NEW YORK CHICAGO

COMPOSITION, ELECTROTYPING, PRESSWORK, BINDING
BY
J. B. LYON COMPANY, ALBANY, NEW YORK

PARTIAL LIST OF CONTRIBUTORS TO VOLUME XXVI

ALDEN, RAYMOND M., Ph.D., Litt.D.
Professor of English, Leland Stanford Jr. University
TOTTEL'S MISCELLANY

ALEXIS, JOSEPH, A.B., A.M.
Assistant Professor of Germanic Languages and Literatures, University of Nebraska
SYNNÖVE SOLBAKKEN

BABASINIAN, V. S., Ph.D.
Professor of Chemistry, Lehigh University
TANNINS
TARTARIC ACID
TOLUENE
TOLUIDINE

BENEDICT, H. Y., B.S., M.A., Ph.D.
Dean, University of Texas
TEXAS

BOGART, ERNEST L., Ph.D.
Professor of Economics, University of Illinois
TARIFF

BOUCKE, EWALD A., Ph.D.
German Department, University of Michigan
SWEDISH LANGUAGE
SWEDISH LITERATURE

BREWSTER, WILLIAM T., A.M.
Professor of English, Columbia University
TALE OF TWO CITIES, A
TESS OF THE D'URBERVILLES

BROOKE, TUCKER, M.A., Litt.B.
Professor of English, Yale University
TAMING OF THE SHREW, THE
TIMON OF ATHENS
TITUS ANDRONICUS

BRUBACHER, A. R., Ph.D.
President of State College for Teachers, Albany, N. Y.
SUMMER SESSIONS

BUCKLEY, EDMUND, A.M., Ph.D.
Editor of "University Lessons in Art"
TAO TE KING
TAOISM

CAIRNS, WILLIAM B., Ph.D.
Associate Professor of American Literature, University of Wisconsin
TALES OF THE ARGONAUTS, THE
TALES OF A WAYSIDE INN

CANFIELD, ARTHUR G., A.M.
Professor of Romance Languages, University of Michigan
TÉLÉMAQUE

CARMAN, E. A.*
Brigadier-General, United States Army
THOMPSON'S STATION, BATTLE OF
TODD'S TAVERN, ENGAGEMENTS AT

CHANDLER, FRANK W., Ph.D.
Professor of English and Comparative Literature, University of Cincinnati
THREE MUSKETEERS, THE

CHOATE, JOSEPH H., LL.B., LL.D., D.C.L.*
New York City
SUPREME COURT OF THE UNITED STATES

COCHRANE, CHARLES H.
Author of "Modern Industrial Progress"
TELEPATHY

CORNYN, JOHN HUBERT, LL.B.
Birmingham Southern College
SYRIAC LANGUAGE AND LITERATURE
TABOO

COUMBE, CLEMENT W.
Technical Art Expert
SYMBOLISM
SYMMETRY
TAPESTRIES

CROSS, WILBUR L., Ph.D.
Professor of English, Yale University
TOM JONES

CUTLER, FRANCES W., M.A.
Instructor in English, Vassar College
TAM O'SHANTER

DAKE, CHARLES LAURENCE, A.M.
Associate Professor of Geology and Mineralogy, School of Mines and Metallurgy, University of Missouri
TERTIARY PERIOD

DARTON, NELSON H.
Geologist, United States Geological Survey
SURVEYS, UNITED STATES GOVERNMENTAL

* Deceased.

Contributors to Volume XXVI — Continued

DAVENPORT, EUGENE, B.S., M.S., M.Agr.
Dean of the College of Agriculture, University of Illinois

THREMMATOLOGY

DAY, JAMES R., S.T.D., LL.D., D.C.L., L.H.D.
Chancellor of Syracuse University

SYRACUSE UNIVERSITY

DOLE, NATHAN HASKELL, A.B.
Author, Editor and Translator

TORRENTS OF SPRING

DRISCOLL, JAMES F., D.D.
Rector, Saint Gabriel's Church, New Rochelle, N. Y.

TEMPORAL POWERS

DUNN, JOSEPH, Ph.D.
Professor of Celtic Languages and Literatures, The Catholic University of America

TÁIN BÓ CÚALNGE, THE CUALNGE CATTLE-RAID

ESTES, DAVID FOSTER, D.D.
Professor of New Testament Interpretation, Colgate University

THESSALONIANS
TIMOTHY AND TITUS

EVAARD, JOHN M., B.S., M.S.
Professor of Animal Husbandry, Iowa State College

SWINE

FARROW, EDWARD S., C.E.
Consulting Military and Civil Engineer

SUPPLY RAILWAYS
TACTICS
TORPEDO BOATS
TORPEDOES

FFOULKE, CHARLES M.
Lecturer and Writer on Antique Art Tapestries

TAPESTRIES, MANUFACTURE OF

FINCK, HENRY T., A.B.
Musical Critic "New York Evening Post"

TCHAIKOVSKY, PETER ILICH

FINEGAN, THOMAS E., M.A., Pd.D., LL.D.
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State of New York

TEACHERS, PROFESSIONAL TRAINING OF

FLEMING, WALTER L., M.S., A.M., Ph.D.
Professor of History, Vanderbilt University

TANEY [illegible]OGER BROOKE
TOOM[illegible]BERT

FORMAN, SAMUEL E., Ph.D.
Author "First Lessons in Civics"

TOWN AND TOWN MEETINGS

GARNER, WIGHTMAN W., Ph.D.
Physiologist in Charge of Tobacco Investigation, Bureau of Plant Industry, United States Department of Agriculture

TOBACCO

GHERARDI, BANCROFT
Chief Engineer, American Telephone and Telegraph Company

RHODES, FREDERICK L.
Outside Plant Development Engineer, American Telephone and Telegraph Company

TELEPHONE

HARRIS, ROLLIN A., Ph.D.
Author of "Manual of Tides"

TIDES

HART, J. M. EDGAR
Instructor of the American Academy of Dramatic Arts

THEATRE, STAGE MECHANICS OF

HARTMANN, JACOB WITTMER, Ph.D.
Assistant Professor of German Language and Literature, College of the City of New York

THOMA, LUDWIG
TIECK, JOHANN LUDWIG

HORNADAY, WILLIAM T., Sc.D.
Director, New York Zoological Park

TAXIDERMY

HOWARD, WILLIAM G., A.M.
Assistant Professor of German, Harvard University

SUNKEN BELL, THE
TILL, EULENSPIEGEL

ISAACS, LEWIS M., Ph.B., LL.B.
Musical Critic and Composer

TALES OF HOFFMAN

JELLIFFE, SMITH ELY, M.D. Ph.D.
Editor, "Journal of Nervous and Mental Disease"

THE ENCYCLOPEDIA AMERICANA

S

SULPHUR, a non-metallic element known from very early times, and proved to be an element by Lavoisier, in 1772. It was not definitely admitted to the list of recognized elements, however, until after the researches of Gay-Lussac and Thénard, in 1809. In the free state, it occurs native in many parts of the earth, usually in volcanic regions or in connection with gypsum and other allied rocks. Until within recent years the commercial supply has been obtained largely from Sicily, though a considerable quantity has been obtained from the Chilean Andes, and from certain parts of Mexico, China, Japan, India and the Philippine Islands. The large deposits of southern Utah are also mined, but the American supply is now obtained almost wholly from the extensive deposits in and near Calcasieu Parish, La. Four general methods have been employed for separating sulphur from the stony and earthy impurities with which it is usually associated in nature. (1) The «ore» containing it may be heated to a temperature high enough to melt the sulphur and permit it to run out at the bottom; or (2) the «ore» may be heated still more strongly, so as to cause the sulphur to volatilize and pass away in the form of vapor; or (3) the «ore» may be lixiviated with a fluid (such as carbon disulphide) in which the sulphur is soluble, the sulphur being afterward recovered by evaporating the solvent. (4) The Frasch process, specially developed in connection with the Louisiana deposits, is described below. The method by melting is almost exclusively used in extracting sulphur from the inert material with which it is associated in nature, the volatilization and solution methods being reserved for the subsequent purification of the product as first obtained by melting. When the sulphur is extracted from an «ore,» the heat required for melting it and isolating it is obtained by various means. In some regions it is obtained by burning a part of the sulphur itself. This method is wasteful in sulphur, but it can be put into practice very simply, and hence its application does not call for skilled labor. In Nevada and California, and, to a more limited extent, in Italy and Sicily, the «ore» is heated by steam under a pressure of 70 pounds or more; the yield by this method being considerably greater, though the expense of treatment is also much greater.

In mining the Louisiana deposits a special method is used, which merits separate description. These vast deposits occur in the form of subterranean beds, having an average thickness of 125 feet, and covered by about 90 feet of soft rock (mainly gray limestone) and 375 feet of clay, sand and gravel. The deposits were first discovered in 1865, and between 1868 and 1895 many unsuccessful attempts were made to work them commercially by ordinary methods of mining. Herman Frasch, an American petroleum expert, then undertook a careful study of the subject, and worked out a method of mining the sulphur that has proved eminently successful. The entire practicability of the Frasch process was first established in 1903, in which year 35,000 tons of sulphur were brought to the surface by means of it. The essential ideas of the Frasch process are (1) the use of highly heated water to melt the sulphur as it lies in its bed, and (2) the use of compressed air to force the molten sulphur to the surface of the ground. Several concentrically-arranged steel pipes are driven into the ground, and highly superheated water is forced down into the sulphur bed through the outer ones. The sulphur is thereby melted, and as it is considerably heavier than water it collects in a subterranean pool, into which the pipe system dips. Air, compressed to a pressure of about 250 pounds to the square inch, is forced down the central pipe (which is one inch in diameter), and as this air returns to the surface of the ground through the annular space between the inner pipe and the next one to it, the melted sulphur is carried upward at the same time. When the operation is properly conducted the melted sulphur and hot water can be kept separate, so that when the sulphur reaches the surface it is only necessary to run it into bins to cool and solidify. The product that is obtained in this way is remarkably free from impurities. In fact it is not uncommonly 99.9 (and sometimes even 99.98) per cent pure, and hence it does not require further purification for technical use. For a good technical description of the Frasch process, consult Thorpe's 'Dictionary of Applied Chemistry,' article «Sulphur.»

Iron pyrites (native yellow sulphide of iron) is utilized quite extensively as a source of sulphur in certain lines of manufacture, but the sulphur of the pyrites is rarely won in the elementary form. Almost invariably the sulphur dioxide that is obtained by roasting the pyrites is used in the preparation of sulphuric acid or other compounds, without being reduced to sulphur.

Native crystals of sulphur are common. They belong to the orthorhombic system, and are usually pyramidal in habit, often with truncated ends. They are transparent to translucent, and are usually yellow in color, with a resinous lustre, a hardness of from 1.5 to 2.5, and a specific gravity of about 2.07.

Sulphur occurs abundantly, also, in combination with other elements, mostly as sulphides and sulphates. Many of the compounds of sulphur are valuable as ores of other elements than sulphur. Galena (sulphide of lead) and cinnabar (sulphide of mercury), for example, are valuable ores of lead and mercury, respectively.

It is difficult to give an adequate physical description of sulphur since the element is capable of existing in many allotropic forms. Six of these appear to have been prepared in a state of satisfactory purity, and others, although they have long been known, are not yet universally admitted to be true allotropic modifications of pure sulphur. A brief description of the six best-known forms follows:

1. **Ordinary Rhombic Sulphur.**— This is the form in which native crystalline sulphur occurs. Crystals of this variety may be prepared by dissolving ordinary sulphur in carbon disulphide, and evaporating the solvent. This variety is also obtained by melting sulphur and allowing it to cool with extreme slowness. Ordinary rhombic sulphur melts at about 240° F., and boils (under a pressure of 760 millimeters of mercury at Paris) at 832.2° F., according to the very careful experiments made by Callendar and Griffiths with the normal constant-pressure air thermometer. In the solid form rhombic sulphur has a specific gravity of from 2.03 to 2.09, and in the liquid form (just above the melting point) its specific gravity is about 1.81. It is practically a non-conductor of electricity at ordinary temperatures, although it conducts to some extent near its boiling point. When rubbed, sulphur becomes negatively electrified, and globes of sulphur were used in the place of glass in some of the earlier forms of static electrical machines. Rhombic sulphur has a coefficient of linear expansion of about 0.0000356 (Fahrenheit scale), and, when at a temperature just above the melting point, it has a specific heat of approximately 0.235. It is easily soluble in carbon disulphide, and, to a lesser extent, in benzene, chloroform, warm concentrated acetic acid and liquid sulphur dioxide.

2. **Monoclinic Sulphur.**— Sulphur may be obtained in the form of monoclinic crystals by melting a considerable quantity of ordinary sulphur, allowing it to cool until a crust has formed upon the surface and then piercing the crust and pouring out the still molten portion. The walls of the crucible will then be found to be covered with the monoclinic crystals. It may also be prepared in mass by melting ordinary sulphur, cooling it almost to the point of solidification, and then throwing in a single crystal of monoclinic sulphur; the whole mass then solidifying in the monoclinic form. (If a crystal of rhombic sulphur is added under these circumstances, the crystalline structure of the resulting solid mass is rhombic). Monoclinic sulphur has a specific gravity of about 1.97, melts at about 245° F., and is freely soluble in carbon disulphide, from which it crystallizes in the rhombic form. It also dissolves in alcohol, chloroform and benzene, the crystals obtained from these solutions being partly monoclinic and partly rhombic. Monoclinic crystals may be obtained by evaporating the solution obtained by dissolving sulphur in an alcoholic solution of ammonium sulphide. Monoclinic sulphur passes slowly into the ordinary rhombic form, the transformation being facilitated by rubbing the monoclinic crystals with a glass rod. When heated, under atmospheric pressure, to 203° F., monoclinic sulphur passes at once into the ordinary rhombic form, the transformation being accompanied by a small contraction in volume, and the evolution of a certain amount of heat.

3. **Soft Soluble Sulphur.**—This variety of sulphur may be prepared in various ways,— for example, by decomposing sodium hyposulphite (or thiosulphate) by means of a limited quantity of a mineral acid. It is a soft, amorphous substance, nearly white in color, which gradually hardens, and eventually passes (like all the other kinds) into ordinary rhombic sulphur. This form of sulphur is not (as its name indicates) entirely soluble in carbon disulphide; it consists, apparently, of a mixture of two kinds of sulphur, one of which is soluble, while the other is insoluble. When heated, it evolves sensible quantities of sulphuretted hydrogen, showing that it contains hydrogen in some form or other; but it has not been determined whether such hydrogen is essential to the existence of the sulphur in this form, or whether it is to be regarded merely as a non-essential constituent, which could be eliminated (if we knew how to eliminate it) without affecting the continued existence of the sulphur in the «soft soluble» form.

4. **Plastic Insoluble Sulphur.**—When ordinary sulphur is melted, it first passes into the form of a clear, yellow liquid; but as the temperature is raised, the liquid begins to thicken and darken at about 300° F., and at about 360° F. it is black and quite viscid. If the temperature is still further increased, the liquid gradually loses its viscidity, until, at about 640° F., it becomes quite fluid again, though it remains dark even at its boiling point (832.2° F.). If sulphur which has been heated almost to its boiling point is suddenly cooled by being poured in a thin stream into water, it becomes converted into a plastic mass, which may be readily kneaded with the fingers. Plastic sulphur is commonly dark brown; but Mitscherlich states that the dark color is due to impurities, and that perfectly pure plastic sulphur is citron-yellow in color. Plastic sulphur soon becomes hard and yellow, the transformation taking place quickly (and with evolution of heat) at temperatures in the vicinity of 212° F. It is not soluble, as a whole, in carbon disulphide, though that reagent dissolves a portion of it.

5. **Amorphous Yellow Insoluble Sulphur.** — Plastic sulphur, when treated with warm carbon disulphide until all the soluble part is removed, leaves a yellow, amorphous powder as a residuum. This form appears to be stable at ordinary temperatures, but at about 212° F. it slowly passes into the ordinary rhombic crystalline form.

6. **Colloidal Sulphur.**—When sulphuretted

hydrogen gas is passed into a cold solution of sulphur dioxide, sulphur is liberated in still another allotropic form. If the current of sulphuretted hydrogen is continued until all the dioxide has been decomposed and the solution (after filtration) is concentrated by evaporation in a vacuum, a yellow solid is finally obtained, which is soluble in water, but which gradually passes into the form of ordinary rhombic sulphur. «Colloidal» sulphur receives its name from the fact that in its aqueous solution it is not diffusible.

Sulphur occurs in commerce in several forms. When cast into cylindrical or slightly conical sticks it is known as «roll sulphur» or «brimstone.» It is very brittle under ordinary circumstances, and when reduced to powder by crushing it is sold simply as «sulphur.» When sulphur vapor is suddenly cooled, the sulphur condenses in the form of a very finely divided powder, which is commercially known as «flowers of sulphur,» or «sublimed sulphur.» «Precipitated sulphur» is the fine powder that is thrown down upon the addition of hydrochloric acid to a solution prepared by heating sublimed sulphur with lime and water.

Chemically, sulphur has the symbol S, and an atomic weight of 32.06 if $O = 16$, or 31.81 if $H = 1$. It combines directly with many of the other elements, producing binary compounds which are known as «sulphides,» and which are analogous to the oxides of the corresponding elements. With hydrogen it forms hydrogen sulphide, or «sulphuretted hydrogen,» which has the formula H_2S, and is gaseous under ordinary conditions of temperature and pressure. (See HYDROGEN). Many of the metallic sulphides occur in nature as minerals, as has been already mentioned. Many of them may also be prepared by passing a current of sulphuretted hydrogen gas through acid or alkaline solutions of various metallic salts, or by adding a soluble sulphate to such solutions. See CHEMICAL ANALYSIS.

Several oxides of sulphur are known, of which two are of great industrial importance. These are the dioxide, SO_2, and the trioxide, SO_3.

Sulphur dioxide, SO_2, is prepared, in the laboratory, by treating sodium acid sulphite ($HNaSO_3$) with concentrated sulphuric acid (H_2SO_4); sulphur dioxide and sodium acid sulphate being formed, as indicated by the equation $HNaSO_3 + H_2SO_4 = SO_2 + HNaSO_4 + H_2O$. It is also prepared by heating strong sulphuric acid with metallic copper, the reaction in this case being $2H_2SO_4 + Cu = SO_2 + CuSO_4 + 2H_2O$.

Sulphur dioxide is a colorless gas with the familiar suffocating odor of burning sulphur. It is irrespirable in the pure state, or even when largely diluted with air. Mere traces of it, when inhaled for some time, produce inflammation of the mucous surfaces of the respiratory tract and of the stomach, followed by nausea. The gas is about twice as heavy as air under the same conditions of temperature and pressure. Its specific heat at constant pressure (as compared with an equal weight of water) is about 0.154; and the ratio of its specific heat at constant pressure to its specific heat at constant volume is about 1.256. When exposed to a temperature of 18° F. under ordinary atmospheric pressure, sulphur dioxide condenses to a colorless liquid having a specific gravity of about 1.43. The critical temperature of the gas is probably about 313° F., and the critical pressure about 79 atmospheres. When cooled to about 105° F. below zero, liquid sulphur dioxide freezes to a transparent solid. Liquid sulphur dioxide evaporates rapidly when exposed to the air, the evaporation being attended with the absorption of a very considerable quantity of heat; a temperature as low as 140° F. below zero being attainable in this manner. On account of this property, liquid sulphur dioxide has been employed to a considerable extent in machinery for the manufacture of artificial ice; though at the present time anhydrous liquid ammonia is usually preferred for this purpose. Gaseous sulphur dioxide dissolves freely in water, especially under pressure; the solution being known as sulphurous acid (q.v.).

Sulphur dioxide is prepared in large quantities, in the arts, by the simple process of burning sulphur with a proper supply of air. When obtained in this manner, the gas contains large quantities of atmospheric nitrogen, but for many industrial purposes this is of no importance. The gas is used for bleaching straw, silk and wool, and (in enormous quantities) in the manufacture of sulphuric acid (q.v.). It is likewise employed extensively in the «sulphite process» for the manufacture of paper from wood.

Sulphur dioxide and sulphuretted hydrogen readily combine with each other to form water and free sulphur, according to the equation $SO_2 + 2H_2S = 3S + 2H_2O$; and it has been suggested that the deposits of sulphur that occur in volcanic districts have been formed, at least in part, by this reaction. In bleaching by means of chlorine compounds, it is found to be impossible to wash the last traces of chlorine from the bleached fabric, and hence it is customary to treat the fabric, after the bleaching is complete, with some substance (called an «antichlor») with which the free chlorine will combine, to produce compounds that can be more easily washed out. Sulphur dioxide gas is very useful for this purpose, since it combines with chlorine (in the presence of moisture) to form sulphuric and hydrochloric acids, according to the equation $SO_2 + 2H_2O + 2Cl = H_2SO_4 + 2HCl$. The dioxide is also used as an antiseptic and disinfectant; but it is inferior to chlorine in this respect, and although it possesses germicidal powers to some extent, it is seldom used in sufficient quantities to be really effective in this application.

Sulphur trioxide, SO_3, may be prepared by distilling fuming sulphuric acid, or by passing a mixture of one volume of oxygen with two of sulphur dioxide over red-hot platinized asbestos; the latter method being now used to a considerable extent in the manufacture of sulphuric acid (q.v.) by the so-called «contact process.» The trioxide appears to be capable of existing in two different physical states. The white fumes that are first obtained in the course of its preparation condense into long prismatic crystals, which melt at 62° F. to a colorless, mobile liquid, boiling at 112.8° F. Upon standing, these prismatic crystals are said to change into needle-like forms, which, when heated to about 122° F., pass directly into the gaseous state. Weber has shown that this second form is not observed unless the trioxide contains some measurable quantity of sulphuric acid, due to the action of the trioxide itself upon moisture. Sulphur trioxide has a powerful affinity for water, in which it dissolves with a hissing noise and the formation of sulphuric acid, as indicated by the equation $H_2O + SO_3 = H_2SO_4$. The reaction is accompanied by the liberation of a great deal of heat.

Sulphur combines directly with carbon, at a red-heat, with the formation of a substance known as "carbon disulphide" (or "carbon bisulphide"), which has the chemical formula CS_2. The vapor that is thus produced may be condensed to a very volatile, mobile liquid, possessing a high dispersive action upon light. Carbon disulphide freezes at about — 166° F., boils (under a pressure of one atmosphere) at 115° F., has a specific gravity of 1.29 and a specific heat of 0.247, and is used as a solvent for resins, sulphur, phosphorus, gutta percha and many other substances that do not dissolve in water. It is almost insoluble in water, but mixes readily with alcohol, ether and many kinds of oil. It is exceedingly inflammable, and its vapor forms explosive mixtures with air. The vapor of carbon disulphide takes fire, when heated in contact with air to 300° F., and this circumstance, taken in connection with the volatility of the substance and the explosiveness of its vapor when mixed with air, renders the use of the disulphide exceedingly dangerous in the presence of any sort of a flame, or even in the presence of bodies heated as hot as 300° F. As ordinarily met with in commerce, carbon disulphide possesses an exceedingly offensive odor; but this is due to impurities, and when these are removed, the pure disulphide has an ethereal odor, which is not objectionable. The vapor of carbon disulphide is poisonous, even when greatly diluted with air.

The known compounds that contain sulphur in combination with two or more other elements are almost innumerable, as are also the uses to which sulphur is put in the arts. Among the simpler compounds containing sulphur with two or more other elements, the various salts of sulphurous and sulphuric acids are exceedingly important. For data concerning sulphur black and the sulphur compounds that are in general use in the coal tar color industry, consult Cain and Thorpe, 'The Synthetic Dyestuffs and Intermediate Products'; also Wahl and Atack, 'The Manufacture of Organic Dyestuffs.'

ALLAN D. RISTEEN.

SULPHUR, Medical Uses of. Sulphur is prepared in various ways for use, both internally and externally, in medicine. It is used in the forms of washed, precipitated or milk of sulphur, and sublimed sulphur, or flowers of sulphur, corresponding to the manner of its preparation from crude sulphur — by washing, precipitation, or sublimation. The precipitated sulphur is regarded as the most efficacious, perhaps because of its finer division, which is chemical instead of mechanical. It is prepared by boiling equal parts of sulphur and freshly slacked lime for an hour, and then adding dilute hydrochloric acid until the alkalinity almost disappears. The sulphur precipitates as a white powder and is washed, and dried at a low temperature. Precipitated sulphur is much employed as a mild laxative, taken in medicinal doses and by its action facilitates evacuation in cases where intestinal or rectal disorders painfully interfere. Sulphur is also a valuable remedy in certain blood-diseases, chronic skin-diseases, chronic bronchitis, chronic rheumatism, etc., both internal administration — especially in the form of mineral waters containing sulphur — and sulphur baths being often efficacious. The administration of sulphur in obstinate chronic cases of many diseases often works such a change in the patient's condition as to give potency to other remedies given without effect. As a parasiticide, and especially in skin affections, ring-worm, itch, etc., sulphur ointment is a specific, or at least an active curative agent.

SULPHUR DIOXIDE. See LIQUEFIED AND COMPRESSED GASES.

SULPHUR DYESTUFFS. See COAL-TAR COLORS.

SULPHUR SPRINGS, Tex., city, county-seat of Hopkins County, on the Missouri, Kansas and Texas, and the Saint Louis Southwestern railroads, about 240 miles northeast of Austin, the capital, and 75 miles northeast of Dallas. It is in an agricultural and stock-raising region and has an extensive domestic export trade in cotton products, wheat, corn, fruit (peaches and plums), honey, poultry and livestock. It has two national banks with a combined capital of $200,000. The educational insitutions are the Central College (Methodist Episcopal, South), opened in 1876, and public schools. Pop. about 5,151.

SULPHURETTED HYDROGEN (H_2S), a gaseous compound of hydrogen and sulphur, found abundantly in nature in gases issuing from crevices in volcanic regions, and occasionally in natural gas. It is one of the common products of decomposition of vegetable substances, especially those of the leguminous family. It occurs in illuminating gas, from which it is scrupulously removed at considerable expense. It is prepared on a large scale by heating together equal parts of vaseline or paraffin and sulphur.

Sulphuretted hydrogen is a colorless, inflammable gas, burning with a bluish flame, and having an extremely offensive odor, similar to that of rotten eggs. It is very poisonous; when inhaled in small quantity producing nausea and headache, and in large quantity, asphyxiation. One part of the gas in 200 parts of air is fatal to horses, and one part of gas to 800 of air is fatal to dogs. It is soluble in water in the proportion of 4.4 volumes of gas to 1 volume of water at 32° F. At higher temperatures less of the gas is held in solution. Alcohol at 32° dissolves 17.9 times its own volume.

The aqueous solution of sulphuretted hydrogen is known as hydrosulphuric acid. It smells of the gas, and decomposes on standing, depositing sulphur, and the hydrogen oxidizing into water. Its solution in glycerine, however, keeps good for a long time.

The gas may be liquefied at ordinary temperatures by submitting it to a pressure of 17 atmospheres — that is, about 250 pounds to the square inch. Liquid sulphuretted hydrogen is a colorless, mobile liquid which freezes or soldifies at — 117° F., and boils at — 79°. In its liquid form it is nearly inert chemically.

Sulphuretted hydrogen is used in large

quantities in the manufacture of sulphuric acid to remove the arsenic which is found in larger or smaller percentage in all acid made from pyrites. It is also used to precipitate copper from solutions containing salts of copper, and for precipitating gold and silver from sweepings and other waste material. In the chemist's laboratory it is one of the most valuable reagents.

SULPHURIC ACID, or OIL OF VITRIOL, a common and exceedingly important oxy-acid of sulphur, having the chemical formula H_2SO_4. It was first prepared by Geber, in the 8th century, by distilling alum; and in the 15th century it was manufactured by burning sulphur with saltpetre, though the identity of the product so obtained with that described by Geber was not established until near the end of the 16th century. Considerable quantities of sulphuric acid were formerly manufactured by the distillation of ferrous sulphate, the practice of this method dating from the early part of the 18th century. At the present time practically all of the sulphuric acid that is used is prepared from sulphur dioxide gas, either by the «chamber process,» or by the more recently perfected «contact process,» both of which are described in this article.

When pure and free from water, sulphuric acid is a colorless liquid with an oily appearance, and a specific gravity of 1.89. It may be readily frozen, the solidified acid melting again at 50.9° F. It exhibits the phenomenon of surfusion to a marked extent, and the liquid acid can be cooled, much below the melting point here given, without inducing solidification; but if a crystal of the solid acid, or a small amount of sulphur trioxide, be added to the supercooled fluid, crystallization begins at once, and the temperature rises until it becomes 50.9° F., after which no further solidification occurs. The presence of a trace of water in the acid lowers the freezing point nearly to 32° F. If five parts (by weight) of sulphuric acid be mixed with nearly one part of water, and the solution is cooled by a freezing mixture, a definite hydrate of sulphuric acid, having the composition $H_2SO_4 + H_2O$, crystallizes out at 45° F. Another solid hydrate, having the composition $H_2SO_4 + 4H_2O$, may also be prepared by cooling, to a much lower temperature, a mixture of sulphuric acid and water, containing 57.6 per cent of water. Several other hydrates are also believed to exist, and special study has been expended upon them, on account of their importance in the illustration of the «hydrate» theory of solutions. (Consult Mendeléeff, 'Principles of Chemistry,' Vol. II). Sulphuric acid has no really definite boiling point. It begins to boil at about 550° F., the distillate containing sulphuric acid, water and sulphur trioxide. (See SULPHUR). The temperature of the liquid may be raised to 640° F., however, before a state corresponding in definiteness to the boiling point of water is attained, the vapor that passes off then consisting entirely of water vapor and free sulphur trioxide. At higher temperatures the decomposition is even more complete. Thus if a stream of the acid be allowed to flow over redhot bricks, it is broken up into sulphur dioxide (SO_2), free oxygen and water-vapor. If the gases resulting from this decomposition are passed through cool water, and the steam that they contain is condensed and the sulphur dioxide removed by solution, a supply of pure oxygen gas is obtained. Pure anhydrous sulphuric acid has a specific heat, at ordinary temperatures, of about 0.34, and a coefficient of expansion (Fahrenheit scale) of about 0.000310. The concentrated acid is a powerfully corrosive poison, destroying organic tissues rapidly, and even charring paper and wood. It is also poisonous (though far less violently so) when administered in any considerable quantity in a highly dilute form. Concentrated sulphuric acid has a powerful affinity for water, its combination with water being attended by the evolution of a large amount of heat. The strong acid is used as a drying agent, for removing moisture from gases. For this purpose it is sometimes sufficient to allow the gas to stand for a time in a receiver containing a dish of the concentrated acid; but a more effective mode of procedure consists in passing the gas through tubes that are partially filled with fragments of pumice that have been wetted with the acid.

Chemically, sulphuric acid is dibasic, either or both of its hydrogen atoms being replaceable by metals or other bases, the compounds that are thus formed being termed «sulphates.» With the metals of the alkalis (which are monovalent), sulphuric acid therefore forms two kinds of sulphates, which may be sufficiently illustrated by the potassium salts. If one of the hydrogen atoms of the acid is replaced by potassium, the resulting salt, $HKSO_4$, is called «hydrogen potassium sulphate,» or «acid potassium sulphate»; while if both are replaced, the resulting salt has the formula K_2SO_4, and is known as «normal potassium sulphate.» Many of the sulphates of the metals occur native in large quantities, and many of them are of great value in the arts. Those that are of especial importance are described, in this encyclopedia, under the metals (or other bases) with which the acid is combined. The sulphate of barium is perhaps the most insoluble salt known. It is formed whenever a soluble barium salt (such as the chloride) is added to a solution of a soluble sulphate; and its formation constitutes a valuable test for sulphuric acid and the sulphates. See CHEMICAL ANALYSIS.

When sulphur trioxide is dissolved in anhydrous sulphuric acid in the proportion of one molecule of the trioxide to one of the acid, a definite compound having the formula $H_2S_2O_7$ (or $H_2SO_4.SO_3$) is obtained. When pure, this substance is known as «pyrosulphuric acid.» It is a dibasic acid, forming salts which are termed «pyrosulphates,» but which are of comparatively little practical importance. Pyrosulphuric acid forms large crystals, which melt at 95° F., and it is easily decomposed by heat into ordinary sulphuric acid and free sulphur trioxide. Fuming sulphuric acid (now commonly known in the arts as «oleum» but formerly called «Nordhausen oil of vitriol») consists of a mixture of pyrosulphuric acid and ordinary sulphuric acid and may be regarded as a solution of sulphur trioxide in sulphuric acid, the trioxide not being present in sufficient quantity to convert the ordinary acid entirely into pyrosulphuric acid. It fumes strongly in the air, gives off sulphur trioxide when heated, and is prepared by the «contact process,» described in this article.

The uses of sulphuric acid in chemistry and in the arts are past enumeration; for this acid is one of the most important chemical substances known, and it is employed is so many industrial processes that it has been said that the wealth and prosperity of a nation can be estimated from its consumption of sulphuric acid. About half of the total quantity manufactured in the United States is consumed in the preparation of fertilizers. The two general methods now in use for manufacturing the acid are described in this article.

The sulphur used for the manufacture of sulphuric acid is obtained (1) from the gases generated by burning iron pyrites (FeS_2), (2) from the sulphur deposits of Louisiana, Sicily and elsewhere, and (3) to a very limited extent from the waste gases given off by sulphide smelters. At the present time pyrites is the most important source, but it is probable that smelter gases will be utilized to a greatly increased extent in the future, and they may eventually compete with pyrites. The sulphur dioxide that is now wasted by discharging the fumes from smelters into the air would far more than supply the United States with sulphuric acid. Moreover, the fumes are exceedingly objectionable, and they are destructive to vegetation.

The fundamental principles in the manufacture of sulphuric acid are (1) to oxidize sulphur or a suitable sulphide, so as to obtain sulphur dioxide, SO_2; (2) to further oxidize this to the trioxide, SO_3; and (3) to effect the combination of the trioxide with water, in accordance with the equation $SO_3+H_2O=H_2SO_4$. In attempting to carry out the second of these processes, however, we are confronted by the fact that sulphur dioxide does not readily take up oxygen, so as to become completely converted into the trioxide. To effect this oxidation we are in fact compelled to resort to one or the other of two expedients: (1) To mix a certain amount of an oxide of nitrogen with the sulphur dioxide and air — the oxide of nitrogen then acting as a sort of «carrier», taking up oxygen from the air and passing it on to the sulphur dioxide; or (2) to subject a mixture of air and sulphur dioxide to the action of a suitable catalyzer. The first of these expedients is used in the «chamber process» and the second in the «contact process.»

The first step in the manufacture of sulphuric acid is to provide a suitable supply of sulphur dioxide gas. This is usually obtained by burning sulphur or iron pyrites in a special furnace and considerable skill and judgment are required in this part of the operation, to obtain gases of proper composition. It is also important to minimize the quantity of dust that the gases carry over into the later parts of the process. Settling chambers, baffle plates, centrifugal separators, parallel-plate separators, and filtration through piles of marbles or other loosely aggregated solid lumps are among the devices used for the removal of the dust.

Chamber Process.— In manufacturing sulphuric acid by the so-called «chamber process» the hot gases from the burners (consisting of air, sulphur dioxide and moisture) pass first over «niter pots,» which contain nitrate of soda and sulphuric acid, and which give off the nitric oxide gas that is to act as an oxygen carrier. Then, after passing through the dust-removing apparatus, the gases are passed upward through a tower (technically known as a «Glover tower») that is loosely filled with fragments of coke, pumice, acid-proof stoneware or other inert material to distribute the flow, and here they are met by a downward stream of aqueous sulphuric acid obtained from a later stage of the process and containing oxides of nitrogen in solution. The precise reactions that occur cannot be discussed here, partly because they are complicated, and partly because they are not fully understood. The general effect, however, is to oxidize the SO_2 to SO_3, and the downward-flowing stream of weak acid dissolves the SO_3 and thereby becomes stronger. In certain plants of recent design the oxidation of the sulphur dioxide and the absorption of the resulting trioxide are carried out in a series of Glover towers, without the use of chambers of any sort; but it is usual, after the gases have passed through one or two Glover towers, to cause them to enter large lead-lined chambers (from which the process takes its name), where the oxidation of the dioxide and the consequent strengthening of the acid are continued. Liquid sulphuric acid settles in the bottom of these chambers, and is drawn off from time to time. Steam or water is sprayed into certain of the chambers, as needed, to provide the H_2O that is required for the formation of the H_2SO_4. The gases coming from the last chamber are passed up through a «Gay-Lussac tower,» which resembles the Glover tower in general construction. The liquid that is sent down through this tower, however, is concentrated sulphuric acid, and its purpose is to absorb the nitric oxide gas that is present, thereby preventing its loss and diminishing the quantity of nitre that must be used in the early part of the process. Upon leaving this tower the gases (which then consist mainly of nitrogen and oxygen) enter a stack and pass off into the atmosphere. The acid that is drawn off from the bottom of the final Gay-Lussac tower contains oxides of nitrogen in solution, and is introduced (diluted, as may be necessary, with weaker acid) into the tops of the Glover towers. As the acid passes down through a Glover tower, however, the heat due to the reactions that occur, added to that which the entering gases already possess, drives off the nitrous oxides, and these keep returning upward through the tower with the sulphur oxides and air, while acid nearly free from nitrous oxides comes away from the bottom of the tower.

Sulphuric acid, as made by the chamber process (and especially when made from pyrites) is likely to be contaminated with lead, arsenic, nitrous oxides and many other substances. Certain of these may be removed in considerable measure by treatment with sulphuretted hydrogen. If an acid of high purity is required, however, it is better to make it by the contact process, presently to be described. When treated with sulphuretted hydrogen for the removal of impurities, the acid should not have a greater specific gravity than 1.4, corresponding to about 50 per cent of actual H_2SO_4, and must be diluted to this strength if it is already stronger. After the removal of the arsenic the purified acid is concentrated by evaporation if a strong product is required. The evaporation may be carried out in leaden pans, but a better product is obtained by effecting the concentration in platinum stills. Owing to the high cost of platinum, however, it is common to perform the evaporation in a series of evaporating dishes constructed of fused silica. These are arranged like a flight of steps, the lip of each one projecting out over the next dish. below. A slow stream of acid is kept running down through the cascades of dishes, while heat is applied to each dish from below. When an apparatus of this kind is properly arranged and operated it gives excellent results. Hoods should be arranged over the dishes, however, to take up the vapors that are given off and dispose of them in some proper way.

The Contact Process.— In the contact process for the manufacture of sulphuric acid, the sulphur dioxide is caused to combine with the oxygen of the air by bringing the mixed gases into contact with finely divided platinum, or with platinized asbestos. The catalytic action of platinum (that is, its power of inducing combination in this way, without being itself consumed or otherwise permanently affected) was discovered by Sir Humphrey Davy, in 1818; and in 1824 Doebereiner showed that finely divided platinum can effect the ignition of a jet of hydrogen, when this gas impinges upon it in contact with air. Peregrine Phillips, of Bristol, England, first produced sulphur trioxide by utilizing the catalytic effect of finely divided platinum upon a mixture of oxygen and sulphur dioxide, taking out a patent for this process in 1831; and Schneider, in 1848, made a working model of an apparatus for manufacturing sulphuric acid by this method. Since that time many attempts have been made to make the contact process practicable for the manufacture of sulphuric acid, and many other catalytic agents have been tried besides platinum. It was not until about 1898, however, that the various practical difficulties involved in the process were satisfactorily overcome, largely through the labors of Herr Knietsch of the Badische Anilin und Soda-Fabrik, a German company for the manufacture of chemical substances of nearly every kind. It was found that the prime condition of success in the application of the contact method is that the gases that are treated shall be absolutely free from dust, arsenic, mercury and certain other substances. The gases from the pyrites-roaster are cooled very slowly and are then purified by filtration and washing. When passed to the tubes containing the platinized asbestos that is used as the catalytic agent, 100 volumes of the roaster-gas contain 7 volumes of sulphur dioxide, 10 volumes of oxygen and 83 volumes of nitrogen (from the air). The catalytic platinum is maintained at a temperature of about 750° F., since it is found that at this temperature the production of sulphur trioxide is about 98 per cent of the theoretical production. The nitrogen that is present has no influence upon the reaction, when the apparatus is working properly. The sulphur trioxide that is produced by this method needs only to be dissolved in previously prepared sulphuric acid containing more or less water, in order to yield an acid that is quite pure. It might naturally be supposed that water would be the best absorbent for the trioxide; but it is found that an acid that contains from 97 to 99 per cent of H_2SO_4 is a better absorbent; and in the practical conduct of the process the trioxide is absorbed by an acid of this strength; the stronger acid that its solution yields being continuously drawn off and continuously replaced by fresh supplies of the 97 to 99 per cent acid, except when fuming acid of a very high degree of concentration is wanted. The minute details of the contact process are trade secrets and are carefully guarded.

The standard work on sulphuric acid manufacture is Lunge's 'Sulphuric Acid and Alkali.' Very good general accounts will be found, however, in Rogers' 'Manual of Industrial Chemistry' and Thorp's 'Outlines of Industrial Chemistry.'

Allan D. Risteen.

SULPHURIC ETHER. See Ether.

SULPHUROUS ACID, an acid having (probably) the formula H_2SO_3, and prepared by dissolving sulphur dioxide gas (see Sulphur) in water to saturation; the acid being formed by the union of one molecule of the dioxide with one molcule of water, according to the equation $SO_2 + H_2O = H_2SO_3$. Sulphurous acid has never been isolated, and is known only in its aqueous solution, in combination with bases in the form of the salts known as "sulphites," and as a solid hydrate. At 70° F. water dissolves about 35 times its own volume of sulphur dioxide; the solubility being greater at lower temperatures, and less at higher ones. When an aqueous solution of sulphurous acid is cooled below 41° F., a crystalline hydrate of the acid separates out, the composition of which is not definitely known. Sulphurous acid has the taste and smell of sulphur dioxide gas, and is strongly acid. It readily gives off sulphur dioxide gas, and upon standing in contact with the air it gradually absorbs oxygen and becomes converted into sulphuric acid. Its composition is also modified by the action of light, probably by the formation of a more complex oxy-acid of sulphur. It acts as a dibasic acid, combining with the oxides, hydrates and carbonates of many of the metals to form salts (that is, sulphites) which are readily decomposed by the addition of stronger acids, with the liberation of sulphur dioxide. It is used in the bleaching of silk and wool but not so much as formerly, having been largely displaced by hydrogen peroxide. When the hydrogen atoms of the acid are both replaced by a metallic base, the resulting salt is called a "normal sulphite"; and when only half of the hydrogen of the acid is so replaced, the salt is called an "acid sulphite," or a "bisulphite." Both of the sulphites of sodium are extensively used in photography; the normal sulphite having the formula $Na_2SO_3 7H_2O$, and the acid sulphite the formula $HNaSO_3$. (See Photography). Industrially, the bisulphites of calcium and of magnesium are of exceeding importance, since the aqueous solutions of these substances possess the power of dissolving the gummy matters by which the fibres of certain kinds of wood are cemented together. Upon this property, the "sulphite process" for the manufacture of wood pulp is based. (See PAPER). Calcium sulphite is also used in the brewing industry.

SULPICIANS, sŭl-pĭsh'ĭ-ạnz. See ORDERS, RELIGIOUS.

SULPICIUS SEVERUS, sul-pĭsh'ĭ-ŭs sĕ-vē'rŭs, Roman ecclesiastical writer: b. Aquitania, 363 A.D.; d. Marseilles, between 410 and 429. He was from a family of high rank and in the practice of the law at Toulouse attained a great reputation for learning and eloquence and led a gay though charitable life. The death of his wife led him to more serious pursuits. Having entered a monastery, he spent some years in preparing an abridgment of the scriptural narrative, which from the purity of its style was long a favorite textbook in the schools of the Middle Ages, but is liable to the charge of serious tampering with the facts, arising in part probably from the desire to rebuke in this guise some contemporary rulers. He continued this history, describing the destruction of Jerusalem and bringing the narrative down to his own time, under the title of 'The Chronicle of Sulpicius Severus,' in which he varies materially from Josephus. His other works are 'Life of Saint Martin, Bishop of Tours'; 'Three Dialogues' and a collection of letters. From the elegance of his Latinity he was called, not undeservedly, "the Christian Sallust." His works have been often printed.

SULTAN, *in Arabic,* signifies monarch, ruler. The title is borne by various Mohammedan rulers, while the Turkish emperor assumes the title of Sultan-es-selatin, 'Sultan of sultans.' The daughters of the sultan have also the title of sultan. The title of sultana is given out of Turkey to the chief concubines of the sultan, but no such title is in use for them in Turkey. If the mother of the sultan is living she is styled *sultan Valide.*

SULU, soo-loo', or **JOLO,** hō-lō', Philippines. (1) An archipelago, consisting of over 400 islands, forming the southern central portion of the Philippine Archipelago, lying between the parallels 4° 30' and 121° 52' N. lat. and the meridians 119° 25' and 121° 52' E. long.; area 1,029 square miles. The archipelago is surrounded by the Sulu and Mindanao seas on the north and west and the Celebes Sea on the south and east. The islands form a long chain extending from northeast to southwest and are divided into five principal groups: (1) Balanguingui; (2) Pañgutárang; (3) Sulu; (4) Tapul; (5) Tawi Tawi. The larger islands are generally high and of volcanic formation; the smaller islands are low and rest on coral; mountain chains traverse the islands of Sulu and Tawi Tawi. The larger islands are fertile; rice, coffee, chocolate, corn, hemp, saffron, indigo, sesame and cotton are cultivated, but not as a rule for export. The raising of horses, cattle and goats is an important industry; there is some metal working in the manufacture of chisels, knives, etc., and weaving for home consumption. The chief industry from the commercial standpoint is pearl and pearl shell fishing, large quantities of pearl shell especially being exported; other exports are shark's fins, beche de mer and native cordage. The trade is largely in the hands of the Chinese. The forests contain many of the most valuable woods of the East. The people of the archipelago are divided into four groups, according to their origin and customs: (a) The Guimbajanos, the aborigines living in the mountains; (b) the Malay and Visayan slaves; (c) the Samales; (d) the Moros proper, the dominating race. Mohammedanism is the prevailing religion; polygamy and slavery are recognized institutions. Piracy was formerly a regular occupation of the people and their depredations were carried as far as Singapore. (See MOROS). Spain never occupied but a few towns on the coast and the native government remained largely independent of Spanish dominion. When the islands were transferred to the United States, after the Spanish-American War, negotiations were immediately begun for establishing satisfactory relations between the United States government and the sultan of Sulu and his datos (or chiefs). In August 1899 a treaty was signed in accordance with which the sovereignty of the United States over the whole archipelagó was recognized, but the government of the sultan and datos continued under this supreme jurisdiction, the rights and religion of the Moros to be respected, with the following important stipulations: the United States shall occupy and control such parts of the archipelago as public interest demands; any person can purchase land with the sultan's consent; piracy shall be suppressed; American courts shall have jurisdiction except between Moros; the American government shall protect the island against foreign aggression. Pop. (estimated) 22,680. (2) A group of islands in the central part of the Sulu Archipelago, lying between the Balanguingui group on the north and the Tapul group on the south; area 380 square miles. All of the larger islands of this group are volcanic, each of them being formed of a central peak sloping to a narrow stretch of level coast land; the islets are generally rocks. All the staples of the archipelago are cultivated; a small amount of hemp and indigo is exported; but cattle raising and fishing occupy a larger number of the inhabitants. The trade between islands is by native craft; the port of export is the town of Sulu. Pop. 14,500. (3) An island, the central and largest one of the Sulu group; area 333 square miles. It is traversed from northeast to southwest by three nearly parallel mountain chains, between which lie fertile valleys; there are several important peaks, of which the highest has an elevation of 2,894 feet. There are numerous small streams; which are nearly or completely dry during the summer season. The climate is particularly good, the temperature being even and unusually cool for the latitude. The soil is fertile and is well cultivated; rice, however, is imported and the chief articles of export, as in the rest of the Sulu Archipelago, are the products of the fisheries. The mountains are heavily wooded and valuable cabinet woods are also among the exports. Under the American jurisdiction, a school has been established on the island. (4) A town, capital of the Sulu Archipelago, situated on the northwest coast of Sulu Island, 540 miles south of Manila. It was the ancient residence of the Sulu sultans, but scarcely a trace of the ancient Moro town remains; the present town was built in 1878 by the Spaniards. It is surrounded by a wall, within which the town is regularly laid out, with three principal streets, broad and well shaded. The houses are mostly well built and there is a large modern market house. It is the chief town and chief port of the Sulu Archipelago and carries on a large trade with Singapore and Manila, as well as a native inter-island trade. In the channel between the roadstead and Maroñgas is a pearl oyster bed, which employs a large number of fishing boats and the town is the centre of this industry.

SULZBERGER, sŭlz'bĕr-jĕr, **Mayer,** German-American jurist: b. Heidelsheim, Germany, 22 June 1843. During the Revolution of 1848 his father came to America with his wife and family, settling in Philadelphia in 1849. He received his early education at the public schools where he graduated in 1859 from the Central High School, being at the same time an apt pupil at home in Hebrew language and literature. On 16 Sept. 1865 he was admitted to the bar, where his career was brilliant and his commanding abilities received their recognition on his appointment as judge of the Court of Common Pleas (1895–1915), and presiding judge (1902–15). Judge Sulsberger edited *The Occident* for a year after its founder's death, was tendered the position of United States Minister to Turkey during President Harrison's administration but declined the honor, is prominently identified with Jewish charities and instructions, and is a trustee of the Baron de Hirsch Fund. He is the author of 'Am ha-Aretz' (the ancient Hebrew Parliament) (1909); 'The Polity of the Ancient Hebrews' (1912); 'The Ancient Hebrew Law of Homicide' (1915).

SUMAC, any shrub or tree of the genus *Rhus*. Some species are poisonous to the touch. (See PLANTS, POISONOUS). One of the most common innocent eastern species of America, and the largest, is *Rhus hirta*, the staghorn sumac, so called because its young, short branches are covered with down, in color and texture not unlike a deer's antlers «in the velvet.» The trees are not more than 30 feet high, but are apt to grow in clumps and have a tropical appearance, with their long pinnate leaves turning to vivid yellow and crimson in autumn. Their autumnal beauty is further enhanced by the torch-like panicles of fruits, small drupes matted together by the crimson plush of the hairs that cover them in to pyramidal bunches terminating the branches. These fruit-masses remain throughout the winter, and are a favorite food of chickadees, in spite of the fur and the acidulous taste. The sour flavor was taken advantage of by the Indians and colonists who made a cooling drink from the plant. The crimson hairs also yielded a red dye, when immersed in boiling water. The wood is yellow and handsomely veined, but is very brittle; it is, however, occasionally made into canes. The fragrant, or sweet-scented sumac (*Rhus crenata*), is a low shurb with aromatic leaves and large panicles of greenish, honey-scented flowers which bloom in spring and are a famous food for bees. *R. glabra* is the upland or smooth sumac, which is smooth and even glaucous; its leaves were added to the tobacco of the aborigines; and an efficient gargle is made from the refrigerant and astringent drupes. The dwarf black or mountain sumac (*R. copallina*), similar in size to the above species, and like them having panicles of bloom succeeded by scarlet masses of drupes, is more bushy in growth, forming low thickets in sandy or dry, almost sterile soil, and is peculiar in that the main stem of its compound leaves bears coriaceous wings between the leaflets. The latter are shining above, and pubescent beneath, and, like those of *R. glabra*, when dried are material for tanning. They are, however, said to be inferior to those of the *Rhus coriaria*, native to and cultivated in the Mediterranean regions, which are especially valuable for tanning fine leathers, as the light-tinted moroccos. They are collected, dried, and exported in great quantities in the shape of a fine dust. The Venetian sumac, or smoke-tree, is also used for the same purpose. (See SMOKE-TREE). The sumacs are very useful tree shrubs to the Indians of the western United States. The twigs of *Rhus trilobata*, the aromatic sumac, having small three-lobed leaves, are soaked, scraped and split, resoaked in water, and then woven into baskets., sometimes in conjunction with other materials. These light, straw-colored withes are used probably more than any material except the willows for native basketry. *R. diversiloba*, the poison-oak, although greatly dreaded by the Cherokees, who endeavor to conciliate it by addressing it as «my friend,» does not seem to injure certain Californian tribes so much. They even use it as medicine, sometimes poisoning themselves internally by the practice, and use twigs of it as water-sprinklers in sacred ceremonies; it is also a material for woven fabrics. Its juice, which turns black rapidly on exposure to air, is utilized as an intense black dye for basketry. *R. trilobata* likewise yields a dye. A strong decoction of the leaves and twigs is made, to which is added roasted pinyon gum and yellow ochre, forming a rich, blue-black fluid, which is practically an ink, the tannic acid of the sumac combining with the iron in the yellow ochre, and being strengthened with the carbon of the burnt gum. The lacquer or varnish of China and Japan is nothing but the sap of another sumac (*R. vernicifera*) or varnish-tree, cultivated in those countries. When the bark is cut, the shrub exudes a juice, darkening after exposure. When kept for some time this sap becomes thick and viscous, blackish-brown in color in one mass, but yellow-brown and transparent in thin layers. When properly applied in successive layers and dried, it becomes a natural varnish of great hardness and unalterability. Nut galls, or iron in solution, added to this, or gold and other metals, make the various kinds of lacquer or japanning, which it often takes years to perfect. Japan wax is a vegetable wax used chiefly for candles and obtained by crushing, steaming and pressing the drupes of this species and of the Asiatic *R. succedanea*.

SUMATRA, soo-mä'trạ, an island in the Indian Seas immediately under the equator. Its extreme limits are lat. 5° 45′ N., and 5° 55′ S.; long. 90° 40′ E., and 106° 5′ E. In the direction of its greatest length it extends from northwest to southeast. Its greatest length is about 1,000 miles, and its greatest breadth about 260 miles; its area is about 161,600 square miles. It ranks in magnitude as the second of the

Asiatic islands, Borneo being the first. The population is about 4,000,000.

Topography.— The west side of the island is mountainous, but the east side has a totally different character, and spreads out into interminable plains nearly as level as the sea. The mountains viewed from the west appear at first view to form a continuous ridge, but a closer examination reveals breaks in the chain, and discloses the fact that two or three ridges lie behind that which is mainly seen from the coast. This chain, known generally as Barisan, extends from the northwest of the island to Sunda Strait. The islands of Pulo Bras and Pulo Wai really form detached parts of it, and near them, at the northwestern end of the island, it attains a height of 5,663 feet in Mount Yamura. Farther south, but still in Achinese territory, are the lofty volcanoes Abong-Abong and Lusé, whose heights are estimated at over 11,000 and 12,000 feet respectively. Mount Ophir, close to the equator, is an extinct volcano 9,610 feet above sea-level. Not far to the south is Mount Merapi, one of the most violent of Sumatran volcanoes. Other notable peaks are: Talang (8,343), an extinct volcano, from which the natives obtain sulphur; Indrapura (12,000), the highest peak yet ascended in Sumatra; Mount Paung; Mount Kaba (5,413); Mount Dempo (10,562), an active volcano; and Mount Tangkamus (7,422), near the Straits of Sunda. Granite, slates, clay-schists and similar rocks abound, and limestones of Carboniferous age occupy much of the surface. The Tertiary formations cover a very large area. All the peaks seem to be volcanic. Various metals have been found in the island, and excellent coal is known to be abundant.

Rivers and Lakes.— The rivers that flow toward the west are naturally short and of small importance for navigation, but those traversing the broad alluvial eastern slopes are long and deep. Many of them form large deltas. In order from south to north the most important are: the Musi or Palembang, about 400 miles long, passing the town of Palembang and entering the sea opposite the island of Banka, an important highway for trade; the Jambi or Batang-Hari, over 500 miles long, and navigable throughout most of its length, important as an outlet for the chief coal-fields; the Indragiri; the Kampar; the Siak, rising near Mount Ophir; the Rakan and the Batu Bara. Of the west-coast rivers the Singkel is the most important. The lakes of Sumatra are mostly mountain lakes, and not a few of them occupy the craters of extinct volcanoes. The largest are: Toba, 500 square miles in area, at the source of the Singkel River; Singkara and Maringin, about the centre of the island near the west coast; Korinchi, near Indrapura; and Danau. Sumatra is almost bisected by the equator, and in consequence the monsoons of its northern extremity have different directions from those of the southern end. During the periods when the monsoon is changing, navigation in the neighboring waters is impeded by squalls. The climate is generally of the usual tropical character, and is on the whole rather unhealthy.

Flora and Fauna.— The flora of Sumatra differs much from that of Java. It is very rich in forest trees, many of which yield valuable timber or other useful products, such as benzoin and gutta-percha. Pepper is the chief cultivated product. Sago and rice are also cultivated, and excellent tobacco and coffee are grown for export. The fauna of Sumatra in some respects resembles that of Borneo more closely than that of the countries with which it is almost in contact. The elephant and the tapir, frequent in Sumatra, are unknown in Java. The former island has the two-horned, the latter a single-horned rhinoceros. The orang-utan is found locally. The tiger occurs both in Sumatra and Java, but not in Borneo; Sumatra has also some species of deer and antelope, the sunbear, a peculiar kind of hare, and the muntjac. The most notable birds are the Argus pheasant, several trogons, bush-shrikes, rain-birds, pheasant-cuckoos, etc. Of the domesticated animals the most important by far is the pig, next to which rank the cow and the horse. The buffalo is more frequent in the low country, but is only valued as food, and never yoked for labor as in Java. The horse of the highlands is small, but vigorous and capable of enduring much fatigue.

Government.— The authority of the Dutch extends, nominally at least, over the greater part of the island, and may be considered to be real over all the coast districts. In the interior, however, there are still considerable tracts under native rulers, or forming village confederations, over which the Dutch exercise little or no authority. The Dutch possessions are divided into six chief divisions. The government of the west coast, with an area calculated at 31,649 square miles, extends along the middle portion of the west coast, and includes Padang and other districts. The governor resides at Padang. The residency of Benkulen lies to the south of that of the west coast, and has an area of 9,399 square miles, Benkulen being the capital. The residency of Lampong comprises the southern districts of the island on the Strait of Sunda, and has an area of 11,284 square miles. The residency of Palembang on the east coast, with an area of 53,497 square miles, lies to the north of Lampong, and has as its capital the large town of Palembang. The district of Indragiri, farther north, belongs to the residency of Riou, which is named after the island of that name. Farther north is the residency of the east coast, its area being estimated at 35,312 square miles; and at the extreme northwest that of Achin, which still remains semi-independent, area 20,471 square miles.

Racial Characteristics.— Sumatra is inhabited by a very mixed population. Malays collected from every quarter of the archipelago inhabit the coast. Hindus appear to have settled at an early age in the north, and to have modified the Malay type of the Achinese. The Arabs in the island, though few in number, have always formed an important class. Chinese are numerous, particularly on the east coast. Northwest of Palembang the Orang-Kubu live in a savage state, and shun any intercourse with the neighboring tribes. The Orang-Kubu must not be confounded with the people of Menankabu, a pure Malay race inhabiting the highlands of Padang, which some are disposed to consider the original seat of the Malay stock. The Battaks are a peculiar and interesting race. Like the Malays they are of short stature, but they differ from the former in being strongly built and well proportioned. The art of writing has been known among the Battaks from a date beyond the reach of tradition. Their characters are peculiar, and also their mode of writing, for they begin at the bottom of the page at the left-hand side, and place letter above letter in a vertical column till they reach the top, when they return to the bottom. Their ancient books are written in a brilliant ink on paper made of the bark of trees, but now they scratch their writings on slips of flattened bamboo. Among all the indigenous tribes of Sumatra the characteristic political tendency is one that could have originated only in the recesses of the mountains. Every village affects independence, but the villages form confederations. The native tribes of Sumatra have no temples and no priests. They are said to believe in the existence of an evil spirit and of demons who haunt the mountains. On the coasts Buddhism appears to have been introduced at an early age, but it has since been completely superseded by Mohammedanism, which, among the Malays, however, is of a very relaxed character.

History.— The first European who visited the island of Sumatra is said to have been Niccolo di Conti, who came there before 1449. In the beginning of the 16th century it was visited by the Portuguese, but no Europeans obtained a firm footing on the island until the Dutch established a factory on the west coast at the end of the 16th century. In 1666 the Dutch took possession of Padang, and soon after enlarged their territories by treaty with the Sultan of Achin. Since that time they have gone on continually consolidating and increasing their dominion much more by negotiation than by force of arms. Their last important accession of influence on the island was gained by a treaty with the kingdom of Siak, concluded in 1868, by which they obtained the virtual control of that state. In 1685 the British formed a settlement in Benkulen, and in 1811 they seized the Dutch possessions on the island. These were, however, restored in 1815, and in 1824 Benkulen was given over to the Dutch in exchange for Malacca. A treaty concluded between the Dutch and English governments in 1834 left the Dutch free to make what treaties they pleased with the native powers in the island of Sumatra, the same liberty being allowed to the British on the Malay Peninsula; but the right of the Dutch to make advances in the island by conquest and annexation was not then recognized. This right was, however, conceded in the treaty of February 1871, in return for the cession to the British of the Dutch possessions on the Gold Coast; and in accordance with this permission the Dutch despatched an expedition against Achin. In April 1873, the forces of the two powers came into collision, and a war ensued which dragged on for a number of years, caused severe losses to the Dutch, and terminated only in the nominal subjugation of Achin. In August 1883 the tidal wave that accompanied the terrific volcanic outburst in Krakatoa, swept with destructive effect the south coast of Sumatra, a total change in the aspect of the Straits of Sunda also resulting from the eruption. Consult Bernard, 'A travers Sumatra' (Paris 1910); Breitenstein, H., 'Sumatra' (Leipzig 1902); Cabaton, A., 'Java, Sumatra and the other Islands of the Dutch East Indies' (New York 1914).

SUMBAWA, soom-bä'wä, an island belonging to the Sunda group, in the Indian Ocean, east of Java, containing 5,192 square miles. The island is mountainous and of extraordinary profile. The volcano of Tomboro or Tombura, 8,940 feet high, is near the northern coast and famous for its eruptions. The island consists of two parts, with two rulers or sultans, who acknowledge the sovereignty of Holland. There are few streams. The chief products are rice, cotton, tobacco, tropical fruits and sappan-wood. Of domestic animals deer and swine are plentiful, and the finest horses of the Indian Archipelago are reared here, and exported. Edible birds' nests are found on the coasts; gold, silver, saltpetre and pearls from the mines and waters, respectively. On the north coast there is a good harbor, and here stands the town of Sumbawa. The inhabitants are Malays and Mohammedans. Pop. 75,000.

SUMBUL, an East Indian name of the spikenard (*Mardostachys*), and also of the valerian, but, more particularly of *Ferula sumbul*, the commercial drug also known as musk-root. The last is an umbelliferous plant, with dissected leaves. The roots reach the pharmacists in transverse segments, light and spongy in texture, with a thin, brown, wrinkled and fibrous skin, but whitish inside. The taste is bitter and balsamic, the odor strong and like musk. Sumbul is used therapeutically as a stimulant and nervine, and was of importance long before its botanical history was known.

SUMERIAN LANGUAGES. The pristine, agglutinous language spoken by the earliest, prehistoric people of Mesopotamia, a region generally referred to in surviving documents as *mat Shumeri u Akkadi*, i.e., land of the Sumerians and Akkadians, probably the biblical Shinar or Shin'aar. It was a non-Semitic people thus dwelling in the lowlands between the Euphrates and Tigris, as comparative philology has of recent years proved beyond a doubt. True, the eminent French scientist, Joseph Halévy, in 1876, and certain of his followers, contended for the non-existence of any such early non-Semitic population. Halévy attempted to account for the early Sumerian documents in cuneiform characters by assuming a Semitic, priestly, secret style of writing, a cryptography, and cited as a parallel the Egyptian hierarchical writing. However, this has since been amply disproved. The meaning of the word Sumerian, or rather Shumerian, refers to the word «reed,» «reedy» in that idiom, evidently because of the marshy, reedy landscape. The Sumerians and the Akkadians seem to have formed one people, though originally they may have come from different parts of the earth. The Sumerians, at any rate, as their tongue, an agglutinous one, shows, must have come from the north, possibly the Ural region, as there were no words or word pictures and phrases in it symbolizing fauna and flora of the subtropics.

So far as the records go, the Sumerians were the earliest nation, and their system of writing, the cuneiform, is likewise the earliest we know of. Later on, the Sumerians, by cohabitation and intermarriage, were gradually amalgamated with the later Semitic invaders, Arab tribes originally coming chiefly from the island of Bahrin. The Sumerian tongue likewise coalesced in a manner with the Semitic idiom, the latter being superimposed on the former, much as the Norman French was superimposed on Anglo-Saxon, and thus the later Babylonian was formed. Sumerian civilization and language, however, were highly developed before the coming of the Semites, as well in the construction of the latter as in its religion, its religious observances, its legislation, arts, science and social life. The Semitic Babylonians imbibed the earlier civilization.

Nevertheless, the «Sumerian problem,» so-called, had for generations perplexed Assyriologists. Oppert, in 1854, first made modest, though in a measure successful attempts to unravel its mysteries. But Prof. Paul Haupt, assisted by Profs. Peter Jensen and Zimmern, somewhat profiting by these initial labors, steadily hewed his way through these etymological brambles, and it is strikingly illustrative of the value of Haupt's pathbreaking labors that all subsequent phonetic and grammatical work in Sumerian has only tended to confirm Haupt's views in almost every instance. Haupt's «Sumerian Family Laws» and «Akkadian and Sumerian Cuneiform Texts» laid the foundation to all later researches. In the investigation of the Sumerian idiom no comparison should be made between Sumerian vocables and those of more recent agglutinous idioms, despite frequent tempting resemblances, such as in Turkish, for instance. Now and then, though, certain similarities are traceable with Esthonian and Finnish. Sumerian, as far as has been shown up to the present, must be held a language standing alone by itself, a «prehistoric philological remnant.»

To Prof. Friedrich Delitzsch is due the merit of having clearly shown the full meaning, the derivation and development of Babylonian cuneiform signs. They were, then, at first pure picture writing and finally grew into conventionalized ideographic and syllabic sign lists. The etymological labor involved in this process of gradual elucidation was surrounded with enormous difficulties.

Sumerian cuneiform was adopted at least about B.C. 7000. By B.C. 5000 we see it already highly specialized, and between B.C. 4000 and 3000 we perceive it applied to the transmission of the invading Semitic language, the Babylonian; and since then the Semitic Assyrians, the Medes, the Turanian Susites, and the Caucasian Armenians have all habitually used the cuneiform.

Besides other evidence tending in the same direction, perhaps the most convincing proof, from a philological point of view, that ancient Sumerian was a real idiom, of natural growth and wholly unartificial, may be found, aside from the internal phonetic changes, in the indubitably established fact that there were two dialects of it. These were the *Emeku*, the man's language, the noble, virile, though harsh form, and the *Emesal*, the woman's language, the softer. There were no geographical boundaries to these two dialects. In R. E. Brünnow's «A Classified List of all Simple and Compound Ideographs» (1889), it is also demonstrated that the Sumerian original idiom was of unaided growth. He and others point out that there were probably eight voice tones employed in Sumerian, similar to the Chinese of to-day, and that the intonation often determined the meaning. As a possible illustration may be cited: *a* = water, weep, moisture, dew, tears, inundation, irrigation; *ab* = dwelling, sea, road, and a grammatical suffix.

After Sumerian had ceased to be a living tongue it was, up to a very late period of Babylonia's existence, greatly used as a ritual one, and was read aloud at worship in the temples, much as is, for example, early Slavonic in Russian and other Orthodox churches to-day.

Author of 'America, Asia and the Pacific,' etc.

SUMMARY COURT. See LAW, MILITARY.

SUMMARY PROCEEDING, *in law,* a form of trial in which the ancient established course of legal proceedings is disregarded, especially in the matter of trial by jury. In no case can a party be tried summarily unless when such proceedings are authorized by legislative authority, as in a committal for contempt of court, the conviction of a person by justices of the peace, etc.

SUMMER, the season of the year which in the northern hemisphere generally may be said to comprise the months of June, July and August. The astronomical summer lasts in the northern hemisphere from the June solstice to the September equinox, during which time the sun, being north of the equator, shines more directly upon this part of the earth, and rises much sooner and sets later, which renders this the hottest period of the year. The period of greatest heat generally takes place in August, since the influence of the sun's rays has then been felt for a long time on the earth, and the wind blowing from the north becomes milder owing to a moderation of the temperature in the polar circle caused by the thawing of the ice. In the southern hemisphere the summer lasts from the December solstice to the March equinox.

SUMMER DUCK. See WOOD-DUCK.

SUMMER REDBIRD. See TANAGER.

SUMMER SCHOOL OF THE SOUTH, a school for teachers established at the University of Tennessee, Knoxville, in the summer of 1902. It was organized to supply the ever-increasing demand on the part of southern teachers for a summer school of high grade and adequate equipment for the best normal training. It receives its financial support from the General Education Board, from the University of Tennessee, from the citizens of Knox County, and from individual donations; the registration fee is small. All the buildings and full equipment of the university are given to the use of the school. The courses number over 150. The work is arranged in the following groups: (1) Common school subjects and methods, including kindergarten and primary grades; (2) psychology and pedagogy; (3) high school and college subjects; (4) rural schools and county supervision; (5) city school supervision; (6) general lectures; (7) library work and educational exhibits; (8) campaigners' conventions. Teachers have free choice of subjects, but are advised not to take work for more than three or four periods a day. The instructors and lecturers are men and women of recognized scholarship and authority, coming from various institutions and different sections of the country. The school has a large attendance and has proved a marked success.

SUMMER SESSIONS. The summer school responds to a specific need. Professional people such as teachers, ministers, doctors and also other workers like social workers, Y. M. C. A. and Y. W. C. A. secretaries and even business men and women, find the summer vacation period a suitable time to undertake advanced educational work in specially selected subjects. The other seasons of the year are devoted to exhaustive labors; the summer study is both recreative and inspirational and may be made to contribute to professional advancement. When systematically planned and extended over a period of years, such summer work may even have recognition in the form of academic credit or academic degrees.

Of the persons listed above teachers in service make the most insistent demand for summer courses. New methods and new educational movements continually call for special short courses. For example, the Montessori method, or the Direct Method in Latin, may be studied to advantage in this way. Teachers may add to their regular accomplishments certain special, perhaps new, activities, such as domestic science and art, various phases of handwork, craftswork, physical education, elocution, etc. Again, a famous teacher from a foreign land may offer courses during a summer session, affording attractive opportunity for special investigation, or for getting a particular method or a particular form of interpretation in a known field. It is a growing practice among municipal school authorities to offer special inducement to public school teachers to take summer courses. The elementary teacher more particularly, but the high school teacher also to some extent is tempted to stagnate. After teaching the same subject several years, the dull monotony of the process deadens the ambition. This is especially true where knowledge of method is more important than knowledge of subject matter as in the elementary school. The opportunity for summer study is especially inspiring in such cases.

Physicians also find it desirable to investigate new treatments, to observe and learn new methods in surgery, to get a new point of view in the profession. The summer session or clinic may give the desired opportunity. Even the farmer demands special opportunities for the observation of special methods and practices and looks to a short session of the Agricultural College to supply his needs. In this case, however, the winter may offer greater advantages.

Recently efficiency experts have advocated the continuous use of educational plants. The idle recitation halls, laboratories and libraries are considered uneconomical. This idleness may continue from 15 June to 15 September, 25 per cent of the educational year. Apparently this records only 75 per cent efficiency for faculties, plants and investments. For the faculty the inefficiency is only apparent since the fallow months are essential to the later increase in fertility and resourcefulness. Of the plant, however, and of the invested funds, the charge of inefficiency is partly true. If a separate faculty can be provided to use the equipment during the summer, a faculty that has its fallow months at another season of the year, then an all year program becomes efficient.

The Four-Term Year.—A continuous session plan was devised at Chicago University by President William Rainey Harper, when that institution was first opened in 1892. It provides (1) four terms of twelve weeks each; (2) twelve terms completed work are required for graduation; (3) that a student may complete twelve terms in three years; (4) that a student may select any three terms as a year's work, devoting the other term to rest or business; (5) that a member of the faculty may elect to be absent from college duties during any one term of any calendar year.

This plan accomplishes all that summer sessions usually seek to do and much more. (1) It incorporates the summer session as an integral part of the academic year. The summer term differs in no essential respect from any of the other terms. (2) Students may begin their college or university courses four times each year. (3) The university equipment is in continual use. (4) The university can use the best men from other institutions in this country and even from foreign universities.

The continuous session plan or the four-term year is the logical development of the summer school movement. Its sponsor, Chicago University, has used it continuously from 1892 to 1918. A quarter of a century has tested the plan thoroughly and has justified it. That few other colleges and universities have adopted it is no argument against it. It seems probable that acquaintance with its features and its satisfactory results will gradually lead to a wide if not universal use of it.

History of Summer Schools.— The Concord School of Philosophy was proposed by Ralph Waldo Emerson as early as 1840 and came to full fruition between 1879–85. The Harvard Summer School has lived from 1869 to the present. The Chautauqua Summer School began in 1874. A summer school of law was opened in 1870 by the University of Virginia. From these beginnings have grown innumerable schools. Not only do most of the colleges and universities conduct such schools but Chautauqua schools, Y. M. C. A. and Y. W. C. A. schools, music schools, tutoring schools, normal schools, library schools, etc., are meeting the growing demand for summer school facilities. According to the latest report (1916) of the United States Bureau of Education 674 schools were in session during the summer of 1915, 47 universities, 40 colleges, 90 normal schools, 39 other institutions, 458 independent schools.

All colleges and universities listed offer academic credit for work completed in the summer session. Of 90 normal schools listed, only 48 offer credit. The basis for such credit is 30 hours of recitations, implying 60 hours of preparation for each credit-hour. A student may usually earn four credit-hours in one summer session. Since a college year is given 15 credit-hours, it will require four summer sessions to earn a full credit-year.

The process is, therefore, slow, but thousands of students persist until they earn the coveted credit-year. Especially is this true of students whose college course was interrupted and who in this way complete work for the bachelor's degree; and many college graduates take this means of earning a master's degree.

A. R. Brubacher,
President of State College for Teachers, Albany, N. Y.

SUMMERS, George William: b. Fairfax County, Va., 4 March 1807; d. Charleston, W. Va., 18 Sept. 1868. He entered Ohio University at Athens, Ohio, in 1819 and graduated in 1826. He then studied law and was admitted to the bar in 1827. In 1830 he was elected a member of the lower house of the Virginia legislature and was later re-elected several times. In 1841 he was elected to the United States House of Representatives, and was re-elected in 1843. In 1850 he was elected to the Virginia Constitutional Convention and took a prominent part in framing the new constitution. In 1851 he was the Whig candidate for governor of Virginia, in the first popular election for governor in Virginia, but was defeated by Joseph Johnson, the Democratic nominee. In May 1852 he was elected judge of the eighth judicial circuit of Virginia, but resigned his office 1 July 1858. He was a prominent member of the «Peace Conference» held at Washington in the spring of 1861 and took an active part in defense of the Union. He was also elected a delegate to the Richmond convention which passed the Ordinance of Secession. In the convention he made an able speech in defense of the Union. At the opening of the Civil War he retired to private life upon his farm and thereafter refused to accept office but continued the practice of his profession. He wielded a large influence in western Virginia.

SUMMERS, sŭm'ĕrz, **Thomas Osmund,** American Methodist Episcopal (South) clergyman: b. near Corfe Castle, Dorsetshire, England, 11 Oct. 1812; d. Nashville, Tenn., 6 May 1882. In 1830 he came to the United States where he studied for the ministry and was «admitted on trial» to the Baltimore Conference, 1835. He was active in the organization of the Texas Conference, 1840, and later was sent to the Alabama Conference. He was professor of systematic theology at Vanderbilt University, dean of the faculty and pastor ex officio of that university. He has published 'Commentaries on the Gospels, the Acts, and the Ritual of the Methodist Episcopal Church (South)'; 'Seasons, Months and Days'; 'Talks, Pleasant and Profitable.' Consult 'Life' by Fitzgerald (1884).

SUMMERSIDE, Canada, town and port of entry of Prince Edward's Island, capital of Prince County, on Bedeque Bay and on the Prince Edward's Island Railroad. It is 40 miles northwest of Charlottetown and has an excellent harbor with anchorage for the largest vessels. There are flour and saw mills, manufactures of plows, etc., and is the centre of the recently developed fox ranch industry. Summerside has regular communication in summer by steamer with Nova Scotia and New Brunswick. Pop. 2,678.

SUMMERSVILLE, Ga., city in Richmond County and suburb of Augusta. It lies in a fertile valley 25 miles north-northwest of Rome, on the Central of Georgia Railroad. On account of its mild winter climate it is a popular winter resort. It contains a government arsenal and ordnance department. Pop. 4,361.

SUMMIT, N. J., city in Union County, on the Delaware, Lackawanna and Western Railroad, 20 miles west of New York and 12 miles west of Newark. It is in an elevated part of the county, about 450 feet above tide water. Summit was settled in 1795, and the first school was built the same year. The first church building was erected in 1840. It was incorporated as a township in 1869 and as a city in 1899. It is a purely residential community, noted for its beautiful scenery and delightful climate. The chief industries which contribute to the prosperity of the city are manufacturing silk goods, cultivation of roses, farming and the cultivation of fruit. Summit is a residential city, and has many New York and Newark business men among its inhabitants. The municipal improvements include gas and electric lights, pure water, an excellent tide water sewerage system, well-organized police and fire departments, free postal delivery and telegraph and telephone service. There are eight churches, Y. M. C. A. building and the Arthur Home for Blind Babies under the International Sunshine Society. The educational institutions are Kent Place School, for girls; Summit Academy, for boys; five public schools, one parish school and a free public library. The two banks have a combined capital of $200,000. The government is vested in a mayor and a council of seven members, who hold office for three years. Pop. 9,136.

SUMMONS, *in law,* an admonition to appear in court, addressed to the defendant in a personal action. It is the writ by which a personal action is always commenced. According to English law it need not state the form or cause of action, but it must contain the names of all the defendants, and must have endorsed upon it the name and address of the person taking it out, whether the plaintiff himself or his attorney. It is the duty of the person taking out a summons to serve it on the defendant in person; but if the judge is satisfied that reasonable efforts have been made to do this, and that the defendant knows that the summons has been issued against him, he may authorize the plaintiff to go on with the action without personal service.

SUMNER, Charles, American statesman: b. Boston, 6 Jan. 1811; d. Washington, D. C., 11 March 1874. His family was English in origin, Charles being a descendant in the seventh generation from William, who came to America about 1635 and settled at Dorchester, Mass. The Sumners lived in the same vicinity for the next 200 years and more, generally as farmers. The father, Charles Pinckney Sumner (b. 1776; d. 1839), graduated from Harvard in 1796. He was a lawyer, was married to Relief Jacob of Hanover, N. H., in 1810 and had nine children, of whom Charles was the eldest. The father took an active interest in politics, was clerk of the Massachusetts House of Representatives in 1806–07 and 1810–11 and from 1825 to 1839 was sheriff of Suffolk County. He was interested in the temperance movement and was strongly anti-slavery in feeling. He was fond of books, conscientious, earnest, grave and stern. It was not strange, then, that he brought up his son in the old Puritan style and the latter's career shows that he was greatly influenced by his father's training, views and character.

Charles was educated at the famous Boston Latin School, having as schoolmates Robert C. Winthrop and Wendell Phillips. His tastes were those of the scholar and he read widely and became proficient in the classics. He entered Harvard College in 1826, where he continued to excel in the classics, but also devoted much time to history and literature and perfected himself in oratory or «declaiming.» After a year spent in private study and diligent attendance on the lectures and orations of the great Boston orators, Webster, Everett, Choate and Channing, he entered the Harvard Law School in 1831 and received the personal attention and teaching of Judge Story, an old friend of Sumner's father. His plan of study was thus described in a letter to a friend: «Six hours, namely, the forenoon, wholly and solely to law; afternoon, classics; evening, history, subjects collateral and assistant to law, etc. Recreation must not be found in idleness or loose reading.» In January 1834 he entered the law office of Benjamin Rand in Boston. In February he made a journey to Washington, where he received his first impressions of slavery in the South. His first subscription for a newspaper was for Garrison's *Liberator*. While in Washington he heard Webster, Clay and Calhoun speak in the Senate, but he still thought he preferred law to politics. During the next three years, 1834–36, he practised law in Boston, but without remarkable success. His arguments were in the nature of learned essays rather than forcible presentations of the case in a manner to convince juries.

