz.: (1) cigar leaf; (2) dark fire-cured export; (3) White Burley; (4) bright flue-cured or yellow tobacco; (5) dark air-cured manufacturing; (6) Maryland and eastern Ohio export; (7) Virginia sun-cured; (8) perique. The cigar leaf type is used almost exclusively in the domestic manufacture of cigars. There are three sub-types of cigar tobacco: (1) wrapper leaf used as the outer covering of the cigar; (2) binder leaf used for holding the cigar's shape; (3) filler leaf which makes up the body of the cigar. Wrapper leaf is grown chiefly in the Connecticut and Housatonic valleys of New England and in the Gadsden-Decatur district of Florida and Georgia. Binder leaf is produced mainly in Dane, Rock, Vernon and Crawford counties of Wisconsin and in the Big Flats district of New York. The leading centres for the production of filler leaf are the Lancaster area of Pennsylvania, the Miami Valley district of Ohio and the Onondaga district of New York. The dark fire-cured type is exported to the extent of about 80 per cent of the total production, being unsuited for domestic manufacture except in making snuff and for limited use as a plug wrapper. This type is grown in some 20 counties of central Virginia, in the Clarksville and Hopkinsville, and the Paducah districts of western Kentucky and Tennessee and the Henderson or Stemming district of Kentucky. Great Britain is the heaviest purchaser of fire-cured leaf and the other principal foreign purchasers have been Italy, Germany, France, Spain, Austria and Belgium. This type of leaf is of heavy body, dark in color, rich in nicotine and possesses a distinctive creosotic or smoky smell and taste because of the combustion products absorbed from the smoke used in the process of curing. The White Burley is distinctly a domestic manufacturing type, but little of it being exported. It burns well, is of light body, rather neutral in flavor and yields a large proportion of light colored leaf. Its one most important characteristic, however, is its remarkable capacity for absorbing the liquid sweetening materials or sauces used in the manufacture of the sweetened type of plug chewing tobacco. For this purpose the Burley has no equal. It is also used very extensively in the manufacture of cut-plug smoking and fine-cut chewing tobaccos and in the production of cigarettes. White Burley is grown chiefly on the rich limestone soils of central and northern Kentucky and in southern Ohio. Considerable quantities, also, are produced in a few counties of western West Virginia and southeastern Indiana. The bright flue-cured or yellow tobacco has come to be the world's most important type in point of quantity consumed. In domestic manufacture the chief uses of this type are in the production of granulated smoking tobaccos, cigarettes and the flat type of plug chewing tobacco. It is our most important cigarette type. In recent years flue-cured leaf has been a very aggressive type in foreign markets and at the present time more than half the total production is exported, the largest foreign buyers being England, China and Canada. There are two subdivisions of the flue-cured producing district, namely, the Old Belt section, embracing the northern central counties of North Carolina and adjoining border counties of Virginia, all in the Piedmont region, and the New Belt section of eastern North Carolina and South Carolina, lying in the Coastal Plain region. The most distinctive characteristic of typical flue-cured tobacco is its lemon or orange yellow color. In the region of Kentucky and Tennessee lying between the Burley section to the east and the dark fire-cured section on the west there are two districts known as the One-sucker and the Green River which produce large quantities of dark air-cured tobaccos used both for domestic manufacture and for export. The one-sucker tobacco is used for the domestic manufacture of twist chewing tobacco and for the so-called rehandling export trade with South Africa, the West Indies and Central and South American countries. The Green River tobacco is used for the manufacture of long-cut chewing and for export to England. The Maryland and eastern Ohio tobaccos have been exported to Europe for centuries, France and The Netherlands being the chief purchasers. The Maryland leaf also is used to some extent in domestic manufacture. This tobacco is comparatively light in body and color, dry and chaffy and has good burning qualities but is rather characterless in aroma. In the eastern Ohio district the old piebald or spangled type has been largely replaced in recent years by White Burley. In a few counties in the vicinity of Richmond, Va., a dark type of leaf known as sun-cured is produced although in late years the old method of partially curing the leaf in direct sunlight has been largely abandoned in favor of air-curing. This tobacco is used in the manufacture of the flat type of chewing tobacco. Perique tobacco is grown only in Saint James Parish, La., and the total production is not large. This type deserves mention because of its distinctive aroma, due primarily to the unique method of curing employed by the growers. Perique is chiefly used in the preparation of fancy smoking mixtures to which it adds aroma. To the above-named domestic types entering into commerce must be added at least three foreign types of special importance, namely, the Cuban, the Sumatra and Java and the so-called Turkish. In a small area of Cuba located in the province of Pinar del Rio in the vicinity of San Juan y Martinez is grown the world's finest cigar leaf, noted for its remarkable aroma. This district is known as the Vuelta de Abajo and the outlying tobacco-producing territory is designated as Semi-vuelta. Other leading Cuban districts are the Partidos of Habana province and the Remedios of Santa Clara province. Porto Rico, the Bahia district of Brazil and portions of the Philippines also produce cigar tobacco of high merit though they do not equal the best Cuban. On the east coast of Sumatra and in portions of Java a very fine grade of cigar wrapper leaf is grown and several million pounds of this product are imported into this country each year for the manufacture of lower and medium-priced cigars. Because of the thinness of leaf, fineness of texture and veins and general uniformity of the grades this tobacco has a great wrapping capacity per pound. In the portion of southern Macedonia around the port of Cavalla and other nearby towns and in the Smyrna, Trebizond and Samsoun districts of Asia Minor are grown the finest cigarette tobaccos in the world. The so-called Turkish cigarettes are made from blends of these tobaccos. Egyptian cigarettes also are made from the Turkish types and tobacco is not grown in Egypt. The Macedonian, Smyrna and Samsoun tobaccos are imported into the United States in large quantities.

Culture of Tobacco.— The tobacco plant may be grown under a wide range of soil and climatic conditions but, on the other hand, the characteristics of the leaf of commercial importance are greatly influenced by both soil and climate. These facts explain the existence of so many different commercial types of tobacco each suited to special purposes of manufacture. Cultural methods, also, affect the character of leaf obtained so that these methods are modified in the different districts according to the special requirements of the type grown, although certain general features are common to all sections. The tobacco seedlings must be grown in a specially prepared seed bed which may be either a hotbed or more commonly a cold frame. The soil must be mellow and friable and must be made rich. The time of planting ranges from January in the South through the month of April in Northern districts. The seed are sown at the rate of about a heaping teaspoonful to 25 square yards of seed bed and are covered only very lightly. The beds are covered with glass or with «tobacco cloth» to protect the young seedlings. When the seedlings have attained sufficient size, usually 6 to 10 weeks after the seed have been planted, they are transplanted to the field either by hand or machine. At the time of transplanting each plant must be watered unless the soil is wet. The plants are set in rows three to four feet apart while the distance allowed between the plants in the row varies from 14 to 16 inches for some of the cigar tobaccos up to three and one-half to four feet for the fire-cured type. The character and condition of the soil used for tobacco is of special importance. Good drainage is essential in all cases. Broadly speaking, cigar wrapper and binder leaf, Maryland tobacco and the flue-cured type are grown on light sandy and sandy loam soils, with sandy or sandy clay subsoils. In New England the Merrimac series of soils are widely used, while in Maryland the Norfolk and in the flue-cured district the Norfolk and Durham series are of special importance for tobacco. In the cigar filler district of Pennsylvania and in the Burley region of Kentucky fertile loams of limestone origin, particularly the Hagerstown loam, are chiefly used. Clay loams of the Miami series are typical tobacco soils of the Ohio cigar filler district. The dark fire-cured and air-cured export and manufacturing tobaccos are grown on rather heavy silt and clay loams usually reddish or brownish in color, with clay subsoils. Both the kind and the quantity of fertilizer applied to the tobacco crop are important. An excess of nitrogen injures the quality of the leaf, especially in the case of the flue-cured type. At least a part of the nitrogen should be derived from organic sources such as cotton-seed meal or dried blood. A liberal supply of potash in the form of sulphate or carbonate favors good burning qualities and reduces susceptibility to leaf spot diseases. Chlorine tends to hinder free combustion in the cured tobacco. Only quickly available forms of phosphoric acid should be used in order to ensure proper «ripening» of the leaf. In Connecticut heavy applications of fertilizers furnishing 100 to 150 pounds each of nitrogen, phosphoric acid and potash per acre are commonly employed while in Southern districts 20 to 40 pounds of nitrogen and potash and 40 to 80 pounds of phosphoric acid per acre are applied to the crop. Barn manure, also, is widely used in Northern districts. Liming is less essential for tobacco than for many other crops though possibly beneficial under some conditions. The soil is tilled for tobacco about the same as for corn or cotton. When the flower head begins to develop or somewhat later the plants are «topped» by breaking off the top of the stalk carrying the flower head and upper leaves, in order to force a better development of the leaves remaining on the plant. Cigar wrapper and binder tobaccos, White Burley and Maryland tobacco are topped high, leaving 16 to 20 leaves on the plant, while the heavy fire-cured type is topped to only 10 to 14 leaves and other types are topped to intermediate heights. The suckers or branches which develop in the axils of the leaf also must be broken off by hand. It is important to harvest the crop at the right stage of maturity. As the leaves ripen they take on a lighter green color and become more or less mottled with light-colored flecks. They also tend to crack when folded between the fingers. There are two methods in general use in harvesting the crop. In the first method the stalk is cut off near the ground and the inverted plants are attached to four-foot sticks either by means of cord or hooks properly spaced on the sticks, or by forcing the stick through the butts of the stalks by means of a removable metal spear head, or, finally, by splitting the stalks from the top to near the base and simply placing the plants astride the sticks. Each stick carries six to 10 plants and thus laden the sticks are arranged 6 to 12 inches apart on the tier poles of the barn. In the second method the leaves are plucked from the plant as they ripen, beginning at the bottom and taking two to five leaves at each picking. The field is thus gone over three to five times at intervals of a week or 10 days. The leaves are strung on cord by piercing the base of the midrib with a needle or the cord is merely looped around the basal ends of the leaves. The free ends of the cord are attached to either end of a four-foot stick, each stick and cord carrying 20 to 40 leaves. Curing, which must be carried out under proper conditions of temperature and moisture supply, is effected in specially constructed curing barns. Three distinctive methods are practised, known as air-curing, flue-curing and fire-curing. In all cases the process must be so regulated as to develop the desired properties in the tobacco leaf. In air-curing natural atmospheric conditions are largely depended upon and little or no artificial heat is employed. The barns are comparatively large and are provided with a maximum of ventilation. From three to 12 weeks are required to complete the process of air-curing. This method is applied to all cigar tobaccos, Maryland tobacco, White Burley and the dark manufacturing types. For flue-curing the barns are small in size, tightly constructed and are provided with a system of metal pipes by means of which artificial heat may be freely applied without allowing smoke to come in contact with the tobacco. Heat is applied throughout the curing and the temperature is carefully regulated, beginning with 90–100° F. and ending with 180° or even 220° F. The whole process is completed in three to five days. In fire-curing heat is supplied by making open fires on the floor of the barn, thus allowing the smoke to come in contact with the tobacco, to which it imparts a characteristic odor. The barns should be tightly constructed but they should be provided with ventilators. In practice heat is not applied until the tobacco has been hanging in the barn for two or three days and the fires are kept going for only a few days at a time. Alternate periods of air-curing and firing are thus continued till the curing process is completed. After curing in the barn is completed the tobacco leaf is too brittle to handle without breaking except after a period of damp weather or when moisture is applied artificially. Under suitable moisture conditions the leaf becomes pliable so that the crop can be handled in preparation for market. After the leaves have been stripped from the stalks they are separated into various grades according to size, color and other important elements of quality. The number of grades made by the grower ranges from two to 10 or more, according to the type and value of the crop. After the grading is completed the leaves are tied into small bundles or «hands» by securely wrapping a folded leaf around the butt ends of the leaves in the bundle. There are several different methods of marketing the various types of leaf tobacco. In the case of cigar tobaccos and, to a limited extent, the dark air-cured and fire-cured types, the buyer inspects and bargains for the crop on the farm, the grower delivering the tobacco at the buyer's receiving warehouse. In the South and, to an increasing extent, in the Western districts the «loose leaf auction system» prevails. Under this system the various grades of the grower are placed in separate lots on the warehouse floor at market centres and sold at auction on a commission basis. In a third system which has been extensively employed, the tobacco, put up in standard containers, is sold from carefully drawn samples without the buyer having seen the contents of the package until delivery has been effected. The sale is made either by auction or by private bargaining. There are three standard containers in which leaf tobacco is delivered to the manufacturers, namely, the box or case, the bale and the hogshead. Cigar tobaccos are packed in cases and bales and Turkish tobacco, also, is put up in bales, while the bulk of other tobaccos is packed in hogsheads. In all cases, after having been packed, the tobacco goes through an important fermentative or aging process which develops the aroma and otherwise improves the quality. In some cases, however, the tobacco is put through a preliminary, more active fermentation in large heaps or bulks before it is packed for storage or transportation. The extent or degree of the fermentation is controlled largely by regulating the moisture contents of the tobacco. The tobacco plant throughout its period of growth is subject to injury by numerous insect pests and parasitic diseases. Among the more important insect enemies are the cutworm, wireworm, flea-beetle, hornworm and budworm. The cutworm and wireworm are best controlled by rotation of crops and the hornworm and budworm by the use of arsenical insecticides or by hand picking, while no effective remedy has been found for the flea-beetle. The tobacco-beetle (not the tobacco flea-beetle), a serious pest in all forms of cured leaf and manufactured tobacco, is best controlled by the use of heat under certain conditions or by fumigation. As important diseases of the tobacco plant should be mentioned bacterial wilt, controlled by rotation of crops; root rot, the most effective remedy for which is the use of resistant varieties; a fusarium root disease, for which a remedy has not yet been developed; "sore shank," a decay of the stem, most effectively combated by rotation of crops; mosaic, an infectious disease disseminated by plant lice and other insects and through the handling of diseased plants by laborers; frenching, a malnutrition disease, the exact nature of which has not been determined; leaf spot, of which there are several forms, becoming destructive only under certain environmental conditions. During the curing process and in all subsequent stages tobacco is subject to injury by molds or decay, which usually can be prevented by proper regulation of the moisture supply.

Production, Trade Movement and Consumption of Tobacco.— The estimated normal production of tobacco for all countries growing notable quantities is shown in Table I.

TABLE I.— WORLD'S PRODUCTION OF TOBACCO.

COUNTRY	Production (pounds)
Canada	15,000,000
United States (Continental)	1,150,000,000
Cuba	75,000,000
Santo Domingo	25,000,000
Porto Rico	10,000,000
Mexico	35,000,000
Argentina	35,000,000
Brazil	100,000,000
Colombia	20,000,000
Paraguay	15,000,000
Russia	250,000,000
Austria-Hungary	175,000,000
Germany	60,000,000
France	50,000,000

Algeria	20,000,000
Union of South Africa	15,000,000
Total	4,205,000,000

The average annual acreage, production and value of tobacco for the 10-year period ending with 1918 in each of the leading tobacco-growing States is shown in Table II.

TABLE II.— PRODUCTION OF TOBACCO IN THE UNITED STATES, BY STATES.

STATE	Acreage	Production (pounds)	Value per acre
Massachusetts	6,600	10,650,000	$356 00
Connecticut	19,550	31,050,000	381 00
New York	4,200	5,200,000	170 00
Pennsylvania	40,100	54,900,000	167 00
Ohio	97,200	86,950,000	118 00
Wisconsin	42,850	49,650,000	150 00
Maryland	26,000	18,400,000	94 00
Kentucky	442,500	376,250,000	104 00
Tennessee	92,850	71,100,000	76 00
West Virginia	14,000	10,900,000	114 00
Indiana	17,650	15,600,000	115 00
Virginia	185,600	134,000,000	100 00
North Carolina	262,100	167,000,000	113 00
South Carolina	46,000	31,800,000	96 00
Florida	3,600	3,300,000	316 00

The production of tobacco in the United States by types for the year 1918 is found in Table III.

TABLE III.— PRODUCTION OF TOBACCO BY TYPES IN 1918.

TYPE AND DISTRICT	Production (pounds)
I. Cigar types:	
New England	52,500,000
New York	3,760,000
Pennsylvania	64,750,000
Ohio-Miami Valley	67,300,000
Wisconsin	65,100,000
Georgia and Florida	7,080,000
II. Chewing, smoking, snuff and export types:	
Burley	269,100,000
Paducah	76,000,000
Henderson or Stemming	85,000,000
One-sucker	45,000,000
Clarksville and Hopkinsville	77,000,000
Virginia sun-cured	11,200,000
Virginia fire-cured	57,050,000
Flue-cured, old belt	171,800,000
Flue-cured, new belt	248,500,000
Maryland and eastern Ohio export	28,700,000
Perique-Louisiana	125,000

The present normal production of tobacco in the United States is placed at 1,150,000,000 pounds, grown on 1,400,000 acres and having a farm value of $1,380,000,000. Nearly all of this crop is grown in 15 States. Kentucky produces fully a third of the entire crop and Virginia and North Carolina together produce nearly another third. Lancaster County, Pa, with a production of nearly 40,000,000 pounds, is the banner tobacco-growing county of the United States. The crop as a whole is made up approximately of 28 per cent flue-cured, 25 per cent White Burley and 20 per cent each of cigar leaf and the dark fire-cured export type, the remainder consisting of Maryland export and dark-air-cured manufacturing leaf. Considerable quantities of fine cigar and cigarette leaf tobacco are imported into the United States from foreign countries and shipped in from non-contiguous territory. The imports for 1914 as given in Table IV may be taken as representing approximately the normal pre-war import requirements of the tobacco industry. The war proved a disturbing factor in the tobacco trade and while the demand was greater than ever before it was not reflected in the imports.

TABLE IV.— IMPORTS AND SHIPMENTS FROM NON-CONTIGUOUS TERRITORIES OF TOBACCO FOR THE YEAR 1914.

IMPORTS	Quantity	Value
Leaf tobacco:		
Netherlands (Sumatra and Java leaf), pounds	7,688,514	$9,744,750
Cuba	25,725,202	14,706,246
Turkey in Europe	9,564,203	5,210,546
Turkey in Asia	11,577,199	3,804,066
Shipments from Porto Rico:		
Leaf tobacco, pounds	6,353,528	2,805,532
Stems and trimmings	1,975,231	222,416

From the earliest days of the colonies, tobacco has always been an important article of export in the international trade of the United States. For many years Great Britain has been the heaviest foreign purchaser of American tobacco. Statistics for the year 1913 may be taken as indicating the normal distribution of our exports of leaf tobacco. The data are shown in detail in Table V,

TABLE V.— EXPORTS OF LEAF TOBACCO FOR THE YEAR 1913.

EXPORTS	Quantity	Value
United Kingdom, pounds...	175,026,020	$20,638,282
France....................	48,154,511	4,152,502
Italy.....................	40,567,680	5,517,813
Germany...................	31,697,427	3,972,062
Netherlands...............	28,997,185	2,908,392
Spain.....................	21,384,529	1,405,988
Canada....................	18,975,921	3,291,268
China.....................	11,940,865	2,044,615
Belgium...................	11,302,150	1,358,866
Japan.....................	5,038,389	726,561
All other countries.........	51,286,989	6,921,545
Total................	444,371,661	$52,937,849

The international trade of the United States in tobacco manufactures, also, is considerable, the chief items being the imports of cigars from the Philippines and Cuba and the exports of cigarettes to Asiatic countries. In 1917 the imports of Manila cigars were, in round numbers, 200,000,000, worth $3,863,000. The normal imports of cigars from Cuba amount from 40,000,000 to 45,000,000 annually, valued at $3,500,000 to $4,000,000. Approximately 175,000,000 cigars are shipped into continental United States each year from Porto Rico and these cigars are valued at about $6,500,000. Nearly 5,000,000,000 cigarettes having a value of $9,600,000 were

1911...	149,917,245	38,598,128	346,544,032	535,059,444
1910...	141,116,460	31,272,319	350,480,904	425,869,679
1909...	136,670,104	23,714,845	344,325,030	504,709,975
1908...	130,440,248	20,665,921	331,907,336	483,013,505

exported to China in 1917 and in 1918 the number had increased to some 7,500,000,000, worth over $12,000,000. More than a billion cigarettes, also, are exported annually to the Straits Settlements. Total exports of plug tobacco and smoking tobacco amount to some 5,000,000 and 2,500,000 pounds, respectively. Our export trade in cigars is of little importance. It now remains to consider the quantity of leaf tobacco consumed in domestic manufactures. The quantities thus used in the manufacture of cigars, cigarettes, smoking and chewing tobacco and snuff are shown in Table VI, for the 10-year period ending with 1917. These figures, which are based on reports of the Bureau of Internal Revenue, do not include the quantities of leaf tobacco consumed in bonded manufacturing warehouses. The tobacco consumed in these establishments in 1917 amounted to nearly 18,000,000 pounds.

The output of the various forms of manufactured tobacco produced from the quantities of leaf tobacco consumed, as above indicated, is set forth in Table VII. In addition to the tobacco leaf large quantities of licorice, sugar and other materials are used in the manufacture of chewing and smoking tobacco. The figures show more or less of an increase in most forms of manufactured tobacco but the outstanding feature of the table is the enormous increase from year to year in the output of cigarettes. In addition to the quantities given in Table VII, which are based on reports of the commissioner of internal revenue, the various forms of tobacco were manufactured to some extent in bonded manufacturing warehouses. There were thus manufactured in 1916 4,594,662,940 cigarettes and 87,654,149 cigars, making a total output of 29,907,149,551 cigarettes and 8,020,264,340 cigars for that year. Thus, the indicated total of cigarettes manufactured in 1917 is in excess of 40,000,000,000.

In 1914 there were 13,951 establishments, with a capital of $303,840,000, engaged in the manufacture of tobacco in the United States. Salaries and wages paid to 195,694 persons engaged in the industry amounted to $99,980,000 and the total value of manufactured products was $490,165,000. Manufactured tobacco is an important source of governmental revenue in the United States. During the decade ending with 1917 the internal revenue collected on tobacco ranged from $49,862,754 in 1908 to $88,063,948 in 1916 and $103,201,592 in 1917.

WIGHTMAN W. GARNER,
Physiologist in Charge of Tobacco Investigations, Bureau of Plant Industry, United States Department of Agriculture.

TOBAGO, tō-bā'gō, British West Indies, an island of the Lesser Antilles, situated 20 miles northeast of Trinidad. It is about 24 miles long by seven miles wide, with an area of 114 square miles. It is hilly, rising at one point to a height of 2,000 feet. The soil is fertile and well cultivated. The chief products are sugar, rum, cocoanuts, rubber, cacao, cotton and tobacco. The capital and chief port is Scarborough, on the south coast, where steamships to Guira make stops. The island has been in British possession since 1814, and in 1889 it was united with the colony of Trinidad. Pop. about 21,000.

TOBASCO, a meat sauce made of peppers, originally manufactured in Louisiana by Col. John McIlhenny in 1868.

TOBIKHAR, tō-bĭk-här'. See SHOSHONEAN INDIANS.

TOBIT, Book of, one of the Old Testament books rejected as apocryphal by the Jews and Protestants, but received into the canon by the Roman Catholics. It contains an account of some remarkable events in the life of Tobit, a Jew carried captive to Nineveh, and his son, who is named Tobias. Ewald ascribes the book to a Palestinian Jew who wrote in Hebrew, and suggests as the date of its composition the middle of the 4th century before Christ. The earliest known text is in Greek. See BIBLE.

TOBOGGAN, a sled-like vehicle, often formed of a single piece of broad flat wood, of birch or basswood, curved up and backward at the front end, and used for sliding down slopes of snow. It is commonly from five to eight feet long, about 15 or 16 inches in width if formed of one piece, or wider if formed of two or more. The curved portion in front is usually fastened by thongs of hide or gut, and the toboggan is strengthened by cross-pieces of hard wood strapped to the body at short distances. Toboggans originated with the Indians, who used them for hauling packs over the snow, and the name is still applied to a class of sleds drawn by dogs. But the toboggan of to-day is chiefly used in the sport of coasting down prepared slides, a popular pastime in Canada and other countries in high latitudes.

TOBOL, tō-bŏl', Asia, a river of Siberia, tributary to the Irtish, which rises in the southern Ural slopes, in Russian central Asia, flows northeast, and after a course of 750 miles empties into the Irtish opposite Tobolsk. It is navigable for more than half its length, but is covered with ice from November to May; its chief affluents are the Uj-Isset, Tura and Tawda. The Trans-Siberian Railway crosses the river at Kurgan.

TOBOLSK, tō-bŏlsk', Asia, in Siberia, (1) capital of a government of the same name, on the Irtish where it joins the Tobol, about 350 miles northwest of Omsk. The principal buildings are the churches, governor's residence, bishop's palace, municipal offices, arsenal, barracks, bazaar and hospital; besides a prison used as a depot for Siberian exiles, assembled from all parts of the country, an episcopal seminary, theatre, gymnasium, etc. The manufactures include bricks, soap and tallow. The trade is unimportant. The town is partly fortified. Pop. 25,200. (2) The government of Tobolsk, in northwestern Siberia, contains an area of 535,739 square miles. The Arctic Ocean borders the northern coast; the principal rivers are the Obi and Irtish, which are navigable when not frozen over. The chief occupation of the inhabitants is agriculture and cattle-raising; fishing and hunting in the north. Pop. 2,885,700.

TOCANTINS, tō-kän-tēnz', Brazil, a river rising in the southern part of the state of Goyaz, and flowing north through Goyaz, Cayapo and Pará, emptying into the Atlantic Ocean through the Rio Pará, the southern estuary of the Amazon delta. On the northern boundary of Goyaz the river receives from the left the Araguayá, which is considerably larger than the main stream. From the source of the Araguaya in the Cayapo Mountains in Matto Grosso to the Atlantic Ocean is fully 2,200 miles, constituting one of the great rivers of the world. The Tocantins is 1,600 miles long, and though interrupted by falls and rapids, it is navigable in stretches aggregating 1,100 miles. Its estuary is 140 miles long, and receives numerous channels from the Amazon, together with which it separates the island of Marajo from the mainland. The country through which these great twin rivers flow is undeveloped, there being not a single important city on the banks, except Pará at the mouth.

TOCQUEVILLE, tŏk'vĭl (Fr. tŭk-vēl), **Alexis Charles Henri Clérel de,** French statesman and writer: b. Verneuil, 29 July 1805; d. Cannes, 16 April 1859. He was originally destined for the military profession, but exchanged it for that of law. In 1827 he was appointed an assistant magistrate at Versailles. In 1831 he was commissioned by the French government to proceed along with his friend, M. Gustave de Beaumont, to America, and to investigate and report upon the penitentiary system of the United States. The results of the inquiry were published in 1833 under the title 'Du Système Pênitentiaire aux Etats-Unis et de son Application en France.' This, however, was only the precursor of the greater and more celebrated work 'La Démocratie en Amérique' (1835), to which the Montyon prize of the French Academy was awarded in 1836, and which, by 1850, had run through 13 editions. It was the first systematic analysis of democracy as exemplified in the institutions and political relations of the United States, and was translated into the principal European languages. Tocqueville was in 1839 elected to a seat in the Chamber of Deputies, and ranged himself with the opposition. After the Revolution of 1848 he was nominated deputy from the department of La Manche to the National Assembly, where he voted always against the propositions of the ultra-democratic party. In the Cabinet of 2 June 1849, he accepted the portfolio of Foreign Affairs, but resigned it the same year, after holding it for five months. After the *coup d'état* of 2 Dec. 1851, he lived retired from public affairs, and devoted his leisure to the production of 'L'Ancien Régime et la Révolution,' published in 1856. His complete works appeared in 1860–65. Consult Jaques, 'Alexis de Tocqueville' (1876); 'Souvenirs d'Alexis de Tocqueville' (1893); and D'Eichtal, 'Alexis de Tocqueville et la Démocratie Libérale' (1897).

TOCSIN, a bell sounded with quick strokes for the purpose of alarm. The word is derived from the French, and the use of the tocsin as a signal to arouse the people was so common during the French Revolution that the word has come to be proverbially used for any loud sound or call marking the commencement of an important event.

TODAS, or TUDA, a singular race of people inhabiting the upper part of the Neilgherry Hills in southern India. They are pastoral in their habits and possess a queer unwritten language. Their religion is the worship of the sun and of departed spirits. They follow the practice of polyandry in both its forms — the brothers of one family having one common wife, yet receiving the right, at certain seasons, of temporary husbands to the women of the subject villages. They are a tall, well-proportioned and a fine muscular race of men, are dominant over the neighboring tribes and receive from them a "goodoo" or tribute of one-sixth of their crops, the Todars holding aloof from tillage of the soil. They have slowly increased in number since 1858 when a count of them showed only 337, a recent estimate placing their number at 750.

TODD, Alpheus, Canadian author and librarian: b. England, 1831; d. Ottawa, Canada, 22 Jan. 1884. He removed with his parents to Canada in 1833; was for some time assistant librarian of the legislative assembly of Upper Canada, and in 1858 he became chief librarian. Upon the Confederation he was appointed to that office with the Dominion Parliament. He was also a writer of high authority on constitutional law and Parliamentary government. Author of 'The Practice and Privileges of the Two Houses at Toronto' (1839); 'Parliamentary Government in England' (2 vols., 1867–69), etc.

TODD, Charles Burr, American author: b. Redding, Conn., 9 Jan. 1849. He received his education in the public schools. For many years he was special writer on the New York *Evening Post*. In 1895 he was secretary to the commission appointed by Mayor Strong of New York to publish the early records of New York City. His published works are 'History of the Burr Family in America' (1879); 'History of Redding, Conn.' (1880; 2d ed., 1906); 'Life and Letters of Joel Barlow' (1886); 'Story of the City of New York' (1895); 'Story of Washington, the National Capital' (1897); 'Lance, Cross and Canoe in the Valley of the Mississippi,' 'Brief History of New York' (1899); 'The True Aaron Burr' (1902); 'The Real Benedict Arnold' (1903); 'In Olde Connecticut' (1905); 'In Olde Massachusetts' (1907); 'In Olde New York' (1907); 'The Washington Crossing Sketch Book' (1914); 'Sketches of the Delaware Valley' (1916).

TODD, David, American astronomer: b. Lake Ridge, N. Y., 19 March 1855. He was graduated from Amherst in 1875 where he became professor of astronomy in 1881. From 1882 to 1887 he held a similar post at Smith College. In order to make astronomical observations he has conducted expeditions to Texas in 1878, transit of Venus, Lick Observatory 1882, to Japan in 1887 and again in 1896, to West Africa in 1889–90, to Tripoli, Barbary, in 1900 and 1905, to the Dutch East Indies in 1901, to the Andes of Chile and Peru in 1908 and to Russia in 1914. He is the author of several textbooks on astronomy, also 'Stars and Telescopes' (1899); 'Lessons in Astronomy' (1902), also articles in magazines and reviews.

TODD, Henry Alfred, American philologist and educator: b. Woodstock, Ill., 13 March 1854. He was graduated at Princeton University in 1876 and later studied at the universities of Paris, Berlin and Madrid, taking his Ph.D. at Johns Hopkins University in 1885. He was professor of Romance languages at Leland Stanford Junior University in 1891–93; and in 1893 he became professor of Romance philology at Columbia University. He was one of the founders of the *Romantic Review* in 1910; was a member of the advisory council of the Simplified Spelling Board; and in 1906 was president of the Modern Language Association of America. He has edited numerous works in the Romance languages.

TODD, Mabel (Loomis), American author: b. Cambridge, Mass., 10 Nov. 1858. She edited the 'Poems' (1890–96) and 'Letters' (1894) of Emily Dickinson and a 'Cycle of Sonnets' (1896) by an anonymous author; also Steele's 'Popular Astronomy' (1899). Her original writings include 'Total Eclipses of the Sun' (1894) and 'Corona and Coronet' (1898); 'A Cycle of Sunsets' (1909). The results of study of the Ainu aborigines in Kitami province, Japan, appeared in various magazine articles.

TODD'S TAVERN, Engagements at. The Virginia campaign of 1864 began on 4 May by the advance of the Army of the Potomac across the Rapidan, the cavalry divisions of Generals Gregg and J. H. Wilson leading.

Wilson crossed the Rapidan at Germania Ford, and marched rapidly by Wilderness Tavern to Parker's Store, from which he sent a reconnoissance toward Mine Run, the rest of his division going into bivouac. During the night he was ordered by General Meade to advance in the direction of Craig's Church, leaving one regiment to hold Parker's Store. Just beyond Craig's Church Wilson encountered Rosser's Confederate cavalry, which was driven back two miles, and at noon, as he had heard nothing of the approach of Meade's infantry, and his own position was threatened, he began to withdraw to Parker's Store, when he heard that the regiment left there had been attacked by Confederate infantry, and that he was cut off from communication with General Meade's infantry. He determined to withdraw on the Catharpin road, by way of Shady Grove Church, to Todd's Tavern, on the Brock road. Before he was fairly on the road he was attacked in heavy force and followed by cavalry, but he reached Todd's Tavern by crossing the Po River at Corbin's bridge. A part of his command was cut off, but came in later in the day. As he approached Todd's Tavern he was relieved by Gregg's division, which, by Meade's direction, Sheridan had sent to assist him, and Stuart's cavalry, which was closely following Wilson, was driven back by Gregg to Shady Grove Church, about four miles. Sheridan was holding the left flank of the army, and covering its trains, while it was grappling with Lee in the Wilderness, and on the 6th had two divisions at Todd's Tavern, covering the roads centring at this point, where he was attacked early in the day by Stuart, who was anxious to get at Grant's flank and his wagon train, but his successive attacks were repulsed. Meade, anxious about his left, directed Sheridan to draw back from Todd's Tavern, closer to the trains, which Sheridan did in the afternoon, and the Confederate cavalry occupied Todd's Tavern. Preliminary to Grant's movement from the Wilderness to Spottsylvania Court House was the necessity to hold Todd's Tavern, which was midway between the two places and on the direct road connecting them; and on the 7th two brigades of Gregg's division and two of Merritt's, dismounted and fighting on foot, attacked Stuart and, after a sharp and closely contested action, drove him from Todd's Tavern, with severe losses on both sides, Fitzhugh Lee's division retreating in the direction of Spottsylvania Court House and Wade Hampton's southward to Corbin's bridge of Po River. Sheridan withdrew and encamped, Gregg's and Merritt's divisions in the open fields to the east of Todd's Tavern. Very early on the morning of the 8th Gregg was put in position to guard the roads from the south and Merritt's division renewed the engagement with Fitzhugh Lee on the Spottsylvania Court House road to open the way for the advance of Warren's Fifth corps from Todd's Tavern to the Court House. Merritt became severely engaged, but slowly gained ground until about 6 A.M., when he was relieved and Robinson's division of Warren's corps took the advance. Hancock's Second corps, following Warren's, reached Todd's Tavern at 9.30 A.M., and took position covering the Brock road, Catharpin and Spottsylvania roads, and began to intrench, holding the extreme right of the army. At 11.30 A.M. Gen. N. A. Miles' brigade, with Gregg's cavalry brigade and a battery, moved out on the Catharpin road toward Corbin's bridge, and when half a mile from it and one and one-half miles from Todd's Tavern, the head of column was opened upon with artillery from the heights on the south side of Po River. Miles formed line, his artillery replied to that of the enemy, there was a skirmish with Wade Hampton's cavalry, which was kept at bay, and at 5.30 P.M., when Miles began to withdraw, he was attacked by Mahone's division of infantry and fell back fighting to Todd's Tavern. Consult 'Official Records' (Vol. XXXVI).

E. A. Carman.

TODDY, or PALM-WINE, a drink made in tropical countries from the sap of various palms, especially when in a fermented state. The word is of Hindustani origin and is generally applied in India to the substance used as yeast to leaven bread. In the Malayan Archipelago, toddy is the sweet juice of the flower sheaths of *Arenga saccharifera.* In Brazil the majestic buriti, or murichi palm (q.v.), is felled, and cavities are dug in the stem in which to collect the sap, from which a fermented liquor is made. This has led to the use of the name of wine-palm for this tree. The spadix of the useful *Nipa frutescens* yields toddy which is changed into vinegar by one process, into arrack by another and may also be converted into a delicious syrup, thick, frothy and clear, with a slightly saline flavor. Sugar is made from this syrup by evaporation. The toddy or jaggery-palm (*Caryota urens*), a palm crowned by drooping bipinnate leaves, with wedge-shaped leaflets, furnishes a similar sap when the flowering stems are cut. This, like that of the nipa, can be boiled down into syrup and will yield a coarse brown sugar known as jaggery or goor. The sap is fermented for the toddy and further distilled for arrack. The cocoanut (*Cocos nucifera*), the palmyra palm (*Borassus flabelliformis*), the date (*Phœnix dactylifera*), and the wild date (*Phœnix sylvestris*), all yield toddy in India, the latter being grown extensively in Bengal, for the sake of this drink and the sugar extracted from it; it is said that the sap can be induced to flow from the upper portion of the stem for many years. The West Africans make their toddy from *Raphia vinifera.*

The word toddy was applied by the Scots to a drink made of whisky and hot water, sweetened. Burns uses the term in 'The Holy Fair.' Whisky and cold water, properly called grog, is also known by this name. Toddy-Cat is the name given in southern India to the palm-civet on account of its alleged fondness for palm-juice.

TODDY-BIRD, a swallow-shrike (*Artamus fuscus*) of India and Ceylon. It is about seven inches long, of dusky plumage and is most abundant in wooded districts, especially where palm trees abound, more particularly the Palmyra or toddy palm, from which it takes several of its popular names.

TODDY-CAT, one of the civets (*Paradoxurus typus*), common throughout the greater part of India, Ceylon, Burma and the Malayan region, which dwells mainly in the Palmyra or toddy palm-groves. See Toddy.

TODHUNTER, Isaac, English mathematician: b. Rye, 1820; d. Cambridge, 1 March 1884. He was graduated from London University in 1842 and from Saint John's College, Cambridge, in 1848. He was elected a Fellow of his college in 1849 and became a lecturer and tutor. He was elected a fellow of the Royal Society in 1862. Todhunter was a man of high attainments in various branches of learning, but is best known as the author of numerous mathematical textbooks. His most important works are 'Treatise on the Differential Calculus' (1852); 'Analytical Statics' (1853); 'Plane Co-ordinate Geometry' (1855); 'Examples of Analytical Geometry of Three Dimensions' (1858); 'Algebra' (1858); 'Trigonometry' (1859); 'The Theory of Equations' (1861); 'History of the Progress of the Calculus of Variations during the 19th Century' (1861); 'History of the Mathematical Theory of Probability from Pascal to Laplace' (1865); 'History of the Mathematical Theories of Attraction from Newton to Laplace' (1873); 'The Conflict of Studies' (1873); 'Laplace's Functions' (1875); 'History of the Theory of Elasticity' (ed. Karl Pearson 1886).

TODHUNTER, John, Irish poet and dramatist: b. Dublin, 30 Dec. 1839. He was educated at Trinity College, Dublin, and after studying at Vienna and Paris, practised medicine for some years in his native city. He was professor of English literature at Alexandria College, Dublin, 1870–74, and later removed to London. He has published among other works 'Laurella and Other Poems' (1876); 'Alcestis' (1879); 'A Study of Shelley' (1880); 'The Banshee and Other Poems' (1888); and several plays, such as 'Helena in Troas' (performed 1886); 'The Prison Flower' (performed 1891); 'A Comedy of Sighs' (performed 1894).

TODLEBEN, tŏt'lā-bĕn, or **TOTLEBEN, Franz Eduard Ivanovitch,** COUNT, Russian general: b. Mitau, Courland, 20 May 1818; d. Soden, Germany, 1 July 1884. He studied at the College of Engineers at Saint Petersburg, and entered the Russian army during its operations against the Circassians in 1848. Having been recognized as a most able engineer in this campaign, he was sent to the Crimea in 1854, where he distinguished himself while under constant fire from the guns of the enemy in the rapid conversion of the city of Sevastopol into a formidable fortress. For this and other valuable service during the Sevastopol campaign he was promoted to the rank of general. At the close of the Crimean War he retired to private life, where he devoted himself to scientific investigation and to the writing of a history of the war. During the Russo-Turkish War of 1877 he was sent to Plevna, where he compelled the commander, Osman Pasha, to surrender his entire army to the Russians. He was afterward made commander-in-chief of the army at Constantinople. At the end of the Russo-Turkish War he entered political life, and was in his later years governor, first of Odessa, and afterward of the province of Vilna. He published an account of the defense of Sevastopol (French trans., 'Défense de Sevastopol,' (1804). Consult Kinglake, 'The Invasion of the Crimea' (1863–87); Brialmont, 'Le général comte Todleben' (1884); Krahmer, 'General-adjutant Graf Todleben' (1888).

TODMORDEN, tŏd-môr'dĕn, England, a town in Lancashire and Yorkshire, on the Calder, 21 miles northeast of Manchester. The churches of various denominations, town-hall, free library, technical school, etc., are the chief buildings. The industries consist of foundries, machine works and manufactories for cotton goods. Pop. about 26,000.

TODY, a term applied to a family (*Todidæ*) of birds closely related to the motmots and kingfishers. They are distinguished by the long flat bill, short and rounded wings and short and square tail. Only four species are known, all of small size, and inhabitants of tropical America. The green tody (*Todus viridis*) of Jamaica is about four inches in length, and green on the upper parts, the flanks rose-colored, the throat scarlet and the belly pale yellow. The bill is red. It frequents the trees along watercourses, and has the habits of a fly-catcher, taking short flights in pursuit of insects and returning to the perch. They nest in the manner of kingfishers, in holes excavated in banks, and lay three or four white nearly spherical eggs. Consult Evans, 'Birds' (New York 1900).

TOFT, an old English word denoting a thicket of trees, a homestead or a piece of ground on which a messuage or home formerly stood. Taken in the second sense toft was frequently used in legal papers in conjunction with the work croft, "toft and croft" meaning a house and homestead, with the stables and outbuildings, the whole surrounded by a thicket or enclosure. Probably from the fact that the house was usually surrounded by trees came the later meaning of soft, which is preserved in the modern word tuft, a grove of trees.

TOGA. See COSTUME.

TOGO, Heihaichiro, COUNT, Japanese admiral: b. Kagoshima, Japan, 1847. He very early became known as one of Japan's most daring naval officers, and a few years before the annexation of the Hawaiian Islands by the United States, he was sent to Hawaii in command of the battleship *Naniwa* to protect the Japanese who were then complaining of persecution by the government. There he nearly became involved in warfare with United States ship *Boston* whose captain supported the demand of the Hawaiian government for the surrender of an escaped Japanese prisoner, and threatened to fire upon the *Naniwa*. When Togo immediately cleared his ship for action, however, the captain of the *Boston* apologized and withdrew his threat. In 1894 Togo practically began the war with China by firing upon Chinese transports carrying troops with an evidently hostile purpose. On the breaking out of the Russo-Japanese War in 1904 he was appointed commander-in-chief of the Japanese navy and conducted the operations against Port Arthur, and the bombardment of that port, defeated the Russian fleet there, driving it back, after severe fighting, to the shelter of the inner harbor, and damaging several Russian ships. On 27–28 May 1905 he met and annihilated the Russian Baltic squadron, only four small cruisers and some torpedo boats escap-

ADMIRAL TOGO

ing. See JAPAN-RUSSO-JAPANESE WAR; MANCHURIA.

TOGOLAND, Africa, a territory on the Gulf of Guinea, between French Dahomey and the British Gold Coast, held as a German colony from 1884 to 7 Aug. 1914, when it was occupied by British and French allied troops. The revenue to Germany in 1913 was over $1,000,000. It has a coast line of 32 miles, but extends 325 miles inland, where it becomes broader. Area, 33,630 square miles. Lome is the chief port and capital. The coast is low and bordered by lagoons, but the interior is crossed by the escarpment of the Sudan Plateau. The country is well watered, the interior by branches of the Volta, which forms the west boundary. The chief products are palm oil, copra, rubber, indigo and dye-woods. Cattle raising is carried on by many of the natives. They also do weaving, make pottery and mine and work a little iron. The inhabitants, who number about 2,000,000, are Sudan negroes, the European population being less than 400. Commerce is rapidly increasing, and there is regular steamship connection with Europe.

TOGUE, a local name in Maine for the lake-trout (q.v.).

TOILERS OF THE SEA ('Les Travailleurs de la Mer'), a novel by Victor Hugo, published in 1866. The scene is laid in the Channel Islands and the book is dedicated to the "Isle of Guernsey, severe yet gentle, my present asylum, my probable tomb."

TOISE, toiz, in the French system of measures used previous to the decimal system, was the unit of linear dimension. It consisted of six pieds or feet, each of which was composed of 12 pouces or inches, each pouce being divided into 12 lignes or lines. The toise was thus the equivalent of 1.94904 + metres or of 6.3946 + English feet.

TOKAT, tō-kät', Asia Minor, a town in the vilayet of Sivas, 70 miles from the Black Sea. It extends between steep rocky walls in a labyrinth of narrow streets bordered by miserable houses. It contains a large mosque, bazaars, foundries and manufactories of carpets, silk, wool and cotton goods, etc. Copper is mined in the vicinity. The town was formerly prosperous, but ill treatment of the Armenian population has largely reduced its inhabitants, believed to number about 22,000 in 1919.

TOKAY, tō-kā' (Hungarian, tō'koi), Hungary, in Semplin County, at the junction of the Theiss and Bodrog, 130 miles northeast of Pesth. Its buildings include a theological seminary, gymnasium, high school, etc. In the neighborhood are rich mineral deposits, as salt, sapphires, etc. The chief occupations are agriculture, fishing, viticulture and timber-trade. The Tokay wine is famous and the best is produced on the hill of Mezés-Máli. Great care is exercised in the culture, gathering and selection of the grapes. The wine is of various qualities, dependent finally upon the amount or lack of artificial pressure. The best kinds are the *Essence* and the *Ausbruch*, of amber color when new, turning green with age. There are 34 wines, grouped as sweet and dry; 2,000,000 gallons are produced, but the celebrity of the wine is such that many imitations are made by French and German dealers, which are even sold in Hungary. Pop. 5,500.

TOKEN MONEY, a name in numismatics applied to pieces of money current only by sufferance and not coined by the authority of the state or government. In England in the 16th century the national coinage was so unsatisfactory and inconvenient that large numbers of private traders and merchants were impelled to have halfpence and farthings manufactured for themselves. These "tokens," as they were called, were made of lead, pewter, latten, tin and even leather, and could only be made use of as currency at the shops or warehouses of their respective issuers. Notwithstanding the endeavors made during several reigns to put a stop to the circulation of this unauthorized coinage, traders' tokens continued to multiply to an astonishing extent, until, in 1672, a proclamation was issued, prohibiting their making or use under severe penalties. From that date until 1787 the issue of private tokens entirely ceased; but in the latter year, owing to the great scarcity of government copper coins, the Anglesey Copper Mines Company struck and put into circulation some 300 tons of copper pence and halfpence. The bold example thus set was speedily followed by other trading firms all over the kingdom, and again the government found it necessary to take action in the matter, which it did by issuing a new national copper coinage. For some years the issue of private tokens was thus effectually checked; but in 1811 the authorized coinage again getting scarce, the copper companies and others recommenced the issue of batches of tokens. This went on until 27 July 1817, when the manufacture was prohibited by act of Parliament, and all tokens in currency ordered to be withdrawn from circulation by 1 Jan. 1818.

In the United States small coins became so scarce in 1862 that tokens made their appearance in large quantities. They were of two classes, war or patriotic tokens, and trade or advertisement tokens. Both kinds were issued with a mercantile view, since they passed for a cent and could be manufactured (in sufficient quantities) for much less. Cards and tokens appeared during 1862, 1863 and 1864. Of the patriotic or war tokens there were something like 400 varieties coined, including mulings and different metals, the latter largely restrikes. Of original pairs of obverse and reverse there must have been less than 200. The common varieties bore the inscriptions "Army and Navy," and "Not One Cent." The first coinage of trade tokens, or store cards, as they were sometimes called, took place in Cincinnati where nearly 900 varieties were issued, fully three times as many varieties as any other city issued except New York. A number of other Western cities soon followed the example of Cincinnati, but it was not until the early part of 1863 that New York began to issue the famous Lindenmuller cents, of which there were more than a million coined; these were followed by the Knickerbocker tokens, consisting of many varieties. Altogether there were between 600 and 700 varieties issued from New York. Ohio issued about 1,300 varieties from 100 different cities and towns, more than any other State issued; New York State comes next after Ohio, with over 900 varieties. New Jersey had but few, and Pennsylvania not many; chiefly from Philadelphia and Pittsburgh. Detroit furnished as many advertisers as New York, and the rest of Michigan nearly as many as Cincinnati. Indiana had about 100; Illinois, including Chicago, not as many as Indiana; and Wisconsin nearly twice as many. When the government stopped the coinage of tokens in 1864 there were upward of 20,000,000 in circulation.

TOKIO, tō'kē-ō, or **TOKYO,** the capital of Japan, situated at the head of the land-locked Bay of Tokio, on the east coast of central Hondo, and at the mouth of the Sumida Gawa. Besides the latter river, which divides the city into two unequal parts, Tokio is intersected by a large number of canals, which are generally crossed by wooden bridges. Some of the canals form concentric courses, enclosing a number of islands, one within the other; and on the innermost of these stands the imperial palace. This large cluster of buildings is surrounded by magnificent gardens, and enclosed by high walls and fosses. On the outer islands are most of the government departments and foreign legations. Surrounding these central islands, the city spreads out on all sides, with a rather irregular and complex street plan. There are numerous parks in and around the city, some of them being large and beautiful. Practically all the houses are built of wood. Besides the palace the only notable buildings are some of the numerous temples, especially that of Kwannon, and the temple of the Shoguns. There are six European churches, the finest being the Russian cathedral. Tokio contains about 70 hospitals of good standing, including the Komagome Hospital for epidemics and the Tokio Charity Hospital. The former is supported by the city and the latter by the Imperial Court. There also exists an asylum for orphans of the poor, established by the city. According to the latest returns on educational affairs there are about 500 public and private primary schools and kindergartens. The number of children of school age is about 225,000 of whom about 80 per cent are in attendance. There are 35 middle schools, public and private, of which six are for girls. The schools higher than middle grade and placed under the direct control of the Department of Education number 13, including the Imperial University, the First High School, the Higher Commercial School, School of Foreign Languages, the Tokio Higher Technical School, Higher Male Normal School and Higher Female Normal School. Besides there are two public normal schools, supported by the Tokio Prefecture. The keiogijiku, Waseda and Women's University are most prominent among the private high class institutions, among which are included 10 other colleges of law, economics, philosophy and religion. In addition to those above mentioned, there are over 280 public and private schools, mostly of the middle school grade, teaching special subjects. The city has a number of libraries opened to the public, including the Imperial Library at Uyeno Park. The sanitary condition of the city is in a fair condition, though street drainage is not so well advanced as in Western countries. Each *ku* (ward) has sanitary organization supported by rate levies from the inhabitants themselves. The metropolis is well supplied with parks and open spaces. The largest parks are the Shiba, Uyeno and Hibiya parks. In the first two are beautiful temples connected with the old Tokugawa family, and here the remains of the Shoguns are buried. At Uyeno also is the Imperial Museum. Automobiles have been introduced as a means of transportation and an «autobus» line is in operation, in addition to the electric tramways. Streets are being laid out regularly of late years and modern dwellings are being erected. Great harbor works have been undertaken by the municipal assembly at a cost of 37,000,000 yen. There are also a modern water-supply system, excellent street railways, gas and electric light, macadamized roads, public works, etc., all carried on according to methods of civilized cities all over the world. The municipal council is elected by the municipal assembly, and the latter is chosen by popular vote. Although the principal railroad centre of the empire, Tokio is not an important manufacturing or commercial city. Its port is Yokohama, near the entrance to the bay. The city was founded in 1456 and in 1590 it became the capital of the Shoguns, the emperors residing at Kioto. With the downfall of the Shoguns in 1868, Tokio (till then known as Yedo) became the residence of the emperors and the sole capital. It has several times suffered from earthquakes and conflagrations. Pop. 2,244,796.

TÖKÖLY, tė'kėl-yĭ, or **TÖKELY, Emerich,** COUNT, Hungarian patriot. See TEKELI.

TOKUGAWA, PRINCE, Japanese nobleman and political leader, known as «the last of the Tycoons.» See HITOTSUBASHI.

TOKUSHIMA, tō-koo-shē'mạ, Japan, the capital of the prefecture of the same name, and the largest city on the island of Shikoku, situated on the northeast coast, on the Kü Channel. It is an important steamship station, with a picturesque location on the coast and a mountainous background. Pop. 70,000. The prefecture population is 775,000.

TOLAND, John, English writer: b. near Londonderry, 30 Nov. 1670; d. Putney, 11 March 1722. He was brought up as a Roman Catholic, but at 16 went over to Protestantism. He was educated at the University of Glasgow, and studied divinity in the University of Leyden. In 1696 he published a work entitled 'Christianity not Mysterious,' which may be regarded as opening the prolonged English controversy between deism and orthodoxy. The House of Commons ordered it to be burnt by the common hangman, and Toland met with determined opposition from many quarters, though Locke gave him a certain amount of support. He subsequently supported himself by literary hack-work and various forms of political party service. Besides the work above mentioned he wrote a 'Life of Milton' (1698), in an edition of his prose works; 'Memoirs of Denzil, Lord Holles' (1699); 'Anglia Libera' (1701), a defense of the Act of Succession, and 'The State Anatomy of Great Britain,' etc. (1717).

TOLEDO, tō-lē'dō, Iowa, city, county-seat of Tama County, on the Chicago Northwestern Railroad, about 50 miles northeast of Cedar Rapids and three miles from Tama (q.v.), a railroad junction on the Iowa River. It was settled in 1844. It is in a fertile agricultural region in which there is considerable attention given to stock-raising. The industries are connected chiefly with the farm products. The principal public buildings are the county courthouse, jail, the churches and schools. The educational institutions are Leander Clark College (U.B.), opened in 1856; a Government Indian Industrial School, public schools, and a library. There are two banks and two newspapers besides a collegiate weekly. The government is administered by a mayor and a council composed of six members. Pop. 1,721.

TOLEDO, Ohio, city, county-seat of Lucas County, on the Maumee River, near its mouth; lat. 41° 30′ N., long. 83° 32′ W. The city is 587 feet above sea-level. It is 96 miles west of Cleveland, 124 miles north of Columbus and 234 miles east of Chicago. The northern corporation line is within two miles of the Michigan boundary. The city lies on both sides of the Maumee River, the principal business section being on the left bank; it extends from the river mouth, where the stream opens into Maumee Bay, to a point nine miles up stream. The area of the city is 31.59 square miles.

Commerce and Transportation.— The location of Toledo, at the western end of Lake Erie, gives it great commercial advantages, for it is at the head of the direct lake route eastward. The distance by lake to Chicago is 691 miles, while it is but 234 miles by rail. Hence there is an enormous traffic between the Eastern cities and the region lying southwestward, of which Toledo is the distributing point. This natural advantage is supplemented by the railway system, the city being the centre of 16 trunk lines, making direct communication to the Atlantic on the east and the Pacific on the west, with direct lines north and south. These trunk lines, including their branches, give a grand total of 23, making Toledo second only to Chicago in the number of railroads; 393 trains and 572 interurbans arrive and depart every 24 hours. Many of the trunk roads reaching the city have dock facilities, with regular steamer connections to all important lake ports. The location of Toledo makes it the most convenient shipping point for a large portion of the "winter-wheat belt," and it is one of the most important primary grain markets of the United States, after Chicago. It has 12 grain elevators, with a storage capacity of 8,500,000 bushels. Toledo is the leading clover-seed market of the world and its quotations govern the prices of clover-seed for the United States. In 1918 Toledo received over 20,000,000 bushels of wheat, corn, rye, oats and barley. Toledo is one of the largest shipping ports for soft coal in the world. This comes by rail from the mines of West Virginia, southern and eastern Ohio and Pennsylvania, and is transported by water to all ports on the upper lakes. The Ohio Central, Hocking Valley, Pennsylvania and Baltimore and Ohio railroads have immense docks on the river front, with steam apparatus by which a carload of coal at a time is conveyed into the hold of a vessel. Similar appliances are used for the rapid unloading of iron ore coming from the Lake Superior mines, which is shipped by the same roads to the iron furnaces in southern Ohio, to mix with the native ores, thus producing a superior quality of iron and steel. There is also a very large trade done in lumber, salt, etc., Toledo being the largest distributing point on the lakes for coal, ore and lumber. More than 50 per cent of all the coal transported on the Great Lakes in 1918 was loaded in Toledo.

The harbor of Toledo lies entirely within the Maumee River, giving full protection to shipping. The Maumee is really a wide and deep estuary of Lake Erie, to the foot of the historic "Rapids of the Maumee," just above Perrysburg, the site of Fort Meigs, famed for Harrison's defense in 1813. Above this the river passes for some 15 miles over outcrops of limestone. At the northern city line the river opens into Maumee Bay, which is three miles north and south by six miles east and west. Through the bay the United States government has dredged a straight channel, 400 feet wide by 21 feet deep and eight miles long from the mouth of the river. The harbor proper embraces the wide channel of the river, which is 700 to 1,400 feet wide between the harbor lines established by the government. The channel of the stream has been improved by the government to the same depth and width as the straight channel. The cost of this channel through the bay, and the corresponding river improvements, has been over $2,000,000. The wharfage space covers both banks of the river the entire length of the city, 18 miles in all, besides several miles on Swan Creek, a deep tributary which enters the river in the middle of the business section. Besides these there is unlimited wharf capacity along the shores of the bay, now being utilized.

Manufactures.— The advantages of Toledo as a distributing point by lake and rail, its proximity to raw material and fuel, have caused its industrial interests to dominate all others. As an example of this is the fact that the renowned Lake Superior iron ores and the coal and coke from the Ohio and West Virginia fields meet at its wharves on a common basis of economy. This resulted in the building in 1903 and 1904 of a blast furnace and steel plant on the river front by the Toledo Furnace Company with a capacity of 400 tons per day. This company is now capitalized at $4,000,000 and its capacity has been doubled. Other great industrial establishments nationally known and with large capital invested in Toledo are the Willys-Overland Company, $75,000,000, producing passenger automobiles. This is the second largest automobile plant in the world; the Paragon Refining Company, $25,000,000, which refines petroleum; the Owens Bottle Machine Company, $15,500,000, producers of the bottle-making machine, which has revolutionized that industry; National Supply Company, $14,000,000, producing oil well supplies and machinery; the Electric Auto-Lite Company, $13,000,000, producing automobile starting and lighting systems; the National Malleable Castings Company, $8,000,000, with the largest malleable casting plant in the world; the Sun Company, $5,000,000, refiners of petroleum products; the Toledo Machine and Tool Company, $3,000,000, builders of presses and machine tools; the Towar Textile Mills Corporation, $2,500,000, producing heavy ducking and belting; the Champion Spark Plug Company, $2,000,000, which produces more than 50 per cent of all the spark plugs in the world;

the Ed. Ford Plate Glass Company, $2,000,000, manufacturers of polished plate glass; the Toledo Shipbuilding Company, $2,000,000, which has built some of the largest ships on the Great Lakes; the Libbey Glass Company, $1,000,000, manufacturers of fine cut glassware and electric light bulbs; the Hettrick Manufacturing Company, $1,000,000, manufacturers of tents, awnings and canvas goods; the Toledo Sugar Company, $1,000,000, which refines sugar from beets extensively cultivated in the territory surrounding Toledo; the Toledo Scale Company, $900,000, manufacturers of the famous Toledo scale; Milburn Wagon Company, $700,000, builders of farm wagons and electric vehicles. There are more than 600 other busy manufacturing plants in Toledo; in the Manufacturing Directory, issued by the Toledo Commerce Club, there are 921 different classifications of articles made in Toledo. Toledo is the centre of the metal wheel industry in the United States. There are four plants in Toledo capitalized at $1,250,000, producing bicycles and children's vehicles and giving employment to more than 1,000 men. More than 60,000 people are employed in the industries of Toledo. Most of the power used in the factories is supplied by the Toledo Railways and Light Company. The Acme Power Company, a subsidiary company of the Railways and Light Company, has completed the first unit of an $8,000,000 plant, which will be utilized to further electrify Toledo's industries. The Standard Oil Company of Ohio has erected a $5,000,000 refinery. This company has a pipe line direct to the mid-contenent field, through which the crude oil is pumped. The $20,000,000 nitrate plant started by the government in 1918 in Toledo is to be converted into a permanent arsenal. Toledo is one of the busiest wholesaling and jobbing centres in the Middle West. The many railroads and electric lines make shipping easy to any territory surrounding the city. Post office records show that 42,000,000 people can be reached with over-night mail service. Large manufacturers in the East and West maintain branch houses and distributing stations in Toledo.

Banks.— There are four national banks and 18 State savings and private banks in Toledo. The capital of the national banks is $3,500,000, and the surplus and undivided profits of these banks amount to $4,499,382. The capital of the other 18 banking institutions totals $4,140,300, with surplus and undivided profits of $2,366,619. In addition to these banks there are eight building and loan companies with a combined capital stock of $26,700,000. At the beginning of 1918 the bank deposits in Toledo passed the $100,000,000 mark; clearings during 1918 totaled $539,114,586. Toledo also is the home of nine bond houses, which do a business upwards of $85,000,000 annually. In 1918 Toledo lead all cities of its class in postal savings deposits. Records show there were 2,950 individual depositors and $1,318,173 on deposit. The post-office receipts in Toledo in 1918 totaled $1,391,000.

Municipal Conditions.— The slope from the river on both sides is gradual, but amply sufficient to ensure good drainage. It is well laid out, with wide streets. These aggregate 423 miles in length, of which 400 miles are sidewalked, 256 miles electrically lighted and 244 miles are paved, chiefly with wood block, brick and asphalt. The residence streets are beautifully shaded, and the absence of all fencing gives this section a park-like appearance. The sewerage system is excellent, there being a total of 292 miles, all emptying into the Maumee River. The waterworks originally cost about $1,400,000 and has a capacity of 70,000,000 gallons daily, with 353 miles of street mains. The city is supplied with natural gas brought from three fields, northwestern Ohio, central Ohio and West Virginia; and there are 25,000 consumers, the gas being used only for household purposes. The electric car system is very complete, covering 120 miles of streets and accommodating all sections of the city. There are 10 distinct interurban electric roads in addition, with freight and passenger stations in the business centre. They have a total of 1,546 miles of track, connecting Toledo with a large number of surrounding cities and villages, including Cleveland and Detroit. The discovery of gas and petroleum in northwestern Ohio in 1887 was one of the contributing causes for the growth of Toledo, as this city is the natural metropolis in the oil area and this business still remains a potent factor. The rapid growth in population caused the expansion of the residence section in Toledo. In the west end of the city, which is the newer area, there are thousands of beautiful homes set among the original forest trees. In more recent years beautiful residential sections have been developed by real estate operators. Ottawa Hills is one of the most beautiful high-class residential developments in the country. Many large homes have been built in the up-river section. Toledo has a greater per cent of home-owners than any city of its size in the country. The working man owns his modest home and takes a pride in his lawns and garden patch. All of the residential streets are well paved and lighted with 3,160 arc lamps.

Buildings.—Among the notable buildings are the courthouse, in front of which is a fine bronze statue of President McKinley, erected in 1903; Museum of Art; the Young Men's Christian Association building; the Masonic temple; the Young Woman's Christian Association building; Newsboys' building; the City Market; the Terminal Auditorium, which will seat 5,000 persons; handsome Toledo Club building; Woman's building; a Soldiers' Memorial building; armory of the Ohio National Guard; the Public Library (which has 50,000 volumes and five sub-stations); the Valentine Theatre, one of the finest and most artistic interiors in the United States, and many modern office and business blocks.

Churches and Schools.— There are 91 church edifices in the city, nearly all having Sunday-schools. Some of the rooms devoted to the latter are up to the best modern standards in plan and equipment. Nearly all have large libraries for the use of the scholars. There are two public high schools, built at a cost of $750,000 each, a manual training school and a vocational high school. There are 51 public school buildings, besides 22 parochial schools belonging to and controlled by the Roman Catholic Church. The latter Church also supports an academy under the Ursuline Nuns,

a similar school by the Notre Dame Sisters, and Saint John's College, an institution for boys and young men, under the direction of the Order of Jesuits. Toledo University with an enrolment of 1,200 students is maintained by the city. There are 10 private schools; two large business colleges, one of which has 500 students. The Museum of Art is an organization for the advancement of art, numbering in its membership the most progressive citizens. It occupies a building built at a cost of $1,000,000 and a valuable gallery of paintings and objects of art.

Charities.—Among the benevolent and philanthropic institutions are the Toledo State Hospital for the Insane, supported by the State. This is an institution on the cottage plan, with accommodations for 1,700 inmates; the Toledo Hospital, a large institution supported by the voluntary contributions of citizens; Saint Vincent's Hospital and Saint Anthony's Orphans' Home, conducted by the Gray Nuns; Lutheran Orphans' Home; Old Ladies' Home; a Roman Catholic hospital for the aged, conducted by the Little Sisters of the Poor; Mercy Hospital; Robinwood Hospital; Flower Hospital; Maternity Hospital; the Country Children's Home; the Young Men's Christian Association and Young Woman's Christian Association; the day nursery, a home for foundlings, training school for nurses and a number of private hospitals.

Parks.— The park system of Toledo em braces a total of 1,532 acres; beginning at the city limits up the river on the west side is Walbridge Park, 64 acres, on a bluff 75 feet high, with an unrivaled river view; Ottawa Park, on the western side of the city, 280 acres; Willys Park, 100 acres; Bay View Park, 202 acres, at the point where the river empties into the bay. Further up the river on this side is Riverside Park, 63 acres, fronting the stream. On the east side are Collins Park, 90 acres, and Navarre Park, 62 acres. Besides these, there are 44 smaller parks and triangular spaces, ranging from one-eighth of an acre to seven acres area. The large parks are connected by a boulevard, which is 10 miles long on the west side, 150 to 200 feet wide, now under construction, extending in a semi-circle from Walbridge to Bay View parks, the most of the necessary land being donated by property-owners. On the east side a similar semi-circle is projected and partially completed. Recreation centres and parks are being increased in number as rapidly as the city budget permits.