In 1837 he went abroad and spent three years traveling in France, England, Italy and Germany. In Paris, where he lived five months, he attended university lectures, visited the museums, galleries and historic places, attended the Chamber of Deputies and law courts, went into society and met many eminent persons. He next spent 10 months in England and met the famous men of the day, Carlyle, Wordsworth, Macaulay, etc. In Italy he studied Italian literature. Then he spent several months in Germany and finally returned to America in May 1840. His foreign travel unfitted him for his chosen profession, to some extent, and still further intensified his longings for the scholar's career.

During his absence abroad the slavery question had become a burning issue, though up to this time he had but slight interest in politics or in the great public questions of the period. From 1841, however, his letters commence to show evidence of more positive views on the slavery question and more determination to oppose the further spread and influence of this institution. His humanitarianism showed itself in his interest in popular education and in the support of Horace Mann, in the work for the blind, in that for the improvement of prison discipline and in his opposition to war under all circumstances. In 1843 he commenced to write against slavery, and contended, in opposition to many, that it was a *national* rather than merely a *local* evil: that the nation was responsible and that it might to a large extent remove the evil by abolishing slavery in the District of Columbia and in the Territories, by compelling the rendition of fugitive slaves, by preventing the slave trade, by remedying the laws of slave States which abridged the right of free negroes in free States, by stipulating the conditions of admitting new States and by amending the Constitution so as to abolish slavery. Sumner made his real début in public life by a Fourth of July oration in Boston, 1845, on the «True Grandeur of Nations,» in which he bitterly denounced wars of all kinds as dishonorable. Four months later he made his first anti-slavery speech at a meeting in Faneuil Hall to protest against the annexation of Texas.

In 1846–47 Sumner made several speeches in favor of the Whig party adopting an anti-slavery attitude. He wrote for the newspapers against the Mexican War; declared that it was unconstitutional, unjust and detestable, opposed further expenditures for it, called for the withdrawal of troops and opposed the opening of the territory to be acquired from Mexico to slavery. He joined the Free Soil party of 1848 and was nominated for Congress in October, but failed of election. When Webster, in his speech of 7 March 1850, refused to vote to exclude slavery from California and New Mexico, he became, in the eyes of many in Massachusetts, an apologist of slavery and this situation opened the door of the Senate to Sumner.

In Massachusetts the autumn campaign hinged on the question whether the State should approve the Compromise of 1850 and the course of Webster in supporting it. There was bitter opposition to the Fugitive Slave Law and the manner of its enforcement. Sumner made an important speech in Faneuil Hall 6 November against the Fugitive Slave law and demanded its repeal. This speech made possible his election as senator in January 1851, for in the State election the combined Democrats and

Free Soilers had a majority of the legislature and chose Sumner rather than Winthrop, the Whig candidate, as senator.

With the entrance of Sumner into the Senate in December 1851 a new force for anti-slavery agitation was present. He was an uncompromising, fiery, earnest and persistent antagonist of slavery. He was the spokesman of the anti-slavery forces in the Senate as Calhoun had been for the pro-slavery interests. Although the leaders of both parties were for peace, Clay and Webster on one side and Cass, Buchanan and Douglas on the other, nevertheless Sumner believed that the Compromise of 1850 was wrong and that «nothing can be settled which is not right.» It was not until August 1852, after both the Whig and Democratic National Conventions had declared their support of the Compromise of 1850, that Sumner spoke of the great question, viz., «Freedom National, Slavery Sectional.» His argument was to the effect that slavery was not recognized in the Constitution, that Congress had no power to establish it and that, therefore, it could not legally exist where the jurisdiction of the national government was exclusive; that the Fugitive Slave Law was unconstitutional and, therefore, should not be obeyed. This speech made Sumner the leader of the anti-slavery party and his doctrines were accepted as sound by its rank and file.

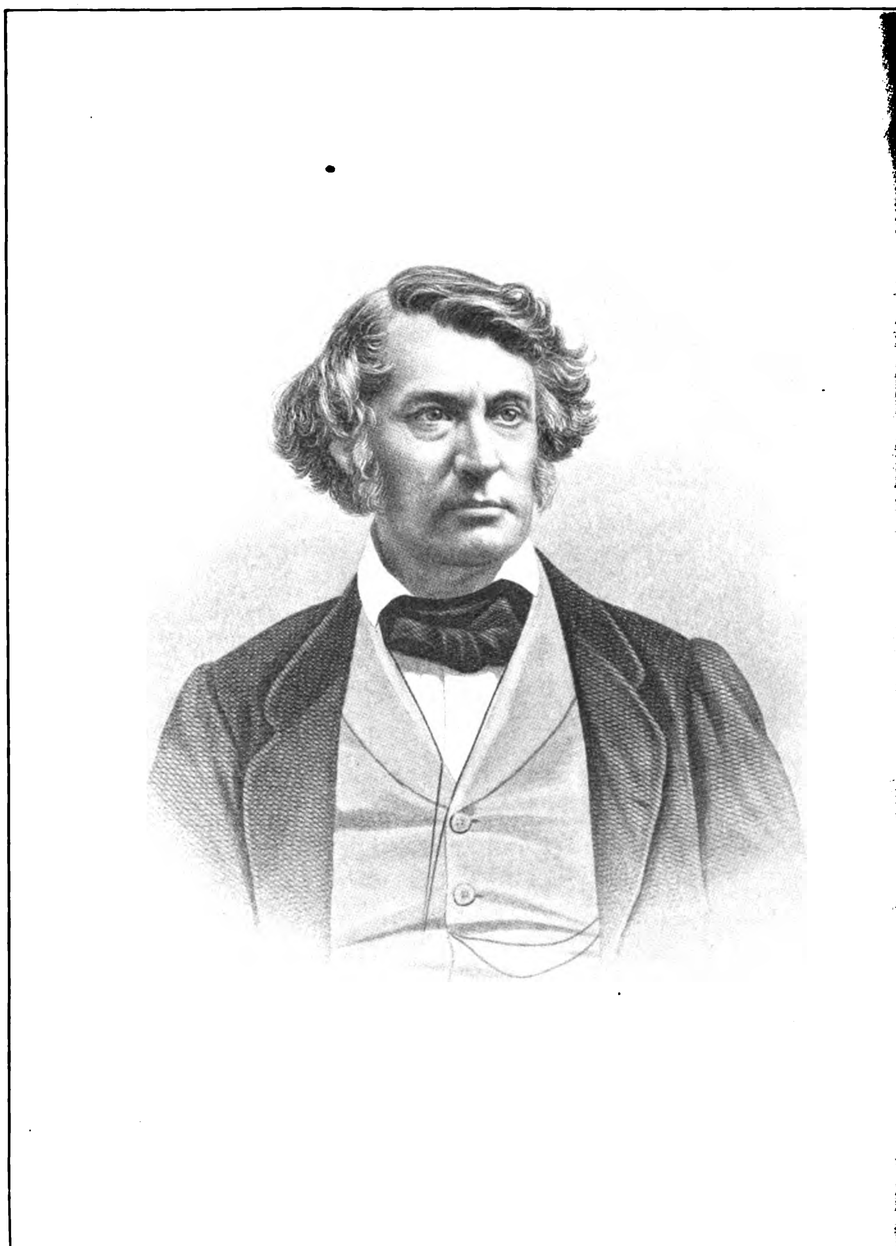
The next Congress, that commencing 5 Dec. 1853, was made famous by the passage of the Kansas-Nebraska Bill, which was designed to repeal the Missouri Compromise. It was on 23 Jan. 1854 that Senator Douglas introduced a bill dividing the Nebraska Territory into Kansas and Nebraska. This bill declared that the Missouri Compromise «was superseded on the principle of the legislation of 1850, commonly called the compromise measure, and is hereby declared in operation.» Sumner spoke against the bill 15 Feb. 1854 and declared that the Missouri Compromise was a binding contract. His speech on 26 June in reply to an attack on Boston and Massachusetts by Southern senators, particularly Senators Butler of South Carolina and Mason of Virginia, aroused great feeling.

The passage of the Kansas-Nebraska Act led to the formation of the Republican party. A Republican convention, composed mostly of Free Soldiers, was held at Worcester, Mass., 7 Sept. 1854 and Sumner spoke for the new party. He advocated resistance to the enforcement of the Fugitive Slave Law and advised the passage of personal liberty laws to nullify its workings. He justified his position by denying that the provision of the Constitution touching the rendition of «persons held to service or labor,» conferred any power on the national government «to establish uniform rules for the rendition of fugitives»; that therefore, each State had the right to determine for itself the extent of the obligation assumed. In consequence the Fugitive Slave Law was unconstitutional and the States had a right to act so as to secure for their citizens claimed as fugitive slaves the right of trial by jury and the privilege of habeas corpus. This view would give the States liberty to construe the Constitution and pass laws which their construction of the Constitution permitted. In case there was a conflict between the Supreme Court and the States in the construction of the Constitution, then no man «will voluntarily aid in enforcing a judgment which in conscience he believed wrong.» This was preaching revolutionary doctrine and was the most violent and extreme position which Sumner had taken up to this date.

In the second session of the 33d Congress, that commencing December 1854, Sumner endeavored to secure a repeal of the Fugitive Slave Law, but was defeated. In the spring of 1855 he prepared an address entitled «The Anti-Slavery Enterprise, its Necessity, Practicability, and Dignity, with Glances at the Special Duties of the North.» This was delivered in Boston, New York and other places. It was in this address that he prophesied the downfall of slavery because of a «moral blockade» against it. «With the sympathies of all Christendom as allies, already it (Anti-Slave movement), encompasses the slave masters by a moral blockade, invisible to the eye, but more potent than navies, from which there can be no escape except in final capitulation.»

Two of the great events of the session of Congress that met 3 Dec. 1855, were Sumner's speech of 19 and 20 May 1856, on «The Crime against Kansas,» and the assault on him by Representative Brooks of South Carolina. It was on 12 March 1856 that Senator Douglas reported a bill for organizing a State government in Kansas. This provided that the steps taken should be prescribed by the territorial legislature. This was the pro-slavery legislature which had been elected in March 1855 as a result of fraudulent votes of Missourians who had entered Kansas for this purpose. Congress had to decide whether it would recognize this legislature or admit Kansas as a free State under the Topeka constitution, which had been formed by the free-state men in the convention which met at Topeka 23 Oct. 1855. The debate on the subject began 20 March and continued for some months. Conditions in Kansas had been going from bad to worse and pro-slavery troops had been disarming free-state settlers, and finally, on 21 May, they made an attack on Lawrence, demanded the surrender of all arms, broke the presses of the newspapers, burned the Free State Hotel and plundered houses and dwellings.

It was under such circumstances that Sumner delivered his famous and carefully prepared speech which he meant to be «the most thorough philippic ever uttered in a legislative body.» In this speech he reviewed the whole case from the passage of the Kansas-Nebraska Bill up to the time of the attack on Lawrence. He criticized the administration and attacked his opponents in the most bitter language, especially Senators Butler of South Carolina and Douglas of Illinois. The former had «chosen a mistress to whom he has made his vows, and who, though ugly to others, is always lovely to him; though polluted in the sight of the world, is chaste in his sight; I mean the harlot Slavery.» Douglas had used language in denouncing Sumner that brought forth the reply that «no person with the upright form of a man» could be allowed «to switch out from his tongue the perpetual stench of offensive personality. Sir, that is not a proper weapon of debate, at least on this floor. The noisome, squat, and nameless animal to which



CHARLES SUMNER

I refer is not the proper model for an American senator. Will the senator from Illinois take notice?" These bitter personalities led to the assault on Sumner on 22 May by Preston S. Brooks, a representative from South Carolina, and a cousin of Senator Butler. The Senate had adjourned and Sumner was seated at his desk writing letters, when Brooks entered and said, "Mr. Sumner, I have read your speech carefully and with as much impartiality as was possible, and I feel it my duty to tell you that you have libeled my State and slandered a relative who is aged and absent, and I am come to punish you for it." He then struck Sumner a series of blows on the head with a gutta percha cane, until he fell bloody and senseless to the floor. An effort to expel Brooks from the House failed because of lack of two-thirds majority. While a resolution of censure was pending Brooks resigned, but was immediately re-elected by his constituents. His action was generally upheld by the Southern leaders and press. The indignation in the North was intense, and the incident crystallized sentiment against slavery more, perhaps, than any other single event had done up to this time.

Sumner was re-elected to the Senate in January 1857, but owing to the state of his health he spent nearly four years abroad, returning in time to resume his seat in the Senate 5 Dec. 1859. It was not until June 1860, however, that he delivered an important speech on "The Barbarism of Slavery." It was intended as a reply to numerous assertions recently made to the effect that slavery was a moral, social and political blessing, and "ennobling to both races, the white and black." The speech was a reservoir of facts drawn largely from Southern sources, and an appeal to the great moral sentiment of the North to help abolish the system.

In the session of Congress which opened 3 Dec. 1860, Sumner devoted himself to preventing any compromise between the slave and the free States; for his object was the destruction of slavery. When the Southern senators withdrew as a result of secession, the committee was reorganized, and Sumner was made chairman of the committee on Foreign Relations. In this capacity he rendered the country signal service during the war. He was largely instrumental in the surrender of the captured Confederate commissioners, Slidell and Mason, who had been taken from the English mail steamer *Trent* by Captain Wilkes while on the high seas. He showed the President that this would be in accordance with our doctrines and an abandonment of claims made by England to which we had always objected. He used all his influence to prevent foreign intervention, and opposed the use of force in an attempt to get the French troops out of Mexico, as it might result in war. He was opposed to the issuing of letters of marque, and when the bill was passed used every effort to prevent the law going into effect, in which he was successful. His argument was that it would embroil us with foreign nations. His speech in New York, 10 Sept. 1863, was a strong statement of the American position. He raked England for her unfriendly acts with respect to neutrality and for allowing Confederate cruisers to be fitted out in English ports, and called France to account for her intervention in Mexico. The speech had an important effect in putting a check on England. He made an exhaustive report on the French Spoliation Claims. He argued vigorously for the treaty for the purchase of Alaska in 1867. He was in favor of settling all questions of dispute with England and in bringing the two nations into relations of harmony and good will, and hence supported the efforts to settle the *Alabama* claims. Owing to a disagreement with President Grant and Republican senators over the acquisition of Santo Domingo, which Sumner opposed, he was removed from his chairmanship of the Committee on Foreign Relations, 10 March 1871.

Sumner supported the policy of emancipation and wished to take the step before Lincoln finally acted because he thought that it would prevent foreign intervention. He made the first public demand for emancipation by a responsible statesman on 1 Oct. 1861, before the State Republican Committee of Massachusetts, and repeated his demand in a number of cities in the next few months. In the session of Congress which met in December 1861, he spoke in favor of legislation to prevent the surrender of fugitive slaves by the Union army, and in favor of the abolition of slavery in the District of Columbia, the first public word on the subject since the Republican party came into power.

During the war and after he was active in furthering the interests of the negro. He was influential in getting ratified the treaty with England for the more effectual suppression of the slave trade. He proposed bills allowing colored persons to become mail carriers, for enlisting negroes freed by Confiscation Act and for receiving colored volunteers. He proposed and carried legislation preventing the exclusion of witnesses in the courts of the District of Columbia on account of color. He voted against the bill to admit West Virginia, because the Senate refused to amend it so that after 4 July 1863 slavery should cease in that State. He was continually urging Lincoln to issue the Emancipation Proclamation. He introduced a bill in the Senate to repeal all fugitive slave laws, and succeeded in getting a similar bill, which had been passed in the House, through the Senate. He began the contest for negro suffrage, was a leader in his effort to prevent the exclusion of colored persons from street cars in the District of Columbia, supported a bill to secure for colored soldiers equal pay with the white and was energetic in getting the bill passed to establish the Freedman's Bureau, which Sumner called "a bridge from slavery to freedom." He also aided in forcing a repeal of the law which excluded colored testimony in the United States courts, and was largely responsible for the admission of a colored man to the bar of the Supreme Court, the privilege being granted by Chief Justice Chase on motion of Sumner. He offered an amendment to one of the reconstruction measures to the effect that "every constitution in the rebel States shall require the legislature to establish and maintain a system of public schools open to all without distinction of race or color."

On the question of reconstruction, Sumner felt that the conditions must be faced by Congress and the President together, and hence opposed the policies of Lincoln and Johnson, viz., reconstruction by the executive. He considered this policy unconstitutional while the Constitution supported the authority of Congress — its duty «to guarantee to every State in this Union a republican form of government.» He voted for the conviction of President Johnson in his impeachment trial.

After his removal as chairman of the Committee on Foreign Affairs, Sumner exerted little influence in the Senate, and occupied his time mainly in pressing civil rights bills for negroes. He supported Horace Greeley for President in the election of 1872, on the ground that he was an «unswerving» Republican, that principles must be preferred to party and that Grant was unfaithful to the Constitution and Republican principles.

The character of Sumner and his services to his country were both based on fidelity to great moral principles. He was sincere, unselfish, simple, kind, conscientious, honest and pure and without envy or personal animosity. He was also energetic, uncompromising, courageous and fearless, and indomitable in his purpose. On the other hand, while not entirely a man of one idea, his intense convictions on slavery often helped to defeat his desires, because of his inability to give sufficient weight to other important interests. He became egotistical, dogmatic, irritable, and was lacking in a sense of humor. Next to Lincoln he undoubtedly did more to win freedom for the colored race than any other man. His other great service was in keeping the country out of war with England and France during the period of the Civil War, when such a catastrophe might easily have led to a permanent dissolution of the Union.

Bibliography.— The best short life of Sumner is that by Moorfield Storey ('American Statesmen Series,' Boston 1900). Other biographies are those by Edward Lillie Pierce, 'Memoir and Letters of Charles Sumner' (4 vols., Boston 1877–93); by Anna L. Dawes, 'Charles Sumner' ('Makers of America Series,' New York 1892); by George H. Haynes ('American Crisis Biographies,' Philadelphia, Copyright, 1909); by G. H. Grimke, 'Life of Charles Sumner, the Scholar in Politics' (New York 1892). The «Works» of Sumner were published in 15 volumes, Boston 1874–83. A famous oration on Sumner is that by L. Q. C. Lamar, 27 April 1874. Consult also Shotwell, W. G., 'Life of Charles Sumner' (New York 1910), and Whipple, E. P., 'Recollections of Eminent Man.' Some of Sumner's most famous speeches have been printed separately, viz., «Report on the War with Mexico,» and «Speech on the Crime against Kansas» (Directors of Old South Work, Boston); «Address on War, containing True Grandeur of Nations»; «War System of Nations»; «Duel between France and Germany» (Boston).

MARCUS W. JERNEGAN,
Associate Professor of History, University of Chicago.

SUMNER, George Watson, American naval officer: b. Michigan, 31 Dec. 1841. He was appointed to the navy in 1858. In the Civil War he participated in the bombardment of Forts Jackson and Saint Philip; commanded the *Massasoit* on the James River, and with the *Onondaga* forced the Confederate ironclads to relinquish the purpose of attacking Grant's transports and base of supplies at City Point, Va. After the war he served in various capacities, was commandant of the naval station, Port Royal, S. C., 1899–1901; and in January 1901 was appointed commandant of the Philadelphia navy yard.

SUMNER, Increase, American statesman: b. Massachusetts, 1746; d. 1799. He was graduated at Harvard College in 1767; admitted to the bar in 1770, and in 1779 was a member of the State Constitutional Convention. He was elected to Congress in 1782, was a member of the United States Constitutional Convention in 1789, and in 1797 was elected governor of Massachusetts.

SUMNER, Samuel Storrow, American military officer: b. Pennsylvania, 6 Feb. 1842. He was appointed to the army from New York in 1861, served in the Civil War, and against the Indians in the campaigns from 1869 to 1878. In May 1898 he was appointed a brigadier-general of volunteers and in the Spanish-American War was assigned to duty in Cuba. He was ordered to England as military attaché, but left there in 1900 to join the United States troops in China. Later he was sent to the Philippines, where he was promoted brigadier-general United States army in 1901, and major-general, August 1903. His last service was in command of the Division of the Pacific, and he retired 6 Feb. 1906.

SUMNER, William Graham, American educator: b. Paterson, N. J., 30 Oct. 1840; d. 12 April 1910. He was graduated at Yale in 1863, studied abroad, was tutor at Yale in 1866–69, in 1867 took orders in the Protestant Episcopal Church, was assistant at Calvary Church, New York, and rector of church of the Redeemer, Morristown, N. J., appointed professor of political economy and social science at Yale College in 1872. His writings include a translation of Lange's 'Commentary on Second Kings' (1872); 'History of American Currency' (1874); 'Life of Andrew Jackson' (in 'American Statesmen' Series, 1882); 'What Social Classes Owe to Each Other' (1883); 'Problems in Political Economy' (1884); 'Protectionism' (1885); 'History of Banking in the United States' (1896); 'Robert Morris' (1892).

SUMPTUARY LAWS, a term often used in American political discussion with reference to laws regulating the sale of liquor. The original meaning, however, was the regulation by law of eating and drinking, wearing apparel and style of living generally. The early settlers of New England adopted harsh laws of this character, which have been exaggerated and caricatured in the fictitious Connecticut «Blue Laws» of the Rev. Samuel A. Peters.

Sumptuary laws existed in ancient as well as modern times. One of the Roman laws or the Twelve Tables aimed at repressing extravagance in funerals. After the establishment of the censorship those holding this office had the right of punishing those guilty of luxurious living. After the Twelve Tables the first sumptuary law passed at Rome was the *Lex Oppia* (215 B.C.), directed exclusively against the extravagance of women in dress, jewelry, etc. This law was repealed 20 years later. The other sumptuary laws enacted at Rome were almost exclusively designed to keep down extravagance in entertainments. The *Lex Julia,* passed in the reign of Augustus, was the last sumptuary law passed at Rome, but a few endeavors were made under later emperors also to repress luxury by decrees of the Senate and imperial edicts. The last attempt of this nature that is known to have been made belongs to the reign of Nero. Sumptuary laws were revived by Charlemagne. Both he and Louis the Débonnaire promulgated capitularies against luxury in dress and furniture. Various other laws and decrees having a like object were made under many of the later kings of France, even down to Louis XV. A royal ordinance, dated 19 April 1737, forbids the common people (*vilains*) the use of calico, which was reserved for the nobility, and there are instances of the wives of commoners being fined in virtue of this decree. In England sumptuary laws began to be enacted in the reign of Edward III, and continued to be passed down to the time of the Reformation. Most of them were repealed by 1 James I, ch. xxv, but they were not all expunged from the statute-book till 1856.

Sumptuary laws in the early colonial period of America were not confined to New England. Directions were sent to Virginia in 1621 not to permit any but members of the council to wear gold in their clothes, «or to wear silk till they make it themselves.» In New England the Massachusetts magistrates prohibited the wearing of gold, silver or thread lace, all embroideries or needle-work in the form of caps, bands or rails, gold and silver girdles, and other extravagances which offended Puritan simplicity. The laws were, however, ignored or but slightly enforced, and gradually became obsolete. At present in the United States dress is solely a question of decency, and sumptuary laws are, in that sense, of the past.

SUMTER, Thomas, American military officer: b. Virginia, 1734; d. 1 June 1832. After the capture of Charleston by the British in 1780 he took the field as a brigadier-general at the head of a body of light horse and soon became one of the most active and able partisan leaders of the South. His bravery, endurance and unvarying cheerfulness and determination under reverses gained him from his followers the sobriquet of the «Carolina game cock,» and Cornwallis confessed that he was one of his «greatest plagues.» After gaining important successes over the British and Tories, he was, in September 1780, routed with considerable loss near the mouth of Fishing Creek on the Catawba by Tarleton. In 1781 he took a distinguished part in the battle of Eutaw Springs. The thanks of Congress were tendered him in 1791, and he was afterward sent to that body as a representative of South Carolina. In 1809 he was appointed United States Minister to Brazil and two years later was elected United States senator.

SUMTER, S. C., city, county-seat of Sumter County, on the main line and several branches of the Atlantic Coast Line Railroad, 80 miles north of Charleston. It is in an agricultural region, producing cotton, tobacco and vegetables, of which it exports large quantities. It also has manufacturing interests of importance which include cotton factories, planing mills, sash and blind factories, etc. There is a national bank and a State bank. The city has a public high school founded in 1889, and is the seat of Saint Joseph's Academy, a Roman Catholic school for girls, and of the Sumter Military Academy and Female Seminary, a coeducational non-sectarian school. Since 1913 the commission form of government administers city affairs. Pop. about 9,400.

SUMTER, Fort. See FORT SUMTER.

SUMY, soo'mē, Russia, a town in the government of Kharkov, on the river Psiol, 83 miles north of the town of Kharkov. It has nine churches, a gymnasium, technical school, banks and a large sugar refinery, besides numerous distilleries. The soil is productive, and agricultural products are exported together with brandy. Four annual fairs give considerable impulse to trade. Pop. 51,500.

SUN, the great central body of the solar system. The aspect of the sun with which all are familiar from infancy shows that it is a shining globe. Astronomical measurements show that this globe is more than 100 times the diameter of the earth, and, therefore, more than 1,000,000 times its volume. Its small apparent diameter is due to its enormous distance of 93,000,000 miles. The following are more exact numerical particulars:

Mean distance (miles)	92,900,000
Eq hor. parallax	8.80″
Density (water = 1)	1.41
Mass (earth = 1)	332,800
Diameter (miles)	866,400
Gravity (earth's = 1)	27.65

For methods of determining the distance and other quantities see ASTRONOMY, *Theoretical.* The aim of the present article is to set forth the physical constitution of the sun, so far as modern research has made it known.

One of the most certain results of research is that the sun is at an extremely high temperature, higher than any that we can produce in our furnaces. This is shown by two considerations. One is the enormous amount of energy radiated, which suffices to keep the earth warm and support life on its surface, notwithstanding the immense distance at which it is placed. Nothing but a hot body could radiate so great a volume of energy. Another proof of the high temperature is shown by the spectroscope, which discloses the vapor of iron and other refractory metals in the sun's atmosphere. It requires a hot furnace to melt iron. Much higher must be the temperature which would make it boil away like water. The temperature of the sun not only does this, but the fact that the spectral lines of iron are dark on a bright ground shows that the solar light emanates from a body yet hotter than the vapor of iron.

Aspect of the Sun.— We can see only the surface of the sun, not its vast interior. To distinguish the two, the shining surface is called the «photosphere.» The latter presents to our view the appearance of a flat disc. The edge of this disc is called the «limb.» When seen without telescopic magnification, through a dark glass or other medium, the disc of the sun appears quite uniform, slightly shading off in tint at the limb. But when carefully examined with the telescope, under good atmospheric conditions, the entire photosphere appears as a darkish background, sprinkled with brighter grains or nodules. These «rice-grains» are quite irregular in size and form, and appear as if bright on a relatively dark or yellowish background. It is probable that they are produced by currents of heated matter from the interior, hereafter to be described, which are constantly rising to the surface, there to radiate their heat and then fall back again. When the intensity of the heat radiated from different parts of the photosphere is accurately measured, it is found that the amount of radiation diminishes from the centre of the disc to the limb, where it is least. The diminution is slow at first, but increases quite rapidly at the limb, where it is little more than one-half of that at the centre. The light diminishes in a still greater ratio than the heat. The tint of the light is also different at the centre and at the limb, although this would hardly be noticed by the eye. The light at the limb has more red in its composition than at the centre. This effect is especially noticeable at the time of a total or annular eclipse of the sun. When the moon has nearly covered the sun, the remaining light has a lurid aspect, as if the sun were shining through a smoky atmosphere, thus giving to observers the illusion that the sky is hazy. There can be no doubt of the cause of this appearance. The sun, like the earth, is surrounded by an atmosphere; but this atmosphere is cooler than the photosphere which sends out the light and heat. The existence of the atmosphere is demonstrated by the lines of the spectrum, as well as by the absorption of heat at the limb, which is greater than near the centre because the light coming from that portion of the photosphere has to pass through a greater depth of the atmosphere than when it rises directly upward from the centre.

The Solar Spots.— When the Galilean telescope was first pointed at the sun, the observers were surprised to find that that object was now and then variegated by dark spots. These were observed by Galileo, Scheiner and Fabritius. The two latter published more or less elaborate treatises on the subject, but with their imperfect instruments they were not able to learn much as to the laws of these objects. We now know, with the modern perfected methods of observation, that the spots are of very different sizes, ranging from the minutest point visible in the telescope to a size so great as to be perceptible to the naked eye. The largest must, therefore, exceed the earth itself in diameter. These objects are usually very irregular in their outline, being frequently jagged and cornered, as if made by a shot or bunch of shot passing through a tin plate or wooden plank. They frequently appear in groups; indeed a spot visible to the naked eye commonly consists of a group of these objects close together. The spots of the group may run into each other to any extent, forming an irregular and jagged mass. Sometimes a spot has almost the appearance of a crack in the photosphere. In the spot two portions can generally be distinguished, a dark interior called the «umbra» and a shaded border much brighter than the umbra, though not quite so bright as the photosphere, called the «penumbra.» When the atmosphere is steady, the latter is seen, with a good telescope, to be not of uniform shade, but to be striated, presenting an appearance somewhat like that of a thatched roof. This can be seen better by a figure than by a long description. A spot seems black only by contrast with the brilliancy of the sun. If it were possible to cut off the sun's light, the light from the spot itself would be of dazzling brightness.

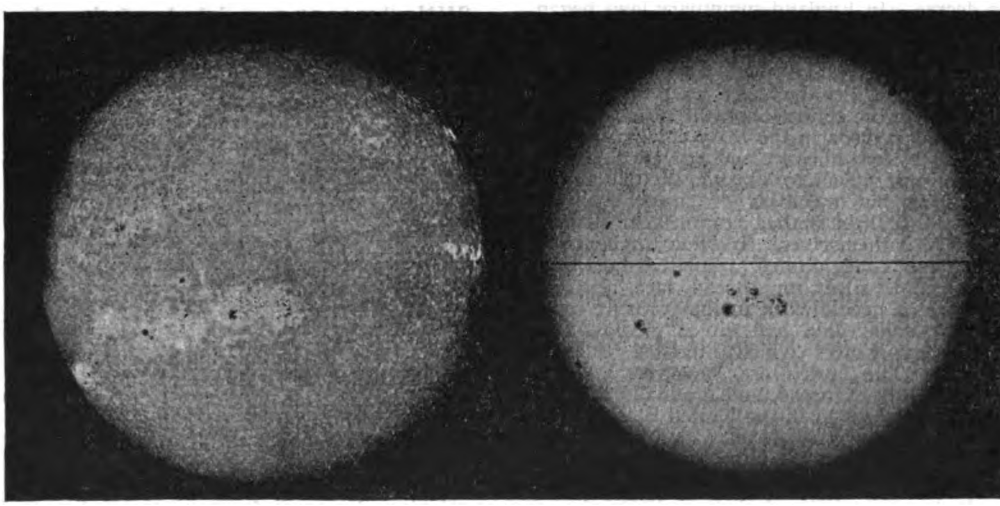


Fig. 6.—On the left is a monochromatic (Spectroheliogram) of the sun taken with the light at the centre of the dark Fraunhofer line known as H, due to calcium vapor. The instrument used was the Rumford spectroheliograph of the Yerkes Observatory. Numerous areas of calcium vapor, lying at a high level in the sun's atmosphere, are thus brought to light. They are not seen on the direct photograph to the right, which shows the sun as photographed in the ordinary way. A considerable number of spots will be noted. The horizontal black line across the photograph gives the east and west direction.

It was formerly supposed that the spots were openings in the photosphere, through which a darker interior was seen. This conclusion was reached because it was supposed that when the spot approached the edge of the solar disc the penumbra looked broader on the side of the spot next the edge. But careful observations made in recent times show that this is not the case. Sometimes the penumbra is broader at one edge and sometimes at another. It was also supposed that the spots might be something in the nature of cooler dark metals floating on the photosphere. But this view also has been abandoned. It has recently been shown by Hale that a sun spot is an immense vortex, in which whirling electrically charged particles produce an intense magnetic field. Thus a sun spot resembles a terrestrial tornado. The observations of Evershed and St. John indicate that the gases are rising from the interior of the sun toward the surface, flowing nearly radially outward above the surface from the centre of the spot. Measurements of the heat radiated from the spot, as compared with that of the neighboring disc, show that the spot is really cooler than the rest of the photosphere. Spectroscopic observations agree with this by showing a great absorption of the light coming from the interior of a spot.

Another salient feature of the sun is its rotation on an axis deviating only six degrees from a line perpendicular to the ecliptic. The time of rotation is shown by observations of the spots on the sun, which we see to move from east toward west. The relation of the sun to its axis of rotation is much the same as in the case of the earth. The sun's axis intersects the photosphere at two opposite points called the *poles* of the sun. A circle passing round the sun midway between the poles is called the *solar equator*. Distances north and south of the equator are called solar latitude. When we look at the sun at noon its north and south poles are near the upper and lower points of the disc; and the equator passes horizontally, or nearly so, across the centre of the disc. The position of the sun's equator is more exactly defined by the following numbers:

Inclination to the ecliptic..................	7°	15′
Longitude of the node......................	74°	29′

The earth in its annual course around the sun passes through the line of the nodes about 5 June and 5 December of each year. At these times the apparent paths of the spots across the sun's disc are straight lines. At the intermediate times they are more or less curved. In March the south pole is slightly turned toward us, and the paths of the spots are curved upward. In September the reverse is the case. We see only the north pole, and the paths are curved downward.

Observations of the spots lead to the unexpected conclusion that the equatorial regions of the sun rotate in less time than those nearer the poles, although the distance they have to go is greater. The sun is so much larger than the earth that, although the time of rotation is more than 25 times as long, yet the absolute linear velocity of the rotation near the equator is four times as great as that of the earth's rotation, being very nearly one mile per second.

The observations of Carrington give the period of rotation as follows:

At the sun's equator..........................	24.9 days.
At 30° of latitude............................	26.4 "

The apparent time of rotation, as we see it, is nearly two days longer, because the earth has carried us forward in its annual motion while the sun is rotating, and the spot has to catch up to our direction before a rotation seems complete.

The rotation of the sun can also be determined by means of the spectroscope, through this instrument enabling us to determine whether a luminous body is approaching the earth, or receding from it. In consequence of the rotation, the photosphere on the east side of the sun is continually moving toward us, and that on the opposite side moving away from us. The observations made by this method agree with those made on the solar spots in giving a period of about 25 or 26 days; but they are discordant as to the variation with latitude. The angular motions in the different latitudes, found by two observers with the spectroscope, Duner and Adams, are as follows:

Daily Angular Rotation of the Sun in Different Latitudes, from Spots and Spectroscopic Observations.

Latitude	Spots (Carrington)	Spectroscope	
		Duner	Adams (1908)
0..........................	14.46°	14.14°	14.65°
11..........................	14.29	13.80	14.43
15..........................	14.13	13.66	14.28
21..........................	13.90	13.40	13.86
30..........................	13.65	13.06	13.64
45..........................	13.10	11.99	12.78
60..........................	....	10.62	11.52
75..........................	....	9.34	10.86

It is a remarkable and interesting fact that the velocities thus determined by the displacement of spectral lines differ systematically when the lines of different elements are chosen. Thus, the values determined by Adams from the lines of iron, calcium and hydrogen, are as follows:

Solar Latitude	Iron lines	Calcium lines	Hydrogen lines
0.3°..................	14.65°	15.0°	15.2°
14.9..................	14.31	14.9	15.0
29.7..................	13.65	14.2	14.6
44.7..................	12.85	13.6	14.0
60.0..................	11.53	12.5	13.7
74.9..................	10.93	13.1	14.3

This difference agrees with much other evidence on the same point in indicating that the different elements effective in producing the lines lie at different levels around the ball of the sun.

The rotation of the sun must produce an ellipticity or bulging out of the equator, as in the case of the earth. But this effect is so small as to elude all astronomical measurement. To all appearance the sun, notwithstanding its rotation, is a perfect sphere.

Two very remarkable laws govern the solar spots, one relating to their frequency, the other to the region of the sun's disc on which they are seen. We recall the fact of the sun having north and south latitude as we have on the earth. The first peculiarity of the spots is that they are rarely seen at more than 35° to 40° of solar latitude, north or south. They are most numerous at about 15° latitude, and from that parallel grow less numerous both toward and from the equator. At the equator they are comparatively scarce. Thus we see that there are two zones of spots; one north and the other south of the sun's equator. The following table of the number of spots observed by Carrington in different zones of latitude illustrates the law:

Limiting lat. of zones	Number of spots
0° to 5°	471
5 to 10	1,940
10 to 15	2,522
15 to 20	2,158
20 to 25	1,303
25 to 30	740
30 to 35	203
35 to 40	84

The other remarkable feature of the spots is their periodicity. At intervals of 11 years they are very numerous, while at the intermediate times they are comparatively scarce, none being visible for perhaps half the time. It is found that the period is almost exactly 11 years 47 days. It was at one time supposed to be the same as the period of revolution of Jupiter, which is somewhat less than 12 years. Had such been the case we should have concluded that the spots were in some way produced by the action of that planet. But it is now proved that the period is more than six months less than that of Jupiter, and does not coincide with any other period known in the solar system. Its average duration is found to be 11.13 years; but it is subject to changes of a year or more. We, therefore, conclude that the cycle of change in the spots is due to a round of processes going on inside the sun itself. What these may be we have no means of determining.

The very careful series of photographs of the sun made at the Greenwich Observatory during the past 30 years show a singular law of variation in the spots with the 11-year period. After a space of two or three years, during which, as we have said, the spots are few and small, the first evidence of a renewal of activity is seen in the occasional appearance of a spot at an unusually high latitude, say 30° to 35° north or south. This may continue for several months, or even a year. Then the spots begin to be more frequent nearer and nearer the equator, while there are fewer beyond 30° of latitude. Finally, after three or four years, they become thickest of all, as we have said, in about 15° of latitude. About five years from the time when fewest are seen, they will be most numerous; then they will also be seen nearer the equator, or even on the equator itself. After five years they begin to diminish rather more slowly than they increased, until they gradually seem once more almost to disappear. The years of minimum sun spots are 1889, 1900, 1911, etc. The years when they are most numerous were 1882, 1893, 1904, etc. But these dates are only approximate, as the intervals between the minima are not always exactly the same.

The Faculæ.— Another curious feature of the sun is the occasional appearance of spots brighter than the rest of the photosphere. These commonly appear in bunches in the neighborhood of the spots, and derive their name from the Latin word *facula,* a torch. They follow a law similar to that of the spots not only in having the same period of frequency, but in being most numerous where the spots are most numerous. But they are seen over a very much wider region of the sun's disc than the spots, sometimes, although rarely, near the poles of the sun.

A third feature of the sun associated with the spots and the faculæ is known as the "prominences." These can be actually seen through an ordinary telescope only during total eclipses of the sun. But they may now be seen at any time, when the air is clear, by means of a powerful spectroscope. Like the faculæ, they are commonly, but not always, found in the neighborhood of the spots, being seen from time to time all round the sun's limb. (See Eclipse). They will be described more fully hereafter.

It is quite evident, from what we have said, that the spots, faculæ and prominences are all results of one series of operations. This fact has been brought out in a very interesting way by the spectroheliograph. This is an instrument invented by George E. Hale of the Mount Wilson Observatory, which enables a photograph of the sun to be taken by the light of a single ray of the spectrum, the light from all the other rays being cut off. A ray frequently used for the purpose is one emitted by calcium. When a photograph is taken with this ray, we have not a general photograph of the sun by all its light, which is what the ordinary camera would give us, but a photograph in which no light is allowed to enter except that emitted by the vapor of calcium. A photograph thus taken is found to be extremely variegated, some parts of the sun's disc being much brighter than others. The interesting feature is that, in the general average, the brightest parts of the disc are those where the spots, faculæ, and prominences are most numerous. But these bright patches may appear on any part of the sun. The general conclusion is that the three classes of objects we have described are all produced by processes going on in the sun which result in the throwing up of great masses of calcium vapor.

Having thus described what the sun is in a general way, and shown its appearances, we pass on to particulars respecting its constitution and surroundings. Our conclusions must be drawn step by step from the phenomena exhibited by the photosphere, combined with reasoning upon the laws of force and the properties of matter. A conclusion most easily reached is that the sun is not a solid body throughout. If it were, its enormous radiation of heat would result in the surface rapidly cooling off, so that, in a very short time, it would cease to emit light. Moreover, a study of the surface shows changes constantly going on incompatible with the idea of solidity. It follows that the heat radiated from the surface must be continually supplied, either by the rising up of hot material from the interior, or by radiation from within outward. It is the latter which is believed to be acting. For the material of the sun is probably transparent, and it is supposed that the enormous heat is absorbed and re-radiated as we pass outward from the center.

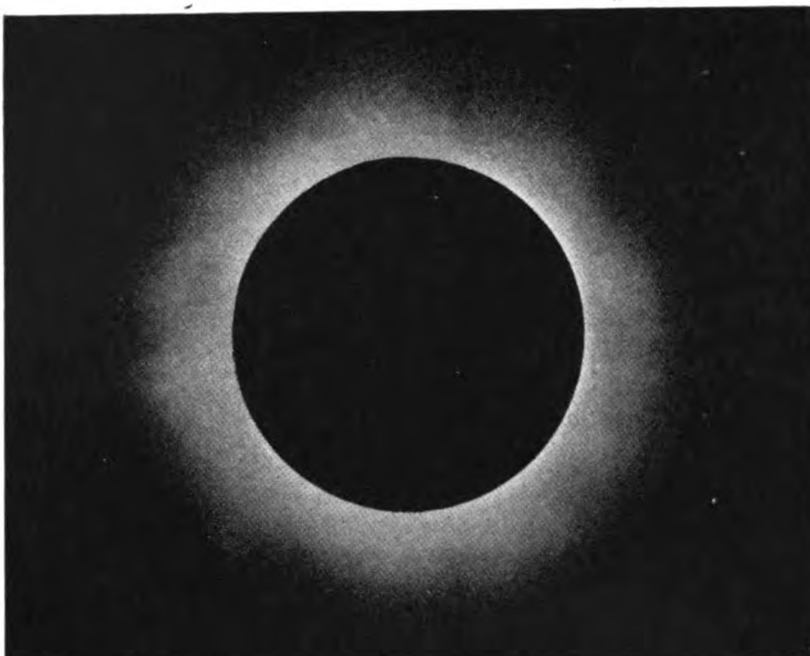
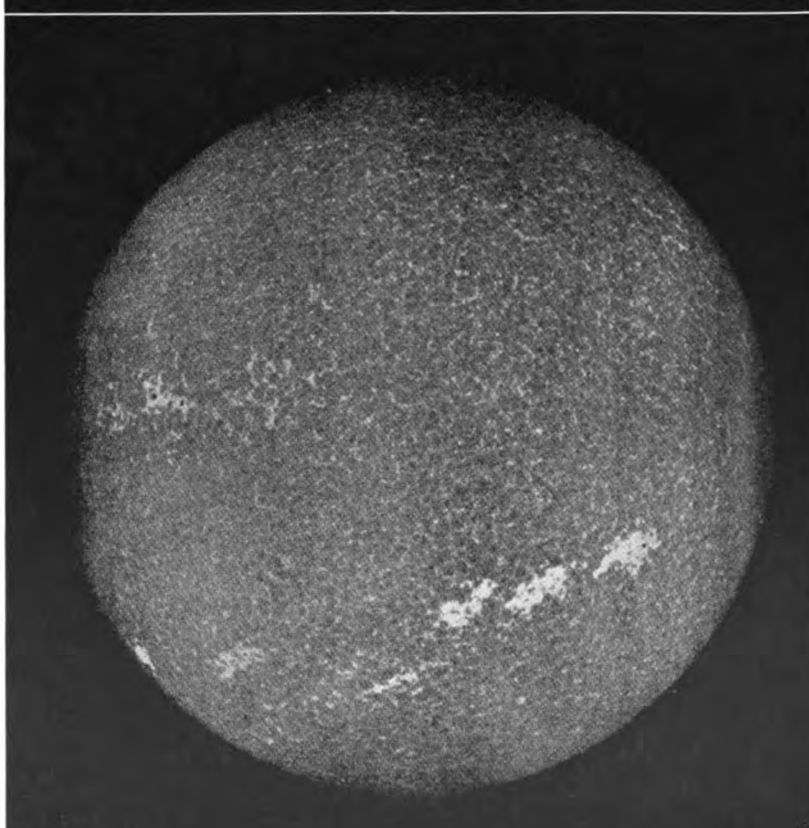
SUN





1 The appearance of the corona during the total eclipse of 30 August 1905
2 Spectro-heliogram of the whole ball of the sun taken at the Yerkes Observatory, 12 August 1903

The absorption and re-radiation from successive layers is almost instantaneous, the velocity of heat transference approaching 180,000 miles a second.

In drawing our conclusions the intensity of gravitation on the sun must be borne in mind. It has nearly 28 times the force of gravity on the earth. A man of ordinary size would weigh two tons at the surface of the sun, and would, therefore, be instantly crushed to death by his own weight, were it possible for him otherwise to exist there. Consequently, the pressure to which the vapors of the sun are subject increases with enormous rapidity below the surface.

The average specific gravity of the materials composing the sun can be determined by astronomical theory with great exactness. It is known that the mean specific gravity is about 40 per cent greater than that of water, and one-quarter that of the earth. It is doubtless much smaller than this at the surface, and, therefore, increases toward the centre. A calculation of the resulting pressure shows that near the centre of the sun the pressure produced by the enormous mass and gravitation of the matter composing the solar orb amounts to about 5,000,000 tons per square inch. This pressure is so far beyond any that we can produce at the earth's surface that we are unable to say what effect it would have upon matter.

Yet another unknown factor is the temperature of the interior. At no great distance toward the centre the temperature exceeds our powers of determination — it may even be 1,000,000°. As the highest temperature which it is possible to produce artificially probably does not amount to 12,000°, it is impossible to say what effect such a temperature would have upon matter. Thus we have two opposing causes, the one an inconceivable degree of heat, such that, were matter exposed to it on the surface of the earth, it would explode with a power to which nothing within our experience can be compared, and a pressure thousands of times any we can produce, tending to condense and solidify this intensely heated matter. One thing which we can say with confidence as to the effect of these causes is that no chemical combinations can take place in matter so circumstanced. The distinction between liquid and gaseous matter is lost under such conditions. Whether the central portions are compressed into a solid, or remain liquid, it is impossible to say.

Modern research shows that the sun, as a whole, is a complex body, the various parts of which are in very different conditions. Beginning at the centre and passing outward, we have first the vast, invisible interior which forms the globe itself, and which our sight can never penetrate. Surrounding this interior is the visible photosphere, or seeming surface, which we see with the naked eye or the telescope, the appearance of which has been fully described. So far as ordinary direct observation could show, this would be the whole of the sun. But the spectroscope, as well as eye observation during total eclipses, has shown most complex surroundings of the sun, which would otherwise have been invisible. The surroundings are formed of two envelopes, the chromosphere and the corona.

The earliest accurate observers of total eclipses with the telescope noticed that during the total phase red cloud-like masses were seen here and there projecting beyond the limb of the dark moon. Moreover, at the beginning or the end of the eclipse, it is found that these projections are connected with a red border extending round the sun. There is, therefore, an envelope which radiates red light and surrounds the sun, and which is invisible except during eclipses. Quite independent of this envelope is a bright effulgence which is seen during a total eclipse. These phenomena are fully described in the article ECLIPSE. What we have now to do is to set forth what they indicate.

The red envelope which rests immediately on the photosphere is called "chromosphere." It is comparatively thin — so thin as to be almost immediately covered when the sun is totally eclipsed. Its nature was first made known by the spectroscope, which showed it to be composed mostly of hydrogen, helium, and calcium vapor. Its principal and lower parts differ in constitution. At the photosphere it comprises nearly all the substances which exist in the latter. This was shown in a very beautiful way by observations of the reversing layer, first made by Young at the total eclipse of 1870. The explanation of the phenomena there described is that the photosphere is hot enough to shine by its own light, and, being a gas, to give bright spectral lines. But the photosphere is so much hotter than the chromosphere that the latter is, in comparison, a cool gas which absorbs the spectral lines from the light radiated by the photosphere. The question of the density of the chromosphere and reversing layer, as its base is called, has given rise to very varied estimates.

The fact that the spectroscope shows bright lines as the last ray of true sunlight disappears at the beginning of a total eclipse shows that the gas from which these lines emanate must be so rare as to be transparent through a distance of thousands of miles. We are, therefore, justified in concluding that the gases of the chromosphere are extremely rare, and the same is probably true of the principal regions of the photosphere.

Among the most extraordinary phenomena exhibited by the sun are the mountainous elevations of the chromosphere, which we see as the red protuberances already described. These are of two kinds, the eruptive and the cloud-like. The latter present to us the appearance of vast clouds floating in an atmosphere of the sun. It seems certain, however, that they cannot be what they seem, because there can be no atmosphere there to support them. They are probably held up by an impulsion of the solar rays, which will be described presently. The eruptive prominences seem to be due to outbursts of intensely hot gases, mostly hydrogen, from the sun. These are thrown up with a velocity of several hundred miles per second, like immense mountains of fire. They sometimes rise to a height of many thousand miles, their ascent being doubtless aided by the impulsion of the solar rays; then they fall back again to the sun. The chromosphere and prominences can now be photographed in projection against the sun's disc with the spectroheliograph. When such photographs are made with the light of the red hydrogen line, they show great vortex phenomena, centering in sun spots and closely related to the vortices in the photosphere which constitute the spots themselves. See Plate III.

The violent forces seen in action in the chromosphere are in singular contrast to the soft white light of the corona. Much mystery still surrounds the constitution of the latter. It was supposed to be an atmosphere of the sun; but this view is rendered untenable by the fact that an atmosphere supported by its own weight would more than double in density for every mile that it was nearer its base. It probably consists of exceedingly minute molecules of gaseous matter, similar to those which make up the tail of a comet, and possibly having some resemblance to the latter. The newly-discovered fact of the impulsion of the solar rays probably affords a clew for an explanation of these and similar phenomena. More than 40 years ago it was announced by Maxwell, as a result of his electro-magnetic theory of light, that light and heat emitted by the sun should exercise a very minute pressure on any object which they struck. Conclusion showed that this pressure was so slight that no apparatus then known was so delicate as to make it sensible. Within the last few years, however, E. F. Nichols and others have succeeded in showing experimentally that on very finely divided matter this action of light can be observed and measured. It follows that particles below a certain size will be repelled by the sun's light with greater force than they are attracted toward it, and will thus be driven from the sun when in its neighborhood, or supported temporarily at a certain height above the sun. Hale has proved, by spectroscopic methods similar to those employed in his discovery of magnetic fields in sun spots, that the entire sun is a magnet, with a field about 80 times as intense as the magnetic field of the earth and with its magnetic axis inclined about six degrees to the sun's axis of rotation.

The Sun's Rotation.—As the light and heat which we receive from the sun are the source of all life on the earth, the important work is at once suggested to measure exactly how much radiant energy we receive from the sun in a given time, and especially, if possible, to find whether this is growing greater or less, or if it varies from time to time. Until so late as 1905 the measurements were comparatively very crude, but the sensitiveness of the instruments employed has recently been so increased and observations with them have been so carefully and continuously carried on that this quantity has now been well determined.

For measuring the amount of heat received on a square unit of the earth's surface, the so-called pyrheliometer is employed, an instrument which presents a surface of known area to the solar rays, the rise in temperature due to the heating being communicated to a stream of water (in the best form), and measured by an electrical thermometer. The unit usually employed is the calory, which is the amount of heat required to raise one gram of water 1° C. The *solar constant* is then the number of calories which would be received on each square centimeter of the earth's surface, exposed perpendicularly to the solar rays, if there were no loss in transmission through the atmosphere.

The following small table gives the mean values of the solar constant obtained from observations made at Washington, Mount Whitney and Mount Wilson. Observations were made at the second station, whose elevation is nearly three miles, in order to test the accuracy of the laws assumed for the absorption of solar rays by the atmosphere.

	Washington	Mount Whitney		Mount Wilson				
	1902–07	1909	1910	1905	1906	1908	1909	1910
Observations	44	1	3	52	62	113	95	28
Mean value	1.960	1.959	1.956	1.925	1.921	1.929	1.896	1.914

Prior to 1905 the true value of the constant was in much doubt; numbers ranging from 1.76 to 4.10 were stated for it, and the average value 3.0 was frequently accepted. There can be no doubt that the value 1.95 is very near the truth, and this may be regarded as the best value now obtainable. It has been well established, however, especially by the recent work of Abbot, that this fundamental constant varies slightly and irregularly. In 1919 a solar station was established at Calama, Chile, at which it is planned to make constant measures of the sun's radiation for several years, in conjunction with northern observations, with a special view of ascertaining, if possible, the law of this variation, and its effects upon terrestrial climates.

The Sun's Magnetism.— In the year 1908, Prof. G. E. Hale of the Mount Wilson Observatory, from an examination of the spectral lines in sun spots, discovered that around each spot there is a more or less powerful magnetic field. A powerful field will double many of the lines of the spectrum; a less powerful one will merely widen them. A few lines were found triple in sun spots, and afterward these same lines were found to become triple in the laboratory when viewed along the magnetic lines of force. Thus the lines of sun spots near the sun's limb tend to become triple, while those from spots near the centre of the solar disc are doubled merely. In many cases a pair of sun spots quite near together are found to have opposite polarity, and while in general the polarity of spots in the southern hemisphere is different from that in the northern, many cases of exception occur. It has, however, been well established that the sun, like the earth, has a north and south magnetic pole; the inclination of the sun's magnetic axis has been determined, and the fact has been established that the magnetic pole is in slow rotation about the pole of the sun.

A curious relation is found by the study of magnetic storms on the earth. The latter consist in occasional perturbations of the magnetic needle, which are very irregular in their character and are felt over the whole globe. They

SUN

2 The chromosphere and prominences photographed in projection against the sun's disk, showing the hydrogen vortices centering in sun-spots discovered at Mount Wilson

generally occur when there is an unusually bright aurora. Now, investigation shows that the number of these disturbances follows exactly the period of the solar spots. During those years when the spots are most numerous magnetic storms are most frequent, and vice-versa. The conclusion is that the sun spots and magnetic storms are due to the same cause. The sun's spots can be due only to something going on in the sun, and it follows that there must be some emanations from the sun which produce magnetic storms. Modern investigation has not been able to detect or define these emanations, though they are supposed to be electrically charged particles, shot out from the sun, and drawn in around the magnetic poles of the earth, where they give rise to the aurora. We have the strongest reasons to believe that neither the magnetic field of the sun as a whole nor the much more intense local fields in sun spots, produce any measurable magnetic effect at the distance of the earth.

Age and Duration of the Sun.— The greatest problem connected with the sun is suggested by modern science. Up to 100 years ago students and philosophers saw no reason why the sun should not continue to shed heat and light on the earth for an indefinite period without undergoing any change whatever. But toward the middle of the 19th century the laws of energy were developed and understood. These laws set forth that the radiation of heat always involves the expenditure of something called energy; and that the latter is necessarily limited in supply. It was also seen that the sun must be a hot body, and must lose all the heat it radiated. To make this subject clear, we must remark that what the sun really radiates is not properly called *heat* in scientific nomenclature; the more exact term is *radiant energy*. But this differs in no respect from what is radiated into a room from a hot fire. Radiant energy goes out from the fire and strikes the walls of the room, where it creates heat, and thus warms the walls. All the heat thus transmitted to the walls comes from the coal, although in its passage from the fire to the walls it passes through an intermediate stage called radiant energy. That the latter does not necessarily warm a medium through which it passes is shown by the striking experiment of making a large lens out of ice instead of glass. When the sun's rays are concentrated on a point by passing through this mass of ice they will burn the substance on which they fall, as if they had passed through glass. We see, then, that however cold the space between us and the sun may be, all the radiant energy reaching us from the sun must come from a source in the sun limited in supply.

If the sun were merely losing energy like an ordinary hot body cooling off, a very simple calculation will show that it would be so cooled off in the course of 3,000 or 4,000 years as no longer to radiate much heat. It is clear that such has not been the case. Yet the most careful study shows no possibility that it can be receiving any considerable part of its energy from any outside source. Moreover, the geologists assure us that the stratification of the rocks, as well as many other other phenomena associated with them, proves that the sun has been radiating heat to the earth at not much less than its present rate for hundreds of millions of years.

The only solution of the puzzle that was suggested until 1903 was based on the mutual convertibility of heat and motion. From the time that the theory of energy was developed it was known that when the motion of a material substance is arrested without any other effect being produced, heat is generated. For example, the waters of Niagara are warmed by about one-quarter of a degree Fahrenheit in striking the bottom of the falls. The blacksmith by hammering a piece of cold iron can make it hot, because the energy which he puts into the motion of the hammer is converted into heat when the latter strikes the iron. It follows that if bodies of any sort are falling into the sun, heat will be generated by the fall. Moreover, owing to the power of the sun's attraction, such bodies may fall with great velocity; and the heat thus generated increases as the square of the velocity. Thus arose the first theory as to how the sun's heat could be kept up. It was supposed that meteors were continually falling into that luminary. But further study showed it to be impossible that meteors could fall in such quantity as to have this effect.

Then it was suggested by Helmholtz and Thomson that if the sun were a gaseous body, as it is now supposed to be, radiating energy, the loss of the latter would continually be made up by the fall of its outer portions involved in the continual contraction of the sun through loss of heat. All bodies, and gaseous ones in a higher degree than any others, diminish in volume when they cool off. Accordingly, when the photosphere of the sun cools off, it diminishes in volume, grows smaller and falls down upon the mass of the sun below it. Careful calculation shows that if the sun contracted about 250 feet per annum, the energy thus generated would keep up all the heat which the sun radiates. An important addition to this theory was made by J. Homer Lane, who showed that if the sun contracted like a mass of pure gas it would continually grow hotter as it contracted. This is now known as Lane's law. But there is a necessary limit to the quantity of heat which can thus be generated. If the sun has been thus growing smaller through long ages, there must have been a time when it filled the whole space now occupied by the solar system. What is more, the contraction must have been far more rapid the larger the sun was; because the force of attraction at the sun's surface diminishes as the inverse square of the diameter of the sun. For example, when the sun was twice as large as it is now, this force was only one-quarter as great; consequently it would have to contract four times as much to generate a given amount of energy as it does now. Finally, exact computation showed that even on this theory there was still a limit to the existence of the sun too narrow to satisfy the demands of geology. It could not have been radiating heat for more than 50,000,000 or 100,000,000 years. Before that time it must, according to the theory, have been a gaseous mass filling the whole space now occupied by the solar system, which contracted and formed sun and planets, in accordance with the theory known as the "nebular hypothesis."

It also seemed very improbable that the sun's heat could have been at all constant for even 20,000,000 years; on the other hand, geologists went hundreds of millions of years. Thus apparently an irreconcilable contradiction was presented to scientific investigators when in 1900 the discovery of radium began to put a new face upon the fundamental theories of physical science. We now know that there is an immense amount of energy stored in the atom, which is a very complex thing. With the so-called «radioactive» substances, the atoms may be broken up, the result of the process being an element of lower atomic weight than the original substance. And in this breaking up of the atom a great amount of energy is liberated. Though it has been known for many years that Helmholtz' theory was inadequate, whether a large part of the sun's energy is of this sub-atomic origin, we do not know, but it is reasonable to suppose that it is. And it is only necessary to suppose that a part of the energy of the atom is in this way changed into heat energy to almost indefinitely prolong the life of the sun.

The most recent semi-popular, but authentic work is 'The Sun' by C. G. Abbot (New York 1911); this contains many references to more extended works or detailed publications. A larger and very important work is 'Physik der Sonne,' by E. Pringsheim (Leipzig 1910). Numerous papers will be found in the Proceedings of the Royal Society, London, and in the *Astrophysical Journal,* Chicago.

SUN, Eclipses of the. See ECLIPSE.

SUN, Order of the. See ORDERS (ROYAL) AND DECORATIONS.

SUN-BIRDS, a large family (*Nectariniidæ*) of small insect-eating birds of the tropics of the Old World, having elongated, slender and curved bills, wings of moderate size and the central tail-feathers usually prolonged beyond the others. These birds occur in the Eastern Archipelago, India and Africa. They take the place of the humming-birds of the New World, and in brilliant coloration and habits much resemble these, but are far removed from them in classification, the honey-eaters (*Meliphagidæ*) being their nearest relatives. They are constantly hovering about flowers seeking the minute insects found within the petals and sipping the flower-juices, so that they have been named sucriers or sugar-eaters, by French authors. Some certainly eat fruits. The song is sweet, but without any special characteristics, and in habits they are exceedingly lively, quarrelsome and even pugnacious. The gaudy plumage is chiefly confined to the male sun-birds and depends for effect upon intensity of color and not upon metallic or prismatic lustre. The nests are built in the hollows of trees or are placed in thick bushes. Some species (such as *Nectarinia lotenia* and *N. asiatica*) make dome-like nests, which are suspended from the extremities of twigs of bushes, and are covered with cobwebs for the purpose of concealment. A magnificent treatise upon the sun-birds, with colored plates, has been written by Shelley, entitled 'A Monograph of the Nectariniidæ' (London 1876–80). The name is sometimes given to various other birds. Thus the sugar-birds or banana-birds (qq.v.) of the West Indies are often so called; and a large South American bird, also called finfoot, for which see HELIORNITHIDÆ.

SUN-BITTERN, an extraordinary somewhat rail-like bird of Brazil and Guiana (*Eurypgahelias*). It is about 16 inches long, body small and thin, neck long and slender, head like that of a heron, with a long, powerful beak compressed at the sides and slightly arched at the culmen; the plumage is minutely variegated with bars and spots of many colors, and it has the habit of spreading wings and tail in courtship or on other occasions of excitement, forming a rosette about its head and neck fancifully compared to a «sunburst.» It is often made a pet by the Brazilians, who call it peacock. A larger species (*E. major*) inhabits Venezuela and Colombia. Their nearest relative is the kagu (q.v.). Consult Newton, A., 'Dictionary of Birds' (New York 1893–96).

SUN CRACKS. See MUD CRACKS.

SUN-DANCE, a ceremony performed, with local variations, by most of the prairie Indians, including the Mandan, Omaha, Pawnee Loup, Cheyenne, Arikara, Hidatsa, Blackfeet, Nez Percé, Winnebago, Yankton, Santee and Kiowa. It is held apparently at the full moon occurring at or next after the summer solstice, and lasts from three to six days. The budding of the wild sage also indicates the times for holding the ceremony, and all neighboring tribes, whether friendly or not, are usually invited. The dance begins at sunrise and ceases at the following sunrise. As may be inferred from the length of the festival, including the fasting and purification of the devotees and other preparatory acts, the actual sun-dance is but the chief episode in a ritual comprising a congeries of ceremonies. The motive or purpose of the dance is to promote welfare through the gratification of desires and wants and to avoid ill-fare through the dispelling of hostile agents. The devotee or sun-dancer indulges in the ceremony to fulfil a vow, made by him during the previous winter or season from various motives, that he would make a prayer to the disposer of what he needs through an appeal to the sun, to «Wakanda» (among the Sioux). The Tetons call the ceremony by a name which means «They dance looking at the sun.» In it the moon is regarded as the representative of the sun, hence the dancers gaze at it just as they do at the sun. Among the principal objects in the festival of the sun-dance is the sun-pole or «mystery tree» (symbolic of the centre of the four quarters of the heavens), the sacred tent of preparation erected within the so-called camping-circle of the tribe, wild sage, a sweet-smelling grass called *wachañga* by the Teton and the dancing-lodge. Each devotee persists in his part until he has received a vision from the sun; but if at the close of the ceremony no such vision has been vouchsafed to him, resort is had to self-sacrifice, which is called «vision-hunting.» One of the characteristic forms of self-sacrifice is that of having two wooden skewers inserted underneath strips of skin raised by slashing the breast or back, to which stout thongs are made fast, by which the devotee is drawn up and fastened to the sun-pole, to which he remains suspended until his weight, sometimes made greater by having a buffalo-skull hung to his person by similar skewers, causes the latter to rend the skin, thus letting the devotee fall to the ground, usually in a faint; another may have a buffalo-skull suspended from thongs passing through raised strips of the skin on the back or breast, which is allowed to hang thus until the skin is parted by violence and the thongs are freed. Some men who do not intend to dance seat themselves near the sun-pole, and small pieces of flesh are cut out in a row from the shoulders of each; these are offered to the being represented by the sun-pole. Women do not scarify themselves in the sun-dance, and self-torture and the shedding of blood are not practised in the Kiowa ceremony. Consult Catlin, G., 'North American Indians' (new ed., 2 vols., Philadelphia 1913); Lowrie, R. H., 'The Sun Dance of the Crow Indians' (New York 1915).

SUN-DEW, any herb of the genus *Drosera*, which is classified near the pitcher-plants and the roses. Several species are found in America. The flowers are very pretty, like that of the saxifrage, five-petaled, and borne at the top of a leafless scape, in a raceme, the buds in which are bent downward, the blossom of each day surmounting the arch and facing the sky. They are white or purplish in color. Sundews grow in bogs or wet ground, the roots are poorly developed and yet the small plants thrive even in sphagnum; this is because they are flesh-eaters, and live on the nutriment obtained from such insects as they can catch on their foliage; the roots, therefore, serving principally to anchor the plants and to supply the large amount of water needed. The leaves, varying in shape in the several species, from round to filiform, are covered thickly on the upper face with wine-red filaments having a glistening drop like dew at the tips. These are stalked glands, destined for a purpose as deadly as that of the tentacles of the octopus. The leaf blades of the *Drosera rotundifolia*, a common sun dew, are round, and are arranged in a rosette around the base of the flower-scape, the smooth green under surfaces resting on the ground. In times of inaction the tentacles radiate in concentric circles and are tipped by their globular translucent glands, which sparkle with a viscid secretion exuded by them. But let a fly light on one of the glands and remain there, glued fast by the viscous fluid, and there is immediately a change in the state of things. In its efforts to release itself, the struggling insect is only besmeared more completely, chokes the organs of respiration and is ultimately smothered. In the meantime, the tentacles, disturbed by the fly, have become excited and have transmitted the stimulus to the other glands so that they all bend toward the tiny body, converging over it, and striving to touch it. They even shift the inert object toward the centre of the leaf-blade, so that the greatest number of tentacles may reach it. Such glands as succeed in touching the meat secrete an acid juice, with the addition of a ferment which is entirely similar to pepsin, and apply this secretion to the fly, digesting it, as it were. The glands then absorb the flesh and blood of the meat, and also their own secretions. The tentacles straighten up, the undigested portions of the insect resting on the dry glands are blown away, and the glands soon begin to exude their viscid secretion again, and make themselves ready for a fresh victim. When a large insect is entangled, the leaf-blade itself folds inward slightly, so that a maximum number of tentacles may concentrate upon the food. *D. filiformis* has erect, very narrow leaves, and when an insect is caught by the glands, the leaves themselves bend toward it. In *D. longifolia* the leaf-blade enfolds the fly. Sun-dew glands respond by bending to repeated touches, although no object rests upon them. It is only nitrogenous food which is obtained by this digestive process; carbonic acid is assimilated from the air as by other plants. Consult Darwin, C., 'Insectivorous Plants' (1875; new ed., 1900).

SUN-DIAL, an hour-measuring instrument known from the earliest times to the Egyptians, the Chaldæans and the Hebrews. It is worthy of remark, however, that no ancient Egyptian sun-dials have been found. Those connected with Egyptian remains have been recognized as all of Greek origin. The Greeks adopted it from their Eastern neighbors, and it was introduced into Rome during the First Punic War. One of the earliest types of sun-dial found in Egypt, and still in use there, consists of a palm rod set upright in the ground, with a circular arc around it set out with stones to mark the hours as the shadow of the rod traverses the circle. Another more primitive form still in existence in Egypt has a rod laid horizontally in a north-and-south direction on two forked uprights, a short distance above the ground. At equal distances east and west of the rod are placed two stones or pegs. When the shadow of the rod lies across the westerly peg the day's work begins; when it reaches the easterly peg the day's work is ended.

It was discovered in very early times that a vertical rod could not throw a shadow that would accurately denote time, and the correct inclination of such a rod or the stile of a sun-dial was evidently a matter of experiment and approximation before the ancient astronomers fixed the angle by calculation. This surmise is borne out by the various inclinations found in ancient dials. Some of these were constructed arbitrarily at 45°, an angle having no relation whatever to the latitude of its location.

The first historic sun-dial dates from about 1000 B.C. It was found in Rhodesia, and is believed to be of Semitic origin. Sun-dials are referred to in Grecian literature in 560 B.C., and a certain sun-dial is specifically spoken of as having been set up at Athens by the astronomer Meton in 433 B.C. It is said of the Turks that wherever they build a mosque they place a sun-dial. In China they are everywhere, and small ones which may be carried in the pocket are very common. The correct use of these portable dials depends, of course, upon their accurate orientation when reading them.

Sun-dials have been classified under three headings, according to their superficial form: spherical, cylindrical and plane. The spherical form is the most ancient. It consists of a hemispherical hollow cut into a rock or built up in that form, the flat of the hemisphere being horizontal. An upright rod was set in the centre of the hemisphere, pointing to the zenith. The hour marks were cut into the hollow surface. A variation of this type was the cutting away of the front half of the hemisphere. This form of necessity can mark only the hours from 6 A.M. to 6 P.M. An old Roman dial is in the form of a spherical shell of which about two-thirds have been cut away, held upon the shoulders of a herculean figure. Cylindrical dials have the hollow in the shape of a semi-cylinder cut through lengthwise. A rod in the position of the axis of the cylinder throws the shadow. A variation of this form is a semi-cone cut through its axis. The plane dials are too well known to need description.

In the placing of sun-dials another classification comes into play; they may be horizontal or vertical. Many of the latter type are set into or carved upon the walls of churches or other buildings or on stone blocks set upon pillars or pedestals. As a rule, the vertical sun-dials are set to face directly south. Where this is not feasible the gnomon may extend toward the south at the angle of a corner of a building, the hour lines being partly on one façade and partly on the other. In some of the odd pillar types the stone block at the top is cut with many facets like a crystal, with a gnomon on each facet.

The leading principles of dialing may be made intelligible to general readers by the following simple illustration:

Let P B *p* D represent the earth as a hollow transparent sphere, having an axis P E *p*, of

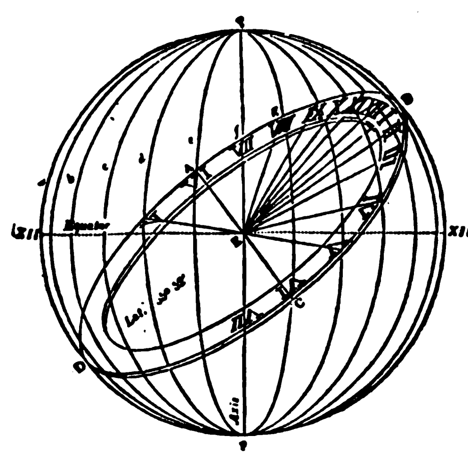

FIG. 1.

which P and *p* are the poles. Let the equator be divided into 24 equal parts and through these divisions draw the meridians, *a*, *b*, *c*, *d*, etc. Let one of these meridians pass through any given place for which a dial is required to be made, and where that meridian cuts the equator let it be numbered XII. The opposite meridian must likewise be numbered XII, the other meridians being numbered as shown in the cut. This being done, these meridians will be the hour circles of the place on the first meridian; so that if the axis P E *p* were opaque, the sun in his (apparent) motion round the earth in 24 hours will pass from one meridian to another in one hour, and cause the shadow of the axis to fall on the hour on the plane D C B A. This diagram has been drawn for the latitude of Glasgow, 55° 52′, and the plane in its present position would form a horizontal dial for that place; but we may suppose it capable of moving round its axis A C, so as to assume different positions

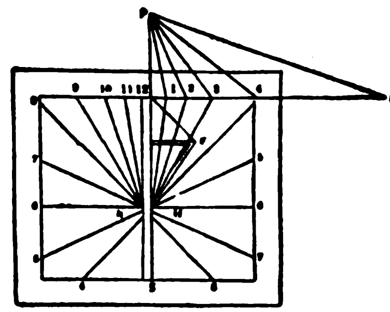

FIG. 2.

in the sphere. If it move round so as to become vertical, that is, at right angles to its position in the figure, we then obtain an erect south dial. The plane may also be made to incline from the meridian either toward the east or west. Thus we have dials of different kinds dependent on the position of the plane with regard to the first meridian, the position of the hour lines of which are all determined by the meridians of the sphere cutting the plane.

We have been considering the earth as the sphere, in our illustration of the nature of dials, but the earth's magnitude is so small compared with the distance of the sun, that no appreciable error will follow in considering a small glass sphere similar to that above described, but placed on the surface of the earth with its axis parallel to that of the earth; then will the sphere show the hour of the day in the manner before specified. The only things absolutely essential for a dial are the axis and the plane, the places of the hour lines having been once determined. Dials may have various forms, many of which are exceedingly curious and intricate, and require for their construction the application of complicated trigonometrical formulæ. We shall confine our attention here to the most common, and, at the same time, most useful form, that is, the plane horizontal dial. On the proposed plane, which may be either of marble, slate or brass, draw a straight line P H S for the meridian or 12 o'clock line, and parallel to this draw 12, h S, leaving a space between them equal to the thickness of the gnomon. The gnomon is a thin triangular plate of metal, somewhat similar in shape to the figure A E B, the side A B being fixed into the plate of the dial, so that the gnomon shall stand perpendicularly, the line A E being directly north and south.

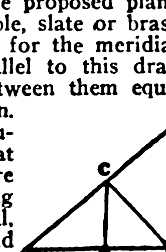

FIG. 3.

The line A E is called the style, and the angle E A B is made equal to the latitude of the place for which the dial is constructed. In the case of a vertical dial the angle E A B must be the complement of the latitude, the line A B the top of the gnomon and the line B E affixed to the dial.

We return again to the consideration of Fig. 2. Draw 6 H 6 perpendicular to 12 H S, and it will be the six o'clock hour line; make the angle 12 H F equal to the latitude of place, and draw 12 F perpendicular to H F; continue S 12 to P, making 12 P equal to 12 F. The line 12 1 2 3 4 is drawn parallel to the line 6 H 6. From the point P draw the lines P 1, P 2, P 3, etc., terminating in the line 12 1 2 3 4, making angles with the line 12 P at the point P of 15°, 30°, 45°, etc., increasing by 15° each line. Next from the centre H draw the lines H 1, H 2, H 3, etc., and thus the hour lines of 1, 2, 3, 4 and 5 P.M. will be found. The hour lines on the other side of the style should now be formed by taking a tracing of the side already formed; the hours are of course numbered differently, and both sides will stand thus, the hour line of both sides corresponding:

1, 2, 3, 4, 5, 6, 7, 8,
12,
11, 10, 9, 8, 7, 6, 5, 4.

Here we have carried the hours beyond 6, which was the extent of the construction but to find the hour lines for 4 and 5 in the morning we have only to produce the hour lines of 4 and 5 in the evening, and in like manner for the hour lines of 7 and 8 in the afternoon, produce the hour lines of 7 and 8 in the morning. The dial gives solar time, and, therefore, the time, according to it, will only agree four days in the year with a well-regulated clock. See EQUATION.

The orientation of the sun-dial after it is made is a necessity of the first importance if satisfaction is desired. This process is carried out usually at night with the aid of two plumb-lines one north and the other south of the position in which the dial is to be set. From the Nautical Almanac the time is found at which the polestar crosses the meridian of the place. The two plumb lines are brought into a line pointing to the star at that moment. The dial can then be placed in the same line conveniently by daylight. It is usual to erect frames of considerable height to hold the plumb-lines so that the sighting upward may be the easier. If the location of the pedestal of the dial is chosen beforehand, the frames for the plumb-lines must be so arranged that both may be moved so as to have the centre of the pedestal in the same line with them and the star.

The sun-dial is daily getting more rare in this age but notwithstanding the superiority of the clock, why has the dial almost everywhere vanished? "If its business use," as has been well observed, "be superseded by more elaborate inventions, its moral use, its beauty, might have pleaded for its continuance. It spoke of moderate labors — of pleasures not protracted after sunset — of temperance and good hours. It was the primitive clock — the horologue of the first world. Adam could scarce have missed it in paradise. It was the measure appropriated for sweet plants and flowers to spring by — for the birds to apportion their silver warblings by — for flocks to pasture and be led to fold by. The shepherd carved it out quaintly in the sun, and, turning philosopher by the very occupation, provided it with mottoes more touching than tombstones."*

Bibliography.— Denison, E. B., 'Clocks, Watches and Bells' (London 1860); Gatty, Mrs. A., 'The Book of the Sun Dial' (London 1900); Hogg, W., 'The Book of Old Sundials' (London 1917); Horner, E., 'Primitive Sun-Dials or Scratch Dials' (Taunton, England 1917); Leybourn, W., 'Dialling' (London 1700); Wells, I., 'Sciographia: or the Art of Shadows' (London 1635).

SUN-DOG, also called **MOCK-SUN** and **PARHELION**. *In meteorology*, a bright, luminous area sometimes seen on either side and at the same altitude as the sun. Sun-dogs are found at the points in which the solar halos cut the horizontal, parhelic circle. Thus two sun-dogs are usually seen on either side of the sun, and at equal distances from it, though four are not infrequent. The nearer pair are 22° from the sun and the outer are 46° distant, while fainter sun-dogs are more rarely seen at 50°, 98° and 120°, and even directly opposite the sun, at 180°. The last is sometimes known as an *Anthelion*.

Bright areas formed at the intersections of any two circular halos near the sun are sometimes also referred to as sun-dogs and such sometimes are seen directly above and below the sun. The parhelic circle is produced by the reflection of the sun's light from ice prisms or snow crystals whose axes lie in a vertical position: so-called "Contract Arches" arise from prisms whose axes are horizontal. It is the latter that give rise to sun-dogs which are vertically above and below the sun.

Sun-dogs are usually reddish on the sides toward the sun and they are sometimes greatly elongated along the parhelic circle which produces them. They vary greatly in brightness and distinctness with the variation of the number and arrangement of the ice crystals in the air.

SUN AND LION, Order of, a Persian order founded in 1808 by Shah Fath Ali, in imitation of the French Legion of Honor, established about six years previously by Napoleon I, then first consul. It includes five classes.

SUN MOTOR. See SOLAR MOTOR.

SUN WORSHIP, a form of nature worship which prevailed in all the ancient civilizations. In numerous primitive religions the sun is not the supreme deity: in many the moon holds the pre-eminence. The mode of reckoning time by moons is more ancient than solar calculation: in the language of the Hottentots, just as in Teutonic, the Moon is "he," the Sun "she"; and rude tribes in both hemispheres still make the moon masculine, the sun feminine: the ancient Germans used to say Hermon (*herrmond*, Lord Moon) as the Germans still say Herrgott: on the other hand, as a mediæval writer tells us, the sun used to be called "Holy Lady": "I knew an old woman who believed the sun to be a goddess, calling her *sancta domina*." The aborigines of North America worship the sun; for them the peace-pipe is the gift of the sun; in the council the pipe is always passed

* "*Horas non numero nisi serenas*" ("I count not the hours unless they be bright") was an ancient dial motto of great beauty and significance.

around, following thus the sun's course. The Natchez lived under a monarchy and the royal family, children of the Sun, like the race of the Incas of Peru, stood high above the common people. In Mexico the sun was pre-eminent over all the other gods. In the Hebrew sacred books there are solemn denunciations of sun worship, for the heathen all around paid adoration to that luminary; and it is clear from 2 Kings xxiii, 5, 19, that some of the kings both of Judah and of Israel favored the worship of the sun.

SUN-YAT-SEN, Chinese revolutionary leader: b. Fatshan, near Canton, 1866. He was graduated (1892) at Hongkong School of Medicine, and started practice at Macao when he became one of the plotters resolved on forcing the Manchu dynasty from power. He fled from Canton after the first failure at revolt and went to Japan, thence to San Francisco. He formed the revolutionary association *Kao Lao Hwei* and carried on his propaganda all over the world, making the United States his headquarters and domicile. Dr. Sun's life was jeopardized by the standing reward of $50,000 for his assassination, but the revolution of 1911 in China succeeded, thanks largely to his indefatigable energy and resourcefulness in propagating the work in every country. He was rewarded by being made Provisional President of the new Chinese Republic but resigned in 1912 in favor of Yuan Shih-kai in order to bring the great Northern influence of the latter into the cause. Sun's later opposition to Yuan Shih-kai in the Peking Parliament caused his expulsion and he had to flee to Japan. Consult Cantlie and Jones, 'Sun-Yat-Sen and the Awakening of China' (3d ed., New York 1913).

SUNBURN (erthema solare or eczema solare), an injured condition of the skin caused by exposure to the action of the heat of the sun's rays. The resulting conditions vary according to the degree of elevation of the temperature, the character of the medium through which its effect is exerted, length of time the skin is subjected to the action. The effect is productive of an erythmatous redness, skin slightly tumified (swollen), with sensation of burning heat. In its course the skin usually desquamates (scales off) and becomes the seat of a "dirty-brownish stain," which passes off later. Such a condition is brought about by several hours' exposure of the bare skin to the sun's rays. Under severe conditions of temperature blistering may arise at times. In the former, ordinary cases a lotion or salve excluding the air from the injury, and to relieve the pain, is applied. Zinc oxide, boric acid, vaseline, etc., are recommended. In severer cases where blistering arises the same treatment must be used as in scalds or burns.

SUNBURY, sŭn'bŭ-rĭ, Pa., borough, county-seat of Northumberland County, on the Susquehanna River, and on the Pennsylvania and the Philadelphia and Reading railroads, about 157 miles north of Philadelphia and 55 miles north of Harrisburg. It was settled in June 1772 by Surveyor-General Lukens and William Maclay. It was incorporated as a borough 24 March 1797. The place was once the site of the Indian village of Shamokin. In 1756 Fort Augusta was erected here as a means of defense against the French and Indians. The city is in a lumbering and coal region. The chief manufacturing establishments are railroad shops, planing mills, silk mills, dye works, sash and door factories, nail factories, a rolling mill and coffin and casket works. It is an important commercial and industrial centre for a large region; extensive coal shipments are made from here. The principal public buildings are the county courthouse, municipal buildings, the Mary M. Packer Hospital, the churches and public schools. The three banks have a combined capital of $500,000. The government is vested in a chief burgess and a council of 18 members, who hold office two years. A small stream separates Sunbury and East Sunbury; the boroughs are one in industrial and commercial interests, but have independent municipal governments. Pop. about 16,000.

SUNDA (sŭn'dạ) **ISLANDS,** a group of islands in the Indian Ocean, comprising three minor groups, namely, (1) the Great Sunda Islands, to which belong, Sumatra, Borneo, Celebes, Java, Madura, Banka and Billiton; (2) the Lesser Sunda Islands, comprising nine islands of smaller extent, and (3) the Timor Group, all forming part of the Malay or East Indian Archipelago. The flora is exceedingly rich and varied. This is the home of sugar-cane and many of the spices, and the different altitudes from coasts upward produce an exceptional variety of plant-life. Some districts, as in Sumatra, reach high elevations, others consist chiefly of grassy plains, or forest-covered slopes.

SUNDA STRAIT, East Indies, the channel which separates the island of Java from Sumatra. It is from 20 to 100 miles wide, and contains a number of volcanic islands, the most noted of which is Krakatoa (q.v.). The strait is an important commercial channel.

SUNDARBANS, soon'där-bạnz, or **SUNDERBUNDS,** soon'dėr-bŭndz, India, the alluvial islet region lying around the mouths of the Ganges River (q.v.), and forming the lower part of the delta. It stretches for 175 miles along the coast, and has an area of 8,000 square miles. The region is intersected by a network of innumerable channels and backwaters, many of which are navigable. The intervening islands are largely marshy, and covered with dense forest jungle abounding in wild animals, snakes, crocodiles, tigers and leopards. The unhealthful climate has hitherto defeated all attempts at reclamation.

SUNDAY, William Ashley, American evangelist: b. Ames, Iowa, 19 Nov. 1863. He was educated at the high school, Nevada, Iowa, and studied at Northwestern University. From 1883–90 he was a professional baseball player in the Chicago, Pittsburgh and Philadelphia teams of the National League. He became assistant-secretary Y. M. C. A at Chicago (1891–95) and started his career as evangelist in 1896. In 1903 he was ordained a Presbyterian minister by the Chicago Presbytery. He has held evangelistic meetings in many of the cities of the United States, drawing large audiences and securing great numbers of converts.

SUNDAY, the Christian weekly festival, by theologians associated with the Jewish Sabbath (see SABBATH), while its observance is often enforced by the citation of the Fourth Commandment in the Decalogue. While the Christian Church has never identified Sunday with the Jewish Sabbath, it has always quoted the Fourth Commandment as sanctioning, if not enacting, rest and relaxation from labor in one day out of every seven. When the Church was made a department of the state by the Christian emperors of Rome, the observance of Sunday was enforced by civil statute. When the Roman Empire passed away, and the office of pontifex maximus, once held by the emperor of Rome, was claimed by the bishop of Rome, Sunday observance was enforced by ecclesiastical as well as civil law. The Third Council of Orleans 538 forbade all rural work on Sunday. Pope Gregory I made at Rome the same law as had been passed in 578 by the Council of Auxerre: "On the Lord's Day it is not permitted to yoke oxen or to perform any other work, excepting for approved reasons." Charlemagne in 813 enacted that on the Lord's Day all servile labor should be abstained from.

By the laws that obtained in England during the Saxon monarchy up to the time of Edward the Confessor (whose Sunday law is dated 1056), abstention from marketings on Sunday and from popular meetings was enforced under penalty of a fine. Equally strict was the Sunday legislation which followed the Norman Conquest. The mediæval Sunday laws in England were but the expansion of the Saxon laws. In 1281 A.D. John Peckham, archbishop of Canterbury under Edward I, explained the Fourth Commandment as follows:

"In the commandment 'remember that thou keep holy the Sabbath day,' Christian worship is enjoined, to which laymen as well as clerks are bound; and here we are to know that the obligation to observe the legal Sabbath, according to the form of the Old Testament, is at an end, together with the other ceremonies in that; to which in the New Testament hath succeeded the custom of spending the Lord's Day, and other solemn days appointed by the authority of the Church, in the worship of God; and the manner of spending these days is not to be taken from the superstition of the Jews, but from the canonical institutes."

A statute of the 28th of Edward III runs as follows: "Item, it is accorded and established, that showing of wools shall be made at the stable every day of the week, except the Sunday and solemn feasts of the year."

In 1359 A.D. Islep, archbishop of Canterbury, issued the following to his clergy: "Whereas, the most excellent prince, our lord, the King of England, is now going to make an expedition in foreign parts with his army for the recovery of his right, exposing himself as a soldier to the doubtful events of war, the issue whereof is in the hand of God; we who have hitherto lived under his protection are, by the divine favor shining on us, admonished to betake ourselves to prayer, as well for the safety of every one of us as for the public good, lest if adverse fortune should invade us (which God forbid), our confession and reproach should be the greater. But, though it is provided by sanctions of law and canon that all Lord's days be venerably observed from eve to eve, so that neither markets, negotiations or courts, public or private, ecclesiastical or secular, be kept, or any country work done on these days, yet we are clearly to our heart's grief, informed that a detestable, nay, damnable perverseness has prevailed, insomuch that in many places markets not only for victuals, but other negotiations (which can scarce be without frauds and deceits), unlawful meetings of men who neglect their churches, various tumults and other occasions of evil are committed, revels and drunkenness, and many other dishonest doings are practised, from whence quarrels and scolds, threats and blows and sometimes murder proceeds on the Lord's days, in contempt of the honor of God; insomuch that the main body of the people flock to these markets, by which the devil's power is increased; whereof we strictly command you, our brother, that ye, without delay, canonically admonish and effectually persuade, in virtue of obedience, or cause to be admonished and persuaded, those of your subjects whom you find culpable in the premises, that they do wholly abstain from markets, courts, and other unlawful practices above described, on the Lord's days for the future; and that such of them as are come to years of discretion, do go to their parish churches to do, hear and receive what the duty of the day requires of them; and that ye restrain all whatsoever that transgress and rebel in this respect, both in general and particular, with Church censures according to the Canon."

The 27th statute of Henry VI is as follows: "Item, considering the abominable iniquities and offenses done to Almighty God and to his saints, always aiders and singular assisters in our necessities, because of fairs and markets upon their high and principal feasts, as in the feasts of the Ascension of our Lord, in the day of Corpus Christi, in the day of Whitsunday, in Trinity Sunday, with other Sundays, and also in the high feast of the Assumption of our Blessed Lady, the day of All Saints, and on Good Friday, accustomably and miserably holden and used in the realm of England: in which principal and festival days for great earthly covetise, the people is more willingly vexed, and in bodily labor foiled, than in other ferial days, as in fastening and making their booths and stalls, bearing and carrying, lifting and placing their wares outward and homeward, as though they did nothing remember the horrible defiling of their souls in buying and selling, with many deceitful lies and false perjury with drunkenness and strifes, and so specially with drawing themselves and their servants from divine service; the aforesaid lord the king, by advice and assent of the lords spiritual and temporal and the commons of this realm of England, being in the said Parliament, and by authority of the same Parliament, hath ordained that all manner of fairs and markets in the said principal feasts and Sundays and Good Fridays, shall clearly cease from all showing of any goods and merchandise (necessary victual only excepted) upon pain of forfeiture of all the goods, aforesaid so showed."

In 1464 A.D., under Edward IV, an addition was made to the act of Henry VI, of 1448 A.D., declaring that — "Cobblers and cordwainers in the city of London, or within three miles thereof, excepting within the precincts of Saint Martinsle-Grand and the palace at Westminster, were forbidden on any Sunday in the year, or on the feasts of the Nativity or Ascension of our

Lord, or on the feast of Corpus Christi to command or cause to be sold, or place or put on any one's feet or legs, any shoes, hose or galoches, under the penalty of the forfeiture of the article and a fine of twenty shillings for every offense; a third part to go to the king, a third to the governors of the guild (mestier) of cordwains, and the residue to the informer.»

In 1523 this act was repealed by Henry VIII (15th Henry VIII, ch. ix).

On coming to the throne in 1547, Edward VI issued the following injunctions: «Whereas in our time, God is more offended than pleased, more dishonored than honored, upon the holy day (Sunday), because of idleness, pride, drunkenness, quarreling and brawling, which are most used in such days; people nevertheless persuading themselves sufficiently to honor God on that day if they hear mass and service, though they understand nothing to their edifying; therefore all the king's faithful and loving subjects shall from henceforth celebrate and keep their holy day (Sunday) according to God's holy will and pleasure, that is in hearing the Word of God read and taught, in private and public prayers, in acknowledging their offenses to God, and amendment of the same, in reconciling theirselves charitably to their neighbors, where displeasure hath been, in oftentimes receiving the communion of the very body and blood of Christ, in visiting the poor and sick, and in using all soberness and godly conversation.»

Elizabeth put forth the following injunction touching Sunday: «All the queen's faithful and loving subjects shall, from henceforth celebrate and keep their holyday according to God's will and pleasure; yet notwithstanding, all parsons, vicars and curates shall teach and declare unto their parishioners, that they may with a safe and quiet conscience, after their common prayer in the time of harvest, labor upon the holy and festival days, and save that thing which God hath sent . . . in every parish three or four discreet men, which tender God's glory, and his true religion, shall be appointed by the ordinaries diligently to see, that all the parishioners duly resort to their church upon all Sundays and holy days, and there to continue the whole time of the godly service; and all such as shall be found slack and negligent in resorting to the church, having no great or urgent cause of absence, they shall straightly call upon them, and after due admonition if they amend not, they shall denounce them to the ordinary.»

Under the Puritan influences attempts were made to bring about a too strict observance of Sunday. To counteract this Charles I republished an injunction issued by his father, James I, in which he declared: «As for our good people's lawful recreation, our pleasure likewise is, that after the end of divine service our good people be not disturbed, letted or discouraged from any lawful recreation, such as dancing, either men or women, archery for men, leaping, vaulting or any other such harmless recreation, or from having May games, Whitsonales and morris dances, and the setting up of May poles and other sports therewith used, so as the same be had in due and convenient time without impediment or neglect of divine service; and that women shall have leave to carry rushes to church for the decorating of it, according to their old custom. But withal we do here account still as prohibited all unlawful games to be used on Sundays, only as bear and bull baitings, interludes, and at all times in the meaner sort of people by law prohibited bowling.»

The act of Charles II (1676) was the law of the American colonies up to the time of the Revolution, and so became the basis of the American Sunday laws. It runs as follows:

«For the better observation and keeping holy the Lord's day, commonly called Sunday: be it enacted by the king's most excellent majesty, and by and with the advice and consent of the lords, spiritual and temporal, and of the commons in this present Parliament assembled, and by the authority of the same, that all the laws enacted and in force concerning the observation of the day, and repairing to the church thereon, be carefully put in execution; and that all and every person and persons whatsoever shall upon every Lord's day apply themselves to the observation of the same, by exercising themselves thereon in the duties of piety and true religion, publicly and privately; and that no tradesman, artificer, workman or other person whatsoever, shall do or exercise any worldly labor or business or work of their ordinary callings upon the Lord's day, or any part thereof (works of necessity and charity only excepted), and that every person being of the age of fourteen years or upwards offending in the premises shall, for every such offense, forfeit the sum of five shillings; and that no person or persons whatsoever shall publicly cry, show forth, or expose for sale any wares, merchandise, fruit, herbs, goods or chattels whatsoever, upon the Lord's day or any part thereof, upon pain that every person so offending shall forfeit the same goods so cried or showed forth or exposed for sale.» «And it is further enacted that no drover, horse-courser, wagoner, butcher, higgler — they or any of their servants shall travel or come into his or their inn or lodging upon the Lord's day, or any part thereof, upon pain that each and every such offender shall forfeit twenty shillings for every such offense; and that no person or persons shall use, employ, or travel upon the Lord's day with any boat, wherry, lighter or barge, except to be upon extraordinary occasion to be allowed by some justice of the peace of the county, or some head officer, or some justice of the peace of the city, borough or town corporate, where the deed shall be committed, upon pain that every person so offending shall forfeit and lose the sum of five shillings for every such offense.»

The Lord's day legislation of Cromwellian days was as distinct and detailed as a fragment from Leviticus, as is shown in the following extract from an act of Parliament dated 1656: «Every person grinding or causing to be ground any corn or grain in any mill, or causing any fulling or other mills to work upon the day aforesaid; and every person working in the washing, whiting or drying of clothes, thread or yarn, or causing such work to be done, upon the day aforesaid; every person setting up, burning or branding beet, turf or earth, upon the day aforesaid; every person gathering of rates, loans, taxations or other payments upon the day aforesaid (except to the use of the poor in the public collections); every chaundler melting, or causing to be melted, tallow or wax belonging to his calling; and every common brewer and baker, brewing and baking, or causing bread to be baked, or beer or ale to be brewed upon the day aforesaid; and every butcher killing any cattle, and every butcher, coffermonger, pouiterer, herb seller, cordwayner, shoemaker or other persons selling, exposing or offering to sell any their wares or commodities, upon the day aforesaid; all taylors and other tradesmen, fitting or going to fit, or carry any wearing apparel or other things; and barbers trimming upon the day aforesaid; all persons keeping, using or being present upon the day aforesaid at any fairs, markets, wakes, revels, wrestlings, shootings, leaping, bowling, ringing of bells for pleasure or upon any other occasion (saving for calling people together for the public worship), feasts, church ale, Maypoles, gaming, bear-baiting, bull-baiting, or any other sports and pastimes; all persons unnecessarily walking in the church or church-yards, or elsewhere in the time of public worship; and all persons vainly and profanely walking, on the day aforesaid; and all persons traveling, carrying burthens or doing any worldly labor or work of their ordinary calling on the day aforesaid, shall be deemed guilty of profaning the Lord's day.»

In the 17th century a number of dissenters fled from England and reached America in 1620, and settled at New Plymouth. In 1629 another band from England joined them. Thus the establishment of Puritanism in America. The theocracy of the Hebrews furnished the model after which their civil government was constituted. Their idea of Sunday is summed up in the enactment of 10 June 1650, passed by the Plymouth general court: «Further be it enacted, that whosoever shall profane the Lord's day by doing any servile work, or any such like abuses, shall forfeit for every such default ten shillings, or be whipped.» Profanation of the Lord's day included traveling, loitering at the door of a meeting house, drinking in an inn, staying at home instead of attending church and it was also enacted by the court, that «if any in any lazy, slothful or profane way doth neglect to come to the public worship of God. shall forfeit for every such default ten shillings, or be publicly whipped.»

In Massachusetts the laws were equally strict.

In 1716 Sunday desecration appears to have been on the increase, since we are told: «Many persons do presume to work and travel on the said day»; so that the authorities saw fit to increase the penalty for «working or playing» to 10 shillings, and that for traveling to 20 shillings for the first offense. For the second offense these fines were doubled and the parties made to give «sureties» for good behavior in the future. A month's continued absence from the public Sunday services was also made finable in the sum of 20 shillings, or three hours in the stocks or cage. In 1727, the fine for «working or playing» was increased to 15 shillings, and that for traveling to 30 shillings for the first offense, and for the second, three pounds. If the offender failed to pay, he was liable to the stocks or the cage for four hours, or to imprisonment in the county jail not to exceed five days. At this time, also, funerals, since they induced «great profanation» of Sunday, by the traveling of children and servants in the streets, were prohibited, except in extreme cases, and then under license from a civil officer of the town. The director of a funeral transgressing this was to be fined 40 shillings, and the sexton or grave-digger 20 shillings. Shops for the retailing of strong drinks were also to be searched by the proper officers, and if any were found there drinking, the proprietor and the drinker were each to pay five shillings.

In 1760 all former laws relative to Sunday gave way to a new code, the provisions of which were as follows: Work or play, on land or water, is fined not less than 10 nor more than 20 shillings. Traveling by any one except in extremity and then only far enough for immediate relief, is liable to the same penalty. Licensed public-house keepers are forbidden to entertain any except «travelers, strangers and lodgers» in their houses or about their premises, for the purpose of drinking, playing, lounging or doing any secular business whatever, on penalty of 10 shillings; the persons lounging, etc., also paying not less than five shillings. On the second conviction the innkeeper is made to pay 20 shillings and on the third offense to lose his license. Loitering, walking or gathering in companies in «streets, fields, orchards, lanes, wharves,» etc., is prohibited on pain of five shillings fine; and on a second conviction the offender is required to give bail for future obedience. Absence from public service for one month is fined 10 shillings. No one is to assist at any funeral, not even to ring a bell, unless it be a licensed funeral, on penalty of 20 shillings fine. In Boston, however, a funeral might be attended after sunset without a license. The observance of the Sunday was to commence from sunset on Saturday. Twelve wardens were appointed in each town to execute these laws; these were to look after all infringements, enter all suspected places, examine or enquire after all suspected persons, etc. In Boston they were to patrol the streets every Sunday (very stormy or cold days excepted), and diligently watch and search for offenders. In case any one convicted on any point in this code failed to pay his fine at once he was to be committed to the common jail, not less than five, nor more than 10 days. These laws were to be read at the «March meeting» of the towns each year.

Practically all the States of the American Union have laws prohibitive of labor on Sunday; but these laws are practically a dead letter. In Arizona and California, however, there are no special Sunday laws. In all other States there are laws, in one form or another, providing for the Sunday-closing of saloons and general places of business, exclusive of drug stores, restaurants and businesses of prime necessity to the general comfort of the community. These laws are pretty generally observed. In some places even barber shops are closed.

SUNDAY CONSTABLE. See Town and Town Meetings.

SUNDAY SCHOOLS, meetings or gatherings in which religious instruction is given to children and young people, usually orally and on Sundays. Such schools are sometimes also known as Bible classes, as the Bible is the textbook in frequent use and often the Bible and the Christian doctrine lessons are arranged in a catechetical form and hence arises the name of the textbook used, catechism, which is sometimes applied to the class or school using such a book. More commonly, however, a Bible class is one of a series of classes in a Sunday school, frequently being a class for adults and older scholars. The work of teaching religion to classes or in schools was practised in very ancient times (Gen. xiv, 14) and by the ministers of God, or their appointed assistants, whenever conditions were such that the young were not taught in their own homes (Deut. xxxi, 10–13). The study of the law was of obligation; and religious schools existed in connection with the synagogues. The catechetical method was at first in general use.

Early Christian Doctrine Schools.— The apostles, or certain persons appointed for the work, gave religious instruction to the catechumens. The religious school, among Christians, seems to have had first place; before the books of the Bible were collected as they now exist, the life of Christ had been taught orally. As Christianity extended the schools came under control of the Christians as nearly all the teachers were Christians, so the religious instruction became a part of the regular work of the school. The differences which arose at the time of Luther (q.v.) led to the establishment of classes and schools for teaching the religious beliefs of different churches. In many cases the religious teaching was continued in the schools and the new classes formed were for the poor and those, both young and old, who were not well instructed. Luther and his followers established such schools. Saint Charles Borromeo (q.v.) was one of the most zealous in founding Sunday schools in all parts of his archdiocese of Milan. He succeeded in arousing the enthusiasm and in securing the co-operation of the laity, men and women, so that he had a large number of teachers. In order to unite the workers and furnish a means of training them for the work, he established an organization called the «Confraternity of Christian Doctrine.» Besides the teachers who were members of this Confraternity, there were also others, who were called Fishers, whose duty was to gather the children and the ignorant and bring them to the places appointed, on Sundays or on week days. At the death of Saint Charles there were in his diocese alone nearly 4,000 members of the Confraternity. They taught in 740 Sunday schools and had over 40,000 pupils. Those receiving religious instruction in the regular schools were not included in this number. This Confraternity still exists. In England there is a large membership. It was introduced into the United States in 1902 and established in the archdiocese of New York by the Roman Catholic archbishop, Michael Augustine Corrigan.

Modern Sunday Schools.— Robert Raikes (q.v.) of Gloucester, England, is the founder of the modern Protestant Sunday school. He first thought of the work in connection with a number of children of wretched appearance whom he saw playing in the suburb of the city where he lived. He was informed by an inhabitant to whom he addressed himself, that on Sundays, when the children were released from work, and the few who enjoyed the benefit of any instruction during the week were free from school, they presented a more afflicting sight of misery and vice. This observation immediately suggested to him the idea that the profanation of the day might be prevented by keeping them occupied; and he engaged several women, who kept schools in the neighborhood, to receive such children as he should send to them on Sundays and instruct them in reading and the catechism, paying each of them a shilling for her day's work. He soon collected a considerable number of children, distributed books among them, gave them advice, settled their quarrels. The effects of his benevolent exertions were so beneficial that his example was followed by other charitable persons in different quarters of the city and in a few years Sunday schools were established in almost every part of Great Britain. Raikes made his first experiment in 1781 and in 1786 it was estimated that 250,000 children were receiving instruction in Sunday schools. A Sunday school society was formed in 1785 and the members were encouraged to give their personal service gratuitously. In 1803 the first Sunday school union was formed in London and the example was soon imitated in many large towns and some of the counties. The Scotch Sabbath schools (first established in Edinburgh in 1787) arose from the English Sunday schools, but from the first were more entirely devoted to religious instruction than the Sunday schools of England. The first Sunday schools united secular with religious instruction. Sunday schools were established in Protestant churches in Scotland, Ireland and America, in the years immediately following their establishment in England; the Scotch Society for «Promoting Religious Instruction Among the Poor» was formed in 1796 and the Irish Sunday School Society was founded in 1809, though a system of Sunday teaching had prevailed in Ireland for some years previously. In later times Sunday schools increased rapidly in connection with all Protestant churches throughout the world. The Sunday school movement was not at first looked upon with favor by the people of New England. It was regarded as a menace to the sacredness of the Sunday (Sabbath) and also as an infringement of the home duties. The Protestant Sunday school, as it exists to-day in the United States, may be said to have had its real beginning in Philadelphia 19 Dec. 1790, when 12 persons held a meeting and decided to begin the work. Sunday schools had been established in the United States shortly after Raikes had begun his work but they existed more as local institutions. On 11 Jan. 1791 a society was established in Philadelphia which had for its object the support of Sunday, or «First Day» schools. The president of the society was Bishop William White and Matthew Carey was the secretary. In New York 13 Jan. 1816, a woman's society for the promotion of the work and in the same place, on the 26th of February of the same year, a society of men was organized for the same purpose. The American Sunday School Union is the outgrowth of the Sunday and Adult School Union, established in Philadelphia in 1817. The new and broader organization took definite form 24 May 1824. On the 75th anniversary, the American Sunday School Union had 100,928 Sunday schools with a membership of 4,070,346 pupils and 578,680 teachers. It had distributed literature amounting to near $10,000,000. The first national convention was held in Chatham Street Chapel, New York, 3 Oct. 1832. National conventions were held 23 May 1833 and 22 Feb. 1859, in Philadelphia; 29 April 1869, Newark, N. J.; 16 April 1872, Indianapolis, Ind.; 11 May 1875, Baltimore, Md. At the Baltimore meeting the convention took upon itself the name international, to which title it had a right on account of the enlargement of the work both in aim and territory. On 1 July 1889 a world's convention was held in London. Other world's conventions have been held in Saint Louis, Mo., 3 Sept. 1893; London 11 July 1898. The organization embraces, besides the usual executive officers, lesson committees and different department workers. In many of the States are held annual State conventions, county conventions and city conventions. The department of field workers is most important. In fact their main work is the financing of missionaries in sparsely settled and neglected localities, where they found and foster evangelical but undenominational Sunday schools. Morris K. Jesup, who was for many years the president; Gen. O. O. Howard, Jay Cooke, William E. Dodge, Louis Klopsch and other prominent men have taken a great interest in the Union's work. In the decade ending 1917, they organized over 17,000 new Sunday schools, reorganized 7,000, besides aiding several thousand public schools. The Chautauqua (q.v.) has been a great aid in the enlargement of the work. In 1908 the Protestant Sunday schools in the United States, including Hawaii and Porto Rico, numbered 140,739, with a membership of 11,355,000 pupils and officers and teachers numbering 1,505,000. In 1917 the Protestant and miscellaneous Sunday schools had over 19,000,000 scholars enrolled and the Roman Catholic schools 2,850,000 more; the Methodist group was the largest, comprising 7,000,000 scholars; the Baptist group followed with 3,800,000; Presbyterian, 2,000,000; Lutheran, 1,000,000; Disciples, 940,000; Congregationalist, 750,000; and Episcopal, Reformed and United Brethren, each nearly 500,000.

All the teaching orders in the Roman Catholic Church, in all countries, give religious instruction in the regular schools, and, when necessary, classes are organized and held on Sundays. The Sunday classes are graded as are the regular school classes. The founder of the first normal school for the training of teachers, Saint John Baptist de La Salle was most earnest in having his teachers prepare themselves well for the work of teaching Christian doctrine. The members of his order (popular name, Christian Brothers) have charge of many Sunday schools. Both Protestants and Roman Catholics have established training classes and normal schools for Sunday school teachers. In New York, in 1901, under the auspices of the Confraternity of Christian Doctrine, a training school for teachers in the Roman Catholic Sunday school was established, and affiliated with it are local training classes.

Conventions and Conferences.— The Protestant Sunday School conventions, international, national, State and county, are most inspiring and educational. The question brought home to the members, most forcibly, and at all the conventions, is that the Sunday school is a necessary feeder of the Church, that to have the adult a communicant, the child must be instructed. As a direct result of the great conventions there has grown up a vast Sunday school literature, the churches have been arranged so as to provide suitable meeting places for the Sunday schools. The Sunday school hymns are also an important outgrowth of the conventions and conferences. In the Roman Catholic Church every educational convention, congress, or conference, has for its beginning and end, the subject of Christian doctrine. Sunday school conferences have been held at the Eastern and Western Roman Catholic Summer schools, and Boston and other cities have had, for some years, regular annual Sunday school conventions.

International Lessons.— In 1872 at the national Sunday school convention of the Protestant Sunday school workers, held in Indianapolis, the plan of having a series of uniform Bible lessons was proposed and met with favor. The lessons were adopted by the Sunday schools of Canada and England, and came into use in many of the Protestant English-speaking Sunday schools of the world. Several periodicals and a large number of books are published as aids for the International Sunday school lessons. Another plan of Bible lessons in use in many parts of the United States is the Blakeslee or inductive system. In the Roman Catholic churches the system in general use is based upon preparation for the sacraments (q.v.). Bible study is correlated with the catechism lessons. In addition to the general system, in many dioceses there is a prescribed course of study for the Christian doctrine work (New York, Philadelphia, Brooklyn, etc.). The Jews have regular courses of study for their Sunday schools, which in the United States are quite numerous.

SUNDERLAND, Jabez Thomas, Amercan Unitarian clergyman: b. Yorkshire, England, 11 Feb. 1842. He was graduated from the University of Chicago in 1867 and from the Union Baptist Theological Seminary in 1870. He was editor of *The Unitarian Monthly* 1886–95, and has held Unitarian pastorates in Milwaukee, Chicago, Ann Arbor, Oakland, Cal., London, England, Toronto, Ontario, Hartford, Conn., and Poughkeepsie, N. Y. He has been director of the American Unitarian Association, secretary of the Western Unitarian Conference, president of the Michigan Unitarian Conference and non-resident lecturer on the Religions of India in the Meadville (Pa.) Theological School. He is a member of the Michigan Authors Club. Has the following honorary degrees: A.B., A.M. and B.D. from the University of Chicago and D.D. (1914) from Tufts College. He was sent to India, 1895–96, by the British and Foreign Unitarian Association, to study the educational, social and religious conditions of the Indian people, and made an extended report on the same on his return to London. In 1913–14 was Billings Lecturer of the American Unitarian Association in Japan, China, Ceylon and India. Was president of the All-India Theistic Congress, 1913. Has written extensively for magazines, reviews and other periodicals in the United States, Canada, England and India. He is author of 'A Rational Faith' (1878); 'What is the Bible' (1878); 'The Liberal Ministry' (1889); 'Home Travel in Bible Lands' (1894); 'A College Town Pulpit' (1895); 'Liberal Religion in India' (1896); 'A Pacific Coast Pulpit' (1898); 'Travel and Life in Palestine' (1900); 'James Martineau' (1905); 'The Spark in the Clod' (1906); 'Causes of Famine in India' (1906); 'The Origin and Character of the Bible' (1907); 'The Bible and Bible Country' (1909); 'Oh, to be Rich and Young' (1910); 'The Orient and Liberal Religion' (1913); 'Liberal Religion as a World Movement' (1913); 'Military Preparedness the World's Menace' (1916).

SUNDERLAND, England, a seaport town and parliamentary borough of Durham, at the mouth of the Wear, 13 miles northeast of the city of Durham and 12 miles southeast of Newcastle-upon-Tyne. The chief buildings are the magnificent Town Hall, Museum, Art Gallery, Libraries and the old parish church of Saint Peters, on the site of the monastery in which the venerable Bede was educated. Sir Joseph Swan the electrician ("Ediswan") was born here. Two lighthouses stand at the entrance of the excellent harbor. The industrial works include shipbuilding establishments, marine engine works, bottle, pottery and rope factories, coal mines, iron works, paper mills, anchor and chainworks. Coal is the chief export. The imports are timber and grain, together with materials for use in manufactures, and provisions. These are brought from Baltic ports and Holland. Pop. about 166,000.

SUNFISH, a fresh-water fish of the family *Centrarchidæ*, closely related to the perches (*Percidæ*) and including also the black bass, crappie, and calico bass. These fishes are among the most characteristic of the fresh waters of the United States, where all of the 12 genera and 30 species are found, and of these only one (*Archoplites interruptus*) occurs west of the Rocky Mountains. Because of their abundance, beautiful colors and forms, interesting habits, courage and gameness, they are perhaps the best known and most esteemed of fresh-water fishes. Most of the true sunfishes belong to the genera *Lepomis* and *Eupomotis*, and the different species are not readily defined without a long technical description; but to the layman, or rather boy, all are known collectively as "sunnies." The commonest and most generally distributed species east of the Alleghany Mountains is *E. gibbosus*, one of the brilliant beauties of our clear brooks and ponds, the type of piscine courage and pugnacity, not fearing to assault any fish that approaches its nest, and itself proof against attacks even from pickerel. Like other sunfishes, it builds a nest of cleaned pebbles on a warm sunny bottom in shallow water, and the male stands guard over the eggs until they hatch and the young are able to care for themselves. This is the boy's favorite game-fish, and it is an excellent morsel on the table. An equally beautiful and larger species, abundant in more sluggish waters throughout the same range and westward, is the blue sunfish (*L. pallidus*). The long-eared sunfish (*L. auritus*) is distinguishable at once by the long appendage of the gill cover. The spotted sunfish (*Enneacanthus gloriosus*) is a most beautiful little fish with gracefully flowing fins and brightly spotted translucent body.

A large marine sunfish is the prevailing species (*Mola mola*) of the plectognath family

Molidæ. It is almost circular in form, and the dorsal and anal fins project posteriorly, with the caudal between. The posterior part of the body looks as if it had been cut squarely off and then the tail replaced, and something like this actually happens in the development of the young. On each side, near the centre, is a small pectoral, and in front of it the gill opening; the gills are arranged in comb-like fringes. It attains a large size, four or five feet in length and three or four feet in depth, with a weight of several hundred pounds; the flesh is white, tough, of a disagreeable odor, unfit for food, and remarkably elastic, the last property depending on the great amount of yellow elastic fibre, interlaced in an intricate manner, almost to the exclusion of white fibre and muscle. It is grayish above and whitish below, with a silvery lustre when alive, and phosphorescent at night, which, with the rounded form, has given rise to a sailor's name, moonfish. It is sluggish in its motions, and is often seen asleep at the surface; when swimming, it is said to turn round like a wheel, and to be able to float with the head and eyes above the surface; the liver is very fat, and its oil is used for lubricating purposes on board ship, and for sprains and bruises among fishermen. Sailors fashion balls from the elastic subdermal tissue. In some seasons it is common in summer in Massachusetts and New York bays, and feeds partly if not principally on medusæ or jelly fishes. There is probably no fish more infested by parasites, internally and externally; the flesh and intestines contain many entozoa, and the skin is studded with crustacean parasites. Consult Gunther, 'Introduction of Fishes' (Edinburgh 1880); Bollman, 'Review of Sunfishes' (Reprint, United States Fish Commission, Washington 1892); Abbott, 'Naturalist's Rambles About Home' (New York 1887); Dean, Bashford, 'Fishes, Living and Fossil' (New York 1895).

SUNFLOWER, the common name of the New World plants belonging to the large composite genus *Helianthus*, so called because their golden-rayed heads are likened to the sun. The robust annual sunflowers (*Helianthus annuus*), native to the prairies of the American West, where they grow over large tracts, sometimes so tall that they hide a horseman riding among them, are often planted as a coarse but brilliant ornamental plant good for concealing fences and the like. The leaves are numerous, rough, very large, and somewhat heart-shaped; the flowers sometimes measure a foot in diameter, generally nodding, and inclining to the sun. The disc is very broad and brownish, and its tubular florets develop four-sided very oily achenes, which are a tid-bit for the Tartars, have been used somewhat for food by the American aborigines, and are the main resource of many western seed-eating animals and birds. In Russia, and in some modern gardens, sunflowers are grown solely for these fruits, which form a valuable food for poultry, and yield an oil, useful for either illuminating or soap-making. They are said also to be a remedy for heaves in horses. The smooth western *H. orgyalis* has narrow graceful leaves, and brown, disked flowers, and is quite apt to bloom from top to bottom, a distance of some 10 feet. *H. decapetalus* var. *multiflorus* is one of the best for cultivation, being not so coarse as other species, and having long-stemmed, clear-yellow flowers, sometimes double, and about three inches across. *H. mollis* is also interesting, for its soft, white velvety foliage, and stands only about five feet high. *H. subtuberosus*, the Indian potato, has thick lanceolate leaves, and fleshy roots, which are thick and edible. It is found on the Northwestern prairies. *H. tuberosus*, with a wider range, has ovate leaves, and fleshy thickened rootstalks bearing the tubers called Jerusalem artichokes. It often grows along roadsides in the East, having been cultivated, doubtless, by the aborigines, and is now largely grown as a fodder for livestock, especially valuable in dry seasons, and as a vegetable for fall.

SUNFLOWER STATE, a popular nickname for the State of Kansas, so named from its prolific growth of sunflowers.

SUNGA. See INDIAN HUMPED CATTLE.

SUNGARIA, soon-gä'rē-ä, or **DZUNGARIA**, a region of central Asia, once an independent kingdom. It is not well delimited but comprises generally the district of East Turkestan north of the Tarim Basin and between the Altai and the Tian-Shan mountains, west of Mongolia. In the 17th century the Sungarians extended their power over a region much greater than that above indicated. In 1670 the Chinese overran the country but were driven out after 40 years, when the Sungarians re-established their independence. The new kingdom did not last long, however, for in 1759 the Chinese conquered and annexed it to their empire. Chinese colonists were thereafter sent there in great numbers.

SUNIUM, sū'nĭ-ŭm, or **CAPE COLONNA**, Greece, a promontory forming the southernmost point of Attica, 28 miles southeast of Athens. It consists of a mountain or hill which in ancient times was fortified and crowned by a marble temple of Athene. Portions of the walls and 13 of the columns (whence the name «Colonna») of the temple still remain. At the foot of the mountain lay the silver-mining town of Sunium.

SUNKEN BELL, The. Gerhart Hauptmann's 'Versunkene Glocke' ('The Sunken Bell') (1896) is commonly supposed to be the poet's elegy on the failure of the hopes which he had set upon the attempt to adapt naturalistic methods to the treatment of an historical subject in 'Florian Geyer' (first played 4 Jan. 1896). Quite as probably, however, Hauptmann symbolized in this fairy drama a mood to which poets as such are no strangers, even without the chagrin of recent defeat: the melancholy sense that ascent to spiritual heights is toilsome and is impeded by fetters to the lower earth. Moreover, there are spirits of the depths as well as of the heights.

The bell-founder Heinrich is thwarted of his supreme ambition, to place a bell in a mountain chapel, by the malice of a wood-sprite who cannot abide the ringing of it, and despairing he plunges into the abyss which engulfs the product of his Christian devotion. His humble, unesthetic wife can give him neither comfort nor the courage to live. Both come to him from a mountain elf, Rautendelein. In association with her, he plans a new masterpiece, half church, half temple to the sun, but he is not destined to accomplish his design. The humdrum dwellers in the valley persecute him as a renegade; the wood-sprites assail him in hostility like Loki's to Balder; the tolling of his submerged bell recalls him to where his wife and children have died of grief. He repulses Rautendelein and hastens below — but only to return and discover, a moment before he breathes his last, that his proper dwelling place is with her on the heights, and that the nether sphere, the realm of failure and of death, is that from which no man can escape.

The play, rich in elements derived from German folklore, with some reminiscences of classical mythology, is enhanced by the contrast of naturalism and fantasy, and contains, along with some hollowness, the most intense and musical poetry that its gifted author has ever written. Translated by Mary Harned in 'Poet Lore' (Vol. X, 1898), by C. H. Meltzer (Garden City, 1915), and by Ludwig Lewisohn (in 'The Dramatic Works of Gerhart Hauptmann' New York 1913–15). Edited by T. S. Baker (New York 1901). Cf. Ludwig Lewisohn, 'The Modern Drama' (New York 1915).

WILLIAM G. HOWARD.

SUNN HEMP. See FIBRE.

SUNNAH, sŭn'ạ, **SONNA,** or **SOONNUT,** the oral teachings of Mohammed, built upon his sayings and practices, and other traditions, which are regarded as authoritative by the orthodox Mohammedans, although not part of the law, as set forth in the Koran. A great number of so-called «Traditions» were fabricated to uphold certain political and sectarian claims, but these were subsequently rejected. The six standard Sunni collections were all compiled under the Abbaside caliphs, and the earliest of them partly during the reign of Al Mamun. The four canonical collections of the Shias are of later date and less trustworthy. See also MOHAMMEDANISM; SUNNITES.

SUNNITES, sŭn'īts, or **SUNNI,** the orthodox Mohammedans, who accept as authoritative the oral teachings of Mohammed, the deliverances of the orthodox imams, and the various traditions assumed to be traceable to those who had the confidence of the prophet, in addition to the Koran, which is received as law by Mohammedans of every sect. The Sunnites regard as heretics the Shiites (Shia) who do not accept the Sunna, as the body of oral tradition is called. While the animosity between the two great divisions of Islam, like that between Christians of different creeds, has vented itself, and among the more prejudiced still finds expression, in bloodshed and bitter persecution, there is a much more tolerant feeling in the present age than existed in the past, and Shiites occupy important places in the Turkish empire, which is almost universally Sunnite. The Sunni contend that Mohammed never intended to establish any hereditary right in his descendants. See MOHAMMEDANISM.

SUNNYSIDE, Washington Irving's estate at Irvington, N. Y. It is close to the Hudson River, about half a mile north of the Irvington railway station. It was bought in 1835 by Irving, who gave it the name of Sunnyside; at that time the estate contained 10 acres, later eight more acres were added. A small stone house was standing on the estate, known as Wolfert's Roost, which during the Revolutionary War was a station of the Dutch «water guards» who watched and constantly annoyed the British ships anchored in the river. It was an old-fashioned mansion, with many gables and according to Irving «as full of angles and corners as an old cocked hat.» Its picturesqueness pleased the author's fancy, and while he had it enlarged and modernized under the direction of an artist, George Harvey, he was careful to keep its «old-time» appearance. English ivy grown from a slip brought from Melrose Abbey, was trained over the front, which it now completely covers. Though additions have been made to the house since Irving's time, the old part has not been materially changed, and maintains the same general appearance.

SUNSHINE STATE. The name given by statute to South Dakota, which is also known as the «Koyote State.»

SUNSTONE, or aventurine feldspar, a variety of feldspar showing a beautiful golden schiller. This is due to the reflection of light from the surfaces of multitudes of minute, tabular crystals of hematite or goethite, enclosed in the spar in parallel position. Under the microscope, or even with a pocket lens, these little crystals appear gorgeously iridescent. Sunstone from Tvedestrand, Norway, the finest known, is a reddish variety of oligoclase; a green microcline sunstone occurs in Pennsylvania.

SUNSTROKE, prostration due to exposure to intense external heat. Such exposure may be to the direct or indirect rays of a tropical sun or to the excessive heat of an engine room. In either case heat and physical exertion combine to bring about the results. A high degree of humidity of the atmosphere is one of the most important features, since this hinders free evaporation of fluid from the body which is one of the most important devices for cooling the body. Sunstroke is an old disease. Osler mentions that two instances are on record in the Bible and many of the ancients described it very well, confounding the severer forms with apoplexy. Two main types are seen — heat exhaustion and heat stroke. Other terms for heat stroke are isolation, thermic fever, coup de soleil.

Heat exhaustion is frequently seen among workmen who are exposed to the direct action of the sun. Bricklayers, drivers, farmers, etc., or firemen and stokers in large vessels, while in the midst of their work suffer from extreme prostration. There is great restlessness, muscular weakness, fainting spells and collapse, and often delirium. The surface of the body is usually cool and the temperature may be subnormal, 95° to 96° F., the pulse is small and rapid and unconsciousness rapidly develops. In heat stroke or thermic fever, the symptoms are quite different. Here marked physical exertion and direct exposure to the sun with high humidity are important factors — in addition some form of alcoholic drink is being taken, notably ale, beer or whisky. In the severe grades the patient may be suddenly struck down and die with rapid breathing, heart weakness and unconsciousness. These cases are rare and frequently, on autopsy, turn out to be something else. The more common type commences with severe headache, dizziness, a sense of weight in the head, and nausea and vomiting. If these signs are disregarded and the patient continues to march, if a soldier; or to stoke, if a stoker; or to work, if a laborer, symptoms of disordered vision develop; diarrhea and increased urination are present and then unconsciousness sets in. Seen in this condition the patient is usually flushed, the eyes blood-shot, the skin is hot and dry, the temperature, an important sign, is very high, 105° to 110° F., or in some cases even higher. The pulse is rapid and bounding; the breathing is apt to be noisy, and the patient, apart from his very high temperature and dry skin, may seem to be suffering from alcoholism. The pupils may be dilated or contracted and there may be an eruption on the skin. In these cases that end fatally the unconsciousness deepens, the temperature mounts, convulsions and twitching occur, the breathing becomes very irregular and shallow. A gradual fall in temperature and a return to consciousness are symptoms of recovery. Many patients after recovery have a permanent susceptibility to high temperatures.

It is important to distinguish between these two forms of heat poisoning as the treatment is radically different. In heat exhaustion there is vasomotor paralysis with cold wet skin and subnormal temperature, and patients should receive alcohol hot bottles and supportive treatment. Heat stroke should be treated by cold and stimulants. The body should be drenched with cold water. The wrists and sides of the neck rubbed with icewater or ice, as the large arteries are here more readily reached and the blood more rapidly cooled. Icewater rectal injections are also useful to reduce the temperature rapidly and also to empty the bowels, an important indication. It may be necessary to immerse the patient directly into an ice bath. During this treatment careful readings of the clinical thermometer must be taken and as soon as the temperature sinks below 102° to 103° F., and stays there, the cold applications may be discontinued. Moderate venesection is not contraindicated, but that is a technical question for the physician to decide. In malarial countries, particularly below Mason and Dixon's line, quinine may be used to advantage to obviate possible malarial combinations. Coal tar antipyretics are not advisable if signs of heart weakness are present. Of cardiac stimulants ammonia is the most serviceable, as it can be breathed by an unconscious patient. Sometimes chloroform is essential to control convulsions.

The mortality from heat exhaustion is about 9 per cent, whereas the high mortality of 25 per cent is recorded for heat stroke or thermic fever. Consult Manson, 'Tropical Diseases' (1900); 'Sunstroke' in 'Encyclopedia Medica' (1902); Wood, 'Thermic Fever, or Sunstroke' (1872).

Smith Ely Jelliffe, M.D.

SUPEREROGATION, performance of more than duty requires, for example, if one commits theft of a dollar and makes reparation of the wrong by giving back two dollars; or if one not only forgives those who injure him, but confers unmerited benefits upon them. The Anglican Church, in the 14th of the 39 Articles of Religion, expressly condemns the notion of works of supererogation as impious: «Voluntary works besides, over and above, God's Commandments, which they call Works of Supererogation, cannot be taught without arrogancy and impiety; for by them men do declare that they not only render unto God as much as they are bound to do, but that they do more for his sake than of bounden duty is required; whereas Christ saith plainly, When ye have done all that are commanded to you, say, We are unprofitable servants.» Supererogation is not a term of theology in the Roman Catholic Church; but that Church teaches that good works done by the faithful in the state of grace are meritorious of eternal reward, and that merits of holy men redound, through the goodness of God, to the spiritual advantage of the whole Church. This doctrine differs not from that taught in the 'Institution of a Christian Man,' published by authority of convocation in 1537:

> "I believe that whatsoever spiritual gift or treasure is given by God unto any one part or member of this mystical body of Christ, although the same be given particularly unto this member, and not unto another, yet the fruit and merit thereof shall, by reason of that incomprehensible union and bond of charity which is between them, redound necessarily unto the profit, edifying, and increase in Christ's Body of all other members particularly."

SUPERFŒTATION, a second conception and the formation of a fœtus after a previous impregnation in the same female, whereby two fœtuses coexist in the uterus. In such a case a woman may be delivered of a full-grown child and of an undeveloped embryo at the same time, the period of conception of each being presumed to be different; or a woman may be delivered of two living children, the one appearing much more developed than the other. In recorded cases women have given birth to twins, the one child being white and the other black, showing that each had a separate father and of a distinct race, and proving the possibility of a double conception. But far more typical cases of superfœtation have been found. Such is that instance in which, as published by Eisenman of Strassburg, a woman was delivered of a second child 140 days after the first, both children being fully developed. In this case, therefore, the second child must have been conceived at a later and different period from the first; and the development of the second child must have been proceeding separately from that of the first, and after the latter was born. Still more remarkable cases of this kind have been recorded. The explanation of these curious cases has afforded a very intricate study and puzzle to obstetricians and physiologists, as well as to those concerned with their medico-legal aspect, which sometimes bears directly upon questions of conjugal fidelity. As the subject at present stands, its full elucidation is still a matter for obstetrical investigation; but there can be little doubt either of the actual occurrence of cases of superfœtation, or of the great importance of the study of its phenomena.

SUPERHEATERS. See Locomotive.

SUPERIMPOSED DRAINAGE. When a stream flowing across a region cuts down and uncovers an old buried erosion surface the drainage is said to be superimposed on that surface. For example, if any familiar region of hills and valleys should sink beneath the sea, and all the old surface be buried beneath sands and muds, a plain would result. If this plain would then emerge and rivers were to start flowing over it, the new streams would pay no attention to the old buried topography, but would wander freely over the plain. As they cut down the region, they would uncover this old topography, and would then be superimposed. Such is much of the drainage in the glaciated regions, where glaciation has filled up the old valleys, and obliterated the old preglacial drainage.

SUPERIOR, Wis., city, port of entry, county-seat of Douglas County, on Lake Superior, and on the Northern Pacific, the Chicago, Saint Paul, Minneapolis and Omaha, the Duluth, South Shore and Atlantic, the Great Northern, the Minneapolis, Saint Paul, and Sault Sainte Marie, the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads opposite Duluth. It shares with Duluth the commercial advantage of being the extreme western port of the Great Lake system of the United States. It has three connecting harbors, well sheltered and deep, making a combined length of 13 miles, with an extreme width of three miles. The city comprises the ports known as East, West, South and Old Superior. The climate is cool in summer and cold in winter. The chief manufacturing establishments are flour and lumber mills, iron and steel works, boiler works, windmill, factories, shipyards, bag factories, tractor factories, cooperage, chair factory, wagon and carriage works. Lath, shingles and other lumber products are also manufactured. It has also shipyards, coal docks capable of receiving 6,370,000 tons of coal, large grain elevators, a large dry-dock and a number of wholesale merchandise establishments. The government census gives the amount of capital invested in industries $7,050,000 and the annual value of the products $11,663,000. There is an extensive lake trade, and railroads furnish transportation for products sent to the interior. The principal public buildings are the government building, county courthouse, municipal buildings, Saint Francis Hospital, Saint Mary's Hospital, Women's Christian Temperance Union Hospital, national and State banks, several business blocks and hotels. The educational institutions are a State normal school, the Finnish University, two business colleges, two high schools, public and parish schools and two public libraries. The commission form of government is in operation. The port's foreign trade has become extensive in recent years, having now an annual volume of about $1,500,000, of which 80 per cent is in exports. The city's annual expenditure on various municipal activities is about $550,000, of which $200,000 is expended on schools, $100,000 on fire protection and $60,000 for police. Pop. about 62,500.

SUPERIOR, Lake, the largest expanse of fresh water in the world and the most westerly and most elevated of the great lakes of the Saint Lawrence basin; lat. 46° 30′ to 49° N.; long. 84° 30′ to 92° 20′ W. It washes the shores of the State of Minnesota on the west, of Wisconsin and the northern peninsula of Michigan on the south and of Canada on the north and east. The greatest length, measured on a curve through its centre from east to west, is 420 miles; greatest breadth, 167 miles; circuit, about 1,750 miles; estimated area, 31,200 square miles; height above sea-level, 602 feet; approximate mean depth, 900 feet; maximum depth, 1,008 feet. It is of very irregular shape, widening out toward its centre and gradually narrowing, partly toward its eastern but much more toward its western extremity, so as to form an irregular crescent, with its convexity on the north and its concavity on the south. The northern shore is generally bold and elevated, presenting almost continuous ranges of cliffs, which vary in height from 300 to 1,500 feet; the southern shore is low and sandy, though occasionally interrupted by limestone ridges, the most remarkable of which, situated toward the eastern extremity, present a perpendicular wall 300 feet high, broken by numerous caverns and projections, and forming, under the name of the Pictured Rocks (q.v.), one of the greatest natural curiosities of the United States. The central portion of the lake is clear of islands, but these are numerous toward both the southern and the northern shores. In the former direction they are small, and, being insufficient to give shelter behind them, only increase the difficulties of navigation without contributing to form a single good harbor. On the north shore several of them, more especially the Isle Royale, are of considerable dimensions, and along with the indentations of the coast afford good shelter for vessels. The water of the lake, remarkable for its transparency, derives its supplies from a basin which is estimated at 54,000 square miles, and is drained by more than 200 streams. The water never freezes except in the shallow regions along shore. About 30 of the islands are of considerable size, but they are almost all impetuous torrents, interrupted by rocks and rapids. Superior discharges into Lake Huron, at the southeast end, by Saint Mary's River, which at Sault Sainte Marie descends 22 feet in three quarters of a mile, navigation being here carried on by means of two ship canals, one on the Canadian, the other on the United States side. Within the lake itself the only obstruction to its navigation are the violent gales to which it is subject. It is well supplied with fish, principally trout, whitefish and sturgeon. There are a great number of fishing-stations. Large deposits of copper and iron are worked on the shores of the lake, especially on the southern shore along the northern coast of Michigan. The boundary line between Canada and the United States, in passing through Lake Superior, proceeds from the outlet nearly through its centre till it approaches Isle Royale, when it bends north so as to give that island entirely to the United States, and is then carried south-southwest to its termination at the mouth of the Pigeon, in lat. 48° N. The chief towns on the shores of Lake Superior are Duluth, Minn., at the western extremity, with an excellent harbor; Superior, Wis., near Duluth; Marquette, Mich.; Fort William, Ontario, also with a good harbor; and Port Arthur, Ontario. Consult Agassiz, 'Lake Superior: Its Physical Character, Vegetation and Animals' (Boston 1850) and Martin, 'Progressive Development of Resources in the Lake

Superior Region› (In American Geographical Society publications, Vol. XLIII, New York 1911).

SUPERNATURALISM, «above nature» or miraculous, in theology, the generally received belief that divine revelation is the sole and ultimate ground of the Christian religion; it is opposed to naturalism, the theory that while the Scriptures contain many truths these truths are only a reassertion of natural religion and therefore unnecessary; it is also opposed to rationalism (q.v.), which makes reason the supreme arbiter in all matters connected with revelation and the religion of Christ. Supernaturalism regards the Christian religion as an extraordinary phenomenon out of the circle of natural events and as communicating truths above the comprehension of human reason. Though the supernaturalist, no less than the rationalist, employs reason in matters of revelation, he does so only to search and judge those claims to a divine origin which Christianity puts forth; when he is once convinced that Christianity contains the direct teachings of God, it becomes his highest, his sole authority; called also supranaturalism.

SUPERPHOSPHATE FERTILIZERS. See Fertilizers.

SUPERSTITION, Popular. That which others believe and we do not, is classed as superstition. The religion of our friend, if differing radically from our own, seems to us a superstition. In the heart of nearly every human being, savage or civilized, exists a settled conviction that he dwells in the midst of an unseen world, peopled with beings of strange powers, who thwart the plans of his own life or assist him in his endeavors. Folklore, legends, ghost stories and witch tales were early in the 19th century regarded as mere fables, but in the light of modern science they are now as worthy of study as the surely not less indelicate recitals of Roman and Greek mythology. Every profession, trade and occupation has its peculiar superstitious lore. Even the farmer who sudies the actions of animals will tell you what they portend concerning the weather and in many cases sensibly, too, for they build their homes and lay in their food through instinct given by Divine Providence with reference to the coming winter; they house themselves before the coming storm; their coats are heavy or light, as the winter shall be severe or otherwise, and they often give the farmer who watches them valuable indications concerning his crops. So to a greater or less extent man has followed the habit of the bird and the beast; he has been guided in all his acts by omens; he has often planted his crops, gathered his harvests, made his journeys, waged war, built his house and gone fishing and hunting according to imaginary signs and superstitious beliefs. Though many of the old omens and superstitions have passed into oblivion, there still remain among every race of people hundreds and thousands of popular beliefs and many of them seem destined to be extant as long as man exists. As indicative of the variety, peculiarity and unusual extent of present-day superstition, the following examples selected from the folklore of the different nations and peoples of the world and now first collected will prove of undoubted interest alike to scientist, student and casual reader.

Superstitions of the World.

Africa.— The snake is held in superstitious reverence by some African natives, who once a year kill a cobra de capello and hang its skin to the branch of a tree, tail downward. Then all the children born during the last year are brought out and made to touch the skin. This, their parents think, puts them under the serpent's protection. The Kaffirs use the venom of the puff adder, to poison their arrows, and when they have any small quantity left they swallow it, having a theory that it will protect them from the effects of future bites. If they find a dead serpent they dress it in clothes and give it a superb funeral.

American Indian.— Various tribes of American Indians have a theory that every white deer has a «mad stone» in his stomach. They believe that the «Great Spirit» places this stone in the white deer's stomach to absorb poisons which that delicate animal may take in while eating grass. Feathers figure very prominently in the religious customs of most aborigines, and remarkably so in the Southwest. Among Navajos and Pueblos alike these plume symbols are of the utmost efficacy for good or bad. They are part of almost every ceremonial of the infinite superstitions of these tribes. Any white or bright-hued plume is of good omen — « good medicine,» as the Indian would put it. The gay feathers of the parrot are particularly valuable. The Navajo Indian will not eat fish under any circumstances, and cherishes the belief that the use of such food will be followed by dreadful punishment.

Arabia.— Many Arabs, when overtaken by severe storms in the desert, cry out, «Iron! Iron!» which they think will propitiate the evil spirits who have raised the storm.

Arctic Regions.— The Eskimos believe in ghosts. Many also believe in the transmigration of the souls, that spirits return in animals, winds, rocks, ice and water, that they are evil, angry or good, as the elements may be favorable or unfavorable, and that they can be appeased by hoodoo rites if the performer is sufficiently versed in occult sciences. To change the wind they chant, drum and howl against it, build fires, shoot against it, and, as a last resort, fire the graves of the dead. Eclipses of the moon create the greatest consternation and almost paralyze the people with fear. When a child dies in some parts of Greenland, the natives bury a live dog with it, the dog to be used by the child as a guide to the other world. When questioned in regard to this peculiar superstition, they will only answer, «A dog can find his way anywhere.»

Australia.— Some Australians say that Mityau, the moon, was a native cat, who fell in love with some one else's wife, and was driven away, to wander ever since. The natives of New Zealand tie the hands of their dead together and pull out their nails; this is for fear that the corpse may scratch its way out of the grave and become a vampire.

Bohemia.— The peasants of Bohemia have a queer superstition by which they think to rid themselves of the depredations of sparrows among their crops. A frequent charm is to plant, in the centre of the field, a stick or splinter of wood taken from the timber of which a coffin has been made, or to scatter about pieces of the coffin itself. It is also considered very effective to lay upon the threshold or window-sill of the barn or storehouse a human bone taken from a grave. In Bohemia the willow is said to be the tree on which Judas hanged himself, and it is supposed to have a special attraction for suicides.

Brazil.— Religious superstitions are common here. Once a year some churchmen dress up a figure to represent Judas (usually with red hair and sandy beard), and give it to the street arabs, who carry it about until it has been riddled by stones and other missiles and then burn it on the commons. In the same country the sailors dress a figure on certain feast days, subject it to all sorts of indignities, winding up the ceremony by hanging it at the yard-arm.

China.— Many Chinese guard their homes from witchcraft by suspending bunches of herbs and magic plants over the door. At the new year the Cantonese clean out their houses and post near the doors a pair of scrolls made of red paper (the lucky color) bearing an inscription such as «Leaves of the moxa, like a banner, procure a hundred blessings.» In China the peony is regarded with superstitious reverence and pride. In China, too, the old man of the moon is known as Yue-loa, and holds in his hands the reins of marriages among mortals. The future husband and wife are tied together by an invisible silken cord, which is only severed at death.

Cuba.—A belief very prevalent among the common people is that the rain water of May has peculiar beneficial qualities which that of no other time possesses. The moonlight in Cuba seems particularly objectionable, and strangers are warned not to go out in it with uncovered head, and not to go out in it at all if it can be avoided; it is thought that this light brings many evil effects and not under any circumstances will a superstitious Cuban sleep in its rays — he thinks that, among other things, it will draw his mouth to one side of his face. The hooting of an owl is taken as a very bad sign. The superstitious Cuban kills any creature of this kind which makes weird sounds near his home. This is supposed to break the spell, and it is not then inevitable that a member of the family shall meet death in the near future.

Egypt.— When Egypt was in the height of her power her people worshipped a black bull with a circular white spot in the exact centre of his forehead, and the advent of such a creature in any herd was the signal of wild demonstrations. Even as late as the time of Cleopatra such animals were shod with gold and had their horns tipped with the same metal. Herodotus tells of a man who died with grief because he sold a cow that soon after became the mother of a black bull calf marked with the sacred white circle in his forehead. In modern times the Egyptian housewives mark their bread loaves with a cross, and housemaids insure a brisk kindling of a newly lit fire by making the same sacred sign over the grate. The sacred ibis of the Egyptians was supposed, from the color of its feathers, to symbolize the light and shade of the moon. It is said that its feathers would scare, and even kill, the crocodile. The bird was believed to deliver Egypt from winged and other serpents that came from Arabia. It was so deeply venerated that it entered the most sacred temples with impunity, and to kill one, even by accident, was a crime punishable with death. After death, its body was embalmed, and thousands of their remains have been found at Thebes, at Memphis and at other Egyptian cities.

England.— In England there existed, even so late as the 18th century, a superstitious belief that a man condemned to be hanged could escape that undesirable fate provided some compassionate woman came forward at the foot of the gallows and expressed her willingness to marry him. Superstition has always clung to the cricket. In Hull it is unlucky to kill them, and in Lancashire, it is said, they cut holes in the worsted stockings of those members of a family that kill them. It is a custom in many parts of England and the Continent to announce to the bees a death in the family, especially that of the master. It is said that if a swarm of bees settle on the dead branch of a live tree a death will occur in the family within a year. In some places it is thought unlucky to sell them. They are given away for another gift. It was a popular superstition in Norfolk that whatever you are doing the first time you hear the cuckoo, that you will do most frequently all the year. The English housewife will not sweep the dirt out of the front door, fearing to sweep away the fortune of the house. In the north of England, the peasantry do not favor naming a child after some respected ancestor; that departed worthy might not like it. In the same locality when the dairy maid churned for a long time without making butter, she would stir the cream with a twig of mountain ash and beat the cow with another, thus breaking the witch's spell. But to prevent accidents of this nature it has long been customary to make the churn staff of ash. For the same reason herd boys employ an ash twig for driving cattle. In England it was thought, and not many years ago, that oak trees were mysteriously protected, and many superstitions clung round the sacred tree. The hawthorn used to be hung up at the entrances of houses in May to guard the dwelling from witches. In Devonshire it was considered unlucky to plant a bed of lilies of the valley, as the person who did so would surely die in the course of the next 12 months.

Fiji Islands.— In the mountain country of the Fijis there is prevalent a superstition called by the natives «Tuka.» The priests profess to possess an elixir of life, which, preventing decay or disease, insures to faithful disciples of this faith everlasting youth and vigor and a robust enjoyment of life. The natives who give their adherence to these priests (and this means the giving up of all they possess to them) are promised the life of immortal youth, the immediate resurrection of their ancestors, vengeance on all their enemies and oppressors, whose wives and property they should inherit, together with all the wealth of the white settlers, these latter being also promised to them for domestic slaves.

France.— Perhaps the most common of all French spread superstitions is the belief met with through all the south of France, that the position of a drowned body may be discovered by a floating loaf of bread. Possibly the only scientific basis is that the loaf is apt to be carried by a current of water just as a body is. The French peasant's faith in fermented grape juice is truly beautiful. If his children are stricken with the measles he gives them beakers of wine, well sweetened with honey and highly spiced with pepper. For a severe cold he administers a quart of red wine and a melted tallow candle mixed. For scarlet or brain fever he gives eggs, white wine and soot, well beaten together. Not all their superstitions are curious — some are pathetic. A mother, for instance, often buries her dead child with its favorite toy, or her own beautiful hair in the coffin, «that it may not feel quite alone.» Along the sea coast, unless the waters are strewn with flowers by the fishermen's wives and daughters, there will be no fish to catch. A curious superstition which is current among the street gamins of Paris and the large cities of France, is that which makes it unlucky to pass a priest. To break the ill luck, the passer must immediately touch a piece of iron. Gamins carry in their pockets pieces of iron to touch, but none of them seem to know the wherefore.

Germany.— Throughout northern Germany and in the Low Countries the stork is held in beloved reverence, for the peasants believe that where the stork has its brood no fire can ever come. There is a German belief that any one who during his lifetime may have made cats his enemies, is certain to be accompanied to the grave amidst a storm of wind and rain. It is said to indicate good luck to have a spider spring his web downward toward you, but bad luck when he rises toward you. If one has a four-leaved clover, and carries it about on Christmas eve it is believed the owner has the power to see witches. In Germany the apple has been deemed potent against warts. In Pomerania it is eaten on Easter morning as a preventive of fever. «If on Christmas night,» says a German proverb, «the wine ferments heavily in the barrels a good wine year is to follow.»

Greece.— Before a Greek selects the day for his wedding he observes most minutely every omen, and with prayer and fasting and sacrifice, takes every precaution. The Grecian mother, before putting her child in its cradle, turns three times around before the fire while singing her favorite song, to ward off evil spirits.

Hawaii.— In the Hawaiian Islands the superstition that the Kanaka holds dearest is that concerning the power of the Kahuna, or native witch doctor. This power is almost limitless. If a native in any way offends a Kahuna he is in deadly fear that he will be condemned to die, and he immediately hunts up a Kahuna higher in rank than the one whom he has offended and asks to have the curse offset and neutralized.

Iceland.— The Icelanders have a superstition which they call «Skipamal,» or the speaking ship. They conceive that utterances came forth from the motionless hulls of vessels; but few can understand the strange language.

India.— The natives of India have many curious beliefs and superstitions, some of which are essentially Oriental in their nature. The Hindus think it brings a person ill luck to be openly admired or praised, and if you should praise or even look too admiringly at a child the mother will hastily withdraw it from notice, and either beat it or say something disparaging of it in order to counteract your ill-omened admiration and avert the jealousies of the gods. In Burma it is rather a suspicious thing to give money for a charitable object. It is supposed to mean that the donor has been very wicked and is desirous to make amends. The Hindu troubled with a wart looks at the new moon, picks up a pinch of dust from beneath his left foot, rubs the wart with it — and when the moon goes so does the wart. In India one may observe the quasi sign of the cross which a Hindu makes should he chance to sneeze while performing his morning ablutions in the Ganges. Having touched his forehead, nose, chin and cheeks with the tip of his finger, he recommences his prayers from the very beginning, and will do so as often as they are interrupted.

Ireland.— The Irish peasant is subject at all seasons to the sense of shadowy supernatural agencies. But at no other time is his helplessness against such fateful and inexorable agencies brought home to him as in Lent. Moreover at this time the auguries and omens assume an especially depressing complexion. Thus the «keen» of the Banshee, always an eerie presager of death, when it occurs during Lent has the gloomy significance of a double funeral. Peasant mothers in Ireland still carry their children to holy wells where the little ones are made to creep on hands and knees beating their infant breasts the while they pray and plead for Lenten mercy on their own and the manifold sins and wickedness of their fellows, and are bathed in the blessed water which is credited with a miraculous power of averting sickness and washing away sin. The ceremony is completed by tying to a tree in the neighborhood of these consecrated springs, shreds of colored rag as a thank-offering and propitiation to the particular patron saint who is believed to preside over the birth of the child and to hold its future in his keeping. The people in the south of Ireland are particularly fearful of the robin entering their houses, for they say that it is always a certain prognostic of severe snows and frosts.

Isle of Man.— One of the superstitious customs in Manxland is for the family on stormy nights to retire to rest at a very early hour, so that the good fairies may unobserved enter to find shelter and repose.

Italy.— In Italy the snake is invulnerable except during the full vintage of the moon, when the serpents are believed to become drunken on the vineyards, and may be slain. The slaying of one of these serpents, though, would be the calling down on the head of the slayer and his family forever some terrible plague. The superstition about snakes as guardians of buried treasure seems to be a favorite one with the Italian peasantry; for they believe that all snakes hover about where such treasures are. In Sicily the time honored superstition of the «Evil Eye» is still so widely spread throughout the island, even among the upper classes, that no one who does not wear a charm is considered safe. A Venetian superstition is that the young girl across whose feet dirt is swept will never get married. The periwinkle has in Italy gained for itself the name of Death's flower, from the ancient custom of raising it for garlands when an infant died.

Japan.— Japanese sailors think it is a good omen to cross the bows of a foreign vessel and frequently they run into considerable danger in order to do it. The Japanese have some curious ideas about their finger nails. One of them is to the effect that they must not be cut before starting on a journey, lest disgrace befall the person before he reaches his destination. Neither should they be cut at night, lest cat's claws should grow out. To throw nail parings into the fire is to invite some great calamity. If, while trimming the nails, a piece should fall into the fire, the person will soon die. They are superstitious about many flowers and will have none of them. Many favorites, as the orchid, gentian, daphne and azalia are utterly prohibited for felicitous occasions. There is also with them an aristocracy of flowers most sharply defined. The iris is of princely dignity, but because of its purple color must not be used for weddings. Some flowers in themselves are regarded as being of ill omen. Such is the camelia, for instance, which is neglected because its red blossoms fall off whole in a manner which reminds them of decapitated heads.

Java.— When search is made for the body of a drowned person a live sheep is thrown into the water and is supposed to indicate the position of the body by sinking near it.

Mexico.— In Mexico the Indian carnation bears the name of the flower of the dead, and when a virgin dies it is customary for a young woman to carry a garland of flowers and sweet herbs in front of the coffin. The high priest of the ancient Mexicans gave aloe leaves, traced over with sacred characters, to people going among volcanoes, to protect them from the incident dangers.

Norway.— Norwegian sailors believe in the existence of a heck or merman, a sea animal represented as having a fish body with the head of a man and the flowing ringlets of a boy. The merman sits upon the waves, plays the harp and, following the example of many of the Norse fishermen, wears a red cap. It is never seen more than once in seven years, and no matter how many vessels appear in its sight they all must inevitably perish. A curious custom is practised in Norway, where those in search of a drowned body row to and fro with a cock in the boat, fully expecting that the bird will crow when the boat reaches the spot where the corpse lies.

Persia.— In Persia the crowing of a cock is the sign of some event affecting the family, and the master of the house hastens to feel the bird's feet. If they are cold it is a premonition of death; but if they are warm the sign is propitious, and the master rejoices in coming good fortune.

Peru.— To procure rain the Peruvians used to set a black sheep in a field, pour chica over it and give it nothing to eat till rain fell.

Philippine Islands.— In the interior mountain districts the natives have gods innumerable; gods of the air, of the water, and in fact of everything imaginable. When sickness or death approaches, the witch or sorceress of the village is called in. An ox and a pig are killed; she places the reeking skull of the pig over her own head and works herself into a frenzy of invocation. The spirits of the dead receive special honors and sacrifices are made in their behalf. Many curious demons and hobgoblins abound in Philippine superstition, too numerous to be described in detail.

Poland.— Poland has a wealth of animal superstitions. The goat is there considered the best harbinger of luck, while the wolf, crow and pigeon are looked upon as unlucky. The skin of a cat worn on the chest is alleged to cure consumption.

Romany.— The people of the gypsy tribe believe that a coin or shell or pebble carried by a person becomes imbued with his or her personality. For that reason the Maria Theresa dollar is sought after by Romany people throughout the world. In all lands this piece of money is held in high esteem for magical purposes. The gypsies believe that witches use egg shells to make plates, pots and dishes to feed from at their banquets.

Rumania.— Rumanian mothers tie red ribbons around the ankles of their children to preserve them from being harmed.

Russia.— Superstition has always found a place in Russia. The Russian General Skobeleff would never ride in battle any other horse than a gray one, since it was on a gray horse that he fought his first battle (in the Russian war, 1863) and he believed that it would be fatal to him to change afterward. The primitive Russians place a certificate of character in a dead person's hands, which is to be given to Saint Peter at the gates of heaven.

Samoa.— The natives of Samoa, in order to secure the admission of a departed spirit to the joys of their paradise, wreathe the head of the corpse with flowers, and offer, as the Chinese do, a baked pig to their god in the name of the departed.

Scotland.— In Scotland it is considered unlucky for the mother and her baby to go out of doors until the child is baptized; to be engaged with a ring containing either opals or emeralds; for lovers to give either a Bible as a present before marriage; to be married in a month where there is a letter *o*, such as May; also unlucky for any of the wedding guests to be dressed in green or black; a crepe bonnet or a band on a gentleman's hat. These ill omens entail lifelong misery to the newly married couple. A young woman who tries on a widow's cap is sure to be a widow after marriage. It is unlucky to try on your bridal dress before the bridal day; to see your future husband on the day of the marriage until the ceremony. To bring flowering hawthorn into a house denotes a death in the family. In Scotland all salt cellars should be full on New Year's Day; otherwise the household having the empty cellars will suffer want during the ensuing year. In Scotland to pass a barefooted woman before going on board ship will result in scaring the fish away, and men bearing the names Rosse, Fullie and White must never be on a fishing boat at the same time for the combination will «hoodoo» the catch. Scotch sailors will not speak of a four-footed animal while on the ocean.

Solomon Islands.— The savages of these islands believe that the world is a cocoanut shell of enormous dimensions, at the top of which is a single aperture communicating with the upper air, where human beings dwell. At the very bottom of this imaginary shell is a stem gradually tapering to a point which represents the beginning of all things. This point is a spirit or demon without human form, whose name is «Root of All Existence.» By him the entire fabric of creation is sustained. In the interior of the cocoanut shell, at its very bottom, lives a female demon. So narrow is the space into which she is crowded that she is obliged to sit forever with knee and chin touching. Her name is «The Very Beginning,» and from her are sprung numerous spirits. They inhabit five different floors, into which the great cocoanut is divided. From certain of these spirits mankind is descended. The islanders, regarding themselves as the only real men and women, were formerly accustomed to regard strangers as evil spirits in the guise of humanity, whom they killed when they could, offering them as sacrifices.

Spain.— The Spaniards never put the left foot down first when stepping on board a vessel, for to do this will surely bring disaster. Spaniards, in the 16th century, believed that spiders indicated gold where they were found in abundance. In Spain the new born infant's face is swept with a pine bough to bring good luck.

Sweden.— In Sweden it is unlucky to kill a stork, a robin or a swallow. If one kills a wren he will break a bone before the year is out. It is also unlucky to kill a marten. Many animals possess the power of curing diseases. Three hairs taken from the «cross» of an ass, that is the mark running up the back and out at right angles over the shoulders, will cure whooping-cough, but the ass will die. Another sure cure for whooping-cough can be obtained by asking and following the advice of a man riding a piebald horse. Swedish sailors will not mention the name of the port for which they are bound.

Switzerland.— If a huntsman, on going out in the morning, sees a fox cross his path, or meets an old woman or friar, he immediately returns home again; as he is persuaded that, in the first instance, he will meet with no game, and in the other that he will shoot a man hidden in the leaves, or do some other irreparable mischief. In the Alps the mountaineers believe that if the cuccoo sings in the direction of the north, it will rain the next day; but if toward the south, the weather will be fine. In the Tyrol if a youngster look pale and sickly his parents suspect that the moon-rays must have found their way into his bedchamber.

Turkey.— In Turkey if a cat enters a chamber where a person is dying and manages to pass over his or her body before being driven from the room, both the dying person and the cat become vampires and live ever after by sucking the blood from living people. If one finds a piece of bread lying upon the ground he must pick it up, kiss it and carry it until he finds a hole into which it can be inserted. To step upon a piece of bread or to leave it lying upon the ground is one of the unpardonable sins and dooms the offender to the third hell, where he is perpetually gored by an ox that has but a single horn, and that in the centre of his forehead. The Turk is convinced that misfortune hovers nigh when he sees a rose leaf fall to the ground, and many people pay particular attention to the flowers and leaves which are decaying, gathering them carefully to prevent them from dropping.

United States.— In Michigan a double cedar knot is carried in the pocket by some to cure rheumatism, and in New Hampshire a man may carry a gall from the stems of goldenrod for the same disease. Hickory nuts, the buckeye and its cousin, the horse chestnut, which brings good luck in New Jersey, are other foes to rheumatism in different localities. Some people wear a strange ring made of a potato with a hole bored through it for rheumatism and others carry a plain potato in the pocket. The charm is more potent if the potato has been stolen. According to a Maine belief, a nutmeg pierced and hung on a string around the neck prevents boils, croup and neuralgia. In some parts of Massachusetts the cows are believed to forecast the future, and if they «moo» after midnight it is a warning of an approaching death in the family. Among the West Virginia mountaineers the crowing of the cock before the door tells of coming company. It is believed on Cape Cod and in many other districts along the New England coast that a sick man cannot die until the ebb tide begins to run. In New England the sailors carry as a talisman a bone taken from a living turtle, a pebble from a fishhawk's nest or a small bone from the head of a cod. In Connecticut the belief holds that beans and potatoes must be planted in the old of the moon to prevent them running to vines. In Texas some superstitious people carry a small bone from a fish's head, but the luck only comes after the charm has been lost. SUPPÉ, soop-pā, **Franz von,** Austrian opera composer: b. Spalato, Dalmatia, 18 April 1820; d. Vienna, 21 May 1895. His musical ability early manifested itself and when he was but 15 years old he composed a mass which was sung at the Franciscan church at Zara. His first opera, 'Sommernachtstraum,' appeared in 1844. His best known works are the operas 'Fatinitza' and 'Boccaccio,' and his overtures 'Poet and Peasant' and 'Morning, Noon and Night.' He was for many years Kapellmeister at Vienna.

SUPPLE-JACK, the popular name given to various strong twining shrubs, for example, certain West Indian species of *Paullinia* and *Serjania* which furnish walking-sticks; or *Cardiospermum grandiflorum* or the high-climbing shrubby *Berchemia scandens*. This last is found in the southeastern United States and has tough, terete branches, oval leaves, small greenish flowers in panicles and oval purple drupes, which render it conspicuous in autumn. The supple-jacks of Australia are climbing, woody varieties of *Clematis aristata*, and that of New Zealand is one of the largest brambles known (*Rubus australis*), reaching to the tops of the tallest trees. It is also called the New Zealand lawyer.

SUPPLEMENTAL EDUCATION. Definition.—«Extension education is for every community and for everybody. It extends the opportunity for education to the whole body of the people, to the whole period of life and to all the vital interests of life.»

Formal education may be said to include the systematic instruction which is imparted through personal contact with the student, whether by class-room work or lectures, when given under the direct guidance and supervision of trained instructors in schools, colleges, universities and similar institutions, as distinguished from knowledge acquired through the more informal methods of study whether or not allied with teaching institutions. These methods vary widely and range from the carefully organized study clubs of university extension courses to the entirely independent research work of single individuals in libraries, museums and similar educational institutions.

General Purpose.—«Universities exist for two purposes: (1) To perpetuate and discover knowledge; (2) to disseminate that knowledge both in its academic and its practical results. Extension teaching furnishes a means of furthering knowledge in both these aspects, particularly the practical.

«By instituting popular instruction in those practical, technical and cultural subjects over which universities tend perhaps unconsciously to exercise a monopoly those institutions can so influence public taste and intelligence as to contribute greatly to social progress.» Nalder.

The chief object of extension work is to provide the best education possible at the lowest practicable cost for those who are unable to attend established educational institutions.

I. Systems.— University Extension.— *History.*—As early as 1831 some forms of university extension were in use in the United States in the work of the American National Lyceum, an organization which, though not associated with any educational institution, had a part in the wide spread of popular education. Lecture courses and debating clubs were begun in many city and country communities. In 1887 an address before the American Library Association on the subject of the English system of university extension aroused much interest, and as a result university extension work was begun in several cities in connection with the work of the city library. In 1889 Columbia University announced to the teachers in and near New York City the offer of certain elementary courses in science, to be given by means of classes outside the university. From this beginning university extension grew steadily as a power in popular education.