Recreation.— Toledo offers all the advantages of a summer resort, because of its proximity to Lake Erie and its fine beaches. Just 45 minutes from the heart of the city is located Toledo Beach. Here will be found many comfortable summer homes along the edge of Lake Erie, extending for a distance of several miles. Hundreds of Toledo people spend the summer months at the beach, going to and from work each day. The street car company maintains a half-hour service to this resort. Point Place and Edgewater, located on the bay just outside the city limits, are meccas for fishermen. On the south shore of Maumee Bay will be found Harbor View Beach, with many cozy summer homes nestled among the groves which border the bay shore. In the city Walbridge, Riverside and Bay View parks are located on the banks of the Maumee River. These are easy of access and daily, during the summer time, attract thousands of people. Yachting and canoeing are favorite sports in Toledo. The river and bay are dotted with small crafts of all kinds. More than $5,000,000 has been invested by the people of Toledo in sailboats, motorboats, canoes and cruising yachts. There are three yacht clubs and a power boat club. Toledo Yacht Club maintains one of the finest buildings of its kind in the country at the mouth of the Maumee River. This club adjoins Bay View Park. The Toledo Power Boat Club is situated on the bay near Bay View Park. The Maumee River Yacht Club is located at the southerly end of Walbridge Park. The Ottawa River Yacht Club has headquarters on Ottawa River near the bay. The city maintains a municipal club house at Riverside Park. There are many other smaller club houses supported by canoe clubs, etc. In the winter time ice boating and skating are the leading outdoor sports. Practically all of Toledo's parks have public swimming pools and the most modern playgrounds equipped for the children. In Ottawa Park there is one of the finest municipal golf courses in the United States. Public tennis courts also are maintained by the city. Fine golf courses are maintained by the Inverness Club, Country Club, South Shore Country Club and the Sylvania Golf Club. There is a keen interest in Toledo in baseball. Toledo supports a team in the American Association, and Swayne Field, the home of the Toledo team, is one of the finest ball parks in the league. There are many semi-professional teams which have large followings. The city maintains ball diamonds in several of its parks. Toledo is a Mecca for excursions during the summer months; people come for hundreds of miles to take trips on the water. Three passenger steamship lines maintain regular service to Sugar Island, Detroit, Mackinac, Put-in-Bay, Cedar Point, Cleveland, Buffalo and other points on the Great Lakes.

Government.— Toledo has a simplified form of the Federal form of government. The people elect the mayor, vice-mayor and one ward councilman. All other city officers are appointed by the mayor, with the exception of the city clerk, who is elected by council. All city offices are for a term of two years. There are 16 wards. The vice-mayor presides over council, but has no vote except in case of a tie. The mayor's cabinet, appointed by him, consists of the heads of various city departments; these are a director of law, director of public service, director of public safety, director of public welfare, director of finance.

History.— The Maumee River was one of the most important routes for travel by the Indians and the white traders. Going by canoe to a point near Fort Wayne, Ind., a portage of a few miles enabled them to reach the headwaters of the Wabash, which they followed to the Ohio and thence to the Mississippi. Another important route was up the Maumee and the Auglaize, a southern tributary, thence by portage to the headwaters of the Great Miami, which reaches the Ohio just below Cincinnati. An important Indian trail also crossed the river at the rapids above the city, by which hunting parties went to Kentucky. A few French Canadian hunters and trappers settled, in the 18th century, at points within the present site of Toledo; but there is no reliable account of the earliest sporadic settlement of Americans on the city plat. In 1805 a treaty was made between the United States and the Indians, at a stockade, named Fort Necessity, which stood on a high clay bluff at the junction of Swan Creek and the Maumee. By this the red men yielded title to the «Fire Lands,» granted to the citizens of Groton and New London, Conn., in recompense for the burning of these towns by the British in the Revolution. In 1817 a company of speculators laid out a town at the mouth of Swan Creek, called Port Lawrence. Very few settlers came, however, and the hamlet languished. In 1832 another settlement, named Vistula, was begun by Major Stickney, for many years Indian agent, a mile further down the river, at the foot of what is now Lagrange street. This spurred the owners of the land at Port Lawrence to new efforts, and a brisk rivalry sprang up between the two villages. The two were wisely consolidated in 1833. A public meeting of the citizens of both was held to determine the name of the united town; and, at the suggestion of Willard J. Daniels, the name of Toledo was adopted. He had been reading a history of Spain, and urged the name of the old Moorish capital for the reasons that there was no town of that name in America, that it has a pleasant sound and is easily pronounced. Toledo was incorporated as a city in 1846.

The town had slow growth until the opening of the Wabash and Erie Canal, from Toledo to the fertile Wabash Valley in Indiana, in 1843, and of the branch from Defiance south to Cincinnati, called the Miami and Erie Canal, which was opened to traffic in 1845. In 1846 these two canals brought to Toledo products valued at $3,000,000, while those going from Toledo to points on both aggregated nearly $5,000,000. The first railroad to reach Toledo was called the Erie and Kalamazoo, which was opened from Toledo to Adrian, Mich., in 1836, the cars being drawn by horses. The next year a locomotive was put on the line, and a contract for carrying the mails was obtained from the government. The road was sold by the sheriff in 1842, and its line is now part of the great New York Central system.

Population.— The population (1840) was 1,222; (1860) 13,768; (1880) 50,137; (1900) 131,822; (1910) 168,497; (1918) est. 262,000.

RAYMOND T. SKINNER,
Toledo Commerce Club.

TOLEDO (Sp. tō-lā'tho), Philippines, pueblo, province of Cebu, on the west coast, 35 miles west of the pueblo of Cebu. Petroleum and natural gas are reported in the vicinity. Pop. about 13,500.

TOLEDO, Spain, in New Castile, capital of a province of the same name, on the Tagus, 45 miles southwest of Madrid. It is the archiepiscopal see of the primate of Spain. The city is walled and occupies an acclivity, around which rise lofty mountains. The city is built compactly, houses crowded, streets steep, winding and narrow. The chief points of interest are the Alcazar (1551), once including fortress and palace, which occupies a central and high point of the town; the great Gothic cathedral (1227–1493), a most imposing edifice of great architectural merit, which has seen many vicissitudes but retains some fine stained glass and a choir of marvelous beauty. The large square of Zocodoven is the fashionable promenade, and thoroughly Moorish in character. Here the heretics were burned and the bull-fights take place. There are besides a theological seminary, monastery, several palaces and hospitals. The manufactures comprise the famous Toledo sword-blades, small-arms, church ornaments and vestments, silk, wool and cotton textiles and confections. Toledo was the ancient capital of all Spain and important in the country's history. It was taken by the Romans 193 B.C.; and subsequently was occupied in turn by Goths, Moors and Castilian monarchs. It was also the seat of the Inquisition (q.v.). The town is now sadly decadent. The Alcazar, so often damaged by fire, has been restored with considerable expense. Pop. about 22,000. The province has an area of 5,919 square miles and a population about 438,071. Consult Calvert, A. F., 'Toledo: an Historical and Descriptive Account' (New York 1910).

TOLEDO NEWSBOYS' ASSOCIATION, The, was organized 1892, with its founder, John E. Gunckel (q.v.), as president. Mr. Gunckel remained president of the association until his death in 1915. Through his untiring efforts the association had a marvelous growth and was the means of reclaiming the heretofore neglected boy and girl and remolding their lives, making them useful and substantial citizens, capable of carrying on and furthering the plans of the great metropolis, which, like all cities, must be trusted to a rising generation. To-day former newsboys of this association are filling and in many instances managing the great business enterprises of the city. Following his death, Mr. J. D. Robinson, one of Toledo's greatest philanthropists, became its president, and again the association was placed on a solid foundation. Never in the history of the association has it enjoyed greater prosperity. The association as in the past is loyally supported by the philanthropic people of the city, and every advantage is offered the boy of the street to become a useful and honored citizen. The boys are constantly warned of the evils and dangers that beset them and urged to refrain from gambling, stealing, lying, swearing, smoking cigarettes, drinking intoxicating liquors, going into saloons or associating in bad company. A fine brick building built in 1908, costing $110,000, dedicated to the newsboys of Toledo, furnishes them one of the finest auditoriums in the city together with a spacious and well-equipped gymnasium and cadet room, swimming pool of large capacity, fine library, playrooms, furnished kitchen and dining-room, lobbies and special rooms for band and orchestra practice, where the association maintains a 36-piece band and 14-piece orchestra. The association now has a membership of 11,500. Sunday afternoon entertainments, a special feature of the association, from 1 October to 31 March, given by the schools, churches and different organizations of the city, are highly appreciated by the boys. Each Sunday the auditorium is filled to its capacity. The association also maintains a court of investigation, where erring boys are required to account for misconduct. An employment bureau within the association proves a valuable asset and many boys are placed in responsible positions, later to become

TOLEDO

1 General Post Office

2 Scott High School

partners or managers. The boys are encouraged to return all found articles to the building. Articles of more than $50,000 have been returned to their rightful owners, for which the finder receives an «honor» badge. Each year the entire association is tendered an outing, or better known «Field day,» which never fails to add a bright page to the history of the newsboy.

TOLEDO WAR, The, a name popularly given to the contest over the division line between Michigan on the north and Indiana and Ohio on the south. It arose out of an error in the location of the southern point of Lake Michigan. In 1805 the Territory of Michigan was organized in conformity with the Ordinance of 1787, which provided that the line between Ohio, Indiana and Illinois on the south, and the territory on the north, should be «an east and west line running through the southern point of Lake Michigan.» This was set down on the maps of the times 42° 32′ N., but when Michigan was organized it was found that the true line through the southern point of Lake Michigan was 65 miles to the south, or 41° 37′ 19″ N., and this more southerly line was adopted. But when Indiana and Illinois were organized as States, the northern line was adopted, and there was thus left a belt 65 miles broad claimed by both factions. Congress ordered a survey, which was completed in 1817, establishing the «Harris» line, near the northern one. But the people of Michigan protested vehemently, as the city of Toledo was in the disputed belt. In 1836 Ohio by act of legislature organized townships in this territory, which had long been under the control of Michigan. Then both Michigan and Ohio appealed to President Jackson, but got no relief. The governor of Ohio called out the militia, the governor of Michigan did likewise and occupied Toledo. When it seemed as if a conflict could no longer be prevented the matter was settled by the admission of Michigan to the Union as a State upon condition of her acceptance of the «Harris» line, and giving her in recompense the northern part of the peninsula of Wisconsin. Great deposits of copper and iron being found in this peninsula, Michigan accepted the conditions and entered the Union as a State 26 Jan. 1837. See United States, the Wars of the.

TOLERATION, a word meaning in its general sense forebearance without approval, as when a state has an established church, but other churches are tolerated — that is, their members are permitted to worship in their own way without interference on the part of the state. In this meaning toleration is different from the system of voluntary support of all churches without a state religion. It was much used in America, however, in a narrower, or perhaps a broader, sense, during the struggle to put an end to the compulsory support of Congregational churches by the taxpayers in certain New England States, especially Connecticut. Toleration is now universal in civilized countries, so far as permission to worship is concerned, but some restriction still exists as to bell-ringing by Roman Catholics in Sweden, and there is a certain degree of intolerance toward Protestants in some South American republics. Nowhere, however, in any country pretending to civilization is persecution on account of religious belief permitted by law.

In all ages enlightened minds have favored toleration. It was the rule among the ancient Greeks, and also among the Romans, until religion became so identified with state affairs that refusal to accept the state religion was treason to the government. Toleration was unknown in practice during the Middle Ages, although it had earnest advocates among Christians, Mohammedans and pagans. In modern times toleration has been a growth of the past three centuries. As late as the early part of the last century men were imprisoned in New England for refusing to pay taxes for maintenance of the local church. England removed Roman Catholic disabilities in 1829, but did not admit Jews to Parliament until 1858. In a legal sense toleration is now coextensive with civilization and semi-civilization, but education only can make it effective by causing a fraternal and tolerant spirit to take the place of intolerance and fanaticism, wherever the latter prevail.

TOLERATION ACT, a statute of William and Mary, under which freedom of worship was granted to Protestant dissenters from the Church of England, provided they made a declaration against transsubstantiation and took the oaths of allegiance and supremacy. See Toleration.

TÓLIMA, tō-lē'mä, Colombia, a volcano rising from the central cordillera of the Colombian Andes to a height of 18,320 feet.

TOLL, Eduard, Baron **von**, Russian explorer: b. 1850; d. 1902. In 1885 he began to explore the Post-Tertiary fauna of the Jana region, and in 1893 found the body of a mammoth in the ice near the delta of the Jana. Later he commanded the *Sarja* expedition which wintered on the west coast of Kotelnoi Island (1901–02) and discovered large deposits of Post-Tertiary fauna, including mammoths, reindeer, etc., in the great ice-cliffs there. With F. G. Seeberg he started south in November 1902, and perished on Bennett Island, where their records were found by Kolchek a year later. Consult Toll, Emma, 'Die Russiche Polarfahrt der Sarja' (Berlin 1909).

TOLL, a tax paid or a duty imposed for a privilege granted, such as the payment claimed by owners of a port of entry for the privilege of landing or shipping goods; the fee exacted by those who erect or maintain a bridge for the privilege of passing over the same; a portion of grain retained by the miller as his compensation for milling; a charge made by the owners of a fair or exhibition for the privilege of exhibiting or selling goods; a compensation for services, especially for transportation, as canal or railway toll. In the United States tolls, as applied to bridges and highways, are a subject for State legislation, while those applying to rivers and harbors are usually in the province of Congressional action. Tolls were at one time of international importance, since they were exacted on certain straits and tidal rivers by virtue of the sovereignty of a particular state, such as the Scheldt tolls and sound dues levied by Denmark. The tendency in the United States is to abolish tolls, and most bridges and highways are now free to the public. See TAXATION.

TOLMAN, Herbert Cushing, American Greek scholar: b. South Scituate, Mass., 4 Nov. 1865. He was graduated at Yale and studied at the universities of Berlin and Munich. He received his Ph.D., from Yale and was honored with the degree of D.D., from Peabody College and S.T.D., Hobart College, and LL.D., University of Nashville. From 1894 he was head of the Greek department of Vanderbilt University and is the author of several works on classical and philological subjects. His ‹Ancient Persian Lexicon and Texts› and ‹Ancient Persian Language and Cuneiform Supplement› were adopted immediately after publication by the universities of Germany and were recognized by foreign philological reviews as superseding what had yet been done in that line of research, while the American *Journal of Philology* and the New York *Nation* spoke of the author as the leading American authority in the field of ancient Persian language. He was the first to identify positively the hitherto unknown season of the Persian month, Garmapada, with June-July, an identification of great value to historians in fixing accurately several important dates. Dr. Tolman was elected president of Hobart College in 1913, but declined. In 1915 he was appointed dean of the College of Arts and Science of Vanderbilt University.

TOLMAN, William Howe, American safety engineer: b. Pawtucket, R. I., 2 June 1861. In 1882 he was graduated at Brown University and from 1894 to 1898 was general agent of the New York Association for Improving the Condition of the Poor. He also served as secretary of the New York commission on public baths and of the improved housing council of the same city. He is founder and from 1908 to 1916 was director of the American Museum of Safety. He has taken part in several international housing congresses and is member of several societies for social betterment, both American and foreign. Dr. Tolman is the author of ‹History of Higher Education in Rhode Island› (1891); ‹Municipal Reform Movements in the United States› (1894); ‹Handbook of Sociological Reference for New York City› (1894); ‹Report on Public Baths and Comfort Stations› (1897); ‹The Better New York› (1906); ‹Social Engineering› (1909); ‹Hygiene for the Worker› (1912); ‹Safety› (1913); also ‹Industrial Betterment,› a monograph prepared for the United States Section of Social Economy, Paris Exposition of 1900, and various review articles.

TOLOWA, tôl'ō-wä, originally the name of a village, but extended to designate a tribe of the Athapascan stock of North American Indians occupying the coast of California from a point a few miles north of the mouth of Klamath River northward to a short distance beyond the boundary of Oregon and the valley of Smith River. They were noted basketmakers and subsisted largely on salmon and other fish. In 1862 they were placed on a reservation, which was abandoned six years later, since which time they dwindled and largely disappeared.

TOLSTOY, COUNT **Lyof Nikolaievitch,** Russian novelist and social reformer: b. Yasnaya Polyana, government of Tula, 9 Sept. 1828; d. Astapova, 20 Nov. 1910. He studied languages and law at the University of Kazan. In 1851 he went to the Caucasus district as an ensign of artillery and he served in the defense of Sevastopol during the Crimean War. To this period of his career belong his earliest literary works, among them the autobiographical ‹Childhood, Boyhood and Youth,› the brilliant descriptions of the Crimean campaign entitled ‹Sevastopol in December 1854,› ‹Sevastopol in May 1855› and ‹Sevastopol in August 1855› and ‹The Invasion.› He left the army on the conclusion of the war and went to Saint Petersburg, where he made the acquaintance of Turgenev (q.v.) and other distinguished Russians and soon after he published ‹The Snowstorm› and ‹Two Hussars.› His first foreign journey was made in 1857 and marks an epoch in his spiritual history and on his return he retired to his estate to live a simpler life. He was greatly interested in the condition of the peasantry and founded a free village school on his property, for which he prepared reading and other textbooks himself. At the end of two years, however, the school was closed, both on account of opposition of the government inspectors and also the lack of interest among the masters and pupils. Later when he asked permission to reopen his school the government flatly refused. His ‹Family Happiness› was issued in 1859 and was soon followed by ‹Three Deaths› (1859), ‹Polikuschka› (1860) and others. In 1862 he married the daughter of a Moscow physician. The next period of his life saw the production of the two works upon which his literary reputation chiefly rests, ‹War and Peace› (1865–68), dealing with Napoleon's invasion of Russia, and ‹Anna Karenina› (1877), a powerfully realistic study of human passion and its effects. Soon after the completion of the latter novel Tolstoy began to develop his characteristic views of religion and its application to individual and social life. He believes that the Sermon on the Mount literally interpreted is the supreme law of the Christian life and he lays special stress on the precept, «Resist not evil.» His system has much in common with the anarchist-communism of his fellow-countryman, Kropotkin, but its peculiar religious basis gives it a unique character. In 1901 he was formally excommunicated by the Holy Synod of the Russian Orthodox Church and in a reply to the edict of excommunication he clearly enunciated his religious and theological views. These include the denial of the Trinity, of the deity of Jesus and his vicarious atonement, of orthodox conceptions of the future world, of every kind of sacramentalism and similar dogmas and are substantially identical with those of modern spiritual Unitarianism. Among the works of his latest period, in which his religious and social views are more or less expounded, are the following: ‹What the People Live By› (England 1889); ‹What to Do› (England 1889); ‹My Confession›; ‹My Religion›; ‹The Death of Joan Ilyitch› (1886); ‹Where Love is there God is Also›; ‹The Kingdom of God is Within You›; ‹The Kreutzer Sonata› (1890); ‹Work while ye have the Light› (England 1890), a tale of the early Christians; ‹The Power of Darkness,› a drama; ‹The Fruits of Enlightenment' (1891), a satirical comedy; 'Master and Servant'; 'Politics and Religion'; 'Patriotism and Christianity' (1894), on the Franco-Russian alliance, and 'What is Art?' (1898). 'Resurrection' (1900) is a powerful novel of the same type as 'Anna Karenina.' There are American translations by Dole, Hapgood and others (22 vols., New York 1902), and by Leo Wiener (24 vols., Boston 1904–05). Tolstoy gave up all privileges of rank in order to live a life of labor and asceticism and during the great Russian famine he found abundant opportunity for carrying out his gospel of social service. (See ANNA KARÉNINA; WAR AND PEACE). Consult De Vogüé, 'Le Roman Russe' (1888); Dupuy, C. E., 'Great Masters of Russian Literature' (New York 1886); Garnett, Constance, 'Tolstoy: His Life and Writings' (London 1914); Howells, W. D., 'My Literary Passions' (New York 1895); Lloyd, J. A. TOLTECS, tŏl'tĕks or tōl-tāks', an Indian tribe said to have occupied portions of the Mexican plateau previous to the advent of the Aztecs. Little is known of the race and that little only through Aztec traditions and picture writing. They are supposed to have come from the north and to have been supreme in their territory from the 7th to the 11th century. Their principal city was Tolan, where they settled about 661 A.D. from which they got the name Toltec. Lists of their kings or chiefs are extant — but these are considered untrustworthy by antiquaries. The hero-god Quetzalcohuatl is supposed to have lived in their cities before their overthrow, which came in 1013, when they were driven south by savage tribes. Aztec records tell no more of the Toltecs, but from the fact that the Quichés and other tribes from the north are known to have settled in Guatemala about this time, the inference is strong that they were banished Toltecs.

TOLUCA, tō-look'kä, Mexico, capital of the state of Mexico, 36 miles southwest of Mexico City, on a division of the National Railway, 8,761 feet above sea-level. Three steam railways — the Mexican National, the Toluca and San Juan and the Toluca and Tenango, all narrow gauge, supply transportation facilities and there is a well-equipped street railway. The city is situated in the beautiful valley of Toluca, just over the mountain range which forms the western background of the national capital. This valley, which lies at the foot of the Toluca Mountain, is one of the most notably productive and beautiful spots of the republic. The city was founded by the Matlatzinca Indians and was advanced to the title and rank of city in 1677. The industries include a brewery, large flour-mill, glass-bottle factory, two packing-houses and several modern creameries. There is a local bank — the Bank of the State of Mexico — a branch of the National Bank and an agency of the Bank of London and Mexico. The city is well paved and provided with beautiful plazas, one of which contains a monument in honor of the patriot priest, Hidalgo, dedicated in 1900. In another plaza is a life-size figure in bronze, of Morelos, while in still another is an imposing monument to Columbus. A museum supported by the state occupies a spacious building and the State Library, containing some 11,000 volumes, is located in the immediate vicinity. The principal buildings are the palace of the state government, the municipal palace, the Scientific and Literary Institute, civil hospital, School of Trades and Arts. Pop. 33,000.

TOLUENE, methyl benzene, $C_6H_5CH_3$, is an aromatic hydrocarbon present in American petroleum, in wood-tar and in coal-tar. Upon distillation coal-tar yields a fraction known as light oil, boiling at 100°–120° C. The toluene of commerce has been obtained from this fraction. Toluene has also been prepared (1) by the dry distillation of tolu balsam; (2) by heating brombenzene with methyl iodide and metallic sodium (Fittig Synthesis); (3) by treating benzene with methyl halide and dry aluminum chloride (Friedel-Craft Synthesis); (4) by heating toluic acid with lime.

The enormous demand for toluene created by the European War, made it the subject of a number of patents. According to Fr. P. 479, 295, the compound is made by passing hydrochloric acid into boiling methyl alcohol in the presence of dehydrated zinc chloride and conducting the methyl chloride produced into a mixture of benzene and dry aluminum chloride. Other patentees claim to have obtained toluene from gas-tar naphtha by distilling under pressure at 130°–240° C. (U. S. 1,225,237); or, from gas-drip naphtha, by passing it with steam and water-gas through checkerwork heated to about 800° C. (U. S. 1,230,087). To these may be added the widely-advertised «cracking» process, according to which toluene and benzene have been obtained by heating oils, containing aliphatic or aromatic hydrocarbons, at prescribed temperatures and pressures. The process has been tried on a large scale, but its success as a commercial enterprise has been seriously questioned. Of much greater importance are the improvements inaugurated for the extraction of the maximum amount of toluene from coke-oven or city gas supplies. It has been known for some time that only a small fraction of the toluene obtained from the by-products coke-ovens is recovered for commercial purposes, the greater proportion finding its way into city gas during the process of distillation. Toluene recovery plants have, therefore, been installed in all parts of the United States with the object of stripping illuminating gas of this material. As a result of this measure the toluene output for 1918 has probably exceeded 20,000,000 gallons. The maximum output for 1912–13 was not over 500,000 gallons.

Toluene is a colorless liquid with a boiling point of 110° C. and a specific gravity of 0.872 at 15° C. It is an excellent solvent for many organic compounds. With a side-chain that readily responds to a number of reagents and with a nucleus that can be nitrated, sulphonated, halogenated or reduced, toluene is capable of forming a large number of derivatives which are either useful commercial products or intermediates for the manufacture of explosives, synthetic dyes, perfumes, drugs, substitutes for sugar and poisons used in chemical warfare. Trinitrotoluene, saccharin, indigo-blue, brombenzyl cyanide, benzyl chloride, benzotrichloride, benzoic acid, nitrobenzaldehyde, toluidine, are some of the more important derivatives of this hydrocarbon.

V. S. BABASINIAN,
Lehigh University.

TOLUIDINE, $C_6H_4\langle^{CH_3}_{NH_2}$ exists like all disubstitution products of benzene in the ortho, meta and para modifications. When toluene is treated with nitric acid, a mixture of ortho- and para-nitrotoluenes is obtained. The reduction of this mixture yields the corresponding ortho- and para-toluidines. These are separated by strongly cooling the product, when the ortho compound remains as an oil, while the para compound solidifies and may be removed by filtration. Or, the mixed toluidines are treated with a quantity of sulphuric acid insufficient to effect complete neutralization; the ortho compound is now removed by distillation, while the para compound remains behind as a sulphate. It has also been noted that the oxalate of para-toluidine and its phosphate are much less soluble than the corresponding derivatives of the ortho compound. Upon these properties are based a number of methods for the separation of the two modifications. On account of the high cost of manufacture, meta-toluidine is used to a limited extent only. It has been obtained by the reduction of meta-nitrobenzal chloride. Meta-toluidine may be readily obtained from meta-nitrotoluene, but the latter can only be prepared on a commercial scale by indirect methods.

Ortho-toluidine is an oily liquid. It boils at 197°–199° C. and has a specific gravity of 1.102 at 4° C. Meta-toluidine is also an oily liquid with a boiling point of 203° C. and a specific gravity of 1.0041 at 4° C. Para-toluidine is a solid which crystallizes in leaflets. It melts at 43°–45° C. and boils at 190° C.

Ortho- and para-toluidines are important intermediates in the dye industry. After diazotization they may be coupled with *G* Acid to form Ponceau *G*, with *R* Acid to produce Ponceau *RT*, with beta-naphthol sulphonic acid *S* to form Orange *GT*, and with dioxy-naphthalene sulphonic acid *S* to yield Azofuchsine *B*. Magenta is an oxidation product of a mixture of toluidines and aniline; Primuline is a fusion and sulphonation product of pera-toluidine and sulphur; Mauveine, Safranine, Chloramine Yellow, Cochenille Scarlet 2*R*, Spirit Yellow *R*, etc., are obtained from toluidines. Simple derivatives of toluidines have also been used for the manufacture of certain pigments; thus diazotized nitro-toluidines have been coupled with beta-naphthol producing Orange *R*, Fast Red *HL*, Lithol and Fast Scarlet *R*.

TOM, known as **BLIND TOM.** See BLIND TOM.

TOM, Asia, a river in southern Siberia, in the government of Tomsk, rising in the Abakanic Mountains and after a course of 450 miles flowing northward into the Obi. It begins to be navigable at Kusnezk.

TOM BROWN'S SCHOOL DAYS, a story depicting English public-school life, written by Thomas Hughes and published in 1857, when the author was a young barrister of three-and-thirty. It leaped at once into a deserved popularity it has never lost. Tom is a typical middle-class lad, with the distinctive British virtues of pluck, honesty and the love of fair play.

TOM JONES. 'The History of Tom Jones, a Foundling,' a novel by Henry Fielding, was published 28 Feb. 1749 — a red-letter day in the calendar of English fiction, for this work in the opinion of many stands at the head of all novels ever written in our language. It succeeded several most interesting experiments in the novel of contemporary manners such as Richardson's 'Pamela' and 'Clarissa Harlowe,' Smollett's 'Roderick Random,' and his own 'Joseph Andrews.' When Fielding wrote 'Tom Jones,' his intellect, wonderfully observant and penetrative, was in full maturity; his pen had been long practised in the drama and the essay and in fiction; his mind was highly cultivated in the ancient and modern literatures; he had associated with all classes of people, the high and the low, and he had thereby gained a knowledge of the men and women of his time unsurpassed by any one then living. His aim was to present the very form and pressure of the age, and on the effort he expended "some thousands of hours." Having in mind the ancient epics, he divided his novel into 16 books, each with an initial chapter on the art and morality of that "new province of writing" which he claimed to be introducing to the British public. In its original form, 'Tom Jones' filled six volumes, containing, all told, about 350,000 words.

For his comprehensive view, Fielding began his delineation of character in the country with two Somerset gentlemen — Mr. Allworthy and Squire Western, the one a Hanoverian and the other a Jacobite. Into the household of Allworthy he placed a sister, Bridget, her maid, Deborah, a pair of nephews, Tom Jones and Master Blifil and their tutors, Square the Deist and Thwackum, the orthodox divine. Into the household of Western he placed a sister, Diana, a daughter, Sophia and her maid and former nurse, Mrs. Honour. Then, after describing life in the country while Tom and Sophia were growing up, he brought most of his characters up to London for contrast and interaction with more highly-seasoned men and women of the town. The manner in which Fielding conducted his story, concealing until the end the mystery of Tom's birth, has received the highest praise ever since the novel first appeared down to the eulogy by the late W. E. Henley. Scott, for example, likened the narrative to the easy flow of a river through lands affording wide prospects; Coleridge thought the nice structure of the plot was equaled only by that in the very greatest dramas, such as the 'Œdipus' of Sophocles. And in general, little exception has ever been taken to Fielding's craftsmanship beyond his introduction of the tale of the 'Man of the Hill,' the matter of which a modern novelist would manage differently. It is not to be inferred that Fielding laid out a plot by compass and rule. At the outset, he probably had in mind his conclusion, but nothing more. He wrote at leisure, remembering what he had seen and heard, letting his story develop as he proceeded, casting his mind backward and forward and gathering up at the end all the threads of his narrative into a consistent and impressive whole. This is the way that literary genius, in distinction from mere literary talent, works, and achieves its ends.

Apparently Fielding drew his characters in the main from real life. Where he followed his model too closely or where he deviated too far from it, his success was only partial. Squire Allworthy, who had an original in Ralph Allen, the philanthropist of Bath, is altogether too good for this world; he lacks those elements which really make a man, lovable and humorous as he is. Likewise Blifil, for whom no original was ever claimed, is hardly more than a stage villian, whose hypocrisy is so transparent that it should have been detected long before it had a chance to work its mischief. Thwackum and Square, though rather artificial creations, are always entertaining, for they have enough of reality to support their humorous pretensions. Partridge, the schoolmaster and barber, superstitious and afraid of his dreams, interested Voltaire greatly. Minor characters, like Diana Western, Mrs. Honour and Bridget Allworthy, are almost always admirable. For a superb creation we turn to Squire Western — the fox-hunting squire who goes to bed drunk and gets up in the morning before daybreak to follow the hounds, who loves his daughter better than all other creatures except his kennel, who quarrels with his sister, swearing great oaths referential. Under the excitement of Sophia's refusal to marry Blifil, he develops into a veritable whirlwind of contending passions. The height of the storm is reached in certain scenes with his sister, which, brutal as they are, have never been surpassed for humor in this language of ours. His daughter, Sophia, for whom Fielding's own wife, Charlotte Cradock sat, is a portrait of unusual charm. She is a real woman depicted in all her beauty, fine breeding, self-poise, modesty, vivacity and independence when the inevitable struggle comes between paternal tyranny and the promptings of her own heart. She wins the first great battle in our fiction for the enfranchisement of her sex.

The crux of the novel has always been the hero, who resembles Fielding himself in temperament but not in the incidents of his career. He is kind, generous, chivalrous and perfectly honest, but he is lacking in practical sense, and so falls into all sorts of mistakes in conduct. He loves Sophia desperately and would win her at all hazards. This passion, however, does not protect him against the allurement of other women, and herein lies the trouble. Generous critics overlook the boy's affairs with Molly Seagrim and Mrs. Waters, but they halt at the intrigue with Lady Bellaston. Had Fielding thrown in a word of explanation over that intrigue, Coleridge would have excused all. Here arises a question that may be interminably debated. Fielding himself thought no explanation necessary. He depicted the young man of his time as he was without comment. In thus keeping his art true to nature he acted rightly.

The influence of 'Tom Jones' cannot be well considered apart from the influence of Fielding's other works. The novel was immediately translated into French, Dutch and German, and subsequently into Spanish, Italian, Polish and Russian. The French imitated it, dramatized parts of it and turned it into a comic opera. The Germans appropriated its disquisitions on the art of fiction and to some extent wrote novels in its style. 'Tom Jones' has probably been reprinted in English a hundred and fifty times. To pass by a host of imitations, it suggested the general outline of plot to Scott for 'Waverley,' his first novel; its spirit permeates the best work of Thackeray, and 'Pendennis' was written in direct imitation. In short, to 'Tom Jones' nearly all succeeding novelists are indebted who have aimed to depict life, not as it ought to be, but as it really is. Since Fielding's day fiction has extended its scope to include things never dreamed of by him; but for method, manner and procedure his art is the source. Scott called him "the Father of the English Novel."

WILBUR L. CROSS.

TOM MOUNTAIN, in Hampshire County, Mass., between Holyoke and Northampton, and overlooking the Connecticut Valley. Though only 1,214 feet in height, thousands of tourists ascend Mount Tom each year on account of the grand view from its summit.

TOM THUMB. See STRATTON, CHARLES SHERWOOD.

TOM-TOM, or **TAM-TAM,** a native East Indian drum used by musicians, jugglers, public criers, etc. It is generally cylindrical in form, the depth of body being about three times the diameter of the heads, of which there are two. It is made of resonant wood or of hard-baked earthenware, and the heads are covered with skins, drawn tight by side-lacings, as in the modern drum. It is beaten with the fingers or the open hand and produces a hollow monotonous sound. Similar instruments used by the natives of western Africa receive the name of tom-tom, as do also certain types of Chinese gongs.

TOMAH, Wis., city in Monroe County, on the Chicago, Milwaukee and Saint Paul Railroad, 42 miles northeast of La Crosse. It is the site of a government industrial Indian school and contains the railroad bridge works and a large saw-mill. Pop. about 4,000.

TOMAHAWK, Wis., city in Lincoln County, on the Chicago, Milwaukee and Saint Paul and the Marinette, Tomahawk and Western railroads. It is 23 miles north of Merrill on the Wisconsin River. The principal industries are saw-mills, woodworking plants, pulp and paper factories and a tannery. Pop. about 3,000.

TOMAHAWK, a weapon of warfare of North American Indians, a light war axe. Before the advent of the white traders the head of the axe was usually a piece of stone sharpened at both ends and put through a piece of wood for a handle; sometimes the stone was two-edged and more like a modern double-axe; sometimes hard horn was sharpened and used in the place of the stone. But the white traders brought the natives, iron hatchet heads and the stone ones were gradually discarded. These hatchets had but one cutting edge, the other shorter end being formed into a hammer-head, or oftener into the bowl of a pipe, which communicated with a tubular hollow made in the handle, thus made to serve as a pipe stem. From the custom of the Indians of burying their tomahawks when they made peace with a foe comes the custom of saying that two opponents who have made peace have "buried the hatchet."

TOMALES, tō-mä'lĕs, a bay on the coast of California, reaching the ocean, about 40 miles north of San Francisco. It is a narrow inlet of the Pacific, the railroad is near and parallel to its eastern shore, and Tomales Point is on the west, separating the bay from the ocean. The village of Tomales is a short distance inland.

TOMAN, or **TOMAUN**, a current gold coin of Persia, varying in value from $1.75 to $2.25 or even higher. In Persia it is reckoned as the equivalent of 100 schahis or shakis.

TOMATO, a perennial herb (*Lycopersicon lycopersicon*) of the family *Solanaceæ*. It is a native of western South America, whence it was introduced into cultivation in Europe during the 16th century. At first the wrinkled fruits were regarded with suspicion or disfavor, and were more popular as garden ornaments than for other purposes. During the 18th century both yellow and red-fruited sorts were known, but not until the middle of the 19th century was there a decided improvement in the form of the fruit. At the beginning of that century the fruits were used to a small extent for pickles and preserves, but less for other purposes. The development of the tomato both in its form and its popularity as a vegetable is mainly due to the care of plant-breeders, who have eliminated the wrinkles from the fruit, and to the development of perfect methods of canning. The annual consumption of tomatoes, both as a salad and cooked or preserved in various ways, aggregates thousands of tons in the United States, where the crop is more widely grown than in any other country of the world. The season opens in mid-winter in Florida and the Mississippi delta, and advances northward until September, when it ends in Canada. Considerable quantities of tomatoes are forced in greenhouses at various seasons, but especially during the spring months.

Though perennial in its native country and in other frostless climates, the tomato is best known in the temperate regions as an annual herb. It is a straggling, clammy, ill-smelling, grayish-green plant with variously formed pinnate leaves and small racemes of small yellowish flowers, followed by fleshy many-seeded berries which in some improved horticultural varieties weigh more than a pound. Several botanical varieties have been recognized, among which the following are best known: Cherry tomato (*L. lycopersicon*, var. *cerasiforme*), grown in gardens for its little yellow or red globular fruits which are used for home-made preserves and pickles; pear and plum tomato (var. *pyriforme*), similar to preceding except in form of fruit; large-leaf tomato (var. *grandifolium*), a group of varieties originated during the closing quarter of the 19th century, and including some of the most important commercial varieties; the common tomato (var. *vulgare*), the most widely cultivated form in America. One other species is cultivated, more for ornament than for its fruit, which, although edible, is too small for general household use; it is the current tomato (*L. pimpinellifolium*), also known as the German raisin tomato. The plant is very spreading and branchy, with small egg-shaped leaves and long racemes often bearing more than 30 currant-like red fruits. It has produced hybrids with the preceding species, and is useful for covering unsightly objects during the summer. The former species has been grafted upon its close relative, the potato, but the two plants have never been known to cross-fertilize. These grafts are interesting as curiosities but not otherwise.

Several other plants have been called tomato; the best known are probably the husk tomato (*Physalis pubescens*), also known as the strawberry tomato, ground cherry and dwarf cape gooseberry. It is popular in gardens for its fruits which are made into preserves or kept in their husks in cool dry rooms until needed for use in mid-winter. The name strawberry tomato is also given to *Physalis alkekengi*, better known by its specific name and as the winter cherry or bladder cherry. The red fruits are edible, but are not generally relished. The plant is chiefly ornamental on account of its very showy blood-red calyces. The tree tomato (*Cyphomandra betacea*) is cultivated to a small extent for its light brown, egg-shaped fruits, which resemble the tomato in flavor but are rather more musky and acid.

In cool climates the seeds are generally sown under glass in early spring and pricked out in flats, boxes or pots when the first pair of true leaves appear, allowing them to stand in the former not closer than three by three inches, or two by six inches. Abundant ventilation should be given at all times and the temperature kept rather low to make the plants grow stocky and able to adapt themselves readily and without check to the conditions of the field. At this time they should be about five inches tall. The sturdier the plant, the less is it likely to suffer under ordinary conditions and care when set in the field, the earlier will it commence to bear, and the more profitable will be the fruit.

Whenever possible the tomato should be planted on rather rich loamy soil of medium texture and well exposed to the sun. Good drainage is essential. It is generally considered best to apply stable manure to previous crops, because the applications made during the current year are thought to impair the flavor of the fruits as well as to induce a rampant growth of vine at the expense of productivity. In the field the plants are usually set four to five feet apart each way, and when grown extensively each sixth or eighth plant in the row is omitted and each 15th or 20th row is skipped, so as to facilitate harvesting with least injury to the vines, wagons being driven across the field to distribute the empty crates and collect the full ones. Until the vines spread and thus prevent tillage, cultivation is given weekly to keep the surface lose and free from weeds. Often a top dressing of some readily soluble fertilizer is given after the plants have been in the field about a month.

For home use and for fancy markets tomatoes are often trained in many ways, especially to stakes, upon slat frames and trellises. For such the plants are subjected to more or less pruning and tying, which usually vary with individual growers. But the single stem is usually conceded to be the best method of growing such plants. The advantages secured by training are early ripening and better colored, larger sized and superior flavored fruits.

Since the vines are tender to frost the tomato is usually cut short before mid-autumn. There are, however, at that time many fruits approximately mature, besides large quantities less advanced. The former may be gathered and ripened in warm rooms or sunny windows, and by storing in cool places from which they can be removed to warmth as needed the season may be extended several weeks after the vines have been destroyed. The greener fruits are widely used for making sweet pickles, chowder and «India relish.»

In greenhouses the tomato is one of the most popular vegetable crops. Though it is often grown in special houses or as the leading crop it is probably more frequently employed as a successor to carnations and some other greenhouse plants, which either commence to fail in the early spring months or have a smaller sale when brought into competition with spring flowers. The fruits are sought about Easter time and from then until the out-door plants commence to bear the greenhouses may often be very profitably employed. Hand pollination is generally considered essential to the setting of the fruit and the labor this involves is often a drawback on account of its expense. The plants are raised usually from seeds, sometimes from cuttings, or the rooted tips of plants which previously occupied the benches. They are planted in soil similar to that in favorable fields, either in solid beds, on shallow benches, or in boxes or pots, the second being preferred. The plants are usually trained to a single stem supported either by a stout cord suspended from the sashbars, or upon a trellis, the former preferred. Two feet apart is the favorite distance; five feet the preferred height; a minimum temperature of 60° is the lowest night temperature; 65° being preferred by most growers. Abundant light and air must be given at all times, but water must be carefully controlled, especially in cloudy weather, because the plants are apt to grow too rapidly to foliage if water is in excessive supply. During the winter months an average crop of three pounds of fruit to each plant trained to a single stem is considered fairly good. In the spring months four pounds is perhaps below the average. Unless 30 cents a pound can be realized during the winter the crop is rarely paying, and many growers set the profitable figure at 40 cents a pound. In the spring a somewhat lower price with a rather higher average production makes the crop profitable.

The more progressive tomato growers are alive to the fact that the so-called plant diseases which have been reported injurious to the tomato are more readily prevented by intelligent management of the plants than by the use of so-called remedies. Every effort is, therefore, made to keep the conditions in the seed bed as well as in the field as favorable as possible. Adequate ventilation, rather low temperature and limited water supply are found conducive to the health of the seedlings. And sturdiness at the time of setting in the field is a safeguard against subsequent troubles. Growers whose methods produce inferior plants, or who are negligent in various other respects, often suffer serious losses; and perhaps the majority still have recourse to fungicides, none of which have been found fully satisfactory and in some instances have failed completely from the first trial.

Many insects feed upon the tomato, but very few are usually numerous enough to do serious damage. The best known are probably the boll-worm (*Heliothis armigera*), the tobacco-worm (*Phlegethontius carolinus*) and various species of cutworms. Flea-beetles, potato-beetles and thrips are also well-known enemies. As a rule, however, they are not responsible for serious damage. The larger species are generally picked off by hand and the smaller are driven away to other plants by the use of repellants such as tobacco dust, Bordeaux mixture, etc. See FUNGICIDES; INSECTICIDE.

M. G. KAINS,
Horticultural Consultant.

TOMB, a vault, cavity, niche, excavation or chamber to receive the dead body of a human being; also the monument erected to his memory, or the combined structure that answers both of these purposes. Among Eastern peoples it early became the practice to place the remains of the dead in excavated chambers or in case the dead bodies were first burnt, to place urns containing the ashes in such chambers. These structures even in times of great antiquity were decorated within or without with appropriate inscriptions. Early tombs often bore character writing, telling of the parentage and the place of residence, perhaps the station of life, of the deceased, and, in the case of heroes, the history of achievement was in all likelihood carved on the walls of the structure. Rude peoples whose only means of written expression was by picture-writing have employed that language to tell of the exploits of dead. Tombs are often designed to contain the remains of more than one person, and of such were the Roman columbarium and the Egyptian pyramids. With some races tombs were made elaborate objects of art; with others, such as the Greeks, they were highly artistic but simple and tasteful. The stele or flat stone set up to mark a grave was often highly carved, and the stele of Dexileos in Athens is famous. Large edifices built as monuments to the dead are not found in Greece, but were common in the semi-Greek lands of Asia, the most noted being that of King Mausolus of Caria, whence comes the term mausoleum (q.v.). Roman monuments were of great splendor, as is attested by the few examples remaining to the present time. They were often of large proportions, the so-called «Castle of Saint Angelo» being nothing else than the tomb of the Emperor Hadrian and his successors, «stripped of its sculptures, its marble colonnade, its probable conical superstructure,» and crowded with defensive works that make of it a veritable citadel. Other tombs of great splendor are found outside of the walls of Rome and although despoiled and in some instances subverted to the purposes of other, adjacent architectures, they testify to the wealth and the artistic attention which the Romans bestowed on them. Pompeii, too, had its long street of magnificent tombs, which has been partially uncovered outside the limits of the city proper. In portions of Italy and in some of the older Spanish-American towns burials in the cemeteries were made in niches which rose row above row, terrace-like. In the niches rested coffins bearing the bodies. Burial in churches was prohibited during the earlier centuries of Christianity, but from the custom of erecting churches or chapels over graves of martyrs the custom arose to bury monarchs under the cover of the church, and the most important tombs of the Middle Ages are generally so situated. The earlier examples consist of a simple stone coffin or sarcophagus, often with a low, gabled lid and a sculptured cross. Following these come the altar-tombs, in the form of a table, and subsequently, in the 13th century, a species of tomb consisting of a sarcophagus bearing a recumbent figure of the deceased, the whole surmounted by a canopy, often of exquisite beauty of design. Still more stable are the churchyard tombs of which fine examples are seen in the tombs of La Scala in the churchyard of Santa Maria Antica in Verona. The tombs of the Renaissance period became more and more complex. The sarcophagus was disguised and subordinated to the decorations of sculptured upholstery and groups of symbolical or mythological figures. Immediately following the Middle Ages the beauty and value of the statuary employed partly compensated for the loss of architectural design, as is the case in Michelangelo's tombs; but in succeeding years this redeeming feature was lost and tomb architecture rapidly declined. The tomb placed in a niche in a church naturally suggested the memorial tablets of more recent years. The tomb of the Virgin Mary is venerated near Jerusalem, in the Cedron Valley. The sepulcher is completely below the present ground level, and is reached by a stone stairway descending 48 steps. Consult the pamphlet by Jean Baptiste Christyn, ‹Les tombeaux des hommes illustrés,› etc. (1674); and the paper by L. S. Mercier, ‹Le tombe di Verona› in ‹Teatro italiano moderno› (Vol. II, 1792).

TOMBAC, an alloy consisting of from about 75 to 85 parts copper, mixed with 15 to 25 parts zinc, and used as an imitation of gold for cheap jewelry. When arsenic is added it forms white tombac.

TOMBIGBEE, tŏm-bĭg'bĭ, a river rising in Tishomingo County, in the northeast corner of Mississippi, and flowing south to Lowndes County where it enters Pickens County in Alabama. It continues an irregular southern course and unites with the Alabama River, 45 miles north of Mobile Bay. From the point of junction the waters enter Mobile Bay by Mobile (q.v.) and Tensas (q.v.) rivers. The total length is over 500 miles. It is navigable for 412 miles from Mobile Bay, to Aberdeen, Miss.

TOMBS, The, a noted city prison in New York. It occupies the entire block bounded by Center, Elm, Leonard and Franklin streets, and is connected with the criminal courts building on the other side of Franklin street by an upper story closed passage, locally known as the «bridge of sighs.» The Old Tombs building built in 1838 was replaced in 1898 by a new structure on the Center street side. Part of the old building still standing indicates something of the fine Egyptian architecture in which the original structure was built. Its proportions are grand in their beauty, but they are dwarfed into insignificance by its situation and by the high commercial buildings surrounding it. The prison covers the site of the pre-Revolutionary gibbet and, therefore, stands on ground long dedicated to penal punishment. Its internal arrangement is into corridors of cells which rise in tiers one above the other. It is used almost wholly for prisoners awaiting trial.

TOMCOD, or FROST-FISH, a species of small cod (*Microgadus tomcod*) of the North Atlantic, usually abundant in the mouths of the rivers after the first frosts of autumn. It is from 4 to 12 inches long, olive green above, and silvery below. It is a valued food-fish, and has several useful relatives on the Pacific Coast.

TOME, Jacob, American philanthropist: b. York County, Pa., 13 Aug. 1810; d. Port Deposit, Md., 16 March 1898. In 1833 he settled in Port Deposit, and there acquired a fortune in business. In 1864 he entered political life as State senator, being chairman of the Senate Finance Committee, and was instrumental in reducing the indebtedness of the State greatly to the public welfare. His public benefactions include a large gift to Dickinson College, and the establishment of a technical school, the Jacob Tome Institute, at Port Deposit, which he erected at a cost of $1,600,000, and by his will permanently endowed with an equal sum.

TOMÉ, tō'ma. See CONCEPCIÓN, CHILE.

TOME, a post-village in Valencia County, New Mexico, on the Rio Grande River. Early in the 16th century it was settled by the Spaniards and for years was the seat of government. In 1708 it was destroyed by the Comanche Indians, since which time it never has regained its importance in the locality. Pop. about 500.

TOME INSTITUTE. See JACOB TOME INSTITUTE.

TOMLINSON, Everett Titsworth, American author: b. Shiloh, N. J., 23 May 1859. He studied at Williams College, and afterward taught in various preparatory schools in the Eastern and Middle States, but in 1894 began to devote himself to literature, particularly to the writing of historical books for children. His publications include: ‹The Boy Soldiers of 1812› (1895); ‹Three Young Continentals› (1896); ‹Tecumseh's Young Braves› (1897); ‹Washington's Young Aide› (1898); ‹A Jersey Boy in the Revolution› (1899); ‹Under Colonial Colors› (1902); ‹Young Folks' History

TOMMASEO, tŏm'mä-zä'ō, **Niccolo**, Italian philologist and philosopher: b. Sebinico, Dalmatia, about 1802; d. Florence, Italy, 1874. He studied law in Padua but turned to literature and became known as a poet and critic. He was forced to leave Florence where he was colloborating with Viessieux in publishing his 'Antologia' which was suppressed by the government. He then went to Paris where he devoted his time to making the French and Italians better acquainted. In 1838 he went to Corsica where he made a collection of popular songs which were published in 1841. He returned to Venice where he was arrested in 1848 for his liberal opinions, but was freed by the Manin insurrection. Finally settling down in Turin he began (1854) to publish his great dictionary of the Italian language. He was distinguished for his vast and accurate knowledge as a philologist and for his constant efforts to educate the people. He was the author of a number of works in Italian.

TOMMY ATKINS, a generic nickname applied to the British soldier. It originated many years ago from certain printed forms — enlistment applications and military accounts, wherein, as a model, the name «Thomas Atkins» was inserted, like the mythical «John Doe» of American documents.

TOMOCHICHI, tō'mō-chē'chē, a chief of the Yamacraw branch of the Creek confederacy: b. in the town of Apalachicola, Ga., about 1642; d. at Savannah, Ga., 1739. He withdrew from the confederacy and with his followers went to live at Yamacraw Bluff on the Savannah River where he was instrumental in making a treaty of peace with Governor Oglethorpe and in securing the ceding of important territory by the Creeks. In 1734 he accompanied the governor on a visit to England.

TOMPKINS, Charles H., American soldier: b. Fort Monroe, Va., 12 Sept. 1830; d. Washington, D. C., 1895. He studied at West Point, but resigned without completing his course. In 1856, however, he enlisted in the dragoons, and was promoted first lieutenant in the Second United States Cavalry in 1861. At the outbreak of the Civil War he was assigned to service in the defense of the national capital and was engaged in one of the first reconnoitering expeditions. He was particularly distinguished for bravery in the Shenandoah campaign, and was brevetted brigadier-general in 1865. After the war he served as chief quartermaster in various divisions of the army, and in September 1894 was retired with the rank of colonel.

TOMPKINS, Daniel D., American statesman: b. Westchester County, N. Y., 21 June 1774; d. Staten Island, 11 June 1825. He was graduated at Columbia College in 1795, and afterward admitted to the bar, but soon entered political life. He was a member of the New York legislature and of the State Constitutional Convention in 1801 and in 1804 was elected to Congress, but was appointed to the State Supreme bench, and accepted that position instead of going to Washington. He was governor of New York in 1807–17 and in 1817–25 was Vice-President of the United States. He took an active part in the War of 1812, and was one of the strongest and most able opponents of slavery. It was largely through his influence that the bill abolishing slavery in New York was kept before the legislature, but he did not live to see its enactment.

TOMPSON, Benjamin, American poet: b. Braintree, Mass., 14 July 1642; d. Roxbury, Mass., 13 April 1714. He was graduated from Harvard and was long a teacher at Cambridge. He wrote 'New England's Crisis,' a long poem of King Philip's War.

TOM'S RIVER, N. J., village, county-seat of Ocean County, on the Pennsylvania and the Central of New Jersey railroads, about 50 miles east of Philadelphia, 36 miles southeast of Trenton and four miles from Barnegat Bay. It is one of the colonial villages of New Jersey, and in the Revolutionary days was a haven for privateers. The salt found here made it a place of importance in the settlement days. On 24 March 1782 the village was burned by the British. It is now a favorite summer resort. The chief industries are connected with the care of summer guests; but there are considerable shipments of cranberries, farm products, fish and oysters. It contains five churches, four schools and one bank. Permanent population about 1,500.

TOMSK, Asia, in western Siberia, (1) capital of the government of its own name, on the Tom (q.v.). It is the seat of a governor and of a bishop and of the educational district of West Siberia. It has 20 Russian churches, monastery, convent, synagogue, mosque, university with three faculties and 900 students, technological institute, theological seminary and various other schools for both sexes; also various scientific societies, Russian musical society, theatre, library, halting station for deported Russians, banks, harbor, etc. The industrial works comprise tanneries, distilleries, wagon factories, etc. There is a brisk transit trade with Siberia. It lies on a branch of the Siberian Railroad. Tomsk dates from 1604. Pop. about 117,000. (2) The government has an area of about 330,000 square miles and is in the south and southeast mountainous, and embraces the Altai system. The Obi and its tributaries are the chief streams. There are vast swamps in the flat districts. The climate is very cold and unhealthful. Storms and earthquakes occur often. Pop. about 4,000,000.

TON, a measure of weight and capacity, equivalent to 20 hundred-weight. As the historical «hundred-weight» of Great Britain and the United States contains 112 pounds, the ton is reckoned as 2,240 pounds. This is known as a «long» ton. In some of the States legislation has made the ton consist of 2,000 pounds, being 20 hundred-weight of 100 pounds each. This is known as a «short» ton. United States laws make the ton equal to 2,240 pounds when not otherwise specified. A metric ton is 1,000 kilograms, or 2,204.6 pounds avoirdupois. A ton of earth is the equivalent of 21 cubic feet. As a measure of capacity, of a vessel or a car, a ton is 40 cubic feet; this is an «actual» ton. The «register» ton contains 100 cubic feet. See TONNAGE.

Applied to liquid measure the word, in the form tun, was in common use with the old English wine dealers. A tun of beer contained 216 gallons, of 282 cubic inches each, while a ton of wine contained 252 gallons of 231 cubic inches each.

TONALITY, *in music,* the character and quality of tone. Good tonality demands: correctness of pitch, the production of sounds slightly out of tune being termed of doubtful tonality; correctness of intonation; and correctness of key relation, a passage wanting in definiteness of key or scale being termed of uncertain tonality. The word has been adopted by art critics and is applied to painting in considering the system of tones, or the color-scheme, of a picture.

TONAWANDA, tŏn-a-wŏn'da, N. Y., city in Erie County, on the Niagara River, Tonawanda Creek and Erie Canal, and on the New York, Central and Hudson River Railroad, opposite North Tonawanda and 10 miles north of Buffalo. Several railroads pass through and electric lines connect with Buffalo and Niagara Falls. It is in a fertile agricultural region, and on account of the good water power extensive manufacturing interests have been developed. The chief manufactures are steel, lumber and lumber products and paper boards. There are about 75 manufacturing establishments making products of the annual value of $2,500,000. The educational institutions are a high school, public and parish schools and a public library. The two banks have a combined capital of over $300,000. Pop. 9,147.

TONBRIDGE, English market town in Kent, 29 miles southeast of London, on the Medway River. It contains the remains of a mediæval castle which stands near the entrance to the town, a parish church and a grammar school founded about 1550. It is noted for the manufacture of a peculiar kind of wooden ware known as «Tonbridge ware.» Pop. about 17,500.

TONDO, tōn-dō', Philippines, a district of the city of Manila, the most northern district on the bay shore. The streets are mostly narrow, the houses built of cane and nipa; it contains a large church and convent, the station of the Manila and Dagupan Railroad, and the city slaughter-house. The inhabitants are mostly fishermen and laborers engaged in the tobacco and cigar industries.

TONE, Theobald Wolfe, leader of the United Irishmen: b. Dublin, 20 June 1763; d. there, 19 Nov. 1798. He was graduated at Trinity College, Dublin, in 1786, practised law for a time without much success and gradually politics became his absorbing interest. He held republican opinions, and believed that Ireland ought to assert her rights as an independent nation; but the objects of the clubs of United Irishmen started at Belfast and Dublin in 1791 were limited to legislative reform. In 1792 he was appointed secretary of the general Catholic committee. The government came to know through a spy that he had given information in 1794 on the question of invasion to an emissary of the French government, but they permitted him to leave the country and go to America. He sailed from New York to France in 1795, and urged the French government to undertake an invasion of Ireland. He was adjutant-general in Hoche's abortive expedition against Ireland in 1796, and he afterward served under Hoche on land. He accompanied one of the small French expeditions sent to assist the Irish rebels in 1798, but was taken prisoner after a brief naval engagement near Lough Swilly. He was tried by court-martial at Dublin, convicted of treason, and ordered to be executed within 48 hours. He, however, cut his throat in prison. Consult the edition of his journals and political works, with a 'Life,' by his son (1826), of which a new edition, entitled 'The Autobiography of Wolfe Tone,' was issued by Barry O'Brien (1893).

TONE, sound considered with reference to its pitch, timbre, duration and volume. Nearly all tones in music are composite, consisting of several simple constituents having different rates of vibration and known as partial tones. They vibrate according to fixed laws, the pitch depending on the nature of the sonorous body and the mode of producing its vibration. The partial tone having the lowest pitch (and usually the loudest sound) is called the prime or fundamental tone, while the other partial tones are called accessories, harmonics or overtones. Tones differ in quality or timbre according to the number and relative force of their partial tones. A pure tone is a simple harmonic vibration. The seventh tone of a scale is called the characteristic tone; two tones coalescing are termed combinational. The interval of a major second is called a tone or whole tone, half of such interval being a semitone. When a piano key is sounded it produces a note, and the character of that note is a tone; the character of all the notes of an instrument gives the tone of the instrument. See NOTE; PITCH.

TONER, Joseph Meredith, American physician: b. Pittsburgh, Pa., 30 April 1825; d. Washington, D. C., 1 Aug. 1896. He was graduated at the Jefferson Medical College in 1853 and established himself as a medical practitioner in Washington in 1855. He was the originator of the plan for the American Medical Association Library established in Washington in 1868 and made a part of the Smithsonian Institution, founded the Providence Hospital and Saint Ann's Infant Asylum in Washington and in 1871 the Toner lectures under the auspices of the Smithsonian Institution. He devised the system of symbols for the indication of geographical localities which was adopted by the Post Office Department and made valuable researches into early American medical literature. His collection of 26,000 medical books and 18,000 pamphlets he presented to Congress in 1882. His publications include

'Maternal Instinct, or Love' (1864); 'Medical Register of the United States' (1874); 'Annals of Medical Progress and Medical Education in the United States' (1874); 'Medical Men of the Revolution' (1876), etc.

TONGA, tŏng'gạ, or **FRIENDLY ISLANDS,** Polynesia, a group of islands under British protection, situated in the south Pacific Ocean, mainly between lat. 18° 30' and 22° 30' S., and between long. 173° and 176° W., southeast of the Fiji Islands and southwest of Samoa. They are sometimes classified as three groups, the Tonga-tabu, Haabai and Vavan. The group consists of about 200 islets with a total area of 390 square miles. The largest, Tongatabu, is 20 miles long. The islands are partly volcanic and mountainous, partly of low coral formation. They have been subject to considerable changes in modern times by volcanic action. The soil is fertile and the vegetation luxuriant. The chief exports are copra, fruits, mats and sponges. The annual imports and exports total each about $350,000, trade being mainly with Australia and New Zealand. The larger islands are visited every fortnight by vessels of the New Zealand Union Steamship Company. The inhabitants belong to the finest of the Polynesian types. They are peaceful, civilized and Christian, being mostly Wesleyan Methodists. Excellent schools and a college have been established by missionaries. The immediate ruler is King George II and native council, whose capital is Nukualofa on Tongatabu. The islands were discovered by Tasman in 1643. In 1845 they were united under one king. In May 1900 they were declared under British protection. Pop. about 24,000, including 380 Europeans.

TONGAS, tŏng'gạz, a tribe of the Kaluschan stock of North American Indians, residing around Cape Fox and at the mouth of Portland Canal, southeastern Alaska. They number about 250.

TONGRES, tôngr, Belgium, a town in the province of Limburg, on the Geer, 12 miles north of Liege. The church of Notre Dame (1240) is the first dedicated to the Virgin in the north. The cloister belongs to the 10th century. The industrial works include tanneries, distilleries and hat manufactories. The population before the war was about 10,000.

TONGUE, the principal organ of the sense of taste and an essential part of the apparatus of speech in human beings. The name tongue is also given to various structures in invertebrates, as the proboscis of a lepidopter or the odontophore of a shellfish. In man the tongue is attached by its base or root to the hyoid bone and to the epiglottis. Its tip, sides, upper surface and part of its under surface are free. Its under surface is fixed to the lower jaw by the genio-hyoglossi muscles and from its sides the mucous membrane is reflected on the inner surface of the gums. In front of the under surface a fold of the mucous membrane is specially developed and is named the frenum linguæ. The upper surface is convex and bears a deep middle line, the raphé, which ends behind in a deep follicle or sac — the foramen cœcum. Two-thirds of the forward portion of the organ are rough and bear the characteristic structures known as papillæ, in which the sense of taste resides. The posterior third is smooth and exhibits the openings of numerous mucous glands. The substance of the tongue consists of numerous intrinsic muscles, which are named superior and inferior longitudinal and transverse muscles. The mucous membrane consists of an upper layer or cutis supporting papillæ and covered with epithelium. This cutis supports the blood-vessels and nerves and into it the muscles of the tongue are inserted. The papillæ, which cause the characteristic roughness of the tongue, are of three kinds. The circumvallate papillæ number from eight to 10. They are of large size and are placed on the hinder part of the upper surface and extend from the raphé in two diverging lines. Each of these papillæ consists of a rounded central and flattened disc, situated in a cup-shaped depression or fossa. The exposed part of the papilla is itself covered with numerous smaller papillæ. The fungiform papillæ are more numerous than the circumvallate and are scattered irregularly over the upper surface of the tongue, but are most plentiful on its apex and sides. They are of large size, of rounded, projecting form and of a deep red color. The filiform or front papillæ are of very small size and are arranged in rows corresponding with the rows of the circumvallate papillæ. In structure the papillæ are like those of the skin (q.v.) and contain loops of capillary vessels as well as nervous filaments. The mode of termination of the nerves in the papillæ is hardly determined. Numerous follicles and mucous or lingual glands exist on the tongue, the functions of these latter being the secretion of mucus (q.v.). The epithelium (q.v.) of the tongue is of the flat or scaly kind, resembling that of the epidermis or outer skin, but the deeper cells of the epithelial layer do not contain any pigmentary or coloring matter. The muscular halves or substance of the tongue are divided in the median line by a fibrous septum. The arteries are derived chiefly from the lingual and facial trunks and the nervous supply is distributed in the form of three main nerves to each half of the organ. The gustatory branch of the fifth nerve supplies the papillæ in front and those of the sides. The lingual branch of the glossopharyngeal nerve supplies the mucous membrane at the sides and base and also the circumvallate papillæ, while the hypoglossal nerve is distributed to the muscular substance of the organ.

The gustatory nerves and glossopharyngeal branches are the nerves which provide the tongue with common sensation and also with the sense of taste, the hypoglossal nerve being that which invests the muscles of the tongue with the necessary stimulus. The conditions which appear to be essential for the exercise of this sense are: (1) the solution of the matters to be tasted — that is, their presence in a form in which their particles may readily come in contact with the nerves of taste, there being thus a strong analogy between the sense of taste and that of touch, since the latter sense must be in a manner exercised before the taste of any substance can be perceived; (2) the presence of a specialized gustatory nerve, a necessary condition for the exercise of this sense. Occasionally it happens, however, that other stimuli than those produced by the actual contact of sapid substances with the nerves of taste may excite that sense. If a current of cool air be directed on the tongue a saline taste is perceived; and a smart tap on the tongue will produce a taste analogous to that excited by electricity. A minute current of electricity can be detected by the tongue which is not observable by the contact of the hand. It appears necessary that the surface of the tongue itself should be moist, in order that the gustatory sense may be exercised, and hence the inability to taste substances when the palate and fauces are dry and parched. The tongue itself does not appear to be the exclusive seat of this sense. The soft palate, uvula, tonsils and upper part of the pharynx in all probability exercise this sense, although in a minor degree when compared with the tongue. The middle of the tongue appears to be most feebly endowed with the sense of taste, the most sensitive region of the organ being the tip and edges. The tongue may occasionally lose its sense of taste and retain its sensibility to touch, or vice-versa. Surprising variations in taste occur. While some substances taste alike when touched by every part of the tongue, other substances taste differently when applied to different parts of the tongue. Sensations of taste, or at any rate of the impressions of taste, may remain for long periods after the substances tasted have disappeared, while the frequent repetition of the same taste dulls the sense. This sense may also be excited by internal stimuli as well as by those of external kind.

In the articulation of words, the modulation of sounds, the tongue plays an important part among the organs of speech; and in mastication, swallowing and nearly all the actions performed by the mouth the tongue is more or less concerned.

Various mechanical devices and structures thought to resemble the human tongue in some respect are so named, as the pole of a wagon, the fastening pin of a buckle, a vibrating slip in a musical reed, the tang of a tool, a strip of leather for closing the front gap in a laced shoe, etc.

TONGUE-FISH, an English name, corrupted from the French *langue*, applied to young soles and other small edible flatfish found along the shores of the English Channel. The term has been applied by Jordan to the American genus *Symphurus* of sole-like fishes occurring on both United States coasts.

TONGUE-TIE, an abnormal attachment or adhesion of some part of the tongue to some portion of the surrounding structures of the mouth. The ordinary form of tongue-tie consists in an abnormal development of the frenum. The tongue, in consequence, cannot be extended beyond the lips, and suction and mastication, as well as speech, are impeded.

TONGUES, Confusion of, the punishment inflicted on the builders of Babel, according to the Biblical narrative, when God so confounded their language that they could not understand each other, though up to that time there had been among them only one language. The result was that the building of the tower was abandoned, and those who had been engaged in its erection were dispersed over various lands (Gen. xi, 1-9).

TONGUES, Gift of, a gift bestowed in connection with the Pentecostal descent of the Holy Spirit. According to the Acts of the Apostles, when the members of the Church had assembled with one accord on the Jewish day of Pentecost, suddenly a mighty, rushing wind entering, pervaded the building in which they had assembled, cloven tongues as of fire descended on each and those on whom they were bestowed began to speak with "other tongues, as the Spirit gave them utterance"— the Parthians, Medes, Elamites and others, who repaired to the place when news of the miracle reached them, bearing testimony to its reality (Acts ii, 1-21).

TONIC SOL-FA. See SOL-FA, TONIC SOL-FA, or MOVABLE DOH SYSTEM.

TONICS, remedies which are alleged to promote nutrition and thus increase the strength or tone of the body when it is reduced. They are assumed to restore the functional activity of various tissues, and not merely increase the vigor of muscular fibres, as was formerly believed. Tonics are of two kinds, medicinal and non-medicinal. The medicinal tonics are variously classified, according to the part of the body they principally act upon, or to the effects they produce. Those that increase the secretions of the alimentary canal, the saliva, gastric or intestinal juice, etc., and so aid digestion, are spoken of as gastric or stomachic, intestinal and digestive tonics. Examples of such tonics are the vegetable bitters, cinchona and its derivatives, quassia, columbo, gentian, taraxacum, nux vomica and the salts of strychnine; dilute mineral acids, small doses of alcoholics and extracts of malt. Valuable adjuncts to the above are vegetable and animal pepsin. Blood or hæmatic tonics are those designed to improve the quality of the blood, and include iron and its salts, arsenic, manganese, mercuric chloride and quinine. Vascular tonics, often administered to increase the tone of the bloodvessels, include belladonna, digitalis, ergot and strychnine. General tonics act chiefly as nutrients, being assumed to gradually increase the weight of the body or exert a stimulating or modifying action upon the tissues. Cod-liver oil and other fats, salts of phosphorus and arsenic act as general tonics. Nerve-tonics, or nervines, which are given to increase the tone of the nervous system, include arsenic, strychnine, salts of iron, zinc, copper and silver, phosphorus, ammonia chloride and quinine; cardiac tonics, digitalis, strophanthus, strychnine stimulate the heart's action. The non-medicinal tonics (usually classed as general tonics) are sunlight, friction, electricity and massage; also exercise in the open air, and cold in its various forms and applications, as air, the shower and sponge bath and sea-bathing. Within recent years there is more and more doubt of the benefit of so-called medicinal tonics and an increased resort to nature's sunlight, air and exercise, the stimulation of the cold bath, etc.

Tonics are employed in conditions of debility of the body generally, or of its different parts, but unless properly used they do harm. For example, bitter tonics should not be used when there is severe pain and tenderness of the epigastrium, a heavily coated tongue and vomiting of blood or much mucus. While iron is an efficient remedy in most forms of anæmia, it is not always easily assimilated and it is generally futile in chronic wasting diseases and in organic affections.

TONIKA, tŏn'ę-ką (also **TONICA** and **TUNICA**), a tribe of North American Indians, forming a distinct linguistic stock, and formerly residing on the Lower Yazoo in Mississippi. They were first described by De Soto as the Tanico. They were allies of the French colonists in their contests with neighboring tribes, and in 1699 were reported to occupy 260 cabins extending over four leagues. In 1706 they were driven away by the Chickasaws and Alabamas, and in 1730 were defeated by the Natchez, who burned their village and killed a number of them. The remainder retired to the lower Mississippi, where, in 1760, they occupied three villages, and in 1802 numbered about 400 souls. The Tonikas were an agricultural tribe; they flattened their heads and wore very little clothing; the women made pottery and a fabric from the mulberry. Polygamy was not common. There are now a very few survivors of the tribe, near Marksville, La., who speak their native language as well as Creole and English.

TONK, India, a small native state of the Rajputana, east of Ajmer-Merwara. Area, 2,553 square miles; pop. about 303,000. It yields Britain an annual revenue of about $650,000. The capital, Tonk, about 60 miles south of Jaipur has a population of 55,000.

TONKA, tŏn'kä, Lower Siam. See PUKET.

TONKA, TONCA, TONGA, or **TONQUIN BEAN**, is the fragrant seed of the leguminous tree *Dipteryx odorata*, native to the northern countries of South America. The tree grows to 80 feet in height and bears fruits which are pod-like, oblong and fibrous and contain a single seed. This is of the shape of an almond, but larger, in a shining black coat. Tonka beans have the fragrance of new-mown hay, due to the same odorous principle, prismatic coumarin, as the sweet vernal grass and melilot. They are used for their aroma, either whole or powdered, for scenting clothes, snuff and in perfumery and even as a substitute for vanilla.

TONKAWA, tŏng'ką-wä, a nomadic tribe of North American Indians, comprising a distinct linguistic stock. They formerly roamed over the plains of Texas, were noted for their cannibalistic practices and were regarded as outlaws by the surrounding tribes. Early in the 19th century they were reported to number between 2,000 and 3,000, but in 1857, when they were settled on a reservation on the upper Brazos River, in Texas, their number was officially estimated at fewer than 1,000. During the Civil War (5 Jan. 1862), owing to their refusal to join the Comanches, Delawares and others in an insurrection against the whites, the latter Indians attacked a party of some 200 Tonkawas, comprising more than half the tribe, killing all of them. The remainder returned to Texas where they stayed until 1884, when they were placed on a reservation in Oklahoma. Here the few survivors now live with the Poncas.

TONKIN, tŏn-kēn', **TONKING**, or **TONGKING**, French Indo-China, a territory under French protection, bounded on the north by China, on the east by the Gulf of Tonkin, on the south by Anam and on the west by Laos. Area, 46,400 square miles. It is divided into 14 provinces and includes about 8,000 villages. It consists of two mountainous regions surrounding on three sides the large alluvial plain and delta region of the Song-koi (Red River), also an intermediate region of plateaux. The Song-koi flows through the centre of the territory from northwest to southeast and opens a navigable waterway extending in the rainy season as far as Lao-kay. The Song-bo (Black River) rises in Yunnan and joins the Song-koi, the largest river in the Mekong, forming a large portion of the western boundary. The principal mineral resources are deposits of coal, iron, copper and gold. The climate is hot and humid and the alluvial plain of Tonkin produces some of the best rice in the world. Sugar, cotton, tea, Indian corn and opium are also cultivated to a great extent, and on the higher ground there are coffee plantations. The manufacturers include silk, paper, cotton textiles, indigo and oils. Commerce has rapidly increased, the exports, chiefly rice, maize, sugar cane, silk, cotton, coffee, tobacco and animal products amounting to about $10,000,000 annually. The imports in 1915 totaled $8,000,000, being largely tools, machinery and beverages. The principal port is Hai-fong, which has steamship connection with Hongkong, Yokohama and Cochin-China. Railroads run from Hanoi to Hai-fong and Nam-dinh to Lungchow and to Yunnanfu and to the Chinese frontier. There are ocean cables connecting with Hongkong and Hue. Hanoi is the capital, and, since 1902, also the capital of the whole of French and Indo-China. Tonkin was an independent state until 1802, when it became a province of Anam. The latter is still its nominal position, although the Anamite vice-royalty was superseded in 1897 by a French residency, and the French protectorate is more direct here than in Anam proper. The provinces are governed by a resident and vice-resident, and each is subdivided into four military territories under commandants. Pop. estimated in 1911 as 6,119,720, with 33,000 Chinese and 6,132 Europeans.

TONKIN, Gulf of, Indo-China, an arm of the China Sea extending northward between French Indo-China and the Chinese island of Hainan. It is about 400 miles long and 200 miles wide. It forms the coast of the protectorate of Tonkin and receives the commerce brought down by the important river Song-koi from a rich agricultural region.

TONKS, Oliver Samuel, American teacher of art: b. Malden, Mass., 24 Dec. 1874. He was graduated at Harvard University, where he took his Ph.D. degree in 1903, and was a Fellow of the American Classical School at Athens (1901–02). He served as assistant curator of the department of classical art in the Boston Museum of Fine Arts (1903), was instructor in Greek at the University of Vermont (1904), lecturer at Columbia (1905) and preceptor in art and archæology at Princeton (1905–11). He then became professor of art in Vassar College. He collaborated in writing 'The Art Museum and the Public School' (1912).

TONNAGE, the carrying capacity of a ship. As this capacity is variously measured the word has several special meanings. As it comes from the shipyard the ship's capacity is rated as "dead weight tonnage." As it is measured by maritime surveyors and registered as of so many tons, its capacity is spoken of as "gross registered tonnage" and "net registered tonnage," both figures being given, as in different ports dues are collected variously, sometimes on the gross and sometimes on the net tonnage. War vessels, which have no "carrying capacity" in the mercantile sense, are rated by their "displacement tonnage." Still another form is recognized among shippers as "cargo tonnage" or "measurement tonnage."

Deadweight Tonnage is the amount of deadweight tons of 2,000 pounds which can be loaded upon a vessel at load-line (q.v.) draught when she has on board her full complement of stores and fuel.

Displacement Tonnage is the weight of sea water actually displaced by the vessel. It is computed usually by calculating from the drawings of the ship by the naval architect the cubic content of the immersed hull in feet and adding to that figure the number of cubic feet in the propeller, the shafting exterior of the hull and the submerged portion of the rudder. This total is divided by 35, as 35 cubic feet of sea water weigh almost exactly one ton.

In ascertaining the carrying capacity of a ship under the old style of measurement (abbreviated O. M.) the depth of the vessel was assumed to be the same as its breadth and the tonnage was obtained by multiplying the length by the breadth by the depth and dividing the product by 94, the quotient being the tons burden. But this rule was found to be impracticable, since shipbuilders sought to evade tonnage and harbor dues by building their ships very narrow and deep. In 1835 the British Parliament remedied these defects by new measurement laws, which were amended by the Merchant Shipping Acts of 1854 and 1894. Under this system, known as the Moorsom, actual measurements of the depth of the vessel are made at certain intervals, the number of which depends on the length of the tonnage deck, and at these points transverse areas are computed.

Gross and Net Registered Tonnage.— For purposes of measuring tonnage the United States practice divides vessels into six classes based upon their length (the British into five). These lengths and the number of longitudinal sections into which they are respectively divided are as follows: I, vessels under 50 feet long, into six parts; II, between 50 feet and 100 feet, into eight parts; III, between 100 and 150 feet, into 10 parts; IV, between 150 and 200 feet, into 12 parts; V, between 200 and 250 feet, into 14 parts; VI, over 250 feet, into 16 parts. These divisions are set out on the "tonnage deck," which in a vessel with less than three decks is the upper deck; in a vessel with three or more decks is the second deck, counting from below. The length of this deck is measured on its centre line from the inside of its innermost plate or plank at the bow to the innermost side of the plate at the stern, but making allowance for rake. The stations being marked off at equal distances upon this line, measurement of the transverse areas are made at each station, the depth being first taken. This is the distance from one-third up the round of the beam at the bottom to the top of the deck timbers, allowing two and one-half inches for ceiling. If this depth at midship is more than 16 feet the figure representing the depth is divided into six equal parts and a transverse measurement is made at each division, and at the top and the bottom. Counting from above, the second, fourth and sixth measurements are multiplied by four, and the third and fifth are multiplied by two. These products are added together, and to the sum thus obtained are added the top measurement and the bottom measurement. This total is then multiplied by one-third of the equal vertical distance into which the depth was divided, and the total is accepted as the transverse area at that station. These transverse areas are numbered consecutively from the bow to the stern. Omitting the first and the last, the second, fourth and each succeeding area with an even number is multiplied by four; and the third, fifth and each succeeding area with the odd number is multiplied by two. These several products are then added together and the first and last also added, and the sum is then multiplied by one-third the equal longitudinal distance between the stations. The total is the cubic content of the ship in cubic feet. This figure is arbitrarily divided by 100 and the quotient is the underdeck tonnage. To this is added the number of cubic feet in all deckhouses and permanently covered-in spaces which are above the tonnage deck, and which are or may be used to pack with cargo or use as transport for passengers. These additions are also divided by 100 and added to the underdeck tonnage to make the *gross registered tonnage.* The *net registered tonnage* is computed by deducting from the gross the cubic content of the engine-room (including the shaft tunnel), the crew space, cable lockers, coal bunkers, chartrooms and all space needed in the navigation of the ship, and such part of the space in the double bottom as is not available for fuel, stores or cargo. In calculating the ship's registry tonnage it is a common practice to compare the engine space with the gross tonnage, and if it is above 13 per cent, and under 20 per cent, to make an arbitrary deduction of 32 per cent for a screw vessel and 37 per cent for a sidewheeler in making the figure for the net tonnage. These deductions from the gross tonnage differ at different ports, and for this reason the ship always carries its gross tonnage figures as well as the net figures for the calculation of port and canal dues by the local authorities.

Cargo or Measurement Tonnage is the true cubic content of the ship in cubic feet divided by 40 — on the principle that a ton (2,000 pounds) of average cargo will occupy 40 cubic feet in the ship's hold. It is on this assumption that the freight charges for transportation are fixed. Where the cargo will weigh more than 2,000 pounds to the 40 cubic feet of space, as with stone, metals, cement, etc., the actual weight of the material is used as the basis of figuring the freight.

The British system of measurement was adopted by the United States in 1864, and subsequently, with slight variations, by all maritime nations. At Suez, Panama and other canals where tolls are based on tonnage, the management have established rules of their own for measurement, as they have to deal with vessels of all nations. Under modern rules account is taken of the space in double bottoms, now commonly utilized for feed, water, oil, fuel, etc., and no allowance of more than 5 per cent of the gross tonnage for crew space is countenanced. Deckhouses, however, which are used only as lounging rooms by passengers accommodated elsewhere in the vessel are also deducted in arriving at net tonnage.

TONOMETER, *in music,* an instrument for measuring the pitch of tones, such as a tuning fork or a set of graduated tuning forks. The best-known tonometer was invented by Scheibler in 1834, and was subsequently improved by König. It consisted of an exceptionally perfect set of tuning forks with an apparatus for determining the exact number of vibrations per second produced by a given tone. An instrument for measuring tension in a liquid, or of the eyeball, is also termed a tonometer.

TONQUIN. See TONKIN.

TONSILS and TONSILITIS. See NOSE AND THROAT, DISEASE OF.

TONSON, Jacob, English publisher: b. London, 1656; d. there, 2 April 1736. In 1678 he opened his shop at the Judge's Head, Chancery lane, near Fleet street. He soon became the publisher of Dryden's works, and continued as such for many years. In 1690 he completed the purchase of the publishing rights of 'Paradise Lost,' and afterward claimed that he made more on that poem than on any other. About 1700 he removed his shop to a place in Gray's Inn Gate. When the Kit-Cat Club (q.v.) was founded he was made its secretary. He purchased a house at Barn Elms and provided a room there for the meetings of the club. In 1710 he moved to the Shakespeare's Head. Here he continued until his retirement from business in 1720. His name is associated with nearly all the literary men of his time: with Pope, whose pastorals appeared in Tonson's 'Miscellany' (1709); with Addison, for whom he published 'Cato' (1713) and for a time issued *The Spectator;* with Congreve, Steele, Waller, etc. Wycherley spoke of him as having long acted as gentleman-usher to the Muses. He published Rowe's edition of Shakespeare (1709).

TONSURE, the shaving of a space on the top of the heads of Roman Catholic and Greek priests, performed as a solemn rite since the 6th century. The custom of cutting away the hair in token of the dedication of a person to the service of God is very ancient, being mentioned as early as the 4th century. The tonsure furnishes a means to distinguish the higher clergy from the lower, as the extent of the tonsure increases with the rank. The shape of the bare space also varied at different peroids. Many religious orders (for example, the Franciscans) allow only a narrow strip of hair around the head to grow; all above and below is shaved. Shaving the hair precedes consecration; it is performed by the bishop. It was never ordered by the Holy See or any "provincial or national council," says W. H. W. Fanning, and by tacit consent the custom has been discontinued in English-speaking countries.

TONTINE, tŏn-tēn', a form of annuity or financial assurance in which gain accrues from survivorship. The word is derived from the name of Lorenzo Tonti, a Neapolitan who settled in Paris in the time of Cardinal Mazarin and who invented this style of life annuity. Tonti proposed the system to the French government as a method of raising money and while the plan was not adopted, still it served as a model on which all future tontines were operated. The members of Tonti's association were to subscribe the sum of money needed by the government and were to receive life shares in the society. There were to be 10 classes of subscribers, according to their age, and for each class a fixed sum was to be divided yearly among the members of the class. When a member died his share was divided with the rest among the members of the class so that the death of each member benefited all those remaining, and the profit to the last few survivors in each class was enormous, while the sole survivor received the entire sum of interest accruing to his class. Upon his death the interest ceased and the borrower obtained the capital. In 1689–92 the system was used by Louis XIV, who was sorely in need of funds. He organized a tontine with a capital of $70,000,000, which lasted for a period of 40 years. The sole survivor drew an annual income of $367,500 from his original investment of $1,500. During the following century the tontine was frequently used in France and in Great Britain, and in at least one instance in the United States, in order to raise large sums of money. A disastrous private tontine in France, known as the "Caisse Lafarge," was established in 1791. When 60,000,000 francs had been subscribed into the company it was found that either through gross error or fraud the interest promised was an impossible one and the subscribers owing to the financial panic then prevailing lost not only their interest but their capital as well. The last public tontine in England was opened in 1789 and the interest, amounting to $210,150, was paid as late as 70 years after that date. The Irish tontines, established 1773–77, drew as many as 3,500 members. Tontines in the United States were at one time popular as a means for raising money for the erection of large buildings. The New York Tontine Society, founded in 1790, was wound up 1870–78, while tontine buildings were erected in New York, New Haven, Albany and other American cities.

Although tontines in their old form were long ago abandoned by financiers, the tontine system as applied to life assurance has given rise to an important modification of the usual insurance policies. What is known as the tontine dividend policy has the following distinctive features: The holders of such policies constitute a class by themselves; they do not participate in profits until after the lapse of the tontine period, usually 10, 15 or 20 years; the representatives of the insured in case of his death before the commencement of the dividend period receive only the sum mentioned as the face value of the policy; no surrender value is allowed to anyone who relinquishes his policy before the dividend period and all profits from whatever source are reserved until that period, when the accumulated dividends are to be equitably divided among the holders of such policies as are then in force. This form of policy is now in very little favor. Modifications from these general principles have been practised by various societies. For further information consult F. De Peyster's 'History of the Tontine Building' (1855). See INSURANCE.

TONTO (Spanish, «foolish»), an inappropriate name applied by the Spanish colonists of Arizona in the 19th century to a number of Indian tribes, namely: (1) To the Tulkepaia, a tribe of the Yuman stock settled in 1875 on San Carlos reservation, Arizona. (2) To the Eoyotero Apaches, an Athapascan tribe. (3) To the Pinal Apaches of the same stock. (4) To a mixture of Yavakai (Yuman) men and Pinal women who have intermarried. The name has been especially applied to the last-mentioned body, who formerly occupied Tonto Basin and the Pinal Mountains of central Arizona, whence some 500 of them were removed to the Rio Verde reservation and later to the San Carlos reservation. They number about 700, and speak a mixed Yuman-Athapascan language.

TONTY, tŏn'tē, or **TONTI, Henri de,** Italian explorer: b. about 1650; d. Fort Louis (Mobile), September 1704. He was a son of Lorenzo Tonti. He entered the French army, served also in the navy, and in 1678 came with La Salle (q.v.) to Canada, went with him into the Illinois country in 1680, undertaking the first civilized occupation of that region, and was placed in charge of Fort Crèvecœur, a little below Peoria, where La Salle left him. In 1681 he joined La Salle at Michillemackinac, and with him descended the Mississippi to its mouth. Subsequently he was in command at the stronghold on «Starved Rock,» called by La Salle Fort Saint Louis, and in 1688, after La Salle's death, unsuccessfully attempted the rescue of the French colonists left in Texas. «There are very few names in French-American history,» says Parkman, «mentioned with such unanimity of praise as that of Henri de Tonty.» He wore a metal hand with which he so effectively disciplined the Indians on occasions that they thought him a great medicine man. Consult French, 'Historical Collections of Louisiana' (Vol. I, 1846); Parkman, 'The Discovery of the Great West' (1869; new ed., 1898).

«TOO PROUD TO FIGHT,» an expression used by President Wilson in the course of an address delivered to 4,000 newly-naturalized American citizens in Convention Hall, Philadelphia, on 10 May 1915. Torn from its context, this now historic phrase accumulated a large amount of more or less intentional misinterpretation. The sentence immediately following it contains the real gist of the President's meaning: «There is such a thing as a man being too proud to fight. There is such a thing as a nation being so right that it does not need to convince others by force that it is right.»

TOOELE, Utah, county-seat of Tooele County, on the San Pedro, Los Angeles and Salt Lake and the Tooele Valley railroads, 35 miles southwest of Salt Lake City. The industries include a large smelter, a flouring mill, saw mills and a creamery. It has a Carnegie library. Pop. about 3,000.

TOOKE, John Horne, English politician and philologist: b. Westminster, 25 June 1736; d. Wimbledon, 18 March 1812. He was educated at Westminster and at Eton, whence he was removed to Saint John's College, Cambridge. In 1756 he entered himself at the Inner Temple; but in 1760 he took orders. He was a warm opponent of the American war, and was prosecuted for sedition for the wording of a resolution by which the Constitutional Society voted £100 to the widows and children of the Americans «murdered by the king's troops,» in the battle of Lexington. For this obnoxious paragraph he was tried at Guildhall in 1777, and sentenced to a year's imprisonment and a fine of £200. In 1780 he published a keen review of Lord North's administration, in a pamphlet entitled 'Facts,' and in 1782 a 'Letter on Parliamentary Reform.' It was in 1782 that he took the name of «Tooke,» being previously known as John Horne. This came about through his being named as heir to William Tooke, a wealthy gentleman of Surrey. In 1786 he published in an octavo volume his work entitled 'Epea Pteroenta' (Greek for 'Winged Words'), or the 'Diversions of Purley.' In 1801 he accepted the seat for Old Sarum. His political life closed with the dissolution of Parliament in 1802. Tooke possessed considerable learning. His 'Epea Pteroenta' is original and ingenious, and has exercised considerable influence on the subsequent development of philological investigation.

TOOLE, John Lawrence, English comedian; b. London, 12 March 1832; d. Brighton, 30 July 1906. He was educated at the City of London School. After serving for some time as a wine-merchant's clerk he took to the stage, and made his first apperance at the Haymarket in 1852. He then played with great success in Dublin, Belfast, Edinburgh and Glasgow, and ultimately became a popular favorite everywhere. In 1880 he began the management of the Folly Theatre, London, which he afterward reconstructed and named after himself. In 1874 he visited America, in 1888 he published his 'Reminiscences' and in 1890 made a successful tour in Australia and New Zealand. He was one of the most popular actors on the stage, inimitable in his personation of semi-pathetic, semi-ludicrous characters. Among his most successful parts were Paul Pry, Caleb Plummer in the 'Cricket on the Hearth,' and Uncle Dick in 'Uncle Dick's Darling.' One of his latest parts was that of Walker in Barrie's 'Walker, London.'

TOOLE, Joseph Kemp, American lawyer and State executive: b. Savannah, Mo., 12 May 1851. He removed to Montana, became established as a lawyer in 1870, and served two terms as district-attorney. He was a member of the Territorial legislature in 1879, and of Congress, 1884–88. He was elected to the Constitutional Convention in 1889, was the first governor of the new State of Montana, 1889–93, and was re-elected governor in 1900 and 1904 but resigned 1 April 1908; and retired into private life.

TOOLS. The almost innumerable variety of mechanical appliances and devices which are included under the general term «tools» may be primarily classified into three important groups according to the nature of the material worked upon: (1) Wood-working tools; (2) Metal-working tools; and (3) Masonry-work tools; each of which include special forms of hand tools and machine tools which may be still further subdivided according to the class of work accomplished with their aid, or according to the character of the machines in connection with which they are employed.

Wood-working Tools.

The small tools used in wood-working are those mainly employed in carpentry work and consist of the various forms of «guiding» tools, «holdings» tools, «rasping» tools, «edge» tools or «cutting» tools, «boring» tools, «striking» tools and «chopping» tools.

The machine tools include the various forms of lathes, borers, shapers and slotters, equipped with suitable accessory devices such as cutters, drills, etc., according to the purposes for which they are used in turning, boring, drilling and other kinds of work in wood. The machine tools are always operated by power and in recent years a good many hand tools, as drills, are power-driven.

The guiding tools comprise the following named devices:

Chalk-line.— This consists of several yards of light cord wound upon a wooden reel. The cord is well rubbed in with chalk or with charcoal and is used for the purpose of making marks where cuts have to be made.

Rule.— This is a thin, flat, narrow strip of hard wood, ivory or metal, frequently two feet in length, and graduated or divided on both sides by a series of lines at right angles to the edge of the strip into inches and tractions of an inch, such as halves, quarters, eighths, twelfths, sixteenths and thirty-seconds.

Straight-edge.— This consists of a long, flat strip of hard wood, or of bright hard steel. Straight-edges range from four to six feet in length and from two to four inches in width. When they are made of wood, well-seasoned material free from winding is essential, and a metal edge is commonly attached, and when made of steel they are often nickel-plated in order to prevent them from rusting. They are used for ruling and marking straight lines.

The Squares or Try-squares.—A square usually consists of a wooden stock or back into which a steel blade is fitted at right angles and secured by screws or rivets. It is used for marking-out work at right angles. Squares vary in size from 3 to 30 inches. Sometimes they are made entirely of plain or of nickel-plated steel and have scales engraved on their edges.

Spirit-level consists of a glass tube partially filled with a quantity of spirit so as to allow of the existence of an air-bubble about half an inch in length within the tube. This tube is enclosed in a framework of hard wood the edges of which are perfectly level and true and parallel to the axis of the tube. It is protected on the most important sides, the edges, by metallic facings and is provided with a sight-hole either on the top or at the side through which the movements of the bubble may be observed. Spirit-levels range in length from 8 to 48 inches and are used for the purpose of ascertaining whether the surface of a piece of work or the portion of a structure is truly horizontal or truly perpendicular.

Plumb-level.— This is a cord attached to the exact centre of the upper end of a vertical straight-edge. A weight suspended from the lower end of the cord swings freely in a pear-shaped hole near the lower end of the straight-edge. A straight line is marked on the straight-edge from the centre of the pear-shaped hole to the point of attachment of the cord. In testing the perpendicularity of a surface, one edge of the straight-edge is placed against the surface under test and the coincidence of the cord with the line marked on the straight-edge is carefully noted.

Gauges.— Three common kinds of gauges are used in carpentry work — the «marking» gauge, the «cutting» gauge and the «mortise» gauge. The marking gauge consists of a head or block which slides along a shank about nine inches long. A spike is inserted near the end of the shank and the movable head is provided with a screw or a wedge by which it may be fixed at any required distance from the spike. It is used for the purpose of making a mark on a piece of wood parallel to an edge which has been previously straightened and along which the head of the gauge is guided while the spike inflicts the mark. It is very useful in dressing several pieces of wood to exactly the same breadth. The cutting gauge is similar to the marking gauge in all respects with the exception of the spike which is replaced by a thin steel plate. This plate passes through the shank and is held in place by a set-screw and is sharpened on one edge so that it is capable of cutting either with or across the grain. It is used for gauging dovetailed work and for cutting veneers to equal breadths. The mortise gauge is also similar to the other two gauges but it is provided with two spikes, one fixed and the other movable and capable of being adjusted at different distances from the fixed spike by means of a set-screw. It is used for the purpose of gauging mortise and tenon work. Compound gauges consisting of combinations of cutting and marking gauges or of marking and mortise gauges are also commonly used for the purposes designated.

Bevels.— These are made somewhat like the squares, but with the exception that the blades are attached to the stock by a pin which permits of their being set at any angle other than a right angle, and held in such position by a thumbscrew; they are used for the purpose of marking lines at such angles to the first side of the piece of work. In some forms the blade is slotted through a part of its length and is called a «sliding» bevel. Others such as the «boat-builder's» bevels have two brass blades, one at each end of the stock, while in the «protractor» bevels the sliding arm works through a semi-circle graduated into degrees.

Mitre-box.— This is a device for guiding a saw so that it will cut at some regular angle, as 45 degrees. In its simplest form it is a rectangular box composed of two vertical sides fastened to the bottom. A saw-cut made at an angle of 45 degrees through the sides guides the saw when it is employed to cut a piece of wood such as a picture molding placed in the mitre-box. Other cuts than those at an angle of 45 degrees may be made in the same box by cutting the guiding cuts at the required angles through the sides of the box. The most convenient form of mitre-box for cutting a wide series of angles is one provided with movable guides which may be readily set at the required angles. As a rule, the mitre-edges of the moldings are left rough from the saw so as to make the glue adhere more firmly, but where sawed mitre-work requires to be planed smooth it is planed up with a «shooting-board» which consists of two pieces of wood screwed together so as to form a step, on the upper one of which two strips of wood are screwed at right angles to each other. These strips act as guide-bars against which the piece of molding to be mitred is held and then planed off on the edge of the step.

Compasses and Calipers.— These devices are made of metal and are employed for the purpose of taking dimensions such as the inside and outside diameters of pipes and other cylindrical work that cannot be taken accurately with a rule. A compass consists of two legs which are movable about a sector joint. In the form called a «wing-compass,» it is provided with a metal arc and a set-screw attachment which permits of its being set to correspond with a definite measurement and remain so set without variation until that particular measurement is no longer required. Compasses are also used for striking-out circular figures.

Calipers are termed «inside» and «outside» calipers according to the character of the dimensions taken by their aid. Inside calipers are made with straight legs which are bent around only at the point and are used for measuring internal diameters. Outside calipers are made with bowed legs and are used for taking measurements of external diameters. «Combination» calipers are an improved form in which the legs are pivoted near the middle point, thus making four movable ends, two of which are bowed and are used for taking outside measurements, and the other two straight and applicable to the taking of inside measurements.

Trammels.— These are appliances in the form of beam-compasses in which the heads slide along a straight bar to which they may be tightened by set-screws. The heads are made either of brass or of hard wood, the former being preferable, and steel points are inserted into the bodies. They are employed for the purpose of taking measurements and for striking arcs which exceed the capacity of the ordinary compasses.

Caliper-rules and Caliper-squares.— The caliper-rule consists of a short steel rule, a portion of which is attached to a closely-fitting slide which may be drawn out until the object to be measured is embraced between the opposing portions of the rule. As both the rule and the slide are graduated into minute fractions of an inch, the thicknesses of the objects measured can be read off directly from the dimensions on the slide. The caliper-square is a square, one elbow of which is fitted with a caliper-rule.

Bell Centre-punch.— This is a useful little device, by the aid of which a square, round, oval or triangular article may be instantaneously and accurately centred for the purposes of drilling and turning. It consists of a punch which is enclosed within a tube the lower end of which is expanded or tapered into the shape of a bell. This tapering mouth adapts itself to bars of different diameters, and when dropped over the end of a bar of any cross-section whatever ensures the marking of the exact centre of the bar by the point of the punch.

The holding tools are represented by the various forms of pincers, vises and clamps.

Pincers.— These consist of various forms of implements shaped somewhat like tongs and are used for the purpose of drawing nails from timber. They are made of iron and faced with steel in the jaws. The faces are made large and nearly flat so as to afford great power of leverage.

Vises.— These are made in a great variety of forms and sizes, the most useful of which are those with parallel movement in the jaws. The ordinary vise consists of a pair of steel-faced jaws one of which is capable of being moved by a screw or by a lever, while the other is fixed rigidly. The improved forms are provided with swivel-bases and swivel-jaw attachments, which enable them to grip the work in any position that may be required for convenience in working. These appliances are usually attached to a work-bench and are used for holding or gripping pieces of work which require to be held firmly, but which have not sufficient weight in themselves to remain stationary or immovable under the operation of the tools. The vise-jaws are usually steel-faced. In fitting them to a vise they are first screwed to the wrought-iron backing and serrated while untempered; they are then removed and hardened and subsequently screwed back into place on the backing. In the smaller forms the steel-jaws are usually welded to the backing. In the form commonly known as the «taper» vise, a loose jaw-piece rounded on the back and capable of movement in a corresponding hollow seating is attached to the fixed jaw. It affords a slewing movement by which the vise may be adapted to different angles for holding various forms of tapered work. The vise-claws or vise-clamps are simply angle strips of lead, brass or copper, which are placed against the jaws in order to prevent the bruising of delicate pieces of work by the serrations on the hard-steel faces.

Clamps.— These comprise several forms of appliances for holding together pieces of work in position for nailing and screwing or for tightening up the joints in glued work in order to allow sufficient time for the glue to harden. An ordinary form consists of a long iron bar and two brackets which slide thereon. One of the backets is capable of being moved freely to any point on the bar while the other is actuated and its amount of travel limited by a screw which is attached to the end of the bar and operated by a lever handle. The bar is provided with a series of holes along its length for receiving the iron bolts by which the freely-sliding bracket may be held stationary at any desired point. Some of the other useful forms are the adjustable «screw-clamp» and the «corner-clamp,» the latter being a very useful device for securely gripping two sides of a picture-frame while they are being nailed or glued together.

The rasping tools comprise the various forms of saws, files and rasps.

The Saws are an important class of tools employed for cutting and dividing substances. In general, the saw may be defined as a tool having a serrated blade and furnished with a handle or frame by means of which it is operated either by hand as in the case of the hand-saws or by belting as in the case of the power-driven saws. The saw-blade or saw-plate is usually made of the best tempered steel and the form, length and pitch of the teeth are designed and made to suit the class or character of the work performed and the nature of the material worked. The various terms used for describing the principal parts of a saw may be briefly defined as follows: «space,» the distance between the points of two adjoining teeth. «Pitch» or «rake,» the inclination or angle of the face of a tooth. This varies from 65 degrees to 70 degrees for cutting soft woods and from 80 degrees to 85 degrees for cutting hard woods. The corresponding «relief-angle» or the angles formed by the base and top of the tooth varies from 45 degrees to 50 degrees for soft woods and from 65 degrees to 70 degrees for hard woods. «Gullet» or «throat,» the depth of the tooth from the point to the root. «Gauge,» the thickness of the saw-blade, usually determined by the wire-gauge. «Set,» the amount of lateral inclination given to the teeth to one side or the other of the plane of the blade for effecting a clearance of the sawdust. «Points,» the number of teeth points to an inch, taken as a unit in estimating the coarseness or fineness of a saw. The teeth of cross-cut saws are usually formed to cut both ways. Saw teeth are designated by various names such as «peg» teeth, «M» teeth, «half-moon» teeth, «gullet» teeth, etc., according to their peculiar form. The various kinds of saws commonly used by wood-workers are the «hand-saws,» the «back-saws,» the «frame-saws» and the «pad-saws.» The «pit,» «deal,» «frame,» «band» and «circular» saws are mostly used in connection with the production of lumber and sawmill-work. See SAWS AND SAWING in this Encyclopedia.

Files and Rasps.— These comprise a class of tools having surfaces covered with sharp-edged furrows or teeth, which are employed for removing particles of wood, metal or other material by the process of abrasion or the cutting action of a multitude of fine points. They are made in a vast number of shapes and sizes and of various degrees of fineness or coarseness to adapt them to various kinds of work and materials. A file differs from a rasp in that its furrows or teeth are made by straight cuts inflicted on its surface by a reciprocating chisel before the metal is hardened, either in a series of single cuts or crossed cuts, while the teeth of a rasp are a number of isolated projections raised on its surface by the pyramidal end of a triangular punch. See FILES AND FILE MAKING in this Encyclopedia.

Edge Tools comprise the various forms of chisels and gouges, the planes and a miscellaneous assortment of spokeshaves or smoothing tools and various appliances such as grindstones, emery wheels and oilstones, used for maintaining a sharp cutting-edge on the various tools.

Chisels and Gouges.— The essential principle of these types of cutting tools is that of the wedge. The chisel in its simplest form practically constitutes the slice of an axe, but as its action or movement is the result of the force applied to it by the blows of a mallet or hammer, the eye of the axe is replaced by a suitable device for receiving the blows. When the element of thrust enters into the operation of a chisel, as in the cases where it is used by the simple pressure of the hand, its action passes into that of the plane iron. Chisels are specifically defined as «chipping,» «cross-cut,» «firmer,» «pairing» and «mortise» chisels. The firmer chisels are the ordinary short chisels used by wood-workers and are so designated in order to distinguish them from the paring chisels which are usually about twice the length of the firmer tools and are almost exclusively used by patternmakers. Paring chisels are seldom driven with the mallet, but are actuated by hand pressure alone. They are made in width ranging from one-fourth inch to two inches. The mortise chisel is a stout wood-workers' chisel which is driven with a mallet and used for cutting mortises where percussion and leverage are rendered necessary. The gouges are forms of paring and firmer chisels which have curved cross-sections. The cutting-edge of the paring gouge is formed by grinding its inner face and that of the firmer gouge by grinding its outer face. Gouges vary in width from one-eighth inch to two inches. The paring gouge differs from the ordinary firmer gouge in its increased length. It is never driven with the mallet, but is applied with a thrusting motion of the hand and is used chiefly by patternmakers for cutting the various curved outlines of their work. It will be observed, that as a rule, the chisel cannot be satisfactorily used over a surface wider than itself, and, therefore, the gouge was devised in order to obtain a tool of greater utility for that purpose. In practice this advantage is partially realized, but there still remains quite a tendency on the part of the gouge to follow the grain of the wood instead of cutting through the fibres at a very slight inclination. All gouges are held and used in the same way as a paring chisel, but if any occasion demands the driving of a gouge with a mallet, it should always be held in a perpendicular position.

Spokeshaves or Drawing Knives are essentially two-handed blades which can only be used by being pulled toward the operator. The general form consists of a long, narrow, chisel-edged blade the ends of which are attached to two handles which stand at right angles to the blade. These handles are of wood and the «tangs» into which the ends of the blade are prolonged are bent around at right angles to the blade and pass right through the handles and are riveted over brass plates at their ends, in order to prevent the blade from being drawn out of the handles when it is drawn toward the workman against the resistance of the wood. These tools are used for cutting thick and heavy chips off the rough edges of boards so as to decrease the amount of the work required in the planing operations and they are also used by patternmakers for the cutting of sweeping curves or «sweeps» in work where great accuracy is not essential. Router types are provided with cutters of varying forms and are effectively used for chamfering, rabbeting and other similar purposes.

Planes.— In its simplest form the plane consists of a chisel-shaped plane-iron, so-called, though made of steel, placed at an angle in a «stock» or box of wood or metal in such a way that the cutting edge projects slightly through the bottom of the box. It derives its value from the guidance imparted to the cutting edge by the sole or bottom of the box. The plane is operated by being pushed forward, over the surface of the material being worked, so that the cutting edge bites into the fibre and removes a thin shaving which slides upward along the upper side of the plane-iron and is thus discharged from the hollow of the box. The depth of the cut or the thickness of the shaving removed may be regulated by raising or lowering the plane-iron, which is usually held in place by means of a wedge or by a screw, and is, therefore, capable of being adjusted. The plane-irons are made both single and double. In the latter case, the back-iron is introduced for the purpose of breaking the shaving so as to reduce the amount of cumulative indrawing force due to the continuity of the fibre of a long shaving. Planes in which double plane-irons are used are called «built-up» planes. There are at least a hundred different kinds of planes in use at the present time, but all of them may be grouped into three general classes — the «jack-planes,» the «trying-planes» and the «smoothing-planes.» The jack-plane is the first plane used for roughing down the timber received from the hands of the sawyer or from the saw-mill. The cutting-edge of its plane-iron is more curved than those of the other planes and consequently takes coarser and narrower shavings. The trying-plane is used after the jack-plane for producing the greatest accuracy attainable in the surfacing of wood by hand. It is usually about 22 inches in length and carries a plane-iron about two and one-half inches in width. The cutting-edge is sharpened perfectly straight transversely, and this, combined with the length of the plane, enables the workman to produce very true surfaces by its use. The smoothing-plane is a small plane used for imparting a smooth finish to surfaces in work where extreme accuracy is not essential. It is made about eight inches in length and is designed to carry plane-irons ranging from one and three-fourths to two and one-fourth inches in width. Some of the more useful and important special forms of planes are the «rabbet» or «rabbeting» plane, employed for making window frames and other similar work in which a rabbet or recess is required to be cut for the reception of the edges of a glass plate or other material; the «plow,» employed for cutting a deep groove along the edge of a board for the reception of a corresponding tongue formed along the edge of an adjoining board, and the «stop-chamfer» plane, employed for cutting any chamfer or bevel-edge ranging from one-eighth inch to one and one-half inches in size, with a constant angle.

Grindstones, Emery Wheels and Oilstones.— The sharpening of the cutting-edges of chisels and plane-irons is performed first on a grindstone or on an emery wheel and then finished to a fine edge on an oilstone. Grindstones are natural stones which are turned into circular form and are made of varying diameters. They are usually arranged to revolve in troughs containing water, but they ought not to run actually in the water as that would tend to soften them and cause them to wear unequally. The water should be fed onto them from a drip-can. They are revolved by a crank-handle attached to the axle and make about 100 revolutions per minute when used for grinding ordinary tools. Various forms of rests or supports have been devised for holding the tool during the process of grinding, but in the case of wood-working tools they are seldom used, the workmen usually preferring to hold the tools by hand against the edge of the rotating stone. Grindstones are «trued» or «turned-up» by hand by means of a pointed bar of steel which is constantly rotated during the operation so as to always present a new cutting-edge to the stone and they are «trued» mechanically by means of a threaded roller of steel which is clamped in a frame and allowed to rotate against the surface of the stone. Such appliances are called «grindstone truers.» Emery wheels are similar in appearance to grindstones, but made of powdered emery cemented together or of emery cemented to a wooden centrepiece. The cementing material usually employed is a silicate insoluble in water and the wheels are usually made in about 10 degrees of coarseness. They are usually of smaller diameter than grindstones and operated at a higher rate of speed. Emery itself is a species of corundum composed of oxide of iron, alumina, silica and a small proportion of lime. The oilstones, sometimes called «hones,» are essentially fine-grained natural stones which are used for producing the final edge on cutting tools by the process of abrasion, with oil instead of water to assist the process. They are usually set in wooden stocks and provided with covers to protect them from dust and grit. The principal varieties are the Turkey, the Charnley Forest, the Arkansas, the Grecian and the Washita stones. As a general rule, oilstones will wear away the most in the middle and become hollow both in the direction of their length and breadth. Sometimes, as in the case of the sharpening of jack-plane irons, this hollowing out is somewhat of an advantage as it imparts a desirable curvature to the cutting edge, but when it extends to an inconvenient degree the surface of the stone is leveled by being rubbed on a flat sandstone or on an emery slab. Gouges and bead-planes are usually set or sharpened by means of oil-slips or thin slips of oilstone about six inches long and two inches broad and ranging from one-eighth inch to one-half inch in thickness, the edges of which are rounded in a transverse direction to fit the hollow faces of the tools.

Boring tools for wood comprise the various forms of awls, gimlets, augers, bits and braces and the drills.

Awls or bradawls are the simplest forms of boring tools and are used for preparing holes for the admission of nails and screws. In its ordinary form the awl consists of a small steel rod one end of which is fastened to a wooden handle and the other end double-bevelled to a sharp V-shaped edge by which the fibres of the wood may be compressed and parted so as to form a hole without producing chips and dust. The greatest drawback in the ordinary forms is the tendency of the steel rod to pull out of the handle when the tool is withdrawn from the hole it has made in the wood. This is especially the case when working in hard woods. In the superior forms this fault is remedied by the use of a hollow handle which contains a number of awls of different sizes, each of which may be fastened to the handle by means of a screw-nut.

Gimlets are of awl-form plus a screw. It consists of a small steel rod, one end of which is attached to a wooden handle which forms a T with the rod, and the other end is shaped into the form of a screw. This end consists of a point in the form of a taper screw and a spiral groove which extends partway of the stem or body as in the case of the «twist-gimlets,» or the body may be hollowed out into a nearly semi-cylindrical shell as in the case of the «shell-gimlets.» The commonest forms are called «spikes,» while other forms are designated as «triple-twist» gimlets, «auger» gimlets, «patent-twist» gimlets and «brewers-twist» gimlets, according to the shape of the spiral body. A complete assortment of these tools are usually required by a wood-worker.

Augers are merely large gimlets. They are made in both the twisted and the shell forms and are operated by both hands by means of a wooden bar thrust through the eye at the handle end of the stem. Their sizes increase one-eighth-inch at a time from three-eighths-inch to two inches in diameter.

Bits and Braces.— The bits comprise the various forms of boring tools such as «centres,» «shells,» «gouges,» «countersinks,» etc. They are actuated by the «brace» or «stock.» These tools were developed in order to overcome the faults inherent in all forms of awls, gimlets and augers, due to the interruption of the continuous rotation of those tools necessitated by the changing of the position of the hands and by the limited amount of pressure applied to the tool. The stock or brace consists of a crank, one end of which is provided with a round head for receiving the pressure of the breast of the operator and the other end recessed for the reception of the bit. In the earlier forms the bit was secured in the receiving end of the brace by means of a thumb-screw which engaged a notch near the end of the stem and constituted the weak point of the compound tool. This defect has been remedied in the later forms by the use of various kinds of expanding devices or expanding-chucks which adapt themselves to all shapes and sizes of stems and hold the bits securely and truly in place. The centre-bit comprises the centre-point, nicker and cutter attached to a shank. The nicker and the cutter are actuated by the brace and rotate about the centre-point. It is used for boring large and deep holes. The countersinks are made in a great variety of forms and are designated as «snail-horn,» «rose-head» and «flat-head» according to the shape of the cutting point. In wood work they are employed for enlarging the entrances of holes when it is desired to let the heads of screws or bolts lie completely below the surface of the wood. Some of the other useful forms of bits actuated by the brace are the «screw-driver» bit, the shank end of which is square-tapered to fit the socket of the brace and which being turned with the brace is quicker in its action than that of a hand-worked screw-driver; the «taper» bit for boring funnel-shaped holes; the «shell» bit, the cross section of which is composed of a convex and concave curve roughly semi-circular in form; the «nose» bit, a shell bit provided with a nose or lip at the cutting-point for the withdrawal of the core from the wood; the «spoon» bit, the cutting-edge of which is formed in the shape of a parabola and, therefore, does not draw out the core as effectually as the nose bit; and the «gouge» bit, the cross-section of which is similar to that of the gouge and is simply rounded at the cutting-point without the provision of a nose or lip. In the ordinary forms of the compound tool the brace is rotated through complete revolutions, thus preventing the boring of holes or the driving of screws in one side of a corner at a distance any closer to the adjacent side than that which is equal to the radius of revolution, but this shortcoming of the tool is remedied in the hatchet brace in which the brace acts as a lever which moves the bit around and at the same time feeds it forward by means of a ratchet and click actuating a square-threaded feed-screw, as the brace is moved back and forth through partial revolutions.

The striking tools comprise the various forms of hammers and mallets.

Hammers.— Ordinarily, a hammer consists of two parts — the iron or steel hammer-head, and the shaft or handle of wood which is driven into a hole in the «centre of mass» of the hammer-head. The angles at which the handles are attached to the heads vary greatly on account of the variations in the position of the centre of gravity of the head relatively to the line of the penetration of the handle, and also on account of the various convexities of the faces of the hammer-head. The form of the «pane» or the narrower or smaller end of the hammer-head also varies greatly in the hammers used for different purposes. When of hemispherical form as in the engineers' hammers, it is called a «ball» pane; when it is made in the form of a narrow, round-edged ridge placed at right angles to the axis of the handle it is called a «cross» pane; and when the ridge runs longitudinally it is called a «straight» pane. In the claw-hammer the pane is curved upwards toward the handle and is divided by a V-shaped groove, and the head is usually attached to the handle by means of side flanges. It is very useful for drawing nails. The hand hammers used by wood-workers range in weight from one-half ounce to 10 pounds. The weight of the head and the balance of the head in the handle are the most important considerations controlling the suitability of a particular hammer, for if the handle is too light for the head it will break off.

Mallets.— These are forms of hammers in which the metal heads are replaced by wooden blocks. They are practically heavy wooden hammers which are used for delivering blows on the handles of chisels and gouges in order to avoid the risk of smashing and splitting them down as is usually the result when iron hammers are used for that purpose. Round-faced wooden mallets are used by molders for rapping patterns in order to detach the sand which adheres to them when they are drawn from the molds. Woodworkers' mallets are either square or round in form. The square mallets are about six inches in length and two by wood-workers range in weight from one-half inches in width. The round mallets are about five inches in length and three inches in diameter. The mallet-heads are usually made of hickory wood, and sometimes of lignum vitæ.

The chopping tools are the axes, the hatchets and the adzes. In each case they represent the combination of a striking tool and a cutting tool. In these tools the shape of the handle or helve and the manner in which it is attached to the blade is of the utmost importance in governing their effectiveness.

Axes and Hatchets are edged tools with handles used in chopping for rough cutting or splitting. They vary mainly as to the weight of the blade, to the shape or curvature of the handle and to the form of the cutting-edge. Axe blades range in weight from two to seven pounds. These blades are usually made by welding the hard tempered steel portion which forms the cutting-edge to the iron portion which contains the «eye» provided for the reception of the handle. The curved form of the handle is designed to counteract the influence of the force of gravity which tends to twist the blade downwards when the axe is used for chopping at various obliquities. The form of the cutting-edge, curved horizontally, and wedge-shaped transversely to the sides of the blade, is designed for the purpose of separating the groups of wood fibres successively, and for equalizing the pressure of the blow on each side of the blade. A hatchet is a light form of axe, with usually a nail-pulling groove back of the blade.

In the adze, the cutting edge stands transversely or at right angles to the handle, which is quite short. The entire outer face of the blade is made slightly curved, and its cutting-edge is formed by beveling from the inner face. It is usually employed for the forming of lengths of wood into curved shapes.

Metal-working Tools.

The almost innumerable variety of metal-working tools and the great variety of purposes for which they are employed make their classification into a series of general groups practically impossible within a limited space. In a general work they may be conveniently divided into various classes according to the character of the work to which they are applied. Such a method of classification would group the main body of metal-working tools under foundry work, forge shop work and machine shop work, the last named including all the turning, gear-cutting and toolmaking tools and appliances. The greater number of these are treated under their special headings in the several volumes of this Encyclopedia, and as in the case of the wood-working appliances, the various kinds of machines employed in the metal-working industries will be found specifically treated under the title Metal-working Machinery. The larger metal-working tools are known as machine-tools, including all those machines that operate cutting tools for shaping metal, as lathes, power-drills, boring-drills, shapers, milling machines and the like.

The elementary descriptions of the various forms of small tools such as the guiding tools, the holding tools, the rasping tools, the cutting tools, the drilling tools and the striking tools already given in connection with the wood-working tools will be found applicable to similar tools employed in metal working, subject, however, to the modifications demanded by the greater hardness of the material worked, and the greater accuracy of execution required in the finished products of some classes of metal work. In the main these modifications consist in the employment of finer and harder materials in the making of the tools, in the particular forms given to the cutting edges and in the methods by which the tools are applied in the execution of the work.

The guiding tools employed in metal work are quite similar to those already described, and comprise the various forms of rules, squares, straight-edges and calipers, all made of metal, and also the various forms of micrometer calipers with vernier attachments which are capable of measuring dimensions as small as 1-10,000th of an inch. These calipers are divided into two general classes — the «yoke» calipers and the «beam» calipers. In the former, the outer end of the shank of the yoke contains a split-nut which is employed for making adjustments for wear. For this purpose, the nut is closed onto the screw by being advanced on the stem toward the yoke. The shell or thimble on which the graduations are marked is attached to the end of the screw and rotates with it, and moves along over the shank. A speeding arrangement for rapidly advancing the screw is provided in the form of a knurled-nut in the yoke, which is also capable of contracting a bushing over the measuring stem so as to lock it in any desired position. The measuring point and the opposing anvil are carefully ground so as to make their faces perfectly parallel with each other. These micrometers are usually provided with a screw having 40 threads to the inch, with the barrel graduated to 10ths and 40ths of an inch. By this arrangement one revolution of the screw advances the thimble one division on the barrel, equal to one-fortieth of an inch, and as the circumference of the thimble is divided into 25 equal parts, one-twenty-fifth of one revolution of the screw advances the measuring point one-twenty-fifth of one-fortieth, equal to one one-thousandth of an inch. By the aid of the vernier attachment applied to the barrel measurements as small as one ten-thousandth of an inch are readily obtained.

Gauges and Indicators.— These tools are employed for indicating the sizes of wire, machine-screws, drills and plate thicknesses. Various systems of gauges are employed, in all of which the dimensions are purely arbitrary. The American or Brown and Sharp gauge was adopted to produce a gauge to overcome the irregularities in spacing of the Birmingham gauge. In this gauge the dimensions increase by regular geometrical progression, the largest dimension No. 0000 being equal to 0.46-inch and the next smaller dimension, No. 000, being obtained by multiplying 0.46 by the constant .890522, each smaller number being the product of the preceding number and the constant. Gauges for indicating the gauge of wire or plates are of two forms — the angular and the notch gauges. Other forms of gauges are the «centre» gauge which is used for gauging lathe and machine centres in turning and grinding work; the «screw-thread» gauge used for grinding threading tools; the «screw-pitch» gauge used for determining the pitch of screw threads; the «depth-gauge» used for measuring the depth of holes and recesses; the «scratch» gauge used for ruling lines parallel with the edge of a piece of work and several forms of «surface» gauges which are principally used in determining the parallelism of the surface of a piece of work with the machine table, housing or other plane of reference. They are also used in testing, erecting and in the setting-up work on machine tools.

Test indicators are a class of tools or instruments used for determining small irregularities in the accuracy of cylindrical surfaces and small variations from the true rotation of such surfaces. They are also used in determining the inaccuracies of a plane surface and in measuring small amounts of end or lateral motion such as the end-motion of a spindle. They are of two types — those which merely indicate the existence of the irregularities and those which give a reading or measurement showing the exact amount of the errors.

Some of the other small tools indispensable to the metal worker may be briefly summarized as follows:

The various forms of «hack-saws» used for severing purposes. They are made of hardened steel to cut metal and mounted in a light frame and may be operated either by hand or by some form of power. Their blades are usually made with 14 teeth to the inch for general work and with 25 teeth to the inch for cutting tubing and thin metal.

The «monkey-wrench» and other forms of wrenches used for screwing and unscrewing the nuts of screw-bolts, etc.

The various forms of «drills» and especially the modern «twist-drill» which is universally used at the present time and which has completely supplanted the old flat forged drill which for many years held the first position as a tool for producing circular holes in metal.

The «reamers» and «broaches,» which comprise a class of fluted tools used for finishing and truing cored or drilled holes. They are solid when used in a socket or with a wrench and shell or hollow when bored out to fit a mandrel.

The «screw-threads,» «taps» and «dies,» which, according to their use, may be divided into two classes — those used for fastenings and those used for communicating motion. There are three forms of screw threads used for fastenings — the «V» thread in which the sides make an angle of 60 degrees with each other and in which the top and the root are sharp; the «United States standard» thread which is similar to the «V» thread with the exception that the top is cut off and the bottom filled in; and the «Whitworth» or «English standard» thread in which the top is rounded off and the root filleted in and in which the sides form an angle of 55 degrees with each other. There are also three forms of screw-threads employed for communicating motion — the «square» thread, the «trapezoidal» thread and «Powell's» thread.

The top is used for producing internal threads and the die is employed for cutting external threads. They are of two kinds — those operated by hand and those operated by power-driven machines. Hand taps are made in sets each of which comprise three taps — the «taper-tap,» the «plug-tap» and the «bottoming tap.» The taper-tap is parallel on the point for a distance equal to one-fourth the diameter of the tap and this point is made the diameter of the roots of the teeth and corresponds to the correct size of the hole to be tapped so as to produce a full thread. In the plug-tap the first three teeth are tapered off and in the bottoming-tap the teeth extend full to the point. The taper-tap is used for starting a thread, the plug-tap for extending it nearly to the bottom and the bottoming-tap for finishing the full thread to the very bottom of the hole.

The dies may be divided into two general classes — those which have to be passed over the work several times in order to produce a finished thread and those by which a finished thread is produced at a single cutting. In the former, the cutting-dies are held in a stock and are capable of being separated so as to permit of their being passed over the work and then closed, by means of a set screw, an amount sufficient to enable them to cut a full thread. In the latter, when they are not of the screw-plate type, the «chasers» or «cutters» are held radially in a cast-iron «collet» surrounded by a wrought-iron ring. These dies are capable of being adjusted to compensate for wear. The bevelled outer ends of the chasers fit into corresponding bevelled grooves in the wrought-iron ring so that when the ring is forced down the chasers are moved toward the centre. A great variety of self-opening and adjustable dies are also used for machine threading.

Masonry Work Tools.

The masonry work tools may be conveniently divided into two general classes — stonemasons' tools and bricklayers' tools. Those employed by either of the two classes of workmen are neither numerous nor intricate in design. The principal tools of the stonemason are the saw, the mallet, the scrabbling hammer and the various forms of chisels designated as the «inch-tool,» the «boaster» and the «broad-tool,» which are distinguished by their size, the first being one inch, the second two inches and the third three and one-half inches in width. In the work of stone cutting, the preliminary operations are performed by a small chisel called the «point» and the finishing work executed by the use of the others in turn according to their size. The principal tools of the bricklayer are the various forms of trowels, the plumb levels and the bricklayers' hammers. For further information relative to the various forms of stone-cutting saws, see Saws and Sawing; Stone-Cutting and Dressing; and also the articles under the titles Files and File Making; Metal-working Machinery; and Wood-working Machinery in this Encyclopedia.

TOOMBS, Robert, American lawyer and statesman: b. Wilkes County, Ga., 2 July 1810; d. Washington, Ga., 15 Dec. 1885. He was the son of a Georgia planter, attended for one year Franklin College (now the University of

Georgia) and was graduated at Union College, Schenectady, N. Y., in 1828. In 1829 he studied law at the University of Virginia and in 1830, being under age, was admitted to the bar by special act of the legislature. Within 10 years he became one of the foremost lawyers of Georgia. In 1836, when the Creek War broke out in Alabama, he raised a company of volunteers and served as captain under Gen. Winfield Scott. In 1837–40 and 1842–43 Toombs was a member of the legislature and during this time became a leader of the State Rights Whigs of Georgia. From 1844 to 1852 he served as representative in Congress and was one of its best orators and debaters. In 1850 he was a prominent supporter of the compromise measures in the House. In 1852 with other Southern Whigs he refused to support Scott for President. After 1852, like Stephens, he acted with the Democrats. From 1853 to 1861 he was in the United States Senate. In 1854 he favored the Kansas-Nebraska Bill as carrying out the principles of the compromise of 1850. Immediately before the elections of 1860 Toombs lectured in the North on slavery. After the election of Lincoln he advised secession of the Southern States and made secession speeches in Georgia in December 1860 and in the United States Senate in January 1861, maintaining that in secession lay the only hope of security for the South. Georgia seceded 19 Jan. 1861 and Toombs withdrew from the Senate four days later. In March he was formally expelled. He was chosen to the Confederate Provisional Congress that met in Montgomery 4 Feb. 1861 and by a considerable minority was considered as a candidate for President. On 21 February he was made Secretary of State by President Davis. He opposed the firing on Sumter that began the contest of arms. Resigning September 1861 to become a brigadier-general in the Confederate army, he fought with distinction in the second battle of Manassas (Bull Run) and at Sharpsburg (Antietam). He resigned his commission in 1863 and in 1864 was made commander of the Georgia militia. He disapproved the policy of the Richmond administration and personally disliked Davis. With Vice-President Stephens and Governor Brown he headed the Peace Movement in Georgia in 1864, thereby doing much to weaken the cause of the Confederacy. In 1865, to escape arrest, Toombs went abroad, visiting Cuba, France and England. Returning in 1867, on the restoration of the privilege of *habeas corpus*, he soon amassed a fortune of $500,000 in the practice of law. In 1872 he was a member of the Georgia Democratic Convention and supported Horace Greeley for the Presidency. In 1874 the Georgia legislature passed a law providing that railroads should be taxed like other property. The railroads resisted, and Toombs, taking the case of the State, won the suit in the courts and collected all back taxes. For 10 years he continued the struggle to force the railroads to pay taxes and give proper service to the public and in 1877 secured the passage of a law providing for a board of railroad commissioners. Other Southern States have since passed laws modeled after the Georgia law.

By his enemies Toombs was considered extreme and intolerant — a «fire-eater.» His friends thought him a statesman of the first order and were disappointed that he made no higher mark. His hasty temper hindered his career in politics. In the army he was an able general, but not a disciplined subordinate. He belonged to the school of Jefferson in politics, believing in strict construction, State sovereignty and strong local government, with much liberty for the individual. His political theories were meant for times of peace, but could not stand the strain of war; consequently he was at variance with the Confederate administration from the beginning. As long as he lived Toombs never ceased to denounce the Reconstruction measures of Congress. His experiences from 1865 to the end of Reconstruction caused him so to dislike the United States government that he refused to ask for a pardon or to take the oath of allegiance and he never again had the privileges of citizenship. Consult Stovall, 'Robert Toombs, Statesman, Speaker, Soldier, Sage' (1892); Trent, 'Southern Statesmen of the Old Régime' (1897).

W. L. Fleming,
West Virginia University.

TOON, or TOONA, a tree (*Cedrela toona*) of the family *Meliaceæ*. It is a native of India and Australia, being found at altitudes of 4,000 feet on the Himalaya Mountains as well as near tide-level. In the former country it is one of the largest trees; in the latter, it often exceeds 150 feet in height and 18 feet in circumference. Hooker mentions a specimen in India 10 feet in diameter at five feet from the ground. The tree is cultivated for its timber, bark and flowers. The wood is soft, open-grained, easily seasoned and worked, little liable to warp and easily polished. The heartwood is reddish and resembles mahogany and veneers taken from the roots or where branches join the trunk are said to be remarkably handsome. The chief uses of the wood are in house-building, furniture-making, carving, etc. Under the names bastard cedar, bastard white cedar and Moulmein cedar the wood is an important export to English markets. The bark is very astringent and is used for making leather which usually is purplish from a dye also present. The flowers yield a reddish or yellowish dye which is in common use in India. A close relative of this tree, *C. sinensis*, is grown in the United States in streets and upon lawns. It resembles the ailanthus in hardiness and its graceful, feathery foliage, but is superior in regularity, denseness of growth and in the absence of disagreeable odor during the blossoming period. Several other species are cultivated in California and the Gulf States, but are not hardy in the colder parts of the country. See Mahogany.

TOOTH-BILLED PIGEON, a large fruit-pigeon (*Didunculus strigirostris*) of Samoa, formerly called «dodlet» under the erroneous impression that it was a surviving relative of the dodo. It is about 14 inches long, body rounded, beak orange, with the lower mandible deeply cleft into three distinct teeth near the tip. Head, neck, breast and abdomen glossy greenish black, rest of back, wings, tail and under coverts deep chestnut. It is now rare.

TOOTH-ORNAMENT, a decoration peculiar to mediæval architecture, consisted of four-leafed flowers, the centres of which project in a point. These are used in series, either in a continuous row or at slight intervals, and are generally inserted in a hollow molding. They are used in great profusion in the Early English architecture, forming one of its characteristic features, and in some of the richer suits of molding the flowers are very thick and the series is repeated several times.

TOOTH-SHELL. See DENTALIUM.

TOOTHACHE, a pain in a tooth or adjacent jaw, arising from various causes. The most common cause is decay of some portion of the tooth, admitting air to the nerve, which causes sharp pangs. If there is a considerable opening it is colloquially called «jumping toothache.» The pain may be stopped by application of oil of cloves on cotton and closing the passage that admits air; if oil of cloves is not to be had diluted chloroform on cotton is a good substitute; creosote is also used, especially in a gum styled toothache gum. But the pain and decay will usually continue unless the services of a dentist are sought. Decay in the root of a tooth often generates gas, which induces a pressure on the nerve, and consequent toothache. The remedy is to bore a small hole into the tooth and release the gas. If this is not done the gas forces itself through the gums, often with severe pain, resulting in a gum-boil. This is not a true boil, but a hole worked through the flesh by the pressure of the gas. When this finds a vent there is some relief, but a permanent cure involves treating the tooth by a dentist. Neuralgic toothache is a purely nervous variety, and may occur either in sound or carious teeth. It comes and goes suddenly in paroxysms, and is accompanied by little or no swelling. As a preventive against toothache the teeth should be kept scrupulously clean, and when they show symptoms of decay the services of a skilful dentist should be secured. The decay of a tooth is arrested by stopping or filling up the cavity.

TOOTHACHE TREE. See ARALIA.

TOOTHED HERRING. See MOONEYE.

TOOTHPICK, a small pick for removing substances lodged in the teeth. The ordinary toothpick is of wood about the size of a friction match, but longer and slenderer and pointed at one end or both. The use of wooden toothpicks has become very common in the United States and many millions of the tiny wooden slivers are manufactured there every year. The seat of this industry is in Maine, near the forests of white birch, which wood is chiefly employed in their making. The felling of «toothpick trees» is not a separate business but one incidental to the Maine lumbermen. After a tree has been felled the branches are lopped off and only the trunk is sent to the mills. There the bark is skinned and the naked trunk is cut by machinery into thin sheets of wood of the thickness of toothpicks and as wide as a toothpick's length. These sheets, known as «veneers,» are run through another machine which in one operation cuts them into toothpicks ready for shipment. Of the better grade of toothpicks large importations are made every year from Japan and from Portugal. The Portuguese toothpicks are made of orange-wood and are smaller but tougher, better shaped and more finely pointed than the domestic picks. The Japanese make their toothpicks from fine reeds, which they shave down to the thinness of paper, retaining the reed's strength and pliability. Metal toothpicks, as of gold, which were formerly common, are now little in demand since their use endangers the enamel of the teeth. Quill toothpicks, cut from the shaft of a hen's feather, are still considerably used.

TOOTHWORT. See DENTARIA.

TOOWOOMBA, too-woom'ba, Australia, a town of Queensland, in the southeastern part of the state, 100 miles by rail west of Brisbane, on an elevation known as the Great Dividing Range. It has a number of churches, two colleges and other educational institutions, and a fine new municipal building. There are flour-mills, saw-mills and a brewery, and in the neighborhood are vineyards. Pop. about 11,000.

TOP-MINNOWS, a group of small, robust minnows, represented by *Gambusia patruelis* of the brackish waters along the Atlantic Coast, which are distinguished by their habit of swimming and feeding near the surface. See MINNOW.

TOP-SHELLS, the *Turbinidæ,* a family of gasteropod mollusks, mostly tropical and oriental, in which the shell is usually turbinate or top-shaped, but may be pyramidal. It is generally nacreous internally. The operculum is horny, and may exhibit a spiral form. In the genus *Turbo* the shell is top-shaped with a rounded base. The whorls are convex, and the aperture is large, the operculum being calcareous. The genus *Trochus* also belongs to the top-shells. In the latter genus the shell is pyramidal and the base flattened, the operculum being horny. The common top is the *T. zizyphnus.* Others are the *T. versicolor,* the *T. imperialis* and the *T. niloticus.* After having been ground and polished to exhibit the nacreous inner layers, they are extensively sold as ornaments.