Purpose and Scope.— University extension provides a means for the acquirement of an education by those who for any reason are unable to attend institutions offering formal instruction. The courses are designed not only to assist such persons but also to supplement the regular work of such institutions by offering an opportunity for continued study to those who may have completed the formal courses.

Extension courses cover a wide range of subjects from those of a very elementary character to those which are of interest and benefit only to a highly educated and cultured class, the courses being adapted to the particular need to be met. In many instances it is difficult to make a clear line of distinction between university extension and the formal instruction of teaching institutions as exemplified in night schools and vocation schools.

Methods.— Extension service as carried on by the universities of this country varies widely in methods. In some institutions there is a separately organized extension faculty entirely distinct from the regular faculty, while in others extension work is conducted by the regularly organized faculties through the medium of the various departments. The former plan, which is relatively more expensive, provides for a highly specialized and intensive type of work, but the other secures co-ordination of effort by the various departments and co-operation on the part of the faculties that would otherwise be impossible.

1. Lectures and Classes.—More or less lecture work is offered in most of the institutions which do extension teaching. Several forms of such work are employed, in some cases all are used in the same institution while in other cases one form may represent the entire work of the institution along extension lines. One form of lecture work is the lecture class — often these classes are held on Saturdays or late in the afternoon of other days for the benefit of students who are fully occupied during the hours of the regular college classes. Frequently the lectures are given by members of the faculty, also by men engaged especially for the work and by local experts in particular lines. One of the chief developments in the establishment of local classes throughout the country has been in connection with engineering work. Classes have been formed in shops and factories, and short courses offered at a number of colleges and universities.

In California out of 300 classes held under the direction of the University of California in eight cities, more than 200 classes were in San Francisco alone, showing to what an extent extension service may contribute to the intellectual, industrial, social and commercial life of a great modern city.

«The welfare work of university extension is based upon the theory that there is a large field of human interests, specifically social in their nature, which is not covered by any other public educational agency. Such interests are those of health, municipal affairs, a public forum, the music interests of a community and the promotion of the economic prosperity of the small town. Many other topics might be mentioned but these are typical and are the more easily organized and directed.»

Extension work in home economics seeks to conserve the home through reaching and training the individuals who compose it. In the South there are nearly 1,000 women who are devoting their entire attention to 15 Southern States. South Carolina has 45 county agents and 20 cotton mill villages organized for community improvement.

The extension work of normal schools includes all forms of educational activity carried on by the normal schools among people who are not enrolled as resident students in the regularly organized classes. The extension work of these schools differs principally from that of the universities in that it lays special emphasis upon the study group or local class method, not upon correspondence work.

2. Study Clubs.— Some of the first steps in university extension were taken in the State of New York and it was the first State in this country to make university extension a part of its educational system. A special feature of the work was the development of the library system in all its branches. Through the traveling libraries division of the University of the State of New York collections of books were sent out as early as 1894 to university extension centres for the use of the study clubs formed in connection with the lectures. From this beginning has grown the present widespread use of the traveling libraries by hundreds of study clubs throughout the State.

3. Debating Societies.— The discussion of public questions of importance and interest has been encouraged and stimulated by the establishment of a service which supplies current information and data on live topics of the day. Package libraries consisting of books, pamphlets, clippings and typewritten material on important social, economic and political questions, on the principles of debating and on the organization and conduct of debating societies are supplied freely to schools, debating clubs and similar organizations. Local libraries co-operate by furnishing available material and in some instances, notably in the case of the New York State Library, the work is carried on directly under the jurisdiction of the library. This work has been very fully developed at the University of Wisconsin.

4. The Co-operative Plan.— The co-operative system has been defined as the co-ordination of theoretical and practical training in a progressive educational program. One of the reasons why the night school has not been able to cope with the problem of the illiteracy of the adult worker with entire success is because it frequently does not connect his education with his work. Co-operation between school and factory helps to solve this problem. This system, whereby manufacturers agree with the school authorities to carry on apprenticeship courses in practical trades while the school gives generalized and special instruction, has already met with practical success. In the co-operative plan the students frequently work in pairs; while one is at the office, shop or laboratory, the other is at school, the two changing places weekly. Courses are properly called "co-operative" because they enlist the active co-operation of the outside practical world in directing some of the educational policies of the school. At the present time there is a growing tendency on the part of manufacturers, department store managers and others to conduct, often during business hours, classes for their employees along the lines of their specific forms of business or on general elementary subjects of education. Such schools are described more fully elsewhere under the subject of Corporation Schools.

Principal Present Day Agencies.— Of the many institutions conducting university extension courses at the present time among the most notable ones are the University of Wisconsin, University of Michigan and Columbia University.

1. Wisconsin.— The University of Wisconsin offers several plans of extension work for the benefit of persons who desire to study any subject as members of a club, class or study group and provides special guided outlines. Such co-operative study makes possible personal visits and class instruction from university professors and specialists. These plans are adapted to the needs of teachers' groups, women's clubs, labor unions, farmers, business men's associations, etc. The outlines which are provided carry the privilege of a lecture or series of lectures and of direction, guidance and assistance by the person who outlined the work. Because of this provision the studies are much more effective and interesting. There is a nominal charge for outlines with the attendant privileges and the cost of lectures varies somewhat with the lecturer. Much work is done in supplying material for debates. The department of debating and public discussion has approximately 10,000 packages of material available for distribution and there is an increasing demand for this service. Recently a Chautauqua circuit has been established in the State for the purpose of providing instruction, inspiration and recreation.

Community institutes are held in various parts of the State to assist local communities to solve certain definite problems. These institutes are in charge of men specially trained in the economic and social problems common to small country communities.

The university in its extension work has free access to the Legislative Reference Department, the State Historical Library, the University Library and the City Library. The Wisconsin Free Library Commission and those in charge of the different libraries co-operate generously in this work. Bulletins are issued, bibliographies and study outlines are prepared and publications are supplied gratis in the State. The Wisconsin Civil Service Commission has co-operated with the university in educational work among State employees by means of conferences, talks, lectures and circulars.

2. New York City.— In New York city a plan is being followed of training persons already in the city public service through the co-operation of the College of the City of New York and the city government. In 1917 a thousand city employees were studying 1,300 courses in the evening classes. The College of the City of New York in co-operation with the board of education offers free extension courses in several centres to the teachers of the New York City schools.

3. Columbia University.— The extension teaching department of Columbia University offers many courses in subjects which form a part of the curriculum of Columbia College and in the more advanced branches of these subjects shares in the work for the higher degrees. Subordinate and subsidiary to this are the courses of secondary school grade for mature students who cannot return to ordinary schools of this type. The professional schools are represented in an increasing number of

courses so that students may pursue their studies in many special branches. In addition to the regular courses of the extension teaching department extramural courses in New York and in outlying cities are offered.

4. Other Agencies.— One that is attempting to reach working people along educational lines is the Young Men's Christian Association. The subjects pursued in the Y. M. C. A. classes may be approximately grouped under six heads: (1) Commercial; (2) political; (3) industrial; (4) scientific; (5) language and miscellaneous — music, first aid to the injured, etc; (6) special schools, such as law, art, automobile, etc.

The Young Women's Christian Association also has educational classes but comparatively little instruction is given in the regular high school subjects. The main effort is to help women who are self-supporting to become more efficient and to put within the reach of those who are not self-supporting the training which will enable them to become so.

The University of Michigan endeavors to conduct its extension service as far as possible through established university channels. Its policy is to render through its extension division the largest possible measure of public service commensurate with the equipment and facilities of the university. It is a condition that all extension lectures shall be free to the public and that they shall be so advertised. In one year 1,000 reprints were made for the 300 lectures offered. The total number of auditors reached throughout the State in the year was 71,500.

II. Home Education.— *Definition.*— There is no distinct line of demarkation between what is termed university extension and home education, but in general the former may be said to provide for the giving of instruction to groups or classes rather than to individuals. The work is conducted for the most part by teaching institutions by means of lectures and other methods which are not comprised within the lines of formal education. It is the extension of the teaching power of an institution beyond the boundaries of regular class-room work. Home education is that which can be acquired in the home independently of association in groups or classes. It embraces all means of obtaining knowledge which are individual in their nature as distinguished from education acquired through association with other individuals by means of classes, study clubs, lectures, etc. Correspondence schools, reading courses, libraries, museums and other similar sources all offer a means of securing an education without the formal instruction associated with class-room work.

Purpose.— A very large proportion of our population leave school before completing either the high school or grammar school course. Within a few years many of these people realize their educational limitations but because of age, hours of labor, financial condition or other reasons it is impracticable for them to resume a course of study in an educational institution. University extension courses and home education facilities are designed to meet the needs of such persons and of all who for any reason desire to continue their studies. The recent increase in the number of persons taking correspondence courses is the best testimony of the need of educational facilities to supplement those of our regular schools, colleges and universities. To obtain an education through individual effort without the personal guidance and inspiration of a teacher requires determination and perseverance, and those who take advantage of these supplementary educational opportunities show evidence of a real desire and serious purpose to acquire an education. There are certain benefits to be derived from formal class instruction which cannot be obtained in any other way, but the serious and ambitious student may find in the United States ample opportunity to pursue his studies in his leisure hours at little or no expense.

Methods.— 1. Libraries.— These are well termed «the people's university» for they constitute the most universal, most accessible and most economical source for self-education. They are storehouses of knowledge which is made readily available to readers by modern methods of classification, cataloging and indexing. Nearly all large libraries in this country are equipped with the latest and best bibliographical aids so that the student has every possible means of assistance at hand. Our libraries are great laboratories for research and are increasingly frequented by those seeking information on all sorts of subjects. Ordinarily only such restraints with regard to the use of the books are imposed as are necessary to protect the rights of readers, and serious students are frequently granted special privileges. Within recent years all libraries have become much more liberal in their service to the public and have been transformed into active rather than passive educational institutions. «There is a sense in which the school may be looked upon as a fairer test of community opportunity than the library. The school is compulsory; it impresses people most during their most impressionable period. On the other hand the library reaches old as well as young. Once established it remains as a centre for the distribution of knowledge and hence of opportunity.»

2. Traveling libraries.— In some States library facilities, to a certain degree at least, are at the disposal of every citizen even though there may be no library in his local community. This distribution of books is accomplished by means of traveling libraries in some cases and in others by sending books by parcel post or express from a central public library or agency such as a State library or library commission. In the State of New York both methods are in use, the traveling libraries having been in operation since 1893. These traveling libraries are small collections of books, usually in units of 25 volumes, which are sent anywhere in the State without charge on condition that the books shall be for the free use of the public. These libraries are intended primarily for communities without any free library facilities but under certain conditions they are sent also to small public libraries. There is a wide use of these libraries also by schools, study clubs and various organizations, and many «house libraries» of 10 volumes are borrowed by individuals. Institutions or individuals wanting only a few books for a month or less may procure them from the New York State Library by paying the return transportation charges. By means

of this library extension service any citizen of the State may secure books either free of all charge or at a merely nominal cost.

3. Reading Courses.— Reading courses on various topics are prepared and made available by libraries, schools, individuals and governmental departments of education and by means of these guides to study, the individual is enabled to inform himself fully on the subjects covered by the courses.

In the Home Education Department of the United States Bureau of Education work is carried on largely through personal correspondence and through the dissemination of reading courses. In 1917 there were 10 courses offered and approximately 100,000 copies of the printed outlines were distributed during the year. The bureau has been able to secure the co-operation of libraries and library commissions in bringing these courses to the attention of the public and in carrying on the work. About 6,000 persons are now enrolled in the National Reading Circle and certificates are granted to persons completing the courses.

4. Museums.— The rise of the museum as a new force in town, city, state and nation is one of the latest phases of educational evolution. The growing museum influence which during the past quarter of a century has been especially remarkable throughout the cities of the United States is largely due to what may be called the new museum idea, namely that the museum is not a negative but a positive educational force and that it has teaching qualifications peculiar to itself. The most important function of a public museum is that of usefulness to the public in an educational way. With the great resources at their command museums are working out plans of various kinds for the definite instruction of the public, such as study rooms, illustrated lectures in the museum or elsewhere, tours of the museum under trained and competent guides, and loan collections.

One of the most interesting and important developments is the Children's museum, or Children's room which is one of the results of the growing conviction that the museum is a public educational institution which should meet the needs of all ages and classes of people.

5. Correspondence Courses.—Certain universities have especially emphasized correspondence-study work. At those institutions where this form of instruction has had the longest trial statistics show that the students who take advantage of the opportunities offered by these courses to do a certain portion of the work required for a degree cannot be classed among those who are seeking easy methods for gaining credit but are earnest students as a rule, frequently doing considerably better work than the average class-room student.

The subjects offered are mainly cultural; those courses for which there has been the greatest demand include the languages, mathematics, history, education, political economy and technical subjects. A large number of biblical and theological courses are offered by some institutions.

Correspondence schools also play a large part in Home Education, but instruction by correspondence can never take the place of class instruction for it lacks the inspiration of personal contact. As a means of helping ambitious people along special lines, however, it has been and is of very great value. In the commercial schools the great bulk of examination and correction of student's work is done by clerks who are under the direction of experienced men, but the textbooks and questions to be answered are usually prepared by competent experts. The system is "business-like" and in the best of the schools it is fairly efficient and satisfactory to patrons. Extensive advertising and organized systems of branch offices contribute greatly to the financial success of these schools. The methods of the stock company schools may not commend themselves to the conservative person but the results accomplished have been in the right direction. Schools of this character are usually incorporated under State laws and are managed by a board of directors. It was from the Methodist camp-meeting that the correspondence school first came into being. The work at Chautauqua, N. Y., developed from a camp meeting and as a part of that work correspondence classes were conducted. These were begun in 1871 and appear to constitute the first complete plan formally announced in the United States for correspondence work. For financial reasons this branch of the work at Chautauqua was dropped in 1900, but through it the way had been marked out for others. The commercial possibilities of correspondence work were soon recognized, several business schools adding that feature to their resident work. Some of the largest of the commercial correspondence schools were established through the interest of certain publishing houses as a means of selling their books.

The largest of these educational schools is the International Correspondence Schools at Scranton, Pa. This institution is representative of the class of schools operated as commercial ventures by stock companies. A daily paper published in Shenandoah, in the coal-mining district of eastern Pennsylvania, had in the early 80's a department devoted to the education of miners in the principles of mining and from this beginning has grown the present great organization. These schools offer over 200 standard courses and an indefinite number of special and combination courses covering many branches of technical education. There are nearly 2,000 persons employed in the various departments of the schools in America alone and hundreds in other countries of the world. The schools have enrolled more than 1,850,000 persons, approximately 100,000 new students being enrolled each year. More than 500 experts, instructors and assistants, are occupied in writing and revising the International Correspondence Schools textbooks and in examining and correcting the work of students. To teach successfully by correspondence requires an entirely different kind of textbook from that used in the class-room and the International Correspondence Schools textbooks constitute the foundation of this system.

In regard to achievements of such institutions as the University of Chicago, Pennsylvania State College, University of Wisconsin and others of a similar type nothing but good may be said. They have carried the higher education to thousands to whom college walls were but a dream. From the University of Chicago correspondence study reaches literally every part of the world. Through the Correspondence Study Department the university offers a large number of the courses given in the classrooms of its different divisions, and all nonresident work for credit is conducted through this department. Each course is designed to be equivalent to the corresponding residence course and calls for an equal amount of work. No preliminary examination or proof of previous work is required of applicants for correspondence work. At the Pennsylvania State College correspondence courses are offered in agriculture, home economics and industrial education, free of charge to any citizen of the State. Students at the summer session are permitted to complete their work in certain subjects by correspondence at a nominal cost. At the University of Wisconsin 300 single courses are offered in 28 departmental lines and 70 of these courses are in engineering subjects. Each course is divided into units designated as assignments and each assignment represents six to eight hours of work. The instruction is carried on in three ways; by special lesson sheets, by correction of the exercises submitted, and by personal letters and other assistance where special needs are not otherwise met.

Education of Adults in Other Countries. —Schools for the education of adults originated in England through the Sunday School movement during the 18th century. The first adult school was opened in Nottingham in 1798 and has continued to the present day. The movement soon spread to other parts of the country and though providing secular instruction it was religious in its association. Parallel with these schools were classes in scientific and civic subjects. In 1851 the English government first made pecuniary grants to evening schools. At the beginning of the 20th century out of every 1,000 of the population of England and Wales about 23 persons voluntarily attended some form of evening class on week days. Several agencies have been influential in the development of this movement — namely the University Extension system, the National Home Reading Union, the Y. M. C. A., the Recreation Evening Schools Association and the Worker's Educational Association.

England had in 1918 a new education bill which provides for national oversight, national direction and compulsory attendance of children from five to 14 years of age, for part time continuation schools for those between the ages of 14 and 18, for medical inspection, physical training and more than 30 other incidental aids to democratic education — this bill will revolutionize education in England.

University extension as a means of carrying higher education to adults has had an unparalleled success in England and the progress of the movement has been remarkable. Instituted by the University of Cambridge in 1873, adopted by Oxford in 1878, with the work of the London Society for the Extension of University Teaching, which was founded in 1876, taken over by the reconstituted University of London in 1900 — these three universities are the world-wide acknowledged leaders of the movement. The original form of university extension teaching has not declined in England as it has in the United States. The characteristic features of the lecture system at local centres, with a class following the lecture and a final examination, have been maintained. Taking Oxford alone some 500,000 persons have attended the courses given in nearly 40,000 lectures by over 200 lecturers and nearly 30,000 students have been examined.

One of the most far reaching educational results of the war of 1870, with its great lesson of the importance of national education, was the law of 1873 passed in Saxony making attendance at continuation schools compulsory for three years (that is up to 17 years of age) in that kingdom. The Saxon law appears to have been justified by the experience of a generation. There is no doubt that in this matter of continuation schools, as in so many other fields of social organization, the adoption of compulsion has been facilitated by the habituation of the working classes to compulsory military service.

Adult education forms an important part of the educational work of Denmark also. Children of ability who can pass the required examinations are sent on from the communal schools to the middle school, gymnasium and university at State expense. Most other children go to work after five years at school but a fair percentage of them go to evening classes not only for technical training but also for higher education generally, and many attend University Extension lectures regularly for years after they leave school. «A great social-educational movement was started in Denmark in the late 80's. The primary object of this movement which was organized and is still worked by students of the Copenhagen University, with the cordial help of the professors, is to draw together the diverse sections of the community, to weave bonds of friendly sympathy between them and to spread the light among even the lowest sections. Students hold night schools in the Copenhagen communal day schools and give lessons there gratis to all the working men and women who care to go. There are more than 100 teachers and more than 2,000 are taught. On Sunday night there are free popular lectures by students and professors to which the working classes flock in thousands. The Danes boast that in their country there is no 'unenlightened class' and they do so with good reason.»

WILLIAM R. WATSON,
Chief Educational Extension Division, State Department of Education, Albany, N. Y.

SUPPLEMENTARY PROCEEDINGS are in the nature of a civil and equitable action whereby property of a judgment debtor may be reached, where said property cannot be taken under the usual process of execution; its object primarily is to discover the property of a judgment debtor which is subject to execution, and to learn if the debtor possesses or controls any property which is applicable to the satisfaction of the judgment. Any creditor who has reduced his claim to a judgment and issued execution thereon may institute supplementary proceedings, and the first creditor who does so and prosecutes the proceeding with due diligence obtains a prior lien on the assets of the debtor. Supplementary proceedings exist and are regulated according to the statutes in each State;

some jurisdictions afford much the same remedy through other means; many States do not allow the remedy against corporations. In some jurisdictions certain classes of property are exempt, as, for example, wages earned by the debtor within a specified time next before the institution of the proceedings, the period varying with the statute. Orders for examination in supplementary proceedings are granted by a judge having jurisdiction according to the statutes under which the right to maintain the proceeding is derived and may be held before a judge or referee appointed for the purpose; this order must be served upon the person to be examined and it may be set aside on account of any defect but otherwise must be complied with. If, from the examination, it appears that the judgment debtor has in his possession or under his control property or money by which a judgment may be satisfied, the judge may, in his discretion, direct the debtor or person holding said property for him to deliver the property to a receiver for the purpose of applying same to the judgment. One who disregards or disobeys the orders of the judge in these proceedings is subject to punishment for contempt.

SUPPLICANTS, the name assumed by the Presbyterian petitioners against the introduction of Archbishop Laud's Service Book and the Book of Canons into the Church of Scotland: as their petition had no effect the Supplicants in 1638 signed the National Covenant and Confession of Faith, which that year were ratified by the General Assembly: thereafter they were known as Covenanters (q.v.).

SUPPLY RAILWAYS. Under this designation are included all railways, except combat railways, that may be constructed or used for the supply of an army in the field. They may vary from a light portable track to a standard-gauge road. Their principal uses are to connect the army with its base; to connect permanent camps with the nearest existing railway; to form a belt line around a besieged place outside the field of observation; to form a belt line inside the line of defense of a besieged place; for the movable gun defense, and for a general supply line to supply an army in a permanent position. In extreme cases a railway may have to be constructed to supply an advancing army when local conditions preclude other means of transportation.

Regardless of the gauge, the same underlying principles govern the construction of all such lines, and having a plan for the operation and maintenance of an existing line of railway, it is easy to adapt it to the requirements of a temporary line. The principal considerations that govern in planning for such a line are (1) the amount of army supplies, troops and animals that must be handled; (2) the time that can be permitted for its construction; and (3) the amount of transportation necessary to place the railway supplies on the work which applies particularly to operations beyond the sea. This latter condition ordinarily necessitates a narrow-gauge railway for a supply railway in a country beyond the sea. Local conditions, such as a large supply of standard-gauge material and rolling stock, may render advisable the building of a standard-gauge railway for operations from a friendly land base; but where conditions extremely favorable to a standard-gauge line do not exist, a narrow-gauge railway will probably be decided upon in the general case of supply railways. The weight of the materials and rolling stock is so much smaller, the bridges can be so much lighter, and the earth work is so much less than for a standard-gauge road that the narrow-gauge railway is decidedly easier and quicker to build.

In case an official report is desired by the commanding general before he decides whether or not to construct the line, the entire survey and the estimates must be finished before the report is made. This report is accompanied by maps and profiles showing the routes considered and the final location decided upon, and the reasons therefor. It also shows the approximate cost of material and of civilian labor, the amount and cost of rolling stock and other equipment, the capacity of the line when it is completed and the time that will be necessary to complete the work as desired. In case it has been definitely decided in advance to build the line, the cost and time are only considered in that they must be kept as low as practicable, and the survey need not be completed before construction work begins. See MILITARY RAILROADS.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

SUPPOSITORY, a medicinal compound prepared in the form of a cone, sphere, or cylinder, for introduction into the rectum, urethra or vagina, there to be dissolved (melting gradually by the heat of the body) for the purpose intended, as action on inflamed mucous membrane, evacuation of the bowel, etc.

SUPPURATION, a morbid process in animal tissues which gives rise to the formation of pus. It is one of the destructive terminations of inflammatory action. The inflammatory leucocytes, instead of developing into fibre-cells and forming tissue, become developed into pus-globules, and the exudation breaks down more or less completely into a creamy fluid called pus, which consists of these globules floating in serum, the liquor puris. Pus-globules, as seen out of the body, are but little different in appearance from leucocytes. The leucocyte, when treated with acetic acid, displays the appearance of a nucleus in its interior, that appearance being usually regarded as the result of a shrinking of the protoplasm of which it is composed. The pus-globule shows more distinct trace of a membrane, and is frequently many-nucleated when treated with acid, a condition which Rindfleisch regards as indicating a tendency to degenerate and break down. Many of the corpuscles of pus display no difference in character from the blood-leucocytes, having only single nuclei, showing the same amœboid movements, and being in fact obviously the same things both in structure and function. Suppuration is not, in most cases, wholly a destructive process, but serves also as one of the usual modes of repair. The result of the process of suppuration is thus twofold, being in part destructive and in part constructive. Suppuration in the interior of the body usually terminates in the formation of an abscess; but in some cases the matter is diffused through the interstices of the part, and is termed diffuse inflammation.

SUPRALAPSARIANS, sū"pra-lăp-sā'rĭ-anz, those Calvinistic theologians who maintain the strict doctrines of Predestination, Election of Grace and Reprobation, namely, that the Creator for His own glory decreed the fall of man and the consequent introduction of sin into the world; and that the election of some to life everlasting and the damnation of others was made «beyond» (or before, *supra*) Adam's fall, and was in no way consequent on it or dependent upon it. See PREDESTINATION.

SUPRANATURALISM. See SUPERNATURALISM.

SUPRARENAL CAPSULES, two small, ductless glandular bodies situated at the front portion of the upper end of each kidney. They are generally classified with the spleen and similar structures as ductless glands. Each suprarenal capsule exhibits a yellowish color. That of the right kidney is somewhat of triangular shape, the left being of somewhat crescentic form. In some cases these bodies may be hardly recognizable on account of their minute size. Their average weight is from one to two drams. Each capsule is connected to its kidney by areolar tissue only, no vascular or other connections existing between the glands; and neither capsule has any outlet or excretory duct. They lie behind the peritoneum, or lining membrane of the abdomen, the front surface of the right suprarenal capsule being in contract with the under surface of the liver, the same surface of the left being in relation with the pancreas and spleen. The capsules derive their blood from the aortic, renal and phrenic arteries, and return their blood by the suprarenal vein, which receives its blood from the net-work of the medullary portion, and also partly from the cortical substance of the organ. The nerves of the suprarenal capsules are numerous, and are branches of the solar and renal plexuses and of the phrenic and pneumogastric trunks. The suprarenal capsules are present in all mammals, and are largest in *Rodentia*, and smallest, proportionally, in the whales, in which they are lobulated or divided into lobes. In birds they are of small size, and exist generally on the inner aspects of the kidneys. In sharks they exist as a single, long, lobular organ lying behind the kidneys; and in frogs and toads they appear as yellowish patches on the kidney. They are also lobular in sturgeons and other fishes, and in newts and *Urodela* generally. That these bodies may have some important function to discharge in connection with the blood-circulation of the embryo is a highly reasonable suggestion; but further than this general statement physiology cannot certainly proceed. Facts of much interest in connection with these bodies, however, have been observed in cases of Addison's disease (q.v.). The actual diseases to which these bodies are liable consists of hypertrophy or enlargement, atrophy or wasting, tuberculous degeneration, fatty disease and occasionally cancerous infiltration.

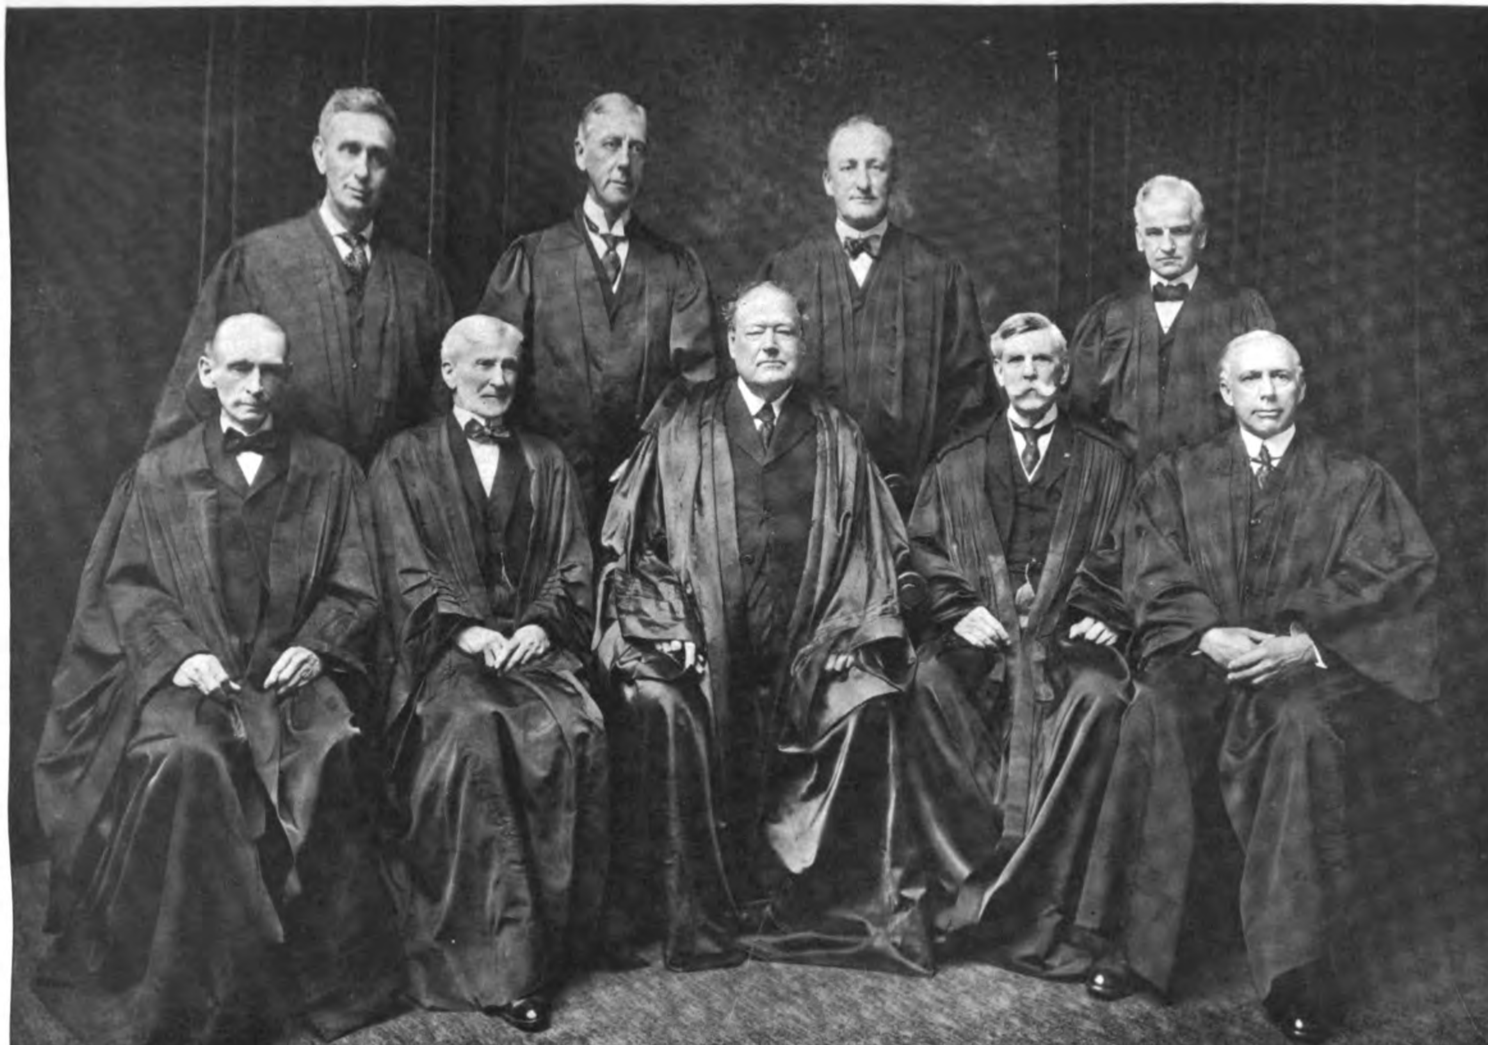
SUPREMACY, Royal, as a term in English law, is practically restricted to denote the authority of the Crown in matters ecclesiastical. After the abolition of the papal supremacy at the English Reformation, the royal supremacy was affirmed by various acts under Henry VIII and Elizabeth, all enforcing an oath of supremacy. The oath was taken by holders of public offices along with the oath of allegiance, and afterward with that of abjuration, until the three were consolidated in one. The revised oath of allegiance imposed upon members of Parliament does not expressly affirm the royal supremacy in ecclesiastical matters. Supremacy acts were passed in 1534, 1559 and 1689.

SUPREME COURT OF THE DISTRICT OF COLUMBIA. See COURT.

SUPREME COURT OF JUDICATURE, a legal tribunal in which are united all the higher courts of justice in England, exclusive of the appellate jurisdiction of the House of Lords and of the Privy Council. It dates from the Act of 1873. See COURT.

SUPREME COURT OF THE UNITED STATES, The, is a cardinal feature of our Federal representative government, balancing and harmonizing all its parts, a tribunal which has received the general approval and admiration of foreign jurists and statesmen, and commands the universal respect and confidence of the people for whom it administers justice. The Federal Convention of 1787, which framed our Constitution and created this unique tribunal, was composed mostly of members of the legal profession, which has always in America been the chief nursery of statesmen; but Washington, the soldier, presided and Franklin, the philosopher, advised at every step. The members of the convention were undoubtedly chosen from the best qualified men that the country could furnish for the momentous work which was set before them, and their merits have been so universally recognized that it is not necessary to repeat any of the emphatic tributes which many great Englishmen have paid to the results of their labors. Their work was finished in four months' secret session at Philadelphia, but most of them had been in training for it through 20 long years of trial and trouble. From 1765, the time of the passage of the Stamp Act, which was passed through both Houses of Parliament with little opposition, the colonists, and especially the lawyers of the Colonies, had been careful and earnest students of the principles of free government.

In 1774, having exhausted in vain all appeals to king and Parliament for a redress of their grievances, they sent delegates to a Continental Congress to deliberate on the state of public affairs, and in this Congress, which lasted for seven years, many of the future framers of the Constitution who were members of it found a most instructive school of statesmanship, and constantly devoted themselves to the social and political education of the colonists in matters of government and of public law and popular rights. In 1776, as the representatives of the United States of America in General Congress assembled, appealing to the Supreme Judge of the world for the rectitude of their intentions, they did, «in the name and by the authority of the good people of the Colonies, solemnly publish and declare that these United Colonies are, and of right ought to be, free and independent States; that they are, and of right ought to be, absolved from all allegiance to the British Crown; and that all political connection between them and the State of Great Britain is, and ought to be, totally dissolved.» They declared



THE SUPREME COURT OF THE UNITED STATES

Front Row (left to right) Justices Day, McKenna, Chief Justice White, Justices Holmes, Van Devanter
Back Row (left to right) Justices Brandeis, Pitney, McReynolds and Clarke

"that as free and independent States they have full power to levy war, conclude peace, contract alliances, establish commerce, and to do all other acts and things which independent States may of right do," and for the support of this declaration, with a firm reliance on the protection of Divine Providence, they mutually pledged to each other their lives, their fortunes and their sacred honor. From the hour of the Declaration, the men who made it, and all the other statesmen of the Colonies, had to give renewed and constant study to the whole science of government. As they proved able by force of arms to make good this declaration, the United Colonies became from its date a new nation, over which Congress, by general consent and acquiescence, exercised the powers of a general government, for all the purposes of the very serious exigency which had called it into existence. But it was a government by Congress only, with feeble and undefined powers, without an executive and without a judiciary. While the war lasted it barely sufficed, and afforded daily object lessons of its own defects and of what was required for a better government when better days should come.

The several individual States, being absolved from the royal charters under which they had before practically managed their own affairs, adopted written constitutions, based in each case upon the sovereignty of the people, to take the place of the former dominion of Parliament. An epoch of constitution making set in, during which the principles of representative popular government were discussed and understood. Virginia, the largest of the States, the home of Washington, Jefferson, Madison and Monroe, who were to be four out of the first five Presidents of the United States, took a leading part. New Hampshire had already framed a temporary form of government "during," as they said, "the unhappy and unnatural contest with Great Britain." South Carolina and New Jersey had followed, but in the case of the former it was expressly declared that the Constitution established was "established until an accommodation of the unhappy differences between Great Britain and America could be obtained."

Massachusetts, in 1780, with the utmost pains and deliberation prepared and adopted a complete Constitution, in which the powers of government were carefully distributed, with the solemn declaration that neither the legislative, executive or judicial department should ever exercise the powers of either of the others "to the end that it may be a government of laws and not of men." During the war the other colonies were engaged in the same business of founding States upon the principles of civil and religious liberty, embodied in written constitutions. Rhode Island alone, founded by Roger Williams, the great apostle of toleration, having received from Charles II in 1603 a royal charter, subsisted under it until 1842 without adopting any written Constitution.

But it was not only in the individual States that the framers of our Constitution were in all those years gathering knowledge and experience in the science of popular government. From the very date of the Declaration, Congress, conscious of the inadequacy of its powers, even for the purposes of carrying on war and conducting foreign affairs, entered upon the novel and difficult task of arranging a scheme which should enable it more efficiently to conduct those affairs which were of common interest to all the people of the 13 States, and which no one of them, nor all of them individually could control. After two years they adopted and submitted to the States what they styled "Articles of Confederation and perpetual Union," but it was not until March 1781 that the powers of Congress were enlarged by the final ratification of these articles by the delegates of all the States. But this attempted bond of union — a crude experiment in the formation of a national government — proved little better than a rope of sand, and utterly failed to accomplish the purposes intended. While the war lasted the tremendous pressure of their common danger and common distress kept the States together and made them obedient to the request of Congress which really had no power to command, but as soon as this external pressure was taken off, they fell apart, and each asserted its independent sovereignty. So jealous were the States, which had just escaped from the dominion of one central power, of anything which should seem to create dominion over them in another, that although upon paper they had laid many restraints upon their own action, and conferred upon Congress extensive powers over their Federal affairs, they had carefully refrained from giving any sanction to those powers and from granting to Congress the means of compelling obedience to its enactments. The Articles provided for no Federal executive and for no judiciary department, although they authorized Congress to provide for the settlement of boundary disputes between States and to appoint courts of prize and for the trial of piracies and felonies on the high seas. Moreover, Congress could not of its own authority raise a dollar of money for revenue or a single man to recruit its armies. It could only make requisitions for men and money upon individual States, which met them or not as they found it convenient. Nor could it proceed at all in the exercise of the principal powers nominally conferred upon it until nine States assented to the same. One of the leading writers of the time thus describes the powers of Congress under this Confederation:

"By this political compact the United States in Congress assembled have exclusive power for the following purposes, without being able to execute one of them. They may make and conclude Treaties, but can only recommend the observance of them. They may appoint Ambassadors, but cannot defray even the expense of their tables. They may borrow money in their own name on the faith of the Union, but cannot pay a dollar. They may coin money, but they cannot purchase an ounce of bullion. They may make war and determine what number of troops are necessary, but cannot raise a single soldier. In short, they may declare everything, and do nothing."

Judge Story says that, strong as this language is, it has no coloring beyond what the naked truth would justify, and even Washington himself wrote: "The Confederation appears to me to be little more than a shadow without the substance, and Congress a nugatory body, their ordinances being little attended to." Of course, under such a system our national affairs drifted steadily and rapidly from bad to worse. Interest on the public debt could not be paid, nor the ordinary expenses of government be provided for. The treaties which had been made could not be carried out, and foreign nations would not deal in the way of new treaties with the envoys of a body which had no head and no power to perform what they should agree to in its behalf. Our external commerce was at the mercy of foreign nations, whose laws contrived for its destruction, Congress could do nothing to counteract. And worst of all, our domestic commerce, which between all the citizens of one nation should be free and equal, was at the mercy of the caprice or selfishness of each individual State. There were many boundary disputes between States which threatened civil war. Federal laws were a dead letter, without Federal courts to expound and define their true meaning and operation, or an executive to see that they were properly executed. There was a general failure as yet to realize in actual enjoyment the advantages we had won by seven years of war, and everything seemed drifting toward bankruptcy, disunion and anarchy. But these very defects of the Confederation, and the evils which resulted from them, demanded the constant exercise of the best brains in all the States to understand and to remedy them, and opened a new school for all our statesmen in the study of constitutional government. When Washington had laid down his sword and surrendered his commission to Congress, after the signing of the treaty of peace which acknowledged the independence of the United States, he exhorted his countrymen by all they held dear to provide for the establishment of a strong and stable government as the only hope of retaining the liberties they had won; and from that hour until the Federal Constitution was made and ratified he and Hamilton, and Franklin and Madison, and all the other great statesmen who made it, or helped to secure its adoption, were engaged in the constant study of the principles of free government and in enforcing them upon the attention of their fellow citizens, so that they came to the performance of their great duties in the Federal Convention as graduates of the best practical school of Constitutional Law that the world has ever seen.

Their allotted task was to create a National Government which should reach, for its own proper purposes, by its own power, every man and every foot of territory in the whole United States, and should at the same time leave untouched and undiminished the complete control by each State of all its internal and domestic affairs — which should be entirely adequate without aid from the States, to govern the people effectively in all matters that involved the general interests of all, to deal with foreign nations with the whole power and resources of the entire people behind it, in all the exigencies of peace and war, and to accomplish all this with the least possible vesting of arbitrary power in any department or officer of the new government. They differed in opinion and sentiment on many points, but all agreed in a supreme dread of arbitrary power, whether it should be exercised by the executive, the legislative or the judiciary department, whether by a single man or by a majority of all, for they considered that the majority without any restrictions upon its power might become quite as dangerous as any other despot. They did not believe with my Lord Coke that absolute despotic power must in all governments reside somewhere. They carried this distrust of arbitrary power so far that they actually tied the hands of the people, whom they regarded as the source of all political power, and deprived them of the right to consider any amendment of the Constitution until it should be proposed by a vote of two-thirds of both houses of Congress or by a Convention called by Congress, on the application of the legislatures of two-thirds of the States, and deprived them of the power of voting directly upon any amendment, which could only be ratified by the legislatures or conventions of three-fourths of the States.

In other words, the people of the United States who ordained the Constitution, deprived themselves of the power to modify it by the direct vote of a majority or two-thirds or even three-quarters of their own numbers, whether that number should be 3,000,000 or 80,000,000. They must act deliberately and indirectly through Congresses, legislatures, conventions and primary elections. Truly a rare instance of political self-restraint at the basis of free popular government. One of the best definitions of the objects of such government is contained in the preamble of the Constitution:

"We, the People of the United States, in order to form a more perfect Union, establish justice, insure domestic tranquility, provide for the common defence, promote the general welfare and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America."

It was to "establish justice" for the people of the United States that the Federal judiciary, with the Supreme Court as its head, was created. It forms the balance wheel by which the affairs of the nation and its relation to the States are kept in working order, and is itself held in check by the power of the President to appoint its members as vacancies may occur, and by the power of Congress to impeach them for misconduct, to regulate the measure of its appellate jurisdiction and to increase or diminish its numbers. The permanent stability of the judicial power is assured by its being imbedded in the Constitution, with a jurisdiction co-ordinate with that of the executive and legislative departments, by the extreme difficulty in the way of any amendment that would impair it, and by the universal conviction which the experience of a century has produced, that its continued existence with the full enjoyment of its present functions is absolutely essential to the successful working of our scheme of popular representative government.

The great achievement of the framers of the Constitution, was so to distribute the powers of government between the States and the Nation, as to give the latter supreme control over all subjects that concerned the general interests of all, and reserve to each of the former exclusive control over local affairs which concerned only its own territory and people, and to do this in such a way that the State and Federal administrations should not clash in actual operation. They knew well the importance of a distribution of the powers of government between the three great departments. They created a Congress on which they conferred legislative powers over 18 enumerated subjects, necessarily involving the general interests of the people of all the States and essential to national sovereignty, including the levying and collection of taxes for Federal purposes, the borrowing of money, the regulation of commerce with foreign nations and among the several States, the coining of money, declaring war, raising and supporting armies, and maintaining a navy. They placed such limits upon the exercise by Congress of legislative power as should prevent its interference with legitimate local administration by the States, or with the fundamental rights of the citizens, and put such prohibitions upon the legislative power of the States as should prevent their interference with the general powers and functions of the Federal government. They vested the executive power of the Federal government in the President, who was made commander-in-chief of the army and navy and of the militia of the States when called into the service of the United States. He was granted power to pardon offenders against the United States, to make treaties, provided two-thirds of the Senate concur, to have a veto power over acts of Congress, which could be overridden only by a vote of two-thirds on reconsideration. He was also to nominate, with the advice and consent of the Senate, ambassadors, judges and all the principal officers of the United States, to recommend to the consideration of Congress such measures as he should judge necessary and proper, to commission all officers of the United States, and to take care that the laws should be faithfully executed.

And, finally, to secure the absolute supremacy of the Federal government over all matters of Federal cognizance, it was expressly provided that «this Constitution and the laws of the United States which shall be passed in pursuance thereof, and all treaties made under the authority of the United States, shall be the supreme law of the land, and the judges of every State shall be bound thereby, anything in the Constitution or laws of any State to the contrary notwithstanding.» This making the Federal Constitution and treaties made, and laws of Congress passed under its authority, the supreme law of the land is the key of our dual system of government, as the omnipotence of Parliament is the key of the British Constitution. But the Federal government, though supreme within the limits prescribed, is not omnipotent; it must keep within those limits. By the 10th amendment, passed immediately after the adoption of the Constitution, to prevent Congress from meddling with the domestic concerns of the States, or exercising powers not granted to them, it was expressly provided that the powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people.

Thus the people of the United States created for themselves two separate and distinct governments, each «of the people, by the people, and for the people,» each independent and exclusive of the other within its own scope and sphere, and each able, without aid from the other, to reach for its own purposes, by its own authority, every person and every foot of land within its territory. Complex as it may appear to people living under other forms of government, this dual system has worked very simply, smoothly, and harmoniously from the beginning until now, except for the single occasion when the terrible question of slavery proved to be too much for all the departments of government combined, and could only be settled by our long years of Civil War. But how has this marvelous result been accomplished? How has it been possible for these two governments, each of prescribed and limited powers, and each department of both similarly defined, to act independently and at the same time harmoniously over the same people? By what magical force has each power, State and Federal, been kept within its own limits? What has prevented constant and hopeless conflict between State functions and officials, and Federal functions and officials, between State and Nation, and between State and State, originally 13 in number and now 48? How has it been possible to secure the due protection of the law to the citizens of one State in each of the other States, and the rights of aliens against local prejudice and discrimination in any State, and how has the faith of treaties been preserved in every locality? These, and a thousand other similar questions and doubts as to the successful working of our system, are answered by pointing to the Supreme Court created by the Constitution, and to the Federal courts inferior to it created by Congress, in which the judicial power of the United States is vested, a power which, as has been said, is co-ordinate and co-extensive with the executive and legislative. Over whatever region Congress may attempt to legislate or the President to execute its laws, there the judicial power extends, to pass, if need be, upon the legality of their acts and the validity of their laws. The Constitution, and each of its provisions, is supreme over President, Congress, Courts and States, and the valid laws of Congress, and treaties made under the authority of the United States, are the supreme law of the land for all its people, and for the courts, legislatures, and governors of each State. The Supreme Court is the final judge of the validity of all laws passed by Congress or by the legislatures of each of the 48 States, when brought to the test of the Constitution of the United States, and of the legality of all official acts when brought to the same test. It and the Federal courts inferior to it furnish the vehicle by which the judicial power of the United States is carried into the whole of its vast territory, to administer justice within the limits prescribed to it, to enforce the Federal laws and to punish offenders against them.

The third article of the Constitution is marvelously brief and simple. The judges, according to that good old rule which has worked so well in England since the days of William and Mary, are to hold their offices during good behavior, and can only be removed by impeachment, and their compensation shall not be diminished during their continuance in office. The Supreme Court has original jurisdiction only in cases affecting ambassadors, public ministers and consuls, and in those in which a State shall be a party. The first branch of this original power has seldom been invoked, but over and over again a great State has been brought to its bar by another State to settle boundary disputes, always the most dangerous to the peace of adjoining States, and in each instance its decree has been submitted to with implicit obedience — a most unique judicial power, and a most convincing example to persuade all nations to settle these most perilous questions by arbitration. It has been well said "that the provision that the judicial power created by the people shall be the arbiter between the States themselves, in all their controversies with each other, marks the highest level ever attained in the progress of representative government." Tocqueville says: "In the nations of Europe the courts of justice are only called upon to try the controversies of private individuals, but the Supreme Court of the United States summons sovereign powers to its bar." John Stuart Mill declares it to be "the first example of what is now one of the most prominent wants of civilized society, a real international tribunal." In all other matters the jurisdiction of the Supreme Court is only appellate. The judicial power extends only to cases as they arise between party and party, and in the Supreme Court as they come to it mostly by appeal from the inferior Federal courts, or by writ of error to the State courts.

The courts of the United States exercise no supervision over, or interference with the President or Congress, or the legislatures of the States. They have no veto power. They do not lie in wait for acts of Congress, to strangle them at their birth. They have no jurisdiction to pronounce any statute, either of a State or of the United States, void because irreconcilable with the Constitution, except as they are called upon to adjudge the legal rights of litigants in actual controversies. They simply pass upon the rights of parties as they come before them, and if a provision of the Constitution, or of a Federal statute, or a treaty is invoked for or against a right claimed or denied, they interpret the Constitution, the law, or the treaty, and determine the right. In this way, and in this way only if an act of Congress or of a State legislature is claimed to be invalid, or an official act is claimed to be illegal under the Constitution of the United States, and the decision of that question is vital and necessary to determine the rights of the parties, they perform the ordinary duty of interpretation, and declare the validity or invalidity of the act, and so determine the right between the parties before them in that particular case, and for no other purpose, and this may happen months or years after the enactment of the statute.

The Supreme Court performs no duties except judicial duties. So, when in 1794 President Washington requested the opinions of the judges on the construction of the treaty with France of 1778, they declined to comply, and when an early Congress enacted that certain pension claims should be considered and passed upon by the Federal courts, the Supreme Court upheld them in refusing to act under it, upon the ground that the power proposed to be conferred was not judicial power within the meaning of the Constitution. Nor will the court give a hearing to a fictitious or collusive case, contrived to raise a question as to the validity of a statute. Keeping strictly within the limit prescribed to it of exercising only judicial power, the Federal judiciary has steadily refrained from exercising any political power, which belongs exclusively to Congress and the President, and so it has been brought into no collision with the other departments. It will not even indulge in discussions, or express opinions upon purely political questions. All attempts, for instance, to induce it to interfere either to restrain or compel the President in the exercise of his power to see that the laws are faithfully executed have failed. In the case of foreign nations, as well as in that of the sovereign States of the Union, the government acknowledged by the President, or by the President and Congress, is always recognized by the Supreme Court. In all such questions as are purely political it holds itself bound by the acts of the other departments. So the question whether and upon what conditions aliens shall be excluded from the United States, belonging to the political departments of the government, the court refused to express any opinion upon the wisdom, the policy, or the justice of the measures enacted by Congress in the exercise of the powers confided to it by the Constitution over that subject. Thus it constantly sets the example to each of the other departments of the government of minding its own business, and keeping strictly within its assigned province. But, careful as the judges are to confine the exercise of the Federal judicial power to cases as they arise, that power does extend to "all cases of law and equity arising under the Constitution, the laws of the United States, and treaties made under their authority, to all cases affecting ambassadors, other public ministers and consuls, and to all cases of admiralty and maritime jurisdiction"; and whenever any such case does come before the Supreme Court it must take cognizance of it, and it cannot shrink, and never has shrunk, from determining the question of private right so arising. It is under these clauses that its unique and peculiar function of testing the validity of State laws and constitutions and of Federal statutes, and the legality of the acts of State and Federal officers arises.

The remainder of the Federal judicial power depends wholly upon the character of the parties to the controversy. It extends "to controversies to which the United States shall be a party." This enables the Federal courts to enforce the acts of Congress, civil and criminal, against all persons within the realm; "to controversies between two or more States," the purpose of which has already been indicated, as making the Supreme Court the arbitrator and peacemaker between sovereign States; to "controversies between a State and citizens of another State, between citizens of different States, between citizens of the same State claiming lands under grants of different States, and between a State, or the citizens thereof, and foreign States, citizens, or subjects." It was wisely concluded that in all such cases justice would be safer and surer, against State or local interest, prejudice or passion, in courts representing and vested with the authority of the whole nation, than in the courts of the State of an interested party, and that foreigners especially should have the right to have their causes heard and decided by national tribunals. These clauses, which make jurisdiction dependent upon the citizenship or character of the parties, have been a prolific source of litigation in the Federal courts, have opened to them the entire field of law and equity; have extended their adjudications to the whole body of jurisprudence, and have given to the decisions of the Supreme Court, by reason of the weight and force of character of the court and its members, a commanding authority with the State courts, and persuasive influence with foreign tribunals. But in this department of its functions the Supreme Court does not differ, in the scope of its powers and duties, from the courts of last resort of other nations, and its distinctive and peculiar character is not involved. The power of the court to declare State and Federal statutes, and the acts of the National and State executive officers invalid, as being in violation of the Constitution of the United States, naturally attracts the attention of foreign observers.

In the 130 years of its existence the court has pronounced 33 acts of Congress, and more than 225 State statutes, to be in conflict with the Federal Constitution, and therefore invalid, and in each instance there has been complete and peaceful acquiescence in the decision. So that instead of being a disturbing element, the exercise of this power confirms the peaceful relation between the States and the Nation, and beween the States as among themselves, protects foreign nations from the breach of treaties, and conserves the rights of property and contract, and the fundamental rights of personal liberty. The Constitution provides that «no State shall pass any law impairing the obligation of contracts,» and the aid of the court has often been invoked for protection against the attempts of States to violate this prohibition. The framers of the Constitution believed, and the people of the United States, in view of the successful operation of this prohibition for more than a century, believe that the States ought not to be permitted to intervene between the parties to a contract, to destroy or impair the binding force of terms by which they have agreed to be bound, and that such intervention is contrary to the principles of popular government. It is true that in the days that tried men's souls before the adoption of the Federal Constitution many attempts had been made by States to intervene for this purpose, which doubtless led to the adoption of this clause.

Mr. Hamilton, in the *Federalist* classing such laws with bills of attainder and *ex post facto* laws, which are prohibited by the same clause, says:

"Laws impairing the obligation of contracts are contrary to the first principles of the social compact, and to every principle of sound legislation. They are prohibited by the spirit and scope of the State constitutions. Our own experience has taught us, nevertheless, that additional fences against these dangers ought not to be omitted. Very properly, therefore, have the Convention added this constitutional bulwark in favor of personal security and private rights. And I am much deceived if they have not, in so doing, as faithfully consulted the genuine sentiments as the undoubted interests of their constituents. The sober people of America are weary of the fluctuating policy which has directed the public councils. They have seen with regret and indignation that sudden changes and legislative interferences in cases affecting personal rights, become jobs in the hands of enterprising and influential speculators, and snares to the more industrious and less informed part of the community. They have seen, too, that one legislative interference is but the first link of a long chain of repetitions, every subsequent interference being naturally produced by the effects of the preceding. They very rightly infer, therefore, that some thorough reform is wanting which will banish speculations on public measures, inspire a general prudence and industry, and give a regular course to the business of Society."

In the celebrated Dartmouth College case the protection of this clause was invoked by the trustees of the college, to recover its property from a person who held it for new trustees under the authority of a law of the State of New Hampshire. In 1769, King George III by royal charter incorporated 12 persons, therein named as «The Trustees of Dartmouth College,» granting to them and their successors the usual corporate privileges and powers, and authorizing the trustees who were to govern the college to fill up all vacancies which may be created in their own body. The application by the founder, who had already established the college, was for a charter to incorporate a religious and literary institution, and stated that large contributions had been made for the object, which would be conferred upon the corporation as soon as it was created, and on the faith of the charter the property was conveyed to it. After the Revolution (in 1816), the legislature of New Hampshire passed an act increasing the number of trustees to 21, giving the appointment of the additional members to the governor of the State, and creating a board of overseers with power to inspect and control the most important acts of the trustees. Admitting that the provision of the Constitution embraced only contracts which respect property or some object of value, and which confer rights which may be asserted in a court of justice, and did not refer to grants of political power or to acts creating institutions to be employed in the administration of government or of public property, or in which the State as a government was alone interested, the court after most mature consideration reached the conclusion, that the charter was a contract which secured to the trustees the property and control of the college — a contract made upon valuable consideration — for the security and disposition of property, and on the faith of which real and personal property had been conveyed to the institution, and, therefore, a contract, the obligation of which could be impaired without a violation of the Constitution of the United States. It held that the statute of New Hampshire did impair it, and was, therefore, void, and rendered judgment restoring the property and control of the college to the trustees who represented the founder. The opinions of Chief Justice Marshall and Judge Story are masterpieces of judicial reasoning, and the principles laid down by them have ever since prevailed. In 56 cases decided by the court, acts of State legislatures have been declared invalid in accordance with these principles, because they impaired the obligation of contracts, and it is not too much to say that, instead of having a disturbing or disintegrating effect upon civil society, these decisions have done more than any other single cause to inculcate a reverence for the law, and for the sanctity of the right of private property, which is one of the chief objects of free government.

It is true that the constitutional prohibition against laws impairing the obligation of contracts does not expressly apply to Congress. In the convention, Mr. Gerry, a prominent delegate from Massachusetts, made a motion that Congress ought to be laid under the like prohibition, but found no seconder. But in the amendments which were proposed by Congress at its first session, almost as conditions on which many of the States had adopted it and which were quickly ratified, other restraints were laid upon Congress which had the like effect. It was expressly declared that no person shall be deprived of life, liberty or property without due process of law, nor shall private property be taken for public use without just compensation, and Congress is bound by these prohibitions. No matter what the emergency, it cannot violate these fundamental principles of personal rights. The court has held that the United States cannot, any more than a State, interfere with private rights except for legitimate governmental purposes, that they are as much bound by their contracts as are individuals, that if they repudiate their obligations it is as much repudiation, with all the wrong and reproach that term implies, as it would be if the repudiator had been a State, a municipality or a citizen. But strict and earnest as the court has been in enforcing its constitutional prohibition against laws impairing the obligation of contracts, it has been ready to recognize and give full force and effect to the statutes of other nations which imposed no such prohibition on the law-making power.

The Canada Southern Railway Company, under its charter granted by the Dominion of Canada, had issued its bonds at a high rate of interest, and had sold them in New York to citizens of the United States, but getting into difficulties the company devised a scheme of arrangement, which was enacted by the Dominion Parliament, by which the interest on the bonds outstanding was scaled down to a lower rate without the consent of the bondholders, a clear case of impairing the obligation of a contract. The bondholders appealed to the Supreme Court, which held that the «Arrangement Act» was valid in Canada, and bound non-assenting bondholders there by force of the scheme; that as it did have that effect in Canada, the courts of the United States should give it the same effect, even as against citizens of the United States whose rights accrued in the United States before its passage; that there was no constitutional prohibition in Canada against the passing of laws impairing the obligation of contracts, and that, under these circumstances, the true spirit of international comity required that schemes of this character, legalized at home, should be recognized in other countries.

The clause of the Constitution giving Congress the power to regulate commerce with foreign nations and between the States, has been another fruitful source of business in the Supreme Court in the way of testing the validity of State laws. At the outset of steam navigation, the State of New York undertook to reward Robert Fulton for his invention and enterprise by an act giving him the monopoly of navigating by fire or steam all the waters within the jurisdiction of the State. Under this act the assignee of Fulton had commenced running a line of boats between certain ports of New Jersey and New York, and obtained from the State courts of New York an injunction to restrain the owners of an opposition line of boats, put on between the same ports, from entering the waters of New York State with their boats. But the Supreme Court held, upon appeal, that the New York enactment was in conflict with the power of Congress to regulate commerce, and with its acts in relation to commerce, and upon this ground vacated the injunction and established the right of all vessels to enter the port of New York under the authority of Congress. It was held that by virtue of the constitutional clause referred to, Congress had exclusive authority to regulate commerce in all its forms in all the navigable waters of the United States, their bays, rivers and harbors, and to make navigation free to all without and restraint or interference from any State legislature. By a long series of decisions that followed under the commerce clause the court, with inflexible firmness and far-reaching sagacity, established the absolute supremacy of the nation over the whole subject of commerce, navigation, travel and intercourse between the States, which went far to strengthen the power of the Union. At the same time they secured to the citizens of every State the full enjoyment of the privileges and immunities of citizens in all the other States, and also that absolute freedom of internal trade throughout the country which has so vastly promoted the prosperity of the people.

The influence of the court in maintaining the faith of treaties has been powerful and far reaching. By the treaty of peace with Great Britain, in 1783, it was agreed that British creditors should «meet with no lawful impediments» in the collection of their claims; and the Constitution said that treaties, like laws, made under its authority, should be the supreme law of the land. Various attempts had been made by several States, before the adoption of the Constitution, to impede or prevent the collection of such claims. The subject provoked bitter and exciting controversies, but the court, against the contention of John Marshall himself, then at the bar, held that the treaty was supreme, and equal in its effect to the Constitution itself, in overruling all State laws upon the subject, and that its words were as strong as the wit of man could devise to override all obstacles directed against the recovery of such debts. Of course, any such law passed by a State after the treaty contrary to its terms would be void.

Perhaps the most striking illustration of the power of the court to declare acts of Congress itself invalid, as contrary to the Constitution, was the celebrated Income Tax (q.v.) case. Congress in 1894 had passed a General Revenue Law, certain sections of which imposed an income tax upon all incomes exceeding a certain amount named. This tax was levied indiscriminately upon all incomes alike, from whatever source derived, whether from the rents of real estate, the income of invested personal property or from earnings. But the Constitution had ordained that direct taxes should be apportioned among the several States according to the numbers of their respective populations, in contradistinction to duties, imposts and excises, which should be uniform throughout the United States. It was contended by those who challenged the validity of the law, that taxes on rent, and taxes on the income derived from invested personal property, were direct taxes within the meaning of the Constitution, and that instead of being levied uniformly, man for man, throughout the United States, they should have been apportioned among the several States according to population. The difference was very considerable and substantial. The effect of the act, if sustained, would be to throw the principal burden of the tax upon a few large States, in which the relative proportion of wealth was in excess of the relative proportion of population, and to exempt the other States proportionally from their constitutional share of the tax. The opponents of the income tax also insisted that any inequality, which should arise from its being apportioned among the States according to population, was an inequality contemplated by the framers of the Constitution, and was intended to prevent an attack upon accumulated property by mere force of numbers. The court, against vehement and powerful opposition at the bar, and from a formidable minority of the members of the court itself, took this view, and declared the tax to have been laid unconstitutionally, so far as it affected incomes from rents and from invested personal property. And as the invalid portions constituted so large a proportion of the whole income tax levied by the act, that Congress could not be deemed to have intended to impose the rest without them, it further adjudged that all the income tax provisions of the act, which constituted a single and entire scheme, must be held void. There were some popular protests against the decision, and direful prophecies that it would disable the nation in future emergencies from raising the revenue it needed, but no such results have yet appeared. Congress, in its subsequent enactments, has conformed to the decision, and when the war with Spain came on, and an immensely enlarged revenue was needed at once, it found no difficulty in imposing taxes constitutionally and so successfully that, the year after the war closed, the Treasury was found to be burdened with so great a surplus that the entire body of war taxes had to be repealed at once. The same case contains a fine illustration of the power of the court to protect the States in the exercise of their legitimate power to manage their own affairs from interference by the Federal government. The income tax was levied also upon income derived from the interest upon bonds issued by municipal corporations, which were but civil divisions of the States, and the court held that as a tax upon the income of municipal bonds tended to cripple the power of the local authorities to raise money for the purposes of local government, it was not within the power of the Federal government to impose it, any more than it would be constitutional for the States to impair the power of the Federal government to raise money for Federal purposes by taxing its bonds.

By the adoption of the 14th Amendment (q.v.), to meet the conditions resulting from the abolition of slavery at the close of the Civil War, new restraints were imposed upon the States, the consideration of which has largely occupied the attention of the Supreme Court. It provides that "No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty or property without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws." Doubtless this amendment was primarily intended for the protection of the newly emancipated slaves, especially in the States where they had so long been held in bondage, but in its language there is no distinction of race or color, and the court held that it could make no such distinction in its application, which must be made alike to all cases and subjects that came within the scope of its language in its natural meaning.

It must not be thought, however, from these numerous restraints imposed by the Constitution upon the power of the States, and the very considerable number of cases (exceeding 200 in all) in which the Supreme Court has pronounced their statutes invalid, that the court is biased against the States or inclined unduly to enforce the limits imposed upon them. On the contrary, it has been quite as jealous and careful to uphold and maintain the reserved rights of the States in all matters of local and domestic concern, and to protect them from violation by the Federal government, as it has been to maintain the exclusive province of Congress in national concerns against intrusion by the State legislatures. It has endeavored, with success, to maintain the just and exact balance of power between them as prescribed by the Constitution. As against the 225 cases in which State laws have been invalidated by its judgments, vastly more numerous cases will be found, in its reports, in which State laws have been maintained by it against attack on the ground that they involved a violation of the Federal restraints. If, then, it be asked — why has it only pronounced about 35 acts of Congress invalid on constitutional grounds; while 225 State laws have been condemned? the answer is that there are 48 States and only one Congress, and that the members and committees of Congress are much more familiar with the Federal Constitution than those of a State legislature, who naturally look first to that of their own State. It is notable, too, that the legislators of some States must be much more studious of the Federal Constitution than others, for while Louisiana, which became a State in 1812 and from its French origin has retained the civil law instead of the common law, has had 20 of its laws pronounced invalid for violation of the Constitution, Massachusetts, one of the original 13 States, has only suffered twice in this way in her whole history.

Congress is, of course, in the first instance the judge of the constitutionality of its own acts, and its members, being mostly lawyers, are familiar with the letter and spirit of the Constitution. The cardinal and wholesome rule of the court has been, not to pronounce either a State or Federal law invalid on constitutional grounds unless the violation is clearly established, that the presumption is in favor of the validity of a statute, and that this continues until the contrary is shown beyond a rational doubt. The Supreme Court has felt that one branch of the government cannot encroach on the domain of the other without danger, and that the safety of our institutions depends in no small degree on a strict observance of this salutary rule. It speaks volumes for the wisdom and caution of the court which is vested with this remarkable and fascinating power, that in so great a mass of State legislation, some of it crude and undigested, consisting of thousands of volumes, it has not found it necessary to exercise the power much more frequently. It has been a source of frequent wonder to foreign observers that a written Constitution, which was framed in the 18th century for 13 feeble States, with 3,000,000 of people of substantially uniform wealth or poverty, scattered along the Atlantic seaboard, and for whose government it was regarded as a precarious experiment, should be found to answer as well in the 20th century for the needs of a great nation of 80,000,000 in 48 States, occupying the breadth of the continent, with gigantic accumulations of individual and corporate property, with conflicting interests and sentiments, and wide differences of social condition. There was much debate in the discussions which resulted in the adoption of the Constitution, whether the government which it called into being could reach and control even a people that was expected to occupy the territory which the Treaty of Peace of 1783 secured to the United States, which extended only from the Atlantic to the Mississippi River, and from the lakes to the northern boundary of Florida. Since that time our territory has expanded more than four times, and now embraces insular possessions of vast extent, at enormous distance from the seat of government and half way round the globe.

The fundamental difficulties of time and space have been overcome by the triumphs of steam and electricity, wholly unforeseen and unexpected in 1787. but which now, in the case of the United States and Great Britain alike, have rendered possible the administration of government from London or from Washington on any portion of the earth's surface. At the time of the adoption of our Constitution it took about as long to travel the length or breadth of the then United States as it does now to go from New York to Manila, or from London to Peking, and orders of either government which then would have taken months to transmit, now reach their destination so as to be put in execution at the other end of the world in a few hours, and sometimes in a few minutes. But in our case, we can account for the fact that a written Constitution, instead of being torn asunder and left by the way as the nation expanded, as new and wholly unexpected conditions arose, has grown with the growth of the nation, like the hide of an animal from its birth to its maturity, so that it still embraces and covers the whole of our vast national life. We owe it, first, to the wisdom of its framers, who inserted in it only fundamental rules and principles, generally and briefly expressed, leaving it always to Congress to fill in and provide for all details; and secondly, to the vigorous and masterly manner in which the Supreme Court has exercised its essential and lawful function of construction. By this it has applied the whole instrument and each of its parts to new conditions as they arose, and has developed and strongly asserted the inherent powers of sovereignty intended to be vested in the government of the United States, and necessarily resulting from their existence as a nation. It was our happy fortune that for 34 years, in that critical period of our history which was to determine whether we were to be a great and powerful nation, adequate for all the needs of a first-class power in the world, or only a league of States like the old Confederation, we had the benefit of the broad and robust intellect of Chief Justice Marshall, to enforce the liberal principles of construction which the genius of Hamilton had laid down.

In a single paragraph he states the whole theory upon which the court has administered the Constitution, and fitted it to the growing wants and changing conditions of the nation:

"The Government is acknowledged by all to be one of enumerated powers. The principle that it can exercise only the powers granted to it is now universally admitted. But the question respecting the extent of the powers actually granted is perpetually arising, and will probably continue to arise, as long as our system shall exist. The powers of the government are limited, and its powers are not to be transcended. But the sound construction of the Constitution must allow to the National Legislature that discretion with respect to the means by which the powers it confers are to be carried into execution, which will enable that body to perform the high duties assigned to it, in a manner most beneficial to the people. Let the end be legitimate, let it be within the scope of the Constitution, and all means which are appropriate, which are plainly adapted to that end, and which are not prohibited, but are consistent with the letter and spirit of the Constitution, are constitutional."

Hamilton, in the *Federalist*, declared that "the judiciary is beyond comparison the weakest of the three departments of power; that it can never attack with success either of the other two; and that all possible care is requisite to enable it to defend itself against their attacks." Montesquieu, whose works, with Blackstone's, were the textbooks of constitutional liberty which the framers had constantly in hand, declared that "the judicial power is next to nothing." And it was said by another French publicist, "It has no guards, palaces or treasures, no arms but truth and wisdom, and no splendor but the justice and publicity of its judgments." But the Supreme Court, sustained generally by the confidence and affection of the people, has more than held its own. Keeping carefully within its own limits, it has for the most part labored to keep the other departments of government within theirs, and the powers of the States and of the nation from coming into conflict. In its hands the judicial power has been the force of gravitation which has kept each member of our Federal system in its proper orbit, and maintained the essential harmony of the whole.

The closing scene in the Federal Convention, which made the court in a way the guardian of the Constitution, will be ever memorable. After months of discussion, sometimes violent, more than once approaching the very brink of dissolution, in hopeless despair of coming to any agreement, at last the grand triumph of compromise and mutual concession was accomplished, and the members met to affix their names to the instrument. Hamilton, one of the youngest, acted as scribe, and after Washington had signed first as "President and Deputy from Virginia," inscribed on the great sheet of parchment the name of each State, as the delegates came forward in geographical order to add their names. When all had signed, Franklin, the oldest and most famous of them all, pointing to the sun emblazoned behind the chair in which Washington had presided through the whole struggle, said to those about him, «In the vicissitudes of hope and fear, I was not able to tell whether it was rising or setting. Now, I know that it is the rising sun.» After more than a century's trial of their work, the sun which Franklin saw is not yet near the zenith — much has been done, but vastly more remains to be accomplished, and it is still morning with our young Republic.

R., 'Jurisdiction, Practice and Peculiar Jurisprudence of the Courts of the United States' (2d ed., Boston 1896); Moore, B. F., 'The Supreme Court and Unconstitutional Legislation' (New York 1913).

JOSEPH H. CHOATE.

SURABAYA, soo-rä-bī'ä (Dutch, SOERABAJA), Java, (1) the seaport and capital of the province of the same name on the north coast of the island of Java. The city is situated on the Strait of Surabaya, which separates Madura Island from Java. It is, next to Batavia, the most important port and commercial station in the Dutch East Indies, and has machine-shops, an arsenal, a mint, sugar and furniture factories, shipbuilding yards and foundries. It exports sugar, coffee and the various products of the region. Pop. about 150,000 including about 10,000 Europeans. (2) The province of Surabaya has an area of 2,327 square miles and a population of over 2,115,000.

SURAJAH DOWLAH, soo-rä'jä dow'la, the last independent nabob of Bengal, under whom was perpetrated the massacre of the Black Hole (q.v.). He succeeded his grandfather, Ali Verdy Khan, in 1756, and within two months of his accession found a pretext for marching on Calcutta. On the arrival of Clive and Admiral Watson he retreated to Moorshedabad, but was routed at the battle of Plassey (23 June 1757). He then fled up the Ganges, but was betrayed by a fakir, and was put to death by order of the son of Meer Jaffier, the new nabob. Surajah Dowlah's reign lasted 15 months, his age at the time of his death being barely 20.

SURAKARTA, soo-rä-kär'tä, a town in central Java, connected by rail with Samarang on the north and Surabaya on the east. It is the residence of the native sultan of Surakarta, who is a vassal of the Dutch government and is advised by a resident. The town (pop. 125,000) is the capital of his kingdom, a mountainous but in part very fertile region, with an area of 2,191 square miles and a population of about 1,100,000.

SURAT, soo-rät', India, a city in the Gujarat division of Bombay, extends for some distance in crescent form along the south bank of river Tapti, (spanned by an iron bridge) in a fertile valley. It is 160 miles by rail north of Bombay. The Nawab's palace lies within the confines of the fort. The remarkable buildings are four handsome Mohammedan mosques, two Parsi fire-temples, several Hindu temples, and a clock-tower (80 feet high). There is also an extensive bazaar, and a Hindu hospital for sick animals. The city in 1512 was burned by the Portuguese, again in 1530 and 1531. The English established themselves there in 1612, and the city came under British rule in 1800. Industry is limited to the manufacture of cotton and silk goods, shawls, etc., articles of ornamentation, jewelry and ivory objects, indigo and pottery. The exports are cotton and grain. The commercial importance of Surat was established in the 16th century, and it was the starting point for pilgrimages to Mecca. Its decline dates from the removal of the East Indian Company to Bombay. Fire and flood contributed subsequently to its decadence. It flourished during the American Civil War through its cotton export. Pop. about 115,000.

SURCOUF, sür-koof, Robert, French naval officer: b. 1773; d. 1827. Much of his life at sea was devoted to privateering and he was known as «the king of the Corsairs.» From 1798 to 1801 and from 1809 to 1811, he scoured the sea for English merchantment as Paul Jones did some years previously. His life was divided between building French ships on shore and scouring the high seas for English merchant vessels. It was his advice to Napoleon: «Attack rich England in her riches — in her merchant vessels; leave your ships of the line at home and send out light privateers!»

SURETY. See SURETYSHIP.

SURETYSHIP, a word derived from the French *sûreté*, from the Latin *securitas*, which means freedom from care. It signifies the obligation of a person to answer for the debt, default or non-performance of another, and to make good any loss occasioned thereby to the extent provided in the contract. The difference between suretyship and guarantee is an essential one, a contract of suretyship being a direct liability to the creditor for the act to be performed by the debtor, whereas a guarantee is liability only for the debtor's ability to perform this act. A contract of suretyship is an immediate and direct undertaking that the act shall be done, and if the act is not done, the surety becomes responsible at once.

The Constitution of the United States makes it impossible for any State to enforce a law which might be construed as impairing the rights of a creditor under a contract of suretyship, but like other contracts it may be vitiated and annulled through fraud or duress in the execution. The surety is entitled to such information both from creditor and debtor as will enable him to know the nature of the obligation which he is assuming, and if there is fraudulent misrepresentation or suppression of the facts with the purpose of obtaining his agreement to the undertaking the surety can obtain relief in a court of equity. On the other hand this relief would not be granted against innocent parties who had, without notice from the surety, incurred expenditure or assumed obligations on account of the existence of the suretyship contract. Of course in such a case the surety would have a right to redress from the creditor or debtor, or both, who had caused him loss by deceiving him.

It should be understood that there is no obligation on the part of the creditor or of the debtor to disclose all facts relating to the risk, but only those the withholding of which, if known to them, or either of them, would constitute intent to mislead. The surety, on the other hand, is expected to use reasonable judgment and precaution in making the contract. The presumption of law is that the suretyship, the surety's signature being admitted, is valid, and upon him rests the onus of attacking its validity, if he so desires.

The surety's responsibility cannot be changed or the contract modified in any manner without his consent, and should any change be made in the contract without such consent, the surety is discharged from his obligation. It does not matter whether the change would be advantageous to the surety or otherwise; he has a right to stand upon the original terms, and cannot be held responsible for any different terms. This applies also to any extension of the term of credit specified in the contract without the surety's approval in legal form.

Upon discharge of his obligation by the debtor, the surety is of course released. The surety is likewise released by tender of payment by the debtor and refusal to receive it by the creditor. In some States the surety is released if the creditor does not sue the principal upon request of the surety. Should the debtor default and the surety have to pay, the surety becomes entitled to all the rights and securities previously held by the creditor against the debtor. If there are several sureties, and the creditor's claim is enforced against one only, the latter can compel his cosureties to pay their several shares, and he also has a claim against the principal for the amount which he has expended in meeting the obligation. See GUARANTEE.

SURF-BIRD, a shore-bird (*Aphriza virgata*), having a distinct place of its own between the sandpipers and plovers. It is about 10 inches long, with the wing seven; dark brown above, lighter on the wing coverts, with white spots and stripes on the head and neck; upper tail coverts and basal half of tail white, the latter terminated with brownish black; under parts white, tinged with ashy in front, each feather having a brownish black crescent. The bill is about as long as the head, with vaulted obtuse tip and compressed sides; wings long and pointed. It is found on the Pacific Coast of North and South America, and in the Sandwich Islands, migrating from northern to temperate regions in winter and back again in summer. It is usually seen on the edge of steep rocks, among the retreating waves, searching for small mollusks and marine animals, allowing the surf sometimes to dash over it, whence the common name; its flight is short, with a quick and jerking motion.

SURF-CLAM. See CLAM.

SURF DUCK, or SURF SCOTER. See SCOTER.

SURF-FISH, one of the many small ovoid fishes of the family *Embiotocidæ,* related to the percoids, which abound upon the Pacific Coast of North America, where they are found numerously in the surf on sandy beaches, and in the mouths of rivers. They are often gayly colored, sometimes in extraordinary patterns of spots or bars; and are easily caught but not valued much as food. The most familiar one is *Amphisticus argenteus;* several others are locally known as the blue, black, red and white perches, the alfione, etc. All are viviparous.

SURF-SMELT, a small, eminently toothsome smelt (*Hypomesus pretiosus*), numerous along the coast of California and northward, where it spawns in the surf, and is caught in great quantities in nets. See SMELTS; WHITEFISHES.

SURFACE, Joseph, a character in Sheridan's comedy, 'The School for Scandal.' He is a mean hypocrite who affects great seriousness and sentimentality.

SURFACE. (1) A physical surface may be defined as formed by the boundaries or limiting portions of a given body. (2) A mathematical surface is the boundary between two given portions of space. It may be of various orders, a plane surface being of the first order, a quadric surface of the second order, etc. A surface through all points of which a straight line may be so drawn as to rest entirely within the said surface, is termed a ruled surface. The cone, conoid and cylinder are examples of this class. A surface is said to be of the *n*th order when it is intersected at *n* points, either imaginary or real, by a given arbitrary line. For a treatment of the subject, consult Eisenhart, L. P., 'Treatise on Differential Geometry on Curves and Surfaces' (Boston 1909); Michaelis, M. L., 'Dynamics of Surfaces' (New York 1914); Smith, Charles, 'Solid Geometry' (3d ed., New York 1891).