TOPAZ, a mineral having the composition of an aluminum fluo-silicate. It is not the topaz of Pliny and other early writers which was chrysolite (q.v.), the names having been interchanged. It generally crystallizes in orthorhombic prisms, colorless, white, yellow, or occasionally pale green or blue. Transparent topaz, in any of its tints, is a beautiful gem. The colorless variety much resembles diamond, and is sometimes sold for it, though its lower hardness (8) affords an easy test. What has been called the largest diamond in the world, among the Crown jewels of Portugal, is probably a colorless or «white» topaz. The yellow variety is most familiar, and is called «Brazilian topaz,» in distinction from «Oriental topaz» (yellow sapphire) and «false,» «Scotch» or «Spanish topaz» (yellow quartz). The «Oriental topaz» is much rarer, harder (9) and denser (about 4); while the «Spanish topaz» is cheaper, less hard (7) and lighter (2.65), the density of topaz being 3.4 to 3.6. It is also distinguished by its eminent basal cleavage. The favorite shade is wine-yellow or sherry-color. Both yellow and blue topaz fade and become white by weathering or exposure to light, and some yellow varieties can be changed to a pale pink by heating, yielding the so-called «burnt topaz» or «Brazilian ruby,» resembling the pale, or Balas, variety of ruby spinel (q.v.).

Topaz occurs usually in metamorphic rocks, like gneiss, but also somewhat in igneous rocks; it is frequently, though not always, associated with tin-ore. The principal localities are in Ceylon, Siberia, Japan, Brazil and Mexico. In the United States it occurs in large masses at Stoneham, Me., and Trumbull, Conn.; in crystals in Colorado and Utah. Fine topaz crystals, colorless and pale blue, have recently been found in San Diego County, Cal.

TOPAZOLITE, a variety of andradite garnet having a light yellow or pale grayish green color. The most beautiful specimens are found in the Ala Valley, Piedmont, Italy. They also occur in California.

TOPE, a Buddhist monument intended for the preservation of relics. The oldest monuments of this kind are spherical or elliptical cupolas, resting on a circular or rectilinear base, with an umbrella-shaped roof, and sometimes with a series of roofs of this form which develop into a spire, pyramid or other architectural ornament. In the interior is a cell or chamber for containing the box with relics; but in some cases no relics have been found, and it is supposed they have been buried underground. The Sanskrit name is *stupa,* mound, from which is derived thupa and tope, meaning top. The older topes are masonry mounds, the cupola top and ornamental roofs and spire forms being later developments for ornamentation. Some of them are of great architectural beauty, rising tier above tier, with a series of graceful «parasol» roofs, the limit of height being about 300 feet. But the typical construction is that of The Great Tope at Sanchi, in central India. This is a hat-shaped mound or dome 42 feet high and 106 feet at the widest point. The flat space on top was for the chhatra or umbrella-like apex, this being the royal emblem. This was like a substantial parasol, as if to guard the relics from the weather. The Great Tope is surrounded with a magnificently carved stone railing, leaving an elaborate ornamental entrance or gateway, over 30 feet high. The chamber or cell in which the relics were kept was generally built with an outer construction of masonry; often enclosing a bronze box, which again enclosed a silver cylinder or case and within this perhaps a casket of gold containing the relics which it was desired to preserve. The number of stones in the topes often indicate Buddhistic symbolism — three, seven and 13 being the numbers rich in meaning. Topes are common in the Orient and there are groups of conspicuous ones at Amravati, Sarnatti and Telelabad in Bengal, at Satdhara and Sonari in central India, at Abayagiri, Ruanwalli and Tuparamaya in Ceylon, etc. Relics of kings and great men were thus cared for, much as we build statues and monuments to-day. See DAGOBA; PAGODA.

TOPEKA, Kan., city and county-seat of Shawnee County, capital of the State and the third largest city in the State, on both banks of the Kansas River, on the Atchison, Topeka and Santa Fé, the Chicago, Rock Island and Pacific, the Union Pacific and the Missouri Pacific, 67 miles west of Kansas City. The city is well laid out with broad streets crossing at right angles and beautifully shaded. Topeka was settled by people from the «Free State» in 1854; an anti-slave constitution was adopted here in 1856 known as the «Topeka Constitution» and the Topeka government was established by national authority. It was incorporated as a city in 1857 and selected as the State capital in 1861. The principal industries are the railroad shops of the Atchison, Topeka and Santa Fé Railway, printing plants, six flouring mills having a capacity of 5,000 barrels per day, creameries, packing-houses, foundries, machine shops, boiler works, preserving works, silo factories, engine works and planing mills. According to the United States census of manufactures of 1914 Topeka had 159 manufacturing establishments with a combined capital of $14,186,000, employing 5,721 persons, paying $3,691,000 in wages and manufacturing a product valued at $20,000,000. Topeka has 10 banks, three of which are national banks and three building and loan associations with assets of $9,000,000. Topeka is an important jobbing centre, there being four wholesale groceries, six wholesale commission houses, wholesale hardware, paper, drugs, etc. It is one of the chief railroad centres between the Missouri River and the Pacific Coast. The State capitol, a handsome stone edifice, is the most important building of the city. The State Memorial building, erected to the memory of the veterans of the Civil War at a cost of $550,000, is the most handsome structure in the city. The government building and the court house are also creditable buildings. Topeka has a municipally owned city building with auditorium annex with seating capacity for 5,000 people. Just west of the city, two miles, is the State Hospital for the Insane; the State Reform School is located just north of the city about three miles. The Colored Industrial Institute is a coeducational institution for colored boys and girls located just east of the city. Orphans Home — two Crittenden Homes, one each for the unfortunate white and colored girls, the Provident Association Building, Ingleside Home for Old Ladies, a Methodist Home for the Aged are among the most notable of its charitable institutions. The Santa Fé Railroad maintains its own private hospital and the public hospitals are Saint Francis, Christ's Hospital and Stormont Hospital. The city has a free public library, a well-organized public school system, including a high school established in 1874; an excellent manual training school is also maintained. It is the seat of Washburn College, a coeducational institution for men and women, and the College of the Sisters of Bethany and three business colleges. Topeka has the commission form of government, having a mayor and four commissioners; a well-equipped fire department and an excellent police department. The city owns its own electric light and water plant. The cost of city government as reported by the United States government reports for the year 1915 shows $20.71 per capita as spent in Topeka for the maintenance of city government. The physical valuation of Topeka is about $56,000,000. The area of the city is 16 square miles. Topeka has over two miles of ornamental lighting system, has 240 acres of city-owned parks and play grounds. Pop. 52,250.

TOPELIUS, tō-pä'lē-oos, **Zachris,** Finnish author: b. Kuddnäs, near Nykarleby, 14 Jan.

1818; d. Helsingfors, 13 March 1898. He was graduated at the University of Helsingfors in 1840, in 1841–60 edited the *Helsingfors Fidningar,* in which many of his earlier writings first were printed, and held at the university the chairs successively of Finnish history (1854–63), of the history of Finland and the northern regions (1863–76), and of general history (1876–78). After Runeberg (q.v.), he is the chief poet of Finland. His religious and patriotic lyrics are particularly valued. Among the collections of his verse are 'Flowers of the Heath' (1845–54); 'New Leaves' (1870). He wrote also several dramas, such as 'After Fifty Years' (1851), and works of fiction, including 'A Surgeon's Stories' (1853–67), a cycle based on Finnish and Swedish history from the time of Gustavus II Adolphus, to that of Gustavus III. There are German translations of several of his writings and an English version of the 'Surgeon's Stories' has appeared in the United States (1883–88).

TÖPFFER, Rudolph, Swiss novelist: b. Geneva, 1799; d. there, 1846. In 1832 he became teacher of æsthetics at the Academy of Geneva and in 1839 his novel 'Le presbytère' attracted general attention to him and ensured his position in the world of letters. He was a voluminous writer and won renown for his 'Voyages en zigzag' (1848) which were continued with illustrations by himself in 1853. Among his best productions are his seven little novels in pictures which were published together in Geneva, 1846–47. Consult Wolterstoff, Hermann, 'Essai sur la vie et lis œvres de Rodolphe Töpffer' (Magdeburg 1894).

TOPHET, or **TOPHETH,** a locality described in Scripture as in the valley of Hinnom, near Jerusalem, where high places were erected, and which was the chief seat of the worship of Moloch, with its fiery human sacrifices and abominations. The good King Josiah suppressed that form of idolatry, and made Tophet a receptacle for the refuse of Jerusalem. Afterward it became a burying-ground. It was shunned with horror by the Jews, and the word has come to be used by Christians as the synonym of a place of punishment after death. The origin of the word is doubtful. It is derived by some from Hebrew *toph,* a drum, in allusion to drums beaten to drown the cries of children burnt in the fire to Moloch, and this seems a probable interpretation. Another derivation is from an Aramæan word signifying to spit or vomit, in allusion to the disgust excited by the place. Consult 2 Kings xxiii, 10; Jer. vii, 31–32; Isa. xxx, 33.

TOPIC, the subject of a discourse, whether written or spoken; the matter treated of in conversation, argument, oration, literary composition, etc. *In rhetoric and logic* topic was restricted to the narrower sense of a common ground of argument, a general maxim or dictum from which other arguments may be started: one of the various general forms of argument employed in probable reasoning, as distinct from demonstrative reasoning. *In medicine* the word is used to denote any remedy locally applied; it is, however, more frequently used in the plural, topics, denoting the class of such remedies, than applied to any one specific.

TOPLADY, Augustus Montague, English theologian and hymn writer: b. Farnham, Surrey, 4 Nov. 1740; d. London, 11 Aug. 1778. He was educated at Westminster and Trinity College, Dublin, and in 1768 was presented to the vicarage of Broadhembury, Devonshire. Though a voluminous writer — and a strenuous defender of Calvinism against John Wesley — Toplady is now hardly known except as the author of the hymn 'Rock of Ages,' one of the finest expressions of evangelical faith and fervor to be found in all hymnology.

TOPOGRAPHICAL SURVEYING. See SURVEYING.

TOPOLOBAMPO BAY, Mexico, a small bay of the Gulf of California on the west coast of the state of Sinaloa. It is noted on account of the attempt made in 1886 by a number of Socialists of the United States to form a coöperative community on its shores. A company was chartered, in which all the colonists were stockholders, and which was to own all the land, and conduct all the business of the community. Everything was to be done as far as possible on the socialistic plan as described in Bellamy's 'Looking Backward.' Several hundred colonists joined in the experiment, and a city was surveyed and laid out on an elaborate plan. The experiment, however, was a failure, largely owing to aridity of the land and the absence of available streams for irrigation. The place was abandoned in 1891.

TOPOPHONE, an instrument for determining the direction from which any sound proceeds. It is valuable for use at sea, during fog, or in the night, to determine the direction of a sounding bell, fog-horn, whistle, etc. The topophone was invented by A. M. Mayer, and consists of a centrally pivoted horizontal bar having at each end resonators, with their openings facing the same way, each with a connecting sound tube for the ears of the observer. In use the bar is turned until a position is found in which the sound is loudest and equally distinct in each ear. The location of the sound is at a right angle to the bar in the direction to which the resonators face.

TORAH, or **THORAH.** See PENTATEUCH.

TORBANITE, a lustreless variety of cannel coal, especially rich in volatile matter formerly used in the manufacture of illuminating gas, paraffin and lubricating oils. It occurs at Torbane Hill, near Bathgate, Scotland, but the supply is exhausted. See BOGHEAD COAL.

TORBERNITE, an ore of uranium consisting of a hydrous phosphate of uranium and copper, $CuO.2UO_3.P_2O_5 8H_2O$, obtained in Utah and Black Hills of South Dakota.

TORBERT, tôr'bẽrt, **Alfred Thomas Archimedes,** American soldier: b. Georgetown, Del., 1 July 1833; d. at sea off the coast of Florida, 29 Sept. 1880. He was graduated at West Point in 1855, was engaged on frontier duty in Texas, Florida, New Mexico and Utah in 1855–60, and at the outbreak of the Civil War was assigned to the duty of mustering in volunteers. He was commissioned colonel in 1861, and led his regiment in the Peninsula campaign of 1862; was assigned to the command of a brigade in that year; and participated in the second battle of Bull Run and in the battles of

South Mountain and Antietam. He was promoted brigadier-general of volunteers in 1862; commanded a brigade at Gettysburg in 1863; for gallantry there was brevetted major in the regular army; in April 1864 was transferred to the cavalry service and placed in command of the 1st division of the Army of the Potomac. He commanded the cavalry in many subsequent engagements, including those at Hanovertown, Milford, Winchester and Waynesboro. In 1864 he was brevetted major-general of volunteers, attaining the same rank in 1865 in the regular army. In 1866 he was mustered out of the volunteer service and resigned his regular army commission. He was United States Minister to the Central American States 1869–71, was transferred as consul-general to Havana, Cuba, and in 1873–78 was consul-general in Paris. He was lost in the foundering of the *Vera Cruz* off the coast of Florida.

TORCELLO, tŏr-chĕl'lō, Italy, an island in the lagoon of Venice, six miles above the city. It is the see of a bishop and possesses an ancient Byzantine cathedral of Santa Maria of the 7th century, with mosaics of the 12th century, curious altar-benches, an antique crypt, octagonal baptistery from 1008 and a belfry; Santa Fosca is another handsome church with a fine interior (12th century). Pop. 130.

TORDENSKJOLD, Peter, Norwegian naval officer: b. Trondhjem, 1691; d. 1720. He endeared himself to the people by his exploits in the navy to which he was appointed a lieutenant in 1711, and in 1716 was given noble rank for his victories. When but 25 years of age he destroyed the Swedish fleet of 44 ships and compelled the raising of the siege of Fredrikshald by Charles XII. He was made vice-admiral (1719) for the destruction of the principal Swedish squadron.

TORGAU, tŏr'gow, Germany, a town in the province of Saxony, Prussia, on the Elbe, 32 miles northeast of Leipzig. Prior to 1889 it was a fortified town, and has considerable historical significance in connection with (1) the Alliance of Torgau, a confederacy formed in 1526 by Saxony, Hesse and other German states in which Protestantism united for the purpose of defense against aggression on the part of their antagonists; (2) the Articles of Torgau, a declaration by Luther and his supporters in 1530, which was the foundation of the Augsburg Confession; (3) the battle of Torgau, fought in the suburb of Luptitz, 3 Nov. 1760, when the Prussians under Frederick the Great defeated the Austrians under General von Daun; (4) the siege of Torgau by Tauentzien in 1814, the city holding out for three months and surrendering 10 Jan. 1814. The Renaissance Hartenfels Castle of the 15th century was a former electoral residence. In the town-hall is a museum of Saxon antiquities. There is here a modern fort for the protection of the railway system. The royal stud farm was long located in the vicinity. Pop. about 13,000.

TORMENTIL, an old provincial name for various species of *Potentilla* (q.v.), a plant supposed to yield relief from the torment of toothache.

TORNADO, from the Spanish *tornada,* «a turning about,» the local name given in various tropical and subtropical regions, notably Senegal, to violent whirlwinds or cyclones, with the usual accompaniment of electrical disturbances and downpouring rain. See CYCLONE; METEOROLOGY; WIND.

TORNADO ALARM, an apparatus which automatically gives an alarm when there is a sudden change of atmospheric pressure, such as precedes a tornado. It is a form of barometer in which the main mercury tube has a cylindrical bulb at the top and is bent in the form of a siphon. Near the lower portion of its shorter member is a secondary tube, the connection being made by means of a short tube connecting with the main tube by a very small opening. The fluid in both the larger tubes will remain normally of equal or nearly equal height in ordinary changes of the weather, but in case of sudden atmospheric changes the small opening in the connection between the tubes restricts the movement in the secondary tube as compared with that in the main tube. Such variation in the movement of the mercury in the two tubes when sufficient to indicate an approaching storm, is made to give an alarm by means of floats in the tubes connected with wires in an electric circuit, there being on one wire a fork and on the other a tongue, by which contacts are made, to ring an alarm when the points meet. This alarm should sound some two minutes before the first blasts of the tornado. Ordinary storms have no effect at all on the apparatus.

TORNEA ELF, tŏr'nĕ-â ĕlf (sometimes written TOME), Sweden, a river at the north, which rises in Lake Tornea. Part of its course forms the boundary between Sweden and Finland, and then empties into the Gulf of Bothnia, after a course of 275 miles. The town of Tornea stands at its mouth and on the opposite side of the river the Swedish town of Haparanda.

TORONTO, Canada, a city and lakeport, the capital of the province of Ontario, situated on the circular Toronto Bay between the mouths of the Don and Humber rivers, on the northwest coast of Lake Ontario, 313 miles west-southwest of Montreal and 60 miles in a direct line northwest of Buffalo, United States. It is the seat of the provincial government, of the higher law courts, of an important university and of the Department of Education of the province; it is also the cathedral city of a Roman Catholic and of an Anglican diocese. In commercial importance it is the second city in the Dominion, and, after Montreal, the chief railway centre. The Grand Trunk, the Canadian Pacific, and many branch lines connect it with the principal cities of Canada and of the northern United States, and it is the headquarters of the Canadian Northern and the Temiskaming and Northern Ontario railways. The fine harbor, five miles long and one and a half wide, is formed by a long, low, sandy island, protected by imposing breakwaters; this island is, in summer, a favorite bathing and boating resort. A great scheme of development, which includes the deepening and extension of the harbor, land reclamation, boulevard construction and the creation of industrial sites is in progress. The city rises gradually from the water's edge to a height of 220 feet; it extends from east to west for about 10 miles along the lake shore and from north to south from three

2 The University of Toronto

to seven miles, and covers an area of about 32 square miles, with streets crossing each other at right angles. An electric street railway system has about 144 miles of tracks. The architecture, especially of the numerous public buildings, is tasteful and imposing, and there are many fine shops and residences. Brick of a pleasing light color, or red, is the chief building material. Of the public buildings, the most striking group is that connected with the University of Toronto. The main building or University College, a fine Norman structure in gray stone, with a massive tower and richly sculptured doorway, was rebuilt after partial destruction by fire in 1890; the Library, the new Medical Building, the Biological Department, the School of Practical Science, with its handsome new engineering building in the Renaissance style, and a number of other large structures, unite with this to make up an imposing group, not wholly harmonious, but in a spacious setting of park land. Adjacent are the "Neo-Greek" Parliament buildings, containing the government offices, and a handsome and well-decorated legislative hall. The magnificent city hall and courthouse is, next to the university, the most striking of Toronto's buildings. Others worthy of mention are Osgoode Hall, the seat of the provincial law courts; the Normal School buildings, offices of the Department of Education; Central Technical School; Trinity College, in connection with the Church of England, an ornate building, in the late Gothic style; the custom house, the post office, the exhibition buildings, where an important annual exhibition is held, and the lunatic asylum, in about 40 acres of ground. A new Union railway station to cost $5,000,000 is in course of construction. The churches most worthy of notice are the Roman Catholic and Anglican cathedrals, both in the pointed style; the latter is an excellent specimen of Early English. There are numerous theatres and many public halls, the chief being the Massey Music Hall, which will hold 4,000 or 5,000 people. Toronto has 1,329 acres of park, the chief being Queen's Park, adjoining the university, and the extensive High Park, at the west of the city. It is a great educational centre. The university (see following article) is one of the best equipped in America. Educational institutions connected with it are Trinity College (already mentioned); Victoria College (Methodist, arts and divinity); Knox College (Presbyterian, theological); Wycliffe College (Anglican theological); Saint Michael's College (Roman Catholic), and colleges for instruction in music, dentistry, pharmacy and veterinary science. Its agricultural college is situated not at Toronto but at Guelph, Ontario. McMaster University is an independent Baptist institution, teaching arts and divinity. Upper Canada College, in spacious grounds, is a residential school for boys, as is also Saint Andrew's College, the site of which was acquired in 1917 for a military hospital. Havergal College is a similar type of school for girls, and besides it are Bishop Strachan's School, Saint Margaret's College, etc. The Toronto Conservatory of Music has a very large number of pupils. The Observatory, at which the weather reports for the Dominion are made up, is in the university grounds. Toronto has suffered from destructive conflagrations, notably in 1849, in 1890 and in April 1904, when more than 100 buildings in the wholesale business section were burned down, some 5,000 persons were thrown out of work, and about $11,000,000 worth of property was destroyed. The industries of Toronto include a great agricultural implement factory, iron foundries, shipbuilding, rolling stock, distilling and brewing, pork-packing, the manufacture of soap, tanning, aeroplanes, etc. The city possesses a well-equipped system of public libraries, with a fine reference library centrally located, in which the John Ross Robertson historical and ornithological collections are housed. Shipping on the lakes is laid up in winter, but during the navigable season several lines of steamers connect with the principal ports on the Great Lakes and the Saint Lawrence. The lake commerce in lumber, grain, coal, cattle and fruit is large. Toronto's bank clearings in 1917 were $3,004,785,565; customs revenue, $35,732,400. The city has over 1,700 manufacturing establishments, employing 80,000 hands.

The name Toronto is derived from the Huron word, signifying "place of meeting." In 1749, when the French were establishing a chain of forts or posts through all the West and down the Mississippi Valley, Fort Rouillé was founded, on a site even then often called Fort Toronto. In 1756 this fort, on the west side of the present city, was destroyed to prevent its falling into the hands of the English. In 1793 Governor Simcoe finding Niagara or Newark, which lay almost under the guns of an American fort, too close to the frontier for the seat of government, removed the capital to the other side of Lake Ontario and established his headquarters in a tent, on a site in the eastern part of the present city. In 1813 Toronto, called York by Governor Simcoe, was captured and partially burned and looted, twice in the same year, by the American army and navy. In the first capture the American General Pike, the discoverer of Pike's Peak, together with many soldiers, was killed by an explosion. In 1834 Toronto was incorporated as a city with its present name. In 1837 it was the chief scene of a brief and ineffectual rebellion under William Lyon Mackenzie (q.v.). At that time and often since Toronto has shown itself to be fervently British in sentiment. Its later history has been purely civic, without other interest than that attaching to prosperous growth. A pleasant society and an attractive situation make it a favorite place of residence. Population has increased rapidly. In 1793, when Governor Simcoe landed, there were only a few families. In 1834 the population was less than 10,000. In 1861 it had increased to 44,821, in 1871 to 56,092 and in 1881 to 86,415. In 1891, including some annexed suburbs it amounted to 181,220, and in 1911 to 376,240. Police census (1917), 535,271.

Consult Scadding, 'Toronto of Old'; Scadding and Dent, 'Toronto, Past and Present'; Adam, 'Toronto, Old and New'; and 'The Toronto Annual.'

George M. Wrong,
Professor of History, University of Toronto.

TORONTO, Ohio, village in Jefferson County, on the Ohio River, and on the Pennsylvania Railroad, 10 miles above Steubenville, the county-seat. It is in a region in which there are extensive beds of clay and large stone quarries. It is near the natural-gas fields of West Virginia. The chief manufacturing establishments are potteries, brick and tile works. The shipments are chiefly pottery, sewer pipe, terra-cotta and fire-brick. Pop. 4,271.

TORONTO, University of, situated at Toronto, Canada, the head of the educational system of the province of Ontario. The first step toward the establishment of the university was taken in 1797 when the council and assembly of Upper Canada petitioned the king for an appropriation of Crown lands for the purposes of education, and the establishing of a university. The appropriation was made, but nothing further was done toward the founding of the university until 1827, when it was chartered under the name of the University of King's College; the organization of the university was further delayed, largely owing to objections to the sectarian character of its charter, which was amended in 1837; and it was not till 1843 that it was opened to students. In 1849 the name was changed to the University of Toronto; in 1853 the university was further transformed by the organization of two corporations, known as the University of Toronto and the University College; to the latter was assigned the teaching in arts and the entire control of its students. In 1887 a further organization of the whole university took place. Under what is known as the «Federation Act» the university became a teaching body once more, with faculties of arts, medicine, applied science and engineering, to which have been added since, faculties of education, forestry, household science and music. In the faculty of arts the subjects were divided as between the University of Toronto and University College, which may be termed the State Arts College, the complement of the faculty of arts of the university. In this reorganization of the faculty of arts there are now Victoria College, representing the Methodist Church of Canada; Trinity College, representing the Church of England; Saint Michael's College, representing the Roman Catholic Church — so that there are four arts colleges giving instruction in the same arts subjects, but sending their students to the university for instruction in other subjects, among which are mathematics, sciences, philosophy, political science, history.

The institutions which have close relations with the university are either federated or affiliated. Among the federated institutions, outside the arts colleges, are Knox College and Wycliffe College, while among the affiliated colleges are the Ontario Agricultural College, the Royal College of Dental Surgeons, the Ontario College of Pharmacy and the Ontario Veterinary College. These federated and affiliated colleges are represented on the senate of the university, which has charge of the educational policy. Each faculty has its own council and has charge of the discipline and control of its students, while the caput is made up of the chief executive officers of the university, together with the heads of the federated colleges.

The university receives a very substantial grant annually from the government of the province of Ontario and is affiliated with the leading universities of Great Britain and Ireland, as well as with the General Medical Council of Great Britain.

The degrees offered by the university include arts, medicine, applied science and engineering, pedagogy, forestry and music, under the regular faculties, while through the affiliated institutions degrees are given in law, dentistry, agriculture, pharmacy, with diplomas in public health and physical training. Extension and summer session work are carried on in the faculty of arts. The university is coeducational and had during the session 1918–19 an attendance of approximately 3,000, which is likely to develop to a greater attendance than in pre-war days, when the enrolment exceeded 4,000.

The important buildings are the main building, convocation hall, the library, household science, the various laboratories and within Toronto the buildings of Victoria College, Trinity College and Saint Michael's College.

Provision is made for the undergraduate activities of the men in Hart House, the gift of the Massey Estate. There are residences for men students of the university and for both men and women in University College, Victoria, Trinity and Saint Michael's colleges.

TORPEDO, a genus of rays of the family *Torpedinidæ,* most remarkable for their electric organs, which lie on each side of the head. (See ELECTRIC FISHES). The electric shock is powerful enough to kill small animals, and specimens two or three feet long can by a single discharge disable a full-grown man. The family, which includes about seven genera and 15 species, is widely distributed over the Atlantic and Indian oceans; *T. marmorata* and two others are common in the Mediterranean, and *T. hebetans* reaches the south coasts of Britain. The American form most often seen is *T. occidentalis,* which may reach a weight of 200 pounds; it is uncommon, but occasionally seen along the coast from Cape Cod to Cuba.

TORPEDO, Automobile. See AUTOMOBILE TORPEDO.

TORPEDO-BOAT DESTROYERS. See ANTI-TORPEDO BOATS.

TORPEDO BOATS. The torpedo boat first made its appearance as an adjunct to the fleet in 1886. At that time its displacement was less than 100 tons, and its speed about 20 knots an hour. From that time on it gradually increased in size and speed until in 1896 its displacement was about 125 tons and its speed about 23 knots an hour. The next evolution was the destroyer. This new type of vessel became necessary, for the dangerous character of the torpedo boat was fully recognized, armed as it was with an inaccurate weapon. During the revolution in Chile in the early nineties a battleship was destroyed by a torpedo fired at night from a large torpedo boat, and during the Japanese-Chinese War in the middle nineties torpedo boats were freely used by the Japanese.

As the years went by the range and accuracy of the torpedo rapidly improved and the torpedo boat increased its size to make it more habitable and seaworthy. Its tonnage soon rose to 400 tons and then merged into the destroyer. As the size of the torpedo boat still increased, destroyer tonnage was compelled to keep pace, the final or present destroyer displacement of about 1,100 tons (with a speed of about 32 knots per hour) having been reached and determined by most nations from a consideration of the strategical and tactical duty of the fleet with which it serves. The offensive weapon of the destroyer was originally the gun, but after the torpedo boat disappeared the torpedo became the important weapon and the guns were retained for defense only. The pivotal characteristics of the destrover were high speed, seaworthiness, moderate radius of action and plurality of torpedo tubes and torpedoes. To enhance these characteristics increased size was necessary and this lessened the chance of being able to surprise an enemy on the alert, and surprise was a corollary in its usefulness. These considerations tended to limit the size and when sufficient tonnage for necessary offensive work was gained, no further increase was thought justified. The present tendency is to increase the destroyer's gunpower for offensive purposes against the submarine and this brings the destroyer back to the original conception of the use of that type. Further development will undoubtedly be toward high speed, moderate size, long-range torpedoes, a plurality of small guns and large radius of action. The destroyer, supported by large cruisers, makes an excellent offensive force, especially when armed with long-range torpedoes. Making contact in the daytime with an enemy's fleet, destroyers can, at night, readily slip through the screen and attack the enemy while in its night formation.

A well co-ordinated destroyer force becomes a most important asset to a fleet when about to go into battle. A well-timed feint upon the battle line of the enemy may give to its own battle line a verv important advantage of position. By the intelligent use ot a *smoke screen,* made by emitting large volumes of oil smoke from destroyers' smoke stacks, a battle line in confusion can be rescued from destruction and permitted to reform or to escape. In the battle of Jutland the German fleet was concealed in a smoke screen formed by German destroyers at the time when the main British fleet was about to bring a superior force against it. When the smoke cleared it was observed that the German fleet had extricated itself from danger.

While the first duty of the destroyers was to run down attacking torpedo boats and sink them with the fire of their small rapid-fire guns, it was also armed with torpedo tubes in order that it might be used as an attacking torpedo vessel and to defend the battleships at night. The smaller type of torpedo vessel — the torpedo boat — was classed as a weapon of defense, employed to guard the home coast from raids by the enemy's warships, while the larger was regarded as an offensive weapon, used to destroy the smaller type and allow capital ships to perform, without danger, their duties of blockade and various war measures. See SUBMARINES.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

TORPEDO DRAG, a device for clearing harbors, river-channels, etc., from floating torpedoes and submarine mines. It consists of a long cable, bearing grappling hooks set at frequent intervals. The ends of the cables are made fast in boats, one on either side of the channel, and as the vessels proceed up and down the channel, abreast, the hooks on the rope between them catch the torpedoes. Sometimes a drag is thrown ahead of a vessel by a small mortar and is drawn in by a windlass; this is to clear the channel through which the vessel must pass.

TORPEDOES. Torpedoes or explosives moving through the water to the object attacked, as distinguished from the mine or stationary explosive, first took the form of what was in reality a towed mine. The Harvey, Menzing and the various French towing torpedoes were weapons of this kind. The torpedo was towed astern of a launch with a rig that permitted a rudder on the torpedo being controlled from the towing boat. The torpedo could be guided to a position on the quarter, while a second torpedo was towed astern. By means of a dipping or detaching apparatus, when the whiskers of the torpedo touched the target, the torpedo would become completely submerged before the explosion took place. Torpedo warfare received great impetus during the Civil War, various types being developed by both the Confederates and the Federals. Dragging for torpedoes and the use of torpedo nets dropped over the sides of vessels were then first practised, but there appears to have been no use of submarine boats until more recently. During this war the spar or outrigger torpedo came into active use and on more than one occasion during that period and later proved its worth. This weapon consisted of a torpedo carried at the end of a spar or pole which projected from a launch. It was so arranged that just before the target was struck, the torpedo could be plunged below the surface to obtain the holding or plugging effect of the water for the explosion. The explosive usually consisted of about 33 pounds of guncotton which could be fired upon contact, or at will, by employing a firing battery. To carry and drive home the spar torpedo a fast seaworthy launch or small torpedo-boat was employed.

In its early stages of development, battle ranges seemed logically to keep the torpedo in the background, except at night, when the speedy torpedo-boat counted upon getting near enough to launch its weapons with a more reasonable promise of making a hit. The naval constructor, accepting the torpedo at its potential value as seen by the majority of the fighting officers simply limited his efforts to fabricating the under-body of his fighting craft so that the damaging effects of a chance blow from a torpedo should be confined to a restricted area. Hence the inner and the outer bottoms, and the water-tight, cellular divisioning of the intervening space. As a matter of fact, the naval constructor's work stood up under torpedo attack and performed its function remarkably well. It is a matter of record, that the general run of torpedoes fired during the Russo-Japanese War did far less damage than was expected of them, and a goodly number of vessels so struck were not sunk as was counted upon, but were able to get into port and be repaired. There were ships lost to both belligerents by subaqueous attack, but the most conspicuous of these disasters were due to the violent blows of passive mines. Where the active torpedo had failed in its mission the anchored floating mine filled the offensive gap. These mines carried larger explosive charges than the torpedoes then in service, and proved two things: First, that the naval constructor had planned well; and, second, that the automobile torpedo must needs be made a more powerful weapon if it were to fill the office intended for it. In the Russian fleet at Port Arthur were several vessels that had been built by the French for the Russian government. In addition to the usual compartmenting of the inter-bottom space, the French designers had reinforced the region most likely to be attacked by torpedoes by means of a caisson built of plating nearly two inches thick. The object of this caisson — assuming that the explosion of the torpedo should be sufficient to rend or rupture the plating of the inner and outer bottoms — was to provide more space in which the guncotton gases could expand and dissipate the most dangerous percentage of their remaining force. The ingenious theory of this style of construction was proved to be all that its originators claimed for it. The Russian ships so built were several times hit by Japanese mines, and while grievously wounded over wide areas of their under-bodies, yet the caissons remained substantially intact and the vessels were able to return to harbor.

The automobile torpedo first came into use in the early seventies. It was the outcome of a series of experiments commenced in 1864 by Robert Whitehead, then superintendent of iron works at Fiume, Austria. This torpedo, known as the Whitehead or fish torpedo, claimed the following capabilities: (1) It could be adjusted to run at any depth from 5 to 15 feet when fired from either a submerged or surface tube, or from a surface detaching apparatus; (2) upon firing, it would make a straight run, provided a proper allowance was made for the deflection due to transverse currents; (3) it could be adjusted to stop at any distance up to its extreme range and after stopping to sink or float; (4) it could make a run of 1,000 yards at a speed of 15 or 16 knots, while 300 yards could be covered at a speed of 19 to 20 knots; (5) it could carry a warhead holding a charge of 33 pounds of guncotton, to explode upon contact. This torpedo was propelled by a three-cylinder Brotherhood engine weighing 35 pounds, driving two propellers and developing 40 horse power. Eventually the Whitehead torpedo came to be used in the United States service, and later the Bliss-Leavitt torpedo was adopted. As heavier armor was added against torpedo attack a large gap developed which the Whitehead torpedo and its various kindred rivals could not fill, and here it was that the genius of an American naval officer, Commander Cleland Davis, placed the torpedo upon a new and more formidable footing. He abandoned the guncotton warhead, which was the accepted instrument of destruction since the inception of the Whitehead, and substituted a gun in its stead. If one will study carefully the photographs of either bursting submerged mines or exploding automobile torpedoes, the most impressive visual sign of the violence exerted will be found in the great volumes of water blown upward. The water has yielded more than the steel structure attacked, and the major part of the energy designed to wreck has spent itself uselessly in blowing hundreds of tons of water into the air. Commander Davis sought so to concentrate the powers of assault in his torpedo that but little of its force should be dissipated in disturbing the surrounding water while the bulk of the energy of his weapon should remain unimpaired and centred in piercing the enemy's defenses and penetrating to the very vitals of the object of attack. He did not discount in the slightest the truly remarkable developments which had taken place in the other departments of the automobile torpedo. Increased range, higher speed and more precise functioning all helped him toward his objective; but it is his invention which made this underwater projectile a graver menace to the largest of fighting craft. This torpedo carries an eight-inch gun capable of expelling an eight-inch projectile with a muzzle velocity of 1,000 feet per second, which is quite enough to carry the projectile through a single plate of Krupp armor, something like four or five inches thick, where virtually in contact with the muzzle of the gun — as would be the case with this torpedo. Ships are not protected under water with plating of these dimensions, and it would be a much easier task for the projectile to pass successively through a number of thinner plates even if their combined thickness were more than the limit set. The projectile fired from this torpedo carries a bursting charge of high explosive of between 35 and 40 pounds. This charge is detonated by a delayed action fuse, which is designed to meet the maximum requirements imposed by the best protected dreadnaughts built. When this weapon is launched upon its sinister errand the little propeller at the upper side of the torpedo's nose revolves and releases the tripping rod, so that the torpedo can be discharged upon contact with its target. When the rod hits the obstruction it is driven backward and engages the trigger which first compresses a spring attached to the firing pin and then releases it so that the pin can strike the gun primer, thus setting off the propelling charge of powder which drives the shell out of the gun. As soon as the projectile hits the outside plating of a ship's bottom the fuse in the base of the shell begins to function, being set to explode the charge in the shell so many hundredths of a second after impact.

The modern submarine torpedo varies in size according to the service for which it is intended and ranges from 14 inches in diameter and 15 feet in length to 21 inches in diameter and 21 feet in length, weighing from 1,000 to 2,600 pounds, the smaller type being used to sink unprotected freight and passenger ships at short range. It is capable of a speed of more than 30 miles per hour and when traveling at normal speed possesses the great momentum of about 65,000 foot second pounds. Generally speaking, the torpedo consists of the following parts: (1) The warhead, which contains the high explosive charge, fired by an exploder upon striking the target, the charge ranging from 200 to 500 pounds, depending upon the type of torpedo; (2) The air flask, a specially constructed shell of steel, very strongly built to withstand a test pressure of 5,000 pounds to the square inch. This flask carries air at an initial pressure of 2,250 pounds per square inch, the air being used to operate all the mechanism of the torpedo in addition to the motive power; (3) The depth control mechanism, which permits the torpedo to be run at any desired depth under water, and which consists principally of a pendulum and a hydrostatic piston actuating horizontal rudders; (4) The gyroscopic steering gear. The gyrostatic compass through the vertical rudders maintains the torpedo on a course parallel to that in which the torpedo began its run; (5) The engines. The air at the high pressure of 2,250 pounds per square inch first passes through a reducing valve which decreases its pressure to that required for use by the engine. This air is then heated by an alcohol flame, which also acts to produce steam of the water in the combustion flask, the air and steam mixing and passing to the engine. The engines are generally reciprocating, but in the Bliss-Leavitt and some other torpedoes are turbines driving two propellers.

Torpedoes are projected by means of special forms of tubes or guns. The tube is usually built into the hull of the submarine, in which case it is aimed by manœuvring the boat. In the case of destroyers and battleships, the torpedo may be projected from submerged tubes or from deck tubes. In general, torpedoes are projected from submerged tubes by compressed air and from deck tubes by a small charge of gunpowder. Submerged tubes on battleships, however, may be designed to use either powder or compressed air. When the torpedo is fired from a submerged tube the compressed air or the gas from the powder follows the torpedo out of the tube with a rush and causes an eruption on the surface of the sea, which is visible for a considerable distance. As a result of the warning given by this eruption, vessels have sometimes been able to escape the torpedoes by a quick manœuvre. The modern torpedo is self-propelled, being driven through the water by its own compressed air motor, the air being supplied from a strongly-built reservoir within the body of the torpedo itself. Torpedoes directly operated by internal combustion engines as motive power are not trustworthy. The range of a torpedo is approximately a mile, those designed for use on battleships and destroyers being longer ranged than those for use on submarines. The great difficulty in getting proper direction and sufficient motive power to give the required speed for a long duration of time renders the long range torpedo impracticable. The latest German torpedo had a range of about 2,000 yards, as the compressed air storage reservoir was reduced in size in order to increase the charge of high explosive in the warhead. The charge was from 300 to 400 pounds. The depth at which a torpedo travels may be regulated to hit the most vital part of the vessel, and that is usually about 10 feet below the surface. In case of torpedo attack against an armored ship the torpedo, to be dangerous, should strike beneath the armor belt, which usually extends about 10 feet below the water line. Torpedoes are usually provided with means to cut, more or less effectively, through nets placed in their paths. The detonation of the torpedo is accomplished through a mechanism placed within its warhead; and if the torpedo is checked in its forward motion the firing mechanism instantly ignites the heavy charge of explosive contained within the warhead. It is not necessary to strike a firing pin on the end of a torpedo to detonate the charge. Many suggestions have been submitted for a torpedo to be electrically propelled from a ship by means of a flexible cable connecting it with the ship. This was the first type of torpedo built, but was discarded for the present dirigible type, as the weight of cable, difficulties in insulation, etc., render it of little practical value. The effectiveness of the Hammond radio-controlled torpedo is promising. The Board of Ordnance and Fortifications recommended favorably to the Secretary of War as to the merits of this invention, and the Secretary recommended to Congress that this new type of weapon be installed in a few of the more important coast defenses.

When firing a torpedo at a moving target there are several important factors which the torpedoist must consider. These are the speed of the target, the course of the target and the speed of the torpedo itself, all of which factors must be known within limits in order to make effective hits. The various nations have their preference for torpedoes. The British use the Whitehead; the Germans, Schwartzkopf; the French, Whitehead and Schneider; the Japanese and Italians, the Whitehead. In the United States the Whitehead and Bliss-Leavitt torpedoes are in general use. See NAVAL MINES; SUBMARINE MINES; SUBMARINES.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

TORQUAY, tôr-kē', England, a fashionable watering place in Devonshire, situated on the south coast, 26 miles northeast of Plymouth, named from the Tor Abbey nearby, which was founded in 1196. It is built on a series of terraces rising from the beach, and is a much frequented bathing and winter resort. It consists largely of villas and gardens, and has a fine promenade, public parks, libraries, a museum, electric light and an excellent water supply and drainage system. There are manufactures of terra-cotta ware, and trade in coal and marble. The name also applies to the borough and the Parliamentary division in which it lies. Pop. of the borough about 39,000.

TORQUE, an ornament of twisted gold or other metal, worn as a collar or a necklace by the ancient peoples of Asia and northern Europe. It consisted of a circle of stiff gold, twisted except at the ends, which remained straight or which in some cases were looped back, so as to overlap. Such collars were considered a characteristic ornament of the ancient Gauls and are said to have been so abundant that about 223 B.C., Flaminius Nepos erected to Jupiter a golden trophy made from torques of conquered Gauls. The Torquati, a family of Manlian gens, attribute their name to their ancestor T. Manlius, who having slain a giant Gaul in single combat lifted from the neck of the dead body an enormous gold torque, which he ever afterward wore upon his own.

TORQUEMADA, Juan de, hoo-än' dā tōr-kā-mä'thä (Latinized form TURRECREMATA), Spanish theologian and cardinal: b. Valladolid, 1388; d. Rome, 26 Sept. 1468. He entered the Dominican order in 1403, and was graduated at the University of Paris in 1424. After serving as prior at Valladolid and Toledo, he was appointed by Eugenius IV master of the sacred palace in 1431. In 1439 he became a cardinal-priest, later exchanged his title for the cardinal-bishopric of Albano, and still later (1464) for that of Sabina. He gave liberally of labor and money to charities and church-building, and won fame as a theological writer and controversialist. He was an influential member of the councils of Constance, Basel and Florence, at the last-named of which drew up the proposals for union between the Greek and Latin churches. Among his works may be mentioned 'Meditationes' (1467); 'Quæstiones Spiritualis Convivii Delicias præferentes super Evangeliis' (1477); and 'Commentarii in Decretum Gratiani' (1519). Consult Lederer, 'Der spanische Cardinal Johannes von Torquemada' (1879).

TORQUEMADA, Tomás de, Spanish monk, first Grand Inquisitor of Spain: b. Valladolid, 1420; d. Avila, 16 Sept. 1498. He entered the Dominican order, was for 22 years prior of the monastery at Segovia, and in October 1483 was made by Sixtus IV inquisitor-general for Castile and Leon. The Inquisition (q.v.) had been established in 1480 at Seville, but Torquemada was the first to give it its organization. He founded four tribunals at Seville, Cordova, Jaen and Villa Real. During his 18 years of office he burned 10,220 persons and condemned 6,860 to be burned in effigy. By these methods the Inquisition acquired vast sums of money. Torquemada was justly hated, and never went about without a body guard. His later activities were directed against the Jews and about 1,000,000 of them fled the country to escape his persecution. He was one of the most bloodthirsty fanatics of history. Consult standard works on the history of Spain and of the Inquisition; also Molènes, 'Document Inéditis. Torquemada et l'Inquisition' (1897).

TORRE DEL GRECO, tŏr'rĕ dĕl grä'kō, Italy, on the Bay of Naples, seven miles southeast of Naples at the foot of Vesuvius. The town has been demolished by earthquake at various epochs, and in 1857 and 1906 a similar disaster greatly changed and damaged the locality. It is much frequented by foreigners as well as Italians on account of its sea-bathing. There are important coral and other fisheries, besides shipyards, manufactories of rope, coral goods and lava ware. Pop. of commune about 36,000.

TORRENCE, Frederic Ridgely, American poet: b. Xenia, Ohio, 27 Nov. 1875. He was educated at Miami, Ohio and Princeton universities, was librarian in the Astor Library 1897–1901, and since 1901 at the Lenox Library, New York. He has published 'The House of a Hundred Lights' (1900); 'El Dorado: a Tragedy' (1903); 'Abelard and Heloise' (poetic drama, 1907).

TORRENS, William Erskine, American promoter: b. New York, 15 July 1870; d. 20 June 1914. After making a study in the mills of New England and Philadelphia of manufacturing methods and finance, he became in 1896 foreign commissioner for the National Association of Manufacturers of the United States, and was thus engaged until 1899. During this time he secured concessions from Brazil, Venezuela, Argentina, Cape Colony, China and Japan for establishing sample warehouses for the exhibition of American manufactured goods. He has written 'Commercial Traveling in South America' (1897); 'Commercial Traveling in South Africa' (1898); 'Commercial Traveling in the East' (1899).

TORRENS, Lake, South Australia, a large shallow salt lake, the central one of a group in the central southern section, 125 miles long and 25 miles wide, about 50 miles north of Spencer's Gulf. In the dry season it is reduced to a salt marsh.

TORRENS SYSTEM, a system of title-registration devised by Sir Robert Torrens, and first successfully used in Australia. Its object is to make the transfer of landed property as simple and as safe as that of any other property and to do away with the necessity of repeated title examinations. The system is operated through a bureau of registration, in charge of a registrar, and becomes effective on the first transfer of any property after the establishment of the system, all land transactions being registered in this office. A title may be registered as absolute or as possessory. Before registry the title is fully investigated by the registrar, who receives from the owner all the documentary evidences of title, descriptions of boundaries, etc. When the registrar is satisfied that the title is perfect, he files away all these old papers and issues to the holder a certificate of ownership, a duplicate of which is filed in the registrar's office. Such certificates bear on their faces notice of all encumbrances on the property. If the estate is vested in fee simple the title is known as «absolute» and the certificate is stated to be an absolute certificate. Should it appear that an absolute title to any land can be held only for a limited period or subject to reversions, then the registrar will except from the effect of registration any estate, right or interest arising before the specified date or under the conditions named, all of which will be entered in the register and noted on the certificate, which is stated to be a «qualified» certificate. In the case of a «possessory» title the applicant is registered as becoming owner on giving such evidence of title as may be prescribed, and the registration of any person as first owner with a possessory title only will not interfere with the enforcement of any estate, right or interest adverse to the title that may then exist or which may arise a later date. And this fact is noted on the «possessory» certificate issued to the owner. This examination and registration of title does not have to be repeated after a certificate has once been issued, the transfer of the certificate with accompanying entry of that fact in the registrar's office completes the transaction. By this method the transfer of a land title certificate becomes as simple and as inexpensive as the transfer of a certificate of stock or of a bank share, and the holder of the title is absolutely free from the usual danger of land title transfers, such as flaws in the title, the neglect of obscure future conditions, etc. Should any person suffer loss through misdescription, omission or any other error in the certificate issued by the registrar, he is indemnified from an insurance fund created for that purpose. This fund is provided by the imposition of a tax of one-fourth of 1 per cent on the value of the land at the time of the first certificate of title being granted, in addition to the registration fees. The registrar is the judge in all cases as to the liability of the fund to such compensation. The fees for registration under the Torrens system are very small, usually being $24 in case of the first registration, and three dollars upon the issue of every subsequent certificate. The system has been vigorously opposed by title guaranty companies and by members of the legal profession who see in it an end to a fruitful source of fees since under it there is furnished State title insurance instead of private title insurance, with nominal cost for conveyances.

The Torrens system is in use in South Australia (1858), British Honduras (1858), Vancouver (1860), consolidated with British Columbia (1866), Queensland (1861), Tasmania (1862), New South Wales (1862), Victoria (1862), England (1862, 1875, 1897), Ireland (1865, 1891), New Zealand (1870), British Columbia (1871), Western Australia (1874), Wales (1875, 1897), Fiji (1876), British Guiana (1880), Ontario (1885), Manitoba (1885), Canadian Northwest Territories (1886), Leeward Islands (1886), Jamaica (1888), British New Guinea (1889), Cyprus (1890), Illinois (1895), Ohio (1896), California (1897), Massachusetts (1898), Minnesota (1901), Oregon (1901), Philippine Islands (1902), Colorado (1903), Hawaii (1903), Nova Scotia (1904), Alberta (1906), Saskatchewan (1906), Washington (1907), New York (1908), North Carolina (1913), Mississippi (1914). The Massachusetts law is the best and the most successful in the United States; the New York law has been in great part a failure, due to defects in the act, of which the opponents of the system have taken advantage. Since the original Torrens Act gave a judicial and discretionary power to the registrar not in conformity with the spirit of American institutions, this portion of the law has been slightly changed in order to adapt it to the requirements of this country. Consult Niblack, William, 'Analysis of the Torrens System' (Chicago 1912); Cameron, A. G., 'The Torrens System' (Boston 1915); id., 'The Torrens System, Its Cost and Complexity; a legal and Practical Treatise' (Chicago 1903); Torrens, Sir Robert, 'Essay on the Transfer of Land by Registration' (London); Beers, W. F., 'The Torrens System of Realty Titles' (New York 1907); Kennedy, J. P., 'List of References on the Torrens System' (Virgina State Library, Richmond, Va., 1906).

TORRENTS OF SPRING ('Véshniya Vódui'), by Iván Sergéyevitch Turgénief, is the tragi-comedy of a man of weak will who succumbs to a passionate impulse, yields to the seductions of the typical "vampire" woman and throws away the happiness of his whole life. "Weak men," says the author, "never bring things to an end; they always wait for the end to come." The title is symbolical and not quite adequate, the comparison being introduced in the wrong place.

Sánin, a young nobleman, is in his 22d year, very good-looking, with handsome graceful figure, kindly bluish eyes, golden hair, a clear skin, a smile like a child's and giving the impression of "freshness, health and softness, softness, softness," a man "recognizable at a glance as the son of a sedate aristocratic family, the type of the fine young *pomyeshchik*, born and reared in our wide steppe-like regions." On his way home from Europe to Russia he is detained for a few hours at Frankfurt-am-Main, and by chance drops into a confectioner's shop conducted by the widow of an Italian Revolutionist. It happened that just at that moment Emilio the only son had fainted and his sister, Gemma, a young girl of exquisite beauty appeals to Sánin to bring him back to life. This the young man does; the family are profuse in their expressions of gratitude and persuade him to remain for a few days in Frankfurt. During a Sunday excursion with the two young people and Grüber, a bumptious and conceited German clerk to whom Gemma is betrothed, an intoxicated officer, Baron von Dönhof, insults the young girl, and when her lover shows no spirit to resent it, Sánin impulsively takes it upon himself to provoke the inevitable duel. This duel is described at considerable length with a wealth of comic detail. Neither party is injured and the Russian and the Baron part almost friends.

It results, however, in Gemma's breaking her engagement with the ridiculous and pusillanimous Grüber, but Signora Roselli begs Sánin to use his influence with her daughter to persuade her not to ruin her prospects and reputation by such an act, an engagement being regarded in Germany as no less sacred than marriage itself. Sánin reluctantly undertakes to fulfil this delicate mission but finds it impossible, since he has himself fallen in love with the beautiful girl and she is no less fascinated with him. He decides to sell his estate in Russia and invest money in the widow's confectionary business. By another turn of fate he meets at this moment his former schoolmate, Pólozof, another type of the lazy, easy-going Russian, who is married to an enormously rich young woman. Pólozof tells Sánin that his wife will perhaps buy his estate and offers him a place in his carriage to Wiesbaden where Márya Nikoláyevna is taking a cure. She is beautiful but unscrupulous and plays all her arts to fascinate Sánin, who weakly yields and never returns to Gemma. Thirty years later Sánin, always unhappy in his remorse for his dastardly behavior finds a little garnet cross which Gemma had given him. It brings up all the details of his soul's tragedy. He goes to Frankfurt and through Baron von Dönhof learns that Gemma had married a rich American. He writes to her and when she replies, enclosing a photograph of her own daughter, he sees in the picture the very image of his lost love and sends her the garnet cross together with a magnificent string of pearls. Gemma is the very ideal of sweet girlish purity and charm and is presented in striking contrast with the fascinating and not unsympathetic Russian siren who ruins men for her selfish amusement. It is an amusing and yet rather repulsive story. Originally published in the *European Messenger* (*Vyestnik Yevropui*) in 1872, it has been translated as 'The Torrents of Spring' by Constance Garnett (1897); 'Spring Freshets' by Isabel F. Hapgood (New York 1904); 'Spring Floods' by S. M. Butts (1874–75), and by E. Richter (London 1896).

NATHAN HASKELL DOLE.

TORRES NAHARRO, B. de., Spanish dramatic poet: b. near Badajoz, about 1500. He is called the creator of Spanish comedy and was the first writer of his time to develop fully his plots. He wrote fluently in both poetry and prose and his collected works were dedicated to Ferdinand d'Avalos, the husband of Vittoria Colonna. It was not until 1520, however, that his plays became known in Spain where they were very popular.

TORRES (tŏr'rĕs) **STRAIT,** the narrow channel which separates Australia and Papua. From Cape York on the northern coast of Australia to New Guinea it measures about 80 miles. Navigation is unsafe owing to the shoals, islands and reefs within its waters. It was discovered in 1606 by a Spanish navigator from Peru.

TORRES VEDRAS, tŏr'rĕs vā'drās, Portugal, a town in the district of Lisbon, situated on the railroad, 25 miles north of Lisbon. It is noted for its extensive lines of fortifications, 28 miles long, reaching to the Tagus River, and protecting 500 square miles of territory. They were begun in 1809, and behind them Wellington in 1810 checked the French advance toward Lisbon. It has hot sulphur baths and an old Moorish citadel. Pop. about 8,000.

TORREY, tŏr'ĭ, **Bradford,** American naturalist and author: b. Weymouth, Mass., 9 Oct. 1843; d. 1912. He was educated in the public schools, taught two years, entered business in Boston, and for many years after 1886 was a member of the editorial staff of the *Youth's Companion*. He has been well ranked as a field ornithologist, and writes entertainingly of his observations. His essays have been collected into the following volumes: 'Birds in the Bush' (1885); 'The Foot-Path Way' (1892); 'A Florida Sketch-Book' (1894); 'Spring Notes from Tennessee'; 'A world of Green Hills' (1898); 'Every-Day Birds' (1900); 'Nature's Invitation' (1904); 'Friends on the Shelf' (1906); 'Field Days in California' (1913).

TORREY, Charles Cutler, American Semitic scholar: b. East Hardwick, Vt., 20 Dec. 1863. He was educated at Bowdoin College where he taught Latin (1885–86). He studied at Andover Theological Seminary (1886–89) and at the University of Strassburg (1889–92) where he took his Ph.D. degree. Since that time he has been instructor in Semitic languages at Andover (1892–1900), director of the American School of Oriental Research in Palestine (1900–01), editor *Journal* of the American Oriental Society (1900–07; 1911–16) and president of the society (1917–18). His publications include 'The Commercial-Theological Terms in the Koran' (1892); 'Composition and Historical Value of Ezra-Nehemiah' (1896); 'The Mohammedan Conquest of Egypt and North Africa' (trans. from the Arabic, 1901); 'Selections from Bokhari' (1906); 'Notes on the Aramaic past of Daniel' (1909); 'Ezra Studies' (1910); 'Composition and Date of the Arts' (1916). Since 1900 he has been attached to Yale College.

TORREY, Charles Turner, American anti-slavery reformer: b. Scituate, Mass., 21 Nov. 1813; d. Baltimore, Md., 9 May 1846. He was graduated at Yale in 1830, entered the Congregational ministry, and held pastorates at Princeton, N. J., and Salem, Mass. Having removed to Maryland to promote the cause of anti-slavery, he became an active agent of the Underground Railroad (q.v.), and was arrested and imprisoned in 1843 for his report of a slaveholders' convention held in Baltimore. The following year he was again arrested, and being convicted of aiding in the escape of runaway slaves, he was sentenced to a long term in the penitentiary. The harsh treatment he received while undergoing his sentence brought on consumption from which he died, and his remains were taken to Boston where he was honored by a public funeral. He was regarded as a martyr in the cause of abolition, and "Torrey's blood crieth out," became an anti-slavery watchword. He wrote 'A Memoir of William R. Saxton' (1838), and while in prison produced a volume of sketches of Massachusetts life, 'Stone, or the Pilgrim's Faith Revived' (1846). Consult Lovejoy, 'Memoir of the Martyr Torrey' (1847).

TORREY, John, American botanist: b. New York, 15 Aug. 1796; d. there, 10 March 1873. He received his first instruction in botany, mineralogy and chemistry from Amos Eaton, and was graduated at the New York College of Physicians and Surgeons in 1818. His leisure from medical practice he devoted to scientific pursuits, particularly to botany, and in 1824 he abandoned medicine and became professor of chemistry, mineralogy and geology at West Point. From 1827 to 1855 he was professor of chemistry and botany at the College of Physicians and Surgeons, serving simultaneously at Princeton. From 1853 until his death he was chief assayer in the United States Assay Office, New York. He participated in the councils of Columbia College as trustee, and in 1860 presented to that institution his extensive herbarium and botanical library. In his special field of scientific research his publications were numerous. One of his earliest was a 'Catalogue of Plants Growing Spontaneously Within Thirty Miles of the City of New York' (1819), which he prepared for the New York Lyceum of Natural History (now the New York Academy of Science), of which he was a founder and for many years president. In 1843, as botanist of the Geological Survey of New York, he published an elaborate work on the flora of that State. Meantime he had issued in connection with Asa Gray (q.v.), parts of a work on 'The Flora of North America'; but this was also discontinued after the completion of the order *Compositæ*. From 1845 onward he published memoirs and reports on the botanical specimens brought back by expeditions to various parts of the West and South by Capt. John C. Fremont and others, among them being reports on the botany of the expeditions for ascertaining the most practicable route for a Pacific railroad and making the Mexican boundary survey. He was president of the American Association for the Advancement of Science in 1855, and was named by Congress in 1863 one of the original members of the National Academy of Sciences.

TORREY, Joseph, American clergyman: b. Rowley, Mass., 2 Feb. 1797; d. Burlington, Vt., 26 Nov. 1867. He was graduated at Dartmouth in 1816 and at Andover Theological Seminary in 1819. He was for a time pastor of a Congregational church at Royalton, Vt., but in 1827 became professor of Greek and Latin at the University of Vermont. In 1842 he took the chair of philosophy there, and in 1862–66 was president of the institution. He translated Neander's ‹General History of the Christian Religion and Church› (1854), and edited ‹Remains of President James Marsh› (1843) and ‹Select Sermons of President Worthington Smith› (1861). A volume of his lectures, ‹A Theory of Fine Art,› appeared posthumously (1874).

TORREY, Reuben Archer, American evangelist: b. Hoboken, N. J., 28 Jan. 1856. He was educated at Yale College and at Leipzig and Erlangen in Germany He was ordained as a Congregational minister in 1878, was superintendent Minneapolis City Mission Society and became associated with Dwight L. Moody in 1889 and served as superintendent of the Moody Bible Institute until 1908. In 1902–03 he made an evangelistic tour of the world. His life has been devoted to evangelistic work in many lands and he has written much on Bible subjects which have been translated in a score of languages.

TORREY BOTANICAL CLUB, a botanical society in New York which is the most important organization of its kind in America, and one of the six scientific societies affiliated in the Scientific Alliance. The club was an outgrowth of a former club, chartered in 1871. This band met in the herbarium of Columbia College, «drawn there by the genial welcome and wide botanical knowedge of its presiding spirit, Dr. [John] Torrey,» and was the nucleus of the present club, finally organized under its present name, complimentary to Dr. Torrey, in 1873. Dr. Torrey was the first president, but, unfortunately, died almost immediately.

The Torrey Club is the centre of botanical interest in New York, and the neighborhood, and is especially valuable for its weekly excursions that may be joined by any botanist, and which take parties out to good botanizing localities under intelligent guidance. Many local floras have been compiled by members of the club, one of the most important of which is that of Dr. Britton and others, ‹The Preliminary Catalogue of Anthophyta and Pteridophyta growing within 100 miles of New York.› The valuable herbarium of the club includes the material for this list, and specimens of the flora, within the same area. It is now deposited at the New York Botanical Garden, which was originated and developed by members of this society. The club issues three regular publications, namely: *Bulletin,* a very scientific and widely known journal; *Torreya,* of more popular scope; and *Memoirs,* which include many valuable monographs.

TORRICELLI, tŏr-rē-chĕl'lē, **Evangelista,** Italian mathematician and scientist: b. Faenza, Italy, 1608; d. Florence, October 1647. He early devoted himself to mathematical studies, and having read Galileo's ‹Dialogues,› composed a treatise concerning motion according to his principles. Galileo having seen this, conceived a high opinion of the author, and engaged him as his amanuensis. He accordingly went to Florence in October 1641, but Galileo dying three months after, Torricelli was about to return to Rome, when the grand duke of Tuscany, Ferdinand II, engaged him to continue at Florence, giving him the title of ducal mathematician and the promise of a professorship in the university on the first vacancy. Torricelli's name is important in the history of science as the discoverer of the natural law according to which fluids rise in an exhausted tube from an open vessel exposed to the pressure of the atmosphere, namely, that the weight of the fluid which rises in the tube is equal to the weight of an equal surface of atmospheric air of the height of the atmosphere. He also improved the telescope and microscope. See BAROMETER.

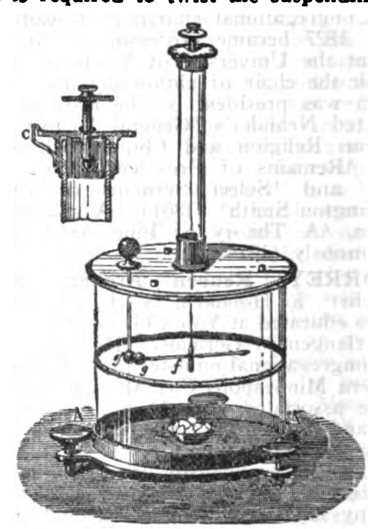
TORRICELLIAN EXPERIMENT, The, so called because made by the Italian physicist, Evangelista Torricelli (q.v.), who discovered the principle upon which barometers are made. Torricelli was led to investigate Galileo's theories of the law that «nature abhors a vacuum.» He filled a glass tube, closed at one end, with mercury, and placing his finger over the open end inverted the tube. He now placed the tube vertically in a small trough containing mercury and removed his thumb from the open end, after it was under the surface of the mercury. The mercury in the tube dropped until it stood at a height of about 30 inches. Here it rested, with a vacuum in the top of the tube, under the closed end. Torricelli concluded that the column of mercury in the tube was sustained by the pressure of the atmosphere on the larger surface of the mercury in the trough and that the height of the column was in inverse ratio to its specific gravity. Other experiments confirmed this theory and led to the invention of the barometer (q.v.).

TORRIGIANO, Pietro, pē-ä'trō tŏr-rē-jä'nō, Italian sculptor: b. about 1470; d. Spain, 1522. He went to England in 1509 to erect the tomb of Henry VII and his queen, still in Westminster Abbey. The works which he executed for English churches were destroyed by the Puritans. He was given a commission to make a statue of the Virgin Mary, and receiving what he considered an inadequate price destroyed it. For this he was imprisoned by the Inquisition, and there starved to death.

TORRINGTON, Frederick Herbert, Canadian musician: b. Dudley, England, 20 Oct. 1837, and was educated there. When but 16 years of age he was made organist (1853) at Saint Anne's Church at Bewdley, England, and in 1857–69 he held a similar position at Great Saint James Street Methodist Church, Montreal, Canada. He then went to Boston where he was organist in Kings Chapel (1869–73) and professor in the New England Conservatory of Music. Returning to Canada he became organist of the Metropolitan Church at Toronto and conducted the Philharmonic Society there and founded (1886) the first Toronto musical festival. Two years later (1888) he founded the first college of music. He was elected president of the Canadian Society of Music in 1892. In 1895 and 1896 he conducted musical festivals at Toronto and in 1903 was assistant conductor of the cycle of musical festivals in that city.

TORRINGTON, tŏr'ĭng-tŏn, Conn., borough in Litchfield County, on the Naugatuck River, and on the New York, New Haven and Hartford railroads, about 23 miles west of Hartford and 18 miles north of Waterbury. Settlements were made in the vicinity in the early part of the 18th century, and in 1740 Torrington was incorporated. In 1887 it was chartered as a borough. It is the birthplace of John Brown (q.v.). The borough has a number of manufacturing establishments; chief among which are bicycle and machine shops, plating-works, brass-works, woolen mills and novelty works. It also manufactures needles, hardware and tobacco products. In 1914 there were 54 manufacturing establishments, with a capital of over $16,000,000, and annual products of over $14,000,000, with payrolls of about $2,500,000. The principal public buildings are the churches, schools and the Young Men's Christian Association building. The educational institutions are a high school, public and parish schools, several private schools and a public library. There are two banks. The borough is the commercial and industrial centre of the town of Torrington, which contains 20,000 inhabitants.