SURFACE TENSION, that property of liquids in virtue of which they tend to take such a form as to have the smallest surface possible. The name "surface tension" has reference to the fact that liquids, when freed from the action of gravity and other comparatively powerful forces, behave as though their surfaces were elastic membranes, which are everywhere in a state of uniform tension. Beginners in the study of physics often form the idea, from their textbooks, that this hypothetical tension is real and that the surface of a liquid really is membranous in nature, and subject to an actual, physical tension. This is not at all the case; for the behavior of the liquid is due to an entirely different cause, as will be understood by reference to Fig. 1. *AB* here represents a liquid surface, and *m m m m m* represents a molecule of the liquid, which is originally in the interior of the liquid, but which is removed from it in the manner illustrated by the successive figures 1, 2, 3, 4 and 5. Consider, first, the state of the molecule *m* in the position 1. It is here surrounded by the liquid on all sides, and the attractive influence that the other molecules of the liquid exert upon it is sensibly the same in all directions. The circle that is drawn about *m* represents a sphere whose radius is the "radius of sensible molecular attraction"; that is, it is equal to the (unknown) distance at which we may suppose that the attraction of one molecule of the liquid for another one ceases to be sensible. The attractive influence of those parts of the liquid which are external to this sphere being by hypothesis insensible, we may regard *m* as influenced solely by such molecules as are within a sphere of the radius shown. It is easily seen, therefore, that the attraction of the liquid for m will be the same in all directions (and therefore without any resultant effect), so long as the sphere remains totally submerged. But when the molecule m approaches the surface so nearly that a part of its sphere projects into the air as shown at 2, it is equally evident that the attractive force upon m is no longer the same in all directions. In order to make it so, we should have to cut off, from the bottom of the sphere at 2, a segment equal to the segment that projects into the air, as indicated by the little shaded area. The mass of fluid that lies between this shaded segment and the surface of the liquid is without any resultant effect upon

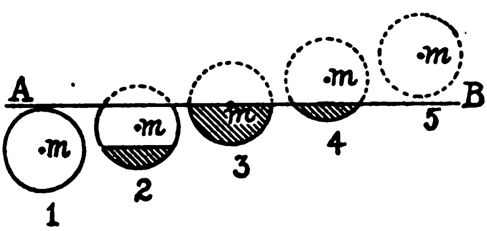


FIG. 1.

m, on account of its symmetry with respect to m; and hence in the position 2 we may regard m as subject only to the unbalanced downward attraction that the shaded segment exerts upon it. In position 3 the molecule has reached the surface of the liquid, and it is subject to a downward attractive force due to the mass of liquid contained in the entire lower half of the sphere. In bringing the molecule from position 1 to position 3, we therefore have to move it upward against a force which tends to pull it back into the liquid again; this force becoming active from the moment that the sphere of sensible molecular attraction first becomes tangent to the surface of the liquid; and increasing in magnitude until it attains its maximum value when the molecule actually reaches that surface. Hence we have to perform work, in order to transport a molecule from the interior of a liquid to the surface; and this amounts to saying that we have to perform work in order to increase the surface of a liquid. But this is just what we should have to do if the surface of the liquid were an elastic membrane; and hence it is permissible to imagine that the surface *is* such a membrane; and it is found that such a conception makes it easier to understand and describe the phenomena that result from molecular attractions in liquids. It will be noted, however, that in extending the surface of a liquid we do not actually *stretch* the existing surface. We merely bring more molecules from the interior, where the forces acting upon them are balanced, to the surface, where these forces are not balanced.

The phenomena of surface tension are most obvious in soap films and in foams, where the mass of the liquid concerned is so small (relatively to the surface) that the molecular forces which give rise to the so-called "surface tension" can easily preponderate over gravity, which is relatively powerful in liquid bodies of large mass and small surface. The French physicist Plateau devoted a vast amount of attention to the phenomena that are manifested by liquid films, and by masses of liquid that are freed from the influence of gravity by being suspended in other liquids with which they will not mix, but which have the same density as the liquid to be studied. Olive oil can readily be freed from the action of gravity, by submerging it in a mixture of alcohol and water, whose composition is regulated by trial until the mixture has precisely the same specific gravity as the oil. A mass of oil which is submerged in this manner, and is not constrained in any way, at once assumes a spherical form; for the sphere has a smaller surface than any other solid of the same volume.

The existence of surface tension can be shown readily and strikingly, even in a large mass of water, by several very simple experiments. Of these, the camphor-movement experiment is one of the best known. To perform it, a perfectly clean vessel is filled with clean water, some of the water being allowed to flow over the sides of the vessel, so that any superficial impurities may be washed away. Very fine scrapings of camphor are then allowed to fall upon the surface of the water; and if the water surface is sufficiently clean, these scrapings at once begin to execute the most violent movements. The motion of the camphor is due to the fact that the surface tension of a solution of camphor in water is less than that of pure water. The camphor particles do not dissolve evenly on all sides; and the horizontal pull exerted upon them by the water is greatest in those directions in which the concentration of the solution in immediate contact with the particles is least. Hence the motions. The great importance of absolute cleanliness in this experiment is well illustrated by touching with a slightly greasy finger a water surface upon which camphor particles are in rapid motion. The entire surface becomes contaminated almost instantly, so that the camphor movements become deadened, or cease altogether.

The effects of surface tension are observable in large masses of liquid, where those masses come in contact with the walls of their containing vessels. The slight elevation of the water in a drinking glass, where the water touches the glass, is due to this cause. This particular phenomenon is more marked in the case of a glass tube of small diameter, dipping in a vertical position into a vessel of water (or any other liquid which actually wets the glass). Let the glass tube be inserted into the water, so that it is wetted up to a certain level, and let the tube be then raised slightly. The glass, in the region which has been submerged below the general level of the water and is now raised above it again, adheres to the water, and as the tube is raised, the column of water within it sinks at the centre, so that its surface becomes concave, as is illustrated in Fig. 2. The weight of that part of the water within the tube which stands above the general level of the water in the external vessel (that is, the weight of that portion which lies between the actual water surface in the tube, and the dotted horizontal line), is sustained by the tension of the curved surface (or "meniscus") that bounds the column at the top; this tension acting everywhere in the direction of the surface of the water, and therefore having an obliquely-upward direction around the edges, and hence a vertical component, which is capable of sustaining the water in the tube. In the case of a liquid which does not wet the tube (for example, in the case of mercury and glass), the curvature of the liquid surface is in the opposite direction from that observed with water and glass; that is, the meniscus is convex upwards, as shown in Fig. 3, and the liquid in the tube

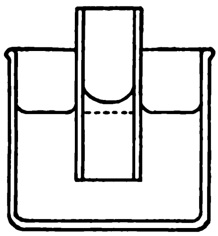

FIG. 2.

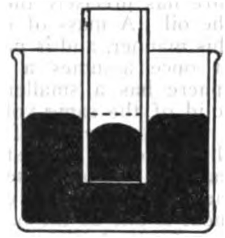

FIG. 3.

stands at a lower level than corresponds to the general level of the liquid surface in the containing vessel. In a barometer, the meniscus of the column is convex upward, and the depression of the column due to the surface tension of the mercury is usually quite sensible; so that in order to be in a position to know the exact height at which the mercury in the column would stand if the tube were large enough in diameter for the effects of surface tension to be negligible, it is necessary to investigate, very carefully, the way in which the depression varies with the diameter of the tube, and with the height of the meniscus itself. Numerous observers have made extensive investigations of this sort, and have given their results in tables. A very good table of this kind, due to Mendeléeff, is given in Guillaume's 'Thermométrie de Précision,' and other tables will be found in nearly all of the works upon meteorology. The property of liquids in virtue of which they stand, in a vertical tube, at an elevation different from that in the vessel into which the tube dips, is commonly called «capillarity,» in reference to the small diameter of the tubes in which the effect is most noticeable (Latin, *capillus*, «hair»).

TABLE OF SURFACE TENSIONS AT 20° C. (68° F.).

LIQUID	Dynes per centimeter	Grams per centimeter	Grains per inch
Water	81.	0.083	3.24
Mercury	540.	.551	21.58
Carbon disulphide	32.1	.033	1.28
Chloroform	30.6	.031	1.22
Alcohol	25.5	.026	1.02
Olive oil	36.9	.038	1.47
Turpentine	29.7	.030	1.19
Petroleum	31.7	.032	1.27

The surface tension of a liquid is measured by the horizontal pull that the liquid can exert upon a straight line one unit in length, lying in its surface; the pull being perpendicular, of course, to the direction of the line. The accompanying table contains the surface tensions of various liquids as determined by Quincke, and quoted by Maxwell. Mercury, for example, is capable of exerting a pull of 21.58 grains upon a straight line one inch long, lying in its surface. The value of the surface tension of water given in this table is certainly too great. Brunner found it to be 75.2 dynes per centimeter, and Wolf found 76.5 and 77.3. Rayleigh's determination, based upon a study of the wave-length of ripples, gave 73.9 dynes at 18° C.; and T. Proctor Hall found that at $T°$ C. the surface tension of water, in the same units, is given by the expression.

$$75.48 - 0.140T.$$

Bibliography.— Boys, 'Soap Bubbles and How to Make Them'; Plateau, 'Statique expérimentale et théorique des liquides soumis aux seules forces moleculaires'; Risteen, 'Molecules and the Molecular Theory of Matter.' Also, any extended treatise on physics.

ALLAN D. RISTEEN.

SURFACES, Theory of. Surface, in the mathematical sense, is the common boundary of two contiguous regions of space. The developments in this vast field of mathematical investigation are essentially of modern origin. The geometers of the Greek school were acquainted with some of the elementary properties of a few surfaces, notably those of sphere, cylinder and cone, but the systematic and fruitful study of surfaces began with their representation by means of equations in Cartesian co-ordinates (see GEOMETRY, CARTESIAN). This was not done until the method of co-ordinates had been employed with success in the study of plane curves, whereupon its application to surfaces presented itself as a natural extension. According to Cantor, 'Geschichte der Mathematik,' Parent (1666–1716) was the first to represent surfaces analytically by means of a single equation $F(x, y, z) = 0$. To each set of values of x, y, z satisfying this equation corresponds a point of the surface. With the introduction of co-ordinates two distinct phases in the study of surfaces present themselves. On the one hand the surface is defined in some purely geometric way, and the problem is to find an equation analytically representative of the surface. On the other hand an equation is assumed, and the problem is to arrive at the properties of the surface from its analytical definition. In the first case no less than in the second, the deduction of geometric properties proceeds, in the main, along analytical lines. It is at once evident that the second phase of the general problem greatly broadens the scope of investigation, and it is from this point of view that the mathematicians have studied the surfaces defined by algebraic equations of second, third, fourth and higher degrees. The algebra brings in imaginaries, and this leads to the introduction of surfaces that are altogether imaginary, and to the consideration of imaginary points and elements in connection with real surfaces.

In what has been said thus far the point has figured as the primitive element of the surface, and in connection with it the surface is a two-dimensional continuum of points. With the expansion of the subject additional primitive elements were introduced, viz., the plane and the line, and from the standpoint of the new elements the surface may be regarded as a two-dimensional continuum of planes, i.e., as the envelope of its tangent planes, or as a three-dimensional continuum of lines, i.e., the envelope of its tangent lines. The theory of a surface as the envelope of its ∞^3 of tangent lines constitutes a special chapter in the general theory of *complexes* of straight lines (see GEOMETRY, LINE, AND ALLIED THEORIES). Along with the analytical method, the synthetic or projective method has been employed, and with special elegance and completeness in the case of surfaces of the second order. With this brief introduction we now pass to a more detailed account of the developments in this branch of mathematics.

1. Algebraic Surfaces in General.—Any surface which can be analytically expressed by an algebraic equation between the Cartesian co-ordinates x, y, z of a point of space is called an *algebraic* surface. The *order* of the surface is the number of points of intersection (real or imaginary) of the surface by an arbitrary straight line. The order of the surface is obviously the same as the degree n of its equation. The *class* is the number of tangent planes of the surface that pass through an arbitrary line. When there is no singularity (see 7) on the surface the class is $n(n-1)^2$. The *rank* of the surface is the order of a circumscribing cone whose vertex is an arbitrary point of space. The rank is $n(n-1)$. The intersection of the surface by a plane is a curve of nth order, and, by the foregoing, the class of this curve is the same as the rank of the surface.

2. The Plane.—This is the simplest of all surfaces, and its equation in the variables x, y, z is of the first degree: $Ax + By + Cz + D = 0$, in which A, B, C, D are constants. It is the only surface of first order.

3. Surfaces of the Second Order, or Quadric Surfaces.—The earliest investigations were connected with the surfaces of the second order, namely, those defined by the general equation of the second degree:

$$Ax^2 + By^2 + Cz^2 + 2Fyz + 2Gzx + 2Hxy + 2Lx + 2My + 2Nz + P = 0.$$

This equation contains 10 coefficients which enter homogeneously. However, only the nine ratios of the coefficients are essential, as the equation may be divided through by any coefficient that is not zero. From this fact comes an important theorem. The substitution of the co-ordinates of a given point in the general equation imposes one equation of condition upon the coefficients; nine such equations determine the ratios of the coefficients, and herewith the equation, and with it the surface. The theorem follows: A surface of second order is in general determined by nine points through which it is to pass.

4. Classification of Quadric Surfaces.—There are in all 16 surfaces of the second order, when the purely imaginary and degenerate cases are included in the numeration. The grouping of the individual surfaces varies with the principle employed. The principle of division may be based on analytical criteria or on geometrical characteristics. Four different varieties of geometrical classification are known. In one the surfaces are divided into (*a*) the surfaces with centre or central surfaces, (*b*) the non-central surfaces. A second classification gives, (*a*) ruled surfaces with real generating lines (see 16), (*b*) non-ruled surfaces (analytically these latter surfaces are ruled surfaces with imaginary generating lines). A third classification rests upon the presence or absence of vertices on the surface. For example, a cone has a vertex and two intersecting planes are a degenerate form of a surface of second order with the line of intersection as a line of vertices. An ellipsoid is without a vertex. The fourth classification is based upon the nature of the conic that is cut from the surface by the plane at infinity.

We now present a classification based upon analytical criteria. This is effected by means of the values of two polynomials Δ and D, functions of the coefficients, and of the roots $k = \lambda, \mu, \nu$, of a cubic equation in k called the discriminating cubic. The polynomials may be conveniently put in the determinant form, as also the cubic equation:

$$\Delta = \begin{vmatrix} A & H & G & L \\ H & B & F & M \\ G & F & C & N \\ L & M & N & P \end{vmatrix}, \quad D = \begin{vmatrix} A & H & G \\ H & B & F \\ G & F & C \end{vmatrix}, \quad \begin{vmatrix} A-k & H & G \\ H & B-k & F \\ G & F & C-k \end{vmatrix} = 0$$

I. Surfaces for which $\Delta \gtrless 0$.

(α) $D \gtrless 0$, (i) Ellipsoid, real, if $\frac{D\lambda}{\Delta}, \frac{D\mu}{\Delta}, \frac{D\nu}{\Delta}$ are all negative.

(ii) Hyperboloid of one sheet if two of the quantities are negative.

(iii) Hyperboloid of two sheets if one of the quantities is negative.

(iv) Ellipsoid, imaginary, if all the quantities are positive.

These are surfaces with centre. By a suitable transformation of the co-ordinate axes to the centre the general equation can be thrown into the form $\lambda x^2 + \mu y^2 + \nu z^2 + d = 0$, in which $d = \frac{\Delta}{D}$ and λ, μ, ν are the roots of the discriminating cubic.

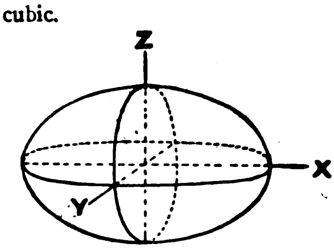

FIG. 1.—Ellipsoid.

(β) $D = 0$, (i) Elliptic paraboloid if λ and μ have the same sign.

(ii) Hyperbolic paraboloid if λ and μ have different signs.

When $D = 0$, one of the roots λ, μ, ν is zero, and it is here assumed that $\nu = 0$. By a suitable transformation of the origin of co-ordinates to a point of the surface, the equation may be made to take the form $\lambda x^2 + \mu y^2 + 2Qz = 0$.

The surfaces (α) *and* (β) *are surfaces without vertices.*

II. Surfaces for which $\Delta = 0$.

(γ) $D \gtrless 0$, (i) Cone, real, if λ, μ, ν are not all of same sign.

(ii) Cone, imaginary, if λ, μ, ν are of same sign.

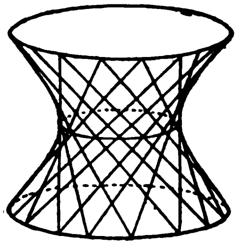

FIG. 2.—Hyperboloid of One Shee

By taking the origin at the vertex of the cone the equation may be brought into the form $\lambda x^2 + \mu y^2 + \nu z^2 = 0$.

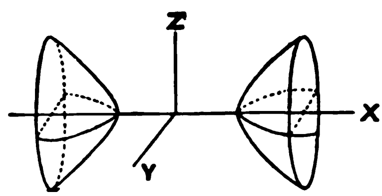

FIG. 3.—Hyperboloid of Two Sheets.

(δ) $D = 0$ (i) Elliptic cylinder, if λ and μ are of same sign and $d \gtrless 0$.

(ii) Hyperbolic cylinder, if λ and μ are of different signs and $d \gtrless 0$.

(iii) A pair of intersecting planes, real or imaginary, if $d = 0$.

(iv) Parabolic cylinder; or two parallel planes, real or imaginary (if all the subdeterminants of D are zero).

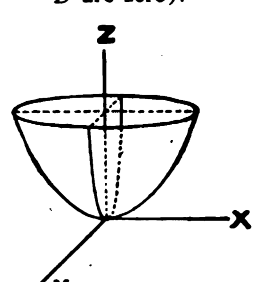

FIG. 4.—Elliptic Paraboloid.

For (i), (ii), (iii), the general equation admits of being thrown into the form $\lambda x^2 + \mu y^2 + d = 0$, and for the parabolic cylinder into the form $Ry^2 + Sx = 0$.

Since a cylinder may be regarded as a cone with infinitely distant vertex, and a pair of planes as a degenerate case of a cone, it follows that the surfaces (γ) and (δ) may be considered as cones, i.e., the *surfaces with vertex or vertices.*

The ruled surfaces among quadric surfaces fall into two categories: (1) the cone and cylinder, each containing one set of generating

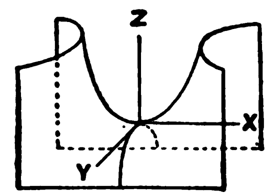

FIG. 5 —Hyperbolic-Paraboloid.

lines infinite in number; (2) the hyperboloid of one sheet and the hyperbolic paraboloid, each containing two sets of generating lines infinite in number. On the two last-named surfaces no two lines of one set intersect, but each line of one set intersects all the lines of the other set.

5. Surfaces of the Third Order, or Cubic Surfaces.—A considerable number of theorems about these surfaces are now known, though their properties have by no means been so exhaustively studied as in the case of quadric surfaces. There are two especially distinguishing properties to be noted concerning them: first, on the general surface there are 27 right lines; second, there is related to the surface a pentaedron whose edges and vertices lie on the *Hessian* of the surface. When there is no singular point on the cubic surface its equation can be thrown into the form $c_1W_1^3 + c_2W_2^3 + c_3W_3^3 + c_4W_4^3 + c_5W_5^3 = 0$, where $W_1, W_2, \ldots$ are linear in x, y, z and the equation $W_1 + W_2 + W_3 + W_4 + W_5 = 0$ holds identically. The Hessian of the cubic is

$$\frac{1}{c_1W_1} + \frac{1}{c_2W_2} + \frac{1}{c_3W_3} + \frac{1}{c_4W_4} + \frac{1}{c_5W_5} = 0,$$

a surface of fourth order. It contains the 10 edges and the 10 vertices of the pentaedron formed by the five planes $W_1 = 0$, $W_2 = 0, \ldots$ The vertices are double points (see 7) of the Hessian. For particulars as to these surfaces consult Salmon, 'Geometry of Three Dimensions,' and also Sturm, 'Synthetische Untersuchungen über Flächen dritter Ordnung' (Leipzig 1867).

6. Surfaces of Fourth Order.— Of these only special surfaces have been thoroughly discussed, among them the ruled surfaces and the Kummer surface. The Kummer surface contains 16 double points and 16 singular planes. Each of the planes is tangent to the surface along a conic and contains six of the double points, and through each double point pass six of the singular planes. Consult Salmon-Fiedler, Vol. II, and Kummer, 'Berliner Abhandlungen' (1866). The results obtained in the study of algebraic surfaces of order higher than the fourth are of more or less fragmentary character and need not be referred to in this brief sketch.

7. Ordinary and Singular Points.— In general the n points of intersection of a line and surface are distinct, but if a point P appears as k coincident points among the n intersections for *every* straight line through it, it is called a k multiple point of the surface. When $k = 2$ it is a double point, when $k = 3$ a triple point. Multiple points are singular points. Through a double point on a surface an infinity of lines can be drawn each of which will pass through a third point on the surface infinitely near the double point. The locus of these lines is a cone of second order. There are three cases: (1) the cone is a proper cone and the double point is called a *conical* point; (2) the cone degenerates into two intersecting planes and the point is a *biplanar* point; (3) the cone degenerates into two coincident planes and the point is a *uniplanar* point or *pinch* point. There may be a curve locus of double points on a surface: for example, the curve of intersection of a surface by itself is such a locus, as is also the curve of contact of two sheets of the same surface with each other. For a detailed study of the character of a surface in the neighborhood of a double point consult Rohn, 'Mathematische Annalen, 22' (1883). As the study of a surface proceeds in general from the equation of the surface, it is to the analysis we must look for a definitive criterion distinguishing ordinary and singular points. A point x_1, y_1, z_1 of a surface $F(x, y, z) = 0$ is said to be *ordinary*, if the F function is developable in an entire series in the neighborhood of x_1, y_1, z_1, and if the three first derivatives $\frac{\partial F}{\partial x}, \frac{\partial F}{\partial y}, \frac{\partial F}{\partial z}$ do not simultaneously vanish at the point. All other points are *singular* points.

8. General Considerations. Curvilinear Co-ordinates.— Modern progress in the theory of surfaces begins with the appearance in 1827 of Gauss' paper, 'Disquisitiones generales circa superficies curvas' (translated into German in Ostwald's 'Klassiker der exakten Wissenschaften'; into English by Morehead and Hiltebeitel, Princeton). Two things in this classical production have profoundly affected subsequent developments in the theory. The first was the systematic employment of curvilinear co-ordinates, and therewith a demonstration of the great advantages which could be derived from their use; the second was the conception of a surface as a two-way extension, *not rigid but flexible,* which could be made to assume new shapes by *bending without stretching.* All surfaces derived from a given surface by bending are said to be *applicable*, or *developable,* upon each other. It is clear that the geometry of figures on such surfaces is the same. The analytical criteria, whether two given surfaces are applicable upon each other, constitute one of the interesting chapters in the general theory. In expressing the Cartesian co-ordinates x, y, z as functions of two variables u, v called parameters:

(A) $\quad x = \phi(u, v),\ y = \chi(u, v),\ z = \psi(u, v),$

a new form of representation of surfaces is established. The elimination of u and v would obviously lead to one equation, $F(x, y, z) = 0$. If u be given a definite value u_0, and v be allowed to vary, a curve will be generated lying on the surface (see CURVES OF DOUBLE CURVATURE). The curve is called the u_0 curve, that is, it is named by the special value of the parameter that is constant at all its points. Assigning a second value to u, say u_1, and allowing v again to vary, there would be formed the u_1 curve of the surface. In this way there could be formed an ∞^1 of curves on the surface constituting the family of u curves. Similarly, there is a family of v curves each characterized by a definite value of v while u is variable. Each point of the surface is the intersection of a u curve and a v curve, and the curves are called its *curvilinear co-ordinates.* One may thus speak of the point (u_0, v_0) of the surface, or in general of the point (u, v), in place of referring to it by its Cartesian co-ordinates. Both co-ordinate systems are put in evidence by writing the point in the form $(x, y, z;\ u, v)$. A restriction upon the values u and v may take, such as an equation $f(u, v) = 0$, defines a curve on the surface.

9. Tangent Plane. Principal Normal Sections.— If to all the curves on a surface passing through an ordinary point $P\ (x, y, z;\ u, v)$, tangents be drawn at P, the line will lie in a plane called the *tangent plane* at P. Its equation is

$$\left(\frac{\partial y}{\partial u}\frac{\partial z}{\partial v} - \frac{\partial y}{\partial v}\frac{\partial z}{\partial u}\right)(\xi - x) + \left(\frac{\partial z}{\partial u}\frac{\partial x}{\partial v} - \frac{\partial z}{\partial v}\frac{\partial x}{\partial u}\right)(\eta - y) + \left(\frac{\partial x}{\partial u}\frac{\partial y}{\partial v} - \frac{\partial x}{\partial v}\frac{\partial y}{\partial u}\right)(\zeta - z) = 0.$$

where ξ, η, ζ are the current co-ordinates of the points of the plane.

The line perpendicular to the tangent plane at P is the normal of the surface at P. Every plane through the normal is a *normal plane,* and the sections made by them with the surface are *normal sections.*

10. The Fundamental Quadratic Forms and the Fundamental Magnitudes of the First and Second Order. The Fundamental Equations. —The entire theory of a surface is implicitly involved in two fundamental quadratic differential forms, and in three fundamental differential equations. The first form is the expression for the square of the arc length ds on the surface between two infinitely near points $P(x, y, z;\ u, v)$ and $P_1(x + dx, y + dy, z + dz;\ u + du, v + dv)$. This is found to be

(α) $\quad ds^2 = dx^2 + dy^2 + dz^2 = E du^2 + F du\, dv + G dv^2,$

where

$$E = \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2,$$
$$G = \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2,$$
$$F = \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v}.$$

The second quadratic differential form is the expression for twice the distance, d, from the point P_1 to the tangent plane at P:

(β) $\quad 2d = D du^2 + 2D' du\, dv + D'' dv^2,$

where

$$D = \frac{\begin{vmatrix} \frac{\partial^2 x}{\partial u^2} & \frac{\partial^2 y}{\partial u^2} & \frac{\partial^2 z}{\partial u^2} \\ \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix}}{\sqrt{EG - F^2}},\quad D'' = \frac{\begin{vmatrix} \frac{\partial^2 x}{\partial v^2} & \frac{\partial^2 y}{\partial v^2} & \frac{\partial^2 z}{\partial v^2} \\ \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix}}{\sqrt{EG - F^2}},$$

$$D' = \frac{\begin{vmatrix} \frac{\partial^2 x}{\partial u\, \partial v} & \frac{\partial^2 y}{\partial u\, \partial v} & \frac{\partial^2 z}{\partial u\, \partial v} \\ \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix}}{\sqrt{EG - F^2}}.$$

The six magnitudes $E, F, G;\ D, D', D''$ on account of their importance are called fundamental magnitudes: the first three as containing derivatives of the first order are called the *fundamental magnitudes of the first order:* the second three as containing derivatives of the second order are called the *fundamental magnitudes of the second order.* The six magnitudes are not independent of each other, but are connected by three partial differential equations called the *fundamental equations of the surface.* These may be obtained by differentiation from the foregoing equations. They are:

$$(\gamma)\quad \frac{DD''-D'^2}{EG-F^2}$$
$$=\frac{1}{2(EG-F^2)}\left(2\frac{\partial^2 F}{\partial u\,\partial v}+\frac{\partial^2 E}{\partial v^2}-\frac{\partial^2 G}{\partial u^2}\right)$$
$$+\frac{E}{4(EG-F^2)^2}\left[\left(\frac{\partial G}{\partial u}\right)^2+\frac{\partial E}{\partial v}\frac{\partial G}{\partial v}-2\frac{\partial G}{\partial v}\frac{\partial F}{\partial u}\right]$$
$$+\frac{G}{4(EG-F^2)^2}\left[\left(\frac{\partial E}{\partial v}\right)^2+\frac{\partial E}{\partial u}\frac{\partial G}{\partial u}-2\frac{\partial E}{\partial u}\frac{\partial F}{\partial v}\right]$$
$$+\frac{F}{4(EG-F^2)^2}\left[\frac{\partial E}{\partial u}\frac{\partial G}{\partial v}-\frac{\partial E}{\partial v}\frac{\partial G}{\partial u}-2\frac{\partial F}{\partial u}\frac{\partial G}{\partial u}\right.$$
$$\left.-2\frac{\partial F}{\partial v}\frac{\partial E}{\partial v}+4\frac{\partial F}{\partial u}\frac{\partial F}{\partial v}\right],$$

$$(\delta)\quad \frac{\partial D}{\partial v}-\frac{\partial D'}{\partial u}$$
$$=\frac{1}{2(EG-F^2)}\left[D\left(\frac{\partial E}{\partial v}G-\frac{\partial G}{\partial u}F\right)\right.$$
$$-D'\left(\frac{\partial E}{\partial u}G-\frac{\partial G}{\partial u}E+2\frac{\partial E}{\partial v}F-2\frac{\partial F}{\partial u}F\right)$$
$$\left.+D''\left(\frac{\partial E}{\partial u}F+\frac{\partial E}{\partial v}E-2\frac{\partial F}{\partial u}E\right)\right],$$

$$(\epsilon)\quad \frac{\partial D''}{\partial u}-\frac{\partial D'}{\partial v}$$
$$=\frac{1}{2(EG-F^2)}\left[D''\left(\frac{\partial G}{\partial u}E-2\frac{\partial F}{\partial v}F\right)\right.$$
$$-D'\left(\frac{\partial G}{\partial v}E-\frac{\partial E}{\partial v}G+2\frac{\partial G}{\partial u}F-2\frac{\partial F}{\partial v}F\right)$$
$$\left.+D\left(\frac{\partial G}{\partial v}F+\frac{\partial G}{\partial u}G-2\frac{\partial F}{\partial v}G\right)\right].$$

Equation (γ) was established by Gauss in the paper previously cited. The first member of this equation, $\frac{DD''-D'^2}{EG-F^2}$, has an interesting geometrical significance in connection with the curvature of the surface (see 12). Equations (δ) and (ϵ) were determined by Mainardi (1857) and 11 years later, independently, by Codazzi. The three equations are known as the *Gauss-Mainardi* or *Gauss-Codazzi* equations. It is evident that E, F, G satisfy the conditions: $E>0$, $G>0$, $EG-F^2>0$. To Bonnet is due the theorem that a surface is completely determined in all respects, except only as to its position in space, by six given functions E, F, G, D, D', D'' of two variables u, v, provided that the six functions satisfy the three fundamental equations (γ), (δ), (ϵ), and the three inequalities. The determination of the Cartesian variables x, y, z as functions of u and v, depends upon the integration of a differential equation of the Riccati type (see EQUATIONS, DIFFERENTIAL).

11. Curvature of Curves Traced upon the Surface Theorems of Mensnier and Euler. Principal Radii of Curvature.—The problem of the curvature of curves traced on the surface through P, and the relations of these curvatures, is simplified by considering first only those curves that have a common tangent at P. Let the common tangent be PT, and, for the sake of definiteness, let it be the tangent through $P(u, v)$ and the infinitely near point $P_1(u+du, v+dv)$. Conceive as drawn the sphere whose radius R and centre are the radius of curvature and centre of curvature (relative to P) of the normal section with the tangent line PT. *Mensnier's theorem* states that the plane of osculation of *any* curve through P with tangent line PT intersects the sphere in the circle of curvature of the curve relative to P. If τ is the angle between the plane of osculation of the curve and the normal section, and $\bar{R}$ the radius of curvature of the curve, then $\bar{R}=R\cos\tau$.

It remains to express the value of R. Newton's Theorem concerning curvature of plane curves gives immediately:

$$(\zeta)\quad \frac{1}{R}=\frac{2d}{ds^2}=\frac{D\,du^2+2D'du\,dv+D''dv^2}{E\,du^2+2F\,du\,dv+G\,dv^2}.$$

To each value of $\frac{dv}{du}$ correspond a tangent direction at P and a normal section, and the equation above determines the curvature of this section relative to P. There are two values of $\frac{dv}{du}$ for one of which R takes a maximum value, and for the other a minimum value. By the usual methods employed in maxima and minima the two values of $\frac{dv}{du}$ are found to satisfy the equation.

$$(\eta)\quad (FD''-GD')\left(\frac{dv}{du}\right)^2+(ED''-GD)\frac{dv}{du}+ED'-FD=0,$$

and the two corresponding values of R, viz., R_1 and R_2, the equation.

$$(\theta)\quad (DD''-D'^2)R^2-(ED''-2FD'+GD)R+EG-F^2=0.$$

The two tangent directions at P thus distinguished are at right angles to each other and are called the *principal directions of curvature at P*, and the corresponding normal sections are the *principal normal sections.* R_1 and R_2 are called the *principal radii of curvature* of the surface at P.

Euler's theorem expresses the radius of curvature R of any normal section in terms of the principal radii of curvature and an angle ϕ. The equation is

$$(\kappa)\quad \frac{1}{R}=\frac{1}{R_1}\cos^2\phi+\frac{1}{R_2}\sin^2\phi,$$

where ϕ is the angle between the normal section in question and the principal normal section corresponding to R_1. In Euler's and Mensnier's theorem the theory of the curvature of curves traced on a surface finds a satisfactory exposition.

12. Curvature of the Surface. Gauss Spherical Representation.— Various definitions of curvature of a surface have been suggested, of which three have found general acceptance. The three curvatures differ in kind. It is found that the mean value of the curvatures of all the normal sections through P (relative to P) is one-half the sum of the curvatures of the principal normal sections at P, viz., $\frac{1}{2}\left(\frac{1}{R_1}+\frac{1}{R_2}\right)$. It would be natural to take this value as the mean curvature of the surface at P, but the mathematical world has chosen to give the name mean curvature to the double of the quantity. Having regard to (ϑ), one has

(λ) *Mean curvature at a point*

$$=\frac{1}{R_1}+\frac{1}{R_2}=\frac{ED''-2FD'+GD}{EG-F^2}.$$

The other two curvatures are connected with Gauss's method of representing a surface upon a sphere by means of parallel normals. At a point P of the surface the positive normal is drawn; from the centre of the sphere a radius is drawn parallel to the normal; the extremity p of this radius is called the spherical image or picture of P. When P describes a curve on the surface, p describes a curve on the sphere, and, in general, to an area on the surface corresponds an area on the sphere. Gauss has called the area on the sphere the *total curvature* (curvatura integra) of the corresponding area on the surface. If $d\sigma$ is an infinitely small area on the surface above the point P and $d\sigma_1$ its total curvature, the ratio $\frac{d\sigma_1}{d\sigma}$ is called the *measure of curvature* (curvatura specifica) or *Gauss curvature* of the surface at P. Gauss showed that this ratio is $\frac{1}{R_1R_2}$, whence the theorem, that the measure of curvature at a point is equal to the product of the principal curvatures of the surface at the point. Using K to represent this curvature, and having regard to (ϑ),

(μ) *Measures of curvature at a point*

$$=K=\frac{1}{R_1R_2}=\frac{DD''-D'^2}{EG-F^2}.$$

13. Dupin's Indicatrix. Lines of Curvature, Asymptotic Lines. Conjugate Directions.— To ascertain the nature of the surface in the immediate neighborhood of a point P, one intersects the surface by a plane parallel to and infinitely near the tangent plane at P. The curve of section is called the *indicatrix* relative to P. The indicatrix is, in general, a conic whose equation is (β) when d is constant. As d is infinitely small of second order, the curve may be regarded as lying in the tangent plane at P with P as centre. Taking the tangents of the principal directions of curvature at P as co-ordinate axes (ξ_1, ξ_2), equation (β) becomes

$$\frac{\xi_1^2}{R_1}+\frac{\xi_2^2}{R_2}\,2d.$$

When R_1 and R_2 have like signs the indicatrix is an ellipse, and when the signs are unlike it is a hyperbola. In the first case P is an *elliptic* point of the surface and the neighborhood of P is *convex-convex* relative to the tangent plane; in the second case P is a *hyperbolic* point and the neighborhood of P is *convex-concave*. If either R_1 or R_2 is infinite at P, the indicatrix is *two infinitely near parallel right lines*. P is then called a parabolic point. A surface may contain a region of elliptic points and a region of hyperbolic points. The curve separating the two regions is a locus of parabolic points. For a surface of parabolic points, K must be identically zero (see 17).

By reference to the indicatrix at every point of the surface, one may define the system of *lines of curvature* as the two series of orthogonally intersecting curves (∞^1 in each series) whose tangent directions coincide with the principal axes of the indicatrix, i.e., with the principal directions of curvature (see 11). From the definition it follows that (η) is the differential equation of the lines of curvature. The integration of (η) for any surface whose fundamental magnitudes are known furnishes the two series of lines of curvature of the surface. It is characteristic of a line of curvature that the normals of the surface at two consecutive points of the curve intersect, and this property is sometimes given as the definition of the curve. By reference to this property a ready means is occasionally afforded for identifying the lines of curvature; for example, on a surface of revolution one of the series of lines of curvature consists of the meridian curves and the other series of the parallel circles. The sphere and plane form a class apart from all other surfaces as regards lines of curvature, for *any* curve on either surface is a line of curvature. To Joachimsthal is due the theorem that, if two surfaces intersect in a constant angle and the curve of intersection is a line of curvature on the one, it is also a line of curvature on the other. It follows in particular that, if a plane or sphere intersects a surface in a constant angle, the curve of section is a line of curvature.

Again, by reference to the indicatrix, one defines the system of *asymptotic lines* as the two series of intersecting curves whose tangent directions coincide with the asymptotes of the indicatrix. Asymptotic lines are real only in the hyperbolic region of the surface. The differential equation of asymptotic curves is (d=0)

(ν) $$Ddu^2+2D'du\,dv+D''dv^2=0.$$

It is characteristic of an asymptotic line that the plane of osculation at any point of it is the tangent plane of the surface at the point.

Two conjugate diameters of the indicatrix of a point give *conjugate directions* at the point; hence to *any direction* there is a conjugate. A system of curves consisting of two series of intersecting curves is *conjugate* when the above condition is satisfied at every point of intersection. In partial illustration of the foregoing definitions it may be remarked that all the points of a hyperboloid of one sheet are hyperbolic, and that the right-line generators are its asymptotic lines. On the anchor-ring surface, i.e., the surface generated in rotating a circle about a line in its plane, the curves described by A and B, the extremities of the diameter parallel to the axis of rotation, are curves of parabolic points; the inner surface of the ring is the region of hyperbolic points, the outer surface the region of elliptic points. The generating circle is in every position a line of curvature. It remains to define an *umbilic* as a point at which the indicatrix is a circle.

14. Isothermal Lines. Minimal Lines. Geodesic Lines — Curvature — Circles — Co-ordinates.— If the ds^2 of a surface assumes the form

(ξ) $$ds^2=a(u,v)[du^2+dv^2],$$

where $E=G=a(u,v)$, $F=0$, the parameter curves u = constant, v = constant, form an *isothermal* system (or *isometric* system) of curves. The parameters u and v are called *thermal* parameters. The distinguishing property of isothermal lines lies in this, that by their means the surface can be divided into a network of infinitely small squares. The division is effected by giving to u and v series of values in arithmetical progression, the two series having the same common difference ($du = dv$). The squares differ, in general, in magnitude. There is an infinity of isothermal systems on a surface, for the characteristic form (ξ) is reproduced in new parameters u_1, v_1, by making the substitutions

$$u + iv = f(u_1 + iv_1),\quad u - iv = f_1(u_1 - iv_1),$$

where f and f_1 are conjugate functions but otherwise arbitrary.

It is noted that (ξ) may be thrown into the form $ds^2 = a(u, v)[(du + i\,dv)(du - i\,dv)]$, and hence, by the substitutions $\lambda = u + iv$, $\mu = u - iv$, into the form

$$(\omega)\qquad ds^2 = \beta d\lambda d\mu,$$

where β is a function of λ and μ. The parameters λ, μ are conjugate imaginaries and the two series of corresponding curves on the surface are imaginary. They are called the *minimal* lines of the surface, as it is evident that along any one of them $ds^2 = 0$. The tangents of a minimal line are the minimal right lines (see CURVES OF DOUBLE CURVATURE). By integrating $ds^2 = 0$, one can determine the minimal parameters and thence a pair of isothermal parameters. Just as there is but one system of lines of curvature and one system of asymptotic lines, so there is but one system of minimal lines on a surface.

A *geodesic* line is a curve such that at every point P of it, the principal normal of the curve and the normal of the surface coincide. The shortest curve traced between any two points of the surface is a geodesic. A given geodesic does not always represent the shortest curve between any two of its points, but the property of shortest distance does hold for sufficiently small segments of the geodesic. On a surface of negative Gauss curvature (K negative at all points) a geodesic does not cease to be a curve of shortest length. On a surface of positive Gauss curvature (K positive), e.g., on a sphere, a geodesic may cease to be a shortest curve when prolonged. A string stretched on a surface lies in a geodesic; keeping one extremity of the string fixed at a point P and rotating about P, the second extremity of the string describes a curve called a *geodesic circle*. It is, in general, not a geodesic curve. If at P and P_1, two infinitely near points of an arbitrary curve c on a surface, geodesics be drawn tangent to the curve, the ratio of the angle between the geodesics to the arc length PP_1 is called the *geodesic curvature* of c at P. Obviously, geodesics are curves of zero geodesic curvature. The torsion of the geodesic tangent to c at P is called the *geodesic torsion* of c at P. A line of curvature is a curve of zero geodesic torsion at every point. The differential equation of geodesics, derived from the definition, is

$$(\rho)\quad \begin{vmatrix} E + F\dfrac{dv}{du} & \dfrac{1}{2}\dfrac{\partial E}{\partial u} + \dfrac{\partial E}{\partial v}\dfrac{dv}{du} + \left(\dfrac{\partial F}{\partial v} - \dfrac{1}{2}\dfrac{\partial G}{\partial u}\right)\left(\dfrac{dv}{du}\right)^2 + F\dfrac{d^2v}{du^2} \\ F + G\dfrac{dv}{du} & \dfrac{\partial F}{\partial u} - \dfrac{1}{2}\dfrac{\partial E}{\partial v} + \dfrac{\partial G}{\partial u}\dfrac{dv}{du} + \dfrac{1}{2}\dfrac{\partial G}{\partial v}\left(\dfrac{dv}{du}\right)^2 + G\dfrac{d^2v}{du^2} \end{vmatrix} = 0,$$

From the theory of these equations (see EQUATIONS, DIFFERENTIAL) it follows, that an infinity of geodesics may be drawn at any point of a surface, each determined by its direction at the point.

The expression for ds^2 takes a notable form when the parameter lines, $v = \text{constant}$, are geodesics and the parameter lines, $u = \text{constant}$, are their orthogonal trajectories. Two cases are of interest:

(1) The *geodesic parallel system*, in which the geodesics are drawn perpendicular to an arbitrary curve c as shown in Fig. 6, and t, t_1, . . ., are the orthogonal trajectories. Any two trajectories intercept equal lengths on the geodesics, and it is from this fact that the trajectories derive their name of *geodesic parallels*. If u represents the distance from c to a geodesic parallel measured on the geodesics, one has

$$ds^2 = du^2 + Gdv^2.$$

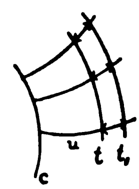

FIG. 6.

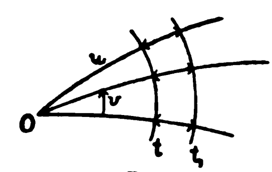

FIG. 7.

(2) The *geodesic polar system*, in which the curve c reduces to a point O as shown in Fig. 7, and the geodesics proceed from O. The orthogonal trajectories are geodesic circles. If u represents the distance from O to a geodesic circle, and v the angle from a fixed geodesic taken as a base, to any geodesic, there follows:

$$ds^2 = du^2 + Gdv^2,$$

where G is a function of u and v satisfying two conditions at the pole point:

$$\left[\sqrt{G}\right]_{u=0} = 0,\quad \left[\frac{\partial\sqrt{G}}{\partial u}\right]_{u=0} = 1.$$

We mention, finally, a system of references in which the curves are *geodesic ellipses* and *hyperbolas*. If a point P moves so that the sum (difference) of its geodesic distances from two arbitrary curves c, c_1 of the surface is constant, it describes what is called a geodesic ellipse (hyperbola); c and c_1 must not be geodesic parallels. Weingarten has shown that the system of geodesic ellipses and hyperbolas is orthogonal. A special case is when c and c_1 reduce to points. Liouville has investigated a class of surfaces on which there is an isothermal system of geodesic ellipses and hyperbolas. The form of the arc element is

$$ds^2 = \left\{f(u) + g(v)\right\}(du^2 + dv^2),$$

and the differential equation of the geodesics can be integrated and brought to the form $\displaystyle\int\frac{du}{\sqrt{f(u) + a}} - \int\frac{dv}{\sqrt{g(v) - a}} = b$, where a and b are constants of integration. Surfaces of the second order and surfaces of rotation belong to the Liouville surfaces. Gauss established the theorem that the sum of the angles of a geodesic triangle (the sides are geodesic lines) is greater than, less than, or equal to, π, according as the triangle lies in an elliptic, hyperbolic or parabolic region. The only surface that can contain an area of parabolic points is a developable surface (see 16), i.e., a surface developable upon a plane.

15. Representation of One Surface upon Another Surface. Conformal Representation. Applicability.— In map drawing one has an instance of the depiction or representation of one surface upon another. To each point of one surface corresponds a definite point of the other surface. The character of the depiction is a matter of the law of relation of the corresponding points of the two surfaces. If the equations of a surface A are expressed in parameters u, v and those of surface B in parameters, u_1 v_1, any equations $u_1 = g(u, v)$, $v_1 = h(u, v)$ will give a law of correspondence of points, provided that to a pair of values of u, v there corresponds a pair of values u_1, v_1, and conversely.

When each *infinitely small triangle* on the one surface is depicted in an *infinitely small and similar triangle* on the other surface, the depiction is said to be *conformal*. It follows that corresponding angles on A and B are equal; also that $ds^2 = kds_1^2$, where ds is arc length on A measured from a point P, ds_1 the corresponding arc length on B and k a quantity depending on the position of P and independent of the direction of ds. The analytical side of conformal representation is completely resolved by recourse to thermal parameters. The arc element of A in the thermal parameters u, v is $ds^2 = a(du^2 + dv^2)$; similarly, arc element of B in the thermal parameters u_1, v_1 is $ds_1^2 = \beta(du_1^2 + dv_1^2)$. The relations

$$u_1 + iv = f(u + iv),\ u_1 - iv_1 = f_1(u - iv),$$

where f and f_1 are arbitrary conjugate functions establish a conformal representation, since, by virtue of these relations, $ds^2 = kds_1^2$. Any two surfaces can, in general, be conformally represented upon each other in an infinity of ways. The functions f and f_1 can be chosen to furnish the most advantageous conformal representation.

Two surfaces are *applicable* or *developable* upon each other if the corresponding infinitely small triangles are *equal in all respects*. This requires that corresponding arc elements shall be everywhere equal, namely, that u_1 and v_1 shall be such functions of u and v as to transform the first member of the equation

$$E_1du_1^2 + 2F_1du_1dv_1 + G_1dv_1^2 = Edu^2 + 2Fdu\,dv + Gdv^2$$

into the second member. The letters with subscripts indicate the elements of the second surface. In general, this transformation cannot be made, and hence two arbitrarily given surfaces are, in general, not developed upon each other. It is obvious that all surfaces derived from a given surface by bending without stretching (see 8) are applicable upon each other. Hence the parameters of any one of them are expressable in the parameters of the original surface. All the surfaces may, accordingly, be assumed definite in the same parameters u, v, whence it follows that the fundamental magnitudes E, F, G will be identically the same for the entire series of surfaces. The three magnitudes E, F, G and all functions formed from them and their partial derivatives are invariants of bending. Some important conclusions can immediately be drawn from these statements. We observe that the left-hand member of equation (γ) is the Gauss measure of curvature and that the right-hand member is a function of E, F, G alone. We conclude that the Gauss curvature does not change in any deformation of a surface by bending. One notes also that equation (ρ) depends only on E, F, G, whence the theorem that a geodesic curve remains a geodesic in the deformation by bending.

As earth-dwellers the most interesting depiction to us is that of a sphere upon a plane. The sphere is not developable upon a plane and, therefore, any depiction is bound to be a distorted image of the original. A conformal representation will at least preserve angles, and the picture and original will be similar in the corresponding infinitely small parts. The two best-known examples of a conformal representation are the stereographic projection (Hipparchus, Ptolemy) and the projection of Mercator. Expressing the sphere of radius one in thermal parameters u_1, v_1:

$$=x\frac{2u_1}{u_1^2+v_1^2+1}, y=\frac{2v_1}{u_1^2+v_1^2+1}, z=\frac{u_1^2+v_1^2-1}{u_1^2+v_1^2+1},$$

and a plane in thermal parameters u, v: $x = u$, $y = v$; the stereographic projection is furnished by the relations $u + iv = u_1 + iv_1$, $u - iv = u_1 - iv_1$, or simply $u = u_1$, $v = v_1$. For the Mercator correspondence one sets up the relations $u_1 + iv_1 = e^{u+iv}$, $u_1 - iv_1 = e^{u-iv}$, or $u_1 = e^u \cos v$, $v_1 = e_u \sin v$. In the stereographic projection the circles of the sphere are represented by circles (or straight lines) in the plane; in the Mercator map the meridians and parallels of latitude appear in the plane as a system of orthogonally intersecting right lines.

SPECIAL SURFACES.

16. Ruled Surfaces.—The continuous motion of a straight line through a simple infinity of position generates a *ruled surface*. When the consecutive generators intersect, that is, when the generating line is always tangent to one and the same space curve, the surface is a *developable surface*. In the contrary case the surface is called a *skew surface*. The *director cone* of the ruled surface is formed by drawing through an arbitrary point of space lines parallel to the generators of the ruled surface. The equations of the most general ruled surface are

$$x = a_1 + \beta_1 u,\ y = a_2 + \beta_2 u,\ z = a_3 + \beta_3 u,$$

where a_1, a_2, a_3; β_1, β_2, β_3 are functions of v alone. The curves $v =$ constant are the right-line generators; the curves $u =$ constant are trajectories of the generators. The trajectory $u = 0$ is sometimes called the director curve. The important elements are: (1) The angle $d\phi$ between two consecutive generators g and g_1; (2) the shortest distance $d\kappa$ between g and g_1; (3) the value of u corresponding to the point, called central point, where the shortest distance meets g. Putting for brevity

$$B_1 = \beta_2 d\beta_3 - \beta_3 d\beta_2,\ B_2 = \beta_3 d\beta_1 - \beta_1 d\beta_3,$$
$$B_3 = \beta_1 d\beta_2 - \beta_2 d\beta_1,$$

the values are

$$d\phi = \frac{\sqrt{B_1^2 + B_2^2 + B_3^2}}{\beta_1^2 + \beta_2^2 + \beta_3^2},$$

$$d\kappa = \frac{\begin{vmatrix} \beta_1 & \beta_2 & \beta_3 \\ d\beta_1 & d\beta_2 & d\beta_3 \\ da_1 & da_2 & da_3 \end{vmatrix}}{\sqrt{B_1^2 + B_2^2 + B_3^2}},\quad u = \frac{\begin{vmatrix} B_1 & B_2 & B_3 \\ \beta_1 & \beta_2 & \beta_3 \\ da_1 & da_2 & da_3 \end{vmatrix}}{\sqrt{B_1^2 + B_2^2 + B_3^2}}.$$

The locus of the central points of the generators is a curve called the *line of striction.* Its equation is the third of the group above. For a developable surface $d\kappa = 0$. The surface is cylindrical if $B_1 = B_2 = B_3 = 0$. The tangent plane to a skew surface at a point contains the generator through the point, and the plane rotates about the line as the point of contact moves on the line. The normals of the surface along a generator form a hyperbolic paraboloid. A ruled surface may undergo a deformation by bending so as to remain a ruled surface. The developable surfaces are so named because they are developable upon a plane. Their linear element ds^2 admits of being thrown into the form of the ds^2 of the plane.

17. Surfaces of Constant Gauss Curvature.—These surfaces are of three kinds: (1) *Surfaces of constant positive curvature* for which K or $\frac{1}{R_1R_2}$ is positive and constant at every point. The sphere is the type of this class. (2) *Surfaces of zero curvature* for which $K = 0$ at all points. These are the developable surfaces (see 16) of which the plane is the type. (3) *Surfaces of constant negative curvature,* $K < 0$, of which the pseudosphere is the type. The pseudosphere is the surface generated by rotating a tractrix about its asymptote. Minding showed ('Crelle's Journal für Mathematik, 19, 1839') that all surfaces of the same constant curvature are developable upon each other, and in ∞^3 of ways. The geometry of figures on a surface of constant positive curvature may, therefore, be studied on a sphere; that of developable surface on a plane; and, finally, the geometry of surfaces of constant negative curvature is identical with that of the pseudosphere. All surfaces of constant negative curvature are called *pseudospherical surfaces.* In employing a geodesic polar system of reference (see 14) the ds^2 of pseudospherical surfaces with measure of curvature $-\frac{1}{R^2}$ takes the form $ds^2 = du^2 + R^2 \sin\frac{u}{R}dv^2$. A characteristic distinction between the geometries of the three kinds of surfaces of constant curvature is indicated by the number of geodesics that may be drawn through a point parallel to a given geodesic. On a pseudospherical surface two parallels may be drawn; on a developable surface only one parallel; on the surface of positive curvature, none.

18. Minimal Surfaces.— They are defined to be the surfaces of mean curvature zero, $H =$ (see 12). At every point of such a surface $R_1 = -R_2$. Historically the theory of these surfaces had its origin in Lagrange's investigation of the surface of minimum area with prescribed boundary curve. It was ascertained that for such a surface $R_1 = -R_2$, but the converse statement does not always hold without limitations. Integrations of the differential equation of minimal surfaces were given by Legendre, Monge and Enneper. We give here the equations as found by Weierstrass:

$$x = \tfrac{1}{2}\int(1-u^2)F(u)du + \tfrac{1}{2}\int(1-v^2)F_1(v)dv,$$
$$y = \frac{i}{2}\int(1+u^2)F(u)du - \frac{i}{2}\int(1+v^2)F_1(v)dv,$$
$$z = \int uF(u)du + \int vF_1(v)dv.$$

F and F_1 are conjugate functions of the conjugate complex variables u and v. All minimal surfaces are contained in these formulas. When the function F is algebraic the surface is algebraic, and conversely. A minimal surface can be deformed by bending so as to remain a minimal surface. For this it is necessary and sufficient that one replace $F(u)$ and $F_1(v)$ by $e^{ai}F(u)$ and $e^{-ai}F_1(v)$ respectively. All the surfaces corresponding to values of a (real constants) are developable upon each other as having the same ds^2. The only ruled minimal surface is the ordinary helicoidal surface with director plane. The only minimal surface of rotation is the catenoid, i.e., the surface generated by rotating a catenary about its base. These two surfaces are developable upon each other. The minimal surface is the only surface (aside from the sphere) whose spherical representation is conformal (see 12 and 15). For particulars as to these surfaces consult Schwarz, 'Gesammelte Mathematische Abhandlungen' (Vol. I, 1890); Darboux, 'Leçons sur la Theorie Générale des Surfaces' Vol. I, 1887).

19. Concluding Remarks.—In addition to the special surfaces here described may be noted the *surface of centres,* i.e., the locus of the centres of curvature of a given surface. It consists of two sheets S_1 and S_2 corresponding to the two centres of curvature at every point. Also may be noted the *W-surfaces* or *Weingarten surfaces,* in which R_1 and R_2 are functionally related. A functional relation, $f(R_1, R_2) = 0$, defines an infinity of surfaces. In passing to the surface of centres of each individual of such a group, Weingarten showed that all the sheets S_1 are developable upon each other and upon the same surface of rotation. The same theorem holds of course for the sheets S_2. Surfaces of constant curvature, and minimal surfaces are special W-surfaces. Finally, there are certain analytical expressions constructed in the fundamental magnitudes, some arbitrary functions, and derivatives of the functions, which have the same value whatever the parameters employed. In other words they are quantities invariant with respect to a change of parameters. When the arbitrary functions are present they are called *differential parameters.* When the arbitrary functions are not present they are called *differential invariants.* Manifestly these magnitudes are connected with those geometrical properties that are essentially independent of the particular system of parameter reference. For example, Gauss curvature $\frac{1}{R_1R_2}$ is obviously an invariant.

Bibliography.— Some of the principal treatises on the theory of surfaces are Darboux, G., 'Leçons sur la Théorie Générale des Surfaces' (4 vols., Paris 1887-96); Bianchi, L., 'Lezioni di G'ometria Differenziale' (Pisa, 2d ed., 1902, translated into German by Lukat, 'Differentialgeometrie,' Leipzig 1896); Raffy, L., 'Leçons sur les Applications Geométriques de l'Analyse' (Paris 1897); Scheffers, G., 'Anwendung der Differential-und integralrechnung auf Geometrie' (2 vols., Leipzig 1902); Salmon, 'Geometry of Three Dimensions' (Dublin 1882); Salmon-Fiedler, 'Analytische Geometrie des Raumes' (Leipzig 1880-98).

JAMES MACLAY,
Professor of Mathematics, Columbia University.

SURGEON IN THE ARMY AND NAVY OF THE UNITED STATES. The history of the connection of a regular staff of surgeons to the army dates back to the siege of Boston in 1775. At that time the Second Provincial Congress of Massachusetts Bay was in session and on 8 May 1775 appointed a committee «to examine such persons as are or may be recommended for surgeons with the army now forming in this colony.» Of the 16 candidates examined only six were rejected. On 21 July 1775 Washington urged in a letter to the Colonial Congress that a «Hospital Department» be established, and on 27 July this department was created, having a director-general, chief physician and 20 surgeon's mates. In April 1776 Congress passed an act that the board of surgeons be increased «not exceeding one surgeon and five mates to every 5,000 men, to be reduced when the army is reduced.» Between 1784-89 no medical department was officially recognized by the government, but was in the latter year recognized and remained the same until 1821, when it took the form which it retained with no decided change until 1908 when the titles of all medical officers, excepting the surgeon-general of the army, became the military rank, major, captain, etc., followed by the words, Medical Corps, U. S. A. Applicants for the medical corps must be between 22 and 30 years of age, be citizens of the United States and graduates of a reputable medical school and have had at least one year's hospital training. After successful examination they are commissioned as first lieutenants. The Act of 1908 also established the Medical Reserve Corps, the members of which rank as first lieutenants and are appointed by the President after an examination. During the Civil War and the Spanish-American War the corps was increased to meet the emergencies, but on the cessation of hostilities was again placed upon a peace footing. Consult Lamphere, 'United States Government' (Philadelphia 1880); Farrow, 'Military Encyclopedia' (New York 1885); Hamersley, 'Army and Navy Register' (New York 1888) and other War and Navy Department records. See UNITED STATES, ARMY OF THE; UNITED STATES, NAVY OF THE.

SURGEON-FISH, a fish of the family *Teuthidæ*, allied to the butterfly-fishes (q.v.) and distinguished by the presence of one or more erectile lancet-like spines on each side of the root of the tail which may inflict an ugly wound. Some 80 species are known, mostly of the genus *Teuthis*, scattered through the warm seas of the world and variously known as doctor-fish, lancet-fish, tangs and among the Spanish-speaking fishermen of the West Indies as barberos and médicos. All are oblong, compressed, brownish or bluish fishes from 6 to 12 inches long, with narrow protruding incisor-like teeth. Several are good food, especially the ocean surgeon-fish (*T. bahianus*) found throughout the West Indies, and the blue tang (*T. cæruleus*), found near Porto Rico.

SURGERY, History of General. The history of medicine, fascinating at all times, is most valuable to the surgeon when applied to the subject of general surgery. At the present time there is much in the literature of medicine that is very instructive and it becomes more and more so as we are put in possession of facts pertaining to prehistoric man and of those presented in the study of manuscripts antedating the Christian era.

Skulls of the prehistoric period have been discovered in caves and dwelling-places which show undoubted evidence that trephining had been performed on them and that healing of the bone had later taken place. The examination of these specimens is exceedingly interesting. Again, as we study the periods between this age and the beginning of the Christian era we note a great deal that leads to the conviction that surgery was understood in those times. The early embalmers, in their familiarity with the human body, must have acquired some knowledge of surgery, and this as far back as 1700 B.C.

While medicine as a profession was confined to the duties of the priest, surgery suffered, and was more and more neglected. Historians of that time have just reason to condemn Egyptian surgery. There are some very excellent books appearing at the present time giving a full description of what little was known, bestowing full credit upon those who practised surgery, or advocated it, and who were making some progress in that branch of medicine. The Egyptians were proud and fond of their work as scribes or writers, their learning in that direction leading them to advise their sons to take up what was then known on the subject of medicine; but very little seems to have been developed in the way of clinical observation, or, more particularly, in surgical procedure.

In the study of medicine by the Hindu one cannot but note that in their writings there is plain evidence that surgery had reached an advanced stage. «Surgery,» says their great Susruta, «is the first and highest division of the healing art, least liable to fallacy, pure in itself, perpetual in its applicability, the worthy produce of heaven, the sure source of fame on earth.» He also makes the very excellent observation that «he who knows but one branch of his art is like a bird with one wing.» This writer was a very careful observer and beyond doubt did much to advance the art of surgery centuries before the birth of Christ. Some of the Hindu works and operations are yet spoken of by modern writers. They knew how to perform successfully the operation of developing a new nose by flaps taken from the forehead and were familiar with like procedures. The surgery of ancient India is worthy our most thorough and careful investigation. Great interest is being manifested in its study and there can be no doubt that good will result from the recent organization of the Charaka Club in

New York. This body of investigators bids fair to give us papers of great value in the elucidation of that period when Hindu surgery developed — and, it may be said, ceased. Why it disappeared so mysteriously has never been shown.

Through the study of manuscripts of succeeding centuries, and of other records of different peoples, one is greatly impressed with the difficult operations performed, now and then, by some predominating man, who, perhaps having more knowledge of the anatomy of the human body, and being somewhat bolder than his fellows, would perform an operation, leaving a report of possible success. Then for centuries this work would be forgotten, then revived, perhaps modified. Possibly to the operator it was a new operation (since he was not aware that it had been performed previously), yet to be developed into a line of work that was to lead to greater success. Thus we see reported very important advances in the line of surgical procedure from our earliest knowledge on.

The early Greek knowledge of surgery is not so apparent or abundant as that of later periods, yet Homeric medicine gives endorsement to the fact that there were surgeons capable of rendering aid in emergencies, such as the removal of foreign substances from the body, and who were able to control bleeding by the application of what were evidently understood to be drugs possessing some styptic power and to bind up and dress wounds. Even fractures and dislocations were treated. In time of war these men were looked upon with reverence and the aid they were expected to render was highly valued. Of their real work there is little known before the Trojan War. The most observing student of cases in antiquity was Hippocrates (q.v.) born 460 B.C. He wrote on the treatment of articulations, luxations, fractures and also on the subject of the use of instruments, but his knowledge of anatomy must have been very meagre. The Greeks had great respect for their dead, which prevented dissection of the human body. They knew nothing of physiology and, therefore, anatomical structures, such as arteries, veins, nerves, tendons, ligaments and membranes were hopelessly confused. Hippocrates gave classifications not unlike those of the present day, «internal medicine» and «external or surgical medicine,» which were convenient, but not philosophical. The period of his life marked the transition from mythology to history. His doctrine and clinical observations were received with great respect. He advanced the science and art of surgery, but only a little later ignorance again reigned in the school which he made celebrated.

Erasistratus (about 300 B.C.) was a close observer as an anatomist and made use of his knowledge of the valves of the heart. He discovered the lymph vessels, described the epiglottis, successfully removed the spleen and performed other remarkable operations.

Aretæus was one of the most brilliant men of the second century before the Christian era. He recognized surgical affections of the brain and described the Syriac or Egyptian ulcer, tetanus and anal fistula.

Galen (q.v.), who died about 201 A.D., must have had considerable knowledge of anatomy. History indicates that he was a vivisector, and to him is due a clear classification of the muscles, which is followed at the present day, as the «flexors and extensors.» He came very near discovering the circulation of the blood, and divided the body into the «cranial, thoracic and abdominal cavities,» whose proper viscera and envelopes he described. This was during a period when encouragement was given to the study of anatomy. The works of one Oribasius (q.v.), who died about 400, were based on the writings of those who had preceded him, but had a distinct importance of their own. He showed much originality in the treatment of hydrocephalus, advised paracentesis of thorax and abdomen, removal of vesical calculi, treatment of aneurism, excision of hypertrophied mammæ in men, etc. Antyllus who flourished about this period was one of the most distinguished and original surgeons of antiquity. He was the first to describe the extraction of small cataracts and is perhaps best known to the surgical world of to-day by his exceedingly bold plan of opening aneurisms, so successfully imitated by the late James Symes.

It is to be remembered that during the Greek period Galen and his followers dissected animals and occasionally a corpse on the field of battle.

In the 6th and 7th centuries the Arabians gave more encouragement to dissection and demonstrated that surgery required a knowledge of anatomy. One of the most celebrated Arabian physicians was Rhazes (q.v.), who died about 932. He compiled from all authors some 37 books on medicine and surgery.

Albucasis (936–1013) in one of his writings gives a most detailed account of necessary instruments and in speaking of their proper use and application to surgery, he emphasizes the fact that surgeons should be versed in the science of anatomy.

In visiting the various museums in Europe at the present time, especially Naples, one is greatly impressed with the variety of ancient surgical instruments that have been recovered from the ruins of Pompeii and other former surgical centres.

Avenzoar (q.v.), who died about 1169, wrote one of the most remarkable treatises on renal diseases, especially in reference to the treatment of calculus and further surgical intervention.

From the 9th to the 13th century the Jews and the Christian clergy shared the honors of the healing art, and during this time references are not infrequently made to the work of the barber-surgeon (see BARBER). Lithotomy (q.v.) seems to have been developed in this period and it is noted (1022) that Henry II, Holy Roman emperor, was cut for stone by Saint Benedict himself.

In the 13th century Rolger of Palermo was evidently one of the most distinguished pioneers in modern surgery. He was the first to use the term «seton.» His pupil, Roland, wrote a treatise on surgery, which became very famous and was mentioned by Guy de Chauliac, «restorer of French surgery in the 14th century.» The latter was probably one of the most famous surgeons of that time. He opened the abdomen for dropsy and operated for the radical cure of hernia and for cataract.

The history of the school of Salerno in the 13th century indicates that practitioners of surgery had to devote a certain time to the study of anatomy, were obliged to pass an examination by the faculty of the university and were licensed by the royal hands. Surgeons recognized the importance of nausea, vomiting and hemorrhage from the ears, in injuries to the head. They used the trephine (q.v.) in treating fractures of the skull and treated hernia cerebri by pressure and caustics. Ligatures were used in wounds of the carotid arteries and jugular veins. The surgeons also treated wounds of the abdomen. Lithotomy was described with care and compound fractures were treated with splints.

The first important work on minor surgery appeared during the 14th century. It was written by Lanfranc, but although it grew into a second and larger treatise, surgery soon after this began to decline. The barber-surgeons of this time seemingly commanded considerable attention, although it is evident that the importance of this body of men has been greatly exaggerated.

From the 15th century through the 19th surgery developed more and more as a science. In England, Thomas Linacre of Canterbury (1460–1524) was one of the earliest writers. Jerome Fabricius (1537–1619) was also a noted writer and authority on the practice of surgery during this period. Benivieni during the same period was, according to Malgaigne, the first to impress upon the profession the importance of searching in the cadaver for the concealed cause of disease. His observations on gall-stones and conveyance of syphilis from the mother to the fœtus were original.

Notwithstanding the progress in surgical science during the 15th and 16th centuries, the practice of surgery was largely abandoned to a class of ignorant barbers and bone-setters. Most of these operators traveled from city to city, individual practitioners limiting themselves to the operation for stone or for hernia. This condition of affairs, together with the prejudice against dissection, was most unfavorable for the profession of surgery.

France at this time presented the only special college for the instruction of surgeons. To the 16th century belongs the career of that most wonderful surgeon, Ambroise Paré. He was an original thinker, had the courage of his convictions and did away with the use of the cautery and boiling oil in amputations, using ligatures to control hemorrhage, the latter being the most important advance until the introduction of ether in 1846 (see ANÆSTHETICS). At the beginning of the 17th century surgery reached a higher social and intellectual plane than it had heretofore occupied. Amphitheatres for dissection developed in many European cities, together with hospitals and dispensaries in connection with the various schools. The term «inflammation» was then introduced and from that time until the present day has been a subject for continuous investigation. From this period may be dated the beginning of consultation work between expert practitioners; and clinical teaching and the presentation of surgical cases then advanced their claims. Surgical history from Valsalva on presents the names of many who became eminent operators, and in their writings did much to advance the art of surgery. Notably was this so among the Italians, who in their plastic surgery developed the Italian method for construction of a new nose.

In France, Morel (1674) invented the tourniquet, Denis performed the first transfusion of blood in man and other French surgeons became very expert in the operation for lithotomy. Mareschal (1658–1736) had a record of eight lithotomies performed in half an hour. He was one of the founders of the French Academy of Surgery.

In Holland, Rau (1658–1719) taught practical surgery upon the cadaver.

Wiseman (1625–86) was the first to develop English surgery. He was also the first to do external urethrotomy for relief of stricture. At this time in France alone was instruction in surgery well regulated, as it was the only country which possessed a proper surgical college.

In the 18th century hospitals began to multiply in Germany, benefiting general surgery to a great extent. Brasdor (1721–76) developed the method of distal ligation of aneurisms, while Sabatier (1732–1811) wrote a treatise on operations and recommended resection of the head of the humerus. DeSault and Chopart did much in developing operative surgery. In Italy Scarpa (1752–1832) advanced our knowledge of hernia and aneurisms. Spanish surgeons did little to improve the science and art of surgery. In England, Cheselden (1688–1752) did much in advancing the knowledge of pathology and general surgery. White, of Manchester, devised a method of reducing dislocations of the humerus with the foot in the axilla. A well-defined operation for excision of the joints was also first practised in England. The investigation of pathology and diagnosis in France at this time had much to do in the 19th century in developing the «new Vienna School.» Percival Pott (q.v.) did much in elaborating and classifying diseases of the joints and especially spinal diseases. John Hunter (q.v.) was the most famous English surgeon of his day. He belonged to a family which in many ways assisted the development of pathological anatomy and surgical technique. At the close of the 18th century, Benjamin Bell was the first to make use of drainage by means of tubes of lead or silver. In France, Bichat (q.v.), although not generally so understood, became a forceful lecturer on surgery and did much to bring hospital-gangrene under observation and control. The Dutch during the 18th century developed some eminent surgeons, and it is interesting to note how dextrous they became in the use of instruments. At the same time their knowledge of anatomy enabled them to present some very able papers on the subjects of hernia and dislocation. Sandifort, of Leyden, first described a downward dislocation of the femur.

In reference to the surgery of our own country in the 18th century, one of the most interesting works, which was of great service to American surgeons during the Revolution, was that of John Jones, 'Plain, Practically Precise Remarks on the Treatment of Wounds and Fractures.'

The 19th century witnessed great advances and from 1838 was one continuous chapter of investigation toward the development of the parasitic or germ theory. Of all the many names associated with this immense work, one can refer to but few: Pasteur, Klebs, Koch, Lister, Tyndall (qq.v.) and others, in their development of bacteriology, have done more to advance the principles of technique in surgical operations and have placed the art and science of surgery upon a more lasting foundation, than any of their predecessors.

The first half of the 19th century was a period of great success for the French surgeons. The English surgeons, in their superior knowledge of gross anatomy, also made great advances in their diagnosis and surgical treatment. This century became noted as the period during which general surgery developed more into an exact science. Its writers did much to eradicate erroneous ideas and to end the transmission of meaningless sentences from one textbook to another. The introduction of anæsthesia in 1846 enabled some of the bolder men to perform operations heretofore deemed quite impossible; yet the ratio of mortality continued high and it was not until the dawn of antisepsis, more particularly the period of true asepsis, that general surgery advanced so rapidly. The death-rate in major operations, in many instances, was in a short time reduced from 66 to 6 per cent, and this ratio was soon applied to all departments of surgical work. As technique became more perfect, all manner of operations were suggested and carried out with great success. Hence to-day there is no part of the human body that the surgeon is unable to reach for the relief of injuries or pathological conditions.

In operative surgery much help has been received from the use of cocaine, eucaine, suprarenal extract, ethyl chloride and other preparations for local and spinal anæsthesia. Bacteriology has taught the surgeon the cause of inflammation, suppuration of wounds and sepsis. New hospitals, aseptic operating-rooms and furniture, thorough sterilization of instruments, hands and the field of operation and cleanliness of person, together with the wearing of rubber gloves, coupled with aseptic dressings, have enabled the surgeon to perform operations unknown before the last decade of the 19th century, reducing mortality to a much lower figure. An important factor which has been of much aid to general surgery is the art of nursing, first recognized in 1840. Too much credit cannot be given to the training schools of to-day for their development of trained nurses who have aided so much in the care of surgical cases.

During the 19th century the microscope became of more and more value. The anthrax bacillus was classified in 1850 and then followed classification of the various micro-organisms known to-day. Koch's identification of the tubercle-bacillus has aided the general surgeon as much in the treatment of osseous tuberculosis as it has the physician in tuberculosis in other parts of the body.

For the past two decades general surgery has presented a mass of material, largely experimental, and much of it bacteriological and pathological. The latter has assumed a better position because of some real practical discoveries, but, during that time there has been a large sifting out of much that was thought of great value, experience, however, demonstrating to the contrary. Let us consider the treatment of fractures. The various methods of plating and suturing, by means of silver wire, have had very strong advocates, yet the use of splints, extension and position have retained their well-recognized effectiveness. There would seem to be a concensus of opinion that when the X-ray shows the fracture has been reduced and the parts brought into a fairly normal position, these cases do fairly well without operative intervention; however, when the positions are faulty, and, even though an anæsthetic is employed, reduction cannot be accomplished satisfactorily, there can be little doubt that they do very much better and more perfect results obtained, by operative proceure. It is now becoming recognized the fractures of the clavicle and other irregular bones demand operative intervention, by employment of plates and like methods.

The knowledge of the anatomical relations of the various joints, especially that of the hip and shoulder, with the aid of X-ray, manipulation, becomes more perfect and more reliable in results.

In dislocations the X-ray has continued to demand greater employment because of its worth.

In the past 10 years it is pleasing to observe that the methods of scientific X-ray work have become very much more extensive and precise; that with the ability to use the X-ray apparatus, in examinations of the head, thorax, abdomen, pelvis and extremities, greater precision has been reached and the results much more reliable and satisfactory; that in the understanding of the location of foreign bodies, much has been accomplished in reading the shadows correctly.

It is in the diagnosis of fractures and dislocations that there has been a steady, continuous improvement. This observation becomes very appropriate when referring to lesions of the spinal column and surgery of the spinal cord.

This knowledge also applies to the better understanding of pathological conditions, especially within the abdomen and the location of stone in the kidney and bladder; however, this must be said, that in the past few years physicians, surgeons and specialists have come to recognize the Roentgenographer as the one alone who can interpret the radiograms and make it clear to the surgeon who is responsible for the case, when an operation is undertaken. In the past it has been too much the custom for the attending medical man to translate the X-ray picture himself and many errors have occurred in that way. This is especially true in reduction of dislocations.

Operations upon the head and teeth, due to the study of X-ray work, have become much better understood, the classifications calling for such procedure much more reliable and showing more and more perfect results.

Compartively recently pathology has demonstrated that septic teeth have much to do with the development of many surgical lesions, in the past overlooked, and, which, like the tonsils, frequently become the bed for the introduction of pathological micro-organisms into the system.

There has been added to the history of general surgery a very interesting chapter on the treatment of phlegmons and inflammatory, septic conditions, by employment of the method known as passive hyperæmia. When promptly and effectively made use of it is of great value in cutting short infective invasion of the lymphatic system, especially when applied to the extremities.

The treatment of malignant disease by means of serums, especially Coley's fluid, maintains a semi-successful position, but, considering the length of time it has been employed, it would seem as though it ought to have offered more encouraging results.

The same applies to X-ray treatment, advocated by some so earnestly in its use previous to, and after, an operation for relief of malignant troubles, yet not establishing itself as a positive curative agent.

The range of general surgery is becoming so great, the multiplicity of theories and papers presented such that one grasps with satisfaction any contribution and conclusion, regarding the methods of diagnosis and treatment that may be said to be final and the results such as to command the confidence and respect of the operator.

The history of modern methods, regarding general surgery, in pathology and diagnosis, through bacteriological, laboratory work, is wonderfully encouraging, but much more time is required than was made use of by the surgeons of a somewhat recent and later date, in their examination of cases.

The thorough study of the blood, bacteriologically and otherwise, the vaccines, are all to be considered in the present history of surgery and proving elements of great importance. This applies to all modern surgery, reaching all points that have developed through research work and of great use in the study of general surgery to-day.

In the study of the history of general surgery, the many papers that are presented in our medical journals, also in our textbooks, from year to year, it is to be observed that advances are being made in the methods of diagnosis and proper treatment. There is this criticism: That too often exploitation of supposed new discoveries, in their proper relation, have failed to maintain the expected high standard of success, for instance, in appendicostomy. At first suggestions for this operation met with a great deal of encouragement in the hope that, as the appendix was permanently fixed in the incision, it could be made the source of successful treatment of pathological changes within the large intestine; however, it does not seem to have found approval to the extent of many cases appearing on record, or employed so extensively as at one time thought possible.

Also, while there have apparently been a few excellent results, yet Edebohl's suggestive treatment of nephritis, by decapsulation of the kidney, does not seem to have sustained the endorsement of the pathologist or the operating surgeon.

In the changes and successes in diagnosis and treatment, during the past decade or two, great progress is to be observed in comparing one period with another — one method with another. That of which so much was expected too often proves valueless, while that which seemed of lesser importance proving of great value, on trial.

In civil life the advances made in surgery of the head, face, neck and thorax, the mediastinal space, the heart, of the lungs and pleura, indicate the calm, steady progress that is now to be observed in all larger hospitals.

Especially does this apply to stab wounds of the heart, to the drainage of abscesses within the pericardium, also in operations upon the lungs and treatment of the pleura for various surgical conditions.

The recent acquisition of the pathology of the thyroid and parathyroids has resulted in the understanding of goitre, far ahead of anything that has ever taken place in the past. The function of these glands, the classification of symptoms and of the pathological condition, has enabled the surgeon to do his work in a more scientific manner and the results much more favorable. The better understanding of the term exophthalmic goitre is exceedingly pleasing in every respect.

In abdominal surgery it is no longer necessary to make use of theories, for practical facts are such that, for instance, in surgery of the liver, gall-bladder, pancreas, gall ducts, the pancreatic ducts, there is now a fixed line of treatment, and not to be deviated from very much. This is becoming more and more positive, and also applies equally well to the appendix.

The surgical treatment of gastric and duodenal ulcer is one of the finest demonstrations of surgery being made more of as an exact science than internal medicine has yet attained.

Injuries and diseases of the pancreas and spleen illustrate much of the advance made in the field of diagnosis and treatment.

The abdominal cavity has come under such thorough observation that the right side can no longer hold its exclusive position regarding operative intervention.

There is no part of this one classification of the human body, and in which Galen was so correct, that is entirely free from possible invasion.

In the past two decades much has been added to our knowledge of intestinal surgery and methods of treatment have reached a more conclusive line of operative procedure.

In civil life no more brilliant results can be shown in any of the various departments of surgery than the treatment of multiple gunshot wounds and ruptures of the intestines and other organs within the abdominal cavity.

This applies particularly to hernia — rupture — and especially for relief of gangrene of the intestine. To the surgeon of many years practice, it is particularly striking to note how few cases we now come in contact with of delayed strangulated hernia, in which we have the complication of gangrene of the bowel. The prompt recognition for early operation in such cases has largely eliminated this catastrophe. Our pathological knowledge is much more clear, also the willingness of the patients to have an early operation, and not trust to mechanical supports. These cases, treated, as they often are, comfortably and palliatively by the application of trusses, still continue to present an excellent history in the good results of operative intervention. We see a gradually increased willingness, in fact patients often seek an operation, the result being so thoroughly satisfactory. All of this applies as well to children as adults.

In the treatment of conditions within the abdominal cavity a greater concensus and uniformity of opinion has been reached than in some other surgical channels.

Perhaps we may say there is yet a lack of uniformity in doing the operation of intestinal anastomosis.

Excision of the large intestines seems to have reached the peak of operative intervention, and present results are being studied with great care, regarding curative results in this class of surgery.

Surgery of the appendix gives a very extensive history regarding what has been written in the past, and, now, regarding diagnosis and treatment, becoming very concise. The general practitioner of to-day is more alert than ever in the recognition of early symptoms and prompt surgical procedure. When these methods are yet more thoroughly considered and carried out, the appendix, from the medical and surgical standpoint, will present a mortality much less than exists at present, though this is exceedingly small.

The history of operations done upon the bladder, for various pathological conditions, is a very impressive one. Decided advances have been made in this direction, and the same can be said of the prostate gland, while surgery of the kidney has reached a point of great precision, the same also to be said regarding the ureters.

In all that pertains to the surgery of the abdominal cavity, much has been accomplished through the study of the Trendelenberg and other positions for the patient during the time of operations, especially upon the kidney or gall-bladder and in pelvic work. Much of this also applies to the treatment of the patient after an operation, particularly in suppurative, septic appendicitis, as has so well been brought out by the writings of the late Dr. Fowler.

In the advances made within the abdominal cavity the searching out of every pathological condition, no organ or tissue being overlooked, is one of the most impressive to be noted in the history of general surgery.

Gall-stones have a way of giving a great variety of symptoms, the same applying to cases of appendicitis, and which, perhaps, has brought out many valuable conclusions.

In operating upon either of these organs and not finding a pathological condition that will accord with the symptoms, it is admitted by most surgeons that a more thorough examination is called for, and in some other unsuspected organ may be found the source of the symptoms, relief being afforded only by doing the operation called for in that direction.

Since the last edition of the Encyclopedia Americana much has occurred in the history of general surgery, regarding surgical procedure, to make clearer new fields of observation, and which applies especially to the abdomen and its contents.

The abdomen has claimed much of the attention of the general surgeon. It has not been possible for the specialist to control this line of work. With our increased knowledge of pathological changes within this cavity, and with the aid afforded the operator through the advances made by the assistance of the experienced radiographer, who is able to interpret radiograms correctly, the success has been so great that patients, or their friends, have little hesitation in entering a hospital, or going to the operating table, when the necessity is made apparent to them. Hence in the building of the many smaller hospitals the past few years, local surgeons have developed an experience that permits of doing many operations deemed impossible for them to perform a few years ago.

In the past two decades much progress has been made in surgery of the bones; in the conservation of limbs and joints; in the better understanding of pathological conditions and especially does this apply to cases of malignant and tubercular troubles.

Surgical lesions of the circulatory system have received much attention, and surgeons have had occasion to discuss the subject of idiopathic aneurisms. Operative surgery in the near past has not met with so many of these cases, and the condition is believed to be due to the more successful treatment of syphilis, this being one of the chief factors in development of this lesion.

The subject of inflammation of the veins — phlebitis — has commanded careful investigation in our laboratories, it so often being the factor in connection with sudden death following an important operation. To relieve the blood clot that forms in the vessel, then suddenly separates, enters the circulation, plugging the heart valves and causing sudden death, calls for surgical intervention, when it can be recognized as being present in the large veins of the extremities.

It is also to be observed that a less number of cases of stone in the bladder are presented, due to the better understanding of calculi originating in the kidney, and this condition corrected by the study of diet, the drinking of properly selected mineral waters or the careful use of plain sterile waters. Here diet has much to do in lessening the development of many surgical lesions.

The medico-legal side of the responsibility of the surgeon has been pretty thoroughly covered the past few years in the history of malpractice suits for foreign bodies left in the abdominal cavity, with the result that the operator, the hospital or nurse share somewhat alike the responsibility, and must give evidence of having exercised every precaution possible to avoid such occurrences. Especially is it the duty of the surgeon to have it well understood with the one nearest in relationship to the patient regarding the extent of an operation. If, in the midst of it, it is found necessary to do more than was explained, the operator must communicate with the responsible person regarding the condition present that requires more serious, additional procedure. This is one reason why every cautious surgeon desires some person near at hand to inform them, should complications unexpectedly arise. Our

British surgeons have had some unpleasant experiences in this direction.

Regarding the anæsthetic in use by the general surgeon, it may be said that sulphuric ether is undoubtedly employed to a greater extent than either one of the other anæsthetics. Chloroform is believed to be advisable in the short operations, and in those upon children, while for those only requiring a few moments the nitrous oxide or ethyl chloride are of great service.

ALBERT VANDER VEER, M.D.,
Professor of Anatomy, 1869–74. *Professor of Surgery,* 1876–1915, *Albany Medical College.*

SURGERY IN AMERICA. If at any time one should purpose writing a history of the progress of surgery on the American continent he must not fail to remember that in the earlier part of its history America was absolutely dependent on Europe, and could not be expected to reflect anything better in the direction of science than that which it received from its mother-country, Therefore, the most suitable introduction that could be made for the history of surgery on this continent would be a review of the status of the 17th century in Europe. Very prominent were two or three philosophical systems which had been handed down from previous thinkers. The skepticism of Montaigne, with its final reduction by Bayle to universal doubt or universal credulity, and the supernatural or mystic philosophy of Böhme, sometimes spoken of as the cabalistic or theosophistic, which includes the discoveries of Pascal and Malebranche, were the prevailing systems or methods of thought. In the meantime Bacon had lived and died (1626), who, though he laid great stress on gunpowder and the compass, had but little respect for the discoveries of Copernicus. Zoology and botany were fairly well advanced and had been extended by dissection and by classification. Hooke had discovered the cell and had founded the cell-doctrine. Kepler and Galileo had been persecuted and had left their discoveries for others to verify. Newton entered the world some years after the date of the first expedition of the *Mayflower* (1642). Continental Europe had many universities, some of which have been discontinued or merged into others. Numerous academies of science had sprung up in different parts of Europe, and the present British Royal Society was remodeled in 1662 by Charles II. Nevertheless, all kinds of superstition prevailed, alchemy flourished, witchcraft was in full bloom, necromancy was generally practised and the divining rod flourished, and all domestic animals were kept under cover during an eclipse lest they be threatened by dire pestilence of unknown character. In 1628 Harvey had published his work on the circulation of the blood, and in 1608 the microscope had been invented by Lippersheim, although by some its invention is attributed to Jansen in 1620. At all events it was greatly improved by Hooke, who died in 1702. Logarithms were not invented until the American colonies were nearly 100 years old (Napier, 1700); but the weight of air had been established by Toricelli in 1643. Previous systems in medicine were then modified, to be reformed on the modified Paracelsism devised by Van Helmont or the humeral views of Sylvius and Willis. Sydenham appeared upon the scene about the time of the first expedition of the *Mayflower*, and, until his death in 1689, the larger number of English physicians who came over in his day had been more or less under the influence of his teachings.

The 17th century is important in the history of surgery, since superstition and self-satisfaction gradually gave way to the inductive method and improved habits of observation. Even among the Dutch, who settled new colonies in this country, surgery now assumed a dignified position, while among the English, French and Germans it had already attained something of this character. These were still, however, the days of the barber-surgeons, who were not considered gentlemen nor fit to associate with gentlemen, who were, for the greater part, an uneducated and illiterate class. The study of anatomy was still pursued with difficulty, the ban of the Church yet covering those who took part in any operation which was accompanied by the shedding of blood. In such a state were the mother-country, the Netherlands and France, while still worse off was Spain, at the time when the early adventurers or pilgrims from these various countries landed upon our shores and began to make American history.

Colonial History.— The English colonists brought their physicians with them on nearly all of their expeditions. Thus when Jamestown was founded, in 1607, we hear of one Wotten, or Woolton, who came out as surgeon of the London Company, who was even considered a gentleman among the others of the expedition, whether by courtesy or right it is not known. Walter Russel followed in 1608. Even within that first half-century came the need for some definite laws regulating the practice of medicine, since throughout the colonies quackery flourished to a considerable extent. There was at this time little to attract travelers to this country except the spirit of adventure, which the better educated men possessed in minor degree. Many of the earlier physicians of the colonies were church deacons or politicians or both. Thus Samuel Fuller, who came to Plymouth in 1620, preferred to be known as a deacon rather than as doctor, although he practised medicine faithfully and, for his time, well. John Winthrop, Jr., was not only a physician but a statesman. In 1667 he became governor of the New Haven colony, and he must have enjoyed much repute in England since he became one of the founders of the Royal Society. Up to 1692, 134 physicians had been catalogued as practising in the colonies. The first person executed for witchcraft was one Margaret Jones, who was also a physician.

In the New Netherlands, controlled first by the Dutch West India Company, it was provided in their charter that they should procure a «Comforter for the Sick.» The first one of prominence under this provision was Bogaerdet in 1637; later came LaMontaigne, who was both a Huguenot and a physician. Prominent during the middle of the century was one Samuel Megapolensis, who was born in this country and graduated from Harvard in 1657, and then went to Utrecht, where he took his medical degree. He practised in Manhattan both as a physician and preacher. In 1772 a Quaker, George Fox, was traveling with John Jay when the latter was thrown from his horse and had his neck apparently broken. Fox at once instituted a manipulation by which, apparently, the dislocation of the upper vertebræ was reduced and by which Jay was restored to life. This must be one of the earliest cases of this kind on record. When William Penn came to this country he brought with him Dr. Wynne, an accomplished Welshman and probably the most competent man of his profession in America at that time.

The colonies were swept during this century with fierce epidemics of yellow fever, smallpox, scurvy, dysentery and many other diseases, by which the colonists suffered great loss. Those who came over with William Penn numbered about 100, of whom one-third died on the voyage of smallpox. This was perhaps the most terrible scourge of all and was not successfully battled with until Dr. Boylston dared to institute the method of inoculation to which his attention had been called by Mather, who had read of its successful introduction into England from Constantinople by Lady Montague. In this is constituted one of the most interesting episodes in the history of medicine in this country. The Rev. Cotton Mather, distinguished both as a politician and divine, still had this on his mind even after he had lost his interest in the burning of witches. In 1721 he read a paper on Turkish Inoculation written by one Timonius, and became deeply interested in it. He endeavored to interest various young men, especially a Dr. Douglas, in the discovery and in the method. Failing in this he turned to Dr. Boylston, then of Brookline, Mass., who saw the importance of the method and the ripeness of the occasion. As soon as his purpose became understood he was at once denounced in the pulpits and attacked by the multitudes, and had as his only backer the man Mather, who had not yet lost his authority with the clergy. Opposed, then, by his colleagues and by the clergy in general, and the universal rabble, Boylston had the hardihood to inoculate first his own son and two negro servants, and this only six weeks after the first inoculation was done for Lady Montague in London, by Dr. Maitland. But Boylston lived to reap glory and profit from his intrepidity. The controversy which he aroused had subsided in this country when he went to London, where he found it still raging, and where he again aroused a storm, but eventually triumphed. (This method must not be confused with vaccination, but consists of the actual inoculation of the disease by pus or discharge from the lesions of the patient suffering from the real malady. It is practically the same method which had existed for centuries in the Orient).

A great part of the 18th century was spent in warfare between natives and the newcomers to this country. The Indians were almost always active, while the English and French fought more or less continually, the scene of conflict extending from Quebec on the north to the Niagara Frontier on the west and Georgia on the south. In spite of the many opportunities thus afforded for the study of military surgery it does not appear that much was done in the way of improvement of older methods or in new discoveries. The wounded soldier of 1776 had but little better treatment than the wounded pilgrim of 1676. There were a few men of such prominence scattered along the coast line in the early and middle part of the 18th century that they deserve to be mentioned, at least by name. Cadwallader Colden was born in Scotland in 1688, and came to this country in 1707. In 1710 he moved to Philadelphia. Here he wrote some of the first medical papers written in this country, particularly on animal secretion. After some years spent in this country he took up his residence in New York, in 1716. He was during the early part of his life an indefatigable student and attained remarkable popularity in his practice. He held numerous public offices and figured rather as a statesman than a physician. He acquired a large estate up the Hudson and became the intimate friend of Benjamin Franklin, to whom he first suggested the foundation of the American Philosophical Society. He left a large number of writings and correspondence with the most eminent savants all over the world.

As the colonies steadily progressed in wealth and size, Charleston became more and more a prominent centre of influence, and here there lived and died during the century a group of five men, namely, Chalmers, Lining, Gardner, Moultrie and Bull, who made important contributions to science and achieved unusual distinction. All of these were of Scotch origin save the last, of whom it was claimed that he was the first person born in South Carolina, as well as the first native to receive a doctor's degree. He was a pupil of Boerhaave, a graduate of Leyden in 1774. He gradually drifted into politics, as did Colden. Lining was perhaps the first American physiologist and published numerous papers in the 'Transactions' of the Royal Society. He also published the first American account of yellow fever, which was the scourge of the century, and which appeared to spread to this country from the West Indies. Moultrie achieved an honorable position. He had a son who was also a doctor, and while both of them attained a high place in the esteem of their fellow-citizens, the death of the father was regarded as a public calamity, after some 40 years of phenomenal activity. Chalmers was already a friend of Colden and the others when he came to this country. He made himself generally known as a writer and developed power which would have made him, under suitable surroundings, a rare teacher. Gardner, like Colden, was a man of culture and fine education; in fact one of the most versatile men of his century in this country. He was made a Fellow of the Royal Society. To these should be added, perhaps, John Mitchell, an Englishman by birth, who came to this country in 1705 and made a reputation which spread to the centres of learning in the old country. He published a number of essays in the 'Philosophical Transactions.'

A great epoch in the medical history of the 18th century was the foundation of the first hospital in this country. This must be duly credited to the energies of Benjamin Franklin, Dr. Thomas Bond and, later, Drs. Shippen and Morgan. Bond was born in 1712, in Maryland. After studying for six years in this country he went to Europe, whence he returned full of the idea of introducing the hospital system which had proved so advantageous abroad. Though he returned in 1734, not until 1751 were circumstances sufficiently propitious to found something more than a mere camp for the treatment of smallpox or a lazaretto for the care of sick seamen. Franklin threw the whole weight of his influence into this movement and finally £2,000 raised by private subscription, added to a similar sum contributed by the colonists, prepared the way for the opening of the Pennsylvania Hospital in 1752. After four years of existence in rented quarters, the cornerstone of a new building for that purpose was laid, bearing an inscription suggested by Franklin himself. This institution had an enormous influence in more than one respect, since its foundation had made possible the creation of the first medical school in this country, which became a part of the University of Pennsylvania, and which owes its inception to the study and liberal enthusiasm of Morgan. Although Harvard College was founded in 1636 and Yale in 1701, it remained for this to become the pioneer medical school in the United States. Albany has a somewhat famous history regarding civil and military hospitals.

Previous to the American Revolution it had cared for many sick and wounded. Just before that period, in connection with the French and Indian wars, it had established a military hospital with accommodations for 500 patients. This was in use during the fighting along Lake Champlain, Lake George, Ticonderoga, Fort Edward, Bemis Heights, Saratoga, Schuylerville and the campaign of the Revolution. Later, during the epidemic of cholera, in 1832, barracks were erected for care of the sick; also in the beginning of the Civil War a large hospital was erected, much in the style of the barracks of to-day, and to this were brought the sick and wounded from about Richmond during the fighting under McClellan.

John Morgan began his study during the period of the French and Indian wars. As he came in contact with the foreign surgeons who came over with the English troops, he found his own ability not at all commensurate with his ambition. So in 1760 he went to London and studied under the Hunters, and then to Edinburgh, where he came under the influence of Cullen, the Munroes and others, and where he graduated. He next went to Paris and was admitted to the Academy of Surgery; he then made a tour of Europe, having the advantage of a personal acquaintance with Morgagni in Padua. Morgan spent five years in this foreign study and upon his return, in 1765, became closely associated with the younger Shippen. The Shippens were a well-known medical family of Philadelphia, and were men of liberal education and social distinction. Shippen had already given private instruction in midwifery and the two men joined hands most heartily in this commendable effort. When the trustees of the college opened the school Morgan and Shippen became professors, respectively, of medicine and surgery. Thus it will be seen that Shippen was the first professor of surgery in this country, and that the first systematic instruction in surgery was given by him in 1765.

The faculty was joined a little later by Benjamin Rush, who became the most conspicuous figure of his day, as a professional man, in this country. He was but 24 years of age when he was made professor of chemistry, and he was but 31 years of age when he became a signer of the Declaration of Independence. The gathering war clouds of the Revolution dampened the ardor of all at this time, and the work of carrying on the hospital and medical school was exceedingly heavy and fell mostly upon the shoulders of three or four men. In 1779 the assembly revoked its charter which was, however, restored in 1793. In the meantime the condition of affairs in New York was not much better.

One man, however, stood out pre-eminently as an efficient physician and broad-minded citizen. This was Samuel Bard, whose name deserves to be closely associated with that of Rush. When he returned to this country in 1765, after a period of foreign study, he was inspired with the thought of founding a medical school in his native land. In 1768 he associated with himself, Clossy in anatomy, John Jones in surgery, Middleton in physiology, Rush in chemistry, Tennent in obstetrics, he himself taking charge of the principles and practice of physic. Thus the medical school of King's College was established. Jones was perhaps the first in this country to distinguish himself as a surgeon. He had been under the best teachers in Europe, and had seen a great deal of military surgery in his day, especially during the French War. He was independent enough to decline to adopt some of the peculiar notions of his colleagues regarding appropriate costumes, but in the end the absurdities which he dispensed with were discontinued by them. He wrote a book for the Revolutionary surgeon, entitled 'Plain, Concise and Practical Remarks on the Treatment of Wounds and Fractures.' Up to this time, midwifery had been practised by untrained women and it can readily be seen what an advantage it was to have the science of obstetrics systematically taught as it was in both schools above mentioned.

During the six years while New York was occupied by British troops there was a cessation of college activity. The faculty was not a unit in its political beliefs and after the Declaration came dissensions. Three years after the war the college went on under its new name, "Columbia," but with very poor success. A spurt was made again in 1792. In 1807 the New York University opened a medical college, but jealousy and strife prevented its success. Finally, in 1811, a union of the two schools was accomplished under the name of the younger and thereafter the College of Physicians and Surgeons prospered and is to-day one of the leading schools in this country, though now again under the ægis of Columbia. Meantime under Bard's influence, the New York Hospital had been founded in 1768 and chartered in 1770. It was in their new building that the Provincial Congress used to meet during the second year of the Revolution; but when the British arrived the hospital was turned into a barracks and Bard and Jones joined the Continental armies. It was not until 1791 that the hospital was fully and finally equipped and began its career of usefulness.

The Revolutionary Period.—At the time of our Revolutionary War the science of military surgery was scarcely yet created and even with the Continental armies the barber-surgeon had a certain place, in which he was almost a menial, and above which he could scarcely raise himself. The English troops were better equipped in this respect than were the Hessians, for instance, while during the latter part of the war, especially when the French sent some of their best men to this country, our raw and untrained army surgeons came in contact with a better class of men and by whom they were, to some extent, inspired. Nearly all of the prominent medical men, save the Tory physicians of Massachusetts, entered the army or took public service, and in the Massachusetts Provincial Congress of 1775 there were 22 physicians. Both the colonial and general governments dealt very stingily with their medical departments and the professional equipments provided were almost meagre. The history of surgery in those days is mostly the history of a few prominent individuals who made it what it became and who deserve to be briefly mentioned. The brothers Joseph and John Warren took a very prominent part during the earlier portion of the war. It was the former who started Paul Revere on his famous ride. He was elected president of the Provincial Congress and just before the battle of Bunker Hill was made major-general of the Continental forces, preferring this office rather than the office of physician-general which he had been offered. During the battle he showed a wonderful spirit of self-sacrifice and, declining his rank, acted as a private, and with musket in hand fought nobly, and was shot dead just at the conclusion of the battle. The younger brother, John Warren, lived to achieve fame and reputation, and transmitted them to a posterity by whom they have been well preserved. He constituted a brilliant contrast to many of the regimental surgeons who had been too often appointed by political influence without regard to attainment. Some regiments were even organized without a surgeon and came into camp without the slightest provision for disease or injury. In 1776 Congress enacted that there should be one surgeon and five assistants to each 5,000 enlisted men. The former was to be paid $1.66 per day and the latter each $1 a day. The reader can imagine the care 5,000 men would receive from six physicians whose services were compensated at this rate. At that time such a thing as camp hygiene was almost unknown and a hospital corps and ambulance drill were quite lacking. But John Warren, then but 23 years old, proved extremely efficient in the organization and completion of, and accomplished a great deal for the improvement of his department. The first surgeon-general of the Continental armies was Benjamin Church, of Boston, who was given the title of director-general and chief physician and was paid $4 per day. Church gave promise of efficiency in his department, but before long was detected in correspondence with the enemy, for which he was court-martialed, imprisoned for one year and allowed to leave the country and was then probably lost at sea. His place was taken by John Morgan of Philadelphia, already mentioned above. He had the politicians to fight and after a long and arduous struggle, failing to satisfy them, he was dismissed from the service, although he was finally acquitted of all blame. This was a time of unrest, excitement and suspicion and had Washington himself been a weaker man, he could scarcely have withstood the dissensions and jealousy with which he was continually surrounded. Morgan was succeeded by Shippen, his old associate, who remained in office from 1777 to 1781. Under his guidance the medical department almost prospered and was at least conducted with dignity and great benefit to all concerned. Smallpox, which had been the scourge of the soldiers as well as the people in general, was kept down by the practice of inoculation, which had been generally accepted by nearly all men from Washington down.

From the Revolution to the Civil War.— The most conspicuous figure in the history of American medicine, which practically began with the conclusion of the Revolutionary War, was Benjamin Rush, of Philadelphia (1745-1813), an exceedingly versatile, many-sided, erratic, obstinate, skeptical man, constant only to his religion which he considered to be a professional duty. He was hated by many of those to whom his methods most strongly appealed. He had rare didactic gifts, but his teachings were abused by his students and followers. As a young man he had spent three years in Europe and had taken his degree at Edinburgh. He had come especially under the influence of Cullen, whose views he had imbibed and later accepted in a modified form. He served two years in Congress, where he advocated and signed the Declaration of Independence. In the same year, 1776, he got his first army medical experience. Rush seems to have been one of the few men who failed to come under the influence of Washington's personal magnetism, and he endeavored in some ways to belittle his commander-in-chief. After a rather ignominious exposure he retired from service and took up his practice in Philadelphia. From that time on he became noted as author, teacher, practitioner and politician. He proposed a cabinet position whose incumbent should be called Secretary of State for Peace. He wrote extensively on many subjects, not all of which were medical. He finally exposed the weakness of Cullen's doctrine and fell rather into accord with that of his great rival, Brown. He taught that yellow fever was not contagious, but warmly advised purgation and excessive letting of blood in its treatment. At his death he was one of the few surviving signers of the Declaration of Independence. He made many contributions to science and it is said of him that since the death of Washington no man was so deeply and universally mourned. A list of his writings would include several pages of titles and would show the mental and physical activity of this great man.

The earlier portion of the 19th century in the large cities of the country was characterized by unfortunate dissensions and jealousies which for many a year kept back medical progress. Prejudice against the study of anatomy was as strong as ever, and the difficulties surrounding dissection were often very great. The so-called "Doctor's Mob" occurred in 1788, when an excited crowd tried to break up a dissection which was being carried on in the old New York Hospital, where the provincial legislature at one time held its sessions. The students and doctors took sanctuary, for the time being, in the jail, the militia were called out, seven rioters were killed and the doctors got no sympathy. Although this was before the 19th century actually began, it nevertheless indicated the spirit of the times. The great benefit of the Revolution came from the presence of the educated and more cultured French and other foreign officers who came to this country and brought their books and wisdom with them.

The greatest figure in American surgery during the earlier part of the previous century was Philip Syng Physick. He was born in 1768 and died in 1837. He came of a good family and had a good education. But it was not until 1789, when, in London, he had the good fortune to be taken into the family of John Hunter, that he developed those qualities which helped to make him great in after life. Had he been willing to remain in the old country he might have become Hunter's partner. He had the best that the old country could afford, spending some 11 years in study, all told, which was a remarkably good preparation for practice 100 years ago. He yielded to the claims of his native land and quickly built up a practice after his return to this country. He had much with which to contend, including indigestion, an absolute lack of humor, in fact a temperament such as to make him unpopular, the only thing that saved him from this being his brains. In spite of all this he left behind him the reputation of being the Father of American Surgery. One of his most celebrated cases was that of Chief Justice Marshall, from whose bladder he removed an astonishing number of calculi. In 1805 he became professor of surgery in the University of Pennsylvania, which chair he held for 13 years. Though clumsy and uncouth in person he was singularly dexterous with his hands, and excelled in deftness with the knife, and with all forms of orthopedic apparatus. He gained great reputation in his treatment of fractures and dislocations, many modifications of which he made which proved very advantageous. For some years he had promise of a successor in his nephew, John Dorsey, who, however, died before his uncle, and never lived out his promised career.

The next great figure in American surgery was Ephraim McDowell, who came from what was then called the «Far West,» in Kentucky. When young he went to a classical seminary, where he got a smattering of Greek and Latin, but did not conclude to study his profession until he was 20. He began reading medicine in Danville, Ky., but was finally sent to Edinburgh by his father. Here he came under the influence of John Bell, whose teachings made him what he became. He returned in 1795 and decided that there was a rare opportunity in Kentucky for an educated physician, in which matter his foresight proved correct. In 1809, when he undertook the first and great historical 'Ovariotomy,' he was already known as an accomplished and educated man, upon whose mind the teachings of John Bell had made a great impression. When Mrs. Crawford came to him, suffering from an ovarian cyst, he was ready to undertake her case despite the protests of others. The case terminated favorably, but it was not until he had performed a number of similar operations that he thought it best to publish anything on the subject. Even then his paper did not see the light as it should, and there was for a time a doubt in the minds of those who should have known better as to whether his report was really authentic and whether he should be credited with this pathfinding expedient. He has been amply vindicated, however, and this fortunate experience of his paved the way for many operations but for whose effects thousands of lives would have been sacrificed.

The next great figure was Valentine Mott. He was born in 1785, and was of Quaker parentage. He was a great classical student, and was well equipped for professional study when he began to study medicine. He then spent two years in Great Britain, especially in London, which was then rich in famous surgeons. Under Hunter, Cooper, Abernethy and Charles Bell he acquired that familiarity with surgical anatomy which was a great help both then and in later years. He returned to New York in 1809, and his personal traits as well as his thoroughness quickly brought him practice and made him known. He became the teacher of surgery in the Columbia School until he transferred his activities to the new school which resulted from the union of Columbia and the College of Physicians and Surgeons, where he lectured for 56 years, inspiring in his classes constant enthusiasm and eagerness for work. The influence of his insistence upon the importance of anatomy still persists, and was brilliantly demonstrated by his work upon the blood vessels. It is said that he tied more large vessels than any other surgeon living or dead. Perhaps his greatest achievement, at least the one that made him most famous, was ligature of the innominate artery. This first operation of its kind was not permanently successful, nevertheless it stamped the operator as a man of wonderful resource and daring. The first successful case belongs to another American surgeon, A. W. Smythe, of New Orleans, who tied at the same time, the carotid artery in the neck. Again he won great repute by removing the entire clavicle for a large tumor. In 1827 he tied for the first time, successfully, the common iliac artery. The previous operation had been made by another brilliant American surgeon, Gibson, of Baltimore, whose patient unfortunately died of peritonitis. In 1835, quite broken in health, he made a tour of Europe, which had about it much of a triumph, inasmuch as he was everywhere received with éclat.

We have already recounted how John Warren served in the Revolution both as a surgeon and patriot. His son, John Collins Warren, was born in 1778, and was reared in an atmosphere of study and refinement. He was thoroughly educated for his work, in which he took the greatest pride, and, like Mott, had the advantage of the teachings and friendship of the most distinguished foreign surgeons. Two events of importance, in which he was conspicuous, were the founding of the Massachusetts General Hospital, and the introduction into surgery of the then new anæsthetic, sulphuric ether, of which we shall have more to say below. He was a bold operator and for his operations on bones, especially the jaws, he became famous. He gathered a memorable collection of his personal cases in his 'Surgical Observations on Tumors,' which are to-day most instructive. He was the founder of the large collection of specimens now known as the Warren Museum, in Boston.

While Warren and Mott were making their great reputations in the East, it remained for Kentucky to produce still another even greater than McDowell, in the person of Benjamin Winslow Dudley, born in 1785, who began life in an obscure way and who raised himself to eminence purely through his own attributes and strength of character. While quite young he made enough money, by a shrewd enterprise, to take him abroad where he remained several years, returning a polished and educated gentleman. Cooper and Abernethy in London, and Larrey in Paris, were men for whom he had much admiration and with whom he became well acquainted. When he returned he was 29 years of age, matured and devoted to his science. As a measure of his success it may be said that in his first 100 cases of cutting for stone in the bladder he lost not one; a statement that could be made by but few surgeons to-day. His early work in the surgical treatment of epilepsy directed attention to what could be done in this almost hopeless disease, and his treatment for hydrocele by excision of the sac is in common use to-day. For 20 years he was prominent in the Transylvania Medical School, in Lexington, Ky., which was later merged into the College of Louisville. Dudley wrote very little, but his personal influence was extraordinary, and he was without doubt the leading practitioner of the West. He died in 1870.

In the interest of economy in space, it will be best, perhaps, to recount the various historical achievements of American surgeons without going into further biographical details. In the department of surgery of the large blood vessels the American surgeons were almost pioneers. In 1803 Cogswell of Hartford tied the common carotid, making the first successful ligation of this vessel on record. In 1807 it was first successfully tied for secondary hemorrhage by Twitchell of Keene, thus antedating Astley Cooper's famous case by eight months. In 1813 Post of New York first tied this artery for the cure of aneurism. In 1823 MacGill of Maryland first successfully tied both carotids simultaneously, the case being one of fungus tumor in both orbits. In 1867 Carnochan of New York first tied both carotids for the treatment of elephantiasis of the face and neck. Post, in 1817, first tied successfully the subclavian artery in its third portion, after it had failed in the hands of some of the great English surgeons. The same artery was first tied in its first portion by Rodgers of New York, an operation hitherto considered impossible, and which was never successfully repeated until 1892, by Halsted, of Baltimore. Mott's first ligation of the innominate artery has already been mentioned, an operation which made him famous all over the world. The internal iliac was first tied by Stevens in 1812, the external by Dorsey in 1811, and both internal and external by Dennis in 1886, while Davidge first tied the femoral and gluteal for the cure of elephantiasis of the lower extremity. Digital compression for the relief of aneurism was first successfully practised by Knight of New Haven in 1848. The use of the elastic bandage in the treatment of varicose veins was first successfully adopted by Martin of Boston, who preceded Estmach in the use of this expedient for controlling blood supply during amputations; while Wyeth recently introduced long pins for the same purpose in amputation of the shoulder and hip.

In fractures and treatment of injuries and diseases of bones and joints, Physick exceeded all men, without question. The so-called American method, which is now so widely accepted, that is, the treatment of fractures by traction with a weight and pulley, was introduced by Daniel of Georgia. Van Ingen of Schenectady added to the method the elevation of the foot of the bed, and Buck increased its value by his coaptation splints. The present universal method is, therefore, a composite of all these, but is distinctly American. So is also the use of elastic traction by the aid of rubber bands. Barton, Bond, Hamilton and Reid, the latter of Rochester, all studied assiduously the mechanism of fractures and dislocations, and described the methods for their treatment and relief. The interdental splint for the treatment of fractured jaw was also of distinctly American origin. Rodgers introduced metallic sutures in the treatment of fractures; Brainard of Chicago, the method of drilling fragments in delayed union, while both Henry Smith of Philadelphia and Nathan Smith of New Haven did very much to improve apparatus for the retention of fragments in their proper place.

In the treatment of dislocations, especially in the matter of their reduction by manipulation, the world owes a great deal to Reid and Moore of Rochester, Bigelow of Boston and Gunn of Chicago, by whose efforts it was brought about that the ponderous machinery of the clinics was completely abandoned. In the removal of diseased bones Jamieson of Baltimore, in 1820, made the first resection of the upper jaw, while the upper and lower jaws were both simultaneously removed by Rodgers of New York. The first removal of the lower jaw was by Deaderick of Tennessee in 1810, while the clavicle was first successfully removed for necrosis by McCreary of Kentucky, in 1803, and for malignant disease by Mott in 1828, and the entire upper extremity, including the scapula and clavicle, by Crosby in 1836, and again the entire radius in the same year. Stone first removed a rib for drainage in 1862, and Mott the coccyx in 1832. Wood of New York had a famous case of entire removal of the lower jaw with almost complete reproduction of bone. Other operations of importance on bones were the first removal of a «V» shaped piece of the hip, and also for the cure of bony anchylosis of the lower jaw. Nathan Smith of New Haven is entitled to the credit usually given Brodie for the trephining of inflamed bones for the relief of inflammation and abscess.

In the matter of amputation Richard Bailey is to be credited with the first systematic amputation of the shoulder joint, in 1762. Crosby's case of the removal of the entire extremity has already been mentioned. The first successful amputation of the hip was made by Brashear of Kentucky in 1806. The patient was a slave boy belonging to the monks of Saint Joseph's College. The first operation of this kind ever done was in England by Kerr in 1774; while the first done for gunshot wound was by Larrey in 1793. American surgeons also made many improvements in genito-urinary surgery. The first successful plastic operation for exstrophy of the bladder was made by Pancost of Philadelphia in 1858. He and others preceded Wood and various English surgeons to whom the credit is usually given. Parker of New York introduced cystotomy for the relief of chronic cystitis. The kidney was removed successfully by Wolcott and by Stoddard of Milwaukee nine years before it was removed by Simon of Heidelberg, who has been credited with it. The first really successful method of operation for cleft palate was introduced by J. C. Warren of Boston, while Cheever, another Boston surgeon, was the first to remove the tonsils by external incision.

In abdominal surgery Americans have almost led the world. Had it not been for McDowell's epoch-making case, in 1809, this branch of surgery would have been much retarded. Any one practising to-day can scarcely realize the moral courage and surgical daring required during that historical incident. Atlee of Philadelphia and Kimball of Lowell were the first to successfully remove large uterine fibroids, and it is claimed that Stevens of South Carolina, as early as 1763, successfully removed the entire uterus, an operation repeated by Briggs in 1830. The first vaginal operation for extra-uterine pregnancy was made by King of South Carolina in 1813, while the abdomen was first opened for this purpose by John Baird as early as 1759. Bobbs of Indianapolis was the first to attack the gall-bladder surgically, while Willard Parker first made clear the surgical treatment of peri-appendical, or as it was then called, perityphlitic abscess. The entire elucidation of the surgery and pathology of appendicitis is due to Americans, especially to Fitz and McBurney. The treatment of gunshot wounds of the abdomen by abdominal section was conceived, developed and perfected in America, especially by Bull and Parkes, while Senn, Murphy and others have made valuable contributions. The first four cases of pancreatic cyst were in the hands of American surgeons. The surgery of the female genital organs owes more to the ingenuity and skill of Americans than to those of all other nationalities combined. Especially valuable in this direction were the labors of Sims and Emmet. Other procedures of distinctly American origin might be named without making the list too long; for instance, the invention of skin grafting by Dr. Frank Hamilton of Buffalo in 1854. The same procedure was independently instituted by Reverdin of Geneva, Switzerland, each being independent of the other. Animal ligatures were first used by Physick in 1844. The innocent character of the metallic ligature, as well as its usefulness, was first demonstrated by Levert, of Mobile. The use of plaster-of-paris splints and jackets was greatly promoted by Sayre of New York, although he was not their originator. The first abdominal section for gunshot wound of the intestines was made by Kinloch of Charleston in 1881. The discoveries and inventions of American orthopedic surgeons have been models for the rest of the world.

The two great events in the history of American surgery in the 19th century were the introduction of anæsthesia and the antiseptic technique. Both stand to the credit of the Anglo-Saxon race, the former being an American, the latter a British device. These two measures together wrought a complete revolution in the practice of surgery, and show that the Anglo-Saxons have done more for it than had been accomplished in the previous 18 centuries. By the latter the devastations of sepsis have been almost completely done away with; and by the former the tortures of pain and the agonies of serious and protracted operations have been abolished.

Period of the Civil War.— The exigencies of the Civil War made demands upon the medical resources of the regular and volunteer armies which at first could not be adequately met; in this as well as other respects both sides were but meagrely equipped either with men or means. It was before the days of antiseptic surgery, bad methods still prevailed and the sacrifices then made to sepsis and to bad sanitation were fearful to contemplate. Wounds of large joints condemned the patient to amputation above the injury, compound fractures were very generally, fatal, hospital gangrene and tetanus were like spectres which stalked by night through the hospital camps. With characteristic readiness measures were rapidly adopted to minimize the slaughter from disease, and within a comparatively short time a well-equipped medical corps, backed by the government Sanitary Commission, had brought order out of chaos, while the Red Cross Bureau had shown what it could do, especially under the guidance of Miss Clara Barton and other devoted women. Military surgery was but emergency surgery practised under peculiar conditions, and as this fact became more greatly appreciated our wounded soldiers received better and better care. The outcome of this extended experience, in two or three different and indirect ways, was remarkable. It led to the foundation of the Army Medical Museum, in Washington, which has since grown to enormous proportions and now occupies the larger portion of a large building, wherein everything pertaining to so-called military surgery finds ample illustration. It led also to the building up of the wonderfully rich and complete library of the surgeon-general's office, with most extensive index catalogues, including the Index Medicus, by which the entire medical literature of the world is catalogued and made available to all. And, thirdly, it led to the publication of the Medical and Surgical History of the War of the Rebellion, in six enormous volumes, which far exceed in magnitude and value anything of the kind ever published. In their efforts to build up these three features the names of Otis, Huntington and Billings will ever stand preeminent.

From the Civil War to the Present Time. — The Civil War developed very many excellent American surgeons, and within a decade after its close the good effects of their experience were manifested in a great many of the civil hospitals throughout the country, particularly in the practice of men who had located in the larger cities and towns. This, together with the development of asepsis, brought out a great deal of beneficial work in this country, in the practice of surgery. It also presented a period when specialists began to develop with greater precision than at any time in the previous history of medicine. This was especially true in regard to gynecologists, and, what at that time were termed, abdominal surgeons. The outcome has been the organization of several national surgical associations, which have included in their fellowship some of the ablest surgeons in the United States, thus enabling America to keep thoroughly abreast of all that was being done elsewhere. There has been a progressive development of bacteriological, biological and pathological laboratories where much research work has been accomplished, aiding very decidedly in the better understanding of surgical lesions, and resulting in a great increase in the possible operations to be performed for relief of the patient. Had the elder Gross, in his early experiments, in 1843, known of or had a laboratory at his disposal, such as exists to-day, greater honors would have come to him in doing intestinal surgery.

Laboratory work, with increased surgical skill, has brought about the establishment of many hospitals in the larger and smaller cities, and it may safely be asserted that in the latter many strong surgeons in the World War just brought to an end will be found doing superior work. Many of these institutions will feel the good impulse of benevolence, excellent nursing and support from Red Cross organizations, while the larger hospitals in cities will become better endowed and less embarrassed in meeting their financial obligations.

It is very impressive to note how willingly communities have accepted going from their homes to the hospitals for treatment. Research work has brought out many surgical conditions associated with illnesses heretofore considered medical, such as lesions of the bones following typhoid fever, also tubercular conditions of the joints, syphilis, actinomycosis and other obscure lesions of internal organs, this advance being conducive to recoveries of cases formerly doomed to a long, painful sickness. Our laboratories have been of incalculable value in the preparation and standardization of absorbable ligatures; in the examination of the blood, and various secretions, and, especially, in the development of tetanus, antitoxin and other serums.

One great advance made by American surgeons has been the surgical treatment of the thyroid gland; another the energetic manner in which they have attacked the gall-bladder, the stomach, the intestinal tract, the spleen, pancreas and the reproductive organs within the pelvis, for conditions considered quite hopeless in the past. Operations upon the appendix, and intestinal tract, with the ability to remove portions of the latter, yet allow normal functions to follow in a healthy manner seem wonderful. This same confident development of surgical procedure has eliminated much of the distress due to lesions of the kidneys, the ureters, the bladder and prostate gland. All of this work could not have been accomplished without our knowledge of pathological micro-organisms, and the employment of sterilization of the operating-room, the field of operation, the operator and dressings.

American surgeons had much to do with the evolution of this chapter in surgery. From the introduction of the carbolic spray, as taught by Mr. Lister, through all the various experiments in the use of antiseptics, and, finally, of asepsis, much has been accomplished. The battle has been to control suppuration — i.e., the formation of pus — and when every precaution has been carried out, when no link in the chain of technic of procedure has been omitted, to the public at large the recovery of patients becomes very noticeable.

In successful work surgery made a stride that commanded the respect and attention of wealthy citizens with a benevolent trend of thought, so that hospitals and laboratories were endowed, and in America we were able to do what for some time seemed only to be known in Europe.

Through the study of germs, in the various laboratories, and their danger to operative surgery, and with the employment of absorbable ligatures, the science and art of surgery has been brought up to a very high plane of activity. The advances made in operations upon the spine, and the transferrence there of splinters from the long bones of the body, for the treatment of curvatures, has been one of the most decided advances in surgery. This is also to be observed in the immobilization of wounds, as illustrated in the fixation of fractures of the extremities.

Very much credit is due the American surgeon for discoveries and advances in local anæsthesia in operative surgery, in hospital construction and for the persistent use of rubber gloves, particularly when operating in septic cases.

Some of the most brilliant advances made in surgery of the nerve trunks, in the removal of the Gasserian ganglia, for relief of neuralgia, has been accomplished by the American surgeon. The investigation, study and progress made in the department of genito-urinary surgery is one of the most convincing arguments that surgery has become more of a fixed science than ever in its past history.

The genius of the American surgeon is well shown, in so many ways, by the invention of new instruments, as well as the improvements made in those long in use, and in hospital furniture.

History of Anæsthetics.— The abolition of pain is in itself a matter of such vast interest and humanitarian importance that a brief history of the introduction of anæsthetics should be much appreciated, especially in a rehearsal of American achievements. Strictly speaking, the term anæsthesia refers to the abolition of sensation of all kinds, whereas for the prevention of pain the term analgesia should be used. The distinction is an important one in certain cases; for instance in the injection of cocaine solution into the spinal canal, it produces the latter without the former, whereas by the use of the anæsthetics now in use general anæsthesia is produced. By general consent the term is restricted to complete loss of consciousness produced by such drugs as ether, chloroform and nitrous oxide, and not to the intoxication produced by drugs like opium, hashish or the mandragora of the old writers. The substance known as sulphuric ether had been known by the mediæval alchemists in 1540, and was spoken of as sweet oil of vitriol. It was not called ether until 1730. In the earlier years of the previous century it was often inhaled for experiment or diversion because of its peculiar exhilarant effects. Nitrous oxide gas had been previously used for the same purpose, and even for the production of anæsthesia. It will be seen, then, that these two anæsthetics had been well known for some of their properties. Chloroform, on the other hand, was not discovered until 1831, and not recommended as an anæsthetic until 1847. The honor of the introduction of ether into surgery is claimed for at least four men, Long, of Georgia; Jackson of Massachusetts, who were physicians; Wells, of Vermont, and Morton, of Massachusetts, who were both dentists. The first public demonstration of the value of ether as an anæsthetic agent, for the prevention of pain during surgical operations, was made 16 Oct. 1846 by Morton, at the Massachusetts General Hospital, before a group of men including some of those already mentioned in this article, especially Warren and Bigelow. In all probability Long antedated this event by its use for a similar purpose in 1842, but in those days in this country the population was sparse, means of travel very slow and no public record of the event was ever made; in fact no account of Long's work appeared until 1849. To Wells probably belongs the credit of first producing anæsthesia by nitrous oxide gas, when he took it himself in 1844. After his own happy experience with it he began its manufacture and introduction to the profession. In 1845 Wells visited Boston, and even called on his old partner, Morton, endeavoring there to introduce his new compound for surgical purposes, but met with no encouragement. In Hartford there stands to-day a monument erected by the public, bearing the following inscription: «Horace Wells, who discovered anæsthesia, November 1844.» Morton had been a student in Wells' office, but not being a good chemist he consulted Jackson, whose office he later entered, and by whom he was advised to experiment with ether. Jackson told him, for instance, that the students at Cambridge often inhaled it for amusement, and in 1846 he first gave it for the extraction of a tooth, the patient stating that he felt no pain. Then came efforts to patent the new anæsthetic which were not to the credit of either Jackson or Morton. Finally came the public demonstration above alluded to, when Morton administered his «letheon,» and Warren removed without pain a tumor from the neck of a young man. At this time Morton endeavored to disguise the odor of the substance he was using so as to prevent its recognition, and it was not until the hospital staff declined to use any substance whose composition was kept secret that Morton revealed his discovery. During the ensuing years there took place a most active and acrid controversy between the partisans of the men most concerned in the introduction of ether into surgical work, as to the respective merits of their various champions.

A dispassionate judgment of the whole indicates that to Wells, doubtless, the credit of the introduction of nitrous oxide belongs. Long probably was the first to use ether in a surgical way, but was slow in making his results known. Morton finally became the promoter of the new agent, partly by virtue of his own energy and partly because of his acquaintances and surroundings. Chloroform, although discovered independently by Guthrie, of Sacketts Harbor, N. Y., in 1831, was introduced into surgical work by Simpson, of Edinburgh, who advised it especially for the relief of the pangs of childbirth, and who was, in consequence, violently assailed by the Scottish clergy as interfering with the spirit of the primal curse which read, «In sorrow shalt thou bring forth children.» Simpson, however, disarmed his opponents by a quotation, also from the Scriptures, to the effect that when God created Eve from one of Adam's ribs, he «caused a deep sleep to fall upon Adam.» It will hence be seen that, at the date of this writing, it is almost 70 years since it became possible to make surgical operations painlessly. What this means both for the surgeon and the patient will be appreciated, while what it has made possible can be easily realized by contrasting the resources of the surgeon of to-day with those of the middle of the 19th century. See VIVISECTION — ITS INFLUENCE ON SURGERY.

ROSWELL PARK,
Author of 'Text Book of Surgery.'
ALBERT VAN DER VEER,
Professor of Surgery, Albany Medical College, 1878–1915.

SURGICAL ASSOCIATION, American, a society organized in 1880, the objects of which are to promote the improvement of the science and art of surgery. The active membership is limited to 125 Fellows and the honorary membership to 25 Fellows. An applicant for Fellowship must be 30 years of age, a graduate of five years' standing from a recognized medical college and have an established reputation as practitioner, author or investigator. Meetings are held annually and an annual volume of *Transactions* is published. Every third year the association joins with other associations constituting the Congress of American Physicians and Surgeons in a meeting held in Washington, D. C.

SURICATE, or MEERKAT, a South African civet (*Suricata tridactyla*), which differs from typical viverrines in several points, notably in having only four toes on each foot. It is dark brown and has dark transverse stripes on the rear of its back. The body and head reach a length of 12 or 13 inches, the tail six inches and the animal has a general resemblance to a small raccoon, but the tail is more catlike. It lives in caves and rock-caverns or sometimes digs burrows. It is diurnal, lives mainly on roots and barks like a dog. Consult Martin, 'Home Life on an Ostrich Farm' (New York 1903).

SURIGAO, soo-rē-gä'ō, Philippines, (1) Town, capital of the province of Surigao, Mindanao, on the extreme north coast of the island of Mindanao. This district was the site of the first Spanish mission in the Philippines; in 1879 a series of earthquakes caused the ground in the neighborhood of the town to sink two feet and many of the government buildings were rendered uninhabitable for a time. The chief industries are the gathering and export of pearl shells and trepang and the placer mining of gold. Pop. 7,749.

(2) Province, island of Mindanao, occupying the northeastern part of the island; area, 6,988 square miles. The principal dependent island is Dinagat, lying off the north coast;

it is mountainous, heavily wooded and has deposits of gold; area, 387 square miles; the second island in importance is Siargao (q.v.), 190 square miles. The mainland of the province is traversed by two mountain ranges, extending from north to south, one near the east coast, the other forming the western boundary; spurs of these ranges extend in both directions. The central valley is drained by the Agusan River, one of the finest in the Philippines. Cotton, hemp, rice, sugar, tobacco, indigo, etc., are cultivated; the cocoanut, betel nut and betel pepper are grown for export. Gold is found in the mountains and in the sands of the mountain streams and is mined; the forests are valuable, and gums and resins are obtained in large quantities; fishing is an important industry, and there is some weaving of native fabrics for home use. There are few roads, the communication is by sea or by the rivers and lakes of the central valley. Civil government was established in the province in May 1901, but the jurisdiction of the provincial government does not extend to the non-Christian tribes. Pop. 115,112.

SURIGAO, Strait of, connecting the Sulu Sea with the Pacific, having Mindanao on the south and the islands of Leyte, Panaón, Bohol, Cebu, Negros and Samar on the north. It was the route taken by Magellan after crossing the Pacific. The San Bernardino Strait is now used more than Surigao during certain seasons, but Surigao is the more direct, deeper throughout and the more advantageous route for vessels bound for the southern Philippines.

SURINAM, soo-rĭ-näm'. See Guiana.

SURINAM TOAD, or PIPA TOAD, a toad of the South American family *Pipidæ;* specifically *Pipa americana.* It is one of the largest and the most repulsive-looking of the toads and is noted for its extraordinary mode of developing the eggs and young. When the female is about to expel her eggs the male mounts upon her back and the eggs as they are extruded are squeezed upward between the back of the female and the belly of the male, where they stick to her skin and gradually sink into the spongy skin, each occupying a pit with a lid. Fertilization takes place by some process not well understood just before the extrusion of the ova. The eggs remain in the pits until they have reached a mature condition (although yet very small) and then escape into the water. Consult Gadow, 'Amphibia and Reptiles' (New York 1901).

SURMULLET. See Mullet.

SURNAMES. A surname is a name added to a baptismal or Christian name which makes it more specific, and is generally a family designation. It may be indicative of descent, habitat, craft, or may have originated in totemistic associations, clanship, personal peculiarities or from vulgar nicknames. A proper name, once given or adopted, becomes in time a part of the individuality. The giving of names is not necessarily proof of an advanced civilized condition. It may be considered coeval with and intimately connected with the gift of speech; the Adamic tradition of the origin of common names is a self-evident proposition when applied to pre-Adamic savagery. The primal family grew into the primal tribe, and proper names became necessary; the land and the gathering of men upon it necessitated proper designations for each, or the same name for both.

All proper names have, at first, a peculiarly appropriate meaning, which in time often becomes obscured and ultimately forgotten. Schlegel traced descriptive epithets in almost all Hindu names, and the older names among the Hebrews, Arabs, in fact all Oriental nations, are highly significant and grotesque; as, "son of wool," "son of wealth," "son of the scythe," "young of dog," "prince of the dogs" among the Tcherkessians of Mount Caucasus. This is measurably true of names of Aryan origin, and noticeably those of Teutonic and Scandinavian lines. The North American native is usually named from some animal, for totemic reasons, and later earns another from some deed of daring performed; and similar practices prevail in all savage tribes. In fact, the origin of heraldry may be looked for in totemic devices and symbols.

The study of proper names is useful in historical and literary researches — as important as numismatics, heraldry, superstitions, symbolism and tradition. The name of a man often retains the impress of his country, and sometimes of the period in which he lived, and may thus furnish a clue to correct a date or vague notion, or to settle a disputed question in chronology, geography or genealogy; the conquerors of Andalusia, the Vandals, gave their name to that province, and it is hence not derived from Andalus, son of Japhet and grandson of Noah; the posterity of one man cannot, in reason, cover 30 degrees of longitude, in three generations, in a barbaric age.

In Rome, family or clan names were hereditary, but surnames remained individual, sanctioned by public consent, as Scipio Nasica, Piso Frugi, Lentulus Sura. In the republics of Greece, notably Athens and Sparta, men's names were significant of the power, valor, virtues or victories of the people, as Agesilaus, Charidemus, Demagorus, Demophilus, Demosthenes, Laodice. In fact it is common among all peoples to exaggerate the importance of the significance of names. Both Greeks and Romans augured well or ill from them. Grecian names are significant, either of religious feeling, the remembrance of great events, some happy omen, chance, friendship or gratitude. Daughters were named from their fathers more scrupulously than were the sons; Homer uses their names in this wise without exception, as Chryseis, the daughter of Chryses; Briseis, the daughter of Briseus. The son's name was frequently an enlarged form of the father's, as it was deemed that polysyllabic names were more honorable than shorter ones, which were given to slaves; the Spartan Hegesander named his son Hegesandrides, and Hiero, tyrant of Syracuse, named his son Hieronymus. There are traces of a desire to adopt family names, among the Greeks, but it generally ended in a vague reference to the hero from whom the family sprung; these surnames were only adopted by those families who pretended to trace back to deities or fabulous periods of history.

The Scandinavians and largely the Germans had none but individual names; every family, as with the Greeks, showed a decided preference for certain names, and these were generally transmitted from grandfather to grandson, or from uncle to nephew, for some occult reason, while the daughter was only known by her father's name (as Alf-hide meaning literally the child of Alf'r). Others retained the root from which the head of the family derived his name, but varying the other syllables (thus, the three sons of the formidable Argrim retained the last syllable which signified rage). There were thus no family names among the Celts, strictly speaking. The songs of the Druids have perished with the names of the heroes they sang of; but more fortunate were the heroes of Erin and Morven, for the ancient national songs still exist in Ireland and Scotland.

The need of surnames began to be felt. Many would naturally prove themselves «dreadful-in-the fight,» «Hardy,» «Stern-of-look,» and the Northern nations soon adopted a method of adding the father's name to the son's; as Oscar son of Ossian, Oscar son of Caruth, Dermid son of Duthnò, Dermid son of Diaran. The introduction of Christianity, which taught the equality of man, breaking up class distinctions, rapidly advanced the adoption of surnames by the use of new or baptismal names — Biblical or saints' names, anything but pagan cognomens — and this caused endless confusion; the new names were almost wholly derived from foreign languages, and as such had no local or personal significance.

The rise of feudal power was another source of change and confusion, as retainers or feoffees often bore the name of their overlord, whose title might arise from his office at court or his most valuable estate. The division of estates led to a new distribution of surnames among the heirs, taken from the inherited estates, only the oldest retaining the father's name by reason of the name being attached to the home-estate. The charters of the 10th and 11th centuries often recited the same individual under different names — sometimes because he had lost the manor which gave him title, or had come into possession of another which was more flattering to his vanity. The law of primogeniture finally cleared away much confusion, the property becoming settled in tenure and the owner desiring to proclaim his patent of nobility; from that time a surname was rarely lost and was further confirmed by the granting of armorial bearings.

In heraldry we find many surnames derived from «canting arms,» which clearly proceed from the arms; as in Sweden, the family whose arms represented the head of an ox took the name Oxenstiern (like the well-known Front-de-Bœf); the Racines had originally placed in their coat-of-arms a rat and a swan (Rat-Cygne), but the writer of «Athalie» retained only the swan, as the rat offended his taste.

To England the Saxons brought their feudal institutions; immense properties were attached to the king and his Thanes, and they farmed them out to substantial tenants who again let them to subtenants for cultivation. William the Conqueror redistributed these lands as fiefs among his Norman warriors; Henry I, in 1100, changed the fief tenure into real or freehold property, but his concession produced no great increase of hereditary names. In 1160 Henry II enfranchised the land in order to counteract the ambitious barons; soon after his time hereditary names became common in England.

It appears that surnames began to be adopted in England about 1000 A.D., coming mainly from Normandy. A few Saxons had surnames: «Hwita Hatte was a keeper of bees in Hœthfelda, and Tate Hatte, his daughter, was the mother of Wulsige, the shooter,» in the Cottonian manuscript shows a transition point. In the time of Edward the Confessor there were Saxon tenants in Suffolk: Leuric Hobbesune (Hobson), Suert Magno or Manni, Godric Poinc, Tedricus Pointel, Siuward Rufus (redhead) and Stigand Soror. In the Domesday Survey they were becoming more common: as Alwin Dodesune (Dodson), Walter Achet, Osmund Angevin, Roger Arundel, Walter Bec, William Bonvaslet; some of these being curious Norman blends of their own names with those of their Norman masters, as above in Arundel and Angevin. When King Magnus assumed Highland dress he became known as Berbeinn (Bareleg), still preserved, probably, in the Puritan «Barebones.»

The terminations *ing, kin, son,* in English names, were derived from the Norse *ingr, kyn* and *sonr,* the *r* being dropped. The Danish make the last sen. The diminutives: Friesian, *ken, ke, ock, cock* (a foolish fellow, hence the Scotch «gowk»); Norman-French *et, ette, let, ot, otte, el;* Old Norse, *i, a, ki, ka, gi, ga, ungr, ingr* and *ling,* became quite common additions to English names, which have since adhered.

The Gaelic *Mac,* Irish *O',* the British *Ap,* the Norse *ungar,* the Friesian *ingar* and *en,* the Anglo-Saxon *ing,* the Norman *Fitz* (probably from Flanders originally; many Irish families substituted Fitz for Mac in Norman times) are all ancient family prefixes. The ancient tribe of Waring or Wearing, the Vœringi or Veringun (originally from the Vœringifjord in Norway) formed the celebrated Varangian guard of the Byzantine emperors, which was afterward largely recruited from the North and especially from England.

In England, as of old in Schleswig, the village community formed the unit of English society. Each such township was still bounded by its mark of forest, mere or fen, which divided it from its nearest neighbors. In each lived a single clan, supposed to of kindred blood and bearing a common name. Many family names are thus perpetuated in England; as the Bassingas at Bassingbourne in Cambridgeshire; at Bassingfield in Notts; at Bassingthorpe and Bassingham in Lincolnshire; and at Bassington in Northumberland. The Billings have left their stamp at Billing in Northampton; Billingford, in Norfolk; Billingham, in Durham; Billingley, in Yorkshire; and Billinghurst, in Sussex. Birmingham, Nottingham, Wellington, Farington, Warrington and Wallingford are well-known names formed on the same analogy. In London alone occur the clan settlements at Kensington, Paddington, Notting-hill, Billingsgate, Islington, Newington, Kennington, Wapping and Teddington. There are altogether 1,400 names of this type in England.

Totemism consists in the belief that each family is literally descended from a particular animal or plant whose name it bears and members of the family formerly refused to pluck the plant or kill the animal after which they were named. The genealogies of the Anglo-Saxon kings include such names as those of the horse, the mare, the ash, the whale. In the ancient poem 'Beowulf,' two of the characters bear the names of Wulf and Eofer (boar); the wolf and the raven were sacred animals. The boar was greatly reverenced and our Christmas boar's head is a survival of the old belief. The oak has left its traces in Oakington, in Cambridge; the birch, at Birchington, in Kent; the boar (eofer) in Evringham in Yorkshire; the hawk in Hawkinge in Kent; the horse, at Horsington, in Lincolnshire; the raven, at Ravingham, in Norfolk; the sun, at Sunning in Berks; and the serpent (wyrm) at Wormingford, Worminghall and Wormington in Essex, Bucks and Gloucestershire, respectively. Every one of these objects is a common and well-known totem among savage tribes and the inference that at some early period the Anglo-Saxons had been totemists is almost irresistible.

The suffix *atte,* as implying residence, if not possession, crept in, and thereby arose such names as Atte Bourne, Atte Brigg, Atte Hash, Atte Hay, Atte Kirkstile, Atte Lane, Atte Maydens, Atte Stile, Atte Well; the modern names Atwater, Atwood and Atwell occur to us today. The *de* and *atte* were often dropped, hence arose names like Wood, Lane, Briggs. Many names that seem to defy all explanation are disguised beyond recognition; as, who would expect to find Sevenoaks in Snooks; Saint Olave's street in Tooley street; Saint Etheldreda in Tawdry; Douglas in Diggles; Wilburgham in Wilbraham; Tuberville in Troublefield; Longueville in Longfellow; Longchamps in Longshanks; Blondeville in Blomfield; Adburgham in Abraham and Abram; Renshaw in Wrencher and Wrinch; Wymondham in Wyndham. As Mr. Lower truly says: «Corruptions which many family names have undergone tend to baffle alike the genealogical and etymological inquirer.» The name of Shakespeare has had at least 27 permutations in old documents; Goodwin, 17; Finnimore or Phillimore 59 and 34 of the latter surname.

When the country became settled under Edward the Confessor and the Norseman, Saxon and Welshman lived together under a semblance of law and order, official names arose: as Lagman (lawgiver), Fawcett (forseti, judge), Alderman, Reeve, Sheriff, Tabberer, Chamberlain, Chancellor, Chaplain, Clerk, Deacon, Beadle, Latimer (Latinarius, an interpreter), Miles (miles, a soldier), Marshall, Sumner (a summoner, as Chaucer's «Sompnoure»), Parker (a park-keeper), Franklin (a freeholder), Botiler (butler). Trade names and craft names are of later origin; but it is an open question whether some of the names popularly ascribed to occupations will not bear different interpretation.

Because America is a country made up of all nations there exists in the United States a greater variety of names than anywhere else on the globe. Russian, Polish and middle European names seem particularly hard for the American to grasp, and, therefore, immigrants, finding their long names a handicap, are apt to shorten them. Tolchinsky becomes Tolins, and Rawitzer is shortened to Rawser. There is also a tendency to translate names. Herr Vogel becomes Mr. Bird, and Mons. Pantoflen is Mr. Slipper. One is amazed at the combinations disclosed in any large city directory, as in the firms of Au and Magenheimer, Stretch and Shrink, and the famous Call and Tuttle, Preserved Hoskins, Singular Onions Gallyhawk and Esa Hogg must each and all bear grudges against those who inflicted such names on them. It is a fact that all three of these names have appeared in city directories.

Consult Lower, 'Patronymica Britannica'; Bardsley's 'English Surnames'; Wagner's 'Names and their Meaning'; Mordacque's 'History of Names'; Barber's 'British Family Names'; Grant Allen's 'Anglo-Saxon Britain'; and 'Origines Genealogicæ,' by Stacey Grimaldi.

SURPLICE, a garment of white linen, sometimes adorned with lace, worn over the cassock by priests, choristers and other attendants in the chancel during the divine service and by ministers in the solemn administration of the sacraments. It is usually a loose, flowing garment, varying in length: in the 12th century it reached to the ankles and this length was prescribed by the Council of Basel (15th century); in the Anglican Church the surplice reaches almost to the feet. In the Roman Catholic Church its length is much less, never extending below the knees, while in the Italian fashion it does not reach nearly so far and is known as the cotta. See COSTUME, ECCLESIASTICAL.

SURRA, a disease of domestic cattle in the Philippines, due to the presence in the system of a protozoan parasite.

SURRENDER, *in law,* the restoring or giving up, as an estate for years, to the reversioner or remainderman, by which act the surrendered estate is merged in the other; also, the written instrument evidencing such surrender. It should be distinguished from a release, which is an alienation of the estate by the reversioner or remainderman to the tenant. It should also be distinguished from a renunciaction, which is the refusal to take an estate to which one is entitled by law. A surrender by agreement must be in writing, but it may take place by operation of law, as where a landlord accepts another person as tenant.

SURREY, sŭr'ĭ, **Henry Howard,** English poet: b. about 1517; d. 21 Jan. 1547. He was the grandson of the Earl of Surrey who was the victor at Flodden, and who, as a reward for his services, was created Duke of Norfolk. He succeeded to the courtesy title of Earl of Surrey when his father became third Duke of Norfolk of the Howard house in 1524. Surrey became companion to the Duke of Richmond, a natural son of Henry VIII, and in 1533 traveled with him to the French court. He took part in the suppression of the Pilgrimage of Grace in 1536 and in the following year was imprisoned for striking a courtier who had repeated a rumor of his sympathy with the rebels. He served in the army on the Continent and in 1545 was appointed commander of Boulogne, but he was shortly afterward defeated by the French and superseded in his command. Shortly before Henry's death Surrey and his father were suspected of aiming at the throne and were arrested and lodged in the Tower and Surrey was tried, condemned and executed. In 1538 there was published his translation of the second and fourth books of Virgil's 'Æneid,' the first attempt at blank verse in English. He also wrote many sonnets after the Italian model. There is an edition of his works in the 'Arber Reprints.' Consult Hales, J. W., 'Folia Literaria' (London 1893).

SURREY, a kind of light carriage having two seats in a box mounted on side bars, four wheels and sometimes a top.

SURROGATE, formerly a deputy, a substitute, a delegate, a person appointed to act for another. In the United States, an officer who presides over the probate of wills and testaments and the settlement of estates. In English law, one appointed by a bishop or his chancellor or by an ecclesiastical judge, to issue licenses for marriages without bans and to deal with probate and kindred matters.

SURROGATES' COURTS. See COURT.

SURTEES, sėr'tēz, **Robert**, English author: b. Durham, 1 April 1779; d. 11 Feb. 1834. He was graduated from Oxford in 1803 and studied law at the Middle Temple till he inherited an estate near Bishop Auckland in 1802. Thenceforth he devoted himself to preparing a 'History and Antiquities of the County Palatine of Durham' (1816–23), to the fourth volume (1840) of which, completed by Raine, a 'Memoir' of Surtees is prefixed. The Surtees Society, founded in 1834 for editing unpublished manuscripts chiefly relating to the northern counties of England, published its 73d volume in 1884. Consult Taylor, G., 'Life of Surtees' (Durham 1852).

SURVEYING, the science of determining accurately the relative locations of points and lines on the earth's surface and of recording the same on maps; it includes also the reverse operation of discovering and locating on the ground points and lines depicted on a surveyor's map.

Two principal kinds of surveying are recognized, plane and geodetic. In plane surveying the area which is the subject of survey is regarded as a plane surface, the curvature of the earth being disregarded. In geodetic surveying, which deals with areas of large extent, the curvature of the earth is considered and given its proper circumstance.

Plane surveying consists essentially of the lineal measurement of lines and the spacial measurement of angles, either vertical or horizontal; together with the subsequent calculation of the content of areas to which such lines and angles appertain. It includes as classes (1) land surveys — the defining of the boundaries of land areas; (2) topographical surveys — the determining of variations in altitude and the denotation of physical characteristics; as, for instance, roads, rivers, forests, swamps, etc.; (3) construction surveys — the staking out of bridges, buildings, sewers, railways, etc. As the earliest records of man refer to skilful measurements and calculations, it is impossible to assign the birth of the science of surveying to any particular year or even century. Foreip states that, according to the Chaldæans, 4,000 camel steps make one mile, 66⅔ miles one degree, from which the circumference of the earth is 24,000 miles. A papyrus in the British Museum, written 1700 B.C., gives rules for calculating the areas of triangles, trapezoids and circles and the works of Hero of Alexandria (285 B.C.) mention mine surveying and the relatively crude instruments used at that time. In 1617 Snellius, in Holland, made one of the first attempts to determine accurately the earth's radius. Picard, in 1667, adapted cross-wires to a telescope. In 1735 the French Academy of Scientists sent out two surveying expeditions, one to Peru and one to Lapland. The latter resulted in the first demonstration that the earth is not a sphere but an oblate spheroid. The invention of the vernier by Venierus in 1631 and of the transit by Roemer in 1672 gave an impetus to the science of surveying, the final results of which are yet to be achieved.

Chain Surveying.—A great variety of work can be done by the use of a chain or tape alone, as, with the measuring of straight lines, the areas of triangles, rectangles and even polygons can be ascertained by dividing the polygon into triangles which are then measured. Angles can be ascertained by laying off equal lengths, b, from the vertex, A, on the two lines, then measuring the third side, a (base of isosceles), and using either of the following formulæ:

$$\text{Tan } \tfrac{1}{2} A = \frac{a}{\sqrt{4b^2 - a^2}} \text{ or Sine } \frac{A}{2} = \frac{a}{2b}.$$

The angle may then be looked up in a table of sines and tangents. The measurement of inaccessible lines can also be accomplished with the use of only an accurate tape line, as shown in the accompanying Fig. 1. Assume CB to represent the distance to be determined. Lay out from C a perpendicular line (CD) to the point D, from which also the point B is visible; and from D lay DC off DC perpendicular to DB, cutting the extension of the line BC at E. There are then the two similar triangles whose corresponding sides are proportional; and we have the proportion — DC:CB::CE:DC — from which we find $CB = \frac{DC^2}{CE}$. It remains only to measure DC and CE with the closest accuracy possible and to substitute their values in the proportion. The laying of the perpendicular is a simple application of the *pons asinorum* of the geometry — "The square of the hypothenuse of a right-angled triangle is equal to the sum of the squares on the other two sides." In surveying practice this becomes the striking of two curves from the points X and Y respectively, these two points being eight feet apart. The radius of the curve from X is to be six feet, and that from Y 10 feet. The point Z where these curves intersect will be in a perpendicular to XY from the point X, the angle YXZ being a right angle. But such measurements are not comparable with work done with the aid of the transit.

Compass Surveying.— The use of the azimuth compass is considerably restricted for several reasons, namely: The magnetic needle points north at but few places on the earth, the disagreement varying from 1° to 50° from true north. This disagreement, or the angle between true north and the magnetic needle, is called the "declination of the needle." The declination does not remain constant, however, there being diurnal, annual and local variations from the normal declination which introduce unknown errors into the compass survey. The diurnal variation is usually not more than 6 minutes but may reach 20 minutes. It is usually zero at 11 o'clock A.M.; the annual, 1 to 2 minutes, and the local variation amounts to as much as several degrees in some localities, owing to deposits of iron ore near the surface. Errors from this source may be avoided by back sights at each station. There are also secular variations in the declination, so that when retracing the lines of a compass survey made several years previously, the surveyor must use the same declination used in the original survey. In making a compass survey it is necessary to determine the declination of the needle by an observation on a polar star, or on the sun with the aid of a solar attachment (see below). The stellar observation is usually made on Polaris which, however, is not precisely at the north pole. It is necessary, therefore, to make the observation exactly at the time of upper or lower culmination, or at eastern or western elongation; a correction being required in the later case. Tables have been published, however, by the United States Land Office for taking the observations on Polaris at any convenient time.

where surveyed correctly — hence the necessity for correction lines every 24 miles as noted above. The distances between the meridians at certain latitudes are in proportion to the cosines of the respective latitudes concerned.

There are several methods of surveying north and south boundary lines of townships and sections so as to make them conform to a parallel of latitude, but the secant method is the one commonly employed (Fig. 4). Briefly stated it is as follows: A straight line, for convenience called a secant, is run upon a certain course, precisely calculated (nearly due west), and dependent upon the latitude, and from such a point as will cause it to intersect the curve of the parallel of latitude (boundary line) at the mile and five mile points. From this secant line offsets, as previously calculated, are measured north or south as required at the mile and half mile points, to points in the curve or boundary line where monuments are placed. Convenient tables are published by the United States Land Office which show the azimuths and offsets required at any latitude in the United States.

Government Land Surveying.— The first public surveys in the United States were made in the State of Ohio under an ordinance of the Continental Congress passed 20 May 1785. This ordinance was slightly modified by an act of Congress, passed 18 May 1796. This act, which is still in force, provided that all public land, except certain private land grants shall be divided into townships six miles square, and that sections shall be subdivided into one-fourth sections one-half mile square. The act further provides that all lines of public land surveys shall be run on either true meridians or true parallels of latitude. The method of surveying townships and sections is as follows: *First* — In each State, or convenient group of States, there is established a principle (true) meridian, and, at right angles thereto, a base line conforming to a true parallel of latitude. *Second* — Standard parallels or correction lines, also conforming to parallels of latitude, are established at intervals of 24 miles north and south of the base line. *Third*— Guide meridians conforming to true meridians are initiated at intervals of 24 miles along all standard parallels, and run due north to the intersection of the next standard parallel. *Fourth* — The rectangles thus formed by the guide meridians and standard parallels are subdivided into 16 townships. As meridians converge toward the north pole the north boundary lines of townships are less than six miles long

Traversing.— This is a method of surveying a polygon by surveying its perimeter only, as distinguished from the method of cutting the polygon up into triangles (Fig. 5). In a

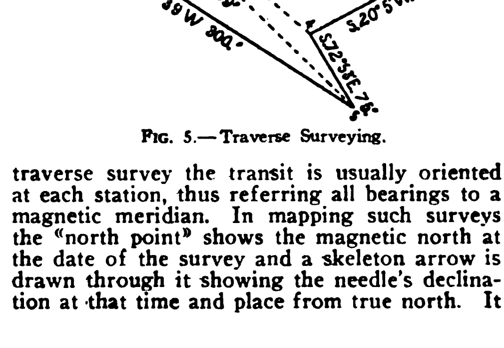

Fig. 5.— Traverse Surveying.

traverse survey the transit is usually oriented at each station, thus referring all bearings to a magnetic meridian. In mapping such surveys the «north point» shows the magnetic north at the date of the survey and a skeleton arrow is drawn through it showing the needle's declination at that time and place from true north. It is not necessary to take convergence of the meridians into account except in geodetic work. The method of procedure is as follows: The transit is set up at station No. 1 and the bearing and distance of the first course determined. The transit is then removed to station No. 2. With vernier "A" still at the previous reading, the lower spindle is unclamped and a plumbed rod bisected at station No. 1, ***with the telescope inverted***. The telescope is then revolved to its normal position, unclamped, and the bearing and distance to station No. 3 ascertained. The transit is then removed to station No. 3 and the operations repeated. To illustrate this important branch of surveying the tabling of a traverse and the rules governing the same are given in the table on the preceding page.

In the foregoing "tabling" the latitude and departure of each course is found by multiplying the distance by the cosine and sine of the angle expressed by the bearing. The latitude and departure ordinates are self-explanatory. The single meridian distances are the departures of the respective stations from the most westerly station. The double meridian distances of the respective courses are equal to the sum of the single meridian distances of the stations at each end of the respective courses. Each North and South area is equal to the product of the latitude of a course into its corresponding double meridian distance. The area of any polygon is equal to one-half the difference between the sum of the North and South areas. When the course and distance of any side of any polygon is lacking it is found as follows: Ascertain the difference between the north and south latitudes and the difference between the east and west departures. Divide the difference in departures by the difference in latitudes for the tangent of the bearing. Divide the difference in departures by the sine of the bearing found, for the distance.

Topographical Surveying.— In order to facilitate the selection of a route for a railroad, to properly locate an irrigation reservoir or dam for power purposes, or to correctly make a geological survey of a large tract it is generally necessary to make a topographical survey of the area under consideration. From the field notes of the survey a map is made showing the surface elevations with considerable particularity by a system of contour lines at stated differences in level, and also showing all important objects, such as buildings, roads, canals, fences, streams, etc. There are several methods of making a topographical survey. First, by the use of a tape, level and transit. Second, by the use of the plane-table. Third, by the use of a transit and stadia rod. The last-named method alone will be discussed here, it being the method usually adopted, on account of its celerity and low cost. Stadia wires are two horizontal wires placed in an adjustable ring so that they appear at equal distances above and below the horizontal cross-wire when looking through the telescope.

The theory of stadia measurements is based on the two following equations:

$$1.\quad i : o :: f_1 : f_2$$

$$2.\quad \frac{1}{f_1} + \frac{1}{f_2} = \frac{1}{f}$$

in which "i" is the height of image or distance between the stadia wires, "o" the height of object or the stadia reading on the rod, "f_1" the distance from the lens to the image, "f_2" the distance from lens to the object and "f" the focal length of the lens. From the above equations and other considerations it can be shown that when the rod is held vertical at various points in the line of sight, the rod readings will be proportional to the respective distances from the rod to a point at a distance "f" in front of the lens of the telescope. It can also be shown that the distance from the stadia rod to the centre of the transit is equal to the sum of three factors, namely, the rod reading, the distance "f," and the distance from the lens to the centre of the transit, "c." But this is true only for horizontal sights, for when the rod is held upon an elevation, as a hill, then "f_2" becomes the slope distance and, moreover, the stadia wires will intercept a length on the rod greater than the slope distance. Therefore, if the stadia wires be adjusted so that they will intercept a space of one foot on the rod at a horizontal distance equal to c + f + 100 feet from the centre of the transit, then the true horizontal distance to any point above or below the horizontal line will be found by the following equation:

$$3.\quad D = 100\ r \cos^2 v + (c + f) \cos v.$$

In which

D = true distance horizontally.
v = vertical angle.
c = centre of transit to object lens.
f = focal length of lens.

The height is found by multiplying the horizontal distance by the sine of the vertical angle. Tables are published containing the factors for the various vertical angles.

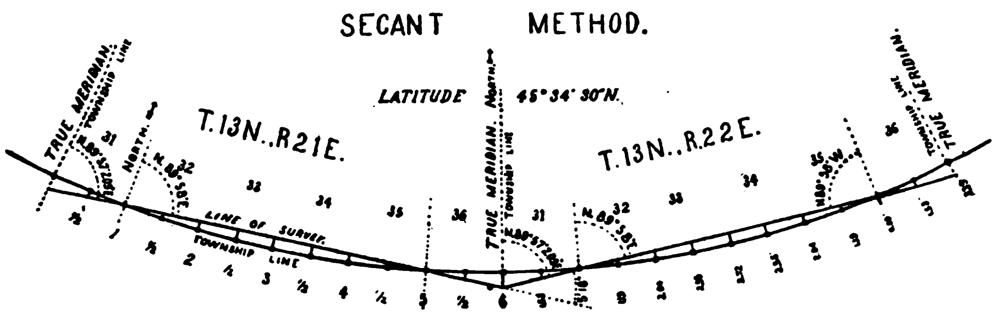

Fig. 4.—Land Surveying Secant Method.

In topographical field work where the area to be surveyed is considerable it is usual to first lay out a triangulation net work, all measurements being made with a tape or by triangulation from an accurately measured base line and the stadia measurements taken from the triangulation stations. In work of less magnitude it is not necessary to lay out a system of triangles, but all measurements from station to station are carefully made and checked by cross-readings. The location of objects is quickly and accurately accomplished by sights from two different points of the measured line. In making a map of a topographical survey there are several methods employed. One requires the use of a T-square and brass protractor, another and a better method is by the use of a protractor sheet larger than the sheet upon which the drawing is to be made. After all distances are laid off and the heights indicated at the various points, contour lines are drawn in by proportioning the distance between points with reference to heights. Sometimes the contour lines are drawn in pencil to be afterward erased and the «hatchure» method of representing topography employed.

Mines Surveying.— The chief purposes of an underground survey are to ascertain the amount of ore «in sight,» to find the «pitch» and position of the «pay chute» with respect to the shaft and levels, to find the «dip» of the vein and also to ascertain and lay out the direction of connections commonly called «holings.» Moreover the laws of some States and countries require plans of the underground workings to be kept on file. Ventilation being one of the serious problems in mining — especially coal mining — it is generally necessary to make passageways or «holings» connecting the various drifts and levels in such a way as to facilitate the circulation of fresh air throughout the mine. In order to make these connections a careful transit survey is necessary, the compass needle being unreliable in the presence of pipes, rails, ore cars, etc. While mine surveying does not call for the precision of a geodetic survey, cases arise requiring great skill and ingenuity. One of the chief difficulties is to transfer the bearing or azimuth of a surface line to the lower workings. This is especially difficult if the survey has to be carried down a deep vertical or inclined shaft. In vertical shafts heavy plumb-bobs suspended in pails of water or molasses at the bottom of the shaft by means of wires reaching to the surface have been successfully used. A transit with a secondary telescope, so attached to the extended axis of the primary telescope that it may be sighted vertically downward, is also used for this purpose. In underground work it is necessary to note both vertical and horizontal angles and to make tape measurements on the slope or level as the circumstances may permit. Illuminated plumb-lines are used for fore and back sights and it is also necessary to hold a candle so as to illuminate the telescope cross-wires. Permanent pegs for future use are usually placed in the roof instead of in the floor of a drift and even then their position must be often checked for ground moves considerably in some mines.

Geodesy.— This branch of surveying has for its object the exact location of points and lines with reference to the true form of the earth. In most geodetic work the earth is assumed to be an oblate spheroid, all measured angles and distances being reduced to spheroidal angles and distances. The United States Coast and Geodetic Survey had adopted the «Clarks spheroid of 1866.» The foundation of a geodetic survey is a base line. This is most carefully measured with specially constructed bars of invar steel (q.v.) encased in wood, called a «Base line apparatus.» Base lines can be measured with steel tapes with an accuracy of one in 1,000,000 under favorable circumstances. These tapes have a screw adjustment for temperature as shown by a thermometer in the handle and there is also a helical spring attachment for regulating exactly the pull used in stretching the tape. Two tapes are used in each measurement and, in case of disagreement are compared with a third and fourth tape. An accuracy of one in 300,000 is generally accepted as satisfactory. With a base line as a nucleus, a system of triangles is laid out over the surrounding country, additional base lines being measured from time to time to serve as a check upon the work. In a primary triangulation the sides of the triangles are very long — 20 to 100 miles. The first series of triangles laid from the base line are as nearly equilateral as they can be made. This conduces to accuracy in the larger triangles. Within the primary triangles secondary and tertiary triangles are laid out, the lines of which are from 1 to 20 miles in length. Angles are measured with specially constructed transits, average results of several readings by the «continuous reading» method being necessary. The unknown sides and angles of the spheroidal triangles are calculated and, when possible, the angles are checked by actual observation. Vertical angles are also read at each station and corrected for refraction and curvature of the earth. The permissible error in a primary triangulation by the United States Coast and Geodetic Survey is one-fourth inch per mile or one in about 250,000; the permissible error in the measurement of an angle is three-tenths of a second and the closing error must not exceed five seconds, or one in about 260,000. As it is impossible to measure angles with absolute accuracy it is necessary to adjust the angular measurement by a system of averaging errors. In determining the azimuth of any geodetic line the convergence of the meridians has also to be taken into account.