TORSION BALANCE, an instrument in which small forces are measured by noting the torsion that they can produce in a fine wire or a delicate fibre of some other material. The invention of the instrument is usually ascribed to Coulomb (1736–1806), who employed it in his extensive researches on electricity. Cavendish also made use of it for the purpose of determining the mass of the earth; his experiment consisting in determining the attractive power of a pair of leaden spheres, and comparing this with the attractive power of the earth itself. In its conventional form, the torsion balance consists of a light horizontal arm, suspended at the centre by the fibre whose torsion is to measure the force that is applied to the arm. Quartz is now extensively used for the suspending fibre, its employment having been suggested by C. V. Boys, who showed how to prepare fibres of this material, which are very strong and elastic. Boys dipped an arrow into melted quartz and then shot the arrow from a bow; the quartz being thereby drawn out into a fibre of exceeding fineness. The upper end of the torsion fibre is attached to a graduated head, by whose rotation the fibre can be twisted through a known angle. In applying the torsion balance to the measurement of electrical repulsions, the horizontal arm, *f*, is provided at one end with a light ball, *g*, which can be charged to a definite electrical potential, and the torsion head is turned so that this ball is brought to a known distance from a similar fixed ball, *g'*, which can also be charged. The reading of the graduated head being observed when the fibre is fre from torsion and the balls, *g g'*, are at a known distance from each other, the balls are charged. They at once separate, owing to the repulsive action exerted between two electrical charges of the same sign. The graduated head is then turned so as to produce a torsion on the suspending fibre, tending to restore the balls to their original position. The twisting of the head is continued until the relation of the balls is the same as at first; and when this state is established, it is evident that the torsion of the fibre is exactly balanced by the repulsion of the charges. In order to deduce the electrical repulsion in definite measure, it is only necessary to determine, by a separate experiment, what force is required to twist the suspending fibre



Torsion Balance.

through one entire turn; and a simple proportion then gives the repulsive force desired. The application of the torsion balance to experimental work of other kinds will be readily understood from the foregoing description of its application to the measurement of electrical repulsions; for the principles involved are the same in all cases, the force that is to be measured being determined by noting the torsion required to neutralize it, in a fibre whose torsional constant has been determined by direct comparison with a known force. The fact that the torsional moment of a homogeneous twisted fibre is proportional to the angle through which the fibre is twisted was established experimentally by Coulomb. In actual service the torsion balance is surmounted by a case of metal or glass, the air in which is kept dry by a dish containing calcium chloride, or phosphorus pentoxide or pumice stone wetted with concentrated sulphuric acid or some other powerful and non-volatile drying agent.

The name "torsion balance" has also been applied to a form of commercial balance in which the pans that contain the weights and the objects to be weighed are supported, not upon knife edges, but upon the middle points of narrow, thin, horizontal ribbons of stretched steel, in such a manner that when the balance descends at either end, the steel ribbons are exposed to a torsional moment which tends to restore the balance to the normal position of equilibrium.

ALLAN D. RISTEEN.

TORSIONAL RIGIDITY, that species of rigidity by which a cylindrical bar of any material resists the action of a force (or «couple») which tends to twist the bar in such a manner as to convert its originally straight, longitudinal elements (or fibres) into a helical form. The torsional rigidities of a pair of cylindrical bars of identical dimensions but composed of different substances may be compared by comparing the twisting moments that are necessary in order to twist both of them through the same small angle. If one end of such a cylindrical bar is held fixed, while the other end is twisted by a lever applied to it after the manner of a wrench, the angle x, through which the bar will be twisted, is given the formula $x = \frac{CLPR}{D^4}$; L being the length of the bar that is twisted, D being its diameter, and C being a constant peculiar to the material of which the bar is composed; while P and R are respectively the twisting force, and the length of the lever to the end of which this force is applied. The minimum diameter that a shaft should have, in order to transmit a given horse power safely, may be calculated by the following formula: $D = F \sqrt[3]{H/R}$, where D is the diameter of the shaft in inches, H is the number of horse power to be transmitted, R is the number of revolutions of the shaft per minute, and F is a numerical factor peculiar to each kind of material. For wrought iron, F may be taken as about 4, and for steel it may be taken as 3.8. Consult Kent, 'Mechanical Engineer's Pocket Book'; Rankine, 'Applied Mechanics.'

TORSK, a Scandinavian species of cod. See CUSK.

TORSO, an art term applied to the trunk of a statue of which the head and limbs are wanting, or to the trunk of a statue considered independently of the head and extremities; also to the trunk or thorax of a model. Many examples of ancient sculpture recovered in the last five centuries have been incomplete in this manner. The most famous is the Torso Belvedere, a torso of a statue of Hercules, seated. It derives its name from the Belvedere, at Rome, in the Vatican Palace where it is preserved, and is attributed to the school of Lysippus, being believed by some authorities to be the work of that master, although a Greek inscription ascribes it to the artist Apollonius. It is considered by connoisseurs one of the finest works of art remaining from antiquity.

TORSTENSSON, tŏr'stĕn-sŏn, **Lennart,** Swedish general: b. Torstena, 17 Aug. 1603; d. Stockholm, 7 April 1651. At 14 he became a page at the court of Gustavus Adolphus and in 1630 accompanied him to Germany as captain of the bodyguard. He was commander of artillery at the battle of Lech, 5 April 1632, was taken prisoner before Nuremberg in August and confined for six months in a subterranean dungeon in Ingolstadt. In 1641 he was appointed commander-in-chief of the Swedish army in Germany. He defeated the Archduke Leopold and Piccolomini at Breitenfeld, 2 Nov. 1642, threatened Prague and relieved Olmütz in 1643, and after the declaration of war by Denmark in December he advanced into that country and in six weeks had conquered the whole peninsula with the exception of the fortresses Rendsburg and Glückstadt. He defeated the Austrian general, Gallas, at Jüterbok, 4 Nov. 1644, and Katzfeld at Jankau, 6 March 1645, pushed through Moravia to the Danube and destroyed the fortifications on Wolfsbrücke before Vienna. His siege of Brünn was unsuccessful owing to the stubborn defense and a pestilence among his troops, and after withdrawing into Bohemia, in 1646, he was compelled by illness to resign his command. He was made Count of Ortaba and governor-general of West Gothland by Queen Christina in 1647.

TORT is a legal term indicating an injury or wrong; tort may be committed with force, as trespass which may be an injury to the person, such as assault or false imprisonment or to property in possession, or a tort may be committed without force, such as an injury to one's character or affecting one's personal liberty. One may be liable in damages for a tort, but same is distinguished from a similar right growing out of a contractural relation. An action in tort is a civil action which undertakes to discover if a wrong or crime is involved. A misappropriation of funds by a trustee, for example, must be inquired into before it can be certainly known: (1) that the fund is short; (2) that the defendant is responsible for the shortage; (3) whether there is a question as to the amount of the misappropriation; (4) whether the defendant simply owes such shortage, or (5) whether he stole it, and should be arrested. Actions in tort are common in cases of breach of contract, libel, trespass, conversion, assault, negligence resulting in accident, etc. Consult Burdick, F. M., 'The Law of Torts' (1905); Bohlen, F. H., 'Cases in the Law of Torts' (1912).

TORTICOLLIS, twisted neck, an affection in which, while the head is bent usually toward one of the shoulders, the twisting of the neck turns the chin to the opposite side. In this condition, known in various forms as stiff-neck or wryneck, lateral movement of the head often causes great pain, especially when the affection is due to rheumatism (q.v.). This attacks the muscles lying on the side of the neck, especially the sternomastoid. In the great majority of cases only one side of the neck is affected, the head being drawn more or less obliquely toward that side; but occasionally, in a form more strictly to be regarded as stiff-neck, both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forward. As long as the head is allowed to remain at rest there is merely a feeling of discomfort; but every movement is apt to be extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the neck, but may also arise from spasm or strain of the muscles of the neck, causing a crick. It is usually temporary, but in some cases muscular contraction renders it permanent.

TORTOISE. See BOX-TURTLE; LAND-TORTOISE; TERRAPIN; TURTLES.

TORTOISE PLANT, a loft climber (*Testudinaria elephantipes*) of southern Africa, resembling a yam, and belonging to the same family. It has slender twining stems, alternate, netted-veined leaves, small diœcious bell-shaped yellowish flowers in axillary racemes, and triple-winged capsules. It is, however, characterized by its globular rootstock, sometimes four feet in diameter, and growing above the ground. This enormous tuberous structure is woody or succulent, and is covered with a soft corky bark, which, cracking by exposure, becomes tessellated with angular protuberant plates suggestive of those of the tortoise. When young it has also suggested the name of elephant's-foot, and its utilization as a food by the natives has given rise to the title Hottentot's-bread.

TORTOISE-SHELL, the material of the large epidermal scales of the hawksbill sea-turtle (*Chelone imbricata*). Thirteen of these plates cover the carapace, and instead of being joined together by their edges so as to make apparently one piece, are thinned off at their posterior margins, and overlap each other like the tiles of a roof. They vary in size according to the part of the shield they occupy. The larger are sometimes from a foot to 18 inches long by six inches broad; the thickness rarely exceeds the eighth of an inch. The beautiful mottled color and semi-transparent characters of this material are well known. A remarkable quality is possessed by tortoise-shell which very greatly increases its usefulness for the ornamental purposes to which it is generally applied, that is, the property of being easily softened by a heat equal to boiling water, and of retaining any form when cold which has been given to it when heated. Pieces can also be welded together by the pressure of hot irons properly applied. The chief use of tortoise-shell is in making combs for the hair; but it is also used for inlaying ornamental furniture and various other fancy objects. By the French cabinet-maker Boule (see BUHLWORK) it was used most effectively in combination with brass as a veneer for rich furniture, and all boule or «buhl» work consists of such a veneering combination. In India, China and Japan many articles are made of it, showing great skill and taste.

TORTOISE-SHELL BUTTERFLY, a butterfly of the genus *Vanessa* as the Camberwell beauty (q.v.), in reference to the reddish-brown, black and white coloration.

TORTOLA, tôr-tō'lą, one of the Virgin Islands, West Indies, lying northeast of the island of Saint John, from which it is separated by a narrow channel; area, 24 square miles. It is hilly and rugged, the highest elevation being 1,600 feet. Only a small part of the land is cultivated, cotton and sugar are raised, and sugar, molasses and rum exported. The island is one of the most important of the Virgin group and contains the chief town, Roadtown.

TORTOSA, tŏr-tō'sä, Spain, a city in Catalonia, 45 miles southwest of Tarragona and 100 miles southwest of Barcelona, on the Ebro River. Its ports are El Fangar and Los Alfaques at the mouth of the river. It occupies an acclivity rising from the left bank, and is fortified, part of the walls being of great antiquity. There are several small squares, and the streets are narrow and crooked, some of them very steep. The houses are built of solid masonry, there is a cathedral and other churches and a monastery. There are manufactures of soap, paper, hats, leather, porcelain, faience, and important fisheries. In the vicinity are fragments of Roman ruins, also marble and alabaster quarries. Pop. about 26,000.

TORTRICIDÆ, a family of moths. See LEAF-ROLLER; MOTH.

TORTUGAS, tôr-too'gaz. See DRY TORTUGAS.

TORTURE, as a means of judicial punishment, descended to the countries of modern Europe from the Greeks and Romans since it appears not to have been practised by the Hindus, the Hebrews or the Egyptians. Torture was judicialy inflicted either to extort confession, purge sin, or aggravate punishment. As practised by the Greeks, it was not applicable to a freedman, except in certain cases, but was commonly applied to slaves. Indeed the word of a slave could not be admitted as testimony, except under torture, and either party to a controversy could demand the torture of his opponent's slaves. The principal modes of torture with the Greeks were the wheel, the rack, the sharp comb, the burning tiles, the vault (into which the victim was bent double), and the injection of vinegar into the nostrils. From the Greeks the Romans got their system of torture and from the Roman laws it was engrafted in the judicial systems of all the modern countries of Europe. The Romans, like the Greeks, exempted freedmen from the horrors of torture, except in cases of treason. But under the emperors the torture of a freedman was not an infrequent occurrence. The Romans chiefly employed the rack, the scourge, hooks for tearing the flesh, and fire in its various uses. Roman contact with barbarian races gave the practice to the latter, but with one exception it made slow headway in replacing the older and more superstitious custom of the ordeal. That exception is in the case of the Visigoths who established a system of torture that remained uninterrupted from the time of their settlement in Spain to modern times, and which furnished a model upon which most of the other European systems were based. Legalized torture became common in France during the first part of the 13th century and in Germany a century later. English lawyers assert that it was never legalized in Great Britain, but certain it is that it was commonly practised, and, if not directly enjoined, was at least sanctioned by the laws of that realm. All Europe came under the system during the 15th century, in consequence of the systematization of the Inquisition (q.v.), and the growth of that institution in power and importance, and with the exceptions of Great Britain and Sweden, torture formed a recognized department of the jurisdiction of European nations until the end of the 18th century. During the time of the Inquisition torture was applied by the civil, not by the ecclesiastical, court, and the ecclesiastics present at the question were there simply as witnesses of the confession and not as agents, as popular fancy has pictured them. A confession extorted by torture was of no avail to the prosecution before an ecclesiastical tribunal, unless it was voluntarily confirmed three days afterward. From the 13th century on, the use of torture increased, until its extreme cruelty and the horror of its practice led to a revulsion of feeling and to its general abandonment in the latter half of the 18th century. In some countries, however, it continued to be officially recognized and sporadically employed until the early part of the 19th century. It was abolished in Saxony in 1783, in Russia in 1801, in Würtemberg and Bavaria 1806–07, in France in 1789 (although it was employed in 1814), in Hanover in 1819, and in Baden in 1831. It is believed, however, that it was practised in Russia even early in the 20th century. It never was sanctioned in the United States, though "witches" were burnt near Salem, and the burning of negroes for rape by lynch law still persists. Consult Lea, H. C., 'Superstition and Force' (1870); Pearsall, R. L., 'The Kiss of the Virgin,' etc. (1838); Sassen, M. J., 'Disputatio de abusu et usu torturæ' (1697); Parsons, 'Studies in Church History' (Vol. II, Art. "Inquisition," 1895). See INQUISITION; RACK.

TORU DUTT, tō'roo doot. See DUTT, TORU.

TORY, Henry Marshall, Canadian minister and educator: b. Guysboro, Nova Scotia, 1867. He was educated at the local academy and at McGill University where he was graduated in 1890 with high honors in mathematics and physics. He studied theology at Wesleyan University and entered the Methodist Church in 1889 but retired in 1892 to become lecturer in mathematics in McGill University and was professor there until 1908 when he was chosen president of the Provincial University of Alberta at Strathcona. He published 'A Manual of Laboratory Physics' (1902).

TORY, the name of a political party, used in Great Britain and other Anglo-Saxon countries, is said to have originally been applied to the Roman Catholic outlaws who lived in the bogs of Ireland during the reign of Charles II. The name became identified with the opponents of the bill excluding the Duke of York from the English succession (1679), and was thus intended to imply Roman Catholic sympathies on the part of the duke's adherents. It was transferred to the court party in English politics, their opponents being classed as Whigs. Since the clergy of the Church of England taught the doctrines of passive obedience and the divine right of kings, they also were known under the name of Tories. In modern English politics the successors of the Tory party are known as Conservatives, but the old term is not infrequently heard in Parliamentary debate. Political parties in British colonies at times followed closely the divisions and names in England, so that in Australia and New Zealand the conservative elements in the representative assemblies were known as Tories. In the American colonies the name was given to the adherents to the policy of the mother country, and during the Revolutionary War was applied to all persons suspected of British sympathies. Consult Bentinck, Lord Henry, 'Tory Democracy' (London 1918).

TOSCANELLI DAL POZO, Paolo, tŏs'-ka-nél'lē dăl pŏt'sŏ, Italian geographer: b. Florence, Italy, 1397; d. there, 1482. He believed that India could be reached by sailing to the westward and so advised Columbus in 1474. He also gave the king of Portugal similar views. It is thought that he strengthened the views of the great navigator to undertake the western voyage, although not alone in doing this. Consult Vignaud, Henry, 'Toscanelli and Columbus' (New York 1902).

TOSTI, Sir Francesco Paolo, frăn-chĕs-kö päölö tŏs-tē, Italian composer: b. Ortona di Mare, 7 April 1847; d. 1916. He was a pupil and later teacher at the Conservatorio Reale, Naples, and in 1869 appeared as a concert singer at Rome. Shortly afterward he became vocal instructor at the court; removed to London in 1875 and in 1880 was appointed instructor to the royal family. He produced 'The Grand Duke' (opera, 1888); 'La prima donna' (opera, 1889) and many English and Italian songs. His 'Good-bye'; 'For Ever and For Ever'; 'That Day,' etc., are widely popular. He was knighted in 1908.

TOSTIG (TOSTI, TOSTINUS), West-Saxon warrior: d. 1066. In 1055 he was made earl of Northumbria, Northamptonshire, and Huntingdonshire, by Edward the Confessor. A stern ruler, he repressed feud and disorder by the exercise of a merciless justice (*patriam purgando talium cruciatu vel nece*), with no distinction of rank. In 1063 he joined his brother Harold in the invasion of Wales, but in 1064, for treacherous murder, was outlawed, while Morcar was chosen to the earldom (1065). He retired into exile in Flanders, in 1066 committed various depredations on the Isle of Wight, Lindesey and the east coast and subsequently joined Harold Hardrada, king of Norway, in an invasion of England. They landed in Yorkshire, but were entirely overthrown by Harold and his household troops at Stamford Bridge. Tostig figures in Tennyson's drama of 'Harold' (1877). Consult Green, 'The Conquest of England' (1884); Freeman, 'History of the Norman Conquest' (Oxford 1887).

TOTARA, or TOTARRA, a tree (*Podocarpus totara*) of New Zealand, of the yew family, excelled only by the kauri for general utility, and most abundant in the central part of North Island. It is from 60 to 80 feet in height and has a fibrous brown bark which is deeply furrowed and was used by the natives for roofing their huts. Its leaves are linear and of a greenish-brown color. The wood is reddish-brown, clear and straight in the grain and does not warp or twist. It is largely used for furniture, cabinet-work and house-building, but is particularly valuable for bridges, wharves and marine piling, as it is durable under the ground or water and resists the attacks of teredos for a long time. The aborigines made canoes from the trunks of these trees. See PODOCARPUS.

TOTEM, a word which appears to have been applied originally to the animal or other thing held sacred by certain American Indians as the sign or symbol of the tribe or of an individual Indian. The superstition is not confined to American Indians and has its counterpart in the symbols of civilized nations. The American eagle, the lion of Great Britain, the thistle of Scotland, the rose of England, etc., and the arms of noble families are illustrations.

The practice can be traced, indeed, throughout all history, among the greatest empires and the most savage tribes.

The totem superstition varies in its features in different countries. The members of the Emu clan of an Australian tribe believe themselves to be descended from the emu and are regarded as forming a kind of blood-group in virtue of their common descent. No member is permitted to marry within the clan, and all the members are bound to support one another in times of necessity. No Emu clansman will knowingly kill or eat an emu. Among some savage peoples the dead totem is elaborately mourned and carefully buried. Besides clan totems there are sex totems and individual totems. The totem having an important bearing on a person's relations to his fellows, it is shown conspicuously, being often tattooed on the skin or otherwise. The importance of totemism in relation to the social and religious institutions of savage peoples was first pointed out by J. F. M'Lennan in 1868 and much fresh light has been shed on the subject by subsequent investigators but no satisfactory explanation of this curious system has yet been advanced. The American Indians were given to totemism and not only set up various animal figures as emblematic of their tribes but individuals were frequently named after animals. The exact meaning and character of their totem practices is little understood. There were rules as to all marriages of those in kindred totems; some took their totems from their fathers, some from their mothers and some from their tribe. Totemism exists also among many African peoples, and numerous instances of it are to be met with in Asia and Polynesia. (See AFRICA; AUSTRALIA; INDIANS, AMERICAN). Consult Lang, A., 'The Secret of the Totem' (1905); Frazer, 'Totemism' (1887); Durkheim, E., 'Elementary Forms of the Religious Life' (Eng. trans., London 1915).

TOTEM POLE, a pole used among North American Indians to exhibit the totem figures. The totem pole is composed principally of three half human, half animal figures, seated above one another and holding erect a pole on the summit of which, for instance, is the totem. See TOTEM.

TOTONICAPAM, tō-tō-nē-kä-päm'. Guatemala, the capital of the department of the same name, situated 60 miles northwest of the city of Guatemala. It manufactures cloth, pottery and wooden implements. It was half destroyed by an earthquake in 1902. The population, consisting almost entirely of Quiché Indians, is about 28,000.

TOTTEL, Richard, English printer and publisher: b. about 1525; d. 1594. He was granted a patent in 1553 to print law books, which was extended for life in 1559. He also published the writings of the men of his day. He was a charter member of the Stationers' Company which he left in 1589 because of poor health. His most notable work was done in compiling and publishing the first poetic anthology in England, 'Tottel's Miscellany' (1557), which contained 271 hitherto unpublished poems. Among his other publications were the translation of 'De Officiis' by Grimaldi (1556) and the translation ot the second and fourth books of the 'Æneid' by Surrey (1557).

TOTTEL'S MISCELLANY. The work which commonly goes by this name was published under the title 'Songes and Sonettes, written by the ryght honorable Lorde Henry Haward [i.e., Howard] late Earle of Surrey, and other,' by the stationer Richard Tottel, on 5 June 1557. Its popularity was such that a second edition was issued in the following month and six others followed within the century. Tottel's method, too, was imitated by other editors and publishers and doubtless stimulated the vogue of what are now usually called the Elizabethan anthologies. In the address of "the Printer to the Reader," he alludes to the verse of well-known Latin and Italian poets, adding: "That our tong is able in that kynde to do as praiseworthy as the rest, the honorable stile of the noble earle of Surrey, and the weightinesse of the depe-witted sir Thomas Wyat the elders verse, with severall graces in sondry good Englishe writers, doe show abundantly." This passage indicates the real significance of the volume: namely, the effort which it represents to beautify English poetry and to show that the art of the Italians could be rivaled by the new courtly or cultivated school of British poets. Compare, to the same effect, a passage in a work called 'The Arte of English Poesie' (1589), attributed to one George Puttenham: "In the latter end of the same kings raigne [i.e., Henry VIII] sprong up a new company of courtly makers, of whom Sir Thomas Wyat the elder and Henry Earle of Surrey were the two chieftains, who having travailed into Italie, and there tasted the sweete and stately measures and stile of the Italian Poesie, as novices newly crept out of the schooles of Dante, Arioste and Petrarch, they greatly pollished our rude and homely maner of vulgar Poesie, from that it had bene before, and for that cause may justly be sayd the first reformers of our English meetre and stile."

Wyatt had died in 1542 and Surrey in 1547, but it was reserved for the publisher Tottel to secure manuscript copies of many of their poems and bring them out for the first time in print. These occupy the place of honor in the volume, being followed by poems attributed to Nicholas Grimald (who has been suspected of acting as Tottel's editor) and by those referred to "Uncertain Authors." A number of the poems in this last group can be identified, one of them, indeed, being a now familiar lyric of Chaucer's; but the majority remain anonymous, nor is any of these comparable to the best work of Wyatt and Surrey. The elements of familiarity and of novelty in the collection are perhaps best illustrated by the metrical form of the various poems. One finds, for example, the old "rhyme royal" stanza of Chaucer, and the loose, sometimes doggerel "septenary," or seven-foot line, which had been popular from the Middle English period; but side by side with these occur specimens of Italian forms not previously naturalized in English. Of these last the most noteworthy are certain poems in the great Italian form, the *terza rima,* and a considerable number of sonnets — the first in English poetry. Wyatt's sonnets, largely versions of Italian and French poems, follow the recognized continental types; while the younger poet, Surrey, seems to have undertaken to modify the form in the direction of English taste, with the resulting type of sonnet, in three quatrains and a couplet, which was to be the favorite in the Elizabethan age and the form chosen by Shakespeare. Outside the work of these two poets, the contents of the miscellany are of slight intrinsic value; but its historical importance is so marked that because of its publication in 1557 it is customary to date from that year the beginnings of modern English poetry.

A convenient modern edition of Tottel's Miscellany is that in Arber's 'English Reprints.' For accounts of the poetry of Wyatt and Surrey consult Courthope's 'History of English Poetry' and Padelford's 'Early 16th Century Lyrics' ('Belles Lettres Series).

RAYMOND M. ALDEN.

TOTTEN, tŏt'ĕn, **Charles Adiel Lewis**, American inventor and military instructor: b. New London, Conn., 3 Feb. 1851; d. Milford, Conn., 12 April 1908. He was graduated at West Point in 1873 and was instructor in military science and tactics at the Amherst Agricultural College, at the Cathedral School, Saint Paul, N. Y. and at Yale University. He patented improvements in high explosives, in collimating sights and in signal-shells; besides a system of weights and measures and improvements in linear and other scales. He patented a war game which he described in a publication entitled 'Strategos, the American War Game' (1880) and has also published 'Important Questions in Metrology' (1883). More recently he issued 'Lost Israel Found in the Anglo-Saxons' (1890) and 'Joshua's Long Day and the Dial of Ahaz' (1891).

TOTTEN, Joseph Gilbert, American military engineer: b. New Haven, Conn., 23 Aug. 1788; d. Washington, D. C., 22 April 1864. He was graduated from West Point in 1805, was engaged in a survey of Ohio and the western territories, and in 1806 resigned from the army. He re-entered the army in 1808, was reappointed second lieutenant of engineers and was in charge of the construction of Castle William and Fort Clinton in New York Harbor until 1812. He was chief engineer in the army on the Niagara frontier during the War of 1812, was brevetted lieutenant-colonel in 1814, and after the war was engaged in the construction of coast defenses until 1838 when he was promoted lieutenant-colonel and chief engineer in the army, and shortly afterward became supervisor and inspector of the United States Military Academy. At the outbreak of the Mexican War he was placed in charge of the engineering operations and in recognition of his services in planning the siege of Vera Cruz was brevetted brigadier-general in 1847. He then resumed his duties at Washington, but was appointed one of the commissioners for arranging the terms of capitulation. He became brigadier-general in 1863 and in 1864 was brevetted major-general. He published 'Essays on Hydraulics and Other Cements' (1842).

TOTTENHAM, tŏt'ĕn-ạm, England, a town of Middlesex, forming a residential suburb of London and situated some six miles north of the Tower of London, just outside of the city limits. It was a favorite resort of Isaak Walton. Among its most interesting buildings are an old church and Bruce Castle, an Elizabethan mansion formerly owned by Robert Bruce. Pop. 150,000.

TOTTENVILLE, formerly an incorporated village in Richmond County, N. Y.; since 1898 in New York City. See STATEN ISLAND.

TOTUAVA. See BLUEFISH.

TOUCAN, too-kän' or too'kạn, a family (*Rhamphastidæ*) of coccygomorphous birds somewhat resembling the hornbills, and distinguished by the great development of the bill, which is curved superiorly and bears a prominent keel, with cutting edges frequently toothed. The outer walls of the bill are extremely thin, its interior is hollowed out into air-cells, and it is thus rendered comparatively light. The tongue is slender and barbed along the sides. The toes are paired, two forward, two backward and the tarsi scuttelated, the wings rather short and the tail long, with 10 quills. The toucans are confined to tropical America, where about five genera and 60 species occur. They are birds of brilliant and striking plumage, and the bill and naked skin about the eyes partake of this brightness of hue. Most of the species are gregarious, spending most of their time in hopping actively about among the treetops and seldom flying far. The times of their greatest activity are the morning and evening, when the woods are filled with their loud harsh cries. While fruits are their chief food, insects and the eggs and young of birds are also eaten. They have a characteristic manner of throwing back the head and bolting their food. When sleeping the head and tail are turned toward each other and rest on the back. All of the species, so far as known, nest in holes in trees, the birds sometimes excavating a suitable place in a decayed stub. Only two white eggs are deposited.

The following are some examples of the species, many of which are familiar in the collections of zoological gardens. The toco toucan (*Rhamphastos toco*) is black with a black and orange bill, blue circumocular areas and white throat and rump. It is nearly two feet long and inhabits Argentina. A well-known relative is the ariel (*R. ariel*). The araçari (*Pteroglossus aracari*) is green with the head and throat black and the bill black and white. A related species (*P. beauharnaisi*) is dark green with the lower back crimson, the belly yellow and red and the bill black, orange and white. Both of these are found chiefly in the forests of the Amazon Valley. A well-known species is *Selenidera spectabilis*, in which the sexes are unlike. The hill toucan (*Andigena bailloni*) of the lowlands of Brazil, has the head, neck and lower parts orange yellow. Consult Sclater, 'Catalogue Birds British Museum,' XIX (London 1891); Bates, 'Naturalist on the River Amazon' (London 1863). See HORNBILL.

TOUCEY, tow'sĭ, **Isaac**, American jurist: b. Newtown, Conn., 5 Nov. 1796; d. Hartford, Conn., 30 July 1869. He received a private classical education, was admitted to the bar in 1818, and established a law practice at Hartford. He was State's attorney for Hartford County in 1822–25, served in Congress in 1835–39 and was again State's attorney in 1842–44. He was governor of Connecticut in 1846–47, and in 1848–49 was United States Attorney-General. In 1850 he was elected to the State senate and served in the United States Senate in 1852–57. He was appointed Secretary of the Navy by President Buchanan in 1857 and served until

1861. His conduct of naval affairs was severely criticized. He was accused of favoring the secession cause by scattering the best ships of the navy in distant seas. The charge was denied, though Toucey continued to be regarded as a sympathizer with the South.

TOUCH, the sense of feeling. See SENSES.

TOUCHSTONE, LYDIAN STONE, or **BASANITE**, a velvet-black jasper, used on account of its hardness and the uniformity of its texture and color as a streak tablet for determining the relative amounts of baser metal and pure gold in alloys. The sample is rubbed on the stone and the color is then compared with a series of standards of kown composition. The expert is able quite accurately to determine the fineness of the sample, the streak becoming redder as the proportion of copper increases, or yellower as the percentage of gold increases. This method of testing has been in vogue from the earliest times, the name Lydian Stone appearing as long ago as 450 B.C. Modern methods of assaying have now largely superseded the use of this stone.

TOULON, too-lon, France, a fortified seaport town and naval arsenal, in the department of the Var, on the Meriterranean, 42 miles southeast of Marseilles. The port is separated from the roadstead by bomb-proof moles and comprises two parts: one, including the merchant shipping; the other, the dockyard, slip, arsenal, foundry, etc. The fortifications are very complete. The cathedral was founded in 1096. This, the hôtel-de-ville and a capacious theatre are the chief of the old buildings; more recent are the Museé Bibliothèque, Marine School, library and observatory, the lyceum and botanical gardens. The Place de la Liberté contains a splendid monument to the heroes of the Revolution; Le Place d'Armes, the Boulevard Strasbourg and Jardin de la Ville are prominent promenades. It has modern fortifications of the first class and is headquarters for one of the five maritime arrondissements carrying stores for the Mediterranean fleet, with important shipbuilding interests. The bay or harbor is defended by torpedoes and commanded by six forts. On the hills north of the city very strong forts are located. Toulon was known to the ancients as Telo Martius or Telonion. The Saracens sacked the city in 889 and Charles V captured it twice in the 16th century. Louis XIV gave Toulon its importance as a naval station, making the dockyards and arsenal the finest of France. Toulon first became famous as a stronghold in the 16th century. Here the English were defeated by the fleets of France and Spain (1744); and in 1793 Napoleon forced the English and Spaniards to evacuate the position — his first memorable victory, while commanding the French Republicans. In time of peace about 600,000 tonnage is entered and cleared annually. The principal trade is in wines, fruits and oils. There are metal manufactories and lace works. Pop. about 107,000.

TOULMIN, Henry, American lawyer: b. Taunton, England, 1767; d. in Washington County, Ala., 11 Nov. 1823. He came to Norfolk, Va., in 1793 and in 1794–96 was president of Transylvania University. In 1796–1804 he was secretary of state of Kentucky and in the latter year was appointed judge of the United States District Court of Mississippi. He assisted in framing the constitution of the State of Alabama, in whose legislature he served. He was author of 'A Description of Kentucky' (1792); 'A Collection of the Acts of Kentucky' (1802); 'Review of the Criminal Law of Kentucky' (1804); 'Digest of the Laws of Alabama' (1823).

TOULOUSE, Edward, French alienist: b. Marseilles, France, 1865. He studied in Paris and became head physician of the asylum at Villejuif where he established a laboratory for experimental psychology. He founded the *Bibliothèque de Psychologie Experimentale* and other journals and was a writer of repute on his specialty. His chief publications were 'Organisation scientifique d'un service d'aliénés' (1900); 'Technique de psychologie expérimentale' (2 vols., 1905; 2d ed., 1911); 'Comment conserver sa santé (1914); etc.

TOULOUSE, too-looz, France, capital of the department of Haute-Garonne, 140 miles southeast of Bordeaux, on the Garonne. It is the centre of railway traffic and river and canal freight in southern France. A fine bridge connects the town with the village of Saint Cyprien. It is a quaint old town, but very enterprising. The most remarkable buildings are the cathedral, church of Saint Sernin, Hotel-de-Ville, museum and Palais-de-Justice. The Musee contains an almost unparalleled collection of objects d'arts from the Gallo-Roman to the Renaissance period. There are several fine academies of art, science and literature (one claiming its origin to have been in games of the troubadours of 1323, namely, Société des Jeux Floraux); professional and technical schools, a large public library of 225,000 volumes, an observatory and botanical garden. Toulouse is one of the larger cities of France, designated as the seat of a State university, which includes faculties of law, medicine, science, letters, etc. It has a library of over 150,000 volumes and nearly 5,000 students. There is also a large Catholic institution with theological, literary and scientific instruction. The old name of the city was Tolosa, dating back before the Christian era. It was sacked by Q. S. Cepio 106 B.C., and rebuilt and regarded as an important city in the 4th century. The Visigoths, under King Wallia, made it their capital in 419. It was taken by Clovis in 507, and was Charibert's capital in 630. For many hundred years it was the foremost city of southern Gaul. The Saracens took it in 718. The name developed into Toulouse about 780, where Charlemagne made his young son Louis, king of Aquitaine, with his capital there. About 850, the first Count of Toulouse established himself, and these nobles governed the city and southern France for over 500 years. The tribunal of the Inquisition was established at Toulouse. It was the scene of Hugenot massacres in 1562 and again in 1572. The manufactures include textiles, leather, cannon, steam-engines, tobacco, brandy, etc. In modern history, the most important event was its defeat by the English, while in ignorance of Napoleon's abdication. Pop. (1911) of commune 149,576, the town proper being about 23,000 less.

TOULOUSE, University of, celebrated French school of higher learning, founded by

Pope Gregory IX in 1230 as a protest against the Albigensian heresy. It was originally a theological school but became noted as a school of law and sided with royalty against the Church. At one time not less than 10 well-endowed foundations were included in it, but under the national system it now includes only the faculties of law, medicine and pharmacy, and science and philosophy. There also is the faculty of Protestant theology of Montauban and two free faculties of theology and philosophy. Its library is noted and contains considerably over 150,000 volumes.

TOULOUSE GOOSE. See GEESE.

TOUMEY, James William, American professor of forestry: b. Lawrence, Mich., 17 April 1865. He was educated at the Michigan Agricultural College in 1889, and was special student at Harvard in 1893. He was assistant in the department of botany in the Michigan Agricultural College (1890–91), professor of biology in the University of Arizona (1891–98), and finally entered the United States Forestry Service and became director of the Yale Forestry School in 1910. He is the author of several books on forestry and kindred subjects.

TOUR, Maurice Quenti de la, mō-rēs kŏn-tăn dė lā toor, French painter: b. Saint Quentin, 5 Sept. 1704; d. there, 18 Feb. 1788. He began his art studies in his native town and subsequently devoted himself to the execution of pastel portraits in Paris, in which city he gained such reputation that the most famous of his contemporaries gave sittings to him. In 1746 he was elected to the Académie He returned to his native town in 1784 and the Saint Quentin Museum now contains 80 portrait pastels of his. His 'Pompadour' is in the Louvre; and there are two other of his pictures in the Dresden Gallery. Consult Patoux, 'L'Œuvre de M. Quentin da la Tour au Musée de Saint Quentin' (1886).

TOURACO, a large and beautiful African bird of the genus *Corythaix;* with a short, rather small, high bill; both mandibles notched and finely serrated; short, rounded wings, with the three first quills graduated; a long rounded tail, short, strong feet and an erectile crest. Their prevailing color is green, with purple on the wings and the tail, the peculiar red of which is furnished by a special pigment called turacin. They feed on fruits, perch on the highest branches of trees. It is a member of the family of plantain-eaters (q.v.). Consult Newton, 'Dictionary of Birds' (New York 1896).

TOURAINE, too-rān, a former province and duchy of France, bounded by Maine, Orleannais, Berry, Poitou and Anjou. Its capital was Tours. It now forms the department of Indre-et-Loire. It was anciently inhabited by the Gallic tribe of Turones.

TOURCOING, toor-kwăn, France, a town in the department of the Nord, nine miles northeast of Lille. Before the war it was a well-built and prosperous manufacturing town with modern churches and schools, also a handsome hôtel-de-ville in Renaissance style. It had improved rapidly in a commercial sense, and the staple manufactures are textiles of all kinds, especially woolen goods, velvet carpets and rugs; besides dye-works, soap-works and sugar refineries. The chief imports were wool, flax, yarn and hemp, and the exports combed wool, yarn, tissues, rags and flax. It was captured by the Germans in 1914, and sadly wrecked during the Great War. The population in 1911 was 82,644.

TOURGEE, toor-zhā', **Albion Winegar,** American jurist and author: b. Williamsfield, Ashtabula County, Ohio, 2 May 1838; d. Bordeaux, France, 21 May 1905. He was graduated at the University of Rochester (N. Y.), enlisted May 1861 as a private in the 27th New York volunteers, was wounded at the first battle of Bull Run, and having been discharged, studied law and was admitted to the bar at Painesville, Ohio. In 1862 he re-entered the military service as first lieutenant in the 105th Ohio, in 1864 resigned, and in 1865 began professional practice at Greensboro, N. C. He was a delegate to the Southern Loyalist convention at Philadelphia in 1866, and in 1867 to the constitutional convention of North Carolina, where he drafted the article on the judiciary. From 1868 to 1874 he was judge of the Superior Court of the State. During his term of office the Ku Klux Klan was exposed and largely broken up, and his services to this end were very efficient. The sworn statements of several hundred members received by him were later utilized in a series of fictional works dealing with Reconstruction times in the South, of which 'A Fool's Errand' (1879) was the best known. Contemporary interest in these books was great, and their sales were very large for those days. Tourgee was made consul at Bordeaux in 1897, consul-general at Halifax in 1903, and from then until his death was again consul at Bordeaux. He was editor of *The Continent* (1882–84; 5 vols.), an illustrated weekly published in New York (Vol. III in Philadelphia), and also wrote a few law books. Among his other works were 'Bricks without Straw' (1880); 'John Eax' (1882); 'An Appeal to Cæsar' (1884); 'Button's Inn' (1887); 'With Gauge and Swallow' (1889); 'Murvale Eastman' (1890); 'Out of the Sunset Sea' (1892), and 'The Mortgage on the Hiproof House' (1896).

TOURJEE, Eben, American musical conductor: b. Warwick, R. I., 1 June 1834; d. Boston, Mass., 12 April 1891. He studied at the academy at East Greenwich, R. I., and later opened a small music store in Fall River, Mass. Later he turned to music-teaching, both privately and in the public schools. After a period of study in Europe he opened a conservatory at Providence in 1864. This institution was removed to Boston in 1867 and became the New England Conservatory of Music which has grown to be the most important music institution of the kind in America. In 1872, when the College of Music of Boston University was founded, he became its dean. He was the organizer of several large choruses, notably that assembled for the Peace Jubilee in 1869, and another of nearly 20,000 singers for the World's Peace Jubilee in 1874.

TOURMALINE, a common and wisely distributed mineral, so called from an East Indian name, and known to earlier writers as schorl. It is a very complex aluminum boro-silicate, with several marked varieties depending on the presence and proportions of other metallic oxides. The precise constitution of tourmaline has been recently studied elaborately by eminent mineralogical chemists both in Europe and America, without exact agreement, save in its general features, as derived from a complicated boro-silicic acid. According to the oxides present, three types are clearly determined,— iron tourmalines, mostly black; magnesia tourmalines, usually brown; and alkali tourmalines, in which some lithia is present, of red, green and other rich colors. These last, when transparent, yield beautiful gems, of a hardness of seven to seven and five-tenths and specific gravity three to three and one-tenth. The black variety is quite common in schists, gneisses and granites; the brown is usually in crystalline limestones; the brightly colored varieties occur in dikes of albitic granite, often associated with lepidolite. The gem tourmalines have received a number of special names; the pink or red is called rubellite or Siberian ruby; the green, Brazilian emerald; the deep blue, indicolite, or Brazilian sapphire; the colorless, achroite. The crystals are rhombohedral, hemimorphic and of prismatic habit, either short and stout or long and slender, with three, six, nine or 12 sides, and with rhombohedral, or more rarely, simple basal terminations. The prisms are often so deeply striated vertically as to completely obliterate the faces. The physical properties of tourmaline are very interesting; it is rendered highly electric, both by heating and by friction and it has remarkable polarizing action on light; so that plates cut from transparent crystals, parallel to their length, are much used in experiments in optics, mounted in the so-called tourmaline pincers or tongs. With this is connected a very high dichroism, such that the color is frequently quite different according as light traverses a crystal lengthwise or across. Entirely distinct from this is another peculiar feature, namely, the intermixture of two or more colors in the same crystals, either transversely (concentrically) or lengthwise, sometimes gradually and sometimes sharply; so much so that elegant gems have lately been cut from some of the crystals from Southern California which are half red and half green, with perfectly sharp demarcation between the two brilliant tints. The most noted localities for bright-colored tourmalines are in the Ural Mountains; the island of Elba; Brazil; Paris, Me.; Haddam Neck, Conn., and above all, several mines recently opened in San Diego and Riverside counties, Cal. (See GEMS). Superb black tourmalines occur at Pierrepont, N. Y.; fine brown crystals at Gouverneur, N. Y., and Hamburg, N. J.

TOURNACHON, Felix, French author and aeronaut; b. Paris, 1820; d. there, 1910. He was educated in Lyons, studied medicine but returned to Paris and founded the *Revue Comique* in 1849 and in 1854 published the *Panthéon-Nadar*, both which brought him renown. His experiments in aerial navigation led him to construct a huge baloon, *Le géant*, with which he made several ascensions. At the siege of Paris he was invaluable as a carrier of information and commanded the company of aeronauts. He was the author of a number of publications including 'Les ballons en 1870' (1871) and 'Le Monde où l'on patange' (1883).

TOURNAI, toor-nā, Belgium, a town in the province of Hainault, on the Scheldt, 50 miles southwest of Brussels near the French border, 15 miles east of Lille. It is the seat of a bishop, has pleasant suburbs, fine quays and streets. Its ancient Romanèsque cathedral has five towers and contains pictures by Rubens. Other churches are Saint Quentin, Saint Brice and Saint Jacob, besides the belfry with its wonderful chimes. Other prominent features are a picture-gallery, a library of 60,000 volumes, an episcopal seminary, five hospitals, an asylum, museum of natural history, city hall, theatre and a bronze statue of Princess d'Épinoy, marble bust of Dumortier and many mediæval buildings. The industries embrace the manufacture of woolen goods, hosiery, valuable carpets, linen, ribbon, faience, soap and candles, much of which is handwork. Tournai was in the 5th century the seat of the Merovingian kings, then belonged to France, but later was incorporated in the Spanish Netherlands. It lies near the scene of many battles in 1581, 1667, 1709, 1745, during which years it belonged to France, and in 1914, when it was devastated by the German invasion. Pop. 37,349.

TOURNAMENT, a friendly contest at arms among warriors of noble birth during the Middle Ages. The use of the term was not fixed and it denotes the gathering of the nobles and knights, the contests and the fetes or carousals which followed. A tournament often lasted several days, a week or two, and during this time the lords and knights would gather at the town in which it was to be held, with their servant and esquires, and each would establish quarters which would be made gay with flags and pennants and would erect his arms or insignia. Meantime there would be prepared the lists, the place where the contests were to be held; this consisted of a rectangular space of large dimensions, fenced in by ropes or a railing and surrounded by galleries erected for the ladies and spectators of honor. Certain qualifications of birth were necessary for admission to the contests and each lord or knight had for sponsor some lady whose champion he claimed to be and whose colors he wore. The knights were attended by their squires who furnished them with arms, raised them if dismounted, etc. The weapons used in the contests were lances with the points covered, swords with point and edge dulled and maces or clubs of wood. The knights wore armor which was heavy or light according to the customs of the section in which the contests took place; the latter were held under very exact rules and under the constant supervision of judges and governors. In some of the tourneys it was not allowed the contestant to dismount; he was to run so many courses with the lance or strike so many blows with the sword or mace, and the successful knights received prizes delivered by some lady who had been selected the queen of beauty. On the second day there was often a tourney for the esquires and perhaps on the third day there would be a general melée of knights or squires or even a small mock battle in the lists.

Such were the tournaments of the latter part of the Middle Ages. Their origin is obscure and they seem to have passed through a period in which they were contests in deadly combat and never a friendly contest for skill. It is thought they arose out of the old trials by ordeal (q.v.) and that at first they partook of a judicial nature. Certain it is that at first they were far more deadly than in later years and that they were not uncommonly fought with the weapons of war. Jousts differed from tournaments in two respects: they were single combats between two men and they were oftenest fought with the weapons of war. Jousts were of two kinds — the *joûte à outrance* or mortal combat, usually fought between two representatives of different nations, and the *joûte à plaisance,* the joust of peace which sometimes took place at the end of a tournament, but which seems oftener to have been a prearranged contest in the nature of a duel. Later, while jousts still retained the aspect of a single combat to decide some question of importance, they lost their vicious nature and blood was rarely spilled. The passage of arms was a favorite practice of roving knights, a party of whom would assemble at some place and suspend, each, several shields of different colors, offering combat to any knight who presented himself. The acceptor of the challenge struck the shield of the knight whom he wished to engage and the color and variety of the shield which he struck determined the nature of the combat and the arms to be employed.

The tournament languished with the decline of chivalry, after the 15th century. The death of Henry II, who was accidentally killed in a tilting contest, had much to do with hastening its abolition, but it is probable that the change in the modes of warfare and the critical temper engendered by the revival of learning were more nearly the causes of their abandonment. The word tournament survives in modern contests in chess and checker play, tennis and other games. The contestants are entered, often classified as to their ability and paired off for individual play until every player has met every other player in the tournament. The one with the highest percentage of wins is then declared the victor and receives the first prize. Consult Léon Gauthier's ‹La Chevalerie›; Hallam's ‹Middle Ages› and Viollet-le-Duc's ‹Dictionnaire du Mobilier.›

TOURNIQUET, a contrivance for compressing a blood-vessel to stop the flow of blood in amputations and in dangerous hemorrhage from wounds and to control the circulation through an aneurism. It is believed to have been first used in France by Morel (1674). As used by this surgeon in amputations of limbs, it consisted of a stick passed beneath a bandage and twisted so that the tight knot would exert especial pressure on the principal bleeding vessel, the rest of the bandage compressing the other vessels of the limb sufficiently. At the present time such a tourniquet is known as an emergency tourniquet, which may also consist of anything tied around the part above the wound in case of arterial hemorrhage (below, in case of venous hemorrhage) and twisted by means of a stick or anything convenient. Compression is increased by placing a pad over the main artery. Compression of a bleeding vessel with the thumb or finger is of service where a tourniquet cannot be obtained. Tourniquets are of various kinds and are named principally from their inventors. Du Puytren's tourniquet consists of a semi-circular piece of metal with a head at one end and is used to compress the abdominal aorta; Esmarch's consists of a piece of flat rubber tubing to be wound about the upper part of a limb, after the blood has been driven out of the limb by an elastic bandage or to be used by itself in compression of the iliac arteries, the abdominal aorta, etc. The field tourniquet, resembling Petit's spiral tourniquet, is a padded strap to be buckled on and pressed down by a screw upon an artery. With the horseshoe tourniquet, named from its shape, pressure is exerted at two points. The provisional tourniquet is one applied loosely, to be tightened in case of necessity.

TOURO, too'rō, **Judah,** American philanthropist: b. Newport, R. I., 16 June 1775; d. New Orleans, La., 18 Jan. 1854. He was the son of Rev. Isaac Touro, who in 1762 was chosen rabbi of the Jewish congregation of Newport, R. I. The son removed to Boston, Mass., where he engaged in business with his uncle, Moses Hays, in whose employ he sailed to the Mediterranean in 1798 as supercargo. In 1802 he settled in New Orleans, where he became a wealthy merchant. He displayed his patriotism in the War of 1812 by enlisting as a volunteer in General Jackson's army and was severely wounded at the battle of New Orleans. The range of his benevolence was very broad; families and individuals, churches and synagogues alike were enriched by him. Toward the erection of the Bunker Hill Monument he gave $10,000.

TOURS, toor, **Berthold,** Dutch composer: b. Rotterdam, Holland, 17 Dec. 1838; d. London, 11 March 1897. He studied at Leipzig and Brussels and going to London in 1861 became musical editor to Novello, Ewer and Company, 1878. His productions were principally religious in character and his ‹Service in F,› ‹Blessing, Glory, Wisdom and Thanks› and ‹O Saving Victim,› were especially favorites. As a church composer he represented, with Stainer and Barnby, a new phase of English Church music which comprehends the introduction of new dramatic and melodic elements for which the entire school is probably indebted to M. Gounod.

TOURS, France, capital of the department of Indre-et-Loire, on the left bank of the Loire, at the confluence of the Cher, 130 miles southwest of Paris. The principal entrance to the city is by a magnificent bridge across the Loire, 1,423 feet long. The banks of the river are enclosed by a quay, lined with handsome houses and finely-planted promenades. Great part of the town is new and many of the streets are spacious and elegant; but the older quarters are inferior. The principal edifice is the cathedral. Its west front consists of three lofty-flamboyant portals surmounted by a window of astonishing dimensions and flanked by two domed towers, 205 feet high. The interior, of the purest Gothic, and lighted by beautifully stained glass, is 256 feet in length and 85 feet in height. Two towers form conspicuous objects from every part of the town; one called the tower of Saint Martin or Horloge, from containing the principal clock; the other the tower of Charlemagne, because his queen, Luitgarde, was buried below it, and both remarkable as the only relics which the Revolution of 1793 have left of the vast cathedral of Saint Martin of Tours, after it had flourished for

12 centuries. The archiepiscopal palace is regarded as one of the most handsome in the kingdom. It is the seat of a college, has other excellent educational institutions and a library of 175,000 volumes. The manufactures consist of silk stuffs, ribbons, cloth, serge, rugs, chemicals and leather, besides steel and ironworks and pottery, and the trade is in corn, wine, brandy, dried fruits, wax, hemp, wool, etc. Tours early acquired considerable importance and under the Romans was known by the name of Cæsarodunum. It was from the gates of Tours that Charles Martel (q.v.) drove back the Moslem invasion of Europe in 732. In modern times it became famous for its silk manufactures and had so extended as to have a population of 80,000, when the revocation of the Edict of Nantes deprived it of nearly half its inhabitants and almost all its industry and inflicted a blow on its prosperity from which it has scarcely recovered. During the Franco-German War Tours was made the seat of the government delegation during the siege of Paris, 12 Sept. 1870. The delegation removed to Bordeaux on 10 December. Tours surrendered to the Germans 21 Dec. 1870. Pop. 73,398.

TOURVILLE, toor-vēl, **Anne Hilarion de Cotentin,** COUNT DE, French naval officer: b. Tourville, department of La Manche, 24 Nov. 1642; d. Paris, 28 May 1701. He entered the navy in 1660, became a captain in 1667, participated in the battle of Agosta in 1676, and in command of the vanguard at the battle of Palermo in 1677 he destroyed 12 of the enemy's ships. He was appointed lieutenant-general of marine in 1680, commanded several expeditions against the North African pirates in 1682–88, became vice-admiral in 1689 and in 1690 was in command of the fleet which supported James II of England. He defeated a Dutch-English fleet off the Isle of Wight in that year, but in 1692 was ordered to attack a superior fleet off Cape La Hogue, in order to facilitate the landing of the Jacobites, and was defeated. He was created marshal of France in 1693 and in that year he captured and destroyed a Dutch-English fleet off Cape Saint Vincent. At the outbreak of the War of the Spanish Succession he was appointed commander-in-chief of the combined naval forces of France and Spain, but died shortly after.

TOUSSAINT, Anne Louisa Geertruida, Dutch novelist: b. Alkmaar, 1812; d. 1886. She lived at The Hague after her marriage to the architectural painter, Jan Bosboom, in 1851 and became noted for her novels, especially her historical works. He 'Het huis Lauernesse' (1841; 10th ed., 1885) was translated into several languages and her Leicester trilogy became famous. Her works were collected in 25 volumes. Consult Ten Brink, Jan, 'Life of Anne Louisa Geertruida Toussaint' (Amsterdam 1886).

TOUSSAINT, too-săṅ, **François Dominique,** called L'OUVERTURE, loo-vĕr-tür, Haitian soldier and liberator: b. 1743; d. Fort de Joux, near Besançon, France, 27 April 1803. He was a full-blooded negro and was born a slave. When the insurrection of the blacks broke out in 1791 Toussaint took service in their army, but not till he had assisted his master to escape. He rose quickly in the army, being made in 1795 a general of brigade. In this position he displayed much military as well as political ability and rendered valuable services to the French republic against the British troops which had been landed on the island. In 1797 the French government made him general of division and subsequently general-in-chief of the troops in Santo Domingo, and as such he signed the convention with General Maitland for the evacuation of the island by the British. He now assumed sovereign authority, but it was only after a severe struggle against insurrectionary movements that he was able firmly to establish his position. In 1801, on the submission of the Spanish forts, he was completely master of the island. He now framed a constitution by which he was appointed president for life of the republic of Haiti, with the right to name his successor. He was simple and abstemious in his own habits, but affected great magnificence in his surroundings and exacted a rigorous court etiquette. His character has been highly lauded by Wordsworth in a poem and by Wendell Phillips, who made him the subject of one of his lectures. He ruled with wisdom and justice. Recognizing the failings of most of his own race he chose as his council white men with one exception. By his vigorous government the commerce as well as the agriculture of the island began to revive. After the Peace of Amiens Napoleon sent a powerful expedition under his brother-in-law, Leclerc, to subdue Toussaint, who after a struggle was forced to surrender and on his oath of fidelity was permitted to retire to his estate. He was afterward detected conspiring against the French and being seized by a somewhat unworthy stratagem, was sent to France, where he died in prison. At the time a suspicion of poisoning was general, but there is no evidence to support it. Consult his 'Mémoires' (1853); the lives by Saint-Rémy (1850), Gragnon-Lacoste (1877) and Schœlcher (1889); Mossell, 'Toussaint L'Ouverture, the Hero of Santo Domingo' (Lockport 1896).

TOWAKONI, a sub-tribe of the Wichitas, of the Caddoan linguistic stock of North American Indians, who in 1719 were found on the Cimarron, near its junction with the Arkansas, in the present Creek Nation, Indian Territory. Later they were on the Brazos and Trinity rivers of Texas and in 1822 were reported to number 1,200. They made their first treaty with the United States in 1837. In 1840 they were said to have numbered 500 and to have resided on the Pecan branch of the Colorado River of Texas, but by 1850 their population was reported at 140 and their home on the Upper Brazos. They are now with the Wichitas on a reservation in Oklahoma, where they number about 130.

TOWANDA, tō-wän'da, Pa., borough, county-seat of Bradford County, on the Susquehanna River and on the Lehigh Valley Railroad, about 50 miles north by west of Scranton. It is in an agricultural and stock-raising region and is the commercial and industrial centre for a large portion of the country. The chief industrial establishments are planing-mills, furniture factories, wagon and carriage works, a large toy factory, a piano factory, foundries and machine shops. The water supply comes from springs 16 miles from the borough. The educational institutions are Susquehanna Collegiate Institute (Presbyterian), founded in 1850, a high school, public and parish schools, a high school library containing about 5,000 volumes and a college library. The two national banks have a combined capital of over $300,000. Pop. 5,000.

TOWER, Charlemagne, American diplomatist: b. Philadelphia, 17 April 1848. He was graduated at Harvard in 1872 and spent four years in study and travel in Europe and the East, part of which time he was attaché to the American legation at Madrid under Daniel E. Sickles, Minister to Spain. After his return he was admitted to the bar in 1878 and in 1882 removed to Duluth, Minn., where he was connected with large railroad and mining interests. In 1887 he settled in Philadelphia and in 1891 relinquished active business affairs and gave his attention to historical studies. He became president of the department of archæology and palæontology at the University of Pennsylvania. In 1897 he was appointed United States Minister to Austria-Hungary; during 1899–1902 he was Ambassador to Russia, and in the latter year became Ambassador to Germany, retiring in 1908. He published a ‹Catalogue of a Collection of American Colonial Laws› (1890); ‹The Marquis de Lafayette in the American Revolution› (1895); ‹Essays Political and Historical› (1914).

TOWER, Zealous Bates, American soldier: b. Cohasset, Mass., 12 Jan. 1819; d. there, 21 March 1900. He was graduated from West Point in 1841 and was appointed second lieutenant of engineers the same year. He was employed in the construction of the defenses of Hampton Roads in 1843–46 and served with distinction in the Mexican War. Promoted major in August 1861, he fought in the first battle of Bull Run and for bravery in the second battle of Bull Run was brevetted major-general. He became lieutenant-colonel in 1865 and colonel in 1874, and was retired in 1883.

TOWER, *in architecture,* a structure more or less lofty, of varied form or plan, whether standing alone or forming a part of a church, castle or other building, but essentially high as regards its surroundings. In ancient times towers were erected as memorials to the dead, for purposes of defense and as religious monuments. Mediæval castles usually had one or more towers, serving for observation and also adding to the sightliness of the structure. The walls of ancient fortifications usually bore towers at intervals for commanding the vicinity, from which defenders might more easily shoot arrows at besiegers. When a tower is very long and slender it is termed a spire, as on many churches. Numerous little towers on a structure are named turrets. In old stone structures, as the Tower of London, the towers were apt to be circular. As Gothic architecture developed, square and rectangular towers were more common. In Oriental architecture there is a tendency to finish a tower with a dome. In modern structures towers are mainly for ornament and are located at one or all the four corners of a building, or centrally. Among towers are included the mosques of the Mohammedans, the lofty bell towers common in Russia, ancient lighthouses along the seacoasts and the round towers (q.v.) of India, Ireland and other countries. The tower bastion of mediæval castles contained rooms and cells. (See BASTION). Water towers are similar to stand pipes (q.v.). See GABLE for a description of gabled towers; also CAMPANILE; EIFFEL TOWER; PISA; MONUMENTS; PAGODA; TOPE.

TOWER, Round, a building peculiar to early Christian architecture, of slender form and usually bearing a conical roof. Windows are few in number and generally small. The type is common to Ireland, and in addition to the Irish bee-hive huts forms its only distinctive contribution to architecture (see IRELAND, *Architecture*). More than 100 exist in Ireland. A few examples are to be found in Great Britain and on the Continent, pointing to the time of the invasion of the Irish missionaries. The smallness of the windows seems to make it improbable that the towers were used for bells and rather points to their employment for defensive purposes. The name is given to remains of structures of American Indians of the Pueblo type. They are found standing in isolation or in connection with walls of rectangular form. They are built of roughly-dressed stone and some are interesting structurally for their two or three concentric walls, with the two outer ones connected by transverse walls on radial lines. See IRISH ARCHÆOLOGICAL REMAINS; IRISH ART.

TOWER BRIDGE, London. See BRIDGE; paragraph *Movable Bridges;* also LONDON.

TOWER CLOCKS. See CLOCKS.

TOWER OF LONDON. See LONDON.

TOWER MUSIC. See CHIMES.

TOWER OF SILENCE. This name is applied to structures built by the Parsees for the disposal of their dead. They are towers — called dakhmas — about 40 feet high and with large diameter. Somewhat below the top of the wall is built a floor of iron grating and upon this the bodies of the dead are placed until by exposure to the elements and to birds of prey the flesh is entirely removed from the bones and they have fallen into a pit below. There are evidences that they were carefully chained. One of these «towers of silence» stands in the neighborhood of Bombay, India. It is believed that their primary purpose was sanitary, to prevent contamination of local soil and water.

TOWER OF THE WINDS. See ATHENS.

TOWHEE BUNTING, a large, black, white and chestnut bunting of the American genus *Pipilo,* several species of which occur in the United States. Several are confined to the southwest, but one species, the chewink, or ground-robin (*P. crythropthalmus*) is numerous in summer throughout the whole of the eastern half of the country, and its sharp, metallic call is familiar to every countryman. In spring the male has a delightful song, but one not frequently heard. The nest of the towhee is made upon the ground in the woods, where the birds spend most of their time, scratching vigorously among the leaves for their food, and its five red-spotted eggs are cleverly concealed by a domed canopy of twigs and leaves. Consult Wilson, Audubon and other writers on American birds.

TOWN, Ithiel, American architect: b. Thompson, Conn., 1784; d. New Haven, Conn., 13 June 1844. With Alexander J. Davis he designed the old Capitol (since razed) at New Haven, the city hall at Hartford and the State capitols at Indiana and North Carolina. Town also designed churches at Hartford and New Haven and a bridge at Richmond, Va., over the James River. He is the author of a number of books on architectural and other subjects. His large library went in part to Yale College. He was one of the original members of the Academy of Design.

TOWN GOVERNMENT. See MUNICIPAL GOVERNMENT; TOWN AND TOWN MEETINGS.

TOWN AND TOWN MEETINGS. In its broadest meaning the word town denotes simply a collection of houses without regard to the size of the collection and without regard to the form of its political organization. In this sense a hamlet without any governmental powers at all of its own may be referred to as a town and likewise a great municipality like New York or London may be thus designated. In some of the Southern and Western States «town» is the legal designation of a municipal corporation whose powers are greater than those of a village and smaller than those of a city. In the New England States, while the word town is often used in a loose or broad sense, more frequently a town denotes a minor civil division (elsewhere called township) which is sometimes wholly rural, sometimes wholly urban and sometimes partly rural and partly urban. An advertised meeting of the voters of a New England town summoned for the consideration of local business is called a town meeting.

The Pilgrim Fathers who settled at Plymouth (1620) and the Puritans who settled (1628–30) at Salem and Boston began at once to develop a system of local government. They settled in compact communities and gave the name town to the thickly inhabited portion of a grant or purchase. The organization of the town was accomplished through the agency of a town meeting. The early settlers of New England were equals in social rank; their average of intelligence was high; they were nearly equal in worldly possessions. Respecting matters of government, they were intensely democratic and at the same time intensely theocratic. They believed that the state should be a «city of God» and that authority in spiritual and temporal matters should flow from a common source. Accordingly their town meetings were religious assemblages acting as pure democracies, except in Rhode Island, where the civil authority did not interfere in matters of conscience. The meetings in colonies where the theocratic principle prevailed were usually held in a church, and all the male church members of the town who were of legal age could attend and take part in the discussions and vote upon any question that might arise. The town was incorporated and its boundaries were defined by the colonial legislature. It was then left to govern itself pretty much in its own way, providing, of course, it did nothing contrary to the laws of the colony. At first, while local government was getting under way, town meetings were called every month or two. In Boston in 1635 10 general town meetings were held. The people soon found, however, that they could not give so much time to public affairs and it was not long before it became the custom to summon the town meeting but once in the year, provision being made for calling special meetings when there was need. The town meetings elected such officers as were required for the management of local business and made such by-laws (town laws) as commended themselves to the judgment of the community. For the management of the affairs of the town during the interval between town meetings a board of townsmen, usually called selectmen, was elected. The number of selectmen in the earlier towns ranged from 3 to 13. These officers administered the finances of the town, appointed sundry subordinate officials, let out contracts for public work and exercised such powers as were necessary to secure and maintain the peace, safety, comfort and religious conformity of the people. As stewards of the people they gave to the town meeting an account of their stewardship in the form of an annual report. A town clerk, who acted as secretary of the meeting and who served as the recording officer of the town, and a constable, whose duties, broadly speaking, were those of a peace officer, were always chosen. The selectmen, the clerk and the constable were the constitutive officers; no town was without them. Among other officers elected in the early town meetings may be mentioned the tithingman, a kind of Sunday constable, who saw that the people came to church and with fox-tail wand kept them awake during the sermon; the fence-viewer, who supervised the erection of boundary fences between adjoining owners; the hog-reeve, who saw that rings were kept in the noses of swine running at large; the field-driver, who impounded stray cattle. Representatives to the colonial legislature were also elected in town meeting. Besides electing town officers, the town meeting acted as a legislature for all matters of local concern. It levied the town taxes; it passed by-laws relating to the use of common fields and pastures; it made assignments of lands to individuals; it provided for the management and support of the schools. In all New England colonies but Rhode Island it regulated and controlled all affairs connected with the church, subject to the superior authority of the colonial legislature. No detail of the civil or religious life of the community was too small for the attention of the town meeting. It prescribed the manner in which the schoolmaster should use the rod; it directed the arrangement of seats in the church; it specified the hour of the day at which the woodman should begin to wield his axe.

Such was the early New England town meeting. Its origin is traced by some students of political science to the Anglo-Saxon *tunscipe* and to the still earlier Teutonic mark. The early New England town certainly bore a strong resemblance to the ancient type of Teutonic local government. The name town itself reminds us of the Saxon tun (Old German *Zun*, a hedge); the selectman reminds us of the Saxon *gerefa*, headman (he was actually called «headman» in Rhode Island); the town meeting was, in many particulars, a counterpart of the Saxon Tunmoot. There is no evidence, however, that the New England settlers consciously imitated any existing or pre-existing type of local government when they developed their town system. They brought to their task English political instincts and English traditions and availed themselves of English experience, but the town as an institution, both in its organization and in its functions, was an outgrowth of the peculiar social, economic and political conditions which prevailed in New England during the first years of the colonial period.

The town meeting system described above had its beginnings in the settlements of Plymouth, Salem and Boston and was adopted by the offshoots of these parent towns. Whenever the population of a grant or purchase became sufficiently large to support a church and conduct local government it was incorporated by the central legislative body and a town meeting was called. Thus the town system grew as New England grew, and was soon deeply rooted in the affections of the people. It resulted in a society that was as purely democratic as any the world had ever seen. During the colonial period the town was the distinguishing feature of New England life, and when the Revolution came the little democracies proved to be powerful aids in the cause of liberty. In the town meeting it could easily be learned who were loyal and who were not. Through the agency of the town organization military stores were secured and the famous minutemen (q.v.) were organized. The resolutions of numerous town meetings voiced in the plainest manner possible the sentiment for independence and were the precursors of the Declaration itself. And their influence in great public affairs continued after the Revolution. «How powerfully,» said Thomas Jefferson, «did we feel the energy of this organization [the town] in the case of the Embargo (q.v.). I felt the foundations of government shaken under my feet by the New England townships. There was not an individual in their States whose body was now thrown with all its momentum into action, and although the whole of the other States was known to be in favor of the measure, yet the organization of this selfish community enabled it to overrule the Union.» In another place the great Democrat says: «They [New England towns] have proved themselves the wisest invention ever devised by the wit of man for the perfect exercise of self-government and for its preservation.»

In its essential characteristics town government in New England has not changed greatly since the days of the early settlers, except in its religious feature; that feature entirely disappeared in the early part of the 19th century, when the separation of Church and State was achieved. Details in the organization and in the powers of the town differ in the different New England States, yet the outlines of town government in all these States are practically identical and are as follows: The State legislature defines the boundaries of the town, incorporates it, and confers powers upon it. As a corporation, the town can sue and be sued, and can acquire and hold real property. A town may be divided by the legislature into two or more towns or can be united with and made a part of another town. The public affairs of the town are transacted in a town meeting which meets annually, and also assembles in special meetings which may be called from time to time. The meeting is held in the town hall or in some other hall sufficiently large to accommodate the mass of voters. When the people have assembled, the town clerk calls them to order and states the purposes for which the meeting is called. A moderator (presiding officer) is then chosen and business proceeds according to parliamentary rules. All questions are decided by a majority vote of the legally qualified voters in attendance. Usually citizens who are qualified to vote for a governor and for members of the State legislature are also qualified to vote in town meeting. Here is democracy in its purest form. Young and old, rich and poor, the obscure and the prominent, are present, and every citizen may not only vote, but, if he chooses to do so, may also bring the full force of his character and influence to bear upon the deliberations of the meetings. Routine business is quickly disposed of, but those matters which happen to be the subject of contention are generally discussed fully and freely. The right to vote on local taxation and appropriations is in some States reserved to taxpayers. The finances of the town are watched keenly, and if there has been mismanagement or extravagance during the past year there is sure to be a merciless exposure in the town meeting. If improvements are needed or if the town is lagging behind its neighbors in progressiveness, the discussion in the folkmoot is likely to be directed toward a remedy. At annual town meetings the following things are done: (1) The rate of taxation for the coming year is fixed. Money is appropriated for the schools, for the care of the roads, for the support of the poor, for the salaries of officers and for other necessary expenses. Sometimes the schools are managed by school districts. When this is the case each district elects its own officers and sometimes also makes its own levy, but the town meeting or town council elects the school superintendent. (2) By-laws are passed. These may relate to such matters as infectious diseases, locations of sidewalks and curbstones, the erection of buildings, the regulation of the speed of vehicles. Many things which in other places are done by a body of chosen representatives are done in town meeting by the people themselves acting as legislators. (3) Town officers are elected. At the head of these stand the selectmen, or councilmen, three or five or seven in number. These are the executive officers of the town. They supervise the construction of roads, grant licenses, care for the poor, abate nuisances, check the spread of contagious diseases, listen to the complaints of those who have grievances of a public nature, select jurymen, canvass the voting list, look after the paupers and represent the town in court when it is sued. When a specified number of voters sign a call for a special town meeting it is the duty of the selectmen to place on the town post a warrant which calls the meeting and states the purposes for which it is called. After the selectmen, the town clerk is next in importance and usefulness. This officer calls the town meetings to order and keeps a record of its proceedings. In addition, he usually keeps a record of the births, marriages and deaths and grants certificates of marriages and the real estate records of the town. Town assessors make out a list of the taxpayers of the town and place an estimate upon the value of their property. Sometimes the selectmen themselves act as assssors. In addition to the officers mentioned the town meeting usually elects tax collectors, a town treasurer, town solicitor, overseers of the poor, a school committee, trustees of the town library, constables (peace officers), surveyors of highways, fence-viewers, milk inspectors and field-drivers, or it refers the election of these officials to the town council. All town officers have a tenure of one year. The list of officers which has been given is not complete, yet it is long enough to show that in every New England community a great many people must take a part in public affairs. Undoubtedly it is this general participation in the business of government that makes the people of this part of our Union such a wide-awake and progressive body of citizens.

In all the New England States (Massachusetts excepted) the town is the unit for representation in at least the lower branches of the State legislature. Government in New England is, therefore, by towns rather than by counties, as in other States. The town has so many functions and absorbs so much local business that little is left for the county to do. Indeed the county in New England exists principally for judicial purposes; in Rhode Island it exists solely for judicial purposes. As it is to-day so it has always been: throughout the whole period of her history the focus of New England life has been the town. «Towns,» says Joel Parke, «have been the arterial system of New England through which has circulated the life-blood which has invigorated, sustained and strengthened her, making her expand in her religious, social, educational, benevolent and political institutions.» The people cling tenaciously to their town system. Boston did not change from town to city government until 1820 when, with a voting population of 7,000, she found that the town meeting could no longer act as a deliberative body. Yet the conditions of population in recent years sometimes make it extremely difficult to administer local government on the town plan. People are moving from the country to the city, depleting some towns and making others too large to meet in mass. Towns in New England vary in population from less than 100 souls to 20,000. As a matter of experience local government in New England is changing with the new conditions. So long as the population of a place remains below 10,000 (the population of Aristotle's ideal city) town government is usually economical, efficient and pure, but when the population greatly exceeds that number the interest of the citizens in local matters begins to flag, the town meeting becomes unmanageable and the town government is in danger of falling into unworthy hands. The remedy is municipal incorporation. The thickly inhabited part of the town secures a charter and becomes a borough or village or city and the people surrender a part of the public business to chosen agents. This change, however, usually does not extinguish town government within the boundaries of the new municipality, although it does take from it many of its former powers.

While town government in its pure form is found only in New England, modifications of it appear in those Western States whose population contains a strong admixture of New England emigrants, notably in Michigan, Illinois, Wisconsin, Minnesota and Nebraska. Each of these States has provided by law for a system of local government which resembles more or less closely the New England system. In Michigan, for example, the voters of a township, after they have elected their local officers, meet in the afternoon in mass for the transaction of certain local business. At this meeting they may regulate the keeping and sale of gunpowder, the licensing of dogs, the vaccination of the inhabitants; they may order the purchase of books for the town library; they may under certain restrictions, and within certain limits, order the raising of money by taxation. In Illinois, in those towns which have adopted the township system, there is a similar meeting of the voters after the township officials have been elected. Here we have the form at least of the town meeting, but it does not appear that the spirit of the New England town vivifies these western meetings. Township government in the West has always been and continues to be essentially representative. A New England town meeting may last for a day, sometimes for two days, and personal attendance for so long a time means inconvenience and money loss. Representative government, on the other hand, requires no such sacrifice. Because town government requires so much of the citizen's time and burdens him with such great responsibility, it has been extremely difficult to transplant it. The example of the town meeting has undoubtedly had great influence upon the course of local government in all parts of the Union, but it cannot be said that town government, either in spirit or in form, is vigorous in any State outside of New England.

Author 'First Lessons in Civics.'

TOWNE, Henry Robinson, American manufacturer: b. Philadelphia, Pa., 28 Aug. 1844. He attended the University of Pennsylvania but left school to become a draftsman in the Port Richmond Iron Works. In 1863 he was placed in charge of government work in the shops and later, in 1864, was in charge of building the engines for monitors and similar important work until the close of the war. In the course of time he took a special course in physics at the Sorbonne, Paris, and in 1866 he became associated with Linus Yale in making his famous locks, and after the latter's death was president of the corporation until 1915. Later he became chairman of the Federal Reserve Bank of New York and was connected with other business interests. He is the author of 'Towne on Cranes' (1883) and numerous technical papers.

TOWNE SCIENTIFIC SCHOOL, a department of the University of Pennsylvania. See PENNSYLVANIA, UNIVERSITY OF.

TOWNELEY, Charles, English art collector: b. Burnley, Lancashire, 1737; d. London, 1805. He was educated at Douai College and began collecting art objects abroad in 1768. He made frequent trips abroad for the purpose and in 1791 was made a trustee of the British Museum. His collection of marbles, known as "The Towneley Marbles," together with his statuary, medals and other gems of ancient art, was bought by the museum after his death. Consult Ellis, 'The Towneley Gallery' (London 1846).

TOWNELEY MARBLES, a notable collection of Greek and Roman sculpture, forming a portion of the gallery of antiquities in the British Museum; so named after Charles Towneley, by whom the collection was made.

TOWNSEND, Charles Elroy, American politician: b. Concord, Mich., 15 Aug. 1856. He was educated at the Jackson High School and at the University of Michigan, and was admitted to the bar in 1895. He was a delegate to the Republican National Convention in 1888 and served on the State Central Committee (1898–1902). In 1903–11 he was elected a member of Congress from the second Michigan district, and on 18 Jan. 1911 was chosen United States Senator.

TOWNSEND, Charles Haskins, American zoologist: b. Parnassus, Pa., 29 Sept. 1859. He was educated at public and private schools and became assistant United States Fish Commissioner in charge of salmon propagation in California in 1883. He remained in the government service in various positions until 1902, when he was made director of the New York Aquarium, a position which he still holds. He is author of numerous monographs relating to fisheries, fish culture, etc.

TOWNSEND, Edward David, American soldier: b. Boston, Mass., 22 Aug. 1817; d. Washington, D. C., 11 May 1903. He was graduated from West Point in 1837, served in Florida 1837–38 and on the Canadian frontier in 1838–41; was promoted captain in 1848 and colonel in 1861. In the year last named he was made chief of staff to Lieut.-Gen. Winfield Scott. In March 1865 he was brevetted major-general United States army, and was placed on the retired list in 1880. He published 'Catechism of the Bible — The Pentateuch' (1859); 'Catechism of the Bible — Judges and Kings' (1862); 'Anecdotes of the Civil War in the United States' (1884).

TOWNSEND, Edward Waterman, American author: b. Cleveland, Ohio, 10 Feb. 1855. He was for some years on the staff of the New York *Sun* and in 1895 became widely known by his 'Chimmie Fadden and Major Max,' in which a typical New York boy of the rougher class is depicted. Later works include 'Chimmie Fadden Explains, Major Max Expounds' (1895); 'A Daughter of the Tenements' (1896); 'Lees and Leaven' (1903); 'Reuben Larkmead' (1905); 'Our Constitution' (1906); 'Beaver Creek Farm' (1907); 'The Climbing Courvatells' (1909).

TOWNSEND, George Alfred, American journalist: b. Georgetown, Del., 30 Jan. 1841; d. 15 April 1914. He was graduated at the Philadelphia High School in 1860 and entered journalism. He was special war correspondent of the New York *Herald* and *World* in 1861–65, afterward engaged as a lecturer, and in 1866–67 he was in Europe as special correspondent in the Austro-Prussian War and later at the Paris Exposition. For many years after 1868 he was an editorial writer and correspondent on the staff of the Chicago *Tribune,* and his contributions to the press, under the penname "Gath," have been widely read. His publications include 'Campaigns of a Non-Combatant' (1865); 'The Real Life of Abraham Lincoln' (1867); 'Washington Outside and Inside' (1871); 'Tales of the Chesapeake' (1880); 'The Entailed Hat' (1884); 'President Cromwell' (1885); 'Mrs. Reynolds and Hamilton' (1890); 'Columbus in Love' (1892); 'Poems of Men and Events' (1899); 'Poems of the Delaware Peninsula,' etc.

TOWNSEND, Lawrence, American diplomat: b. Philadelphia, 13 Aug. 1860. He was educated at the University of Pennsylvania and spent some six years in Europe in the study of international law and the history of diplomacy. He was first secretary of the American legation at Vienna 1893–97, Minister to Portugal 1897–99 and Minister to Belgium, 1899–1905.

TOWNSEND, Luther Tracy, American Methodist clergyman: b. Orono, Me., 27 Sept. 1838. He was graduated from Dartmouth in 1859 and from Andover Theological Seminary in 1862, served in the Federal army during a portion of the Civil War, and in 1864 entered the Methodist ministry. He was professor of Hebrew in Boston University 1868–70 and of practical theology there 1872–93. He has since been professor emeritus. He has published among many other works 'Credo' (1869); 'Bible Theology and Modern Thought' (1883); 'Evolution of Creation' (1899); 'God's Goodness and Severity' (1903); 'God and the Nation' (1905); 'Doctrine of the Trinity' (1910); 'Bible Studies' (1913); 'God and War' (1915); 'Hell Is No Myth' (1917).

TOWNSEND, Thomas Seaman, American compiler: b. New York City, 27 Aug. 1829; d. there, 1908. He was given a classical education but devoted himself to commercial life. His renown rests chiefly on a compilation of newspaper clippings relating to the Civil War which fills 125 large volumes and forms a mine of information for the historian of the times from 1860 to 1901. The collection is in Columbia University Library and is entitled the 'Townsend Library of National, State and Individual Civil War Records.' He also lectured and gave addresses on the War of the Rebellion.

TOWNSHEND, town'zĕnd, **Charles, 2D** VISCOUNT, English statesman: b. Rainham, Norfolk, 10 March 1674; d. there, 21 June 1738. On the death of his father, the first viscount, in 1687, he succeeded to the peerage and took his seat as a Whig in the House of Lords, 1695. He was one of the commissioners for arranging the Scotch Union (1706), was joint plenipotentiary with Marlborough in the conference at Gertruydenburg (1709), and as Ambassador to the States-General signed the Barrier Treaty at The Hague, 29 Oct. 1709. He was censured by the House of Commons for this action and declared an enemy of the queen and kingdom. He accordingly entered into correspondence with the elector of Hanover, who, on his accession as George I, appointed Townshend Secretary of State, 1714. In 1717 he was made lord-lieutenant of Ireland; was again Secretary of State from 1721 to 1730, when he retired by reason of disputes with his brother-in-law and colleague, Sir Robert Walpole.

TOWNSHEND, Charles, English statesman: b. 29 Aug. 1725; d. London, 4 Sept. 1767. He was grandson of the 2d viscount Townshend, was educated at Leyden (probably also at Oxford) and entered Parliament in 1747. The next year he received a minor office and in 1754 became Lord of the Admiralty. From this post he rapidly advanced and became a member of the Privy Council in 1757, Secretary at War in 1761, and in 1766 Chancellor of the Exchequer. Pitt's entrance into the House of Lords and eventual incapacity through ill health left Townshend virtually at the head of the government, and he defied his nominal chief in declaring the right of the East India Company to territorial revenue and made use of his official position to secure for himself a large share in a public loan. In 1767 he was defeated on his proposition for a land tax. On 13 May he introduced measures dealing with the American colonies, virtually reviving the principles of the Stamp Act, which had lately been repealed. The American Revolution was caused by the imposition of taxes which he proposed. His reputation as an orator was scarcely second to that of Pitt himself. Of his qualities Lecky has written: «Exuberant animal spirits, a brilliant and ever ready wit, boundless facility of repartee, a clear, rapid and spontaneous eloquence, a gift of mimicry which is said to have been not inferior to that of Garrick and Foote, great charm of manner, and an unrivaled skill in adapting himself to the moods and tempers of those who were about him, had made him the delight of every circle in which he moved, the spoilt child of the House of Commons.» Consult Cobbett, ‹Parliamentary History of England to 1803› (1806–20); Fitzgerald, ‹Charles Townshend, Wit and Statesman› (1866).

TOWNSHEND, Sir Charles James, Canadian jurist: b. Amherst, Nova Scotia, 22 March 1844. He was educated at King's College and became a noted barrister. He was at one time a member of the law faculty at King's College and practised successfully at Amherst, was a puisne judge (1887), and since 2 Nov. 1897 has been chief justice of Nova Scotia. He was knighted by King George in 1911. He was conservative member of the House of Commons (1884–87) and held other positions of honor. Among other papers he is the author of ‹A History of the Courts of Judicature in the Province of Nova Scotia.›

TOWNSHEND, Charles Vere Ferrers, British soldier: b. 1861. He joined the army from the Royal Marines in 1886 and was a major-general in 1911. His life was one of constant activity and in the Great War he commanded the Mesopotamia campaign until compelled to surrender at Kut-el-Amara for lack of food after a five months' siege by the Turks. Previously he had served in the Sudan and Nile expeditions (1884–85), participated in the South African War (1899–1900) and was with the British army in India (1907–09).

TOWNSHIP, a local minor civil or political division of territory within a county in the United States, outside of New England where they are termed towns. See TOWN AND TOWN MEETINGS.

TOWNSLEY, Clarence Page, American army officer: b. De Kalb, N. Y., 24 Sept. 1855. He was educated at the Potsdam Normal School, Union College (1876) and the United States Military Academy (1881). He also attended the Government Artillery and Torpedo schools and was active in various positions, reaching the superintendency of the United States Military Academy at West Point (1912–16) and being appointed commander of the 30th division, National Guard, in 1917.

TOWNSVILLE, Australia, the most important town of northern Queensland, Australia, situated on Cleveland Bay on the east coast. It has a number of fine buildings, including a new cathedral, a new custom-house, the Supreme Court building and a large prison. The chief industrial establishments are an iron foundry, an ice plant, a soap factory and meat packing houses. The town has a good harbor, well fortified; it is the terminus of a railroad to Hughenden and the chief outlet for the products of northern Queensland. The great Commonwealth Bank has a branch here. The exports amount to nearly $15,000,000 annually. Pop. 13,835.

TOWSE, John Ranken, American dramatic critic: b. Streatham, England, 2 April 1845. He was educated at Cambridge University and came to New York in 1869. He took up newspaper work and since 1874 has been dramatic critic of the *Evening Post.* He published ‹Sixty Years in the Theatre: an Old Critic's Memories› (1913–16).

TOXICOLOGY, the study of poisons. The word poison is difficult to define, since many substances which in minute amounts exercise no harmful action on the body may in large quantities produce disastrous effects. Then again, some substances which are harmless when taken into the stomach, as water, for instance, if injected into a blood-vessel prove very dangerous, causing death at times from the destructive action of the water on the blood-cells. Moreover, the many studies of recent years on bacteria and other low forms of life have resulted in a new series of conceptions regarding the poisonous actions of the compounds formed by these bodies; and still further, certain forms of perverted metabolism of the human body result in the production of certain products which, retained by the body, work harmful effects. (See AUTO-INTOXICATION; METABOLISM). If all the different factors are taken into consideration, a strictly scientific definition of the word poison cannot be given. In general it is said that a poison is any substance which brings about a change in the molecular composition of an organ or organs, causing its functions to depart very distinctly from the normal. But what grade of molecular disturbance is necessary to make a substance a poison, or how far from the normal must be the functional alteration, it is impossible to say. Many substances, strychnine for example, while being distinctly poisonous in appreciable doses, are very useful and helpful to the body when given in small amounts. Infinitesimal doses of copper salts act as pronounced poisons on certain forms of lowly organized plants, while a higher plant, the potato, does not suffer from large doses used as a spray to kill insect or fungus-parasites.

The modern conception of poisonous action is essentially a physico-chemical one, the distinction between a molecular physical action and a molecular chemical action being difficult to make. But it is believed that for practically all forms of poisons a distinct alteration in the character of the cells of the body takes place, as well as a change in the chemical composition of the poisonous substance. It is impossible at the present time to summarize these changes. It is rarely that the reaction between the body-cell and the poison is purely of a physical nature, yet this very frequently happens in many poisons that act on the blood. By some of the poisons — the anilines, for example — the blood undergoes changes, not so much due to new chemical compounds formed, as to physical changes in the tension of the blood-serum and the blood-corpuscles, whereby the blood-coloring matters stream out into the plasma, and the oxygen-carrying function of the blood is lost. Similar types of poisoning result from some of the metals, and the poison of the cholera organism is thought to act in a like manner. In other poisons there is a direct union of the ions of the poison with some constituents in the cells of the body, making new chemical compounds, and thus interfering with the molecular activities of the cells.

Von Jaksch has divided the poisons into two classes: the exogenous poisons, or those that come from without the body, and enter by way of the skin, the lungs, the stomach or the intestines; and the endogenous intoxications that result from changes within the human body through disordered metabolism. Occasionally the former class may cause such changes in the body that death results from an intoxication of the second variety. Thus a severe irritant to the kidneys, such as cantharides, may cause such an acute inflammation of that organ that it cannot secrete urine, and the patient may die of uræmic poisoning. In much the same manner certain bacteria find entrance into the body and develop poisons both within the tissues and also in the intestinal canal, and furthermore provoke putrefactive processes in the food in the intestinal canal. This brings about a triple form of poisoning, as it were.

The different types of poisoning are many. They cannot all be given in the space here available, but the symptoms and general treatment of a few of the more common types of poisoning will be mentioned. Poisoning by the mineral acids, nitric, sulphuric, hydrochloric, is not uncommon. In these there is a marked caustic action, with intense burning pain when taken by the mouth. The lips are stained yellow, black or white respectively, according to the acid taken. There is nausea, vomiting and diarrhœa, with all the symptoms of an intense gastro-enteritis, with collapse, pale face, cold sweating extremities, small, feeble pulse, rapid respiration; and the patient dies in intense agony. Treatment is by prompt washing out of the stomach with an alkaline solution, soap, washing soda or other mild alkali being useful. Then comes the use of heat, of mucilaginous drinks, such as white of egg, gum arabic, slippery elm, olive oil, milk, etc. The technical details require prompt medical attendance as soon as the washing out with the alkaline solution is commenced.

Oxalic acid is frequently swallowed by mistake. Here the staining is usually absent; the gastro-enteritis is marked as in poisoning with the mineral acids; there is great muscular weakness and twitching of the muscles, particularly about the face; sometimes there are convulsions and further symptoms of collapse are present. In treatment wash out stomach by tube, or by drinking large quantities of water with lime — teaspoonful of lime to quart of water — and stimulants. Following oxalic poisoning large quantities of water should be taken for a week or so to flush the surplus oxalates from the kidneys.

Poisoning by alkalis is infrequent. Occasionally sodium hydrate, or potassium hydrate, is swallowed. Lime is also taken by accident; so (rarely) is ammonia. The symptoms are much like those of poisoning by the mineral acids. There are no marked discolorations, as noted, but otherwise the symptoms are similar. Treatment is by rapid washing of stomach with weak acids, vinegar being the most convenient, and by demulcents, as in acid-poisoning.

The halogen compounds are very markedly poisonous as gases, notably chlorine, bromine, fluorine; and the iodides and bromides cause forms of chronic poisoning known as iodism and bromism (q.v.).

The heavy metals as such are not poisonous, but their soluble compounds are all poisonous. They vary widely, however, in strength. In order, from the strongest to the weakest, they are caustic or astringent; severe caustic metallic salts being, in order, mecury, tin, silver, antimony, copper, zinc, iron and aluminium. But in poisoning the acid part of the salt is of importance. From strongest to weakest these acids run: hydrochloric, nitric, sulphuric, phosphoric, acetic, citric, tartaric. If a caustic metal is combined with a caustic acid the resulting salt, if soluble, is a very powerful poison, mercuric chloride, or corrosive sublimate, being an illustration. If a weak metal like iron is combined with a strong acid the result is an intermediate poison like chloride of iron; when a weak metal, as lead, is combined with a weak acid, as acetic, lead acetate, sugar of lead, a weak poison, is formed. Thus the strength of a metallic salt may be calculated from the comparative positions of the metallic and acid ions. In all these metallic poisons albumen compounds are formed. The coagulum varies in all and according to its solubility or insolubility the burning of the poison is more or less deep. In all the symptoms are analogous; there is severe gastro-enteritis, with symptoms of collapse. The treatment is similar in all: washing of the stomach, white of eggs, milk, demulcents, artificial heat, respiration and afterward careful feeding.

Arsenic and phosphorus are poisons that

give very similar symptoms: acute gastro-enteritis, with nausea, vomiting, purging; then some grade of apparent recovery, to be followed after a few days with a recrudescence of the gastro-enteritis and the development of secondary blood-vessel changes, which may cause minute hemorrhages in any part of the body. Then follow fatty degeneration and death. The commonest form of salt causing arsenic-poisoning is Paris green; while rat-poison and matches are responsible for most cases of phosphorus poisoning. Treatment of arsenic poisoning calls for prompt washing of the stomach, small doses of magnesia and water every 15 minutes for several hours and stimulant supportives. Phosphorus can usually be detected by the odor. There should be prompt washing, and avoidance of oils, although castor-oil may help in getting phosphorus out of the intestinal canal. Authorities, however, prefer the saline cathartics. A prompt oxidizing agent, permanganate of potash or hydrogen peroxide, should be used, or small doses (1 to 2 grains), diluted, of copper sulphate.

For the effects of poisoning by the alcohols, see ALCOHOLISM. Practically all of the anæsthetics (ether, chloroform, ethyl chloride, etc.) and hypnotics (chloral, paraldehyde, trional, sulphonal, veronal, etc.) belong to the alcohol group (see ALCOHOL), and the symptoms are closely allied.

Phenols form a distinct group in which carbolic acid, creosote, creolin, lysol, resorcin, pyrogallic acid, thymol, guaiacol, naphthaline, salol, etc., belong. They cause symptoms closely resembling one another. Carbolic acid may be taken as the type. This causes gastro-enteritis, with severe pain, white scar of lips and throat, buzzing, dizziness, smoky to blackish urine, pale, bluish face, weak heart, quick breathing, coma and sometimes convulsions. Treatment is by quick washing of the stomach. A mixture of lime and sugar of syrupy consistency, Epsom salt, milk, white of eggs, cardiac stimulants and artificial respiration are all valuable.

Another large group of poisons, the anilines, includes many of the modern drugs, such as acetanilid. Closely allied are different aniline dyes. Also phenacetin, antipyrin. In these the characteristic signs of poisoning are somewhat similar to those seen in the phenol group, but in the more pronounced ones of this series the main changes occur in the blood. There is blueness of the skin and lips, difficulty in breathing, sometimes pinkish to purplish urine, rapid and feeble heart action. The chief changes are due to a partial destruction of the red blood-cells. In phenacetin the blood rarely disintegrates as in antifebrin or acetanilid; whereas in antipyrin there is no real blood action. The treatment of these forms is by prompt evacuation, cardiac stimulation, oxygen and, most important of all, artificial respiration.

Alkaloidal poisons (see ALKALOIDS) are numerous. The commonest forms of poisoning from these, the most powerful poisons, are morphine (opium, laudanum, paregoric), strychnine (nux vomica), atropine (belladonna), cocaine (coca), aconitine (aconite) and nicotine (tobacco). In acute opium poisoning the classical symptoms are drowsiness, coma, small pin-point pupils, loss of pain, slow breathing (six to eight to a minute), moist skin, dry mouth, rousing with more or less active consciousness and quick relapse. Treatment is by washing the stomach with hot strong tea or coffee, by mouth or by rectum, and by artificial respiration. Too much walking of the patient about is not desirable.

Strychnine poisoning causes twitching of muscles, cramps, irregular muscular movements, convulsions at slightest jar or touch, fixation of muscles of breathing, with cyanosis. Treatment is by great quiet, alcohol, chloroform and stimulants.

Belladonna poisoning shows wide-awake, restless consciousness, sometimes active, busy delirium; dry mouth, skin hot and flushed, pupils widely dilated and paralyzed to light and accommodation, rapid feeble heart and rapid respiration. Treatment is by prompt evacuation of stomach, sodium bromide, opium, caffeine or coffee.

Another group of glycoside poisons is characterized by a great similarity in action. Many of these are used in medicine and some were used as arrow-poisons by wild natives. This group contains digitalin (digitalis), strophanthin (strophanthus), convallarin (lily-of-the-valley), bryonin (bryonia), apocynin (dogbane), oleandrin (oleander), scillain (squills), etc. These are all heart poisons. They first quicken the heart, then slow and regulate it, hence their usefulness in many heart diseases; but in overdoses they paralyze the heart by overstimulation. As these drugs rarely cause poisoning, the treatment is omitted.

Tox albumins form a group of special character, and all are very violent. Some are of vegetable and others of animal origin. The most important are abrin (in jequirity-seeds), ricin (from the seed-coats of the castor-oil bean — frequently causing death in children who eat the whole bean), phallin (in poisonous mushrooms), rattlesnake poison, cobra poison, heloderma and the poison of lizards. etc.

The most important of the bacterial toxins, some of which might be classed here, are discussed under their respective heads. For the endogenous intoxications see the articles on the infectious diseases, cholera, diphtheria, tuberculosis, pneumonia, tetanus, typhoid, etc.; also the diseases of metabolism, uræmia, diabetes, Basedow's disease, Addison's disease — thyroidism, myxœdema, cretinism, etc. See TOXINS AND ANTITOXINS.

SMITH ELY JELLIFFE, M.D.,
Editor of 'Journal of Nervous and Mental Diseases.'

TOXINS AND ANTITOXINS. Mitchell and Reichart (at the University of Pennsylvania) first demonstrated that the poisonous constituents of snake venom are proteins, or closely related bodies. This statement did not meet with favor in Europe, especially in Germany, at the time, but further studies have confirmed it and it is now a well-established fact that some of the most powerful poisons known are proteins, or at least so closely associated with proteins that all attempts to obtain them free from proteins up to the present time have failed. Such bodies have been found in animal, vegetable and bacterial life, but are limited to certain genera and species. In 1887 Sewall (at the University of Michigan) reported a research which should be recorded as the first step in the discovery of methods of securing immunity to the action of these protein poisons, now known as toxins. Sewall studied the effects of the venom of the rattlesnake on pigeons. Having ascertained the minimum fatal dose of this poison he at first administered less than this quantity, and, by gradually increasing the dose, established an immunity which enabled the pigeons to bear without apparent harm many times the minimum fatal quantity. That this investigator at the time appreciated the possible bearing and significance on protection against disease of his results is shown by the following quotation from his report: «This work was undertaken with the hope that it might form a worthy contribution to the theory of prophylaxis. I have assumed an analogy between the venom of the poisonous serpent and the ptomaine produced under the influence of bacterial organisms.» In 1891 Ehrlich, in a similar manner, succeeded in establishing in animals a high degree of immunity against two of the most potent protein vegetable poisons known — ricin, from the castor bean, and abrin, from the jequirity bean. One gram of ricin is sufficient to kill one and one-half million guinea pigs, and the potency of abrin is about one-half that of ricin. To these poisons immunity, as Ehrlich demonstrated, is easily established by feeding the animals by the mouth upon small and gradually augmented doses. While these vegetable products differ from snake venom in being absorbable from the alimentary canal, the resemblance in potency and in the production of immunity is striking. Moreover, like snake venoms these are protein poisons. Ehrlich made two important advances over preceding workers. He found that the immunity produced with these substances is specific. An animal immunized to ricin has no immunity to abrin, and vice versa. It was later found that this specificity holds good with all poisons of this class. In the second place, Ehrlich found that the blood serum of the immunized animal contains the immunizing agent, and that transference of this serum to a fresh non-treated animal confers a passive immunity upon the recipient. Moreover, this transferred immunity is quantitative. If the first or actively treated animal has been given an immunity of 10 times the fatal dose, and no more, then one-tenth of its blood will be required to give the fresh animal immunity to one minimum lethal dose, while if the actively treated animal has been immunized to 100 fatal doses, one-hundredth of its blood serum will immunize a fresh animal to one fatal dose, and one-tenth of its serum to 10 fatal doses. Furthermore, he found that the immunity of an actively treated mother may be transferred to the nursing young through the milk. Roux and Yersin of the Pasteur Institute found that cultures of the diphtheria bacillus, especially cultures four or five weeks old, when freed from the living organism by filtration through porcelain, contain a poison similar in many respects to snake venom and the vegetable products ricin and abrin. The bacteria — free cultures — when injected into guinea pigs even in minute doses, killed the animals in the same time and with the same symptoms and lesions that result from inoculation with the living organism. Von Behring later immunized larger animals, first goats, then horses, to filtered diphtheria cultures, and demonstrated that the blood of animals thus immunized has both protective and curative value in the treatment of diphtheria.

The toxin of diphtheria is prepared by growing a virulent culture of the diphtheria bacillus at 38°C. for two weeks or more and then removing the bacteria by filtration. In other words, diphtheria toxin is an old filtered culture of the diphtheria bacillus. The potency of the toxin solution depends upon many conditions, all of which must be considered when one attempts to secure a highly active product. The medium generally employed for the growth of the diphtheria bacillus consists of beef tea containing 1 per cent of sodium chloride, from 1 to 3 per cent of peptone, and made feebly alkaline with a solution of sodium carbonate. This medium is placed in glass flasks, each of which should not be more than one-third full in order that there may be a large surface exposed to air which favors the growth of the bacillus and the production of toxin. The flasks are inoculated by floating small masses of diphtheria bacillus growths, taken from agar tubes, on the surface of the beef tea in the flasks. After having been thus inoculated, the flasks are kept at 37°C. for about 14 days, when they are filtered and the filtrate constitutes the diphtheria toxin. The toxin solution quickly loses its potency when freely exposed to air and light, but when properly protected it remains without material deterioration for months, and under most favorable conditions, for years. Protection is secured by covering the toxin solution kept in dark bottles with a layer of toluol. In this way both air and light are excluded. Protection is made more complete by keeping the bottles in a dark room, the temperature of which does not rise above 15°C. When portions of the solution are to be used, withdrawal is made by sterilized pipettes introduced through the layer of toluol. Under these precautions, the toxin solution may be kept without marked loss in toxicity for two years or even longer. Before the toxin prepared as stated above is used in the preparation of antitoxin, its strength must be determined. This is done by ascertaining the minimum amount of it necessary to kill a guinea pig of from 200 to 300 gram-weight within from three to five days. This amount is known as the minimum lethal dose. In most laboratories engaged in the preparation of diphtheria antitoxin, the toxin is not regarded as sufficiently potent unless the minimum lethal dose does not exceed 0.02 cubic centimeter. However, it is not always easy to secure a preparation of such high potency, and weaker solutions may be used. Occasionally a much stronger product is obtained, and when this happens the preparation is greatly prized and carefully kept under the conditions mentioned above. Horses free from disease are carefully selected by skilled veterinarians. Usually they are submitted to a malein test to be sure that they are free from glanders. During the procedure the animals should be carefully guarded against wounds however slight, since these may serve as ports of entry for tetanus infection. Into these horses the toxin solution is injected, at first in small amounts. The first dose is usually followed by a transient disturbance in health. This may be slight, and indeed may not be in evidence at all. However, often after the first dose the animal's coat roughens, the appetite is impaired, and it may show some elevation of temperature. When there is complete return to health, usually after three or four days, a second injection of the toxin is made. It is safer to make the second injection no larger than the first. Indeed, the practice is to make the second injection slightly less than the first. In this case there is usually no recognizable disturbance in the well-being of the animal. After the third or fourth treatment the quantity of toxin used can be rapidly increased and it soon develops that the animal bears without apparent effect many times the amount which if used without previous treatment would have caused death. After this condition of immunity has been secured, a portion of blood is drawn from a vessel in the neck of the horse, allowed to coagulate, and the separated serum tested for its antitoxic strength. This process is known as the standardization of the antitoxin. The procedure consists in ascertaining how much of the blood serum of the treated horse is necessary to neutralize 100 minimum lethal doses of the toxin. The serum of the horse and the toxin are mixed in varying proportions in vitro, and the mixture injected into guinea pigs of from 200 to 300 grams weight. The amount of toxin taken in these mixtures represents 100 minimum lethal doses, and the minimum amount of serum which must be added to this so that the mixture will have no effect on the guinea pig is known as an immunity unit. It will be seen from what has been said that the filtered culture of the diphtheria bacillus constitutes the toxin, while the blood serum of the immunized horse constitutes the antitoxin. Both of these are standardized, and one neutralizes the other quite as effectively as acid neutralizes alkali. Diphtheria antitoxin, which is the blood serum of an immunized horse, is put on the market in tubes fitted with hypodermic needles and ready for use without transfer. This avoids the possibility of contamination after the preparation leaves the laboratory of the manufacturer. Such containers are labeled showing the number of immunity units contained, and this is wholly without reference to the amount of fluid in the tube. When such a preparation is labeled "5,000 Immunity Units" it is to be understood that all the fluid in that tube, whether it be 5 cubic centimeters or more, contains enough antitoxin to neutralize 5,000 times 100 minimum lethal doses of the toxin as tested on a guinea pig. The practice of medical men most skilful in treating diphtheria is to use an antitoxin of the highest obtainable potency, and doses of from 20,000 to 40,000 immunity units are now commonly employed.

When a child is suffering from diphtheria, its throat constitutes the flask in which the bacillus is growing and elaborating its toxin. The toxin filters through the walls of the pharynx into the blood. The physician injects under the skin of the child the serum of the immunized horse which he calls antitoxin, and this passes into the blood of the child and neutralizes the toxin absorbed in the throat. Thus, the acid and alkali are brought together and a harmless product results. The toxin being neutralized as fast as it is absorbed from the throat, does not attack or injure the body cells of the child. It must be evident that the earlier in the infection the neutralizing agent can be used, the more satisfactory is the result. Here, hours count. It has been shown that when the antitoxin is injected into the child on the first sign of the disease the percentage of recoveries is 100. Out of 2,428 cases studied by Hilbert the percentage of deaths varied with the day on which the antitoxin was administered as follows:

First day	2.2
Second day	7.6
Third day	17.1
Fourth day	23.8
Fifth day	33.9
Sixth day	34.1
After the sixth day	38.2

According to Wernicke the saving of lives during the first year of the use of diphtheria antitoxin in Germany amounted to 20,000, and if the agent were promptly and properly used the saving of lives would amount in that country to 45,000 annually. The value of diphtheria antitoxin is even greater than is indicated by the lowering in the death rate from this disease. For every sick child treated with antitoxin, on an average five are saved from being sick. While the curative value of antitoxin is great, its preventative value is still greater. The physician called to a family in which one child has diphtheria gives a curative dose of antitoxin to the sick child and immunizing doses to the others. Even when the sick child has been neglected so long that the curative value of the antitoxin is lost, its preventive value in the others is still potent. Diphtheria antitoxin has lowered not only the mortality rate but still more the morbidity rate. In 1880, before the discovery and employment of this agent, deaths from diphtheria in the registered area of the United States amounted to 112.6 per 100,000; in 1913, after the general employment of diphtheria antitoxin, it was 18.8. Certainly it is no axaggeration that the discovery of diphtheria antitoxin is one of the most beneficent of all agents, and it could not have been made without animal experimentation. The preparation of this agent necessitates the annual sacrifice of the lives of hundreds of guinea pigs, and it leads to the saving of the lives of thousands and tens of thouands of children.

State and municipal laboratories are employed in the detection and recognition of diphtheria, and antitoxin is furnished free to those who cannot afford to pay for it. When a physician sees a case which he suspects to be diphtheria he makes a swab from the throat of the child and transfers this in a sterilized test tube to the municipal laboratory. Here a culture is made and after 12 hours a positive statement can be furnished as to the nature of the disease. Even this delay is unnecessary if the physician is sufficiently confident that he has a case of diphtheria to deal with. Under proper precautions there is no danger in the administration of this agent. In the more enlightened communities school medical inspectors are constantly on the watch for the first evidence of this disease and the child of the poorest citizen is transferred and treated in a municipal hospital with as much skill and care as the richest can secure. Since diphtheria toxin has not been obtained in a pure state, its nature, so far as its chemistry is concerned, remains unknown. There is still doubt as to in just what group it should be classified. Usually it gives at least some of the general protein color tests, but preparations have been secured which do not respona, altogether at least, to these tests. The molecular weight of the toxin is much less than that of the antitoxin because the former filters readily through porcelain and diffuses quickly through gelatin, while the antitoxin is largely removed from solution by filtration through porcelain and does not diffuse through gelatin. From these facts it is inferred that the molecule of the antitoxin is much larger than that of the toxin. The toxin is highly susceptible to heat, a temperature of 60°C. being sufficient to markedly reduce, although it does not wholly destroy its toxicity. A like effect is induced by the presence of both mineral and vegetable acids. Even lactic and tartaric acids speedily render it inert and its toxicity is reduced, although not completely destroyed, by borax and boric acid. It is highly susceptible to the action of oxidizing agents such as potassium permanganate, chlorine, iodine, etc. It diffuses through parchment but does not pass through animal membranes or collodion sacs. It is insoluble in alcohol, and prolonged contact with this agent destroys its toxicity. It is also robbed of its virulence by the digestive ferments present in the alimentary canal, and therefore is harmless when taken into the mouth, provided there is no break in the continuity of the mucous membrane. From solution it is carried down mechanically on the addition of calcium chloride, which precipitates calcium phosphate. In this respect diphtheria toxin closely resembles the enzymes. There are other respects in which this resemblance is evident. Some of these are as follows: (1) It is destroyed by heat; (2) in its purest preparation it does not respond to all the tests characteristic of proteins; (3) it is active in high dilutions; (4) it is a product of cell activity; (5) when introduced into the body there is a period of incubation before the development of its effects; (6) when introduced into animals in progressively augmented doses it leads to the production of an antibody.

The chief objection to accepting the theory that toxins are enzymes or ferments lies in the fact that in their action on animals and in their reactions with their antibodies their effects may be measured mathematically and follow the law of multiple proportion. In other words, the toxins do enter into the reactions and are exhausted or neutralized in doing so. On the other hand, the weight of evidence is that enzymes or ferments do not enter into the reactions caused by their presence and that they are not consumed in such reactions. For instance, the hydrolytic enzymes, such as diastase and pepsin, cause starch and protein to take up water and pass over into sugar and peptone while the enzyme itself does not enter into the reaction and is not consumed in the process. It might be stated differently as follows: An enzyme changes the tempo of a reaction which would more slowly occur without its presence, while a toxin combines with its antibody much as an acid combines with an alkali.

When a fatal dose of diphtheria toxin is injected into a susceptible animal, such as a guinea pig, there is a period of incubation during which the animal shows no marked departure from the normal. This incubation period varies somewhat with the size of the dose, but is never less than about eight hours, even when many times the fatal dose has been used. However it should not be inferred that nothing happens during this period of incubation. The disturbance simply does not rise to the plane of gross clinical observation. The toxin begins to act soon after its introduction into the body. Within an hour or two the clinical thermometer, which is not a highly delicate indicator of changes in temperature, shows an elevation which proceeds slowly until a short time before death, when there is a progressive and rather rapid fall in temperature which may reach some degrees below normal before death. The skin about the point of injection becomes edematous and later necrotic. The interval between injection of the toxin and death is the same as after inoculation with the living organism. When sublethal doses are given there is often paralysis, beginning in the posterior extremities and gradually extending over the body. The internal organs are hyperemic, with minute hemorrhages in the adrenals, stomach and intestines. Occasionally a gastric ulcer is produced. Diphtheria toxin apparently has a special avidity for nervous tissue. Whether this action is primarily central or peripheral has not been satisfactorily determined, though it is most probably the latter. When the toxin is injected into a susceptible animal it soon disappears from the blood current and manifests its activity on certain organs and tissues. It has not been found in the urine except when massive doses have been given. In unsusceptible animals it remains for a long time in the blood stream and is of course without action on the tissues, and it is for this reason that the animal is refractory. Animals differ widely in their susceptibility to diphtheria toxin. This is true of individuals, and still more markedly true of species. The most susceptible animal is the guinea pig. Horses, sheep and goats are susceptible, while rabbits are less so, and white mice practically refractory.

The toxin is a secretion of the living bacillus and different strains of the organism vary widely in the amount of toxin which they elaborate. There is apparently no constant and fixed relation between the virulence of a given strain of the bacillus and its toxin production. A strain isolated by Park of New York, and generally known as Park No. 8, has proved in both American and European laboratories to be a most efficient toxin producer. It was obtained from a relatively mild case of diphtheria and it has shown no great virulence as tested by the experimental inoculation of guinea pigs. With this strain filtered products have been obtained with as low a minimum lethal dose as 0.0015 cubic centimeter. However this strain sometimes fails to produce a satisfactory toxin. Through another strain Madsen once reported a toxin whose minimum lethal dose was as low as 0.0005 cubic centimeter. This is the most powerful diphtheria toxin yet reported. The cellular substance of the diphtheria bacillus contains a protein poison, as was first shown in the writer's laboratory. Against this poison diphtheria antitoxin has no neutralizing effect and it must be regarded as a poison, but not a true toxin. It will be seen that the word toxin has come to have a distinct and specific meaning. All toxins are poisons, but all poisons are not toxins. Those poisons which when injected into animals in gradually augmented doses produce antibodies are known as toxins. The serum of horses immunized to diphtheria toxin, and known as diphtheria antitoxin, is usually preserved by the addition of 0.5 per cent phenol or 0.3 per cent tricresol. Filtration of the serum through porcelain removes the antitoxin on account of the large size of its molecules. Heating antitoxin to from 60° to 70° C. destroys its value, but the dried antitoxin will bear a temperature of 110° C. for half an hour without injury. Diphtheria antoxin is quite certainly a protein. It is true that it bears some resemblance to ferments. It is in and of itself perfectly harmless to the animal body. All disturbances which may result from the administration of diphtheria antitoxin are due to other constituents of the serum and may be induced by the use of the serum of a normal horse. The antitoxin may be precipitated from the serum by metallic salts as other protein constituents are, but it is not carried down mechanically as happens to the toxins and the ferments. It is more than probable that the antitoxin is a globulin. It is precipitated with this protein fraction, and the concentrated antitoxin has been prepared by this method. Unfortunately the immunity induced by diphtheria antitoxin is only temporary, lasting from three to four weeks, while one attack of diphtheria does not give immunity to another. For this reason it frequently happens that a child who has once had an immunizing dose may, a few months or possibly a few years later, need a curative dose. The fear of anaphylactic shock has led many physicians to hesitate about a «reinjection» of horse serum after an interval of 10 days or longer, but with proper care one may do this with safety. In all cases of «reinjection» after an interval of 10 days or longer one drop of the antitoxin should be administered and if no untoward symptoms follow within an hour, any amount of the serum may be injected with safety. This procedure should be adopted not only in all cases of «reinjection» but when the patient has shown at any time asthmatic symptoms. With these precautions no physician need fear to use diphtheria antitoxin in the treatment of this disease. When antitoxin is used early in the disease the extension of the membrane in the throat usually stops in a few hours. For this reason laryngeal diphtheria is now rarely seen except in neglected cases. Not only does the extension of the membrane stop on the administration of the antitoxin, but as a rule that already formed begins to recede, becomes detached and fades away.

In all civilized countries the manufacture of diphtheria antitoxin is under government control. In the United States this is one of the functions of the United States Public Health Service. No one can manufacture diphtheria antitoxin without a permit from this service and such permits are not granted until personal inspection has convinced the service of the reliability and scientific intelligence of the manufacturer. Besides this, every batch of diphtheria antitoxin prepared is tested not only by the manufacturer but in the Hygienic Laboratory at Washington. It is highly essential that the preparation and standardization of so valuable an agent as this should be under government control.

Tetanus, or lockjaw, is one of the most strikingly distressing and fatal diseases known. Therefore it is not strange that it is mentioned in some of the earliest medical writings. It was known to the writers of classical times that tetanus was in some way connected with wounds and that it was much more common in military than in civil life. Furthermore, it has long been known that the frequency of the development of tetanus does not run parallel with the extent or gravity of the wound. Indeed it is more likely to result from a trivial penetrating wound than from a large open one. The infectious nature of this disease was first demonstrated by French physicians, especially Verneuil. However the experimental transfer of tetanus was first made by two Italian physicians, Carle and Rattone, in 1884. They inoculated 12 rabbits with matter taken from a pustule on a man who had tetanus. Within a few days 11 of these animals developed the disease, and from these it was transferred to other rabbits. Soon thereafter Nicolaier induced tetanus in rabbits, guinea pigs and mice, by inserting bits of earth under the skin. This investigator also discovered the specific bacillus, but failed to separate it from associated bacteria. This was done by a Japanese bacteriologist, Kitasato. The tetanus bacillus develops spores which are highly resistant to heat and other adverse agents and may retain their vitality quite indefinitely. In some localities 100 per cent of rabbits inoculated with the soil develop this disease. As a rule, the spores are most abundant in filthy soil, especially that richly impregnated with horse manure. Before the days of aseptic surgery tetanus was especially prone to follow operative procedures, as was noted by Larrey, Napoleon's great surgeon, and many other operators both in the field and in hospitals. Among certain primitive dirty people tetanus of the newly born is frequent on account of the methods of cutting and dressing the cord. On certain islands, as Réunion and Cayenne, the infantile death rate from this cause has in some years been as high as 50 per cent. In other localities tetanus works havoc among women in the puerperal state. Some savage tribes smear their arrowheads with mud rich in tetanus spores. The marked mortality from Fourth of July celebrations in this country a few years ago was due to tetanus infection. Fortunately the barbaric rites with which we were accustomed to celebrate the birthday of our nation have been beneficially modified, largely through the knowledge spread by the *Journal* of the American Medical Association. The parts of our country most abundantly infected with this virus seem to be the Atlantic States, especially Long Island and the Valley of the Hudson. Commercial gelatin and catgut used by surgeons have been the bearers of this infection, and most thorough sterilization is necessary in order to destroy the spores. Formerly we spoke of idiopathic and traumatic tetanus. Now, we are quite sure that the former does not exist. The wound may be so trivial that it is healed before symptoms of the disease develop. In other cases the wound may not be on the skin, but on a mucous membrane, as in the mouth, nose or throat. The writer saw a case in which the virus had entered through the gum from which a tooth had been extracted. It has been claimed that tetanus is more prevalent in black and mixed races than among whites, and some have endeavored to show the existence of racial susceptibility. The truth is that filthiness is the predisposing agent rather than a racial difference. The simple custom of drying the wash by spreading the clothes on the ground has been found to play a part in the prevalence of this disease. The distribution of the tetanus virus seems to be world-wide. It has been found in every land, in the temperate and torrid zones at least, and in many waters such as those of Lake Geneva and the Dead Sea. It may be present in bilge water and men on ships have been infected from this source. Many years ago on an English ship after a naval battle 16 of the wounded died of tetanus. It may be carried into wounds with bits of infected clothing or with the dirt on the skin, and it has been found on nearly every article worn by the soldier, from his shoes to his collar. Virgin forest soil has generally been found free from this virus, but the sweepings from the streets, stables, houses, boats and cars frequently produce tetanus when introduced under the skin of animals. Of our domestic animals, the horse is the most susceptible and is a frequent victim. The ox comes next, followed closely by sheep and goats. Dogs and cats are not easily infected, but do succumb to inoculation. When swallowed, the tetanus bacillus has no effect unless there be some break in the mucous membrane and it is eliminated with the fæces unchanged. In this way the fæcal matter of men and animals pollutes the soil.

Tetanus toxin, one of the most potent poisons known, is prepared by growing the tetanus bacillus in bouillon or blood serum under anaerobic conditions. The bacillus is removed by filtration and the filtrate constitutes the toxin. It is of delicate nature and is easily destroyed by both physical and chemical agents. Light and air rapidly render it inert. Even in filtration of the culture both light and air should be excluded. According to Kitasato, exposure to sunlight completely destroys the toxin within from 15 to 18 hours. Other investigators have reported the time as only half of this. Oxidizing agents such as dilute solutions of potassium permanganate, mineral and vegetable acids, destroy it promptly. From its solution in the filtered cultures tetanus toxin is thrown down on the addition of ammonium sulphate, and by dialysis and evaporation in vacuo it can be obtained in dry form, not pure but mixed with the proteins carried down with it by the reagent. The purest preparations yet made still give the protein reactions and there are those who claim that the toxin is an albumose, but this does not necessarily follow. According to Brieger and Cohn, the fatal dose for a mouse is about 0.0000005 gram and for a man, about 0.00023 gram. It requires 2,000 times as much of the poison per kilo of body-weight to kill a rabbit as it does to kill a horse, and the chicken is 100 times less susceptible than the rabbit. It is highly poisonous when introduced subcutaneously or intravenously, but is most potent when administered subdurally or intracerebrally. This is due to the fact that it has a predilection for nervous tissues. It has been shown quite conclusively that when injected subcutaneously the toxin is conveyed to the nerve centres through the axis cylinders of the motor nerves, and that symptoms of tetanus first develop when the anterior horns of the spinal cord are reached. This explains why there is always a period of incubation, both after subcutaneous injection of the toxin and as a result of wound infection with the bacillus. It also makes plain the observation so frequently recorded that the period of incubation is shorter the nearer the site of inoculation is to the central nervous system. That tetanus toxin does combine with certain constituents of the central nervous system was demonstrated some years ago by Wassermann who found that when the toxin is rubbed up in a mortar with brain or spinal cord tissue it is completely fixed and neutralized. In other words, it forms a compound with some constituent of this tissue. This is probably what happens when the poison is generated by the bacillus in the animal body and as a result of the injury thus caused to the nervous tissue tetanic spasms occur. A tetanus antitoxin is prepared in a manner similar to that employed in the preparation of diphtheria antitoxin. Unfortunately, however, the brillant practical results obtained in the treatment of diphtheria have not been secured in the treatment of tetanus. The value of tetanus antitoxin as a protective agent has been recognized for many years and has been fully confirmed in the treatment of the wounds of the World's War. Before the United States entered the war, American laboratories were busy supplying the armies of the Allies with this material. Soldiers received a protective dose before they went into battle and all wounded were treated with this agent as soon as possible. In this way a high death rate from tetanus has been avoided, notwithstanding the fact that a large proportion of the wounds are infected with the bacillus. If one waits until symptoms of tetanus have developed the administration of the serum fails in a large proportion of the cases to effect a cure. However, even under this condition the treatment is not wholly without value. The cessation of trench warfare was followed by a notable decrease in the number of wounds infected with the organism of this disease.

In certain parts of Germany, especially in Württemburg and neighboring parts of Baden and Bavaria, where sausage, a favorite article of diet, has been imperfectly cured and eaten raw, poisoning from this article of food has long been known. Rarely, similar cases have occurred among those in the United States who persisted in the Old World method of preparing and eating sausage. As a rule, food which produces this form of intoxication has been prepared for a long time before it is eaten. The disease thus produced is known as "botulism" and it should be clearly understood that this does not include the ordinary form of food poisoning which leads to vomiting and purging and generally ends in recovery. In 1885, some 30 cases of botulism developed in a small Belgian village and were studied by Van Ermengem of Ghent. In this instance, the food was a ham which had been kept in dilute brine. It was from a sound animal, other portions of which had been eaten while fresh without harm. In fact the companion ham, from the same brine, had been eaten without disturbing those who had partaken of it. The sound ham lay near the surface and was not wholly covered by the brine while the faulty piece lay on the bottom of the vat and was completely excluded from the air. It was not noticeably decomposed, but was marked by soft colored spots and gave off the odor of butyric acid. In this meat the bacillus botulinus was found. An aqueous extract of the ham was injected into animals and proved to be intensely poisonous. In cats it caused dilatation of the pupils and abundant mucous secretion in the mouth and pharynx, prolapse of the tongue, roughness of the voice followed by complete aphonia, difficulty in swallowing and paralytic symptoms resulting in death within from four to eight days. Mice and guinea pigs, rabbits and apes were affected in much the same way. The apes were found to be equally susceptible when fed by mouth, while cats, rats, dogs and chickens were not susceptible when fed. Other outbreaks due to the same cause have been reported from time to time in this and other countries.

The bacillus botulinus is strictly anaerobic, except when grown with other organisms which consume the air. It grows only feebly at animal temperature, but at lower temperatures and when the air is excluded it develops its toxin. It will be seen that it does not cause an infection but an intoxication. Indeed, the bacillus does not multiply in the animal body, or does so only to a slight extent. It is a toxicogenic, rather than a pathogenic, organism. A striking characteristic of this toxin is that it affects some animals, including man, when taken by the mouth. It also has a predilection for nervous tissue. According to Marinesco and others it induces marked changes in the cells of the anterior horns, leading to chromatolysis, and disintegration of Nissl's granules. Like tetanus toxin, it combines in vitro with nervous tissue, forming an inert compound. An effective antitoxin has been prepared and has proved efficient in animal experimentation. The writer is not aware that this antitoxin has been used in the treatment of botulism in man. This toxin may occur in canned vegetables as well as in meats. There was quite a scare in the United States in 1917 concerning the possibility of botulism being widely prevalent on account of the new methods of preserving food proposed at that time by the Agricultural Department. This fright has not been justified by subsequent events. Apparently the bacillus botulinus is not widely distributed. So far, it has been found only once except in food and that was in the fæces of hogs. As has been stated, it grows only in the absence of air or in association with other organisms which consume the air, and it has been found in canned foods. In such, it produces gas which bulges the ends of the can and food from such containers should not be eaten. In brine of more than 10 per cent strength it will not grow. It is of special interest because it is essentially a saprophytic organism producing in food in the absence of air a most potent poison which affects man when taken into the stomach.

Reference has already been made to the fact that the toxins were first found in the venom of snakes. Antitoxins to these venoms have been prepared, their value demonstrated experimentally on animals, and some slight use of these preparations have been made in the treatment of men bitten by poisonous snakes in India. However, these antitoxins like all others are strictly specific and an antitoxin must be prepared for the venom of each species of poisonous snake. The rarity of death from this cause in most parts of the world and the difficulty of preparing and keeping on hand an antitoxin for the treatment of the bite of each species limits the use of this preparation. Within recent years an antitoxin has been prepared and used successfully in the treatment of cerebrospinal meningitis. In this instance a definite amount of fluid is withdrawn by puncture under aseptic precautions from the spinal canal and is replaced by the injection of the antitoxin. Furthermore, it has been demonstrated in our own camps during the war that the intravenous injection of this antitoxin is beneficial.

Scientific investigations and experimental studies on animals have given to man almost absolute control of diphtheria and of such enteric diseases as typhoid fever and its allies. Tuberculosis, formerly known as the "Captain of the Hosts of Death," has been greatly curbed but to-day pneumonia,— or as we should say, the pneumonias,— is the mostly deadly disease that we have to deal with in both military and civil life. The medical profession has recently come to a realization of the fact that etiologically there are many forms of pneumonia. In the first place, there are several types of the pneumococcus. In the second place, other organisms belonging to the streptococcus and staphylococcus groups may cause pneumonia. In the Rockefeller Institute there has been prepared a serum for the treatment of that form of pneumonia due to pneumococcus Type I. Animals have been immunized to this organism and the sera of such animals have been used in the cure of this disease. However, it is not certain at present that such sera have true antitoxic values. Some claim that the sera of animals immunized with this type of pneumococcus have a bactericidal action, while others think that they only render phagocytic action more effective. In order to be of service in the treatment of pneumonia due to pneumococcus Type I, a relatively large amount of the serum must be used. In other words, a certain degree of concentration must be reached. The law of multiple proportion which holds good between diphtheria toxin and its antitoxin fails here. Our experience in the World War has demonstrated the great destructiveness of the pneumonias and the lesson that we have learned should lead to the greatest effort toward the discovery of both preventive and curative measures in these diseases. On the battlefields of France the gas bacillus, known also as the Welch bacillus, proved a most distressing and destructive agent. Shortly before the war closed Bull and Pritchett at the Rockefeller Institute discovered an antitoxin for the poisons of this organism and fully demonstrated its value in experimental animals. The cessation of trench warfare led to a rapid reduction in the number of wounds infected by this organism and the time has not yet come for a correct estimate of the practical value of the antitoxin. See IMMUNITY; MEDICAL SCIENCE AND THE WORLD WAR; SERUM THERAPY.

VICTOR C. VAUGHAN,
Dean, Department of Medicine and Surgery, University of Michigan.

TOXODON, a genus of large Pleistocene mammals whose complete remains are found in the Pampas formations of Argentina. They were about the size of a hippopotamus; the teeth consist of large incisors, very small lower canines and strongly-curved molars, all with persistent roots. According to Cope, the tarsal bones more nearly resemble those of the *Proboscidea* than any other known ungulates. With a smaller genus, *Nesodom*, it constitutes the sub-order *Toxodontia*.

TOY, Crawford Howell, American Oriental scholar: b. Norfolk, Va., 23 March 1836; d. Cambridge, Mass., 12 May 1919. He was graduated at the University of Virginia in 1856, studied in Berlin (1866–68), and became professor of Hebrew in the Southern Baptist Theological Seminary in 1869 and professor of Hebrew and other Oriental languages and lecturer on biblical literature at Harvard in 1880. From 1909 until his death he was professor emeritus. His published works include 'The Religion of Israel' (1882); 'Quotations from the Old Testament in the new Testament' (1884); 'Judaism and Christianity, a Sketch of the Progress of Thought from Old Testament to New Testament' (1890); 'Hebrew Text and English Translation of Ezekiel' (1899); 'Commentary on Proverbs' (1899); 'Introduction to the History of Religion' (1913), and others.

TOYAMA, tō-yä-mä', Japan, the capital of the prefecture of Toyama, situated near the head of Toyama Bay, west coast of Nippon, 170 miles northwest of Tokio. It has considerable trade in drugs and leather. Pop. of the city about 64,822; of the prefecture, 829,596.

TOYNBEE, toin'bē, **Arnold,** English social economist and philosopher: b. London, 23 Aug. 1852; d. Wimbledon, 9 March 1883. He was interested in various movements of popular reform and the betterment of the laboring classes. Though called a socialist, he was certainly a conservative one and vigorously opposed in two lectures the doctrines of the 'Progress and Poverty' (1880) of Henry George (q.v.). Toynbee Hall in Whitechapel, London, was established in his memory in January 1885 and was the first "universal settlement." His writings were posthumously collected as 'The Industrial Revolution' (1884; 4th enlarged ed., 1894). Consult Montague, 'Life' (Johns Hopkins historical series, 1889); Milner, 'Arnold Toynbee: a Reminiscence' (1895).

TOYNBEE, Paget, English critic and author: b. Wimbledon, 20 Jan. 1855. He was educated at Balliol College, Oxford, and from 1878 to 1892 was a private tutor. An Italian scholar, he has been a contributor to *Romania* and the *Giornale Storico della Letteratura Italiana*, and published 'Index of Proper Names in the Works of Dante' (1894–97); 'Dictionary of Proper Names and Notable Matters in the Works of Dante' (1898); 'Ricerche e Note Dantesche' (1899); 'A Critical Text of the Divine Comedy' (1899); besides editions of the three parts of Cary's 'Vision of Dante,' with introductions and notes (1899–1901–02); a 'Life of Dante' (1900; 2d ed., 1901), and 'Dante Studies and Researches' (1902).

TOYNBEE HALL, a social settlement, the first in the world, founded by Canon S. A. Barnett in memory of Arnold Toynbee, who while a student at Oxford became interested in the White Chapel district poor. The settlement was opened in 1884 and was a success from the start, gradually becoming a centre of educational and social endeavor and rallying to its work many of the leading young men of the time. Consult Gell, Philip L., 'Account of the Work of Toynbee Hall in East London' (Baltimore 1889). See SOCIAL AND UNIVERSITY SETTLEMENTS.

TOYS, American, Manufacture of. To tell the story of the art of toy-making from its earliest days it would be necessary to follow the industry back through many centuries, for the archæologists, in delving among the tombs of ancient Greece and Egypt, have made the surprising discovery that children played with dolls—and jointed dolls at that—more than 5,000 years ago. Moreover, by the side of these dolls the scientists have unearthed other playthings that children still crave: dolls' furniture, the utensils for cooking and for keeping shop, and, what is perhaps more interesting from the point of view of the antiquarian, the articles used by the priests in making the sacrifices, cleverly duplicated in miniature, showing that the children of those times also played at having religious exercises for the benefit of their dolls.

Scientists now claim that the custom of playing with dolls is one that is practically as old as the world itself, and they base their assumption upon the theory that playthings are and always have been just as necessary a constituent of human health and development as either food or medicine. The most eminent modern psychologists support this theory. They claim that the reason why children crave toys is that their nature requires them, and that to deprive them of such playthings would be to retard their mental growth and development.

In spite of the early origin of toys the progress in the manufacture of playthings was so slow that even as late as 100 years ago they were few in number, simple of construction and extremely costly, especially in the United States. At that time no such articles were systematically manufactured in this country, and as the cost of importation added materially to the price, there were comparatively few persons who were financially able to purchase such puppets for their little ones. Instead, the children of those days accepted more primitive playthings — dolls that were often not dolls at all, but pieces of cloth, either folded and pinned in such manner as to suggest the «shape» that was not there, or with head and bust stuffed hard with sawdust, the features being indicated by pen and ink drawing. In addition to these dolls there were a few other toys that could be purchased for children, but hoops, jumping-ropes, ten-pins, marbles, pop-guns, the jack-in-the-box the battledoor and shuttlecock, a few simple games, some roughly illustrated books, alphabet blocks, etc., represented the limit of the toy-sellers' stock.

So far as America is concerned the toy-making industry is of so recent an origin that it can scarcely be said to have a history. Before 1875 more than 90 per cent of the toys sold in this country were of foreign manufacture, and we have made no attempt to export such few articles as we did make into other countries. To-day, on the other hand, scarcely 5 per cent of the toys we sell are made abroad, while our exports are increasing rapidly.

To obtain anything like an accurate idea of the great progress that this nation has made in the art of toy-making it is necessary to remember that up to about 1875 there was not a doll factory in the United States, and that such other toys as were manufactured in American turning mills were cheap in quality and unprepossessing in appearance. When the American manufacturers began to make toys, about a quarter of a century ago, they found that it would be extremely difficult for them to compete successfully with the foreign toy-makers in the field which they had occupied for so long. In the first place material was cheaper in Europe, and there could be no comparison between the comparatively good wages paid to workmen in this country and the miserable pittance allowed in those German and Swiss villages where the entire population was held under contract to produce such goods at prices that barely enabled them to keep body and soul together. To overcome this difficulty American inventive genius was called into play, with the result that the local manufacturers not only established many new lines of toy specialties but that they evolved countless ingenious contrivances that the foreign producer has never dreamed of making. Thus while we still import some dainty toys from France and Switzerland, nearly all the newest and most unique productions are now made in America.

Simple toys are made mostly of wood and metal, using the same principles employed by mechanical engineers in the making of duplicate machinery. A design having been decided on, and reduced to its most simple elements, gigs are fashioned so that each piece is a duplicate of every other piece, and the construction is pushed through on the American factory system. Many toys are really model machines, as steam-engines, locomotives, cars, carriages, fire-engines, automobiles, tanks, etc.; others are mere figures or puppets, as the Noah's ark men, wooden soldiers and the like; others are miniatures of common household articles, as chairs, tables, plates, cups, spoons, etc., assured to be proper for the furnishing of a doll's house. Others are very elaborate and costly as goat's carriage, push-mobiles, working locomotives, contractors' machinery, imitation large figures of elephants, dogs and Teddy bears, hobby horses, etc. Some single toys in playthings sell at retail between $100 and $200, which is not considered extravagant by the rich.

The United States census compiles together the manufacturers of toys and games. It is not possible wholly to separate the two, but it appears that there were in 1914 about 200 establishments wholly devoted to toy-making, and as many more partly devoted to the industry, which gives employment to about 5,000 persons, with annual products valued at $8,000,000.

TRACERY, *in architecture,* permanent openwork in a window, the top of a doorway, etc., characterized by geometric and ornamental management of the prominent lines of the design. It is common in the cathedral structures of Europe, especially in the older French and Italian structures. The term is extended to similar decorative work of a conventional character, as on a dado or ceiling decoration.