Hydrographic Surveying.— This includes surveys for determining the depths of water in rivers, bays and harbors for purposes of navigation; the determination of velocity and direction of currents; the location of hidden rocks or shoals and buoys, lights, etc.; and the determination of the amount of silt or sediment carried by streams and deposited in bays. Permanent bench-marks and stations are generally made on shore, and the points at which soundings are taken located by triangulation. There are several methods of locating sounding points. First, an observer with a transit is stationed at each end of a base line. At the instant the man on the water makes a sounding he signals the two transitmen to take their observations for azimuth. Second, by the «three point problem.» That is, by reading from the boat two angles to three points on shore whose relative positions are known. Of course, sextants only can be used for measuring angles from the boat.

Soundings are taken in feet or fathoms, the mean water level being taken as the datum plane. For tide waters the average sea-level is ascertained by means of a tide-gauge. In some cases automatic tide-gauges are kept in operation for one or more years to determine an average sea-level.

The velocity of water currents in large streams is ascertained by means of a current metre, several styles being in use. The flow of the water in small streams is best determined by means of a weir.

Photographic Surveying.— The use of the camera in surveying is comparatively recent and, though its use is restricted in many ways, it has come into quite general use. It may be called a successful rival to the plane-table. Photo-surveying has been used with success in Italy, India, France, United States and Canada. In the latter country it has supplanted the plane-table almost entirely.

The advantages of a photo-transit are that with it more rapid and cheaper work can be done than by any other means. The results, however, are not as satisfactory as with the plane-table. The photo-topographer must have a thorough knowledge of perspective drawing, descriptive geometry and photography. The instrument used consists of a compass or a horizontal, graduated plate with a vernier, to which is attached a camera having a sensitive level and a means of very accurately measuring the focal length at the time each view is taken. If a box camera having a universal lens is used this latter requirement is not necessary. There is also attached to the top or side of the camera a telescope having stadia wires and a vertical circle. Some styles have a scale so placed in the box that it is photographed on the plate when the view is taken. In any case four projecting needles or two cross-wires are so placed in the box that they will indicate the horizon and line of sight in the developed negative. The stadia rod is also photographed as a part of the record. The topographical map is drawn in accordance with the principles of perspective drawing and descriptive geometry, from measurements taken from the photograph, the compass bearing and stadia measurements being taken into account.

Plane-table Surveying.— A plane-table consists essentially of a drawing board mounted upon a tripod together with an alidade, an alidade being a graduated ruler carrying a telescope. (Fig. 3). A graduated vertical circle for measuring vertical angles is attached to the telescope, and stadia wires for measuring distances are often inserted in it. In operation, the drawing board is covered with a sheet of drawing paper and the alidade telescope sighted consecutively to the various objects which are to be represented in the drawing, pencil lines being drawn upon the paper along the edge of the ruler at each sighting. The plane-table is then set up over another station whose relative position has been fixed by survey with respect to the first station, and sights taken to all the points sighted from the first station. The pencil lines will intersect at the points which represent the respective objects. Stadia readings are often taken with the alidade telescope, the true elevation and horizontal distances being taken from a slide rule constructed for that purpose. The plane-table is much used by the United States Coast Survey and the United States Geological Survey, as more topographical work can be done in less time by its use than by any other means except photo-topography. Errors in azimuth are impossible and more complete work can be done by making the drawing in the field than by plotting from field notes in the office.

Railroad Surveying.— Railroad surveys are either preliminary, for the study of the terrain, or for the purpose of actual location. A preliminary survey is often nothing more than a topographical survey of a comparatively wide strip of country through which it is expected to run the line, a paper location being made in the office and the location survey of the paper location afterward made upon the ground. While a topographical survey gives little or no information regarding cuts and fills it is of great value in deciding upon the most advantageous location.

Briefly stated a railroad location survey consists of a survey of curves, the tangents joining them and the grades. Tangents and curves are laid out with a transit, the grades and cross-sections being worked out with a level. From the cross-section field notes the cubic yards of earth or rock in the cuts and the volume of the fills is computed in the office. The grade line is so located that the material taken from cuts will furnish enough material to make the fills. All straight portions of a railroad are called «tangents,» and the curves are surveyed as the sides of an inscribed polygon of equal sides, each side being 100 feet. (Fig. 6). The «degree of curve,» D, is the angle at the centre

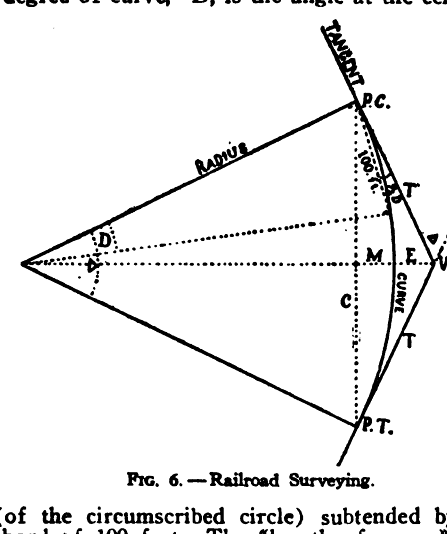

FIG. 6.—Railroad Surveying.

(of the circumscribed circle) subtended by a chord of 100 feet. The «length of curve,» L, is the sum of the sides of the inscribed polygon. The «central angle,» Δ_1 is the angle at the centre included between the radii which pass through the tangent points. It is equal to the external angle of the polygon, that is, the deflection angle of the tangents. The «tangent distance,» T, is the distance from the vertex to either tangent point. The conditions are such that in any simple railroad curve:

1. $\sin {}^1/_2 D = \frac{50}{R}$ 4. $\sin {}^1/_2 d = \frac{C}{100} \sin {}^1/_2 D$

2. $T = R \tan {}^1/_2 \Delta$ 5. $R = T \cot {}^1/_2 \Delta$

3. $L = 100 - \frac{\Delta}{D}$

By means of the above and other formulæ all the elements of a railroad curve can be computed. Where tracks are to be laid especially for trains of certain speed it is the practice to lay out compound curves approaching closely the parabola, in order to make a more gradual transition from tangent to curve. When passenger and freight trains run upon separate parallel lines the outer rail of the passenger line is made higher than the outer rail of the freight line, to better counter the higher centrifugal force at the greater speed. There are several methods of surveying a railroad curve: by tangent offsets, by ordinates from a long chord, by middle ordinates, by offsets from chords produced and by deflection angles. Circumstances determine the method to be used. Tables are published giving the formulæ and other information needed by the railroad surveyor.

Leveling.— Ordinary leveling is usually done with either a «Dumpy» or a «Y» level, the latter being favored by American engineers. The superiority of the «Y» level is due to its construction, which permits the telescope to be reversed in the Y's. Some levels have stadia wires inserted for reading distances and in some cases these are so placed that they can be thrown out of focus by revolving the eye piece, thus making it impossible to make an error by reading a stadia wire instead of the central cross-wire. In order to increase the clearness and sharpness of vision, levels are often rendered «inverting» by omitting one lens. Ordinary level rods are made to telescope — that is, lengthen or shorten — and are usually graduated into feet, tenths and hundredths of feet, but they can be read to thousandths of a foot by the aid of a vernier attached to the target. In precise leveling three methods are practised by the United States government, depending upon the instruments used. The United States engineers employ the «Kern» level and a «speaking» rod, the United States Coast and Geodetic Survey employs a peculiar instrument called a Geodesic level, which requires lengthy and expensive computations. The United States Geological Survey employs a modification of the ordinary Y level and either «speaking» or target rods. In precise leveling the fore and back sights must be taken at the same distance, otherwise a correction for curvature of the earth must be applied. One method of checking a line of levels is to level back over the same line of pegs. Another and a better check method is to employ two rods and two rodmen with one levelman, two independent lines of turning points being run. Precise level rods are usually non-telescopic, that is, made in one piece, and the wood is heated and then paraffined. Graduations are sometimes on strips of metal countersunk into the wood. The limit of permissible error of the United States Coast and Geodetic Survey is $.02 \times \sqrt{\text{distance in miles}}$, the product expressed in feet.

Solar Attachment.— This is an instrument which may be attached to a compass or transit to aid in determining the meridian, latitude and time by observations made on the sun. There are various forms manufactured, the Burt and the Smith being those most extensively in use. The solar is usually secured to the transit telescope and it is used at any time of day, the early morning, late evening and noon hours being avoided for reasons too lengthy to be explained here.

In order to determine the true meridian from the sun it is necessary to ascertain the declination of the sun at the time of observation. A solar ephemeris or nautical almanac will give the sun's declination at noon at Greenwich, England, for each day of the year. The surveyor must correct this declination for longitude (q.v.), hours from noon, and refraction before making the observation. The refraction correction varies with the latitude (q.v.), hours from noon and declination of the sun. Having found the declination of the needle, the compass-box is moved so as to bring the needle at N. and S. in which case it will indicate true bearings.

SURVEYING, Marine. See SURVEYING.

SURVEYING INSTRUMENTS. The instruments used in the business of surveying fall into two general classes: those used in the field work and those used in recording the field work on maps. In both classes there are three objects to be attained, and suitable instruments are provided for each — the marking of points, the measurement of lines and the measurement of angles.

In field work the «pin» is the instrument used for the temporary location of a point. It is made of stout iron wire, or slender steel wire, about eight inches long, and with a ring turned at the top. Ten pins go in a «set.» In field use it is customary to tie a bit of red flannel rag in the ring of the pin, so that it may be found quickly by the chainman. If the point is one which is to be marked permanently, the pin is replaced by a wooden «hub» with a copper nail, or with a

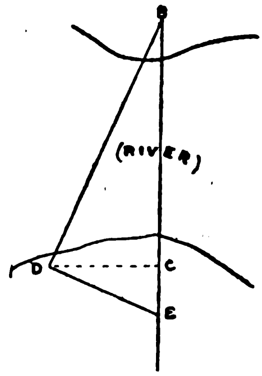
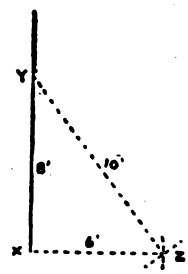
3 Plane Table

stone monument marked with a simple cross cut into the stone, or a bronze bolt may be set into a hole drilled in the top of the monument.

For making linear measurements a long-recognized standard has been the surveyor's or Gunter's chain. It is 66 feet in length, made up of 100 links of stiff iron wire or steel, with a ring-shaped loop at each end, the adjacent links being connected by two rings. Each measured link is 7.92 inches long, including the span of a connecting ring at each end. This chain is still in use for retracing the lines of old surveys in which it was originally used, particularly in the resurvey of government public lands. The more modern engineer's chain is 100 feet long, and has 100 links; each, with its two adjacent rings, comprising one foot. Both of these types of chains are comparatively rude instruments, and for close work have been supplanted by the narrow steel ribbon or tape, which, however, in surveyors' parlance goes by the name of «chain.» This is a continuous strip of steel, one-eighth to three-sixteenths of an inch in width and one-fortieth to one-thirtieth of an inch in thickness. It may be 50 feet or 100 feet in length. Ten-foot divisions are marked by small blocks of brass soldered upon the steel, the exact points being indicated by notches filed in the brass. These ribbons are generally provided with a compensating handle for the forward end of the «chain.» This handle is of two sections of brass tubing, one of which contains a thermometer and an adjustable scale, so that the length of the «chain» may be made longer or shorter according to the reading of the thermometer — the «chain» having been tested according to a given temperature. The other section of the handle contains a spirit level, to ensure that the measurement is strictly horizontal; and a stout helical spring which must be drawn out to an index mark, and thus ensures that in every measurement the same degree of tension is exerted upon the «chain.» This type of chain cannot be bundled up as with the link type, and a folding reel is provided upon which it is safely carried about. For short and precise measurements the steel tapeline is employed. This is a ribbon of steel about half an inch in width and one-eightieth to one-hundredth of an inch in thickness. It is graduated in feet, tenths and hundredths of a foot, so etched upon the steel that the divisions appear in relief. This type of tape line rolls up by means of a cranked handle into a leather case. Linen tapes and combination tapes of linen and brass wire are useful in some instances, but cannot be depended upon where accuracy is important. Tapes and ribbon «chains» may be authoritatively tested if sent to the Superintendent of the United States Coast Survey at Washington. Measurements of extreme accuracy, as in the establishment of a base line for triangulation, are made with «base bars» or «compensation bars» so constructed of iron and brass that they remain the same length regardless of changes in temperature. These bars are carried about in cases of wood, and are used in sets of six, being each supported on two stout tripods. Another form of base bar is provided with a trough in which is kept continually while in use a mixture of ice-water and ice — thus ensuring a constant temperature of 32°, to which the bars are standardized. The steel alloy known as «invar» (q.v.) is also used with entire satisfaction within a certain range of temperatures, in which the metal does not expand in length. For measuring small vertical distances, as in leveling, a telescoping rod is used. The type most in use is known as the New York Leveling Rod. This rod is of maple, about two inches square and nearly seven feet in length, and has a brass shoe and a brass cap. The face of the rod is graduated into feet, tenths and hundredths of a foot, up to 6.50 feet. A sliding target of oval outline has its centre cut away so that the graduations of the rod are visible. On one of the inner edges of the target a vernier is provided so that thousandths of a foot may be read. The rod is made in two longitudinal sections dovetailed together, the back section sliding upon the front. When a vertical distance of more than 6.50 feet is to be measured, the target is clamped at that figure, a lower clamp loosened and the back part of the rod raised upward until the target comes into line. The reading now is taken on the side of the rod, which also is graduated, so that distances up to 12 feet may be measured to the thousandth of a foot. To ensure the verticality of the rod in the hands of the rodman, when measurements are being made, the target is sometimes constructed with two target faces, one three or four inches back of the other, the ends of the front face being cut away, so that a yiew of both discs is had at once. Any deviation from a vertical position is immediately noticed through the lack of agreement of the horizontal line of both discs. There are several other forms of leveling rods, but in the United States the New York rod is almost universally in use. «Speaking rods» are those which are so painted as to be easily read by the observer at the instrument, without dependence upon the rodman. This type is exceptionally useful in rapid reconnaissance work, where long sights are taken. They are not so accurate, however, as the target rod when it is carefully used. The type most in favor is the Philadelphia rod, in which the graduation is in figures six one-hundredths of an inch in height, set with their centres on the lines marking the tenths of the foot. It is quite easy for the leveler to estimate the hundredths of a foot with great accuracy, but impossible to read to thousandths.

The level is obviously an essential instrument in using the leveling rod, to mark the upper limit of the vertical distances measured upon the latter. It consists of a telescope, 20 inches in length, in which the line of sight is carried by the intersection of cross-hairs, and to which is attached a «bubble tube» of glass filled with a mixture of ether and alcohol except for the long bubble of air. This tube is about eight inches long and three-fourths of an inch in diameter, and is curved to a long radius, the convexity of the curve being set uppermost. Upon this face of the tube is a centre line and graduations on either side of it. The tube is so attached to the telescope that it may be adjusted and brought accurately parallel to the line of sight through the telescope. The combination of bubble tube and telescope is reversible in its Y-shaped bearings, from which it is called a Y-level; and is mounted upon a frame with a long conical spindle held by a pair of plates between which are four leveling screws, the whole being attached to a tripod, as shown in the accompanying illustration. A pair of stadia wires is often added to the cross-hairs of the telescope, so that the distance of the leveling rod may be computed by taking a second reading, above or below the level line at the time when the level is fixed. An ingenious device renders the stadia wires invisible when the cross-hairs are being used, and vice-versa. A small pocket level known as the «Locke Level,» is of great usefulness in reconnaissance work. In this instrument the bubble tube is attached to





the top of the tiny telescope, the upper part of which is cut away, and a semi-circular mirror at 45 degrees placed beneath it in the telescope. The image of the bubble in the mirror decides when the instrument is held in a true level position, and at the same moment the point at which the level line strikes the leveling rod is in plain view.

For the measurement of angles in the field the commoner instruments are the magnetic compass and the transit. The former depends upon a continual reference of the direction of a line to the magnetic north-and-south line indicated by a magnetic needle swinging in a compass box, the rim of which is graduated to 15 minutes of arc; from which the angle can be very closely estimated to five minutes. By an attachment to the compass it may be made a solar compass, a necessity where the principal lines of the survey are referred to the true meridian, as in government surveys of the public lands. The compass may be still further improved by the addition of a telescope, which may be clamped to the rear sight, and this telescope may have a long bubble tube, making it available for running levels, and it may also carry a vertical circle for measuring vertical angles.

The transit is the engineer's instrument of precision for angular measurements. Its essential factor is the plate, from five to seven inches in diameter, bearing graduations of exquisite accuracy, to 30 minutes of arc in the smaller instruments and 20 minutes in the larger ones. Verniers are affixed at opposite sides of the plate by which the angular measurement may be made to 30 seconds in the one case or to 20 seconds in the other. The telescope which carries the line of sight with the intersection of cross-hairs is often fitted with stadia wires also, so that the tangents of the distances may be measured upon a leveling rod. A long bubble tube enables the engineer to use the transit for all ordinary leveling work. It is not uncommon to have a four-inch vertical circle attached, carried on four arms, and reading to single minutes. A solar attachment, consisting of three arcs of circles, on which the latitude of the place, the declination of the sun and the hour of the day may be set off, converts the instrument into a solar transit. Where a vertical circle is a part of the instrument, this serves for the latitude arc. The transit shown in the illustration is equipped with the popular Saegmuller solar attachment mounted above the primary telescope. A special form of the transit for mining engineers has the axis of the telescope extended beyond the standard at one side, and a second telescope mounted upon it so that a sight may be made directly downward. For very accurate and extended work, as in geodetical work, the telescope of the transit is sometimes 36 inches in length, the horizontal graduated circle 36 inches in diameter and the vertical circle 24 inches in diameter.

The plane table is practically a drawing board, usually 24 by 36 inches. In its simplest form the ruler or «alidade» carries two sights at the ends by which the direction is obtained, the line of this direction being then drawn along the ruler upon a sheet of paper attached to the board. In the better class of instrument the sights are replaced by a telescope, which sometimes carries stadia wires for measuring distances, a compass box for orientation and short vertical arcs for measuring tangents which cannot be covered by the stadia wires. The plane table is of use chiefly for rapidly filling in topographical details upon the may made by ordinary surveying methods. The plane table shown in the accompanying illustration is equipped with reels for carrying a continuous roll of drawing paper. See SURVEYING.

SURVEYS, United States Governmental. From an early period in its history the government has made provision for exploring expeditions of various kinds, mainly in the vast region west of the Mississippi which for many years was a but little known wilderness. Some of these explorations were for military routes to the west and later came surveys of public lands. The first official surveys were made by a geographer attached to the Continental army in the Revolution and in 1781 Thomas Hutchins (q.v.) was attached to Greene's division (Southern) as geographer. After the Revolution he was retained to supervise surveys of the Western lands and continued in office until his death in 1789.

The earliest governmental explorations in the West could hardly be regarded as surveys although many of them prepared maps which added greatly to knowledge of a little known region. Position were determined astronomically, and route maps were the principal products. The first of these was the Lewis and Clarke expedition sent out by President Jefferson in 1803. One of its products was a map of the country between Lake Superior and the Pacific Ocean between the 39th and 49th parallels. Major Z. M. Pike's expeditions in 1805–07 to the sources of the Mississippi and of the Arkansas and Red rivers were fruitful of geographic results. Major S. H. Long's expedition from Pittsburgh to the Rocky Mountains in 1819 and 1820 was under order of the Secretary of War. In 1823 Long made another journey to the Great Lakes and the source of Saint Peter's River. Sextant and pocket chronometer were used, distances were estimated and courses were taken by compasses. The most elaborate early survey was that of J. C. Brown of a road from Osage to Taos in 1825–27. Chain compass and a good sextant were used and a large scale map prepared. Similar to it are the surveys by R. Richardson of a road from Little Rock to Fort Gibson in 1826, and a survey by Dimmock in 1838 for a military road from Fort Smith to Fort Leavenworth. In 1832 Lieutenant Allen on the Schoolcraft expedition made an excellent map on a scale of 5.75 miles to an inch, of the head of the Mississippi Valley but all the distances were estimated. He was the discoverer of the source of the great river.

The Bonneville expedition in 1832–36 was not under governmental authority although Bonneville was an army officer. The Wilkes expedition in 1841 surveyed part of Columbia River. The first of the early expeditions which could be regarded as a geological survey was made by Featherstonhaugh in 1834 to the Ozark region, The following year his observations were extended along the Couteau des Prairies between the Missouri and Minnesota rivers. In 1838 Nicollet was sent by Colonel Abert of the United States Army Engineers to make a map of the hydrographic basin of the Mississippi River. In 1839 and 1848 D. D. Owen made surveys of mineral lands of the Northwest extending to Lake Superior and covering an area of 57,000 square miles. These surveys were made for the United States Land Office. In 1847–48 C. T. Jackson and J. D. Foster and J. W. Whitney operating under orders of the Secretary of the Treasury extended this work in the copper district of the Lake Superior region.

Corps of Engineers, United States Army. — A large amount of surveying was done by the topographical engineers of the United States army. The first notable expedition under that bureau was N. Nicollet's explorations of the basin of the upper Mississippi River in 1836–40 which resulted in a map which is regarded as a most important contribution of American geography. His surveys were largely instrumental and he used a barometer for ascertaining elevations. The Fremont expedition in 1842 resulted in a valuable map on the millionth scale, of the country from the forks of Platte River to South Pass between the 43d and 45th parallels. Expeditions by Fremont in following years 1843–46 extended his observations westward to the Pacific Ocean and the surveys made were the basis for important new maps.

The following is a list of some of the more notable army expeditions and surveys from 1836 to 1879 (excepting the surveys for Pacific railroads which are noted on following page):

List of Principal Surveys under the Bureau of Topographical Corps of Engineers, United States Army.

1836–40	I. N. Nicollet	Upper Mississippi Basin.
1842	Lieut. J. C. Fremont	Missouri River to Rocky Mountains.
1843–44	Capt. J. C. Fremont	Rocky Mts. and to Oregon and northern California.
1846	Capt. G. W. Hughes	San Antonio to Saltillo, Mexico.
1845	Lieut. J. W. Abert	Between Platte River and 35th Parallel to Rocky Mts.
1846–47	Maj. Wm. H. Emory	Fort Leavenworth, Mo., to San Diego, Cal.
1849	Lieut. G. H. Derby	Part of Sacramento Valley.
1847	Lieut. J. D. Webster	Rio Grande from north of Matamoras.
1849	Lieut. J. H. Simpson	Road from Fort Smith to Santa Fé.
1849	Lieut. J. H. Simpson	Navajo County.
1849–50	Capt. H. Stansbury	Valley of Great Salt Lake.
1849	Capt. John Pope	Red River of the North.
1850	R. H. Kern	Rio Pecos.
1850–51	Capt. Sitgreaves and Lieut. Woodruff	Survey of Creek Boundary.
1851	Capt. Sitgreaves	Down Zuni and Colorado rivers.
1852	Lieut. Derby	Colorado River Mouth to Fort Yama
1852	Capt. R. B. Marcy	To sources of Red River.
1853	Capt. J. H. Reno	Big Sioux to Mendota.
1854	Lieut. G. H. Derby	Oregon and Washington Territories.
1855	Lieut. G. H. Mendell	Snake River.
1855	Lieut. G. K. Warren	Dakota and Sioux County.
1856	Lieut. G. K. Warren	Missouri and Yellowstone rivers.
1857	Lieut. G. K. Warren	Territory of Nebraska and Black Hills.
1857–58	Lieut. J. C. Ives	Colorado River from Fort Yuma to Grand Canyon.
1859	J. N. Macomb	Santa Fé to junction of Green and Grand rivers.
1859	Capt. J. H. Simpson	Great Salt Lake Valley.
1859–60	Capt. W. F. Reynolds	Headwaters of Yellowstone and Missouri rivers.
1859	J. B. Dixon	Route from Fort Dallas, Ore., to Great Salt Lake Valley.
1869	Capt. Chas. W. Raymond	Yukon River Basin.
1869	Lieut. Geo. M. Wheeler	Southern and southeastern Nevada.
1870	Capt. D. P. Heap	Northern Montana and Dakota.
1871	Capts. J. W. Barlow and D. P. Heap	Upper Yellowstone County.
1871	Capt. W. A. Jones	Uintah Mountains.
1873	Capt. Wm. Ludlow	Yellowstone River.
1873	Lieut. E. H. Ruffner	Ute County.
1873	Capt. W. A. Jones	Northwestern Wyoming and Yellowstone Park.
1874	Lieuts. E. H. Ruffner and Anderson	Fort Garland, Colo., to Fort Wingate, N. Mex.
1874	Capt. Wm. Ludlow	Black Hills.
1875	Capt. Wm. Ludlow	Carroll, Mont., to Yellowstone Park.
1876	Capt. W. S. Stanton	Bighorn and Yellowstone Valley.
1877	Capt. W. S. Stanton	Routes in Wyoming.
1869–79	Capt. G. M. Wheeler	Geographical Surveys west of 100th Meridian.

There were also many reconnaissance trips and explorations for roads which can hardly be called surveys. Some of the maps were not published but remain on file in the War Department.

Black Hills Survey.— In 1874 Capt. W. Ludlow made expeditions through the Black Hills of South Dakota with N. H. Winchell as geologist. The results were given in a quarto volume issued in 1875. Later the Indian Bureau sent an expedition under W. P. Jenney and H. E. Newton to investigate reports of gold in these hills and a quarto report with folio of maps was published by the Survey of the Rocky Mountain region.

Pacific Railroads.— In 1853 the War Department began a series of explorations for routes for railroads across the Far West. The expeditions were conducted by army officers but had topographic and geologic assistants, who made surveys of various kinds. Among these geologists were Jules Marcou, Thomas Antisell, J. S. Newberry, W. P. Blake and James Schiel. The routes surveyed were not far from the several transcontinental railroad lines of to-day. The results were published in 13 quarto volumes which contain not only geographic results of the surveys but a large amount of information on natural history, resources, etc.

International Boundaries.—The boundaries of the United States have been surveyed by various organizations. In 1818 surveys were begun on the northern boundaries of New York, New Hampshire and Maine by United States army engineers. In 1822(?) the Northwest Boundary Commission, appointed under the Treaty of Ghent, made a survey of the boundary in the region about the outlet of Lake Superior, and in 1857–61 the United States Commission working under direction of the State Department surveyed the boundary west from longitude 110°. In 1872–75 the United States Boundary Commission under the State Department surveyed the Canadian boundary along the 49th parallel and a narrow strip of contiguous country from Lake of the Woods to the Rocky Mountains, connecting there with the survey from the west. The Louisiana-Texas line survey in 1840 was made jointly by engineers of the United States army and surveyors appointed by Texas. The results are in Senate Ex. Doc. 199, 27th Congress, 2d Session. Considerable boundary surveying has been done by the Coast and Geodetic Survey. The Mexican Boundary Survey was made by Maj. W. H. Emory in 1855–56 and its results were published in two quarto volumes which included geological observations by Parry and Schott. Detailed remapping of this boundary in 1889 was done by a joint International Boundary Commission consisting of three Mexican members, two army engineers and a member of the United States Coast Survey. The result was a folio of maps showing topography and profiles from El Paso to the Pacific. The southern boundary of Kansas was surveyed by Lieut.-Col. J. E. Johnson in 1857 and the Texas boundary in 1858–60 by a commission organized by the Interior Department.

Lake Survey.— A survey of the Great Lakes was made by the War Department (corps of engineers) in 1841 to 1881. Very detailed charts (79) were prepared of the lakes, their shores and of the straits and rivers immediately connected with lake navigation. In 1876–79 this work was extended down the Mississippi River to Memphis.

Hayden Surveys.— The survey under F. V. Hayden began in 1867 for the General Land Office and its work was in Nebraska Territory, but it was not until 1871 that it began much surveying. In 1873 it became the United States Geological and Geographical Survey of the Territories and in the next five years covered 170,000 square miles with topographic and geologic mapping, mostly in Colorado, Wyoming, Idaho and Montana. James T. Gardner was chief geographer and A. D. Wilson and Henry Gannett were in charge of parts of the work. The principal geologists were A. C. Peale, W. H. Holmes, A. R. Marvine, F. H. Endlich and F. V. Hayden. Twelve annual reports and a series of quarto memoirs were published.

Geological and Geographical Survey of Rocky Mountain Region.—These surveys were organized and conducted by Maj. J. W. Powell under the Interior Department. In 1869 Major Powell made his famous boat trip through the Grand Canyon under auspices of Smithsonian Institution. In 1871 continuation of his explanatory work in the West was provided for by the government and from that time to 1878 an area of 67,000 square miles was covered by topographic and geological surveys. A. H. Thompson was chief geographer and G. K. Gilbert, E. E. Howell, Capt. C. E. Dutton and C. A. White were assistant geologists.

Fortieth Parallel Survey.— This survey organized and conducted by Clarence King and under direction of the chief of engineers, United States army, operated from 1867 to 1872. It prepared topographic (contour) maps and geological map of a wide strip of country contiguous to the 40th parallel west of the 105th meridian. The geological work was by Clarence King, S. F. Emmons, Arnold Hague and James D. Hague. John D. Gardner was in charge of topographic work. The results were published in seven quarto volumes and a folio.

Wheeler Survey.— From 1869–79 extensive explorations were made in the West under direction of Capt. G. M. Wheeler of the United States army engineers. The title of the organization was United States Geographical Surveys west of the 100th meridian. Many hachured topographic maps were prepared of parts of Arizona, Utah, New Mexico and Colorado and the geology of various regions was mapped by G. K. Gilbert, A. R. Marvine, E. E. Howell, J. J. Stevenson, I. C. Russell and others. The principal results were published in three quarto volumes issued in 1875, 1881 and 1889.

United States Geological Survey.— In 1876 there were four geological surveys in progress, the Hayden, King, Wheeler and Powell with some duplication of work, a condition which roused so much criticism that Congress referred the consideration of the continuance of the work to the National Academy of Science. That body recommended the substitution of a single organization for the topographic and geologic work, and accordingly in 1879 Congress created the United States Geological Survey (q.v.) as a bureau of the Interior Department. This survey has been continued by annual appropriation (about $1,500,-

000 in 1917). It has made detailed topographic maps of 40 per cent of the area of the United States. Large areas have also been mapped geologically, considerable public land classified in various ways and water resources determined. The maps are on various scales and sold at cost of paper and printing, most of them by the survey. Many of the geological reports are for gratuitous distribution. Two hundred and eleven folios of the Geologic Atlas of the United States have been issued which sell from 25 to 75 cents each.

Reclamation Service.— Many detailed surveys have been made by the Reclamation Service in connection with its various projects, and many suggested ones. Some of the resulting maps have been issued in the various annual reports of the bureau and others are filed.

Isthmian Surveys.— Many surveys have been made by parties sent to the Central America and Panama by the United States government to obtain data for canal routes.

General Land Office.— The General Land Office created in 1812 (see PUBLIC LANDS) and since 1849 a bureau of the Interior Department, has surveyed a large proportion of the public lands in the States west of the Mississippi River, except Texas, and also Ohio, Illinois, Indiana, Florida, Alabama, Wisconsin and Michigan. Many of the State lines were run by the Land Office. In the surveys by this bureau public lands are divided into townships six miles square, comprising 36 sections one mile square, the latter divided into quarter sections of 160 acres and in some cases, minor divisions, a system devised by Lieutenant-Colonel Mansfield in 1803. The enclosing lines are due north and south and east and west and owing to convergence of meridians and varying length of parallels at different latitudes the divisions are only approximate. The townships are numbered east and west from prime meridians, and north and south from standard parallels. The sections, ordinarily a mile square, are numbered thus:

6	5	4	3	2	1
7	8	9	10	11	12
18	17	16	15	14	13
19	20	21	22	23	24
30	29	28	27	26	25
31	32	33	34	35	36

Thus, for instance, a piece of land is designated NW¼ Sec. 28, T. 19 S., R. 28 W. New Mexico. Farther subdivision is indicated by ¼, ½ sections, and odd areas as lots. The maps are prepared on a scale of two inches to one mile and in most cases the configuration of the land is represented by hachures excepting in later work in a few Indian reservations where contour lines have been used. This mapping covers most of the smooth surfaced or rolling lands but large areas of mountain lands are not yet subdivided. The maps are not issued but held in file in the general land office and local land offices in various public land States. The bureau does, however, issue general maps of the States and of the United States compiled largely from its own surveys.

Coast and Geodetic Survey.— The work of mapping the coast of the United States was initiated by Congress, 10 Feb. 1807, on recommendation of Thomas Jefferson, with an appropriation of $50,000. F. R. Hassler was its first superintendent, beginning work in 1816 and continuing to 29 April 1818 as a bureau of the Treasury Department. The surveys were then continued by the United States army engineers and by officers of the navy until the bureau resumed operations again in 1832 under the Navy Department with Hassler again as superintendent. On reorganization late in 1843 A. D. Bache became superintendent and he continued in charge until his death in 1867. Pierce, Patterson, Hilgard, Thorn, Mendenhall, Duffield, Pritchett, Tittmann and Jones were later superintendents. The geodetic work or determination of the form of the earth was made an additional function of the survey in 1878. The survey has prepared charts of the coasts and exterior waterways of the United States and of parts of its possessions, and mapped more or less of the coast, the District of Columbia and other areas. Many special reports on geodesy, tide tables and scientific researches of the bureau have been issued. The charts which are issued in sheets of various sizes and scales are sold at low rates directly by the bureau and by local agents in seaboard cities.

Mississippi and Missouri River Commissions.— The Engineers corps, War Department has made a detailed survey of the Mississippi River and of its principal tributaries, showing topography of the shore, 1876–84. These surveys were intended primarily for guidance in the many engineering problems connected with improving the waters for navigation, a task on which the government had expended nearly $150,000,000 up to end of June 1916. The War Department has made special surveys for many river and harbor improvement projects.

Hydrographic Office (q.v.).—To this branch of the Navigation Bureau of the Navy Department is entrusted the preparation of many kinds of data relating to navigation. Numerous maps are produced in many cases based on original surveys.

Forest Service.— The Forest Service of the Agricultural Department has made surveys in most of the Forest Reservations in some cases with detailed representation of topography and distribution of various kinds of timber. A series of atlases has been published and many maps are on file in the various offices of the bureau. Some work of this kind was also done by the United States Geological Survey in 1897-1900 and many maps were published in annual reports and professional papers. Since 1897 this survey obtains data as to forested areas in all districts mapped topographically.

Soil Surveys.— The Agricultural Department has made surveys of soils in many parts of the United States, publishing the results on the detailed topographic maps by the United States Geological Survey. These soil maps are issued for gratuitous distribution.

Biological Survey.— The Agricultural Department is also conducting a survey to ascertain the geographic distribution of animals and plants.

Wheeler, 48th Congress, Second Session. H. of R. Ex. Doc. 270, 1885); Emmons, S. F., 'The Geology of Government Explorations' (Geological Society of Washington, 1896); Merrill, G. P., 'Contributions to the History of American Geology' (Report of United States National Museum, 1904, pp. 189–734).

N. H. DARTON,
United States Geological Survey.

SUSA, soo'sä, Persia, capital of the province of Susiana or Elam, on the Choaspes River, 50 miles west of Shuster, was one of the celebrated cities of the Old World, renowned in Biblical history. Shushan, meaning lilies, is alluded to in the Old Testament and on the cuneiform tablets of Assyria. It has a rectangular form without walls, but possessed a strongly fortified citadel, which enclosed the stately palace and one of the most important treasuries of the Persian kingdom. Numerous rivers water the plain in which it stands, some of which partly surrounded the ancient city. All the Persian kings, beginning with Darius I, erected beautiful palaces, the remains of which belong to the most magnificent ruins of Asia. It was here that Esther's intrigue was developed; Daniel saw the vision at Shushan, and here he was buried. Consult Billerbeck, 'Susa' (Leipzig 1893); Dieulafoy, 'L'Acropole de Suse' (Paris 1888–92); de Morgan, J., 'Fouilles à Suse' (Paris 1900).

SUSAN NIPPER, a character in 'Dombey and Son' by Charles Dickens. She is an attendant upon Florence Dombey and is noted for her sharp tongue.

SUSANNA, soo-zăn'a, the Jewish woman who figures in the book of Susanna, as the intended victim of two elders who obtained her condemnation to death on a false charge. The prophet Daniel proved her to be innocent, and obtained a reversal of the sentence. The date of about 600 B.C., is ascribed to the event. See SUSANNA, BOOK OF; BIBLE.

SUSANNA, Book of, the 13th chapter of Daniel in the Septuagint version of the Old Testament. It is accepted as canonical by Roman Catholics, but rejected by Protestants. (See BIBLE). Consult Kay, D. M., in Charles, 'The Apocrypha and Pseudepigrapha of the Old Testament' (Oxford 1913).

SUSPENSION, *in canon law,* a censure of which a clergyman is forbidden to exercise his order or to enjoy the fruits of his benefice. Partial suspension inhibits a cleric from the exercise of his spiritual functions, or from the administration of his benefice, or only from a part of his sacred functions: for example, a bishop may be suspended from ordaining, and yet be perfectly free to govern his diocese. Entire suspension prohibits all use of order, jurisdiction or benefice. In the English canon law, as in that of the Roman Catholic Church, a suspension is removed by absolution, by revocation of the censure by the person inflicting it or by dispensation.

SUSPENSION BRIDGE. See BRIDGE.

SUSPENSION RAILWAY, a railway in which the carriage is suspended from an elevated cable or track. See MONORAIL.

SUSQUEHANNA, Pa., borough of Susquehanna, on the Susquehanna River and on the Erie Railroad. It is 38 miles north of Carbondale and 23 miles southeast of Binghamton, N. Y. It has machine shops, chemical works and manufactures of washing machines and metal ware. Pop. 3,478.

SUSQUEHANNA, sŭs-kwē-hăn'a, a river formed by two branches, an eastern or northern and a western, which unite at Northumberland in Pennsylvania. The eastern branch, which is considered the main stream, issues from Lake Otsego in New York, and has a length of about 250 miles. The western branch rises in the western slope of the Alleghenies, and flows very circuitously east-southeast for about 200 miles. The united stream flows south and southeast, passing Harrisburg, Wilkesbarre and Binghamton, N. Y., enters Maryland, and after a course of about 150 miles flows into the northern extremity of Chesapeake Bay at Port Deposit. The navigation was much obstructed by rapids, but by constructing canals the river has been made navigable for a considerable distance from the Chesapeake.

SUSQUEHANNA COMPANY, The, in American history a land company formed in 1754, chiefly by Connecticut farmers, for the colonization of the Wyoming country. By a treaty with the Five Nations, 11 July 1754, an enormous tract of country was purchased for $10,000. It began at the southern boundary of Connecticut and followed in a northerly direction the course of the Susquehanna to northern Pennsylvania. In 1785–86 many disputes arose between the Susquehanna Company and the Pennsylvania claimants of the territory. This was called the «Pennamite War.»

SUSQUEHANNA UNIVERSITY, a Lutheran institution of higher education at Selingsgrove, Pa., founded in 1858. The faculty numbers 22; the average annual attendance of students is 325; tuition fees are $75 to $90; living expenses, board, etc., $175 to $225; the productive funds amount to $72,000; the total income, including tuition and incidental charges, amounts to $42,000. The college colors are orange-maroon. The library contains over 16,000 volumes. The number of graduates since organization number over 1,000.

SUSSISTINNAKO, the Spider, was according to the Sia Indians of New Mexico, the first of all beings in the lower world. He lay out the directions by drawing one line of meal from east to west and another from north to south. Within the magic confines thus laid out he sang his magic songs and rattled his magic rattle, and as he sang and rattled people, animals, birds and insects appeared at his call. He created two mothers who were the mothers of all; then he divided the people into clans, after he had created the earth for them, and he made the Cloud People, the Lightning People, the Thunder People and the Rainbow People, and he commanded them to work for the people of Haarts (the earth). He divided the world into three parts: Haarts (the earth); Tinia (the mid-plain); and Huwaka (the upper plain); and to the Clouds and the Rainbow he gave the Middle Plain. When all this had been done he had the two original mothers create the sun, the moon and the stars.

SUSTENTATION FUND, the name specifically applied in the Presbyterian denomination to a fund for the support of poorer churches. All important religious bodies have funds of this character. The object is to enable communities unable from their own means to support properly a pastor or minister, to have the benefit of religious services.

SUTHERLAND, Alexander, Canadian Methodist clergyman: b. Guelph, Ontario, 17 Sept. 1833; d. 1910. He learned the printer's trade, but studied for the ministry and in 1859 was licensed as a preacher and stationed at Niagara. He removed to Therold in 1861 and afterward preached at Drummondville, Hamilton, Yorkville, Toronto and Montreal. He was secretary of the Conference in 1870–71, and after the union of the Methodist churches in Canada he was secretary and treasurer of the missions of the Church. In this capacity he made extended tours of Canada; and in 1879 he inaugurated a campaign to raise $75,000 for the purpose of clearing the missions department of debt and succeeded in raising $116,000. Author of 'A Summer in Prairie Land' (1882).

SUTHERLAND, George, United States senator: b. Buckinghamshire, England, 25 March 1862. He came to the United States with his parents in 1864, received his academical education in Utah and studied at the University of Michigan in 1882–83. He was admitted to the bar in 1883 and engaged in practice at Salt Lake City. He was elected to the first Utah senate by the Republican party in 1896; served in Congress in 1901–03 and in the United States Senate in 1905–17.

SUTHERLAND, Howard, United States senator: b. near Kirkwood, Mo., 8 Sept. 1865. In 1889 he was graduated at Westminster College, Fulton, Mo., studied law at Columbian (now George Washington) University, but did not complete course. In 1889–90 Mr. Sutherland was editor of the *Republican* of Fulton, Mo., and from 1890 to 1893 served from clerk to chief of population division of the 11th census. In 1893 he removed to Elkins, W. Va., where for 10 years he was connected with the Davis-Elkins coal and railway interests, becoming their general land agent. For some years he has engaged in coal and timber land operations on his own account and is president of the Greenbrier Land Company of Valley County. In 1908–12 he was member of the West Virginia State senate and from 1913 to 1917 was a member of the 63d and 64th Congresses, serving as member-at-large from West Virginia. In 1916 he was elected to the United States Senate for the term 1917–23. Senator Sutherland is a member of the American Academy of Political and Social Science.

SUTLEJ, sŭt'lĕj, India, a river forming the eastern boundary of the Punjab. It rises in Tibet, in the sacred lakes of Manasarowar and Rakas-Tal, flows through the latter lake at an elevation of 15,000 feet, follows a circuitous course through the Himalayas, finally joining the Indus at Mithankot. Its principal tributaries are the Li, Beas and Chenab; it passes in its upper course through scenery of a wild and savage grandeur. Its entire length is 900 miles; a swift current marks its upper course, often forming deep cascades and waterfalls; it is navigable only in its lower course. The river is spanned by splendid bridges, that of the Indus Valley Railway connecting the shores near Bhawalpur, and another iron bridge of the Sind, Punjab and Delhi Railway, near Jullunder.

SUTPHEN, William Gilbert Van Tassel, American author: b. Philadelphia, 11 May 1861. He was graduated at Princeton in 1882; since engaged in editorial work. He has written 'The Golficide' (1898); 'The Cardinal's Rose' (1900); 'The Golfer's Alphabet' (1899); 'The Nineteenth Hole' (1901); 'The Doomsman' (1903); 'The Gates of Chance' (1904), etc.

SUTRA, soo'tră, in Sanskrit literature, the technical name of aphoristic rules and of works consisting of such rules. There is a bibliography of sutra texts in Macdonell's 'History of Sanskrit Literature' (London 1913). See SANSKRIT LITERATURE.

SUTRO, soo'trō, **Adolph Heinrich Joseph,** American engineer and philanthropist: b. Aix-la-Chapelle, Rhenish Prussia, 29 April 1830; d. San Francisco, 8 July 1898. Coming to the United States in 1850 he went to California where he engaged in business for 10 years. In 1860 he visited Nevada and planned the Sutro tunnel, a charter being secured on 4 Feb. 1865. It was begun on 19 Oct. 1869 and cost nearly $4,000,000. The main tunnel is 20,000 feet long, 1,650 feet below the surface, 12 feet wide and 10 high. On the discovery of gold, years before, he had invested heavily in San Francisco real estate and became very rich. In 1894 he was elected mayor of that city, to which he gave a park and other gifts. His library of 250,000 volumes was peculiarly rich in works on the history of the Pacific settlement. The library was almost totally destroyed in the fire following the earthquake of April 1906. The 100,000 volumes saved were, after continued litigation, turned over to the State Library in 1913.

SUTRO TUNNEL. See TUNNELS AND TUNNELING.

SUTTAS, Buddhist, a collection of the most important religious, moral and philosophical discourses taken from the sacred canon of the Buddhists. It gives the most essential, most original and most attractive part of the teaching of Buddha, the Sutta of the Foundation of the Kingdom of Righteousness and six others of no less historical value, treating of other sides of the Buddhist story and system. The translator, T. W. Rhys Davis, gives as the dates of Buddha's life of 80 years about 500–420 B.C.

SUTTEE, sŭ-tē', in India, a term applied to the self-immolation of Indian widows on the funeral pile of their deceased husbands. The origin of this practice is of considerable antiquity, but it is not enjoined by the laws of the great legislator, Manu, nor is it based on the Vedas. This practice was abolished by Lord

Bentinck, governor-general of India, in December 1829, and may now be said to be extinct, though perhaps rare cases still occur. Until then the British government had permitted it, provided the act was perfectly voluntary (which the religion of Brahma also prescribes), and if notice of such resolution had been previously given to a magistrate, who was required to see that the suttee was public and that all the requisitions of the law were fulfilled. The ceremonies of a suttee were various and lasted from a quarter of an hour to two hours. Sometimes the widow was placed in a cavity prepared under the corpse of the husband; sometimes she was laid by the body, embracing it. If the husband died at a distance from home, anything which belonged to the deceased — his garments, slippers, walking-staff — might be substituted for the corpse. Consult Bose, J. C., 'The Hindus as they Are' (2d ed., London 1884), and Tylor, E. B., 'Primitive Culture' (4th ed., 2 vols., New York 1903).

SUTTER, John Augustus, American pioneer: b. Kandern, Germany, 15 Feb. 1803; d. Washington, D. C., 17 June 1880. He was graduated at the Bern Military Academy in 1823 and came to America in 1834, locating at Saint Louis. Receiving favorable accounts of California he crossed the Rocky Mountains in 1838; sailed down the Columbia River and thence to Hawaii. After going to Sitka, Alaska, he cruised along the Pacific Coast and was stranded at the site of San Francisco in July 1839. During that year he established the first white settlement on the site of Sacramento. In 1841, after receiving a large tract of land from Mexico, he built a fort which he named New Helvetia on the site of the present Sacramento, Cal.; was made governor of the frontier country by Mexico, but was held in suspicion by the Mexicans owing to his friendly feelings toward the United States. In 1848, when California was ceded to the United States, he owned many thousand head of cattle, much land and other property, but owing to the discovery of gold his estates were overrun by miners, and his workmen left him, and not being able to secure others he was financially ruined. He appealed to the Supreme Court, but was not sustained. Later the legislature of California granted him a pension of $250 a month. He moved to Littz, Pa., in 1873. (See SACRAMENTO, CAL.). Consult Dellenbaugh, F. S., 'Frémont and '49' (2d ed., New York 1914).

SUTTNER, Bertha, BARONESS VON, Austrian author and worker for universal peace: b. Prague, 9 July 1843; d. Vienna, 21 June 1914. She was the daughter of Count Franz Kinsky, an Austrian field-marshal, who died in her infancy. She was excellently educated, traveled extensively, and in 1876 she was married to Freiherr Arthur Gundaccar von Suttner, the novelist, who died in 1902. She was for a time secretary to Alfred Nobel, and for the greater share of her life was an indefatigable worker for world peace. She was widely known as a writer of fiction, on social science and on a world union to ensure peace. She was awarded the Nobel Peace Prize in 1905. Author of 'Inventarium Einer Seele' (1882); 'Die Waffen Nieder' (1889); 'Hanna' (1894); 'Krieg und Frieden' (1896); 'Schack der Qual' (1898); 'Die haager Friedenskonferenz' (1900); 'When Thoughts Will Soar' (1914); 'Der Kampf um die Vermeidung des Weltkriegs' (2 vols., 1917), etc. Consult her 'Memoirs' (Stuttgart 1908; Eng. trans., Boston 1910).

SUTTON, Mass., village and township in Worcester County, eight miles southeast of Worcester, on the New York, New Haven and Hartford Railroad. There are manufactures of cotton goods. Pop. town, 2,829.

SU TUNG P'O, or SOO TUNG P'O, also known as **SU SHIH,** Chinese poet, essayist and statesman: b. 1031–36; d. 1101. He was educated under the care of his mother and passed first on the list when he was examined for his degree. He was at various times the holder of high offices at court, but was several times banished through the jealousy of enemies. He was a brilliant writer of verse and essays, and holds a high place in Chinese literature. Consult Giles, H. A., 'Gems of Chinese Literature' (1884); 'A History of Chinese Literature' (1901).

SUTURE, a line along which two things are joined, as by sewing, etc., so as to form a seam or something resembling a seam. In anatomy a suture is the immovable junction of two parts by their margins. The sutures of the skull are the lines of junction of the bones of which the skull is composed. Various types of suture exist, as the serrated or dentated suture, the squamous or scaly suture and the harmonic suture or harmonia. Arranged according to their situation, there are coronal, frontal, fronto-parietal, occipito-parietal and many other sutures. In surgery a suture is the uniting of the lips or edges of a wound by stitching. In zoology sutures are the outlines of the septa in the *Tetrabranchiata,* so named from their resemblance to the sutures of the skull. When these outlines are folded the elevations are called saddles and the intervening depressions lobes. In botany a suture is the line formed by the cohesion of two parts. If the suture formed by the carpellary leaves in a pistil face the centre of a flower it is called the ventral suture; if it face the perianth, the dorsal suture. The former corresponds to the margin and the latter to the midrib of the carpellary leaf. Consult Da Costa, J. C., 'Modern Surgery' (7th ed., Philadelphia 1914).

SUVA, soo'vä, the capital of the British colony of the Fiji Islands (q.v.). It is about 1,100 miles distant from Auckland, New Zealand. It has a population of over 1,300 Europeans.

SUVALKI, soo-väl'kē, Poland, (1) capital of the province of the same name, on the Czarna-Hancza, near the Prussian frontier, 152 miles northeast of Warsaw. It contains two churches, municipal buildings and a large market-place, various schools of primary and grammar grades, two breweries, etc. Pop. about 33,000. The town was taken by the German forces in 1915. (See WAR, EUROPEAN). (2) The province of Suvalki lies in the extreme northeastern part of Poland. In the north is covered by thickly-wooded plains and on the Prussian frontier by forests, swamps and lakes. The fertile region is at the south. The chief streams are the Niemen, Bohr, Scheschupe and Pissia. Agriculture is the principal occupation.

There are numerous factories, including tanneries, distilleries and mills. There are some schools. Area, 4,763 square miles. The population is about 700,000, of whom 50 per cent are Lithuanians.

SUVOROFF-RIMNIKSKI, soo-vō'rŏf rim-nyĭk'skĭ, **Alexander Vasoilievitch** (Prince Italieski), a celebrated Russian general: b. in Moscow according to one account, in Finland according to another, 24 Nov. 1729; d. Saint Petersburg, 18 May 1800. He entered the army as a private, fought bravely in the war against Sweden and by his distinguished conduct during the Seven Years' War gained the rank of colonel (1762). He participated in the suppression of the Polish uprising of 1768–72, capturing Cracow in the first year of the conflict and attaining the rank of major-general. When war with Turkey broke out in 1773, Suvoroff as general of division achieved notable victories at Turtukai and Hirsuva, and in conjunction with a force under Kainenskvi completed the overthrow of the Turkish armies at Kosludji beyond the Danube. Subsequently he fought against the pretender Pugatcheff, whose overthrow was largely due to his exertions, and made successful campaigns in Crimea, against the Kuban Tatars and against the mountain tribes of the Caucasus. Upon the renewal of war with Turkey in 1787 he was entrusted with the chief command, and after inflicting decisive defeats upon the enemy at Kinburn, Otchakov and Tokshani, performed the most splendid feat of arms of the entire war by effecting the rescue of the Austrian army under the Prince of Saxe-Coburg, which was surrounded on the banks of the Rymnik by a vastly superior Turkish force, which Suvoroff utterly overthrew, gaining thereby the title of Rimnikski and the rank of count. In 1790 he stormed Ismail, where his troops were guilty of the most bloody excesses. Sent in 1794 against the Polish insurgents he gained the title of field-marshal by his storming of the Praga, suburb of Warsaw, and the occupation of the Polish capital. After five years of retirement, he was summoned to take command of the Russian forces which were to co-operate with the Austrians against the revolutionary armies of France in Italy. At 70 Suvoroff was to achieve the most notable triumphs of his career. Arriving in Italy in April 1799 he succeeded within four months in driving the French from the northern part of the country, after he had defeated their armies at Cassano, 27 April, on the Trebbia, 17–19 June and at Novi, 15 August. Thereupon he crossed into Switzerland to effect a junction with a second Russian army under Korsakoff. The crossing of the Saint Gotthard pass was accomplished only after fearful hardships, with the loss of one-third of his army and all his guns. In Switzerland he found that Korsakoff had been defeated by Masséna and that the French were masters of the country. He thereupon began a retreat through the Grisons and Vorarlberg, in which he displayed some of the highest qualities of his generalship. Setting out on the way to Russia, after he had been named commander-in-chief of all the Russian forces with the title of Prince Italieski, he lost the favor of the Emperor Paul before his arrival in Saint Petersburg, where after a short ailment he died. Consult Smith, F., 'Suworow's Leben und Heerzüge' (Vilna 1833–34); also his 'Autobiography,' edited by Glinka (1819); and biographies by Polevoi (1853); Spalding (1890). Consult also Macready, E. N., 'A Sketch of Suwarrow and his Last Campaign' (London 1851), and Reding-Biberegg, 'Der Zug Suworows durch die Schweiz' (Zürich 1869).

SUWANNEE, sū-wā'nē, a river in southern Georgia, in the Okefinokee Swamp, which flows in a winding, generally south-southwest course through Florida into the Gulf of Mexico, about 10 miles north of Cedar Keys. It is the subject of the popular ballad, 'Old Folks at Home,' beginning «Way Down on the Suwannee River.» Its total length is about 240 miles.

SUWARROW, soo-vä'rŏv, or **SUVAROF**, a group of islands in the Pacific Ocean, between Samoa and the Manihiki Islands, is generally included in the Tokelan Islands. It has important pearl fisheries. Great Britain annexed the islands in 1889.

SUYEMATSU, Kencho, Viscount, Japanese statesman, son-in-law of Marquis Hirobumi Ito (q.v.): b. Bunzen, Kiusiu, August 1855. He served in the Satsuma Rebellion as civilian staff officer to the commander-in-chief of the army, and later engaged in journalism on the staff of *Nichi Nichi*. In 1890–95 he was a member of the Japanese House of Commons, and after he was created baron in 1895 he served in the House of Peers. He was director of the Legislative Bureau in 1892–1905; Minister of Communications in the Ito Cabinet in 1898; and held the portfolio of the Interior in the Seiyukai Cabinet in 1900–01. He served as a non-official agent for Japan in London during the Russo-Japanese War in 1904–05. He was made a viscount in 1907. He translated into English 'Genji Monogatari'; and is author of 'The Risen Sun: A Fantasy of Far Japan' (1915).

SUZZALLO, Henry, American university president: b. San José, Cal., 22 Aug. 1875. He was graduated at the California State Normal School in 1895, at Leland Stanford Junior University in 1899 and took his Ph.D. at Columbia University in 1905. He was connected with the faculty at Leland Stanford Junior University in 1902–07; was professor of the philosophy of education at Teachers' College, Columbia, in 1909–15; and since 1915 has been president of Washington University, Seattle. He has edited the *Riverside Educational Monographs* since 1909, has lectured extensively and is a contributor to educational magazines. He was appointed chairman of the Washington State Council of Defense in 1917.

SVERDRUP, svĕr'drŭp, **Otto**, Norwegian Arctic explorer: b. Harstad Farm, Helgeland, 1855. He went to sea at 17, went with Nansen to Greenland in 1888, and again in 1893, as commander of the *Fram*, which he brought back to Norway in 1896. He led an expedition to the northern regions in 1898, with the intention of exploring the north of Greenland. The expedition received its financial support mostly from two brothers of the name of Ringnes, and the Norwegian government renovated and equipped the *Fram* for his use. On reaching Smith Sound, between Ellesmere Land and Greenland, he found it impossible to force his vessel further north through the ice, and sent two expeditions to the southwest across Ellesmere Land, which penetrated a region never before explored, and found in the southern part of Ellesmere Land a large glacier district. Later in 1899 he brought the *Fram* down to Jones Sound, to the south of Ellesmere Land, and from there conducted a number of sledging expeditions, exploring the southern and western portions of Ellesmere Land. On the southeast coast of Ellesmere Land, north of Jones Sound, a large bay was discovered about 100 miles in breadth and penetrating into Ellesmere. On the northern side of this bay large and complicated fiords are situated. On the west coast of Ellesmere Land, in about 89° W., a large system of fiords was discovered. To the west of Ellesmere Land, about 130 miles north of the Parry Islands, Sverdrup discovered two islands, to the north and west of which nothing was visible but rough polar ice. He returned to Norway in 1902. The discovery of the islands and the mapping of the western and southwestern coasts of Ellesmere Land are the most important results of Sverdrup's expedition. He brought back also a valuable series of meteorological reports, and a representative natural history collection. In 1914–15 he led a relief expedition to the Arctic and wintered on the shores of Kara Sea. He published 'New Land: Four Years in the Arctic Regions' (1904).

SVETLA, Karolina, Bohemian novelist: b. Prague, Austria, 24 Feb. 1830. She gained the attention of the literary critics by her first novel 'A Double Awakening,' published in 1858. She has attained high rank in Bohemian literature, many of her novels being translated into French, German, Polish and Russian. Among them are 'Láska k básnikovi' (1860); 'Vesnicky roman' (1869); 'Kriz a potoka' (1871); 'The Atheist' (1873).

SWABIA, swā'bĭ-a̦, or **SUABIA** (German, SCHWABEN), capital Augsburg, now part of the republic of Württemberg, formerly a duchy in the southwestern part of Germany, occupying the area now covered by Baden, Württemberg and a part of Bavaria. It extended from the Rhine on the west to the Lech on the east, and from Switzerland northward to the Rhine Palatinate. It is a mountainous country, and probably the most picturesque portion of Germany. The region was known in ancient times as Allemannia, and received its present name from the Suevi, who entered it in the 5th century and amalgamated with the Allemanni. In the 10th century Swabia was raised into a duchy which continued in the house of Hohenstaufen until 1268, when it was resolved into a number of lesser principalities among whom there was continual feud. In 1488 these little states formed the famous "Swabian League" for the purpose of securing internal peace and giving mutual aid to each other. In 1512 the emperor, Maximilian I, made Swabia one of the 10 circles into which Germany was divided, and enlarged its territory. This division continued until 1806, when the modern kingdom of Württemberg was founded. (See BADEN; WÜRTTEMBERG). At present the name of Swabia is retained by one of the southwestern provinces of Bavaria. Consult Stalin, B. F., 'Geschichte-Württemberg' (Gotha 1882–87); Schneider, Eugene, 'Württembergische Geschichte' (Stuttgart 1896). See WAR, EUROPEAN.

SWAGE (swāj) **BLOCK,** a heavy iron block or anvil provided with notches and perforations, used by blacksmiths in shaping metal. The swage block is so arranged that it may be readily clamped in any desired position and may as readily be released whenever it is necessary to adjust the anvil to a different position. The block has trunnions or journals which engage open bearings formed on the top of the standards of the frame. The standards are connected with each other at their lower ends by bolts. Midway of their height they are connected by a clamping device which consists of a rod revolubly secured to one standard and threaded into a nut in the other standard. By operating a crank on this rod the upper ends of the standards may be drawn together to bind against the ends of the swage block and hold it from turning. Inwardly-directed flanges are formed on the standards just below the trunnion bearings, and these on being drawn inward form firm supports for the swage block when in horizontal position. The recesses lying between these flanges receive and securely hold the swage block when turned to vertical position. When the swage block is held at other angles the flanges sink into grooves formed in the ends of the block around the journals. The usual variety of notches, recesses, perforations, etc., are provided for assisting in upsetting bolts, shaping horseshoes and forming all other devices which a blacksmith may be called upon to make. The construction of this swage block is the extreme of simplicity.

SWAIN, swān, **George Fillmore,** American civil engineer: b. San Francisco, Cal., 2 March 1857. He was graduated at the Massachusetts Institute of Technology in 1877 and then studied in Berlin, Germany. In 1887 he accepted the chair of civil engineering at the Massachusetts Institute of Technology, where he remained until 1909. He also served as consulting engineer of the Massachusetts Railroad Commission and was member of the Boston Transit Commission and its chairman in 1913. In 1909 he was made professor of civil engineering at the Harvard Graduate School of Applied Science. He is the author of 'Notes on Hydraulics' (1885); 'Notes on Theory of Structures' (1893); 'Report on the Water Power of the Atlantic Watershed' (in Vol. XVII of the 'Tenth United States Census') and 'Conservation of Water by Storage' (1915).

SWAIN, Joseph, American college president: b. Pendleton, Ind., 16 June 1857. He was graduated at the Indiana University in 1883, was assistant professor of mathematics in 1883–86 and full professor, 1886–91. He was called to the chair of mathematics in the Leland Stanford Junior University in 1891, which he held till 1893, and was president of Indiana University, 1893–1902. Since the last-named date he has been president of Swarthmore College. He is the author of numerous scientific papers. In 1913–14 he was president of the National Education Association.

SWALLOW HOLES. See SINK HOLES.

SWALLOW-TAILED BUTTERFLIES, butterflies of the family *Papilionidæ*, typical species of which have the hinder wings extended into prolongations called «tails.» See BUTTERFLY.

SWALLOWS, a family (*Hirundinidæ*) of passerine birds which are the counterpart in this order of the swifts (q.v.). This family is distinguished by the small, flat, triangular bill which has its sides gradually compressed toward the tip and the deeply cleft mouth, the margins of which bear very small bristles or none; the nostrils rounded at the base of the bill, either exposed or covered by a scale. The wings are long, while the tail is forked in nearly all species and the outer feathers may be prolonged. The feet, although small and weak, are totally unlike those of the swifts, the hind toe being never versatile, the number of phalanges not different from that of ordinary birds and the squamation normal; sometimes the tarsi and toes are feathered. In striking contrast to the somber-hued swifts, many of the swallows are adorned with rich iridescent colors and sometimes the sexes differ. Anatomically the swallows are truly passerine, but the fissirostral bill and mouth, together with their peculiar adaptations to life awing, makes them one of the most clearly circumscribed and natural families of that order. Owing to the many interesting modifications of the type the genera are numerous and many of them restricted in distribution; but the more generalized genera, like the typical *Hirundo*, are, like the family, cosmopolitan. About 100 species have been described. Belonging to the North American fauna are 10 species representing no less than seven genera, most of which are peculiarly American. The barn-swallow (*Hirundo* or *Chelidon erythrogaster*) is abundant throughout North America and is easily distinguished by the elongated outer tail-feathers, the lustrous steel-blue color of the upper parts and the ruddy breasts. (See BARN-SWALLOW.) The cliff or eaves swallow is colored much like the barn-swallow, but the tail is shorter and only slightly forked; it makes retort-shaped nests outside of barns, etc., under the eaves, as it formerly did on the faces of cliffs.

One of the swallows which retains its original habits is the beautiful white-bellied or tree-swallow (*Tachycineta bicolor*). It is of a fine lustrous green above, pure white below, with a tail only slightly more forked than in the last. The tree swallow is abundant in most parts of temperate North America, but especially so coastwise where great numbers nest in holes of trees from New Jersey northward. It is one of the first swallows to move northward in the spring and is frequently forced to retreat before a belated snowstorm or cold snap, being, therefore, one of the species to which the common saying, «one swallow does not make a summer,» is especially applicable. In the West a related species, the violet-green swallow (*T. thalassina*), is found. Another conservative member of the family is the bank-swallow, which is found in Europe as well as in America. Closely resembling it is the rough-wing.

Biggest, handsomest, jolliest, most domestic of American swallows and ever ready to defend his home is the purple martin (*Progne subis*), a familiar species throughout temperate North America, distinguished as a genus (*Progne*) by the strong bill with curved edges, by the moderately-sized forked tail, and by the strong and large feet. The sexes are quite dissimilar, the male being entirely blue black, the female and young, dull sooty gray on the breast. Except in the wilds where it continues to nest in hollow trees, it takes up its abode among the habitations of men. A common practice is to hang up gourds, properly hollowed, for its convenience in nest-building; and in the more settled parts considerable expense is sometimes incurred in preparing for it a suitable residence. The eggs are four to six in number and white. In the country it renders essential services by attacking and driving away crows, hawks, eagles and other large birds. Its note is loud and musical. The regularity with which this species arrives from the South is noteworthy. The western variety is distinct and another species enters Florida.

Of exotic species of swallows the *Hirundo rustica* takes the place in Europe of our barn-swallow. On account of its frequent use of disused chimneys for nesting places this species shares with the swifts the name of chimney swallow. The migration of these birds has always attracted attention from the well-known and unvarying character of their movements. They fly southward at the end of October or sometimes sooner, to winter in Africa, some finding their way to India. The majority arrive in Great Britain in April, some stragglers later and a few coming before the great body of birds. They generally return to the nests they have constructed the previous year. The house martin (*Chelidon urbica*) with the tarsi and toes feathered is of small size. It is of smaller size than the common swallows, and builds its nest under the eaves of houses, in the corners of windows, etc., the nest being a hemispherical structure of clay, with a round opening for entrance. A related species is the fairy martin (*C. ariel*), found in South Australia, where it arrives in August, leaving again in September or October. The nest, built in some tree, under eaves or in rocks, is formed of mud, and is of flask-like shape. Each nest appears to be built by a number of these swallows. The wire-tailed swallow (*C. filifera*) of Abyssinia is so named from the presence of the two elongated tail-feathers, which, being unprovided with a web, consist of the shafts of the feathers alone, and appear as long filaments. The genus *Atticora* includes the white-breasted swallow of South America (*Atticora cyanoleuca*), which makes its nest in the deserted burrows of animals. A number of other South American swallows have similar habits, occupying the nests or holes of various birds and mammals.

Consult Sharpe and Wyatt, 'Monograph of the Hirundinidæ' (London 1885–94), with bibliography and numerous colored plates; Forbush, 'Useful Birds and their Protection' (Boston 1913); Wilson, 'American Ornithology' (Philadelphia 1828); and recent works on field ornithology.

SWAMMERDAM, swăm'mĕr-dăm, **Jan**, Dutch naturalist: b. Amsterdam, 12 Feb. 1637; d. there, 15 Feb. 1680. He was educated for the ministry but turned his studies to the profession of medicine. He was devoted especially to the study of insects; and his 'General History of Insects' and other works laid the foundations of the modern science of entomology. These works include 'Tractatus de Respiratione usuque Pulmonum' (1667; Allgemeene verhandeling van bloedeloose dierjes' (1669); 'Biblia Naturæ, sive Historia Insectorum in certas classes Redacta' (1737–38).

SWAMP. See Bog.

SWAMP ANGEL, in the American Civil War the popular name of an 8-inch Parrott gun, so called by the Federal soldiers. It was mounted on a battery constructed on piles driven into the swamp near Charleston, S. C., and was used in the siege of that city. It burst 22 Aug. 1863, and was sent with a lot of old metal to Trenton, N. J. The gun was rescued from its impending fate and set on a granite base on the corner of Perry and Clinton streets in the city of Trenton.

SWAMP DEER, or BARASINGHA, an East Indian deer (*Cervus duvaucelli*), about four feet in height, rich light yellow in color, found in large herds in moist situations. The antlers are large, with a long beam which branches into an anterior continuation of the main portion, and a smaller posterior tine which is bifurcated.

SWAMP GRASS. See Grasses in the United States.

SWAMP HICKORY. See Hickory.

SWAMP LAND GRANTS. The need of reclaiming the swamp and overflowed lands within the territory of the United States was brought to the attention of Congress in the early part of the 19th century. It was not, however, until the Act of 2 March 1849 that Congress made provision for the reclamation of such lands. This Act applied exclusively to the State of Louisiana, and provided that in order to aid the State in constructing the necessary levees and drains to reclaim the swamp and overflowed lands therein the whole of such lands that may be found unfit for cultivation were granted to the State with the proviso that the proceeds of the sales of all such land shall be applied exclusively as far as necessary to the construction of levees and drains for their reclamation.

This was followed by the Act of 28 Sept. 1850 which provided for a similar grant to the State of Arkansas. This act contained a section which extended its benefits to each of the other States of the Union in which such swamp and overflowed lands may be situated.

By the Act of 12 March 1860 the provisions of the Swamp Acts were extended to the States of Minnesota and Oregon which had been admitted to the Union since the passage of the Act of 1850. The reasons assigned for these grants were the worthless character of the lands in their present condition, the unhealthful effects of these lands and the enhancement in value of the adjoining government property.

At the time of this legislation it was estimated that the area of lands involved would be about 5,000,000 acres. However, up to 30 June 1918 there had been conveyed to the several States under these grants 64,258,731.04 acres. In addition there have been granted to the States 744,385.23 acres as indemnity for lands which had been disposed of to settlers prior to the time when the several grants became effective and also a cash indemnity in lieu of lands which would otherwise have been granted, amounting to $2,095,466.70. Comparatively small additional claims are coming in under these grants.

In spite of these liberal grants of land and money the States have not drained the great body of land actually granted and in many cases the proceeds from the sales of the lands have been used for other purposes. The same reasons for reclaiming these lands which formed the original basis for these grants, therefore, still exist and the United States government has in recent years spent considerable sums to aid in the development of plans for the reclamation of small bodies of these swamp lands. There has also been a widespread sentiment that something definite should be done to make these lands available for agricultural purposes as the area of actual swamp land in the United States is estimated at from 75,000,000 to 80,000,000 acres.

Morris Bien.

SWAMP LOCUST. See Locust.

SWAMP RABBIT, or WATER HARE. See Hares.

SWAMP SASSAFRAS. See Magnolia.

SWAMPSCOTT, swŏmp'skŏt, Mass., town in Essex County, on Massachusetts Bay, and on the Boston and Maine Railroad, about 12 miles northeast of Boston and two miles northeast of Lynn. The town contains the villages of Beach Bluff, Mountain Park, Phillips Beach and Swampscott. It is a favorite watering place, and has an excellent beach and good accommodations for transient guests. There are several churches, a town high school, district schools, a public library and several private schools. Most of the inhabitants are employed in Lynn. Pop. 7,345.

SWAN, James, American soldier and author: b. Fifeshire, Scotland, 1754; d. Paris, 18 March 1831. He came to Massachusetts at an early age, became an artillery captain, a member of the legislature in 1778, and was subsequently adjutant-general of the State. He went to Paris in 1787 where he wrote 'Causes qui sont opposées au Progies du Commerce entre la France et les Etats-Unis de l'Amérique' (1790). He returned to America in 1795 only to go back to France in 1798. In 1815 he was arrested and imprisoned for 15 years at the suit of a German with whom he had had business relations. Among other books of his are 'On the Fisheries' (1784); 'Fisheries of Massachusetts' (1786).

SWAN, John Macallan, English sculptor: b. Old Brentford, 1847; d. 1910. He studied at the Worcester School of Art and the Lambeth Art School and under Gérôme and Frémiet in Paris. In 1885 he received honorable mention at the Salon, and in 1889 received the silver medal at the Paris International Exhibition. He received the first and second gold medals at Munich and the first class gold medal for painting and the first class gold medal for sculpture at Paris, 1900. Most of his sculptures are studies of animals and in representing the cat tribe he is particularly successful in giving vivacity and vitality to the rapid furtive advance of the leopard or tiger. His principal works are 'Leopard Running'; 'The Prodigal Son'; 'Lioness defending her Cubs'; 'Polar Bears Swimming'; 'A Dead Hero'; 'The Jaguar'; 'Puma and Macaw' (1900); 'Wounded Leopard'; 'Tigers Drinking,' owned by Henry Frick, New York; 'Ceylon Leopards.' In 1905 he was made a Royal Academician. Consult Baldry, 'J. M. Swan, R.A.' (New York 1905).

SWAN, Joseph Rockwell, American jurist: b. Westernville, N. Y., 28 Dec. 1802; d. Columbus, Ohio, 18 Dec. 1884. He removed to Columbus, Ohio, in 1824 and was there admitted to the bar. He was prosecuting attorney in 1830–34, and judge of the Court of Common Pleas (1834–45). In 1854 he became judge of the Supreme Court and 1859 rendered his most important decision. The United States District Court in Ohio had sentenced a prisoner for violating the Fugitive Slave Law. Under a writ of habeas corpus the Supreme Court of the State sought to set aside the sentence, but it was sustained by Judge Swan, who declared that the State could not reverse the decisions of the United States courts. His publications include 'Treatise on Justices of the Peace and Constables in Ohio' (1836); 'Statutes of Ohio' (1841); 'Manual for Executors and Administrators' (1843); 'Practice in Civil Actions and Proceedings at Law in Ohio and Precedents in Pleading' (1845); 'Swan's Pleadings and Practice' (1851); 'Commentaries on Pleadings under the Ohio Code' (1860).

SWAN, Sir Joseph Wilson, English inventor: b. Sunderland, 31 Oct. 1828; d. 1914. He invented the carbon process of making autotypes, and with Woodbury introduced Woodburytype. To him also is due the invention of the dry plate, which has revolutionized photography. His name is, however, best known in connection with a form of incandescent electric lamp devised by him, which was the earliest in date of the many electric lamps now in use. His other inventions include a miner's electric safety-lamp, and various improvements in photo-mechanical printing and electro-metallurgical deposition. He was a knight of the Legion of Honor, and in 1898–99 he was president of the Institution of Electrical Engineers. He was knighted in 1904.

SWAN, a sub-family (*Cygninæ* or *Oloridæ*) of the duck family, characterized by great size and length of neck. The swans have the legs (tarsi) short and reticulated, the front toes being strongly webbed, while the hind toe is not webbed, and has no lobe; and the loral region (between the eyes and the bill) is naked.

In the water the swans are the type of grace and beauty of figure, the long arched and flexible neck, the elevated wings, and their buoyancy and skill in turning and gliding over the surface, all contributing toward this effect. On land, however, the very posterior position of the legs renders them awkward and slow. Unlike the fussy ducks and geese there is a calmness and dignity about the behavior of swans which has always excited admiration and has caused these birds to figure much in poetic literature. Swans are generally quiet birds and some appear to be constitutionally mute, but most of them possess the most powerful and sonorous voices, though none of the musical ability attributed by poets to their death song. These great vocal powers are due to the sounding apparatus developed by the coiling of the greatly elongated trachea within the sternum, much after the fashion of the same organ in certain cranes (q.v.). Not over 10 clearly marked species of true swans are known the world over and nearly every part of the world has its one or more species, for these birds are strong of wing and wide ranging. No species, however, breeds in Africa. They are arranged in four or five genera.

The North American swans belong to the genus *Olor,* distinguished from the typical *Cygnus* by purely technical characters. The two species, the whistling swan (*O. columbianus*) and the trumpeter swan (*O. buccinator*) are much alike in appearance, being chiefly white, but the latter is the larger, attaining a length of five feet and a spread of eight feet. And the tail contains 24 quill feathers, whereas the whistling swan has but 20. The former is the more widely distributed and the one usually seen on both the Atlantic and Pacific coasts, while the trumpeter swan is most characteristic of the Mississippi Valley, up and down which it migrates, breeding in the upper parts and wintering along the Gulf coast. The whistling swan breeds only in the far north entirely beyond the limits of the United States. It winters in considerable numbers in Chesapeake Bay and the sounds of North Carolina. They associate with wild geese and like these feed largely upon water plants. On account of their large size they are considered great prizes among gunners, but the younger birds, distinguished by the duskiness of their plumage and their less brazen voices, are preferred for table use. The nests are on the ground and are lined with dried grass and down. The two to five eggs are about four and one-half inches long and of a yellowish-white color. Except for the differences resulting from its distribution and fresh-water habitat the habits of the trumpeter swan are essentially similar.

The common domesticated white or mute swan (*Cygnus olor*) is a native of Europe, Asia and Africa. Those of Great Britain are all of the introduced domesticated variety. The swan has, from a very early date, been especially protected by both legal and regal interference. In Henry VII's reign the theft of a swan's egg was deemed an offense punishable by a year's imprisonment; and the theft of a swan itself was very severely punished. Swans at a prior date were declared to be exclusively "royal" or "king's" property; and no subject was entitled to hold possession of these birds, save under special favor from the sovereign. To such subjects as possessed the permission to keep swans a special "swan" mark was attached, and this mark was cut on the bill of the birds as a distinctive badge of ownership. The process of marking is known as "swan-upping" or "hopping," and the ceremony in the Thames on the part of the Crown and of the Dyer's and Vintners' companies takes place on the first Monday in August. At the present time but few swanneries remain, but in some places cygnets are carefully raised and bred for the market and a few of these birds are kept for ornamental purposes in most large parks. Several other wild species occur in the Old World and one true swan in South America. The black swan (*Chenopsis atrata*) is an Australian species, first discovered in 1698; the general plumage is black, the bill being deep red, the primary wing-feathers white and the trachea does not enter the sternum. It is well known in the United States as an ornamental bird. Consult Beebe, C. W., 'The Swans' (in 'Tenth Annual Report of the New York Zoological Society,' New York 1906); Stejneger, 'Proceedings U. S. Nat. Mus.' (Washington 1882); Newton, 'Dictionary of Birds' (Vol. IV, London 1896); Grinnell, 'American Duck Shooting' (New York 1901).

SWAN, Knight of the, according to a legend of the lower Rhine, a knight who comes from an unknown country in a boat drawn by a swan, delivers a prince's daughter from her hated suitor and marries her himself, and afterward is obliged to leave her since in spite of his forbidding her to do so she inquires and learns his origin, her ignorance of which is the sole condition of his remaining with her. This fable, which has parallel forms in the earliest mythologies, is varied in many ways by the poets and story-tellers of the Middle Ages. Thus in the French variant 'Roman du Chevalier au Cygne,' Godfrey de Bouillon is the hero of the story. This version is followed by the unknown author of the tale 'Lohengrin'; while Conrad of Würzburg in his poem, 'The Swan Knight,' places the incident in the days of Charlemagne. Consult Hagen, 'Die Schwanensage' (1845); Müller, 'Die Sage vom Schwanen'; Jaffray, 'Two Knights of the Swan' (New York 1910); Newell, W. W., 'Legend of the Holy Grail' (Cambridge, Mass., 1902).

SWAN, Order of the, an order of knighthood created in 1440 by the Elector Frederick II of Brandenburg. Its headquarters were in a monastery on a hill near Brandenburg and in Ansbach. It was composed of members of the nobility and its object was to encourage more enthusiastic homage to the Virgin Mary, and perseverance in works of mercy. The order was abolished at the time of the Reformation, but was revived by Frederick William IV of Prussia 24 Dec. 1843 in the form of a free association of men and women of all ranks and creeds for the purpose of alleviating the moral and physical misery of others. Consult Hanle, 'Urkunde und Nachweise zur Geschichte des Schwanenordens' (1874).