TRACHEA, trā-kē'ạ or trā'kẹ-ạ, or **WINDPIPE,** the principal air-passage of the body; a tube extending from the larynx to a point opposite the third dorsal vertebra, where the tube divides into two chief divisions or bronchi, one of which supplies each lung with the air necessary for respiration or breathing. The trachea is of cylindrical form and is both membranous and cartilaginous in its structure. Its length is about four and one-half inches and its diameter from three-fourths inch to one inch; that of the male being larger than that of the female. The front or anterior surface of the organ is convex and is covered in the neck and chest by various structures, including the isthmus of the thyroid gland, the inferior thyroid veins, the sternohyoid and sternothyroid muscles, the first part of the sternum, the arch of the aorta, etc. The trachea rests on the gullet or œsophagus, while in the chest it is situated between the pleuræ or membranes lining the thorax and has the pneumogastric nerve on each side. The trachea is composed of rings or zones of a gristly or cartilaginous nature, known as the cartilages of the trachea. It rests on the gullet or œsophagus, while each cartilage forms an imperfect ring, being unclosed behind and having the gristly edges merely joined by fibrous membrane. The cartilages are separated from each other and also connected together by narrow bands of fibrous tissue. The first cartilage of the trachea is broader than the others and may be divided at one extremity, while the last cartilage is thick in the middle and curved backward at the point where the trachea divides into the two bronchi. Sometimes two of the cartilages may unite. The muscular fibres of the trachea exist in longitudinal and transverse layers and are composed of unstriped or non-striated fibres. (See Muscu-

LAR SYSTEM). The trachea itself is lined by delicate mucous membrane, which is covered by epithelial cells provided with delicate vibratile processes or cilia. The trachea derives its blood from the inferior thyroid arteries. Its nerves arise from the pneumogastric trunks and recurrent branches, as well as from the sympathetic system. Foreign bodies falling into the trachea most frequently enter the right bronchus, because of the larger size of the latter and because of the more oblique position of the left bronchus.

Diseases and Injuries of the Trachea.— The trachea is liable to inflammation and its products and frequently suffers from extension of disease from the larynx. Acute inflammation may occur as an idiopathic affection or a symptom of other disease, as smallpox, measles, typhus, tuberculosis, croup, etc. The symptoms are pain in the windpipe from the top of the sternum, expectoration of mucus, sometimes in regular rings and a peculiar brazen-like cough. Chronic inflammation usually accompanies follicular pharyngo-laryngitis, tuberculosis and syphilis, and may extend to the submucous tissues and the cartilaginous structures, resulting in ulceration, cicitrization and stricture. The treatment consists in rest, the application of warm poultices, the inhalation of steam impregnated with balsamic or anodyne substances and the administration of antiphlogistic remedies. Constriction of the trachea may be produced by aneurismal or other tumors pressing externally on the trachea; or the symptoms may be produced by pressure on the nervous trunk or the inferior laryngeal fibres. Foreign bodies occasionally pass through the larynx into the trachea and the accident is a formidable one, which not unfrequently proves fatal. The accident occurs most frequently among children and is caused by a sudden inhalation while holding something in the mouth. Occasionally, however, a foreign body may, during the act of swallowing and without an inhalation, pass under the epiglottis and into the upper part of the larynx. Foreign bodies in the windpipe may be arrested above the rima glottidis, between the vocal cords, in the cavity of the larynx or in the trachea. In such cases the patient is suddenly seized with convulsive cough and dyspnœa. The speech is more or less affected and the breathing is whistling or stridulous; but the diagnosis rests mainly on the sudden accession of the symptoms. When the presence of a foreign body is made out, it ought to be removed at once. When the body is loose in the trachea, a free opening lower down should be at once made and the opening may be either longitudinal or transversely valvular. It is advisable in nearly all cases to open the trachea, as, by securing a free aperture for respiration, spasm of the glottis is obviated and the foreign body may be removed through the artificial opening, or it may fall through the glottis into the mouth. Fracture of the trachea occurs from direct violence and in such cases the wounded part should be laid freely open, so as to secure the passage of air to the lungs. Union of the wound by suture is to be avoided, that by suppurative inflammation being preferable, the head and neck being retained in a suitable position. Foreign bodies in the trachea and all kinds of injury from external violence are serious affections, as disease of the lungs is apt to be induced.

The term trachea as applied in respect to invertebrates connotes a more or less complicated arrangement of air-tubes and spiracles (q.v.), most fully developed in insects and constituting the respiratory system. See INSECTS. For the general subject, see ANATOMY; LUNGS; NOSE AND THROAT; RESPIRATION.

TRACHEOTOMY. See NOSE AND THROAT.

TRACHOMA. See OPHTHALMIA.

TRACHYTE, trā'kīt, an igneous or pyrogenic rock of the effusive type and consisting of a ground mass of slender hair-like crystals of orthoelastic feldspar and ferro-magnesian silicates (hornblende or augite) and generally phenocrysts of sanidine feldspar. It differs from rhyolite chiefly in the absence of quartz. Trachyte occurs in the Black Hills, in Custer County, Colo., in Montana, along the river Rhine, where the Drachenfels furnishes the most typical variety, in the Auvergne, in Italy, and in the Azores. The compact pre-Tertiary varieties are classed as felsites (q.v.) or as porphyries.

TRACING PAPER, transparent paper which enables a drawing or print to be clearly seen through it when laid on the drawing, so that a pen or pencil may be used in tracing the outlines of the original. It is prepared from smooth, unsized, white paper rendered transparent by an oily application, as of oil of turpentine with an equal part of Canada balsam, nut-oil, etc.

TRACT NUMBER 90. See TRACTS FOR THE TIMES.

TRACT SOCIETIES. The circulation of religious appeals in writing preceded the invention of printing and was used by Wyclif and other reformers at times and places when and where open preaching might have been too perilous. The printing-press made it possible to multiply such appeals and it was largely used for this purpose in the religious controversies of the 16th and 17th centuries. The 17th century and the beginning of the 18th witnessed the organization of several societies within the Church of England for promoting Christian knowledge and «the dispersion both at home and abroad of Bibles and tracts of religion.» It was not, however, until 1750 that members of different Protestant denominations united in London to form the «Society for Promoting Religious Knowledge Among the Poor.» This and other societies with a similar object circulated many religious books and tracts.

In the United States the Methodist Book Concern, established in Philadelphia, issued its first publication in 1789, and removed to New York in 1804. In 1822 a bindery was established and in 1824 a printing office was added. The division of the Methodist Church on the slavery issue led to the establishment of a separate book concern at Nashville, Tenn., by the Methodist Episcopal Church South. The publications of the Book Concern are of three classes — first, the bound volumes, denominational papers and some pamphlets; second, those of the Methodist Episcopal Sunday School Union, and third, those of the Methodist Episcopal Tract Society. The Concern has developed far beyond the «tract society,» being now a large religious publishing house. The salaries of bishops and other expenses of the Methodist Episcopal Church are paid out of the profits of the Book Concern.

The American Tract Society was founded in the spring of 1825. In this society Christians of various Protestant denominations united to publish and circulate «whatever would best diffuse a knowledge of our Lord Jesus Christ as the redeemer of sinners and promote the interests of vital godliness and sound morality,» the material circulated to be such as would receive the approbation of all evangelical Christians. The society established a system of colportage, gave wide circulation to tracts and sought to place Christian literature in every family. Periodicals were established for young and old and the needs of the large foreign population were met by religious publications in their own languages. The society has contributed from its earnings nearly $1,000,000 to assist missionaries abroad in printing books approved by the society. In donations and legacies the society has received over $7,000,000 and has expended that amount in its gratuitous work, besides printing and circulating over 800,000,000 tracts, pamphlets, books and periodicals, many of which were sold. Among the nationalities reached in their own languages by publications of the American Tract Society are the Swedish, Danish, French, Spanish, Dutch, Italian, Portuguese, Polish, Bohemian, Hebrew, German-Hebrew, Hungarian, Lithuanian, Finnish, Welsh and Armenian. It has furnished religious reading matter to the American soldiers in large quantities. Besides the American Tract Society, every important denomination has an organization for the circulation of its denominational literature.

TRACTARIANISM, the name usually given to a system of religious opinion and practice promulgated within the Church of England in a series of papers published under the title of 'Tracts for the Times,' between September 1833 and March 1841. The immediate object of the writers seems to have been to rouse a large number of nominal adherents of the Church of England from their apathy, by awakening their interest in what the writers conceived to be the distinctive principles of that Church. For this end they sought to mark out a middle way between «Romanism» and what they called ultra-Protestantism. The leaders in this movement were J. H. Newman, John Keble and E. B. Pusey, and they were assisted by not a few devoted adherents, such as R. H. Froude (brother of the historian), Hook, Palmer, Perseval, Isaac Williams and others. In the first stage of the movement little else was attempted than the inculcation of the peculiar and exclusive powers of ministers episcopally ordained by the laying on of hands in a direct and unbroken line from the apostles, and it was not till the publication in 1838 of the 'Remains' of R. H. Froude, under the joint-editorship of Newman and Keble, that any suspicion was created in the public mind of the ultimate tendencies of the movement. The volumes published under that title were pervaded by an unmistakably anti-Protestant spirit, and the fact of their being edited and defended (as they afterward were) by two who were known to be leaders in the Tractarian movement caused that movement to be denounced by many who had hitherto treated it with indifference or forbearance, or had even bestowed upon it a certain measure of approval. From that date the bishops began a series of charges all bearing more or less strongly against the authors of the tracts, and treating them not as heretics but as disturbers of the Church. Still the movement went on more actively than ever. A multitude of controversial writings appeared on both sides, and the tracts gradually showed more and more of a leaning to the Roman Catholic Church. At last, in Tract No. 90, written by Mr. Newman, and published in March 1841, an attempt was made to prove that there is no insurmountable barrier between the Roman Catholic and the Anglican communions; that the Thirty-nine Articles, although prepared by Protestants, are susceptible of a Catholic interpretation not inconsistent with the doctrines of the Council of Trent. On the 15th of the same month the hebdomadal board of the University of Oxford condemned the tract as teaching a mode of interpreting the Thirty-nine Articles inconsistent with the statutes of the university, and the bishop of the diocese of Oxford recommended that the series of tracts should terminate with that number, which it did. A few years later (1845) Newman went over to the Church of Rome, as several of the other partakers in the movement had done before him. The effects of the movement can still be traced within the English Church in the extreme development of ritualism in a section of the High Church. See GREAT BRITAIN — THE CHURCH OF ENGLAND; NEWMAN, FRANCIS WILLIAM; PUSEY, EDWARD BOUVERIE; PUSEYISM; RITUAL.

TRACTION, Electric. The history of the development of electric traction follows closely that of other great technical developments — starting with experiments on a small scale, having no practical outcome, followed by experiments on a larger scale, showing the physical possibility of the system, and finally using the experience so obtained in a successful, commercial application of the system to practical operating conditions. It was not until the invention and development of dynamo-electric machines made it possible to obtain electrical energy at a reasonable cost that the commercial application of electric traction became possible, and even after that, electric machinery had to be improved before electricity could compete with the existing means of traction. Among the first to study the problem seriously were Siemens, in Germany, and Edison, Field, Daft and Vandepoele in this country. Before 1884 a few roads had been built for exhibition purposes and from that time until 1888, although some small roads were equipped with a few cars, yet it had not been proved that electricity could be profitably substituted on tramways for cable or animal traction. In February of 1888 the Sprague Electric and Manufacturing Company finished the equipment of the tramways in Richmond, Va., with the Sprague Electric Railway system, and operated the road so successfully that railroad managers from other parts of the country were convinced that they had something to substitute for animal traction that would increase their facilities for transportation and decrease the cost of operation. From this time the development of electric roads in the United States has been rapid. At first horse tramways were electrically equipped, then cables were displaced by electric trolley roads, then the tramways were extended further to the suburbs and surrounding towns, and towns were connected by interurban roads equipped electrically, running at high speeds and offering a service impossible with steam locomotives. For city train service on elevated roads, the substitution of electricity has taken a longer time, as the steam locomotives were efficient and as the changes involved an expenditure which would not have been advisable unless decided advantages with respect to service and cost of operation were shown.

Direct-current Railway Motors.— On all the electric roads in this country, and on a large proportion of those abroad, direct-current motors are used for traction. These motors are of the series type, and are usually connected to the axle through a single spur gearing. The characteristics of the direct-current series motor are admirably adapted to traction work. The speed is dependent upon the tractional effort, and the motor slows down when the tractional effort increases, having something of the effect of a variable speed gear; this is very important in practical railway work, for if the motors ran at a constant speed, the energy demanded on grades would be greatly exaggerated and much larger motors would be required. It is also true that this type of motor gives a greater flexibility to the system, as far as speed is concerned, and this flexibility is important in practical operation. To show the difference between a series motor and a shunt motor, suppose the track resistance is 10 pounds per ton weight of the car; then if the speed were constant (as would be the case with a shunt motor), the power required on a 5 per cent grade would be 11 times as much as on a level — air resistance being omitted — while with a series motor it would be only three or four times as much.

It might be well to briefly trace the development of electric railroad motors in the United States. The motors used by Sprague in the equipment of the Richmond road had too small a capacity for the work required and very often burned out. They were two-pole machines, of a rated capacity of 7.5 horse power, and at first drove the axle through a single reduction gearing; the work, however, was so heavy that it was found necessary to change to a double reduction gearing, the teeth of the pinion stripping on the heaviest grades. These motors were unprotected from moisture and from the dust and dirt of the streets. The methods of suspending the motor and some of the details of the regulation are still retained. The field magnets of the motor were sleeved on the axle, thus centring the armature on the axle and allowing a satisfactory relation between the two. The first motors had a double commutator, which was soon abandoned, as it greatly increased commutator troubles, which were at that time serious. The brushes first used on these motors were of copper and a number of forms were experimented on, it being necessary to reverse the motor without injuring the commutator. None of the experiments with copper brushes were successful, and it was not until the introduction of the carbon brush by the Thomson-Houston Company that the commutator difficulties were largely obviated.

Soon after the Sprague Company entered the railway field, the Thomson-Houston and Westinghouse companies took up electric railway work, and greatly aided its development by adding their immense resources to the resources of the Sprague Company. From this time the development of street railway apparatus was rapid. The first motors of all the companies used double reduction gearing, and one of the first improvements, after the introduction of the carbon brush, was the design of a comparatively slow-speed motor which allowed a single reduction gearing to be used. The first motor of this kind was made by the Wenstrom Company, and within a short time other manufacturers were making slow-speed motors — some going so far as to attempt gearless motors; the latter, however, were not successful owing to their great weight and lack of efficiency at reasonable speed. Most of the slow-speed motors that were made at this time were not thoroughly enclosed, their efficiency being such that a better ventilation than could be obtained by a totally enclosed machine was necessary. The machines were, as a rule, of the four-pole type, with parallel armature windings, requiring four brushes and causing, under certain conditions, unbalancing in the circuits that greatly increased the armature losses and decreased the efficiency. The next step in motor development was made by the Westinghouse Company in what they called their No. 3 motors, a machine much like those at present in use. It had four poles, each of them provided with a field coil, while the armature was provided with what is called a series winding, necessitating only two brushes and doing away with the unbalanced armature circuits of the earlier machines. This type, with the modifications suggested by experience, is the one used in this country at the present time, and almost universally used abroad.

Controllers.— The first method used for regulating railway motors was by inserting resistance in the circuit of the machine; this was modified and developed until, in the Richmond motors of the Sprague Company, the series-parallel system was used, combined with a variable resistance obtained by making different combinations of the coils into which the field windings of the machine were divided. On starting and for slow speeds the two motors were used in series, while for the higher speeds they were placed in parallel. This system was abandoned, and for some years a parallel system for operating two motors on a street car was used. One difficulty found in the early series-parallel control was the liability of the motors to slip when in series position. The slipping on one pair of wheels would allow the motor connected to these wheels to revolve at such a high speed that its counter-electromotive force would cut off the power from the other, and the car would not start. This difficulty, which always exists, but which is not of importance on ordinary roads, was further complicated by the electrical difficulties in the controller — the method of control not being as efficient as that used at present. In the Sprague system, there was no resistance outside of the motors, but the motor fields were divided into a number of coils, and the relations of these coils were varied, giving first a high resistance and a very strong field for a given current, and afterward a comparatively low resistance and a comparatively weak field. The difficulty of this system lay in the fact that all the heating incidental to the low efficiency of the motors on starting was liberated in the field; and, further, the inductance of the fields was greatest at the breaking of the circuit, when all the coils were in series. The Thomson-Houston Company modified this by placing a variable resistance directly in the motor circuit, the resistance being regulated by a movable contact arm, controlled by the motorman. This gave better results than the Sprague system, but it also lacked efficiency. In 1891 the General Electric Company brought out a series-parallel controller, similar in some respects to the early Sprague control, but differing from it in the fact that the regulating resistances were not obtained by variations of the different motor field windings, but by resistances outside of the motor. This system, with variations due to different conditions of operation, is still used and gives excellent results. Perhaps the most important development in controller work was due to the introduction of the magnetic blow-out devised by Prof. Elihu Thomson. This apparatus is so placed as to control the breaking of the circuits, and almost entirely eliminates the destructive effects of sparking, due to the breaking. The method of operation is as follows: At first the two motors are placed in series, the resistance being also in series with them; then the resistance is gradually cut out, until finally the motors are in series across the line with no outside resistance in their circuits. Then the resistance is again cut in and one of the motors is short-circuited; the next operation cuts out the short-circuited motor, the next places it in parallel with the other motor, a large part of the resistance still being in series with them; the rest of the operations consist in cutting out the resistances until finally the motors are in parallel across the line. The shifting of the circuits, due to the various operations necessary for regulation and cross circuiting, is carefully guarded against by enclosing the different sections in compartments.

Multiple-unit System of Control.— In urban train service, where a number of cars are operated in one train, with frequent stops, the question of acceleration is of the utmost importance. In order to accelerate quickly, it is necessary to have a large margin of tractive effort on the train — that is, it is necessary to have a large proportion of the total weight of the train on the driving wheels. When the question of displacing steam locomotives for elevated railway service first came up, and was attacked on the basis of using electric locomotives, the advantages of the latter were not apparent. There was, of course, some advantage in the matter of expense, but not enough to justify the expenditure necessary to change from steam to electric service. Mr. Sprague devised a system by which a number of cars on a train could be equipped with electric motors and controlled from any one of the cars; this system he called the «multiple-unit» system. At first it was opposed by most of the manufacturing companies and by many electrical engineers. With his customary energy, however, Mr. Sprague worked his system out to a practical demonstration, and to-day all trains operated by electricity employ his fundamental methods. The advantages of this system are these: It gives a large proportion of the total weight of the train on the driving wheels, and at the same time distributes this weight over the whole length of the train. In the first place, this allows rapid acceleration without slipping of the wheels, and in the second place, it does not impose an undue strain on any elevated structure. It is also possible, of course, to change the number of units on a train without changing the relative weights of the driving mechanism of the car. It furthermore utilizes all the train space for the transportation of the passengers. Its disadvantages, compared with a single locomotive, lie in the fact that it necessitates a greater number of motors, thus adding to the cost of installation and repairs, and it greatly complicates the system of control.

In the Sprague system each car is equipped with a controlling device operated by a pilot motor, the motor being operated through a circuit controlled by the motorman. The system is to a considerable extent automatic, as the rate at which the different positions of the controller on each car are changed depends upon the flow of current into the motors, and is not determined by the motorman. This is an important feature of the apparatus and makes the acceleration uniform, and at a rate to give the greatest efficiency. The General Electric method of control is somewhat different from this, each car having a master-controller, very much like the ordinary tramway controller — the speed at which the current is cut into the motors being determined by the rate at which the motorman turns the handle of the controller. In the Westinghouse controller, the apparatus which supplies current to the motor is operated pneumatically, the valves of the pneumatic system being worked by magnets in a local circuit, which has as a source of energy a few storage batteries on each car and is operated by a master-controller on each car of the train. This makes all the operations independent of the line current and gives very positive and efficient action.

Overhead Trolley System.— For collecting the current to run electric cars, a number of devices were used, until finally Sprague's success at Richmond fixed a type of collecting device that is still considered standard in this country and is largely used abroad. Until actually determined by experiments, it seemed impossible that a moving contact device could collect the current necessary to supply the energy to the cars without such destructive sparking and heating that it would be inoperative. In the first experiments on electric railroading, the current was collected from the rails; afterward it was collected through small carriages running on the overhead wire; and finally it developed into a rotating wheel having a contact on the underside of the trolley wire and pressing against it by some spring arrangement. What is called a «bow» trolley was first used — that is, a wire bent into the shape of a bow, pressing against the underside of the wire, but having no rolling contact. This is still used to a considerable extent abroad and presents some advantages over the trolley wheel used in this country. A number of modifications of both of these systems have been devised and employed. The overhead trolley wires, from which the current is collected, are usually of copper; they are either suspended from insulators fastened to a span wire between poles on the two sides of the track, or from brackets fastened to a pole and projecting over the track. In this country they are almost universally placed over the centre of the track, but abroad they are sometimes placed on the side of the road, the trolley being so constructed as to make a side-bearing contact.

Underground Trolleys.— From the earliest application of electricity to railways, attempts were made to do away with the overhead wires used in the ordinary trolley systems. Conduits having a slot through which a current-collecting device could pass were placed beside the tracks or between the rails; conductors were placed in these conduits and the collecting devices on the cars were made to bear against the conductors. At first the conduits were not large enough, not enough space was given for insulation, and the results were unsatisfactory. The first successful system to be installed was a tramway at Budapest, designed by the Siemens Company. Here the conduit was on the side of the track, the tram rail forming part of the slot. The conductor was supported from below by insulators and the system was constructed on a larger scale than had been previously employed — the details were carefully worked out and the road has operated successfully from the time of its installation. In the meantime, in this country, the necessity of some such system in the cities of New York and Washington, where overhead wires were not permitted, had forced the different electrical companies to take up seriously the question of conduit construction, with the result that successful systems were worked out for both Washington and New York, the systems being practically the same. The slot in these systems is in the middle of track. The conduit is constructed as follows: Cast-iron yokes supporting the tramrail and slot rail are placed at intervals of five feet, the rails are attached to the yokes and the whole structure is blocked up in its proper position; then sheet steel is placed between the yokes, forming a tunnel of the proper dimensions, and concrete is packed around the yokes and the forms, supporting the structure in its proper position and forming a tunnel for the conductor rails. The steel forms are then taken out. The conductors are made of T-iron, held from above by porcelain insulators placed in cast-iron boxes along the track. The details of the different systems that have been installed vary, but the above is practically the standard type of construction. The current for the car is collected by means of what is known as the plow, which passes through the slot and has two cast-iron contact shoes held against the conductor rail by springs; the rail is supported on cross-rods on the car and has a wide limit of lateral motion. It is usual to place ducts beside the track, these ducts containing the feed wires that are connected at various intervals with the conducting rail.

The Generation and Distribution of Current.— In the earlier roads, and, in fact, in many of the roads now operated in this country, the current for the motors is obtained from direct-current machines, having a voltage of between 500 and 600 volts. These machines are, as a rule, compounded so that their voltage increases with an increase of load. There were two reasons for this: One is that the increased voltage compensates to a certain extent for the loss of voltage in the distributing system; the other, and most important reason, is that the strengthening of the field prevents the sparking that might otherwise be caused by the armature reactions. It is the custom to ground the negative side of the machines and connect the trolley wires through what is called «feed wires» to the positive brushes. These feed wires are carried along the line, connected at intervals to the trolley wires, it being usually the custom to divide the road into sections and feed the different sections from different feed wires. At the voltage which has been adopted as the standard — that is, from 500 to 600 volts — the economical distribution when the service is heavy is limited, and if a direct-current system is to be employed for a large area, a number of stations must be installed. For this reason, when the distances are great, it is sometimes necessary to employ a high potential alternating system, reducing it to a 500-volt continuous-current system at centres of distribution called sub-stations. On interurban lines, for instance, where the distances are great compared with the number of units in operation, this method becomes imperative, as otherwise the variations of load on the central station would be excessive, and the cost of power would be practically prohibitive. This method of operation may be described as follows: The central station, located at some point where the greatest economy of operation can be obtained, generates alternating currents at a high potential; these alternating currents are taken to the sub-stations, situated at reasonable distances from one another along the line, and are there changed to alternating currents of lower potential by means of transformers and then converted into direct currents of the proper potential by means of rotary converters. In this way a large area can be supplied from one central station and a comparatively large number of units can be operated at one time from this station, thus giving conditions of maximum economy. On the sub-stations themselves, there is, of course, a fluctuating load and it is the custom to install storage batteries in connection with the rotary converters to equalize the load; the battery storing energy when the load is light and giving it out when the load is heavy.

The Return Circuit and Electrolysis.— In most of the overhead traction systems, the current passing through the motors goes through the wheels of the car to the rails, and then returns to the station, «bus bars» finally appearing at the negative brushes of the dynamos. When a system is operated in this way, the rails are bonded — that is, two adjacent rails are connected by conductors securely attached to the rails and giving a low resistance to the electric current. If the bonding is good, a considerable part of the current passes along the rails while a small portion strays through the earth to other conductors, such as water pipes and gas mains, using these as a return conductor. If the bonding is bad, however, a considerable portion of the return current is carried by the underground pipes, causing them at times serious injury. For this reason, and also because of the fact that low conductivity in a rail return causes loss of energy, it is of importance that the bonding of the rails should be as thoroughly perfected as possible; it should also be carefully inspected at intervals, as the bonds are liable to break and produce a high resistance between the adjoining rails, thus diverting a considerable amount of current to the underground pipes. The matter of the electrolysis of underground metallic structures received little attention during the first two or three years of electric railroad development; the effect, however, naturally increased with time and the development of the systems until the serious damage that occurred became evident, and means for preventing it was sought. These means, as a rule, consisted in connecting different points of the rail circuit to the negative bus-bars of the station, by return feeders, and in making metallic contacts between the rail and pipes at points where the current was leaving the pipes; also in metallically connecting the pipes near the station with the negative bus-bars. No electrolytic damages is done when the current leaves the pipe through a metallic conductor; it is only when the current passes from the pipe through an electrolyte, such as is furnished by moist soil, that corrosion takes place. In some places, the joints of the pipes have been insulated to prevent the current from passing through them and this is perhaps the most efficient means of avoiding electrolytic troubles.

Alternating-current Motors.— The most important drawbacks of the induction motor are these: In the first place the motor has practically the same characteristics as a direct-current shunt motor and, therefore, does not afford the variation of speed with load that is one of the most important and valuable features of a series motor. In the second place three circuits are necessary to operate the machine and while the track can be used for one of these circuits, the necessity of two wires over each track, the wires having a considerable difference of potential, makes the practical operation of such a traction system difficult. Numerous systems have been devised for regulating these motors, but they are either complicated or inefficient and it is the opinion of the writer that induction motors will not be used for railroad work except under special conditions. The only advantage such a system offers is the high potential that can be used and this advantage is neutralized by the fact that the three conductors necessary make high potentials practically unavailable. Electrification offers a wonderful opportunity for saving in capital expenditure, where expanding demands new facilities which by other means would be inordinately expensive to provide. The higher sustained speeds of electrically-hauled trains on heavy grades offers an irresistible opportunity to expedite traffic and the flexibility of make-up and movement of multiple-unit suburban trains is a most valuable consideration. The fact that electricity as a source of railroad motive power offers the only possible connecting link between the waterfall and the locomotive gives it an unique position, analogous to that of alternating current in the general power distribution field. It is more difficult to *prove out* the economy of electric operation on this basis, but it is certainly sound over-all conservation to use to the limit a form of motive power that cuts down materially the rate at which the supplies of coal and fuel oil are being depleted.

During the last few years the new cars have been made considerably larger and hence the propulsion equipment has become proportionately more powerful than that formerly provided. The latest motors are specified to perform any service, on cars weighing 75 tons loaded, that is now being performed by the motors on the original 58-ton cars and it is required also that they shall operate satisfactorily on trains made up indiscriminately of the old and new types of cars. These motors are provided with tapped field commutating poles and self-ventilation. They operate normally at 600 volts direct current but are capable of successful operation at voltage up to 750. Space restrictions have had a marked influence on the design, owing to the use of clasp brakes and the desire to utilize standard electrical construction and to this end the gear face has been reduced to four and one-half inches in place of the five-inch face that would ordinarily have been used. Acceleration is accomplished either automatically or by hand, the former being under control of the current-limit relay on each car and there are 10 notches for forward running and six for reverse, these including the running positions made available by the field control as well as the customary intermediate running points.

In some of the single-phase locomotives of recent construction spur gears and coupling rods have been adopted for transmitting the power from the motor to the driving axles. Each truck is provided with two motors geared to a common intermediate shaft which is connected to the driving wheels by means of the coupling rods. The latter are arranged one on each side of the locomotive with an angular displacement of 90 degrees. The pinions on the motor shaft are fitted with springs to give circumferential flexibility. This arrangement is adopted to equalize the tooth pressures on the two pinions and to compensate for the sudden alterations of tongue chiefly due to the coupling rod drive with its changing reciprocating forces. Two strongly constructed centre pins supported from the trucks take the weight of the locomotive body and the electrical equipment. The control switches with their operating apparatus are mounted together with the transformer so that the whole forms a complete unit which can be installed or removed bodily through an opening in the roof. The two motors of each pair are connected in series, while the two pairs are in parallel with one another.

Electric locomotives are now generally considered in two groups, regardless of system of current supply, namely, the powerful machines which are used in heavy electrifications on the main lines of important steam roads and the lighter locomotives which find their field of application in less conspicuous duty in the electrified zones of steam roads and in handling freight cars on interurban lines. The former locomotives are of special designs, each railroad system having its own requirements. The design of the lighter machines tends more to standardization. Standard interurban freight locomotives are usually of the *steeple* type which is preferable to the box type in appearance and is free from compressor noise.

1 Self-Reversible Tractor carrying its own Plows
2 Tractors hauling 12-disc Plows and Spike-toothed Harrow Trailing

1 Tractor hauling Hay Wagon and Loader

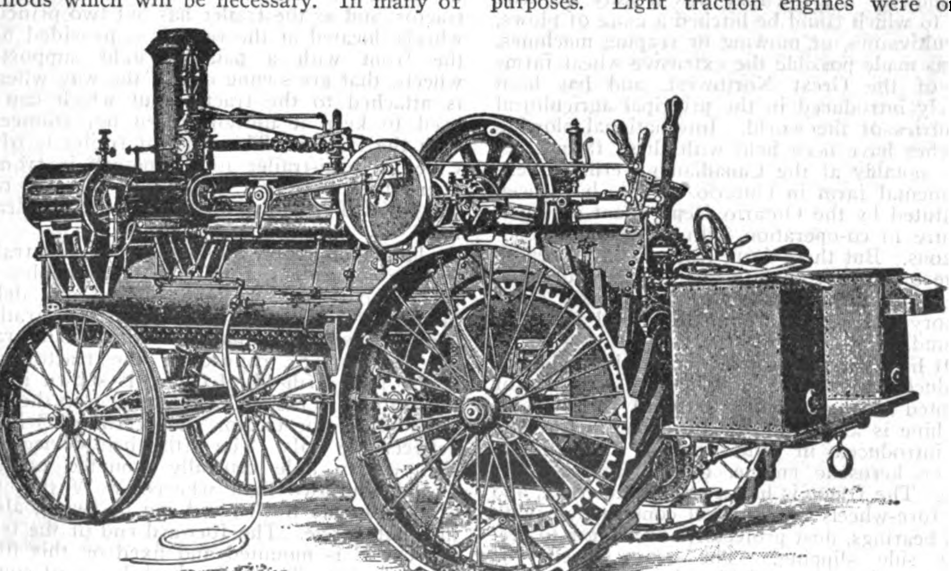
2 Tractors hauling Reapers and Binders

Design features introduced to ensure reliability and low maintenance cost include particularly (1) Form-wound armature coils, with special insulation in the ends of the slots; (2) Strap-wound field coils securely fastened and held against vibration; (3) Substantial brush-holder design and construction; (4) Mica insulated, undercut commutations; (5) Bearings of ample size with oil-gauging pockets, lubricated by oil drawn up and filtered through waste; (6) Two-point gear case suspension. The unit switch control has proved itself capable of handling the heavy currents encountered and also to withstand the bumps to which the locomotives are subjected, particularly in switching work, low-speed, drag-freight service or main-line service. In this control the various main circuit connections are made by unit switches, actuated by compressed air taken from the air-brake system; the admission of air to the switch cylinders being controlled by magnet valves, which valves are operated by current from a control circuit through a train line from the master controller. Current from this control circuit is tapped from points on the control resister which is connected between trolley and ground, or may be supplied by a storage battery.

In late years the solution of the electric railway problems has become more difficult. The automobile has become a most serious competitor; at this time more than 6,000,000 pleasure cars are licensed. The automobile has not only decreased riding upon the trolley cars during business hours, but it has deprived the railway of practically all of its pleasure riding. The entire economic basis of the industry has been undermined and if the business is to survive it must be a radically different business in the future than it is at the present time It must, in the first place, secure prompt and adequate relief by a sufficient increase in revenues to enable it to function as a public utility; for a rejuvenation of credit is essential to carrying through the radical readjustment in operating methods which will be necessary. In many of the smaller cities, the companies must turn to one-man cars, permitting more frequent service with reduced operating cost. In the larger cities the companies and the public must face the necessity of abandoning the theory of a flat five-cent fare covering the entire city area and of charging the passenger according to the distance which he rides. See AMERICAN STREET RAILWAYS; RAILWAYS, STREET.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

TRACTION ENGINE, an engine designed for drawing loads on ordinary roads or across country, and thus distinguished from the locomotive which hauls loads over steel or iron rails. The traction engine is designed to withstand severe jolts and to climb gradients of at least 1 in 10 and on a surface which sinks somewhat beneath the weight of the engine, thus presenting a continual slope upwards in front of the wheels. The speed seldom exceeds eight miles an hour and consequently it is usual to reduce the speed of the driving-wheels from that of the engine shaft by intermediate gearing. Usually attached to the main axle is a winding drum, by which heavy loads may be drawn up bad hills on a wire rope, the engine having previously ascended, light, to the top. A heavy fly-wheel and a high-speed governor are provided. The driving-wheels of a traction engine have tires or treads of great breadth to distribute the weight of the boiler and engine over a large area of yielding roadway. The tires are also usually corrugated or roughened to give adhesion. A very efficient means of steering is always provided in the traction engine to enable it to make the sharp turns required in ordinary roads, and it is furthermore usually so designed that by throwing out the intermediate gearing from connection with the traction-wheels, the steam-engine proper can be used as an agricultural engine for threshing, milling, pumping and other similar purposes. Light traction engines were once



Common Form of Traction Egnine.

favorites in drawing plows but have been displaced by the tractor of the internal-combustion engine type, although these are really traction engines. It is, however, usual to limit this term to the older type of land engine propelled by steam. This type appears to hold its place in America for hauling threshing machines from place to place and for driving them. In roadless countries, such as parts of Australia, Africa, etc., a heavy type of traction engine is employed to haul trains of wagons, as well as to act as portable engines for providing power for threshing machines etc. Engines designed for threshing outfits are supplied with fire-boxes capable of burning wood, straw and refuse fuel. Since the opening years of the present century the steam traction engine has been displaced to a very great extent by tractors and engines of the internal combustion type. (See TRACTOR). Consult Maggard, James H., 'The Traction Engine: Its Use and Abuse' (3d ed., Philadelphia 1915).

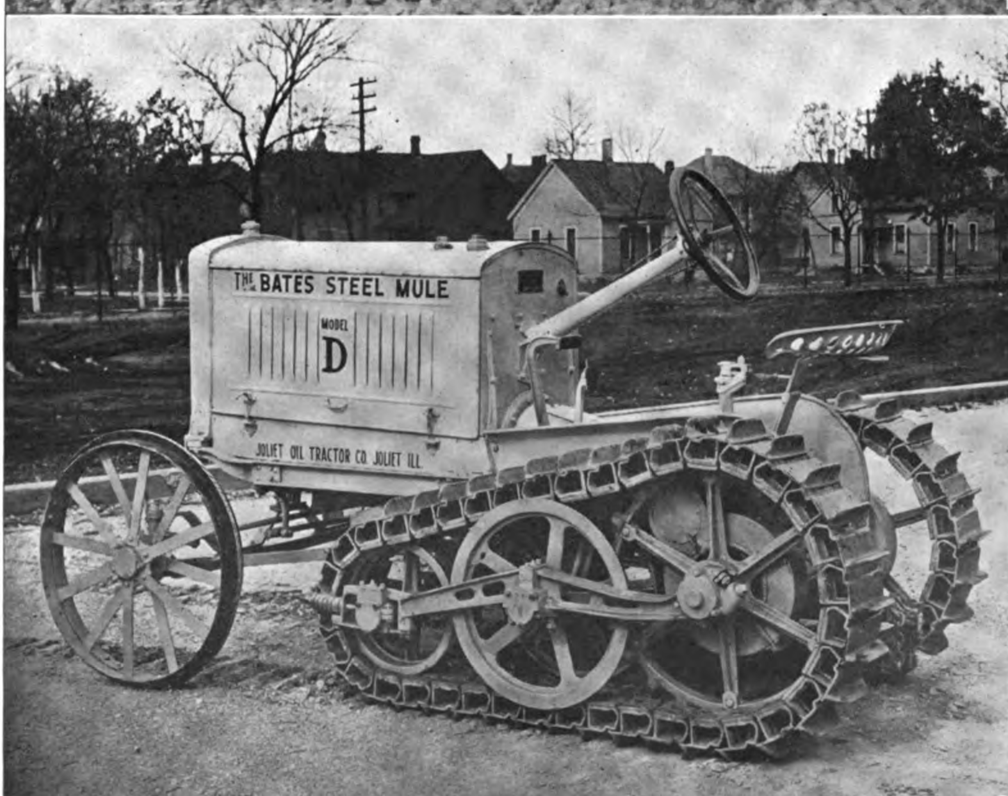
TRACTOR, a machine that draws a load, especially a power-engine mounted on wheels for traveling on roads or rough ground and hauling wagons, trailers, plows, cultivators or the like; a traction-engine. The locomotive (q.v.) was the first common form of tractor, but does not bear the name, and by common consent the term has been confined mainly to road-engines that do not operate on a track or ride on rails. The word tractor began to be used when steam plowing became general. For this purpose a road-engine was developed with massive wheels, having broad metal tires that would not sink readily in soft soil, and to give them greater grip on the ground, or tractor capacity, cross-pieces were fixed on the rims, so as to resist slipping when there was hard pulling. This engine was provided with a long, horizontal boiler, an upright smokestack and many of the conveniences of a locomotive. At the rear was usually a drawbar, to which could be hitched a gang of plows, or cultivators, or mowing or reaping machines. It has made possible the extensive wheat farming of the Great Northwest, and has been largely introduced in the principal agricultural countries of the world. International plowing matches have been held with these farm tractors, notably at the Canadian government experimental farm in Ontario. These have been instituted by the Ontario Department of Agriculture in co-operation with Plowmen's Associations. But these farm tractors have been so large and costly that their use was prohibited on small farms, and they have been satisfactory only on approximately level areas of ground.

It has remained for Henry Ford and Son to produce a small and inexpensive tractor adapted to the use of the small farm. This machine is known as the Fordson tractor, and as introduced in 1918 carried a 22 horsepower kerosene engine, of the four-cylinder type. The frame is like a small auto-truck, and the fore-wheels are of steel construction, with ball bearings, dust protector, and flanges to prevent side slipping. The rear wheels — 42 inches in diameter and 12 inches wide — are the drivers, and carry most of the weight; the gripping flanges of these are of angle-steel, set at an angle of 45 degrees. The driver's seat is between the driving wheels, and the method of control is very similar to that of a light autotruck. A bevel-pinion and sector are connected with the steering wheel, and entirely enclosed and lubricated by oil splash. Directly under this is the throttle lever, the spark lever being mounted on the dash. The distance between the wheels, constituting the tread, is but 38 inches, and the machine can turn a complete circle within 21 feet.

The ordinary plowing speed is two and three-quarters miles an hour, with a low speed of two and one-half miles an hour, the drawbar pull being 1,800 pounds and 2,500 pounds, respectively. When traveling or doing light work, a speed of six and three-quarters miles an hour is available. Fairly good ground can be plowed at the rate of about three-quarters of an acre an hour, varying, of course, with conditions. A little less than three gallons of kerosene per acre is a fair average consumption. With fuel and water tanks full the machine weighs 2,700 pounds.

Automobile Tractors.— As soon as the modern auto-truck was perfected and began to have a considerable sale, it became apparent that it was a convenience to separate the truck into two or more parts, one being a tractor and the others trailers. Many of the manufacturers of auto-trucks build tractors on the same general lines as their trucks, but instead of providing them with a rear body for carrying a load, there is simply space for attaching a «fifth-wheel» device, or else a draw-bar, to which a trailing car can be easily attached. A typical form of these is shown in the illustration, the tractor having four low heavy wheels, with radiator, motor and cab in front, and the rear of the chassis clear for supporting a fifth-wheel or turntable device, on which the forward end of a trailing car may be supported and swiveled. About 40 per cent of the weight of the trailer is designed to be carried on the tractor, and as the trailer has but two principal wheels, located at the rear, it is provided near the front with a pair of light supporting wheels, that are swung out of the way when it is attached to the tractor, but which can be used to keep it upright when not connected with the tractor. This type of trailer is often called a semi-trailer to distinguish it from a four-wheeled trailer, that bears all its own weight, and is pulled by some form of drawbar.

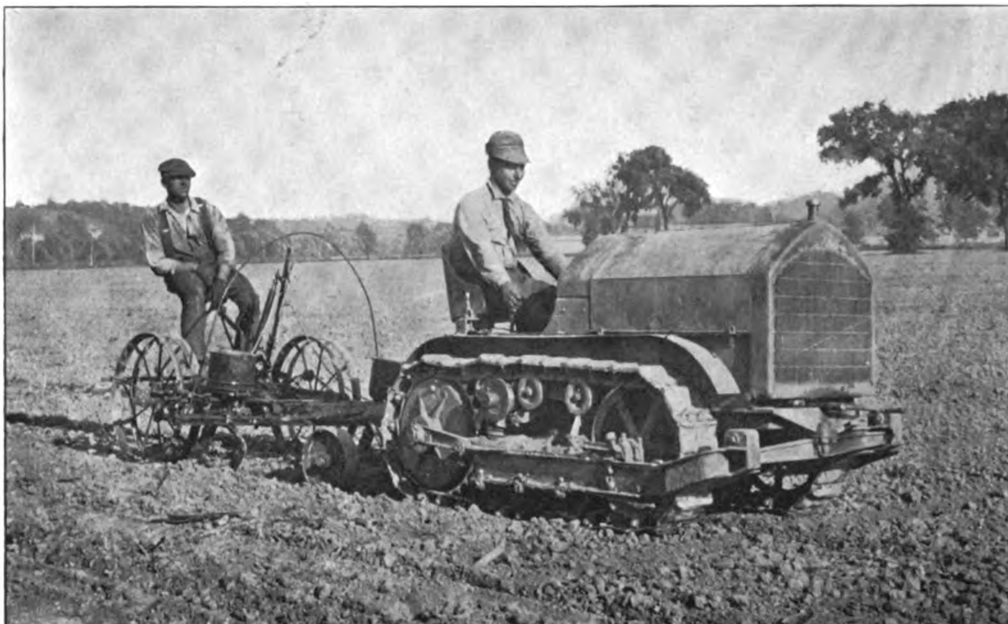
The combination of auto-tractor and trailer is very convenient, for it not only enables the tractor to deposit its load without any delay, but it can be used to haul all sorts of trailing cars, and often a number of them in a train. The method of connecting the tractor and trailer by a fifth-wheel device is shown in the illustration. Tracks T are mounted on the rear frame F of the tractor, and a swivel S is set between the rails. The fifth-wheel device consists of an axle centrally mounted on this swivel, and two light wheels W W that run around on the tracks, and can be swung about in a half circle. The forward end of the trailing car C is mounted and fixed on this fifth-wheel device. The fifth-wheel device of course takes its name from the fifth wheel on the front axle of an ordinary wagon, though it



1 Caterpillar Tractor hauling a Three-gang Plow

2 Caterpillar Tractor, especially effective on soft ground

TRACTORS



1 Caterpillar Tractor for farm work

2 Caterpillar Tractor for army work

has been developed into a mechanism that is much more than a wheel. Some manufacturers use a swiveling pair of bolsters instead of this fifth-wheel device. When a trailer is loaded ready to start, the tractor is backed up to it, and hitched on by simply guiding the two small wheels of the fifth-wheel device up the tracks; or, if an automatic coupler is used, the method of connecting may be very similar to that used in coupling railway cars. It is necessary to provide trailers with brakes, else they might create trouble in going down hill, and these have to be connected with the tractor, so as to be operable in unison with the brakes when set by the driver. The connection between tractor and trailer must also be such as to permit a rocking motion, so that when passing over uneven roads all the wheels shall travel on the road without straining the framework.

Military Tractors.— The military «tank» which attained fame in the World War was based on a peculiar form of tractor designed to work in a rough country, as in logging operations, canal building, etc. The very heavy endless chains, bearing feet on each link, fitted these machines for the most arduous pulling work under the most trying conditions, and some military man among the British recognized their possibilities when armored, and the military «tank» was the result, introducing this type of machine to untold thousands who otherwise would never have heard of it. Though too slow of operation to compete with the ordinary tractor of auto-truck type, yet the tank-tractor has such superiority in marshy, stony and very rough ground, that it has obtained considerable use.

The Synmotor.— Another peculiar form of tractor that has been invented by a New Jersey genius is called the synmotor. It is an adaptation of the motor-cycle to agricultural traction. Instead of pneumatic tire wheels, this machine is provided with steel rims and angle grips, like the wheels of big farm tractors, and is designed to draw cultivators, seeders and small mechanism used in truck farming. Its peculiarity lies mainly in its being attached by a wire to a central post, around which it circles in reducing spirals. When started on a circle of ground it does its work automatically until the entire circle of 100 or more feet in diameter is plowed or cultivated, excepting a small portion in the centre. It operates in a four- to seven-foot swath, and uses gasoline fuel.

The drawing or pulling device of a ropeway or wireway is also termed a tractor. See MOTOR TRUCK; TANK.

TRACTOR, Caterpillar. A tractor employing, instead of the usual drive wheel, a flexible steel belt, or track, which supports the weight of the machine, even in very soft ground and gives it greatly increased tractive efficiency under all conditions. Invented by Benjamin Holt, of Stockton, Cal., about 1900, it was first used in the peaty soil of the San Joaquin delta, or «tule,» country. It is particularly adapted to cultivation of orchards or other plowed ground since there is no soil packing; to reclamation work in swampy land; to hauling where roads have not been established, as in desert, forest or in military operations; to climbing grades, since the track principle affords unusual pulling effort in proportion to weight, and to other extreme conditions. It is also used, of course, wherever ordinary tractors can be used and is often preferred because of absence of injury to pavements. «Caterpillar» is a trade-marked word properly applied only to the Holt tractor. Other tractors following the same general principle are referred to as «Crawlers,» «Creepers,» «Alligators,» «Centipedes,» «Tracklayers,» etc. See TANK.

TRACTOR ENGINE. See INTERNAL COMBUSTION ENGINE.

TRACTS FOR THE TIMES, a series of short essays or theological pamphlets published in Oxford between 1833 and 1841 by the leaders of the Oxford movement — Newman, Keble and Pusey. See TRACTARIANISM; OXFORD MOVEMENT.

TRACY, trā'sĭ, **Benjamin Franklin,** American lawyer and politician: b. Oswego, N. Y., 26 April 1830; d. 1915. He was admitted to the bar in 1851, was district attorney of Tioga County in 1853–59, helped to organize the Republican party in New York State and served in the legislature during 1861–62. At the opening of the Civil War he recruited two volunteer regiments in New York, the 109th and the 137th, and became colonel of the former. Later he was colonel of the 127th regiment of United States negro troops, and at the close of the war was brevetted brigadier-general of volunteers. As United States district attorney for the eastern district of New York, 1866–73, he drafted an internal revenue bill which more than trebled the United States revenue at a time when the huge war debt was being liquidated. In 1881–82 he served as judge of the Court of Appeals, and in 1889 became Secretary of the Navy in President Harrison's Cabinet. His term was marked by a large increase in the navy and the formation of a reserve naval militia. At the close of this service he resumed his law practice in New York. He was president of the commission that drafted the charter for Greater New York in 1895–96, under which he was the Republican candidate for mayor in 1897, but failed of election. In 1899 he was counsel for Venezuela in the boundary arbitration between that country and England.

TRACY, Joseph, American Congregational clergyman: b. Hartford, Vt., 3 Nov. 1794; d. Beverly, Mass., 24 March 1874. He was graduated at Dartmouth in 1814, ordained to the ministry, and was pastor of churches at West Thetford and West Fairlee in 1821–29. He edited the *Chronicle*, Windsor, Vt., for five years, the Boston *Recorder* for one year and then became president of the Massachusetts Colonization Society and of the American Colonization Society for Massachusetts, which positions he held until his death. He was associate editor of the *American Theological Review* for many years and published 'Three Last Things' (1839); 'The Great Awakening, a History of the Revival of Religion in the Time of Edwards and Whitefield' (1842); and 'A Memorial of the Semi-centennial Anniversary of the American Colonization Society' (1867).

TRADE. See COMMERCE; IMPORTS AND EXPORTS.

TRADE, Acts of. See ACTS OF TRADE; GREAT BRITAIN — NAVIGATION ACT.

TRADE, Board of. (1) In the United States a body of men selected from among the business men of a city, and appointed to represent and act for the whole business community in advancing and protecting their interests. (2) A similar body acting for a trade or industry, usually for the regulation of trade abuses. (3) In England, a permanent committee of the Privy Council, presided over by a member of the Cabinet, and divided into seven departments, each having its separate staff. It controls the issuing of patents, registering of joint-stock companies, handles trade insurance, settles disputes, etc. The British Board of Trade conducted highly useful work during the great World War, exchanging commercial intelligence, and assisting manufacturers and merchants in the unusual problems confronting them.

TRADE ASSOCIATIONS, business organizations composed of the individuals, firms and corporations engaged in a trade or industry, formed and operated to deal with those things in which the membership have a community of interest, as wage scales, uniform rules and measures, guarding of legislative interests, maintaining prices, exchanging of information as to credits of customers, etc. These associations in the United States developed mainly after 1870, largely as a result of the growth and activity of the trade unions. (See UNIONISM). The demands by workmen for better pay and conditions were generally resisted, and employers met and began to organize against their employees. Before such meetings the proprietors in a particular trade rarely had any personal acquaintance, knowing each other only by name, and usually having a poor opinion of each other, because of sharp competition and business rivalry. Brought into contact over labor difficulties, their views as to each other changed; they learned to respect their competitors, and warm friendships sometimes developed between them. They began to talk with each other about trade problems, and soon saw the wisdom of combined action in securing trade reforms. Their anti-union associations took on a broader scope; they engaged secretaries and business managers, and began to do business in those things which were for the common interest and benefit of the trade. So came into being the American Newspaper Publishers' Association, the National Association of Stove Manufacturers, the Association of Wool Manufacturers, the Typothetæ (q.v.), The National Erectors' Association, the Coal Operators' Association, the Photo-Engravers' Association, National Metal Trades Association, National Founders' Association and hundreds of others. As time went on, each of these associations tended to enlarge its scope and sometimes several organizations were formed in one trade, to care for different branches of the work. For instance, in New York City, the Typothetæ, the oldest organization among employing printers, concerns itself largely with exchanging information as to costs, bookkeeping, preserving fair competition, watching credits, etc. The Printers' League handles all labor difficulties, makes agreements with the unions, settles disputes as to shop rules and the like. The Master Printers' Association concerns itself with the well-being of the smaller printing offices, the job printers, insists on uniform treatment by paper jobbers, the charging of a fair profit on engraving, binding, etc., reports on customers who are slow pay, etc. In most cities, however, one local organization serves a trade wholly, and no need is felt for two or three to look after various branches of work. It is practically true that in every large city there is a trade organization in every trade represented by a considerable number of houses. These conditions have naturally led to combinations to keep up prices, and the public has been jealous at times of certain organizations, which they classed as a trust in certain trades and industries. At times the suspicion of taking unfair advantage of the public was well founded, and at other times the members of a trade association have only sought fair protection from competition that was ruinous and not advantageous to the community. Where the trade organizations have gone too far, and used their power of co-operation to push prices above a fair level, there has usually been a reaction; either district attorneys have brought criminal suits charging «combination in restraint of trade,» and caused the dissolving of trade associations, or else the increased prices have brought new firms into the field, that did not belong to the association, and these have undersold, and brought down the level of prices to a basis of keen competition. Of late years there is a tendency in the United States for the large trade organizations to work together for business reforms. They call upon each other for assistance in securing needed legislation, and they have formed a National Association of Manufacturers, whose influence is very powerful. See TRADE, BOARD OF; CHAMBERS OF COMMERCE.

TRADE DOLLAR, a former coin of the United States, containing 378 troy grains of silver and 42 troy grains of alloy. Trade dollars, issued under Act of Congress 12 Feb. 1873, were legal tender to the amount of $5. Those issued under the Act 22 July 1876 possessed no legal tender power. They were intended for trade with countries doing business on a silver basis. As silver depreciated in value the trade dollar depreciated, and speculators bought them abroad at 80 or 90 cents and circulated them in the United States at face value. This was easy because specie payment had just been resumed by the government in 1875, and the public liked the silver. When the lower value was generally understood, and they continued to fall in price, they were objected to and gradually disappeared from circulation.

TRADE-MARKS. Certain marks or inscriptions set on manufactured goods for the purpose of establishing the identity of their manufacture or selection. An examination of the evolution and development of the trade-mark in the United States of America is substantially an examination of the evolution and development of the vast commerce of our country.

Definition.— A trade-mark is a mark or sign indicating the source or origin of the article to which it is affixed. Unlike a patent (q.v.) it is not a monopoly. In its very existence it evidences competition, and lays claim to a degree of superiority in such competition. A trade-mark may consist of a word or words, or of a symbol, design, device or picture; or it may be constituted by an original and distinctive shape or form of package in which the goods are packed or contained; or it may consist of a combination of some or all of these elements; but in whatever form the trade-mark appears on the market, its office is either to indicate the origin or source of manufacture of the article, or when used, as it may be, by the dealer who sells to the ultimate purchaser or consumer, but who does not manufacture or produce the article, it may then indicate selection or endorsement of the manufacture of the article bearing such dealer's mark.

Office of the Trade-mark.— Not only does the trade-mark indicate the source or origin of the goods to which it is attached, but it also performs the office of guaranteeing or assuring to the purchaser, whether he be an intermediate or an ultimate one, that the honest skill of the owner of the trade-mark, the good quality of the goods, the carefulness of selection, the purity of ingredients or correctness of weight or measure are to be found in the articles to which such mark is affixed. Further than this the protected and defended trade-mark builds up for the manufacturer to whom it belongs that following in the market which becomes immensely valuable in appraising the goodwill of such a business.

The Origin of the Trade-mark.— The introduction of the trade-mark into commercial use was natural, and when once effected rapidly became a trade necessity.

A chemist in the olden days prepared a mixture or lotion and recommended it to the customers of his shop, who found it efficacious. A shoemaker made shoes for his patrons which by reason of good quality and superior workmanship won favor for him among his patrons; so that these trades-people, pursuing their various lines of industry, not only retained their custom, but were recommended by their patrons to others, such customers becoming accustomed to resort to the shop of the one or the other of the tradesmen who supplied such wants, a habit which is known in law as the goodwill of a business.

So long as the customer of the chemist transacted his business face to face with him in the same old shop, or so long as the shoemaker measured his patrons and delivered his goods to them in person, so long was it unnecessary for such manufacturers to mark their wares.

Their customers and patrons obtained a personal delivery and needed no other assurance or guaranty as to the genuineness of the articles purchased by them; but after a while, some of these purchasers and users of these various articles removed to other localities, and would desire to continue to use the same lotion or wear the same shoes; and they would order the same directly, if they could, or through some agent middleman if they could not; and then in the latter case, to quiet any apprehension which such customers residing at a distance might feel regarding the genuineness of the articles delivered to them, the chemist would affix a label to the bottle or jar containing the lotion, which would bear his name and address; and the shoemaker would mark on some part of the shoe his name and address; after a while the producers of these various articles found that the mere use of their name and address. while constituting a good and sufficient indication of the origin of their products, was nevertheless subject to several matters of inconvenience; the first was that perchance many of the customers could not read; and the next was, that the use of the name of the manufacturer alone was attended by a legal difficulty, to wit, that while a man's name would constitute a most perfect trade-mark, yet any other man bearing the same name had an equal right to use it, provided he did so honestly and fairly, and if engaged in the same line of business, a trade confusion would naturally and often did arise, as witness the Brown Iron Bitters case.

Adoption of Symbols and Arbitrary Words.—To reach and remedy these difficulties, manufacturers then began to adopt and use symbols consisting of pictures or devices, at first simple in their nature, such as shields, stars, geometrical figures or representations of animals and the like; they also coined arbitrary and fanciful names, not descriptive of kind or origin, which were generally used in connection with the name and address of the manufacturer; and so it came to pass that symbols, devices and arbitrary designations or titles were slowly, gradually, but generally substituted in the place of the mere name and address of the manufacturer; the goods in due course of time became known by such marking; the marks, in turn, served to indicate origin, as well as to guarantee the peculiar excellence which the purchasers or consumers expected and had a right to find in their purchases with respect to quality, purity, measure or value.

So public usage has also often given an accidental meaning to a trade-mark, not at all contemplated originally; as witness the case in France, where a man named Jean Bardon manufactured cigarette paper, marking it with his initials, «J. B.,» which he separated by a lozenge, so that the mark appeared to be the word «JOB.» The public became accustomed to call for «JOB» paper, and that name was duly protected as a trade-mark, although it had never been intended to invent or use the word «JOB» in connection with Jean Bardon cigarette paper.

Requirements of a Valid Trade-mark.— Inasmuch as the markets of commerce are «markets overt» or «open markets,» it soon became evident that, in order to secure a trade-mark which would be unique, and the exclusive property of the person or firm originating and adopting it, such mark would of necessity have to be one which others did not have an equal right in law to use for the same class of merchandise; so that it became an established rule of construction of the law of trade-marks that no mark would be protected as the exclusive property of any one person which others had an equal right to use; as, for instance, a mark indicating quality, or a geographical mark, indicating that the goods bearing the mark were made or produced in a certain locality; or a mark which merely consisted of the statement of ingredients, or the generic or class title of the article; to be perfectly plain, every person living in New York, making hats or shoes, or other articles of commerce, would have the right to label and mark such articles as «New York Hats» or «New York Shoes» or the like; so every person would have the right to make the «Best Quality Hats» or the «Best Quality Shoes» or «Superior Hats» or «Superior Shoes» or the like.

Kinds of Trade-marks.— There are two distinct kinds of trade-marks, to wit, a mark consisting of a word or words, or a mark consisting of a symbol or picture.

The former kind may be designated as an «ear-mark,» and being mainly distinguished, when used, by its sound, it has been held by high authority that the use by another of a similar word, alone or in any form or combination, or in connection with any style of label or form of package, is unlawful, and would constitute an infringement upon the original mark.

The other kind of a mark, consisting of a symbol or picture, may be designated as an «eye-mark,» because it appeals to the sense of sight. To constitute an infringement upon such a mark, the defendant's mark must be of so close a resemblance as to be likely to mislead a purchaser using ordinary attention. There may be also an infringement upon important parts of a trade-mark, without the whole of the mark being copied. This will be restrained, because the law does not look for complete identity in the imitation trade-marks, but similarity will be held sufficient to warrant the interposition of a court of equity.

«Secondary Meaning» Phrases Protected. —In dismissing this branch of the subject, it may be stated that no mark which merely indicates an essential element or quality of the article to which it is applied can be exclusively appropriated as a trade-mark, subject, however, to one important qualification which has attended the evolution of the law of protecting industrial property in this country, and which was rendered necessary by the natural and proper desire on the part of our courts and judges to do equity and to protect the purchasing public.

The exception to which we refer is when a term, phrase, title or designation which is used in connection with a trade-mark acquires what is known as a «secondary meaning» in the market.

By this we mean that when a phrase, title or designation, which of itself could not be protected as a technical trade-mark, because primarily conceived and designed to merely invite trade or catch and engage public attention, becomes in time so identified and associated with the articles of merchandise to which it is affixed, that the public, on seeing it, at once recognizes that it stands for the goods to which the trade-mark proper is usually attached, even though that mark should be absent.

An illustration of this may be found in the case of a trade-mark for a certain medicine; the words «Candy Cathartic» are certainly descriptive, as fully descriptive as any words well can be; but they had been used to so large an extent and were so thoroughly advertised in connection with the medicine in question that it was shown that many purchasers instead of calling for the trade-marked name of the article would ask for «Candy Cathartic»; and, vice-versa, druggists handling the article so associated and identified the secondary phrase or title, «Candy Cathartic,» with the trade-mark proper that when «Candy Cathartic» was called for a box of the tablets would be promptly handed out. The court accordingly protected such descriptive phrase against use by a competing firm.

«Camel's Hair,» a purely descriptive term for belting, was protected after it had acquired a secondary meaning on the market, as applying to a particular make of belting. Likewise, «Stone» was upheld as a designation for ale, the name Stone being the name of the village in which the brewery was located, and which through such use had come to designate a particular product.

Likewise, a geographical name may acquire a secondary meaning, especially against infringers who do not reside in the same geographical territory or locality; as witness the fact that «Saint Louis» was protected as a mark for lager beer against brewers using the same title, but not doing business in the city of Saint Louis. The history of the «Durham» tobacco case may also be profitably considered, where Blackwell, the proprietor of «Durham» smoking tobacco, failed in his attempt to restrain another tobacco manufacturer of Durham from using such title in connection with tobacco, whereat certain Virginia tobacco manufacturers outside of Durham, becoming emboldened by the defeat of the Blackwell concern, began to use the title «Durham» in connection with their tobacco, but were promptly enjoined from so doing by the courts.

It by no means follows, however, that the defense of such trade-marks by the courts establishes the wisdom of their selection as such marks. On the contrary, they are to be avoided as leading to litigation more or less annoying and expensive. In the selection of a trade-mark every precaution should be taken against personal, geographic and descriptive names, and equally against such marks as in appearance or in sound as spoken shall simulate trade-marks already owned by others. An error in these respects, even though it escapes legal prosecution, may result in the partial or total waste of money spent in advertising, which, indeed, may redound as well to the advantage of a competitor as to one's self. Another point to be remembered in devising or selecting a trade-mark is that it should be simple and easily recognized. Few customers give keen and close observation to goods purchased, and the ultimate value of the goodwill of a manufacturing business may be largely dependent upon the instant and unqualified recognition of favorite brands.

The Doctrine of "Clean Hands."—Another and most important matter to be considered by the owner of trade-marks is in their correct use of their trade-mark.

The usual protection and relief sought against infringement and the invasion of trade-mark property is by means of a suit in equity brought to restrain the infringer from continuing to imitate or use the infringing mark, and for an accounting for damages; but as such a proceeding in equity is governed by well-settled principles of equity, one defense which has been very often successfully urged and raised to defeat any action on the part of the owner of a trade-mark is what is known as the defense of «unclean hands.»

It is a well-settled principle of equity that "he who enters a court of equity, seeking equity, must do equity, and come with clean hands."

In other words, a party will not be heard to complain of the wrongful acts of another as against himself, if that same party has been guilty of similar wrongful acts of fraud, misrepresentation or deceit against the purchasing public.

The United States Supreme Court in the celebrated and leading case of Manhattan Medicine Company against Wood, many years ago, laid down the doctrine that a party would find no relief in a court of equity as against an alleged wrongdoer if he himself were guilty of wrongdoing in using the mark to deceive the purchasing public.

Having this important fact in mind, it behooves trade-mark owners and users to be very careful in the use of their marks, labels and packages, and the following simple rules may well be observed for their protection and benefit.

No misstatements concerning the origin, quality or quantity of the articles to which the mark is attached should be used in connection with the labels, packages or accessories of the goods. So, also, if a trade-mark was not originally adopted by a party but was acquired by transfer or assignment, such fact must be distinctly announced on the labels or packages. The courts, however, will not countenance the transfer or assignment of a trade-mark except as a part of the transfer of the business which it has represented. The business cannot be transferred to one party and the trade-mark to another.

While the doctrine of "Unclean Hands" has been carried to a very great extent by the courts, it has been held in many cases that too strict an application of such a rule would lead to the destruction of valuable industrial property, and, at the same time, relegate the purchasing public to the tender mercies of false, fraudulent and infringing marks.

The courts have in many cases recognized the fact that where there is no vicious or wrongful intent on the part of a trade-mark owner, who is shown to conduct a legitimate and honest business, that slight lapses or immaterial misstatements, not persisted in or continued, and statements which are substantially true, although not entirely so, will be overlooked and not visited with the punishment of denying equitable relief to the trade-mark owner who is guilty of such infractions.

The understanding which the public has of certain trade customs or usages are also allowed to prevail; as witness the "Hennessy Brandy" cases, decided by the New York courts of appeals, where the defense was interposed that the plaintiff's bottles were not full or actual pints or quarts in size, and that, therefore, the owners of said trade-mark were guilty of inequity and misconduct; but the court held that inasmuch as such pints or quarts were known as "commercial" pints or quarts, and understood so to be by the purchasing public, that no fraud was either contemplated or had been committed, even though the bottles to which the mark was attached were not of full measure.

How Trade-mark Property is Acquired.— Property in a trade-mark is acquired by priority of adoption and continued use on the market. A mere announcement of an intention to adopt a certain title or symbol which is not followed or accompanied by use on the market does not confer any trade-mark rights. Moreover, the law requires that the trade-mark shall be in actual use in trade before application is made for its registry. The title to a mark may be lost by deliberate abandonment or the transfer to others of the title or goodwill of a business in which the mark has been used.

The person who adopts and first uses a certain distinguishing mark for his goods, becomes possessed with what is known as the common-law right of ownership thereof, and such right is an enforceable one, and will be protected by the courts of this country.

Patent Office Registration.— Trade-marks may be registered under the existing registration statutes only when the same are used in commerce with foreign nations, or among the several States or with Indian tribes. The provision for marks used among the several States is new and in force since 1 April 1905. Under this law marks exclusively used for 10 years preceding the passage of the law can be registered, irrespective of the prohibitions in the law, which would otherwise apply. Registration confers no greater property rights than are acquired under the common-law right of ownership, except that triple damages may be recovered in certain cases. Registration, however, does not create a right to a trade-mark; this is gained only by priority of adoption. The trade-mark thus signifies a public claim to such adoption and use; if it is not in accordance with the facts the registration may be canceled. Before registry a trade-mark is published 30 days in the *Official Gazette* of the Patent Office, during which period any person having good grounds for believing that its registration threatens his rights may oppose its registration. Besides the national law in the matter most of the States have trade-mark laws which protect the intrastate use of a trade-mark, a use which is not covered by the Federal law.

Assignment of Trade-marks.— Trade-marks may be assigned with the goodwill of the business in which they are used, or a transfer of the business itself; or they may descend by inheritance; but such an assignment must be recorded in the United States Patent Office within three months of its date or the goodwill thereof does not vest in the assignee any enforceable right or title. A trade-mark has no value or standing apart from the goodwill of the business of which it has been a part.

Partnership Marks.— Upon the dissolution of a partnership, either partner may thereafter continue to use the trade-marks of the partnership, unless the same are otherwise disposed of upon the dissolution, or where other contractual relations exist governing the future disposition of the same upon a dissolution.

Defenses.— In cases of infringement, actual deception by the infringer need not be proven. The likelihood of deception is sufficient to warrant the interposition of a court of equity. So it is no defense that the infringing article is superior in quality to the genuine, nor is the absence of intent to deceive a defense. Laches or delay in asserting rights are generally held to deprive the owner of the right to claim damages or obtain a preliminary injunction. Abandonment is also a good defense, but strict proof of an intention to abandon ownership is essential to the establishment of this latter defense.

Patented Articles.— Where a new trade-mark consisting of a word-symbol is affixed to a patented article, the right to use such name or title for such article will become public property upon the expiration of the letters patent, as was held in the «Castoria» and «Singer Sewing Machine» cases. Otherwise the monopoly enjoyed by the owner of a trade-mark is perpetual.

State Laws.— In many of the States, acts have been passed making it a criminal offense to refill or use again without the owner's consent bottles or other packages which have been registered under what are known as «Bottling Acts» or Trade-mark Registry Acts; so in many of the States the imitating or counterfeiting of trade-marks is made a criminal offense.

Labor Union Marks.— In many of the States labor unions or associations of working men are permitted to register their labels or trade-marks, indicating that the goods to which such labels or marks are affixed were manufactured by union labor, and such acts have been sustained as constitutional in most of the States.

Copyrighting of Labels.— New labels, not previously used, and containing some artistic or novel character of design, may be copyrighted in the United States Patent Office and will be protected for 30 years. But labels which merely describe an article, or only indicate size, number or weight, or are only the result of the application of the typesetter's art, are refused copyright entry.

Unfair Trade Competition.— An article on the subject of trade-marks and their protection in this country would at the present time be incomplete without some mention of the cognate subject of «Unfair Trade Competition.»

The evolution of the law of trade-marks in course of time satisfied the courts of this country that the mere enforcement of strictly technical trade-mark rights fell far short of the practical requirements and necessities of our commerce, inasmuch as the purchasing public was being constantly cheated and defrauded in having goods not of a genuine source of origin foisted upon them, while the owners of such genuine goods, as well as the purchasing public, were frequently left without redress or legal protection. To remedy this defect of the administration of justice, the restraining of unfair trade competition was applied to cases where technical trade-mark rights could not be enforced.

The essential difference between a case brought to restrain the infringement of a technical trade-mark, and to restrain a case of unfair trade competition, may be summarized as follows:

Both suits are brought to restrain a fraudulent act of the defendant; both proceed on the theory that a court of equity will protect the property rights of the owner of the trade-mark, and at the same time, guard the purchasing public against being deceived; but while in a case brought to restrain the infringement of a trade-mark, no proof of actual deception is now required, nor is any proof of damage to the owner of the imitated trade-mark required to enable him to recover, in a case of unfair trade competition the essence of maintaining the suit is in the establishing of the fraud practised by the defendant and the actual deception caused thereby upon the purchasing public. Probable deception is ranked with actual deception in constituting infringement. It is construed as an attempt to steal the goodwill of an established business.

It thus follows that in the extension of the principles of doing equity and according the fullest protection to the purchasing public, a man may even be restrained from using his own name in the transaction of his business, where such use is of a fraudulent character, calculated to breed trade confusion and designed to mislead and deceive the purchasing public, already accustomed to that name as connected with another line of merchandise.

History.— Trade-marks are of extreme antiquity, being found on bricks unearthed by explorers among Egyptian and Assyrian ruins, and upon Egyptian pottery dating back to 6000 B.C. Such marks have also been found on gold and silver ornaments and even upon carved jewels, and the containers used by the Roman pharmacists for their salves, creams and lotions. In more recent times historic mention of laws protecting workers in metals, smiths and armorers in such trade-marks as early as 1374. In the Middle Ages guilds of artisans in Germany, France and Italy compelled the use of trade-marks by their members as a protection to the purchaser as well as to the trade in general. Trade-mark protection in England did not begin until 1783, and it was not until 1838 that laws were passed which afforded really adequate protection. In the United States agitation for a trade-mark law began in 1791, but the Federal trade-mark law was not placed among the statutes until 1870. The present law bears date of 1905.

Trade-mark law in the United States has substantially been made during the past few decades; for the first reported American trade-mark case found in the books is that of Bell against Locke, decided by Chancellor Walworth in the Court of Chancery in the State of New York in January 1840. The following reported American trade-mark cases are desultory and sporadic until about the year 1870, when they became more numerous. Since that time, trade-mark litigation has vastly increased.

The Philosophy of the Law of Trade-marks.— The whole legal and underlying principle of the law embraced in this subject and its entire philosophy are founded upon the theory of securing honest trade and fair trade in the commerce of our national markets, and the doing of strict justice between man and man, while protecting the extremely valuable property rights which are at the present time found to exist in the transaction of modern business, both in the ability to enjoy unmolested and secure from invasion the marks of commerce, as well as to retain the goodwill of the business in which they are used. In brief, no one has or can have the right to sell his goods as ostensibly the product of another who has built up a goodwill by pronounced excellence of his products.

Equity has been poetically termed the «flower of justice»; and equity, with its long arm, and with the acute conscience of the court, is able to prevent and remedy acts of injustice, where the law itself would otherwise prove powerless and futile. See PATENTS.

MORRIS S. WISE,
Editor of the 'Trade-Mark Record,' New York.

TRADE AND TECHNICAL PRESS, American. The principal function of the trade and technical publication is the advancement of the commercial, industrial, professional, scientific or other interest, which they represent, by keeping the reader informed as to the prevailing conditions of his trade throughout the country, and even the entire world. Thus a well-edited, broad-minded, accurate and progressive trade journal will exert a great influence toward welding together the separate units of each great profession, trade or industry into one vast community of interest. The general newspaper and the trade journal differ in the fact that the former appeals to the whole public, whereas the latter caters to a smaller class of professional, commercial, technical or scientific readers, giving within its compass only such knowledge as pertains to its special field.

These organs, of which every great trade in the country has its own, bring to the attention of those interested any invention or discovery which is, or in time may become, of great importance, but which to the general public would be of little or no interest; they present the conditions of the home and foreign markets by giving tables of quotations otherwise inaccessible to the trade; and gather all possible information which may be a guide to, or throw any light upon, future conditions. Improved processes or methods of manufacture and changes or improvements in other industries which would possibly have a bearing upon a certain trade; the many items of general interest to the lines with which they are concerned, and the public questions which vitally affect those interests; the almost innumerable changes taking place in the industrial world; all these, and more, are chronicled in every issue of the trade journal and discussed with a knowledge of detail, a grasp of the subject and fullness of treatment to be found nowhere else.

Such papers are of much importance to the trades they represent. Some are merely advertising sheets; some contain literary matter along with the special news; others are deeply scientific; yet each is conducted to subserve the interest of the respective trade. Of these papers some are published weekly; some semimonthly and others monthly; and a number of the financial papers, which may be considered as belonging to this class, are published daily. Some instances among trade journals have enjoyed remarkable and continued success, and have financially prospered far more than had been hoped, but the history of journalism is strewn with the wrecks of others whose existence was of such short duration that they did not pay for the original investment.

That the trade and technical journal may have the highest standard of editorial service and supervision, it is necessary that experts should be employed in the writing of articles, and none but the ablest men in each separate line should contribute, for the reader is generally an expert in the topic of which they treat, and any inaccuracy of statement or error of judgment is not only noticed, but is remembered. This tendency to inaccuracy or error is in a large measure lessened by the employment of a large corps of trained and skilful reporters who ascertain the tendencies of the market before they have become apparent, and also by having, in a great many instances, confidential relations with the leading minds of the trade. Thus a reputation is established, the paper becomes a power in its branch of industry and is quoted by all as an authority when discussing subjects of which it treats, and of which, in the nature of things, their knowledge is limited.

The trade journal also occupies an important position in the field of advertising, for the judicious advertiser selects the publication which is read by the class to which his merchandise will appeal, and this method is more economical and profitable to him than employing the ordinary newspapers which reach the general public and are not carefully consulted for technical matter. The vast number of advertisements which they publish in every issue, and the prices which they receive per line for such advertisements are astounding when the competition that exists for all these is considered. That it is profitable, however, to the advertiser, is plainly apparent from the enormous amount of advertising which each journal carries.

The *American Railway Journal*, of New York, first published in 1830, was the first paper which met the desires of one particular class of merchants. This was the pioneer of the specialty commercial journals, and it was for some time the only one of its kind, for though a few others had attempted to enter the field, their stay had been of short duration, and it was not until 1846 that one which still exists, was founded. This was the *Dry Goods Economist*, but though it began in the largest trade, it experienced much difficulty in attracting attention among either the buyers or sellers, and as conditions at that time were unfavorable to a journal of this character, it was not for a long time and only after a bitter struggle that it rested on firm ground.

These journals were soon afterward followed by those in the hardware and leather trades, known as the *Shoe and Leather Reporter* and *The Iron Age*, both of which experienced the same difficulties in gaining a foothold in the commercial world.

Meanwhile, the scientific field had been more successful as to the number of papers and periodicals published. The *American Journal of Science* was founded in New Haven, Conn., in 1818, by Professor Silliman, and the *Journal of the Franklin Institute,* in Philadelphia, in 1825. About 1820 a law periodical was founded in New York, but legal journals did not become common until nearly 50 years later. Medical journals soon sprang up in New York, Boston and Philadelphia, and are now to be found everywhere; a little later a journal was established treating of the drug trade. The *Scientific American* was founded in 1845 and since then many scientific or semi-scientific journals and various professional journals, not touching upon scientific subjects, have been started. By 1860 there were about 20 trade papers and 50 other technical papers; by 1872 this number had increased to 124 trade and 132 other technical papers, representing 41 different lines, in which religious, agricultural, educational and sporting journals were not included. See ADVERTISING; AMERICAN PUBLISHING; AMERICAN NEWSPAPERS; AMERICAN PRINTING TRADE; NEWSPAPERS; PERIODICALS; JOURNALISM; PRINTING; PRINTING PRESSES; BOOKS; ETC.

TRADE SCHOOLS. The differences in meaning between such words as vocational, industrial, manual training, technical, trade, part-time, co-operative, continuation, apprenticeship and corporation are not always understood and the terms are frequently used as if they were interchangeable, consequently brief definitions are necessary before the subject of «trade schools» can be satisfactorily treated.

Vocational education is an inclusive term for all forms of occupational training such as industrial, agricultural, commercial and household arts. A *vocational school* has for its controlling purpose the fitting of students for useful occupations. The pupil must have reached the age when work papers can be secured and the courses are below college grade. The aim of such a school is to supplement general education and not to take the place of it.

Industrial education is used in a broad as well as in a restricted sense. The term covers all education connected with the industries such as the industrial and household arts of the elementary and secondary schools, technical and trade instruction for industrial workers and training in engineering schools. The term *Industrial school* is used at times in America to indicate instruction of a primary order which gives pupils one or more branches of industry in order that habits of work and thrift shall be inculcated. This form of school is often used for reclaiming young offenders from evil habits, or for dependent and neglected children.

A manual training school offers activities of a more or less trade-like character with the idea of developing or educating the individual, that hand and mind may be trained together and each help the other. The aim is not to give a wage-earning vocation. The general education in these schools has usually little relation to the trades and is carried further than is necessary or possible for the ordinary apprentice. In some of the schools vocational elements are being introduced.

A technical school may be elementary in character or it may train engineers. The aim in both cases is to give theoretical and scientific knowledge connected with a chosen occupation. It prepares the overseer or superintendent rather than the apprentice or worker. In its simplest form such use of tools or apparatus is taught as will show the connection of theory with practice. Handwork is given to explain the science rather than to fit a student directly for a trade. The highest development of this type of school is found in the great technical institutions where both the application of art to industry and the most thorough scientific training are provided. The Massachusetts Institute of Technology and the great German and American textile schools are examples. The night technical classes so numerous in Europe and America are adding trade features in order to be especially useful to workers who are beyond 16 years of age, the aim being to provide instruction directly related to the employments. Many of the courses offered in the Young Men's Christian Associations are examples. In England the polytechnic schools offer training of this kind and public instruction in America is rapidly meeting this same need. Industrial and household arts, science, drawing and forms of industrial arithmetic and English are offered to enable ambitious older workers to get ahead in their trades.

A trade school may be advanced or preparatory in character. The first offers several years of training for full apprenticeship or for journeyman. The Williamson Free School of Mechanical Trades in Philadelphia is such a school. A preparatory trade school offers short courses of from three months to a year to workers (from 14 to 16 years of age) who are entering trade. The Manhattan Trade School for Girls in New York City is a school of this order. Trade schools are founded to teach a single trade such as watchmaker or tailoring or they may offer a number of occupations. The simplest form is a workshop where the manipulation of some trade is taught which requires the expert use of tools. This kind does little for the development of the worker. An all-day trade school, such as The Manhattan Trade School for Girls, aims to give a preparation which shall abolish the drudgery and waste of the regular workroom and supply an economic and vital instruction. Actual shop methods are followed in all of the trades, practice occupies most of the eight-hour day, and industrial art as related to each trade, hygiene and social, civic and industrial teaching start the student well equipped for wage-earning. *Part-time, co-operative and continuation schools* are used for trade instruction. The aim is to co-operate directly with the industry and train workers while they are wage-earning. The training may be given during the working day in the factory itself, the workers being paid and also given an education. Or the classes may be in a near-by school building, the students being allowed to leave their work for several hours per week. Salesmanship classes illustrate this form of training. Public instruction may be responsible for the teaching in both cases. Courses are given on subjects which are difficult to learn in the rush of the workroom. The experience which the worker is gaining in the trade itself is thus supplemented by instruction during the day for the younger workers and at night for the older ones. Technical courses, general education, science, drawing and design, business arithmetic and English are frequently given. These schools are being organized in many States as laws are enacted making it compulsory for employers to allow workers between 14 and 16 years of age to attend such schools during the day, for five or more hours per week, without loss of wage. Germany has done much to develop the continuation school during the day and at night. *Apprenticeship and corporation schools* have been organized by some of the railroads and great business enterprises for training their own employees. The work is of the part-time character and the workers are paid their full salaries. The aim is to increase the ability of the worker for his own sake as well as for the corporation.

This article deals with the trade school as it trains apprentices or journeymen, by day, or supplements their work in the regular trade by part-time classes by day or night. It deals with the wage-earner rather than with the overseer, superintendent and director. The textile and engineering schools and institutes of technology belong to the technical rather than the trade-school field and the instruction is usually of college grade. Some of them have special sections for apprentices, however. Many of the agricultural and mechanical colleges in the United States have trade departments but this work does not always lead to a degree. Drexel and Pratt institutes deal with trade courses in addition to their regular technical and normal aims. Regular all-day trade schools and part-time classes are not yet numerous all over the United States, therefore, other institutions are undertaking trade work to meet the demand of communities to help the workers.

Education for trade has for centuries received attention on the continent of Europe. Complete systems of industrial education have been developed in many countries, from the manual training of elementary and secondary education, through the trade and technical schools to higher engineering and scientific institutions. These schools are generally under government support and control. Within the last 50 years they have become increasingly important and are graduating competent workers for both men's and women's employments. The thoroughness of the courses in these continental schools has rightly given them a high reputation. The length of the trade courses abroad is from three to five years, a fact due to some extent to the demand of the trade unions for a long period of apprenticeship. The United States has some trade schools offering a like preparation. Conditions of artisan life with us are so different that the foreign type of trade school does not altogether meet our needs. The aim here has been rather to give the trade work in as short a time as possible, often in only a few months. This course is frequently accomplished by considerable drill in the theory as well as in the practice of the trade. The New York Trade School offers in its day classes three to four months' preparation in various building trades, a certificate of proficiency being issued on the completion of the work. European schools do not usually give such short courses as these. The Wilmerding School of Industrial Arts, for Building and Architectural Drafting, the Lick School of Mechanic Arts and the Lux School for Girls, all in San Francisco, and the Williamson School of Mechanical Trades in Philadelphia, correspond more nearly to the European model of thorough training for three or four years. In these schools the aim is to teach the trades with the science underlying them, together with thorough academic courses corresponding to our manual training high schools. The Manual Training High School of the United States surpasses anything of the kind abroad and is a distinctly American type. It does not aim, however, to give trade instruction, and hence the Williamson and the three California schools are not strictly manual training schools.

The value of trade schools has been recognized by foreign governments and they not only control, but also support or subsidize them. The war has temporarily interfered with this instruction in the warring countries, but as peace is established the work will continue. The trade schools already organized with us often began under private management but passed into public control, as with The Manhattan Trade School for Girls in New York and the Boston Trade School.

Germany has been foremost in developing trade instruction to supplement shop experience. The poverty of the workers there, as well as here, forces them early into the shops to earn a living. In order to help these workers to obtain better positions and better salaries, special day, evening or Sunday instruction has been arranged in the Continuation Schools (Fortbildungschulen). Each German state has made a study of the best way to help its different trade workers. These schools have been so satisfactory that they have not only developed all over the empire, but also in other countries. In Germany they are preferred to the all-day trade school. Belgium and France are renowned for their day trade schools; Austria and Hungary have unusually complete systems of trade instruction, and Switzerland and Italy also provide carefully for this class of education. For 35 years Russia has had trade schools to train the workmen in various fields. England's well-organized technical instruction includes trade work also.

Germany.

The awakening of Germany to the importance of training her wage-earners took place about the time of the Centenntial Exhibition in Philadelphia in 1876, which showed Germany's products to be distinctly inferior to those of other continental countries. The French Exposition of 1878 still further manifested the lack of art in Germany's manufactured goods, and a commission was appointed to investigate reasons and to suggest action. The result of the work of this commission is now seen in the systems of trade and technical schools which have been organized, and in the reputation which Germany now has for the application of science to industry. These schools have been great factors in this change. The German section in the Saint Louis Exposition of 1904 gave evidence that not only in the connection of science with, but also in the application of art to industry, that country has pushed to the front and now takes rank with or even excels those nations which have in the past controlled the industrial field. Germany has become thoroughly imbued with the idea that money devoted to trade instruction is wisely spent. The earnest study which she has given to the subject has shown her the problem in its complexity and difficulty. The solution has been varied to suit the needs of different localities and also of all classes of workers from the wage-earners of small skill to the directors of great industries. A satisfactory interrelation between workers, employers and schools has been the aim as well as social efficiency.

These schools have been founded and are supported in various ways: by the state, by the municipality, by the commune, by the trade guilds, by associations of workers and by private individuals. There is a marked tendency, however, for the governments of the German states to assume the entire control and administration. Small tuition fees are frequently charged. In some of the great technical or technological institutes gratuitous instruction is offered to apprentices, but a fee is required of those who wish to study for more advanced positions. The tuition fees, however, cover but a small part of the expenses.

Germany is giving attention to the training of apprentices for trade in many classes of institutions. Different sections of the republic vary in their way of meeting the problems. The following kinds of institutions are representative: Trade Continuation (Fortbildungschulen) and Industrial Continuation Schools (Gewerbliche Fortbildungschulen); Trade Schools (Fachschulen); Industrial Drawing Courses; large technical schools, with sections for apprentices; apprentice workshops (Lehrwerkstätten).

Of these the *Continuation Schools*, generally conducted by trade guilds, are by far the most popular for training the ordinary wage-earner. General education is compulsory in Germany up to the 14th year. After this time a majority of the children of the laboring class must begin to work to contribute to the support of their families. The continuation schools are formed to aid those of both sexes who are forced to work, their object being to supplement the trade in which the worker is daily employed. In industrial centres the curriculum is connected with the trades of the locality. In other sections, the character of the instruction may be general, commercial or even agricultural, as the need is felt. The courses deal more with the theoretical part of the work than with the actual manipulation of tools. The aim is to give such instruction as the worker cannot well get in the shops. It correlates with the daily shop work and thus aids the workers with the greatest economy, as the students are productively employed and expensive laboratories and shops are not necessary.

The beneficial effect of these continuation schools on the development of industry and on the condition of the working class has been felt so keenly that the imperial government has provided by law that employers must always permit their employees under 18 years of age to attend such schools. The state has made this education compulsory, it being felt that all employees should have an education which will enable them to better understand the nature of their trade. It often happens that these busy day workers are too tired when night comes to benefit by such instruction, and week day and Sunday classes have, therefore, been opened.

The continuation schools found in Prussia give instruction of a general character, but they emphasize drawing, bookkeeping and such branches as are likely to be of value to those engaged in shop or factory work. For girls they add embroidery, dressmaking, sewing, ironing, millinery, mending and cooking. In Bavaria the work of the industrial continuation schools is so specialized for individual trades or groups of trades that they are really trade continuation schools. Dr. Kerschensteiner, the schulrat of Munich, has been a force in developing continuation and trade schools in Munich and throughout Bavaria. His aim is always to make the students understand the materials on which they are working and to develop in them thought and wise action. It is said that 56 trades are taught in the schools there.

The trade continuation and trade schools proper usually differ from the industrial continuation school in giving more specialized trade instruction. An illustration of continuation work for boys is the Artisan School, No. 1, in Berlin. The aim is to "give to apprentices and workmen, especially during their leisure hours, a knowledge of drawing and the applied sciences and arts which concern their respective trades and which serve as the necessary complement to their shop practice." All of the drawing, mathematics and sciences are specialized in separate courses directly adapted to some trade. The hours of instruction are in the afternoon and evening of week days and on Sunday morning. All-day courses in trades are also given at this school.

Trade Schools with all-day work in a single trade are numerous, but are not always largely attended. Schools of watchmaking, basketmaking, cabinetmaking, horseshoeing, toymaking and other trades have been opened in response to local needs. The following is a partial list of the occupations provided for in the trade schools: Artistic darners, artificial flowermakers, bakers, barbers, basketmakers, blacksmiths, braziers, bookbinders, cabinetmakers, chimney sweeps, cooks, carpenters, confectioners, dressmakers, dyers, embroiderers (hand and machine), engravers, gardeners, garment makers, glaziers, goldsmiths, horseshoers, hairdressers, handsewers, ironworkers, joiners, knitters, lacemakers, leatherworkers, locksmiths, laundresses, masons, modelers, machinesewers, menders, milliners, paperhangers, painters, photographers, potters, printers, rugmakers, saddlers, spinners, stonecutters, stuccoworkers, strawplaiters, shoemakers, tinsmiths, tailors, trunkmakers, woodworkers and carvers, weavers, wickerworkers, watch- and clockmakers, wagonmakers, wheelwrights.

Trade work for girls in Germany is not as extensively developed as that for boys. The sentiment of the German people, that woman's place is in the home, has caused these institutions to combine strong housekeeping features with the trades. These housekeeping-trade schools are doing excellent work, but the trade continuation schools organized for women are of more general importance in training for definite trades. Most of these schools offer three distinct fields to women: (1) The commercial subjects, which prepare for clerkships or secretarial work, training stenographers, typewriters, etc.; (2) the domestic industries such as housekeeping, cookery, needlework, repairing and ironing, and (3) special trades for women, such as dressmaking, millinery, white work, art needlework, designing, bookbinding, composing and photography. In Berlin the nine municipal continuation schools for girls maintained by the city, and the Victoria Continuation School maintained by private funds, are typical schools of this character. They offer day as well as night work. The Women's Work Schools (Frauenarbeitsschulen) found in many cities, notably in Nuremberg, Bavaria and Reütlingen, Wurtemberg, are day trade schools as is also the Potsdam Trade School for Girls.

The Lette Society of Berlin has done much to foster trade instruction for girls. The aim of the society is the improving of the working class by (1) the removal of obstacles and prejudices in the way of female employment; (2) the fostering of commercial and industrial education; (3) the furnishing information for opportunities for learning trades and securing situations and help where existing institutions are inadequate; (4) the establishment of exchanges for the exhibition and sale of women's handwork; (5) the protection of women against harm, morally or otherwise, especially regarding lodging houses. This society has opened a number of different kinds of schools. The trade courses range from four to six months of all-day work.

The Schools and Courses of Industrial Drawing and Art have made their curricula so practical that they adapt themselves directly to the various trades. There are also, in many instances, workshops in connection with these art schools, in order that the student may have practical experience of the value of his designs and plans. The building and textile trades and such art industries as the making of jewelry, metal and wood working, engraving, gold and silversmithing, painting on glass and china, ornamental designing and decorative painting, are especially considered in these schools.

Elaborately developed systems of special *Technical Schools* provide for all grades of positions in the building and textile trades. They touch to a small degree the problem of training an apprentice. These great day schools have been very successful. Over 50 of them are to be found for the building trades, and Prussia alone has eight for the textile trades. There are three grades of labor in the building trades: (1) architects; (2) those who execute the architect's plans, and (3) the workmen. The evening continuation school sometimes provides for the lowest grade, and at other times the building trades school offers a special section. The textile trades have also three grades, and weaving workshops are provided for the apprentices, either in all-day work, or in evening and Sunday classes. In some of the textile schools women are admitted, the one at Aix-la-Chapelle offering an elaborate course of textile darning, the girls being paid wages according to the value of their work. The School of Textile Art in Plauen, Saxony, has also a department for women. Instruction in embroidery and the making of lingerie is given, the aim being to train superintendents of workrooms.

Apprentice Workshops are organized both in connection with public trade schools and as private institutions. They aim at a more comprehensive and systematic training than can be obtained in the ordinary shop. The Krupp Steel Works at Essen offer a complete course of apprenticeship.

Itinerant Trade Courses are also provided in such industries as weaving, garment cutting, embroidery, machine work, straw plaiting and bookkeeping. These courses have been beneficial in small towns where there are cottage industries.

The effort of organized labor to preserve handwork and the small trades has been of vast service in Germany in the development of trade schools. The various trade guilds have dealt carefully with the subject of apprenticeship and have been untiring in their efforts to have favorable conditions attend such instruction.

Belgium.

Education is not compulsory in Belgium, but the schools are well attended. The primary school is followed by an excellent system of trade education for both sexes. In many particulars the schools are similar to those in the neighboring countries, but they also present characteristic features. For boys the elementary trade schools are followed by superior trade and technical schools, and those again by the great technological institutions.

Trade-instruction is carried on in the industrial schools (écoles industrielles) and in the trade schools (écoles professionelles). The first gives theoretical instruction in industrial operations with practical courses in design. The second gives trade work combined with theoretical instruction, has all-day sessions, and is the trade school proper, although many of the écoles industrielles have trade sections.

Trade training of an elementary grade is given in the following institutions:— For boys: Industrial schools, trade schools, Saint Luke trade schools, apprentice shops, trade courses. For girls: Trade schools (including trade schools proper, trade and housekeeping schools, housekeeping and trade schools), trade courses, apprentice shops.

The length of the courses in the trade school proper is from three to five years. The trade schools for girls were organized before those for boys. They offer the most advanced form of trade education for girls. The industrial school is the largest and most important class of institution in Belgium for the training of young men. As these latter schools are supplementary to the trade and do not give regular trade instruction, and as their courses are given at hours when workmen can attend, they resemble the continuation schools of Germany. The number of these schools is rapidly increasing.

Trade instruction in Belgium is justly renowned for certain features: (1) The excellent system of economical administration and wise supervision; (2) the thoroughness of its instruction in general education applied to the various trades and also in the teaching of the trades; (3) the importance of art in all of the schools and the practical use made of it in designing in each of the trades; (4) the adaptation of all of the trade work to local needs.

The trade schools are with few exceptions under government control, although no general law governs their formation. Schools have been established by communes (écoles communales), by private individuals (écoles libres), and by provinces (écoles provinciales). Complete liberty of organization is allowed to local authorities or to private individuals, in order that the schools may be adapted to local needs. This freedom has made these schools really local institutions, conforming to no uniform model. A system of subsidizing them has been devised. A certain sum of money is voted annually for this purpose, and placed at the disposal of the minister of industry and labor. When the schools desire a portion of this appropriation they must submit a formal application, accompanied by details of their work which will enable the ministry to judge if the school should receive assistance.

The government exercises regular supervision over schools receiving the subsidy. Each year they must send to the ministry for approval of their accounts, their budgets for the ensuing year, and any changes in their organization or in their programs. The supervision of these schools is most efficient. An inspector-general of industrial and trade education is at the head, and under him is an expert corps of inspectors. Inspections are also made by such provincial or communal authorities as aid in the support. Religious bodies, industrial organization and private individuals also help these schools. Some of the schools give free instruction, some require an entrance fee, and others charge for tuition. Students who are too poor to pay for instruction or to attend even when it is free are aided in various ways.

The difference between a manual training and a trade course is very marked in Belgium. The trade schools may differ in characteristics, but they all keep strictly in view the fact that they are preparing students to earn a living in some particular branch of industry. Drawing and industrial design are at the base of all instruction for girls as well as for boys, and are taught with reference to their use in particular trades. A practical general education is also considered a necessary part of the instruction in the trade, and usually occupies the first half of the day. Libraries, museums, collections of scientific apparatus for demonstration, public exhibitions, and provision for traveling scholarships are means used to develop the highest efforts of students.

The provision made for teaching girls is very thorough. *The Trade Schools* proper (écoles professionnelles) have programs in theoretical as well as in practical work. There are at least 50 of them in the kingdom. The aim is to teach such trades as are open to girls, and at the same time to carry forward the regular school education. The trades taught are dressmaking and cutting, waistcoat- and corset-making, fine lingerie, millinery, artificial flower-making, industrial drawing and ornamentation, embroidery, designing for lace and embroidery, and painting on glass, china or silk. Commercial courses are also given. The general course, which is compulsory, includes the French and Flemish languages, arithmetic, history, geography, hygiene and domestic economy, writing, drawing, singing and gymnastics. The instruction is excellent and has been especially adapted to the trades and to the needs of women in their households. A high place is given to domestic economy in Belgium. Its full development is in the housekeeping schools (écoles ménagères), but some of it is required in the trade schools also. The trade courses for girls vary in different schools according to the needs. The length of the course is usually three or four years, but five years are sometimes required.

The pioneer trade school for girls in Belgium is the Bishoffsheim, 94 Rue de Marais, Brussels, established in 1865. The age of entrance is 12 years, and the length of the course is four years. The trade courses are numerous and well taught. The courses in drawing, including designing for lace embroidery and garment decoration, painting on glass, porcelain, china, fans and textiles, and the dressmaking and the artificial flowermaking are especially notable. The reception room at this school is decorated with fine examples of porcelain tiles and china painting, and the windows are of stained glass, this work all having been done by graduate students. The Communal Trade School for Girls on the Rue du Président, Brussels, is noted for the fact that each of the trade instructors is also the teacher of the course in design in connection with the trade. The course in embroidery and applied design is especially fine. Another Brussels communal school on the Rue du Poinçon, 26, noted for its dressmaking and commercial courses, and the Antwerp School, Rue des Architects, with its five-year courses in some of the trades, are also examples of the excellent professional training for girls in Belgium.

An advanced trade course of one year for dress designers, dressmakers and intending teachers in trade schools is given in Brussels, a study of the evolution of dress in all countries being a notable part of the work.

The Trade-Housekeeping Schools (écoles professionnelles-ménagères) and the housekeeping-trade schools (écoles ménagères-professionnelles) are also giving more or less time to trade work.

Apprentice Shops for teaching trade work to girls are not numerous, but are doing good work. They were opened in response to local needs rather than as a part of regular trade instruction. One of their distinguishing features is that the students after a time receive financial remuneration for their work. There are several of these schools, as the one at Bassenge for straw plaiting and straw-hatmaking; at Jemelle for lingerie and dressmaking; at Maldeghem for hand and machine embroidery and crochet work on tulle, and at Saint Trond for lacemaking.

The Industrial Schools (écoles industrielles) for boys are similar to the continuation schools of Germany. They are very numerous in all parts of the country and have been organized with reference to local needs. They teach a large number of technical subjects connected with the trades which the boys follow during the day. Some of these are also day trade schools and have advanced as well as elementary work. The school at Verviers is an example, the aim being to give a training to the workmen who are employed in the numerous industries in that city, including the departments of mechanics and construction, dyeing and weaving. The Industrial School at Tournay, which is one of the oldest and most important in Belgium, also partakes of the nature of a trade school. It has no shops of its own, but it has entered into contract with local manufacturers to direct the pupils' practical education. This is an excellent method of combining theoretical with practical instruction. The school gives its theoretical instruction in the early morning or in the late afternoon. The Industrial School of Morlanwelz has departments of mining, building construction, engineering, electricity, shop technology and mechanical drafting. The organization of the school population, the equipment, the excellence of the instruction and the ability of the teaching force make this school a power in the kingdom. The age of the students entering is from below 14 to over 20. The schools of Ghent, Seraing, Châtelet, Charleroi, La Louvière and many other cities are adapting themselves to local industrial conditions and are doing good work. Certain work in the industrial schools is also open to girls, but, with the exception of the commercial courses, they are not well attended.

The Trade School proper for boys is also well developed. Under this head are the day trade schools (for teaching actual trades), the trade continuation schools (for supplementing the day shop work), and the trade schools of fishing. Some of the day trade schools teach but one specific trade, while a number of trades are taught at other schools. An illustration of the first class is the Brussels Trade School of Tailoring. A four years' course is offered. The leading tailoring houses of the city show their interest in this school by contributing to its support, supplying it with order work and helping to place the graduates. The students pay a small entrance and tuition fee. They are paid a small sum for their work, and this money is placed in the state savings bank and given to the student when he completes his apprenticeship, but if he leaves the school before that time he loses the right to the money. The Gun Makers School at Liège for making arms was originally begun by the manufacturers but is now conducted by a committee composed of labor men, city officials and manufacturers. The school is open day and night.

The H. Nicaise Trade School of Metal- and Woodworking at Ghent is an illustration of the class of school offering instruction in several trades.

Jewelry work, chasing, upholstery, furnishing, printing and many other trades are taught in evening or in Sunday morning continuation classes. The trade schools for fishing are placed at the seaports.

The Saint Luke Trade Schools are similar both to the day trade school and to the trade continuation school. They aim particularly to train for artistic branches of the handicraft trades. They were established by the Roman Catholics. The school at Schaerbeek, Brussels, is an illustration of this class of trade school.

Apprenticeship Shops have been organized for weaving and stone cutting and are doing successful work.

France.

France began to plan and legislate for the training of her handworkers centuries ago. The forerunner of the trade school began in 1799, but the great development of the subject has been during the last quarter of a century, following the French Exposition of 1878. The number of such schools receiving help from the government increased from 48 in 1880 to 292 in 1904. France appreciates that her industrial success depends on the education of her workmen, hence the government takes a direct part in developing the system of trade instruction. Schools are provided to teach all grades of workers from the semi-skilled artisan in the ordinary trades to the engineer for the more advanced scientific and technical work. Trade training is always founded directly on primary education, design is considered fundamental and a large amount of shop work of a practical nature is given.

Manual apprenticeship schools have been organized to give boys instruction in their chosen industry or to fit them for the secondary technical schools. There are four *national trade schools* (écoles nationales professionnelles), situated at Armentières, Nantes, Vierzon and Voiron, and 32 *practical commercial and industrial schools* (écoles pratiques de commerce et d'industrie), 26 for boys which are situated in various parts of France, and six for girls at Boulogne-sur-Mer, Havre, Marseilles, Nantes, Rouen and Saint Etienne. In addition to these, the municipalities of important cities have established schools for the elementary teaching of trades, industries and arts. Religious bodies, societies, business enterprises and private individuals, encouraged by the success of the national and municipal schools, have likewise organized instruction for the improvement of the artisan.

Government control requires that the schools receiving subsidies should all conform to certain requirements. The *Practical School of Industry* at Saint Etienne (école pratique d'industrie) may be taken as a type of these institutions. The trades of weaving, modeling in wood, machine fitting, cabinetmaking, electricity and gunmaking are taught here. The work is on an elaborate scale, the course being four years in length. The first year is preparatory and completes the student's primary education while also giving him shop practice of various kinds to discover his aptitude for any trade. During the next three years he studies his trade practically and theoretically, and continues his general education which is closely adapted to his trade needs. Here, as in other schools, much emphasis is laid upon the study of art.

The greatest and most progressive system of *municipal trade schools* is in Paris. The Diderot School was the first one organized, having been established in 1872 for wood and metal work. The courses are three years in length, entrance being by examination. Practical work occupies the greater part of the day, but considerable time is given to drawing and theoretical instruction. By an ingenious arrangement a first-year student is put between a second and third year student that he may profit by their experience. Apprenticeship is made less of a tax on the city from the fact that the products of the classes are sold. The Boulle School trains skilled artisans and mechanics in wood and metal. The furniture construction is justly noted. The products are artistic as design is especially emphasized. The course is five years in length, primary academic instruction, trade work, technical art and a scientific course being included in its curriculum. Schools of printing and publishing, applied physics and chemistry, industrial art and industrial drawing are also supported by the municipality of Paris.

There are six municipal trade schools for girls in Paris. The instruction includes art, academic work and the chosen trade, and the courses are either three or four years in length. The trades taught are similar to those in Belgian trade schools for girls. The aim is to educaté for a trade, to develop the intelligence of the workers, and to teach them to be self-reliant and resourceful. The French schools execute practical order work in their departments, and every trade school in Paris has its clientèle. The model for these municipal schools is the private school begun in 1864 by Elisa Lemonnier. There are two of the Lemonnier schools in Paris at the present time. They offer courses of four or five years' in length.

The training for girls in the practical schools of commerce and industry (mentioned above) is similar to that offered in the Paris municipal schools. Schools are also organized which offer both home-making and trade. These are well patronized as many women desire both subjects.

UNITED STATES.

The United States had not many examples of the all-day trade school until recent years, for her problems of national development had taken her full time. The beginnings were usually under private control — illustrations being the New York Trade School for Boys and the Manhattan Trade School for Girls. The subjects of instruction at the former are the various building trades such as carpentry, bricklaying, sheet metal and cornice work, electrical work, house and fresco painting, plumbing, steam and hot water fitting, sign painting, plastering, blacksmithing and printing. It was founded in 1881 by the late Col. Richard T. Auchmuty, who originated the system of instruction. It includes the theoretical as well as the practical branches of the trade. The courses are made as short as possible — usually about four months for the day classes, which provide trades for younger men. The night courses aim to give additional skill to those already in the trade. The students come from all over the United States, and several thousand have received the certificate and twice as many more have been enrolled. It is claimed that this school has greatly helped the building trades and also has raised the standard of intelligence and efficiency in the working class. The Baron de Hirsch Trade School, also in New York city, offers similar trade training.

The Williamson Free School of Mechanical Trades, near Philadelphia, is a different type of trade school. The course is three years in length and the school term extends throughout the year. The pupils are regularly indentured as apprentices and live at the school. Scholastic examinations are required for admission, and there is no charge for board, clothing or instruction. The trades taught are carpentering, bricklaying, including range, furnace and boiler setting, and the machine trade in all of its usual details, patternmaking, steam and electrical engineering and steam fitting. Each student takes but one of the trades named, and his instruction in mechanical and freehand drawing is in the direction of his particular trade. The academic work continues throughout the three years, and special attention is given to ethical training that the pupils may be good citizens as well as good mechanics. It can accommodate but one-fifth of those desiring admission. There are three notable trade schools in San Francisco. The Wilmerding School of Industrial Arts trains for the building trades, the Lux School offers girls home-making and wage-earning courses and the Lick School of Mechanic Arts gives the metal trades. All three schools are under the same principal though financially independent. There is no charge for tuition, use of tools, instruments or materials. The courses cover four years and the aim is to send intelligent citizens as well as well-instructed workmen into the trade. Graduate courses are also given. The schools are built on adjacent lots and the students can use the shops of either institution. They are free, and the latter school is open to both sexes. A competitive examination is held for entrance at the School of Mechanical Arts. A preliminary course of more than two years in general education and manual training is followed by the selection of some trade and apprenticeship in it. The school aims to solve a general problem of teaching various trades as an integral part of education, rather than to meet some special need of the community.

The Wentworth Institute in Boston trains for various skilled mechanical trades in both day and night classes. Like other schools of its type it was of great service in training men for war occupations during 1917 and 1918.

The Carnegie Technical Schools of Pittsburgh offer trade work on a large scale to both sexes as a part of a huge plan of technical instruction. The School for Apprentices and Journeymen gives classes for those already at work. The instruction is both theoretical and practical, with the object of turning out skilled mechanics. The Margaret Morrison School for Women offers training in home-making and also in wage-earning pursuits.

The Manhattan Trade School for Girls in New York city is a short-time all-day preparatory trade school. It trains for skilled trade work. It is a pioneer school in this class of education and was begun in 1902 under private control, passing into the public school system in 1910. The aim is to shorten the period of apprenticeship of those girls who leave the public schools to go to work, and to create in them an appreciation of the meaning and value of their trade and its relation to the work of the world. The school is open throughout the year, students may enter at any time, are on probation for a time, and each is advanced according to her ability, hence there is no definite length of course; experience has shown that it may be anywhere between six months and two years. The trades offered are: (1) Those which centre about the needle, such as dressmaking and millinery; (2) those that use foot-power and electric-power machines, including such machines as those for embroidery, hemstitching and buttonholes; (3) those that depend on the expert use of paste or glue. such as labeling, sample mounting, pocket-book and card-casemaking, library outfits, blank book covers, and novelty boxmaking. Practical academic work, as well as drawing and color, are also taught, but always with an eye single to their bearing on the needs of each trade. A certificate is given only after a girl has been tested in a position and has shown her proficiency and also a good spirit in the workroom. The tuition is free, and in especially deserving cases some financial aid may be given to pupils. The school has the cordial support of some of the foremost philanthropists. trade unionists, social workers and employers of labor of New York city. The Boston Trade School follows closely the plan of the Manhattan Trade School for Girls. It was begun in 1904 and taken over by the city in 1908. Similar trade schools for girls adapted to their communities are found in other cities, Worcester, Massachusetts and Milwaukee, Wisconsin, being especially notable.

Schools for specific trades are to be found all over the United States. The Brewers' Schools of New York, Chicago and Milwaukee; the Schools of Watchmaking and Repairing in Waltham, Mass., and at the Bradley Polytechnic in Peoria, Ill., and the Barbers' Schools in Nebraska and other States are instances. Shipbuilding, photography, linotype and many other trades are taught in this class of school.

Business enterprises have also opened trade schools. Many of the institutes for dressmaking, so numerous in the large cities, were organized by some firm to teach a special system of drafting patterns.

The Apprenticeship or Corporation School is also found, being represented by such instruction as is given their workmen by the school of Messrs. R. Hoe and Company, manufacturers of printing presses, and the Carriage Builders' National Association (both in New York city), the Ladies' Home Journal, Philadelphia, the General Electric Company, at West Lynn, Mass., and great railroads, such as the New York Central and the Atchison, Topeka and Santa Fé.

Night classes for teaching trades are to be found in connection with the work of social and religious bodies. The Saint George's Trade School of New York city belongs to this class. The Catholic Protectory, near New York city, is teaching numerous trades for both sexes as a part of its scheme of reformation, and similar work is done in other institutions of this character.

Trade or technical teaching in institutions with other educational aims is found frequently. The pressure to introduce this work has been so great that trade classes have been offered in a variety of places, some of them receiving State or Federal aid. Much of the instruction is of a supplementary character, to take the place of apprenticeship. The technical features are usually more prominent than the special shop practice. Pratt Institute, Brooklyn, offers classes which resemble those of the trade continuation schools. The fundamental aim of the institute is for «industrial and technical instruction,» but it has responded to the call for trade training and has opened night classes to fit boys for carpentering, machine work, plumbing and fresco painting. Trade classes for girls are also given. The technical classes are justly noted, but they do not aim to prepare apprentices for the trade. The Drexel and Spring Garden institutes in Philadelphia, the Mechanics Institute in Rochester, the Hebrew Technical institutes for both sexes and the Clara de Hirsch Home in New York city and the Christian associations are instances of institutions with other aims giving attention to trade instruction.

The great schools for the colored people and Indians have been foremost in inaugurating trade education as an adjunct to their academic or normal aims. The Hampton Normal and Agricultural Institute in Virginia, the Tuskegee Normal and Industrial Institute and the Agricultural and Mechanics College in Greensboro, N. C., are examples of these schools. They have developed for both sexes almost all of the leading trades. The work is given in the most practical manner, as the shops are for productive industries and not alone for theoretical instruction. Trade teaching in these schools has been placed on a high ground and the results have justified the wisdom of the methods chosen.

Continuation, co-operative and part-time classes are increasing in number, Massachusetts, New York, Wisconsin and Indiana have been foremost in enacting laws to further vocational education and have organized various forms of trade classes to help their working people. Other States are following rapidly. Department stores are using the continuation schools for training their sales-people and are also organizing part-time classes in their own buildings. In Massachusetts the trade schools in Beverly and Fitchburg have begun an interrelation with the industries in their towns and the school in part-time instruction. Prevocational work in the later grades of the school is rapidly increasing and serves to guide young workers into occupations suited to their ability, thus preparing them for entering trade or taking further training at a school.

The passing of the Federal bill for vocational education gave a great impetus to training boys and girls below college grade for trades and industries. The aim of the measure, stated tersely, is to promote training in agriculture, trades, industries and home economics, and also to train teachers for vocational positions. The Federal board is also authorized to make investigations and to send out reports. It supervises and controls the work it assists, and works in connection with the State boards — the Federal and State boards acting as an agent. During the European War (by special legislation) it prepared men for various branches of war work and is still giving training to disabled soldiers, sailors and marines.

Austria.

The Austrian government has developed an exceptionally logical system of trade instruction for both sexes. The legislation in regard to fostering handicrafts has been similar to that taking place in Germany and has had a great effect on the development of trade training. The schools of all grades are carefully classified and grouped. The elementary education for trade is given in schools for particular trades and in the industrial continuation schools.

Another group, known as the Central Industrial Educational Institutions, which are most of them in Vienna, have for their function the promotion of industrial education and to serve as models for other schools of the empire. Some of these schools offer both a lower and a higher trade education in connection with their other important lines of investigation.

The Schools for Particular Trades are very numerous. There were about 100 state schools and more than half that number of private or state subscribed schools in the report of 1899. Important examples of this class are the schools for lace work and hand and machine embroidery in Dornbirn and Laybach; for weaving in Reichenberg, Vienna, Schönberg and Warnsdorf; for wood, iron and stone work in Bergreichenstein, Bozen, Chrudim, Bruck aus der Mur and Laas; for earthenware and glass-work at Teplitz and Oberlentensdorf; for metal work in Klagenfurth, Swiatniki and Nixdorf and for other trades in Gablonz, Turnau and Karlstein.

The Industrial and Trade Continuation Schools are also extensively developed and are similar to the German ones of the same name. They have reached their highest development in Vienna. A great central school enrolls about 8,000 pupils. The school is open for 10 months, six days a week. The work is compulsory for four years for both sexes. A watch and clock making all-day school is in the same building.

Switzerland.

The Swiss are an industrious and practical people and their schools show the national characteristics. This country has the distinction of having provided the model for the first French trade school. As early as 1599 Saint Francis de Sales conducted a school which maintained an industrial section. The Duke de la Rochefoucauld, while traveling in Switzerland, heard of the school, and, at his own expense, founded a similar one in France, which later became a National School of Arts and Trades.

The Federal government has developed an excellent system of subsidizing and supervising trade schools. The continuation school is the favorite, and they are similar in character to those of Germany, though the special trade features are not so well developed. They are found in all of the cantons and are for both sexes.

The Industrial Art Schools are giving training to apprentices in the trade, as well as advanced instruction. The cantonal School of Industrial Arts at Geneva, devoted purely to the art industries, and the Trade and Industrial Art School in Bern, combining other industries with its art work, are examples. Certain classes in both of these schools are open to women.

The Trade Schools proper cover a wide field of occupations. Of those teaching a simple trade, the watchmaking schools are the most numerous. Woodworking, embroidery and weaving schools are also characteristic of Switzerland. Many of the schools teach several trades. The course is usually three years in length and includes such art and academic work as is felt to be necessary for the understanding of the trade. These schools have had for their models the German, Belgian and French institutions of a similar character. The art work is generally less notable, however. The cantons of Appenzell, Bern, Geneva, Neuchatel, Saint Gall, Soleure and Zürich have successful trade schools as well as apprentice shops.

Trade instruction for women is also well developed. Many of the trade schools include the housekeeping element as is the case in Germany, Belgium and France. The Trade and Housekeeping School (école professionnelle-ménagère) in Geneva offers a three-year course. The work produced resembles the French in precision of technique and beauty of execution, but has, perhaps, less artistic value. Of the trade schools proper a good example is the school for ladies' tailoring and lingerie making at Zürich. Pupils must be over 14 years of age and present certificates showing a good general education. Courses of three or four years are offered, which include practical work at the chosen trade, theoretical instruction concerning it, auxiliary academic subjects, drawing and drafting and at least six months' service in a salesroom connected with the school. The Bern Women's Handwork School (Frauenarbeitsschule) also gives trade training, but does not at present include art or academic work in its curriculum.

Schools for housekeepers and servants have been developed in Switzerland and give excellent courses of several months' duration. All of the ordinary work of housekeeping, cooking, baking, preserving, serving, cleaning, sewing, repairing, washing, ironing, gardening, sweeping and putting rooms in order is included in the course. An effort to lengthen the time of training is being made. Lenzburg, Bern and Boniswil have good schools of this class.

The Swiss trade school is felt to have a beneficial effect on the working man and woman as well as on the industries, and is favored by the labor unions. Although the schools have not created new industries, they have been the means of developing many. The schools of wood-carving have done much to improve this trade, and machine embroidery has been, through the schools, brought prominently forward. The products of this industry are largely exported to the United States.

England.

The trade school proper was not developed to as great an extent in England as on the Continent. Although technical education has received attention, there have been until recently but few instances where the day schools aimed to take the place of actual apprenticeship. This was due largely to the Education Act of 1889, which forbade the practice of any trade, industry or employment in the schools. The education acts later took a more favorable attitude toward trade instruction, and government aid can now be given for fostering such schools. They are rapidly increasing.

Supplementary trade work is largely offered in the night continuation classes, which resemble those of Germany, and attract large numbers of students. There are 4,000 of these classes in London alone. Mr. Robert Blair, of the Mosely Educational Commission, says in his report on technical education in the United States: «We are in the main trying to do in one institution — the evening school — what Germans and Americans are in the main endeavoring to do in two.» The night classes are open to both sexes. Girls do not take much advantage of them, however, for the reason that nine or 10 hours of work during the day leave but little energy for resuming workshop practice.

Although the polytechnics have done much for the industries, it is only of late years that they have fostered real trade instruction in the day classes. Such instruction, however, has recently been increasing. A late report gives the number of day trade students in or near London as 5,800. These are provided for in 35 well-equipped workrooms (principally in the polytechnics) in which 200 courses are given bearing on 53 different trades. The evening classes are doing a fine work in training older workers for better positions. Day preparatory trade schools are being organized. Engineers of high rank are urging educational facilities for apprentices, workmen and experts equal to those offered on the Continent of Europe.

Trade training for girls has not been greatly encouraged by the working class. The germ of it has been in the excellent domestic economy schools. The Women's Industrial Council of London is doing much to foster trade schools for girls as a part of education. The London County Council has opened an All-Day Trade School of the preapprenticeship type. It began under private control but was taken over by the city in 1907. A girl can enter at 14 and remain two years. A day continuation school has also been opened for girls at work. The Borough Polytechnic in London opened in 1904 Day Trade Waistcoat-Making School for Girls, and other polytechnics have followed the example. General education, art and domestic science are included in the one-year course. The council is urging that similar day courses be offered at each technical institute in London, in order to train workers for all good trades employing women.

Italy.

Education for industrial pursuits began seriously in Italy after the national union. In 1898 vigorous reforms took place in the schools which raised the standard of teaching and reorganized the courses of study. The schools were founded chiefly by individuals. They differ widely in type, in object and in program. Many of the schools receive subsidies from the state as well as from the provincial or communal authorities, or from chambers of commerce, or from the savings banks. The government exercises a certain class of supervision over those schools receiving subsidies. Although there is no co-ordination between the schools there is a response to local needs. As in other countries, there are several grades of schools, The schools of arts and trades (scuole d'arti e mestieri) train the workmen. These institutions are very numerous in the cities and small towns, and are unevenly distributed through Italy. Piedmont, Lombardy, Campagna and Tuscany have the greater number. The instruction in many of them deals more with the technical features than with the academic and theoretical. As in other continental countries there are two classes of schools for apprentices: The day school to train workmen for trade, and the night or Sunday courses to improve workmen engaged in the industries. Everywhere there is the emphasis on the artistic side of industry. The Casanova Institute of Arts and Trades in Naples and the Municipal School of Arts and Trades in Genoa are illustrations of the day trade schools for boys.

Trade education for girls (scuole professionale) has received serious attention. The schools are largely attended. The parent institution is in Rome. It still remains a model for other schools. The girls enter at 12 years of age, on completing their elementary education and continue to attend the classes for three, four or even six years. The compulsory subjects are drawing and cooking. Optional subjects are languages, needlework in all branches, laundry work, lace and artificial flowermaking, hair-dressing, bookkeeping and arithmetic. There is also a nurses' training school. Similar schools are to be found in Florence, Milan, Venice, Turin, Parma, Bologna, Palermo and in some of the smaller towns.

Mary Schenck Woolman,
Specialist in Vocational Education; Formerly Professor of Domestic Art, Teachers College, Columbia University, and Director of the Manhattan Trade School for Girls.

TRADE UNIONS, as defined by the Federal statutes, are associations of working people for the several purposes of aiding members toward greater efficiency, promoting their general intelligence, raising of funds for the benefit of sick, disabled or unemployed members or the families of deceased members, and for the regulation of their wages and hours and conditions of labor, and the protection of their individual rights in the prosecution of their trades. The primary object was to assist members in contests with employers, and it was not for some time later that the unions introduced funeral benefits, homes for incapacited workers, schools for instruction, etc. See AMERICAN FEDERATION OF LABOR; GUILDS; UNIONISM.

TRADE UNIONS, General Federation of, a labor organization of Great Britain, aiming to unite all the British trade unions for mutual assistance and the advancement of the interests of labor. It admits any trade union to membership, but no branches or individuals. It was organized in 1899 at a special session of the British Trades Union Congress. The government is vested in a general council of representative delegates meeting annually, and in an executive «management committee» of 15, no two to be of the same trade. District committees may also be organized. Any union dissatisfied with ruling of the management committee may appeal to the council, and from the council to the vote of the general membership. The federation deals solely with industrial questions, particularly with the conduct of strikes, and aims to preserve industrial peace. All unions joining the federation pay an entrance fee of one penny (two cents) per member and regular dues are paid on two different scales, the higher scale, sixpence (12 cents) per quarter per member, the lower scale, threepence (6 cents) per quarter per member; all payments are calculated on 90 per cent of the membership. In case of a strike approved by the general council or the management committee, unions that have belonged to the federation 12 months are entitled to a strike benefit of five shillings ($1.25) per week per member on the higher scale, and half that amount on the lower scale. Several large and representative unions have joined the federation; among them are the Amalgamated Society of Engineers, the Boot and Shoe Operatives, the Cotton Spinners, the Shipwrights, the Tailors and the Gasworkers and General Laborers; the membership approximates 1,000,000. See UNIONISM.

TRADE WINDS, one of those perpetual or constant winds which occur in all open seas on both sides of the equator, and to the distance of about 30° north and south of it. On the north of the equator their direction is from the northeast (varying at times a point or two of the compass either way); on the south of the equator they proceed from the southeast. In some places the trade winds become periodical, blowing one-half of the year in one direction and the other half in the opposite direction. They receive their name because their known regularity is an assistance to trading vessels which often lay their courses so as to receive as much assistance as possible from favorable breezes. See also CURRENTS, OCEAN; METEOROLOGY.

TRADING STAMPS, printed slips given by some merchants as an inducement to the trading public. They are usually gummed so that they may be pasted in a book which is furnished and which when filled has a value in premiums offered. These stamps are used extensively and are said to be of considerable value in working up trade. They have been the cause of lawsuits brought against the issuing firms under the laws forbidding lotteries.

TRADITION, the body of oral information, opinion, inexact records, statements and evidence of things long past communicated from older generations to the present. That evidence of ancient things which is not committed to writing and vouched for by competent authority. As applied to profane history it signifies knowledge of the past handed down by word of mouth from generation to generation. In this sense the line between tradition and myth is often hard to distinguish, one merging into the other. Historical tradition, however, has usually, if not invariablv. a substantial foundation and both tradition and myth are of the highest value in tracing human experience and progress both in the historic and prehistoric periods — for it should be unnecessary to state that the so-called historic period is not a uniform era, but varies with different races of mankind, according to the age at which they come within the range of historic observation.

Tradition in the religious sense holds a place not less important than in its profane meaning. It is a chief ground of doctrinal division in Christianity and also in Mohammedanism, between Roman Catholics and Protestants in the former faith and between Sunnites and Shiites in the latter. A similar division existed among the Jews of the later Scriptural period. In the Roman Catholic view the term tradition is applied to the doctrines believed to have been communicated by Christ to his Apostles and handed down by them orally to their successors. The writings of the Fathers are regarded as witnessing these traditions. The Council of Trent teaches that the truth of Christ is contained partly in the sacred writings and partly in unwritten tradition received by the Apostles from Christ, or from the Holy Ghost, and entrusted by them to the Church, and that Scripture and apostolic tradition are alike to be reverenced. See CATHOLIC CHURCH; JEWISH SECTS; MOHAMMEDANISM; PROTESTANTISM; SHIITES; SUNNITES.

TRADUCIANS (from *traduco,* transmit), a name which the Pelagians anciently gave to the Catholics because of their teaching that original sin was transmitted from father to children. More commonly the term is applied to the theory that souls are transmitted to children by the parents, instead of being created by God. Saint Augustine appears to have inclined to this belief, without committing himself to it.

TRAFALGAR, trăf-ăl-găr', or tră-făl'gar, a cape on the southwest coast of Spain, at the northwest entrance of the Strait of Gibraltar. It is low and sandy and terminates in two headlands, on the east of which is a martello tower. The famous naval battle in which Nelson lost his life, after defeating the combined French and Spanish fleets under the command of Villeneuve and Gravina, was fought off this cape 21 Oct. 1805. Consult Corbett, Sir J. S., 'The Campaign of Trafalgar' (London 1918).

TRAGACANTH, GUM TRAGACANTH, GUM TRAGIC, a gummy exudation from the stem of various species of *Astragalus*, natives of the mountainous regions of western Asia. It comes on the market as irregular leaves or ribbon-like pieces, of a white or brownish-white color and somewhat translucent. It swells up in water; does not readily dissolve but forms a gelatinous mass which is sometimes utilized as a mucilage. Used in pharmacy to give consistency to lozenge or pill mass. It is also used to stiffen calicoes and other fabrics.

TRAGEDY, a serious drama or poem, representing an important event or a series of events in the life of some person or persons, in which the diction is elevated and the catastrophe melancholy. Tragedy originated among the Greeks in the worship of the god Dionysus or Bacchus. See DRAMA.

TRAGOPAN, a pheasant of the genus *Ceriornis*, closely allied to the common fowl. *C. satyra*, a common species, is a native of the Himalayas where it inhabits the forests at 8,000 to 11,000 feet elevation. The plumage is spotted, exceedingly brilliant and variegated in colors and two fleshy protuberances hang from behind the eyes. When the bird is excited it can erect these protuberances till they look like a pair of horns. A large wattle hangs at either side of the lower mandible. Unlike most pheasants they build their nests in trees.

TRAILL, trāl, **Catherine Parr Strickland,** Canadian writer, sister of Agnes Strickland (q.v.): b. London, 9 Jan. 1802; d. Lakefield, Ontario, 29 Aug. 1899. She was married in 1832 to Capt. Thomas Traill with whom she removed to Canada in 1833 and made her home for the rest of her life at Lakefield, Ontario. Among her works are 'The Backwoods of Canada' (1835); 'Canadian Crusoes' (1852); 'Ramblings in the Canadian Forests' (1854); 'Afar in the Forest' (1869); 'Studies of Plant Life' (1884); 'Pearls and Pebbles' (1895).

TRAILL, Henry Duff, English journalist and man of letters: b. Blackheath, Kent, 14 Aug. 1842; d. London, 21 Feb. 1900. He was graduated at Saint John's, Oxford, 1864, called to the bar in 1868, but soon took to literature. He was connected with the *Pall Mall Gazette* (1873–80), the *Saint James' Gazette* (1880–82), *Telegraph* (1882–96) and the *Saturday Review* (1883–94). From 1889 to 1891 he was editor of the *Observer*, from 1898 to 1900 of *Literature*. Among his publications are 'Lives' of Strafford (a very original work with a new view) (1889); William III (1888); Sterne (1882); Coleridge (1884) and others; also 'Central Government' (1881); 'Recaptured Rhymes' (1882); 'The New Lucian' (1884; revised and enlarged 1900), his best work; 'Saturday Songs' (1890), satirical verse; 'From Cairo to the Soudan Frontier' (1896) and 'The New Fiction and Other Essays on Literary Subjects' (1897).

TRAIN, Elizabeth Phipps, American novelist and translator: b. Dorchester, Mass., 1 Sept. 1856. She was educated at Wells College, Aurora, N. Y., and her first literary work consisted entirely of translations from the French. They include 'The Apostate' (1889); 'Recollections of the Court of the Tuileries' (1891), etc. Her first original publication was 'Dr. Lamar' (1891) and she has since written 'Autobiography of a Professional Beauty' (1895); 'A Social Highwayman' (1895); 'Queen of Hearts' (1897) and other works.

TRAIN, George Francis, American financier and eccentric author: b. Boston, 24 March 1829; d. New York, 18 Jan. 1904. In 1850 he was put in charge of the Liverpool branch of an American business house and three years later was admitted to partnership. Another branch was established in Melbourne, Australia, in 1853, under his supervision, and during the three years of his stay there he introduced a sailing-ship service between Boston and Australia. In 1858 he interested English capital in the building of the Atlantic and Great Western Railway and afterward undertook street-railway enterprises in England and other European countries, but his plans, through opposition and otherwise, were frustrated. His next railroad enterprise was the building of the Union Pacific Railway, ground for which was broken at Omaha 2 Dec. 1863 and the connection that linked the eastern and western extremities completed 10 May 1869. He made a tour of the world in 80 days, arriving in Marseilles, France, 20 Oct. 1870, where he organized the Commune, was arrested and imprisoned for 13 days at Lyons. In 1872 he became an independent candidate for President of the United States. He was a man of eccentric habits and extravagant speech and in November 1872 was arrested on the charge of having published obscene literature. The passages objected to were wholly quotations from the Bible. Mr. Train was discharged from custody after having been adjudged insane by legal decision. His later years were spent in New York, where he adopted the habit of speaking only to children. He called himself "Citizen of the World," and while his title to property valued at $30,000,000 at Omaha, Neb., remained in litigation he affected a simple style of living and spent his last years at a cheap hotel, where he died. Among his publications are 'An American Merchant in Europe, Asia and Australia' (1851); 'Young America Abroad' (1857); 'Young America in Wall Street' (1858); 'Young America on Slavery' (1860); 'Championship of Women' (1868) and 'My Life in Many States and in Foreign Lands.'

TRAIN BANDS, a body of citizens partaking of the nature of both militia and volunteers, instituted by James I and dissolved by Charles II. The term was afterward applied to the London militia, from which the third regiment of the line originated and in which the renowned John Gilpin was a captain.

TRAJAN, trā'jan (MARCUS ULPIUS TRAJANUS), Roman emperor: b. Italica (near Seville), in the Spanish province of Bætica, 53

A.D.; d. Selinus, Cilicia, 117. He was the son of Trajanus, a Roman commander under Vespasian. He accompanied his father in a campaign against the Parthians and also served on the Rhine with such ability that when Nerva came to the throne he adopted the young soldier and raised him to the rank of Cæsar (97). Nerva dying a few months after, he succeeded to the throne (98). He was at that time in Germany, where he remained for more than a year, to settle a peace with the German tribes, and in 99 set out with a numerous escort to Rome. After largess to the soldiers and people he took successful measures for supplying the capital with corn. He punished and banished informers, reduced the taxes and filled the most important posts with men of talent and integrity. He moreover founded libraries, and under his patronage the studies were revived which had suffered from the persecution of Domitian. By the unanimous voice of the Senate he was awarded the title «Optimus.» In 101 he set out on an expedition against Decebalus, king of the Dacians, who had forced Domitian to purchase peace by an annual payment of money, and after two years defeated the Dacians and returned to Rome to enjoy the honors of a triumph with the name of Dacicus (103). In this year Pliny was made governor of Pontus and Bithynia, which circumstance gave rise to a series of letters between him and Trajan still extant. Among these are the epistles respecting the Christians, whom he directs Pliny not to search for, but only to punish if brought before him. In 104 Decebalus renewed the war with the Romans in pursuing which Trajan constructed a bridge over the Danube, below the modern Orsova, which was one of the greatest works of antiquity (105). He then marched into Dacia, reduced the capital of Decebalus and turned Dacia into a Roman province. It was in commemoration of his wars in Dacia that he erected the sculptured column which still bears his name. In 114 he dedicated the Forum that he had built in Rome and set out on a new warlike expedition against Chosroes, the Parthian. The result of this war was the reduction of Armenia to a Roman province. His war with the Parthians was completed in two campaigns, after which he sailed down the Tigris and entered the Persian Gulf. During his absence the Parthians revolted. After giving a king to the Parthians he laid siege to Atra, the capital of an Arabian tribe, but was obliged to withdraw to Syria. In the following year (117) he proposed returning into Mesopotamia, but was attacked by a disorder, which induced him to repair to Italy, leaving the army under the command of Hadrian. He had proceeded no farther than Selinus, in Cilicia, when he died, after having adopted Hadrian for his successor. His good qualities as a ruler were such that, at the distance of 250 years from his death, the senators, in their acclamations on the accession of a new emperor, were accustomed to wish that he might be more fortunate than Augustus and better than Trajan.

TRAJAN'S COLUMN. See ROME; TRAJAN.

TRAJAN'S WALL, Rumania, a fortified line in the Dobrudja extending east from the Danube to Kustendji on the Black Sea, a distance of 37 miles. It is a double, in some places, a triple, earthwork on the south side of a natural fosse consisting of a narrow marshy valley. Another wall of the same name, built by a Roman legion, 105–155 A.D., extends from the Pruth east to the Black Sea.