SWAN MAIDEN, The. See VALKYRIES.

SWAN RIVER. See AUSTRALIA, WEST.

SWANEVELT, svän'ę-fělt, **Hermann,** Dutch painter: b. Woerden, 1618; d. Rome, 1690. He set out for Italy when very young, carefully studied the scenery of its beautiful districts and, captivated by the pictures of Claude Lorraine, became a scholar of this famous master. He equaled, or perhaps surpassed, his master in his figures both of men and animals, and will always hold a first place among the greatest of landscape-painters. His etchings, 116 in number, partly of subjects of his own invention and partly of actual scenery, are very much admired. His pictures, even during his lifetime, brought very high prices.

SWANK, James Moore, American economist: b. Westmoreland County, Pa., 12 July 1832; d. 21 June 1914. He founded the Johnstown *Tribune*, 1853; was chief clerk Agricultural Department, 1871–72; secretary American Iron and Steel Association 1873–85. He is the author of 'History of Iron in all Ages'; 'Iron Making and Coal Mining in Pennsylvania,' and over 50 tracts on the tariff question.

SWANSEA, swŏn'sē, or **ABERTAWE,** Wales, an important seaport, capital of the county of Glamorgan, on the right bank of the river Tawe, at its mouth in Swansea Bay, 35 miles west-northwest of Cardiff. The town contains a fine town-hall with a Corinthian façade; the Royal Institution of South Wales, including a library, museum, etc.; a large building in which are housed the public library, art gallery and schools of science and art; a grammar, technical and other schools; the general hospital, a deaf and dumb institution, a blind asylum, etc.; remains of an ancient castle dating in its present form from the 16th century, though first built in 1099; and several public parks. The harbor is an excellent one with ample modern docks. The staple industries are the smelting and refining of copper, gold, silver and pyrites, which are imported for the purpose from many countries, the manufacture of tinplate and the working of iron, steel, zinc, nickel, lead and other metals. Chemicals, patent fuels and alkali are also made in considerable quantity, and there are flour-mills, shipbuilding yards, etc. Swansea is also a leading seaport, its imports average annual value $22,000,000, being chiefly the raw material for its metallurgical industries, wheat and other grains, sugar and timber; and its exports average annual value $30,000,000, mainly coal, coke and patent fuel, iron and iron and steel manufactures, wrought and unwrought copper and chemical products (dyestuffs, sulphate of copper and carbide of calcium). The vessels annually at the port have an average total tonnage entered and cleared of about 5,000,000 tons. Swansea has municipal tramways worked by electricity, and the town is served by the Great Western, London and North-Western, Midland and some local Welsh railways. The first charter of the borough was granted by King John, and subsequent charters were conferred by Henry III, Edward II, Edward III and Cromwell. The copper industry of the town began to attain importance early in the 19th century, and since about 1830 the town has rapidly advanced in consequence of the development of this and other industries. Pop. 114,663.

SWANSON, Claude Augustus, American senator: b. Swansonville, Va., 31 March 1862. He was graduated at the Randolph-Macon College in 1885 and at the University of Virginia in 1886, afterward engaging in law practice at Chatham, Va. He served in Congress as a Democrat in 1893–1905, when he resigned after re-election, and in 1906–10 he was governor of Virginia. In 1910 he was appointed United States senator to fill the unexpired term of John W. Daniel, and was subsequently elected to that office for the terms 1911–17 and 1917–23.

SWANTON, John Reed, American ethnologist: b. Gardine., Me., 19 Feb. 1873. He was graduated at Harvard University in 1896, later studied at Columbia University and took his Ph.D. at Harvard in 1930. He has been ethnologist of the Bureau of American Ethnology, Washington, since 1900. Author of 'Contributions to the Ethnology of the Haida' (1905); 'Haida Texts and Myths' (1905); 'Social Conditions, Beliefs and Linguistic Relationship of the Tlingit Indians' (1904–05); 'Tlingit Myths and Texts' (1909); 'Haida' (1911); 'Indian Tribes of the Lower Mississippi Valley and the Adjacent Coast of Mexico' (1911), etc. He is joint author of 'Dictionary of the Biloxi and Ofo Languages' (1912); 'Anthropology in North America' (1915), etc.

SWARTHMORE (swârth'mōr) **COLLEGE,** located at Swarthmore, Pa. It was founded by the liberal (or Hicksite) body of the Society of Friends, and was first opened in 1869. The main building was destroyed by fire in 1881, but was immediately rebuilt. The college now confers regularly but one baccalaureate degree, that of A.B. This was the original custom until 1874, when the practice of conferring the three degrees of A.B., B.S. and B.L., and the special degree of bachelor of science in civil engineering was adopted; in 1903 the college returned to its first practice. Courses in engineering and mechanic arts are offered, and provision is made for a special course leading to the degree of bachelor of science in civil engineering. The A.B. course includes certain prescribed studies, one major study in any one department in which three full years of college work must be completed, and electives to complete the required number of hours. The prescribed studies include English, Bible study, history or economics, at least one language and one science, and mathematics, or engineering. In the departments of biology, chemistry and physics courses are planned to prepare for the study of medicine. The degrees of master of arts and civil engineer are conferred for graduate work. Swarthmore has been from the first a coeducational college, being the second institution east of the Alleghany Mountains to offer instruction to men and women on absolutely equal terms. Though it is a small college, and not a university, it is especially well equipped for an institution of its size, especially in the science and engineering departments. It has a campus comprising more than 200 acres, bordered by the gorge of Crum Creek, and including the farm on which Benjamin West, the artist, was born. The chief buildings are Parrish Hall (the main building), Science Hall, the observatory, the two gymnasiums, the president's house and residences of the professors, Wharton Hall (a new dormitory). There are two fellowships and 17 scholarships. The productive funds amount to about $1,600,000 and the annual income to $170,000, the library contains 35,000 volumes, including the Friends' Historical Library. The students number 450 and the faculty about 50.

SWASTIKA, a symbol of the sun in the nature-religions of Aryan races from Scandinavia to Persia and India; and similar devices occur in monumental remains of the ancient Mexicans and Peruvians, and on objects exhumed from prehistoric burial mounds within the limits of the United States. The Swastika consists of a Greek cross, either enclosed in a circle the circumference of which passes through its extremities ⊕, or with its arms bent back thus 卐, and it is found invariably associated with the worship of the Aryan sun-gods (Apollo, Odin), it is believed to represent the sun. Consult d'Alviella, Eugène Goblet, 'La migration des symboles' (Paris 1891); de Milloué Léon, 'Le Svastika' (in *Annales du Musée Guimet,* Vol. XXXI, Paris 1909); Wilson, Thomas, 'The Swastika, the Earliest Known Symbol and its Migration' (in United States National Museum, *Annual Report,* 1894, Washington 1895).

SWAT, swät, India, a territory or district of the Northwest Frontier Province, occupying the valley of the Swat River, north of Peshawar and south of Chitral. It was well known to the ancients, but seldom visited by Europeans until the uprising of the frontier tribes in 1895. It is a narrow valley between lofty mountains, and inhabited by industrious, liberty-loving Afghan tribes. Pop. about 40,000.

SWATOW, swä-tow', China, a treaty port in the province of Kwang-tung, situated at the mouth of the Han River, 175 miles northeast of Hongkong. The total trade of the port amounts to nearly $34,000,000 annually. The chief exports are sugar, tobacco, cloth and fruits. The port was opened to foreign trade in 1858. The imports reach annually the sum of about $30,000,000, and the exports to $11,000,000. Pop. 66,000.

SWAYNE, swān, **Noah Haynes,** American jurist: b. Culpeper County, Va., 7 Dec. 1804; d. New York, 8 June 1884. He was admitted to the bar in 1823; settled in Coshocton, Ohio, in 1825; and was prosecuting attorney of the county in 1826–29. In the latter year he became a Democratic member of the legislature. He was United States district attorney for Ohio in 1831–41. He was an associate justice of the United States Supreme Court in 1862–81. In the latter year he resigned owing to advanced age.

SWAZILAND, swä'zē-lănd, South Africa, a native state between the Drakensberg and Lobombo ranges, on the borders of the Transvaal. Its surface is mountainous but fertile, and it is thought to contain rich gold and coal deposits. It possesses fine prairies, which offer fine pasturage, especially in winter. There are also extensive forests which contain fine timber — a rarity in South Africa. Water is plentiful, the climate is healthful. The Swazis are a Zulu tribe and were subject to the intrigues of Great Britain and the Transvaal. The Boers obtained supremacy in 1895, which passed with their conquest and annexation by England in 1902. Authority passed to the high commissioner of South Africa in 1906. The Roman-Dutch law is in force. The British resident commissioner is located at Mbabane. Area, 6,536 square miles. Pop. 107,117.

SWEABORG, svä'ä-bŏrg, or **SVEABORG,** Finland, a fortress and naval arsenal, three miles southeast of Helsingfors, which it defends, on a series of islands in the Gulf of Finland. The fortifications are so important as to entitle the islands "The Gibraltar of the North." The principal works occupy five islands which are connected by bridges. The island of Bärgo contains the chief military departments, arsenal and school of marines; the shipping docks hewn in solid rock, powder magazine and the monument to the Swedish Field-Marshal Ehrensvärds, who erected the fortifications. The strongest fort stands on the island south from here and is called Gustavsfard. Sweaborg was taken by the Russians in 1808; in 1855 it was bombarded by the French and English allied troops. After the revolution in Russia in 1917 Sweaborg was taken by the Finns, and upon the establishment of Finland as an autonomous state it was incorporated therein. Civil pop. about 1,000.

SWEARING, Profane, the use of oaths in a light and familiar manner by way of asseveration or emphasis. As popularly understood, «profane swearing» involves also many terms of a gross and obscene character. Profane swearing and cursing are made punishable in England by the Act of 19 Geo. II, ch. xxi, which prescribes a graded tariff of penalties for offenders according to their social rank: for each profane oath or curse a laborer, soldier or sailor incurs a penalty of a shilling; other persons under the rank of gentleman two shillings; a gentleman or any one above that rank, five shillings. In several of the States of the American Union profane swearing is variously declared punishable by the statutes. See BLASPHEMY.

SWEAT. See PERSPIRATION.

SWEATMAN, Arthur, Canadian Anglican archbishop: b. London, England, 19 Nov. 1834; d. Toronto, Canada, 24 Jan. 1909. He studied at the University of London and was graduated at Cambridge University in 1859. He was ordained priest in 1860 and in 1865 he removed to Canada where he became head master at Hellmuth Boys' College, London, Ontario, a position he occupied in 1865–72 and 1874–76. He was chaplain to the bishop of Huron, and secretary to the Synod of the diocese of Huron in 1872–79, and held other offices in the Church. He became canon of the cathedral at London, Ontario, in 1875 and was made archdeacon later in that year. In 1879 he was appointed bishop of Toronto, and in 1907 he became archbishop, metropolitan and primate of all Canada.

SWEATING SICKNESS, a febrile epidemic disease of extraordinary malignity which prevailed in Europe, particularly in England, at different periods toward the end of the 15th century and the beginning of the 16th. It appears to have spared no age nor condition, but is said to have attacked more especially persons in high health, of middle age and of the better class. Its attack was very sudden, producing a sensation of intense heat in some particular part, which heat afterward overspread the whole body, and was followed by profuse sweating, attended with insatiable thirst, restlessness, headache, delirium, nausea, an irresistible propensity to sleep and great prostration of strength. The patient was frequently carried off in one, two or three hours from the eruption of the sweat. It seems to have first appeared in the army of the Earl of Richmond upon his landing at Milford Haven in 1485, and soon spread to London. This body of troops had been much crowded in transport vessels, and was described by Philip de Comines as the most wretched that he had ever beheld, collected probably from jails and hospitals, and buried in filth. It broke out in England four times after this, in 1506, 1517, 1528 and 1551. The process eventually adopted for its cure was to promote perspiration and carefully avoid exposure to cold. The violence of the attack generally subsided in 15 hours. The disease is endemic in parts of Picardy, France, and in Italy, being known in the latter country as miliary fever. In 1906 there was an epidemic in France. It appears to be allied to influenza. Compare the epidemic of the latter disease in the armies operating in Picardy in 1918, whence it spread throughout the world. Consult Hecker, J. F. K., 'Epidemics of the Middle Ages' (London 1859) and Osler, W., 'Modern Medicine' (Philadelphia 1914).

SWEATING SYSTEM. See FACTORIES AND FACTORY INSPECTION; FACTORY SYSTEM, THE.

SWEDBERG, svād'bĕrg, afterward **SWEDENBORG,** swē'dn-bôrg, Swed. svä'dĕn-bŏrg, **Emanuel,** Swedish theologian: b. Stockholm, 29 Jan. 1688; d. London, 29 March 1772. His father, Jesper Swedberg, was a chaplain and court-preacher to the king, Charles XI. Swedberg's paternal ancestors had been opulent miners in the province of Dalecarlia, and it is also claimed that the heroic blood of Engelbrecht, who liberated Sweden from Denmark in 1434, flowed in his veins. On the side of his mother, Sarah Behm, he descended from Gustavus Wasa, king of Sweden from 1523 to 1560. The name «Swedberg,» as well as Swedenborg, which was given to the family later when they were ennobled, was derived from «Sveden, by which name the homestead was called, and which means a clearing in the forest made by fire.

About all that is known of Swedenborg's childhood and early youth is contained in his autobiographical statements made in two letters, one to Dr. G. A. Beyer, a celebrated clergyman of Sweden, the other to Rev. Thomas Hartley, of the Established Church in England. In the former he writes: «From my fourth to my 10th year I was constantly engaged in thought upon God, Salvation and the spiritual ills of mankind; and several times I revealed things at which my father and mother wondered; saying, that angels must be speaking through me. From my sixth to my 12th year I used to delight in conversing with clergymen about faith, saying that the life of faith is love, and that the love which imparts life is love to the neighbor; also that God gives faith to every one, but that those only receive it who practise that love. I knew of no other faith at that time, than that God is the Creator and Preserver of Nature, that he imparts understanding and a good disposition to men, and several other things that follow thence. I knew nothing at that time of that learned faith which teaches that God the Father imputes the righteousness of his Son to whomsoever, and at such times, as he chooses, even to those who have not repented and have not reformed their lives. And had I heard of such a faith, it would have been then, as it is now (1769), above my comprehension.»

In the second letter he says: «In the year 1710 I went abroad. I proceeded first to England, and afterward to Holland, France and Germany, and returned home in the year 1714.

In the year 1716, and also afterward, I had many conversations with Charles XII, king of Sweden, who greatly favored me, and the same year offered me an assessorship in the College of Mines, which office I filled until the year 1747, when I resigned it, retaining, however, the official salary during my life. My sole object in tendering my resignation was that I might have more leisure to devote to the new office to which the Lord had called me. A higher post of honor was then offered me, which I positively declined, lest my heart should be inspired with pride. In the year 1719, I was ennobled by Queen Ulrica Eleanora, and named Swedenborg; and from that time I have taken my seat among the nobles of the rank of knighthood, in the triennial Diet of the Realm. I am a Fellow and Member, by invitation, of the Royal Academy of Sciences in Stockholm; but I have never sought admission into any literary society in any other place, because I am in an angelic society, where such things as relate to Heaven and the soul are the only subjects of discourse; while in literary societies the world and the body form the only subjects of discussion.» In the same letter he speaks of his special mission as follows: «I have been called to a holy office by the Lord Himself, who most mercifully appeared before me, His servant, in the year 1743; when He opened my sight into the spiritual world, and enabled me to converse with spirits and angels, in which state I have continued up to the present day (1769). From that time I began to print and publish the various arcana that were seen by me or revealed to me, concerning Heaven and Hell, the state of man after death, the true worship of God, the spiritual sense of the Word, besides many other most important matters conducive to salvation and wisdom. The only reason of my journeys abroad has been the desire of making myself useful, and of making known the arcana that were entrusted to me. Moreover I have as much of this world's goods as I need, and I neither seek nor wish for more.»

In the year 1709 Swedberg finished his studies at the University of Upsala. In September 1710 he went to London, where for two years he studied astronomy, chemistry, physics, mathematics and other sciences. Then he journeyed through Holland to Paris and after a full year of studies and researches there proceeded to Germany in pursuit of knowledge at the universities, returning to Sweden in 1715.

During the following five years Swedberg wrote 21 separate treatises and works on various scientific and practical subjects. Among these were descriptions of his own discoveries and inventions in science and the mechanic arts, as the construction of air-pumps, ear-tubes and flying machines, improvement in mining and smelting ores, the building of sluices and canals, the nature of fire and color, the manufacture of salt, the regulation of the coinage, and various astronomical, geological and mathematical subjects, besides an important and original little work on 'Tremulation,' being a theory of sensation in the human body. Up to this time Swedberg had written in Swedish for the most part, but afterward all his works were published in the Latin language.

In 1719, as above mentioned, the family was ennobled and took the name Swedenborg. In 1721 Emanuel Swedenborg set forth again on a Continental tour of 15 months, publishing the same year at Amsterdam treatises on 'Chemistry,' on 'Iron and Fire,' and astronomical and mechanical subjects. At Leipzig in 1722 he published his 'Miscellaneous Observations on Natural Things.' Returning to Stockholm he devoted the next 11 years to his duties in the College of Mines, his office in the Diet, and in elaborating a great work on the theory of creation or cosmogony which he published at Leipzig in 1734 while on a third foreign journey. This treatise, the 'Principia,' forms Part I of his 'Philosophical and Metallurgical Works,' of which Parts II and III treat of 'Iron' and 'Copper' respectively. The same year he published 'Outlines of a Philosophical Argument on the Infinite, etc.' The next year was devoted to duties at home, and the preparation of an extraordinary work on the 'Brain.' In 1736 he left Sweden for a fourth time, traveling by way of Hamburg and Amsterdam to Paris, where he remained through the following year, proceeding to Rome in 1738. The next year he returned to Paris and in 1740 published at Amsterdam the 'Economy of the Animal Kingdom, Part I.' The next year he published at the same place the second part of this remarkable work on the composition, essence and circulation of the blood; the arteries and veins, the heart and brain; the circulation in the fœtus, etc. Swedenborg's ruling aim and end in all his work now was to discover, if possible, the soul. Says he: «Bending my course inward continually, I shall open all the doors that lead to her, and by Divine permission, contemplate the soul itself.»

'The Animal Kingdom,' a great work elaborating still further a rational and philosophical view of human anatomy, was published in The Hague in 1744. It is notable that many of the doctrines in these books, discoveries and conclusions original with Swedenborg, have since been confirmed by modern investigation, but the honor has been attributed to others. Among such anticipations may be mentioned, the true office of the lungs; the animation of the brain, and of its coincidence, during formation, with the systole and diastole of the heart, and after birth, with the pulmonary respiration; the vitality of the blood, etc.

In 1745 appeared at London his 'Worship and Love of God,' the last of his publications previous to the opening of his spiritual sight, when he became a seer and revelator. He records three manifestations of the Lord to him calling him to his new office. The first was in 1743 in Amsterdam during a «preternatural sleep.» The second was at Delft in Holland in 1744 when, as he says, the Lord manifested himself in person and spoke with him. «It was a countenance with a holy expression, and such that it cannot be described; it was smiling, and I really believe that his countenance was such during his life upon earth.;

The third appearance of the Lord to him, Swedenborg relates, was in 1745 in London when the Lord manifested himself again in person, commissioning Swedenborg and calling him to the office of revealing the Doctrine of the New Jerusalem. «From that day,» he says, «I gave up the study of all worldly science and labored in spiritual things, according as the Lord commanded me to write.» Then followed two years of preparation and illumination before it may be said that he was gifted with a full state of inspiration and a perception of the inmost or celestial sense of the Word.

From 1748 to 1756 the 'Arcana Cœlestia' in eight vols., quarto, was published in London. This work, the first of Swedenborg's Theological and Doctrinal series, sets forth the internal sense of Genesis and Exodus as it was revealed to him, he declares, immediately by the Lord alone. Then followed (1758) 'Heaven and Hell,' describing the spiritual world and the life of man after death, as well the happy state of the blessed as the miserable lot of the infernal. In the same year appeared 'The White Horse'; 'The Earths in the Universe'; 'The Last Judgment'; 'The New Jerusalem and its Heavenly Doctrine.' During 1757-59 Swedenborg was engaged upon an explanation of the spiritual sense of the Apocalypse, which work he left uncompleted after writing 1,992 pages. It was published in 1785-89. 'The Last Judgment' describes that event itself which, as he testifies, Swedenborg witnessed in the spiritual world in 1757. 'The New Jerusalem and its Heavenly Doctrine' teaches that the New Jerusalem means the New Church now being established both in the natural and spiritual worlds, the doctrine of which is called Heavenly because it is received by angels and will be received on earth by men of angelic minds. In 1763 appeared 'The Four Doctrines of the New Jerusalem: The Lord, The Sacred Scripture, Life and Faith,' which as revealed in the Word are fundamental teachings of the Church; and 'The Divine Love and Wisdom' treating of the Lord as the Sun of heaven, the Creator of the Universe; of the nature of the Divine and its method and order in bringing ultimate finite and human creatures into existence and being. In 1764 'The Divine Providence' was published, showing how the created universe is perpetually sustained and setting forth the laws of God by which he governs man in even the least things of his life to eternity. 'The Apocalypse Revealed' (1766), discloses the internal and real meaning of the «Apocalypse» or «Revelation,» describing the New Jerusalem as to its quality of life among all who receive the Heavenly Doctrine in this world and by obedience to its teachings are inaugurated by the Lord into his New Church. 'Delights of Wisdom Concerning Conjugal Love' (1767-68) setting forth the laws of spiritual and eternal marriage which must exist between the souls of wedded consorts. Disclosing the insanities and horrors of adultery together with a prescription of laws for the preservation of the conjugal quality in the mind, in the heart and in the life of the man who is unmarried but who regards marriage as a heavenly and blessed estate and condition. 'The Brief Exposition of the Doctrine of the New Church' (1768-69) wherein is shown the utter variance of the theological dogmas prevailing throughout what is known as the Christian world, both in the Roman Catholic and Protestant churches, from the genuine doctrine of the Scriptures. In the preparation of this work Swedenborg had especially in view the clergy of the Christian church and he distributed the book to them and to theological seminaries in Europe. The last and crowning work of this series of philosophical and doctrinal expositions of the Internal Sense of the Word and of the nature of the Spiritual World is 'The True Christian Religion or the Universal Theology of the New Church' (1771). In this book is presented a general view of the Doctrines of the New Church fully explained together with wonderful accounts of things seen and heard in the Spiritual World related by Swedenborg as a witness thereof.

Among the writings of Swedenborg published since his decease may be specially mentioned 'The Spiritual Diary' (1748-65), comprising a chronicle in the form of notes about persons and things in the Spiritual World, memorable for one reason or another, which he either met or was in some way concerned with on account of his mission.

In another posthumous little work, 'The Consummation of the Age,' etc., Swedenborg explains that now is the end of the Christian Church, the Second Advent of the Lord and the beginning of the New Church which is signified by the «New Jerusalem» in John's Apocalypse.

Bibliography.— Complete edition of works issued in England by the Swedenborgian Society of London, also concordance by J. F. Polk (6 vols., 1888 et seq.). There is also the edition of Rotch (32 vols., Boston 1907).

Edition de luxe issued by the Swedish Royal Academy of Sciences.

SWEDEN, or SVERIGE, svā'rē-gĕ, a northern European state, forming with Norway (q.v.) a united kingdom, occupying the whole of the peninsula known in ancient times by the name of Scandinavia. Sweden is situated between lat. 55° 20′ and 69° N.; and long. 11° 40′ and 24° E.; and is bounded north and west by Norway; southwest by the Skager-Rack, Kattegat and Sound; south by the Baltic; east by the Baltic and the Gulf of Bothnia; and northeast by the Tornea and its affluent the Muonio, separating it from Finland. In addition to the mainland it has a great number of islands, most of small dimensions, lying close to the coast. The largest, and also the most distant, is Götaland, or Gothland, in the Baltic.

Sweden consists of the three historical divisions of Swealand or Sweden proper in the middle, Götaland, or Gothland, in the south and Norrland in the north. For administrative purposes it is divided into läns or governments. The area is estimated at 173,035 square miles, of which 3,700 are occupied by the larger lakes;

the population in 1917 was estimated at 5,757,-566, of whom 2,817,950 were males and 2,939,616 females. The average density is 33.3 per square mile. For 1916 the total recorded births numbered 121,214; deaths, 77,683; and marriages, 35,156. The same year 10,571 persons emigrated, 7,268 going to the United States. The recent increase in population chiefly affected the larger cities. In 1917 Stockholm numbered 111,823 inhabitants; Göteborg, 191,535; Malmo, 35,783; Norrköping, 55,623; Kälsingborg, 35,-783; Gäfle, 36,623; Orebro, 34,453; Eskilstuna, 30,111, and Karlskrona, 28,556.

Between 1860 and 1916 the town population had risen from 434,519 to 1,617,116, showing an increase of from 11 per cent of the total population of Sweden in the first-named year to 28 per cent in 1916; and between 1840 and 1910 the number of persons dependent on commerce and industry had risen from 10.75 per cent to 45.39 per cent. At the present time the proportions are about equal.

Topography.— The coast-line, above 1,400 miles in length, is serrated rather than deeply indented; its bays and creeks, though very numerous, having neither the width nor tortuous lengths by which the fiords of Norway are characterized. The west coast is very rocky, but seldom rises so high as 30 feet. Along the south and southeast coast low shores alternate with precipitous cliffs, which, however, are of no great elevation. As above stated many islets are scattered near the shores, and these where they form the archipelago of Stockholm are especially numerous. The whole of the upper part of the shore of the Gulf of Bothnia consists of sandy alluvial deposits, which are brought down by the rivers in such quantities that they seem destined at no distant period to convert a large portion of the gulf into dry land. It would appear, however, that alluvium is not the only agent employed in carrying on this process of shallowing, since it has been proved that the whole coast of Sweden is continually rising, the rise being greatest in the north.

The interior of Sweden is by no means generally mountainous, and its surface has far less of a highland than of a lowland character. The most elevated portion of it commences in the west near the parallel of 62°, and is continued north along the frontiers of Norway, not so much in a continuous chain as in isolated mountain-masses rising from an elevated table-land, which, where loftiest, is at least 4,000 feet, and forms the base of several summits which rise more than 6,000 feet above sea-level, and owing to their high altitude are covered with perpetual snow. The two loftiest mountains, Sarjektjakko and Kebnekaisse, both in Swedish Lapland, attain a height of about 7,000 feet. Other lofty peaks are Sulitjelma and Sylfjellen, between lat. 63° and 67° on the Norwegian frontier. These mountains and their table-land slope east toward the Gulf of Bothnia, sending down numerous torrents, which in their course often expand and form chains of lakes and dreary swamps. The same slope is continued south of 62° N., but besides it there is a south slope which attains its lowest level near lat. 59° N., on the shores of the magnificent lakes which there stretch almost continuously across the country east to west. To the south of 59° N. the country is generally flat, though in many parts finely diversified. This region has several fertile and well-cultivated tracts, but a good deal of it is covered by barren sand or stunted heath, though interspersed with forests, green meadows and cornfields. What is called the Plain of Scania, occupying the whole of the south peninsula between the Sound on the west and the Baltic on the south and east, is generally a fine tract of land.

Hydrography.— The rivers and lakes are numerous; the latter in particular on a large scale, giving to the scenery of the country several of its grandest features. The rivers all belong to the basins of the Baltic Sea and the German Ocean. The former receives the far larger share. To it belongs the Torneå, which, rising in the Norwegian mountains, pursues its course south-southeast for nearly 290 miles, augmented by numerous large affluents, and falls into the northern extremity of the Gulf of Bothnia; the Luleå, Piteå, Skellefteå, and united Windel and Umeå, which flow precipitously southeast into the same gulf; the Angermann, which flows 230 miles, and in the lower part of its course becomes so wide and deep that vessels of 600 tons can ascend nearly 70 miles from the sea; and the eastern and western Dal, which, uniting their streams, receive the discharge of numerous lakes, and pursue a more circuitous course than usual in Swedish rivers. The principal rivers belonging to the basin of the German Ocean are the Klar and the Göta, the former of which, issuing from Lake Fämund, on the edge of the Doverfield Mountains, furnishes Lake Wener with its chief supply of water; while the latter, which may be considered only as its continuation, discharges it into the ocean. The lakes not only add to the beauty of the scenery but yield large supplies of fish, and both by their natural depth and the canals which have been cut to connect them are of vast navigable importance and furnish a long line of internal communication. In this way a direct channel has been opened from Göteborg on the west to Söderköping on the east coast, and communicating with the important towns of Wenersborg, Carlstad, Mariestad, Jönköping and Linköping. In the same manner the capital has been enabled to extend its connections with the interior. In general, however, the rivers are too rocky for navigation. The largest lake is Lake Wener (area, 2,014 square miles); the next in size Lake Wetter (715 square miles). Lake Mälar, better known than the other large lakes, from having the capital on its shores, is also remarkable for the number of islands which so crowd its surface that it is scarcely possible to find a square mile of open water. Hjelmar, which has both a natural and an artificial communication with Lake Mälar, has an area of 188 square miles.

Geology and Minerals.— The mines of Sweden are rising in importance as rapidly as new mining machinery is being introduced. In 1916 they already engaged 48,166 persons and yielded large quantities of iron and other ores, as well as lead, silver, copper and gold. In the year mentioned the amounts in tons were: iron ore, 6,986,298; coal, 414,825; zinc ore, 60,700; sulphur pyrites, 27.848; copper ore, 13,895; manganese ore, 8,894; silver and lead ore, 3,707; pig iron, 732,734; bar iron, 526,353. Besides, there were produced 230 tons of gold ore, 3,707 tons of silver and lead ore, and 8,894 tons of manganese ore. Almost the whole of the country is composed of gneiss, partially penetrated by granite. Patches of porphyry and greenstone, of Silurian rocks, of oolite, and of cretaceous rocks, appear in various localities. Iron not only occurs in beds of immense thickness, enclosed in strata of gneiss, but forms the principal mass of whole mountains. The most celebrated iron-mines are those of Danemora in län Upsala, where the iron worked is perhaps the best in the world, and is admirably adapted for steel. The quantity produced, however, is much smaller than in some other districts where the quality is also excellent.

Climate.— The climate of Sweden varies considerably with the latitude and elevation. There is hardly any spring or autumn intervening between the heat of summer and the cold of winter, but in the north the winter lasts for nine months, in the south only for seven. Speaking generally, the climate of Sweden, though modified by the proximity of the sea, so as to be milder in all respects than the interior of the northern parts of the Russian and Asiatic continents, is much more extreme than that of our own islands, even where the two countries are in the same latitude, and experiences greater degrees both of cold and heat. Hence at Stockholm the thermometer has been known to descend 26° below zero in January, and to rise in July to the almost tropical heat of 96.8°. The climate, however, is favorable to health, and no country furnishes more numerous instances of longevity.

Forestry and Flora.— Most of the public forests, covering an area of over 19,000,000 acres, belong to the government and yield considerable timber. In the very northern extremity of Sweden fine trees of pine, fir and birch are found. These, however, occupy only occasional patches, and the true forest-land must be considered as having its limit near 64°. Below this latitude, and chiefly in the central and southern parts of the kingdom, the forests occupy at least one-fourth of the whole surface, and sometimes stretch continuously for 80 miles in length by 20 miles in breadth. Many of these, however, consist of trees of stunted growth, available chiefly for domestic fuel or the supply of the smelting furnaces, and seldom of much use as timber. Forests in which oak and beech are the prevailing trees occur only in the south. The flora is of the post-glacial period, and of Finnish characteristics rather than of more southern and continental latitudes. Wild brier berries are plentiful.

Fauna.—Among the larger wild animals the wolf and bear abound in the forests, and often commit great ravages. The elk and deer are also found, but in more limited numbers. Of smaller animals the most destructive is the lemming, which at intervals of years descends in immense numbers into the low country and lays it waste. Among birds the most remarkable are eagles, capercailzies and woodcocks.

Fisheries.— The rivers and lakes are well stocked with salmon and trout, but the fisheries on the sea-coast have long ceased to be productive. Herrings, which used to visit the coast of the Baltic, have almost entirely disappeared, though large numbers of a fish resembling herrings are taken along the east coast. About 34,000 persons find employment in the fisheries.

Agriculture.—About 9.1 per cent of the total area is under crop, 3.3 in natural meadow and 54.7 per cent in forest, the latter furnishing a staple industry. Only a small portion of the arable land, and that mostly in the south, is favorable for the growth of wheat; but there is now a considerable export of oats and some of other cereals to Great Britain. Until recently the grain grown in Sweden did not suffice for domestic consumption. Potatoes are grown in almost all parts of the country, and form one of the main articles of food among the lower classes. The most important auxiliary crops are beet-root for sugar, hemp and flax, the latter of excellent quality; on a few favored spots tobacco, hops and madder are grown. Cherries, apples and pears are tolerably abundant in the southern districts. The principal domestic animals are cattle, sheep and reindeer. The last supply food and clothing. In 1917 there were 447,695 farms under cultivation, the products of which form a staple export.

Commerce, Manufactures, etc.— Of all the countries trading with Sweden, Great Britain is the one with which the largest amount of business is done, Germany coming next. The total value of the exports to all countries in 1916 was nearly $206,991,000, of which 5.3 per cent came from the United States, the exports to Great Britain amounting to half that amount. The total imports amounted to about $194,-811,000 (United States, 27.4 per cent). The principal exports are timber, iron, butter and wood pulp; imports, iron and steel, wrought and unwrought, coal, machinery, woolen and cotton goods. Next to agriculture the most important industry in Sweden is iron-mining. Other industries now of some importance are iron-founding and engineering, the spinning and weaving of cotton and woolen goods, paper-making, brewing, sugar-refining, match-making and glass-making. In 1917 there were 9,368 miles of railways, of which 3,268 miles belonged to the state. The public telegraph and telephone lines in 1917, 341,013 miles, belong wholly to the state. A tram ferry service operates between Trelleborg and Sasnetch in Prussia.

The mercantile marine in 1917 engaged 2,801 vessels of 1,128,435 tons burden. The tonnage entered and cleared in 1915 was 28,799,114 tons. Göteborg is the principal port and Stockholm comes next.

Weights and Measures.— The denominations of money are the *öre* and the *krona*, or crown (silver); 100 öre (each = .132*d.*) = 1 *krona* = 1*s.* 1⅛*d.* The greater part of the currency, however, is in paper, which is circulating in sums varying from 5 to 1,000 kronor. The metric system of weights and measures was introduced in 1883. Among old measures are the *skalpund* = .937 lb. avoirdupois; the *centner* (100 skalpund) = 93.7 lbs. avoirdupois; the *nyläst* (100 centner) = 83.67 cwts.; the *kanna* = 4.6 pints imperial; the cubic *fot* (10 kanna) = 5.76 imperial gals.; the cubic *aln* = 46 gals.; the foot (*fot*) = 11.689 inches imperial; the *tunneland* or acre = 1 acre 35 poles; the mile = 6.64 United States miles, and the square mile = 44 United States square miles; 10 *linier* = 1 *tum;* 10 *tum* = 1 foot; 10 feet = 1 *stöng* (= 9.74 United States feet); 10 *stänger* = 1 *ref;* 360 *ref* = 1 mile.

Government.— The crown is hereditary in the male line. The king must be a member of the Lutheran Church, and has to swear fidelity to the laws of the land. His prerogatives consist of the right to preside in the high court of justice, to grant pardons, to conclude treaties with foreign powers, to declare war and peace, to nominate to all appointments civil and military and to veto absolutely any decree of the Diet or Parliament of the kingdom. He also possesses a power of administrative legislation. The princes of the blood-royal are excluded from all civil employments. The Diet consists of two chambers, which are both elected. The first or upper chamber consists of 150 members. The members are elected by 25 provincial landstings (or provincial assemblies) and the corporations of Stockholm, Göteborg, Norrköping, Malmö and Gefle. All the members must be above 35 years of age, and a property qualification is required to the taxed value of 50,000 kronor, or $13,885 in real property, or an annual income of 3,000 kronor or $830. They are elected for six years. The second chamber, elected on universal male suffrage for three years, contains 230 members, 150 elected by the rural population, being one for each 40,000 inhabitants; and 80 by the towns, being one for every 10,000 inhabitants. Members of both houses are paid 1,200 kronor or $335 per session of four months, in addition to traveling expenses. The election is by ballot on a basis of proportional representation. The executive power is in the hands of the king, under the advice of a council of state consisting of 11 members, eight of whom are departmental heads. The eight departments are: The Ministry of Justice, the Ministry of Foreign Affairs, the Ministry of War, the Ministry of Marine, the Ministry of the Interior, the Ministry of Finance, the Ministry of Education and Ecclesiastical Affairs and the Ministry of Agriculture. All the ministers are responsible for the acts of the government. The administration of justice is controlled independently of the government by the Justitie Kansler, appointed by the king, who acts for the Crown; and the Justitie Ombudsman, appointed by the Diet, who exercises a supervision over the law-courts.

Finances.—A large part of the revenue is derived from national property, including railways; the remainder from customs, excise, income tax, etc. The total estimated revenue for 1917 amounted to $107,000,000 and the expenditure was rather more. Part of the expenditure — civil, military and ecclesiastical — is defrayed from Crown lands and does not appear in the public accounts. The public debt is over $225,000,000. Sinking funds are provided for the payment of the debt.

The Riksbank, or National Bank of Sweden, belongs entirely to the state and is managed by directors elected for three years by the Diet, except one, the president, who is designated by the king.

Army and Navy.— The army has hitherto consisted of enlisted troops, a militia maintained by landowners and Crown domains, and conscription troops, drawn by annual levies; but it is now undergoing reorganization, which will take some years to complete, the result being an increase in numbers. Military service is compulsory. The active military force in 1916 consisted of 2,657 officers, 537 non-commissioned officers, 16,370 volunteers and a contingent of recruits. The total (including conscripts) was 83,000 men. The naval strength includes 15 armored coast defense vessels, four old torpedo gunboats, 10 torpedo-boat destroyers, 45 torpedo boats and submarines.

Ethnology.—Almost all the inhabitants of Sweden, with the exception of the Laplanders and Finns, found only in the north, are of Teutonic origin, and preserve the original features of the race in great purity, particularly in the central and southern provinces, where they are characterized by a tall, robust stature, light hair, blue eyes and light complexion. They are active and enterprising, and manifest a marked predilection for scientific pursuits. The state of morality is on the whole favorable. Heinous crimes are few, but a great number of minor delinquencies figure in the calendar and are evidently accounted for by the far too prevalent use of ardent spirits; but a considerable improvement in respect of the consumption of intoxicants seems to have taken place in recent times.

Religion and Education.—Almost all the inhabitants belong to the Evangelical Lutheran Church, which is the religion of the state, at the head of which is the archbishop of Upsala. Other religions are tolerated; but appointments in the public service can be held by Lutherans only. Education is gratuitous and compulsory. Primary education is well diffused. In 1916 there were 704,000 pupils in the elementary schools. The proportion of illiterates among recruits is 0.16 per cent. The University of Upsala (2,344 students in 1916) has done much to foster the cultivation of the higher departments of science and scholarship. There is also a university at Lund (1,341 students in 1916).

Language and Literature.— See SWEDISH LANGUAGE; SWEDISH LITERATURE.

History.— In the case of Sweden, as of many other countries, the industry of chroniclers has supplied details about ages with which they were unacquainted. These early chronicles, called Sagas, contain lists of kings at variance with each other, and stories of adventure of the kind to which the epithet heroic is usually applied, in which it is impossible to separate the fabulous from the historical. The first dynasty of Swedish kings, according to the legendary chronicles, belonged to a family called Ynglings, from their founder, Freyer Ingve, the reputed grandson of Odin, from whom the family claimed to be descended. The last of them was expelled by Ivar Widfadm, representative of the Danish family of the Skioldings, also descended from Odin, who united Sweden and Denmark under one rule. This event is referred to about 630 A.D. Near the end of the following century Ragnar Lodbrok, the reigning representative of this house, fell in battle on the English Coast, and his second son, Biorn Ironside, inherited Sweden, which was again separated from Denmark. Christianity was introduced under his grandson, Biorn II; but it was first established by Olaf, who reigned in the beginning of the 11th century (1001–26 A.D.). Until the beginning of the 12th century the chronicles contain rival lists of kings. From the first appearance of Sweden in history two rival tribes or confederacies, both of German origin, the Goths and the Swedes, contended for ascendency, and the confusion of the chronicles is probably due to the mingling of the lines of separate chiefs or monarchs reigning simultaneously in different districts. Emund Slemme, the last of the descendants of Biorn, was defeated and killed by the Goths in 1056, when the two nations were united under Stenkil, the Gothic monarch. On the death of his descendant, Inge II, in 1129, the Swedes raised a private individual, Sverker I, to the throne. To conciliate the Goths it was agreed that Erik, a descendant of Stenkil in the female line, should succeed Sverker, and that the two families should reign alternately. This arrangement, which seems to indicate that the power of the monarchs was merely that of leading chiefs, was continued, though the cause of much dissension and civil war, for several reigns. During the reign of Sverker the kingdom was divided into four dioceses (1152). Erik IX, called Saint Erik, succeeded about 1155. In his reign the Finns were conquered and converted to Christianity. Charles VII, son of Sverker, who succeeded about 1162, was defeated and killed by Knut Erikson, who succeeded in 1168. Sverker II, the son of Charles, was likewise defeated and killed by Erik X, son of Knut, who succeeded him in 1210. John I, son of Sverker II, and the last of his line, was succeeded in 1253 by Erik XI, the last of his, who died in 1260. Waldemar I, nephew of Erik, was raised to the throne by election, and founded the dynasty of Folkungar. Waldemar made a voyage to the Holy Land, leaving his brother Magnus regent, in 1272; on his return a civil war took place, but Waldemar abdicated in favor of Magnus in 1279 and failed in subsequent attempts to recover the throne. Magnus assumed the title of king of the Swedes and the Goths. His son, Birger II, in whose reign the conquest of Finland was completed, was expelled by the people in 1319, who chose his nephew, Magnus Snek, an infant, as his successor. He had already succeeded, in right of his mother, to the crown of Norway, which he gave to his son Haco in 1344. Scania, consisting of the two southern provinces, Malmöhus and Kristianstadt, which then belonged to Denmark, yielded to him in 1332, but he restored them on affiancing his son Haco to Margaret of Denmark. Magnus was deposed by the states and obliged to carry on a civil war for the crown with his son Erik, whose death again left him in possession of the kingdom; but aiming at absolute power, he was again deposed in 1365 in favor of his nephew, Albert of Mecklenburg, who had already been in possession, since 1363, of the supreme authority. Albert formed a league with Schleswig, Holstein, Mecklenburg and the Hanse towns against Denmark and Norway. He succeeded in driving the king of Denmark out of his dominions, but was defeated by the king of Norway, who besieged him in his own capital. Peace was concluded; but Albert, aiming, like his predecessor, at absolute power, made himself unpopular with his own subjects, who invited Margaret of Denmark and Norway, the Semiramis of the North, who had united the crowns of these kingdoms, to replace him. Albert, though supported by Holstein, Mecklenburg and the Hanse towns, was finally overcome and returned to Mecklenburg. Margaret succeeded in 1389, and by the union of Calmar the three kingdoms were formally united, each retaining its own constitution. Under the reign of her grandnephew Erik (1412–41) the Swedes revolted under Engelbrecht (1433). The union was renewed 1436, but both Danes and Swedes revolted against Erik, and Charles Knutson, grand mareschal of Sweden, was chosen regent. His rule proving oppressive, the joint crown was conferred in 1441 upon Christopher of Bavaria, nephew of Erik. On his death in 1448 Charles VIII (Knutson) was chosen king of Sweden. Norway also acknowledged him, but soon threw off the yoke. The severance of the union also produced a war with Denmark. Charles' reign was stormy and his subjects repeatedly revolted against him. He died in 1470. Christian I, king of Denmark, had been crowned king of Sweden in 1458 by the party opposed to Knutson, but on the death of Knutson his party chose his nephew, Sten Sture, administrator of the kingdom. Christian attempted to take possession of the kingdom, but was defeated and forced to retire. In 1483 John I, son of Christian, was recognized as king of Sweden in virtue of the Union of Calmar. The country was divided between the Danish and the national parties, but Sture contrived to hold the administration, and raised an army to drive the Russians out of Finland. In 1497 John invaded Sweden with a powerful army. Sture was completely defeated at Rotebro, 28 October. John conferred on him the government of Dalecarlia; but the Swedes again revolted and proclaimed him administrator in 1501. He died in 1503 and was succeeded in the administration by Svante Sture, who concluded peace with Russia and formed an alliance with the Hanseatic towns in order to prosecute the war with Denmark. The clergy and a large portion of the Senate favored the Danish alliance, but the peasantry were strongly opposed to it. Svante Sture died in 1512 and was succeeded by his son, Sten Sture the Younger. In the following year Christian II succeeded to the crown of Denmark. After the death of Sture, Gustavus Vasa raised the peasants of Dalecarlia, defeated the Danes, and, having embraced the Lutheran religion, was crowned king by a Protestant archbishop of Upsala in 1528. The Lutheran religion was formally established in Sweden in 1529. Christian II having been driven from Denmark, his title was acknowledged by his successor, Frederick I, and in 1544 was declared hereditary in his house. He died in 1560. His son, Erik XIV, reigned only eight years. Erik was one of the candidates for the hand of Queen Elizabeth of England and also of Queen Mary of Scotland.

To balance the power of the great nobles Erik created a secondary nobility and introduced the titles of count and baron into Sweden. A war with Russia, undertaken for the protection of the Teutonic order, resulted in the acquisition of Esthonia by Sweden; but war having subsequently broken out with Denmark was, in the confusion caused by the king's insanity, ill-conducted, and resulted in repeated disasters to the Swedes. John III, the brother of Erik, succeeded him on his deposition. By the peace of Stettin with Denmark, 13 Dec. 1570, Sweden renounced her claims to Norway, and surrendered a large part of Götland, including the west coast to Denmark. This treaty was made with a view to a war with

Russia. In this war the Swedes were successful in foiling the designs of Ivan IV on Livonia. Peace was concluded in 1582. John had married Catherine Jagellon, daughter of Sigismund, king of Poland, and through her influence endeavored to restore the Catholic religion in Sweden. A formidable opposition arising, headed by his brother Charles, and the queen dying, he abandoned the project. Sigismund, his son, was, however, brought up in the Catholic faith, and in 1587 he was elected king of Poland under the title of Sigismund III; John died 1592. Charles, Duke of Sudermania, who held the regency in the absence of his nephew Sigismund, endeavored to deprive him of his crown on the ground of his religion, but on the return of Sigismund with an army he was compelled to relinquish the government to him. Sigismund, on receiving the crown, returned to Poland, and left his uncle Charles regent. Charles again attempted to seize the crown and defeated Sigismund in the battle of Stängbro (September 1598). The states now conferred on him the title of hereditary prince, and insisted upon Sigismund sending his son to Sweden to be educated in the evangelical faith. Failing to comply, he and his posterity were excluded from the crown, and in 1604 Charles was acknowledged as king-elect of the Swedes, Goths and Vandals, and his son, Gustavus Adolphus, was recognized as his successor. He took the title of Charles IX. From these events arose a war with Poland, which was not terminated by a permanent peace till 1660. Wars also with Denmark and Germany continued till the end of Charles' reign. Charles IX died 1611, and was succeeded by his son, Gustavus Adolphus, then engaged in conducting the war with Denmark. One of the first acts of Gustavus was to select as his chancellor Alex Oxenstiern, who became one of the first statesmen of Europe. Failing to make peace with Denmark, Gustavus took the field in person, and nearly lost his life in the battle of Widsji; but in 1613 he succeeded through the mediation of England in making peace. The Russian throne was then vacant. The Swedes and Poles each set up candidates for it, Charles Philip, brother of Gustavus and Ladislaw, son of Sigismund. Both had invaded the country and made extensive conquests and Gustavus granted favorable terms to Denmark that he might turn his attention to this quarter. Michael Romanoff, elected in 1613, was compelled to make peace with Sweden by the cession of all his Baltic provinces; and Sweden, which notwithstanding internal troubles had been advancing in political importance since the time of Gustavus I, now became the leading power of the North. The war of succession with Poland still continued and in 1621 Gustavus turned his arms against that country and captured Riga. The war continued for nine years, and was concluded by the six years' truce of Altmark in 1629. Gustavus retained four frontier towns of East Prussia.

Sweden was now about to take for the first time a leading part in the affairs of Europe. Gustavus had been watching with anxiety the course of events in Germany, and had determined to interfere on behalf of the interests of religion and the political rights of the Protestant princes. (For the events of this war and the effects of the intervention of Sweden in the affairs of Europe see GUSTAVUS; PRUSSIA; RICHELIEU; THIRTY YEARS' WAR, and other articles). The body of Gustavus, who fell at the battle of Lützen, was brought back to Sweden in 1632, and his daughter Christina was recognized as his successor. She was a minor, and the management of affairs devolved upon the Chancellor Oxenstiern. He confirmed his alliance with the German rulers, and made arrangements to prosecute the war with vigor. His power continued absolute till 1644, during which time the war in Germany continued. At the beginning of this year a war broke out with Denmark, provoked by the scheming of the queen-mother, who was jealous of the power of Oxenstiern. Denmark was suddenly invaded by Torstenson. Christina assumed the reins of government on 5 Dec. 1644, her 18th birthday. The peace party now prevailed, and the treaty of Brömsebro was concluded with Denmark, which ceded to Sweden the greater part of her possessions in Götland, and exempted Swedish vessels from Sound and Belt dues. The peace of Westphalia, 24 Oct. 1648, gave Sweden western Pomerania, the duchy of Bremen and other acquisitions in Germany, with a seat and triple vote in the diet.

The reign of Christina began under favorable auspices. She had received a masculine education, and showed great attention to business and determination in supporting her views. Contrary to the advice of Oxenstiern she exerted herself to promote peace both with Denmark and Germany. She patronized learning, and drew many distinguished men to her court; but she was extravagant in her expenditure, licentious in her behavior, and soon brought herself into inextricable difficulties by the profusion with which she lavished the crown domains on worthless favorites. In these circumstances she renounced the crown in 1654 in favor of her cousin Charles Gustavus, son of the count palatine, professed the Catholic religion, and after an extraordinary career died at Rome in 1689. The short reign of Charles X was distinguished by some brilliant military enterprises, which extended to Poland, Prussia, Russia and Denmark. In January 1658 he crossed the sea on the ice, and occupying the island of Fünen without resistance, advanced to Copenhagen. By the mediation of England and France peace was concluded at Roeskilde, 8 March 1658, Denmark surrendering the remainder of her possessions in Götland. Charles, however, had set his heart on the conquest of Denmark, and was not long in recommencing operations against that country. He died suddenly on 13 Feb. 1660, leaving a son, Charles XI, only four years of age. A council of regency was appointed, which soon concluded peace with Poland, the emperor and the elector of Brandenburg. Peace with Russia was not concluded till 1661. Sweden formed an alliance with England against Holland in 1665, and took part in the triple alliance against France in 1668. The common policy of Sweden was to ally herself with France, and her change of policy was due to the failure of French subsidies. By the treaty of Stockholm, 14 April 1672, she agreed to assist France if attacked by any German power during her war with Holland. In consequence of this treaty the Swedes invaded Brandenburg in 1674. They were defeated by the elector at Fehrlallin, 28 June 1675. After this victory Denmark entered into a league with the elector against Sweden. In the hotly contested war which ensued Sweden was defeated by the elector on land and by the Danes at sea, but her ally was victorious, and Louis XIV compelled the elector by the treaty of Saint Germain-en-Laye to restore to Sweden all her German possessions except a district beyond the Oder, and by the treaty of Fontainebleau Christian V engaged to restore all his conquests to Sweden. Peace was concluded on these terms between Sweden and Denmark at London, 26 Sept. 1679.

Sweden, whose financial resources were always limited, had, however, been impoverished by the war, and the nobility, who during the minority of Charles had acquired the chief power in the state, although the king had assumed the government in 1672, became unpopular. A revolution was accomplished in 1680, in which the states, under the guardianship of a military force, declared Charles absolute and irresponsible, and entitled to dispose of the government by his last will. The remaining years of Charles XI were employed in organizing the army and restoring the finances. He adopted a regular system of conscription, which greatly strengthened the military power of the nation. He died 15 April 1697. His son, Charles XII, born in 1682, was declared of age in November. His youth induced Denmark, Poland and Russia to enter into a league against him to partition his dominions. Embarking for Copenhagen in 1700, he soon disconcerted the plans of the allies, and refusing peace began a career of conquest, which after many marvelous successes ended in the disastrous battle of Poltava, 8 July 1709. After an exile in Turkey he returned to Sweden in 1714, reconciled himself with Peter the Great, and was pushing the conquest of Norway when he was killed at the siege of Frederickshall, 30 Nov. 1718. The Swedish states passing over Charles Frederick, son of Charles' elder sister, named the second sister of Charles, Ulrica Eleonora, queen, who in 1720 associated with her husband Frederick I. The revolution was accomplished so suddenly that it led to a suspicion that Charles' death had been anticipated, and it has always been suspected that he fell by the hand of an assassin. The new government allied itself with Great Britain, and ceded the duchies of Bremen and Verden, the cause of quarrel between Charles and England, to George I. Peace was concluded with Poland on the basis of the treaty of Oliva, and with Prussia, to which Sweden ceded the territory between the Oder and the Peene, Stettin, the islands of Wollin and Usedom, etc. By the Treaty of Stockholm, 12 June 1720, Sweden paid Denmark 600,000 rix-dollars, and renounced the freedom of the Sound, while Denmark restored Rügen and other conquests in Pomerania and elsewhere. War still continued between Sweden and Russia. It was concluded by the Treaty of Nystadt, 10 Sept. 1721. Sweden received $2,000,000 for Livonia, but she finally lost the valuable Baltic provinces for which she had so long contended. Of her conquests Russia only restored Finland.

Sweden was now under the hands of an oligarchy. This council was easily bribed by foreign powers. It was divided into two factions, called (after 1738) the Hats and Caps, the former of which preferred to sell themselves to France, the latter to Russia. On the breaking out of the war of the Austrian Succession, the Swedes, who had been irritated by the murder, at the instigation of the Russian Empress Anna, of their Ambassador to the Porte, were easily induced by France to declare war with Russia. The war on the part of Sweden, from military incapacity and the selfishness of her civil rulers, was ill conducted. On the accession of Elizabeth peace was concluded by the Treaty of Abo, 17–18 Aug. 1743, by which Sweden renounced forever her claim to the provinces ceded by the Treaty of Nystadt, the recovery of which was the main object of the war, and ceded part of Finland, the boundary between the two states being fixed at the river Kymené. By the influence of Russia Adolphus Frederick of Holstein was elected successor to the Swedish crown, to which he succeeded on the death of Frederick in 1751. During this reign Sweden took some part in the Seven Years' War. At home the country was distracted by the rivalries of the Hats and Caps, and the royal power sank to a shadow. Adolphus died in 1771 and was succeeded by his son Gustavus III. His reign was distinguished by a monarchical revolution. He undertook a war against Russia, which brought him fame indeed, but was productive of no other result. Gustavus was assassinated in 1792. In 1809 his son Gustavus IV was deposed, and his family declared forever incapable of succeeding to the crown. (The leading events of his reign will be found under GUSTAVUS IV). His uncle, the Duke of Sudermania, was declared king with the title of Charles XIII. He concluded a war with Russia, begun by Gustavus, by the Treaty of Fredericksham, 17 Sept. 1809, by which Sweden surrendered Finland, the Aland Isles and part of West Bothnia to Russia. In 1810 the states elected Jean Baptiste Bernadotte, crown-prince. In the final struggle with Napoleon previous to 1814 Sweden joined the Allies, while Denmark took the part of France. The Danes were driven out of Holstein by Bernadotte, and the Treaty of Kiel was concluded between Sweden, Denmark and Great Britain, 14 Jan. 1814. Sweden by this treaty ceded to Denmark her last German possessions in Pomerania, and the Isle of Rügen, while Denmark was compelled to cede Norway to Sweden as a compensation for the loss of Finland. The cession was confirmed by the Norwegian Storthing on 4 November. Greenland, the Faroe Islands and Iceland, which had belonged to Norway, were retained by Denmark. Sweden now held the whole Scandinavian Peninsula, and had lost all her other European possessions. Bernadotte succeeded to the crown in 1818, under the title of Charles XIV. Under his reign Sweden advanced greatly in agricultural and mercantile prosperity. He died in 1844, and was succeeded by his son Oscar I, who introduced extensive reforms in the government. (See OSCAR I). He died 8 July 1859, and was succeeded by his son, Charles Louis Eugene, under the title of

Charles XV. Charles XV died 18 Sept. 1872, and was succeeded by his brother, Oscar II, who, dying on 8 Dec. 1907, was succeeded by his son, the present king Gustav V. On 7 June 1905, owing to the refusal of Sweden to grant separate consulates to Norway, the Storthing of Norway passed a resolution to dissolve the union, which was finally ratified by the Treaty of Karlstad by both countries on 16 October. On 20 November Prince Charles of Denmark was made King of Norway.

In 1909 Sweden experienced one of the most extensive industrial strikes in the history of labor disputes. Beginning in a few industries, this strike soon involved nearly 300,000 men and lasted for two months, completely paralyzing all trade, commerce and transportation facilities and ending in the defeat of the strikers.

Sweden in the World War.— The World War, while it stimulated agricultural production and certain branches of mining, entailed great hardships on the majority of the people, and «hunger» demonstrations became frequent, especially in the urban districts. Up to the later stages of the war the attitude of the Court (the Queen was formerly Princess Victoria of Baden), the military and official classes generally, was one of «benevolent neutrality» toward the Central Powers, while that of the Socialists, although neutral, was more favorable to the Entente. The strict enforcement of the British blockade by the seizure of «contraband» designed to be sent through Sweden to Germany, and the detention of mails from the United States, caused intense irritation; and on the other hand, the German submarine campaigns, and the sinking of Swedish ships, raised considerable feeling against Germany. Sweden's position as a neutral was seriously compromised by the revelations made by the United States government in September 1917 that the Swedish Foreign Office was permitting German official messages from foreign countries to be sent as its own messages, these including messages from Count Luxburg, German Chargé d'Affaires at Buenos Aires, in reference to the sinking of ships of the Argentine Republic by submarines, the most extraordinary of which advised his government that Argentine vessels should not be sunk at all, or «sunk without leaving any trace» (spurlos versendt). These revelations raised a storm of indignant protest in all Allied countries, and a breach of diplomatic relations between Germany and the Argentine was narrowly avoided. Two changes of government were made in Sweden in 1917, the return of the second of which, under the premiership of Mr. Eden, ensured a national policy more acceptable to the Entente nations. The attempt to hold an International Peace Conference, promoted by Socialist groups in warring and neutral countries, was prevented by the refusal of the French, British and Italian governments to issue passports.

SWEDISH LANGUAGE.— The North Germanic dialects seem to have differed very little from each other originally. A fairly uniform language was spoken all over the North which in English and Scandinavian sources is often referred to as «Donsk tunga.» During the Viking age, between 700 and 1100, four dialects developed from the original Old Norse: Icelandic, Norwegian, Danish and Swedish. The former two are grouped together as Westnorse, the latter two as Eastnorse. Among the distinguishing features may be mentioned the passive ending -s for Eastnorse, where Norwegian and Icelandic have -sk, f. i. kallas «to be called» versus kallask. The Old Swedish period extends to the time of the Reformation and covers geographically not only Sweden proper, but also the coast districts of Finland and Livonia. Our knowledge of the earlier stage of Old Swedish is based on Runic inscriptions which only in the 13th century were replaced by the Latin alphabet. During the later Middle Ages many phonetic changes took place which tended to differentiate Swedish more and more from the other Scandinavian branches, such as lengthening of vowels, the Genetive ending -s instead of -r, the relative pronoun sum in place of aer, etc. The vocabulary absorbed many foreign elements, especially from Danish and German, as f. i. numerous industrial and commercial terms, all the verbs in -era (= German -ieren), the suffix -het (= heit), the prefixes be-, bi-, unt-. From this somewhat chaotic stage of transition which is characterized by absolute lack of linguistic norms or standards, modern Swedish emerges gradually as a literary language. The first complete Bible translation which is named after Gustavus I and appeared in 1541 is regarded as the first monument of modern Swedish literature. Throughout the 17th century grammarians and purists made efforts to create national standards and to eliminate foreign elements. In spite of that, however, a large number of French words crept into Swedish, especially in the 18th century and have maintained themselves to this day. The internal linguistic changes concern chiefly the simplification of case endings or inflections and the adoption of certain sound-shifts which are characteristic of modern Swedish, such as the sh-sound for combinations like sj, stj, sk, skj. The pronoun of address became ni instead of I. Since the middle of the 18th century Swedish grammar has changed very little, while the vocabulary shows quite a different appearance, particularly since the enormous wealth and variety of expression which is stored up in the dialects has been utilized by modern writers. The dialects of Dalarna and the island Gottland are especially noteworthy on account of their quaintness and archaic character.

Accent.— Longfellow who first introduced

Swedish writers to the American public, characterizes the Swedish language as soft and musical with an accent like the Lowland Scotch. Jacob Grimm considered it even the most musical of all Germanic languages, comparable to Italian among the Romance languages. This musical character of Swedish is partly explained from the fact that it has retained full endings like -a and -o in many positions where the other Germanic languages have substituted -e or dropped them entirely. More important, however, are the peculiar laws of pitch and modulation which hardly any other language has developed with such consistency. Certain combinations of stress and tone result in definite forms of a musical cadence of «tonlag.» The simple tonlag, or acute accent, differs very little from that employed in other languages, the compound tonlag occurs only in Norwegian and Swedish: the voice first sinks about two tones and rises suddenly two or three tones on the second syllable with a weak secondary stress. The question of accent and modulation is one of the chief difficulties in the study of Swedish.

Bibliography.— For history of the language: Noreen, A. G., 'De nordiska språken' (Upsala 1887). By the same scholar the authoritative grammar, 'Vårt språk' (Stockholm 1903 et seq.). A shorter grammar in Swedish is by Sunden, D. A., 'Svensk språklära' (Stockholm 1885). For pronunciation and accent consult Storm's article 'Om Tonelaget i de skandinaviske Sprog' (Christiania 1847). Also Sweet's treatment in the Transactions of the Philological Society (London 1877). Two practical grammars for American students are Vixner, E. J., 'A Brief Swedish Grammar' (Rock Island, Ill., 1914) and Elmquist, A. L., 'Elementary Swedish Grammar' (Chicago 1914). The official dictionary of the Swedish Academy is still in progress, 'Ordbok öfver svenska språket' (Lund 1893 et seq.). For dialects consult Rietz, J. E., 'Svensk Dialectlexikon' (Malmö 1867). For etymology Tamm, F., 'Etymologisk svensk ordbok' (Stockholm 1890). For American readers Björkman, 'Swedish-English Dictionary' (Stockholm 1889) and Wendström and Lindgren, 'English-Swedish Dictionary' (Stockholm 1889).

German Department, University of Michigan.

SWEDISH LITERATURE. The intellectual life of the North has been at all times more or less dependent on central Europe, especially on German and French civilization. Swedish literature shows these influences in a marked degree and has only within the last generation produced writers of distinct originality and more than national significance. The mediæval period appears rather meagre as compared with those of Norway and Iceland. Codes of laws, chronicles, legends of saints, adaptations of chivalrous romances and didactic writings: these or similar categories cover a literary activity which is altogether imitative and chiefly of philological interest. Among the historical documents may be mentioned the Erics-chronicle, covering the period from 1230–1320, the New Chronicle (1490) and the so-called Small Rhymechronicle which contains some interesting autobiographies of Swedish kings. The most conspicuous religious character of the later Middle Ages was Saint Birgitta who, after an extended experience as wife and mother, turned her mind to things spiritual, undertook reforms of all kinds, founded a religious order, came in touch with the leaders of German mysticism and died 1373 in Rome. She contributed to Swedish literature a volume of visions or «revelations» which in spite of their abstruseness exhibit a remarkable power of imagination. Her personal influence and the activity of the Birgitta order which was centred in Vadstena, can be traced through the whole intellectual life of the North, especially in the direction of building up a national church and encouraging the use of the mother tongue. The ballad literature of the 14th and 15th centuries is not as extensive as that of Denmark or Germany, but corresponds otherwise in subject and form. Many of these lays and ballads wandered evidently from one country to the other and exist in numerous versions. More than 60 have been counted of the famous ballad 'Elveskud' (translated by Herder as 'Erlkings Daughters') which describes the dangerous lure of dancing elves. The Swedish ballads have been collected by Geijer and Afzelius as 'Svenska folkvisor' (new edition by Bergström, 1880).

Swedish thought and literature received a powerful stimulus from the gradual adoption of the Lutheran faith in the course of the 16th century. This movement is closely associated with the names of the brothers Petri, Olavus and Laurentius, and of Laurentius Andreae. All three of them contributed to the translation of the Bible which appeared complete in Upsala in the year 1541 and which for the history of the literary language in Sweden may claim a similar position as Luther's translation for German. Apart from a rich controversial literature called forth by the religious movement, we meet with attempts in the dramatic field, such as treatment of biblical stories, allegories and school comedies. The most versatile writer of this period is Johan Messenius who, among other things, planned a systematic dramatization of subjects taken from Swedish history but who only completed six of such plays.

The heroic century of Modern Sweden, the age of Gustavus Adolphus and Charles XII, proved to be relatively unproductive in the field of literature. The dominant influence of Renaissance poetics throughout the 17th century discouraged spontaneous expression and established in most European countries classicistic standards and a rule of formalism. Sweden reveres her «father of literature» in Georg Stjernhjelm (1598–1672), a stern disciplinarian who aimed at purity of language and formal perfection. He wrote a number of epic and didactic poems of an allegorical character, among them his famous 'Hercules at the Crossroad' and distinguished himself besides as a scholar and scientist in many fields. He introduced a number of classic and romantic metres into Swedish poetry and handled them with remarkable skill. His contemporary Gunnar Dahlstjerna employed even the Ottave rime (with six iambic feet) in his patriotic poem 'Kungaskald,' and is still appreciated as the author of 'Götha Kämpevisa' in which Charles XII and Peter the Tsar are the leading characters. The greatest metrical genius of his age was Johan Runius (d. 1713), while the Finlander Jacob Frese shows more natural poetic talent. Samuel Columbus and Jesper Svedberg contributed some of the most popular Swedish hymns. The anatomist and botanist Olaf Rudbeck (1630–1702) still arouses our smile as the author of the treatise 'Atlantika' in which he tried to prove that Plato's Atlantis was identical with Sweden and that here or nowhere else must have stood the cradle of civilization. Rudbeck taught at Upsala which under the reign of Queen Christine had become a great centre of learning and attracted temporarily scholars from all parts of Europe, even men like Descartes, Hugo Grotius and others.

The literary sceptre of Stjernhjelm as dictator in the republic of letters passed later into the hands of Olof von Dalin (1708–63) who in his literary style and ambitions might be compared with the English rationalist Pope. He began his career by editing a periodical *The Swedish Argus* which was modeled after Addison's *Spectator,* and developed later into an excellent prose writer and brilliant satirist. His 'Saga om Hästen' («tale of the horse») is still enjoyable as a specimen of rationalistic wit and allegory. While Dalin leaned at first on English models, the literary taste of the age continued on the whole to be French, first in the manner of Voltaire as in the case of the «dioscuri» Creutz and Gyllenborg, or of Kellgren and Leopold, later in the manner of Rousseau whose theories were introduced into Sweden by Thomas Thorild. Among the literary productions of this school deserve special mentioning Creutz' 'Atis and Camilla,' a charming idyl in the style of Gessner, Kellgren's 'Nya Skapesen' (the new creation), and Wallenberg's novel 'Min Son på Galejen' (my son on the galley), a great favorite to this day on account of its splendid humor. King Gustavus III (1771–92), nephew of Frederick the Great and one of the most gifted rulers of his age, did not only further the arts and sciences in the most generous way, but wrote several patriotic plays of considerable merit. Among Gustavus' immediate friends who attained temporary fame are Count Ehrensvärd, Count Oxenstjerna, Bengt Lidner, the poet of sentiment and passion, G. Adlerbeth, author of 'Ingjald Illråda,' the most famous Swedish tragedy of this age. The revolutionary pathos of Thomas Thorild inaugurates the new emotionalism in Sweden which worshipped at the shine of Rousseau, Klopstock and Ossian. Before entering upon this new phase a word ought to be said about the most unique lyric poet of this century who is still dear to the hearts of his countrymen: Karl M. Bellman (1740–95). He belongs with Robert Burns, or the French vagabond Villon to the class of literary bohemians who seem to be entirely free from the shackles of school or convention, who appeal to us more like voices of nature or immediate transcripts of the life around them. Bellman's best-known poems, among them those dramatic sketches of tavern life, are contained in the collection: Fredman's epistles. They seem more like free improvisations than finished works of art, but it is this wonderful freshness and bold impressionistic manner which fascinates the modern reader as much as their original audience.

The transition from the older 18th century formalism to the Romantic age in Sweden presents quite a dramatic spectacle. The first writers who showed a more adventurous spirit, were Franzén and Wallin, the latter still known as the editor of the Swedish psalm-book and as the author of a glowing ode addressed to George Washington. After the revolution of 1809 the Swedish Academy ceased to be arbiter of public taste, and soon the leading writers of the Romantic movement in Germany were eagerly studied and imitated. Two parties formed and carried on a lively feud for a number of years: the Phosphorists, so called after their periodical 'Phosphorus,' were more interested in the speculative elements of German mysticism, as represented by Schelling or Novalis, the Gothicists wished to strengthen national ideals and to revive the old sagas and ballads of the romantic Middle Ages. The head of the first group was Peter Atterbom (died in 1855), whose phosphorescent visions recall somewhat the ethereal, transcendent style of Shelley or Keats. Other members were Nyberg, Dahlgren and Stagnelius, a mystic and seer, reminding of Blake. The leading minds of the Gothicists were Erik Geijer, equally great as poet and historian, Per Ling who tried to revive the old saga style, and his much greater follower Esaias Tegnér, author of the Frithjofs Saga, Sweden's national epic. Somewhat independent of either school remained Karl Nicander who selected chiefly Italian subjects and themes for his poetry, Chr. Fahlcrantz, still quoted as a humorist, and Johan L. Almquist (1793–1866), an erratic genius who combined exquisite delicacy of sentiment (as in his collection of lyrics: Törnrosens bok) with an extravagant, even lawless imagination and quite heterodox views on love and marriage.

The chief by-product of the Romantic movement, the historical novel, flourished in Sweden perhaps even better than in England or Germany. Gumälius, Crusenstolpe, Ridderstad, Sparre and many others have contributed to this genre. The Finlander Topelius' so called 'Surgeon's Stories' which cover nearly two centuries of Swedish history, were widely read in this country at one time, but slumber now peacefully on the shelves of our libraries side by side with Rydberg's famous novel 'The Last Athenian,' and with Frederika Bremer's once so popular stories and sketches of Swedish home life. The last-named writer appears already quite emancipated from Romantic doctrines and points toward the coming age of Realism. Swedish literature, as may have been noticed, is immensely rich in the field of lyric poetry, whereas the realistic novel of the Dickens or Eliot type is rather poorly represented. Fr. Cederborgh, Karl Wetterberg, August Blanche, Sofie von Knorring and a few others present various aspects of Swedish life and society in their novels. The realistic note which had already been heard in the poems of Anna Lenngren (died 1817), becomes more and more prominent, and is reinforced by humor and satire in the songs of W. von Braun, Wennerberg, Sturzenbecker, and the witty improvisations of Johan Wadman. But all these minor talents disappear by the side of the greatest poetic realist of his age: Johan L. Runeberg, the pride of Finland. His chief work is a collection of patriotic poems and ballads: 'Ensign Ståls Tales,' which were inspired by the second Finnish War in 1809, and are rightly considered the most beautiful tribute that has ever been paid, to the patriotic enthusiasm of a small nation. The idyls 'Elkhunters' and 'Hanna' show the influence of Goethe's epic style and, with a large number of exquisite lyrics, give evidence of Runeberg's remarkable power to invest the simplest and most primitive aspects of life with genuine pathos and poetic dignity. He deserves to be classed in this respect with poets of the rank of Goethe or Wordsworth. Runeberg taught for many years in Borga, Finland, and died in 1877.

Two years after Runeberg's death, in 1879, there appeared a novel in Sweden under the title 'The Red Room' by August Strindberg, which inaugurated a new type of Realism and a new literary era. A few years later Geijerstam attempted in his first novel 'Erik Grane' to epitomize the great intellectual and social revolution which had gradually spread from one country to the other and was inspired by three constructive ideals: a political and social democracy, a reconciliation of science and religion, and a new æsthetic creed which subordinated beauty to truth. The commanding figure in this movement is August Strindberg, epochmaking in all fields of literature and at all times a seeker of truth. Most of his writings are now accessible in English translations. Gustav af Geijerstam (1858-1909) who as a novelist has gained great popularity both in Sweden and Germany, is practically unknown to the American reader. This may be explained from the distinctly national or even provincial character of his art, partly from the peculiar inwardness and subtlety of his analysis which avoids striking plots or situations and instead delves down into the deeper strata and hidden recesses of soul life. However, such stories as 'Astray in Life,' 'Pastor Hallin,' or some of his short stories deserve to be translated and might appeal more than some of Strindberg's rather morbid productions. Among the younger followers of the new realism may be mentioned Albert Engström, editor of the periodical 'Strix' and known through his descriptions of peasant life, sailors and fishermen. Two Swedish American novels may be added, one by Hilma Angered-Strandberg, called 'The New World' describing the struggle and failure of two people who have come to this country, the other by Henning Berger, 'Isail' which contains a splendid description of Chicago as the great melting pot of races. The influence of Maupassant and Flaubert is noticeable in Hjalmar Söderberg's clever sketches of Stockholm society ('Historietten' and 'Blunders'), as well as in his novel 'Martin Birk's Youth,' a story of disillusioned youth. Sigerid Siwertz, a short story writer, seems to develop in a similar direction, as f. i., in his collection 'The New Robinson.'

Since 1890 the pendulum seems to have swung back in the opposite direction of an idealistic or neoromantic interpretation of life. Such is the literary creed of Selma Lagerlöf, the leading writer of the day, whose wondrous tales from Gösta Berling to the 'Emperor of Portugallia' are being read in many languages. Her art certainly bears out Walter Pater's definition of the romantic as 'strangeness added to beauty.' Far less known is Verner von Heidenstam, author of the 'Karolinerna,' a series of tales grouped around the heroic figure of Charles XII. This book has already become a classic. Oscar Levertin (died in 1906) may be regarded as the leading critic and essayist of this school. His earlier lyrics, like those of Heidenstam's, reveal a dreamy brooding mysticism and great delicacy of feeling. Even more elusive are Ola Hansson's interpretations of nature and soul-life in his 'Sensitiva amorosa' and 'Young Ofeg's Ditties' (transl. by G. Egerton). Per Hallström has attracted attention as a stylist of pronounced individuality and a lover of southern beauty in a number of delicately chiseled stories and sketches. His prose writings correspond somewhat to the lyrical poetry of Count Snoilsky (died 1903), which is distinguished by great formal beauty and its rich cultural suggestiveness. Quite an opposite type, though equally great in his way, is Gustaf Fröding (died 1911), who renewed the impressionism of Bellman and his model Robert Burns but covers a wider range of experience. He is an enthusiastic worshipper of life tempered by an element of irony and even cynicism. ('Guitar and Accordion' 1891). The youngest generation is represented by the Finlander Gripenberg, the naturalists Bååth and Bo Bergman, and Sigmund Agrell, a follower of Hallström. Present day novelists are Sven Lidman (the life of Swedish nobility), Gustaf Janson (cosmopolitan and visionary), Mathilde Roos (conservative). A group of writers make Norrland, the country of sawmills, the background of their novels, like Erik Forsslund in 'Storgården,' Martin Koch, Olaf Högberg, L. Nordström. The drama, at all times strangely unproductive in Sweden, has little to show, since the days of Strindberg, but temporary successes like Hallström's charming 'Venetian Comedy,' Harold Morlander's 'Rococo' and Söderberg's 'Gertrud' (1906). The most promising dramatist of the day is Ernst Didring.

Bibliography.— The best anthology is the 'Läsebok i svensk litteratur' by Hildebrand, Bergstadt and Bendixson (Stockholm 1897). Of older histories of literature may be mentioned Malmström, Grunddragen af svenska vitterhetens historia, Oerebro 1866-69. The best modern book is the 'Illustrerad svensk litteraturhistoria' by Schück and Warburg (2d ed., 1912-16). The only English treatment of Swedish literature, but extending only to 1880, is to be found in Horn's 'History of the Literature of the Scandinavian North' (translated by Rasmus Anderson, Chicago 1884). It contains valuable and quite extensive bibliographical material, especially in the field of English translations. Very few articles have appeared in American magazines within the last 20 years, one by Harboe, Silhouettes of some Swedish writers, in the *Bookman* (October 1906); another by Stork on Gustaf Fröding (in the *North American*, Vol. 204). G. Brandes has written short essays on a number of modern Swedish writers which are to be found in Vol. III and XVII of his 'Samlade Skriften.' Runeberg is treated by Gosse in his 'Northern Studies,' London 1879. For general reference consult the svensk bokkatalog (1866 et seq.) and the årskatalog för svenska bokhandeln.

German Department, University of Michigan.

SWEDISH MOVEMENT-CURE, a system of therapeutics devised by Pehr Henrik Ling (1776–1839), a Swedish poet, and fostered and developed by the Swedish government. It consists of remedial or localized movements of muscles to restore the normal movement of the contents of cells when it has become disarranged. This method, as variously modified by the development of modern mechanotherapy, is often associated with massage. The muscular movements (active or passive) are effected either by various machines or by the hands of the operator, which flex, extend, twist, tap, knead, rub and roll the various muscles. The Swedish movement-cure, or, to speak more broadly, the movement-cure in general, embraces scientific and valuable modes of treatment. But their application requires good judgment. If properly used, mechanotherapy as thereby employed improves the nutrition of the whole body, relieves congested and engorged organs and tends to restore animal heat to its normal point. Improperly used, such methods may do much harm. See MECHANOTHERAPY; THERAPEUTICS.

SWEENY, Thomas William, Irish-American military officer: b. Cork, Ireland, 25 Dec. 1820; d. Astoria, L. I., 10 April 1892. He came to the United States in 1832 and settled in New York where, after finishing his education, he was apprenticed to the printing business. He early identified himself with the military companies of the city and at the breaking out of the Mexican War in 1846 became second lieutenant in the First New York Volunteers, commanded by Col. Ward B. Burnett. Lieutenant Sweeny participated in all the battles of the campaign under Gen. Winfield Scott from the siege of Vera Cruz to the storming of Churubusco, where he was twice severely wounded, losing his right arm 20 Aug. 1847. On his return to New York, in 1848, he was given a reception ball at Castle Garden and was presented a medal by the Corporation of New York. He was engaged in almost constant operations against the Yuma and other Indian tribes until the fall of 1853, when he was sent to New York on recruiting duty. In 1854 he was ordered to Fort Pierre, Nebraska Territory, where he took part in the Sioux campaign of 1855–56 as aide to Gen. William S. Harney. On 19 Jan. 1861 he was promoted captain, second infantry, and soon after was sent to Saint Louis, Mo., by order of General Scott, and placed in command of the arsenal, which he saved by threatening to explode the 40 tons of powder stored there in case the Secessionists attacked him. He was at the capture of Camp Jackson, where he was second in command of the Union forces and, owing to the disability of General Lyon, carried on the negotiations which brought about the surrender. He became brigadier-general of Missouri Volunteers in May 1861. Previous to the battle of Wilson's Creek, when General Lyon had expressed his intention to retreat, he prevailed upon Lyon to remain and give the enemy battle. In the subsequent battle he led the Second Kansas Regiment, and was severely wounded in the right leg. He accepted the colonelcy of the 52d Illinois Volunteer Infantry in January 1862 and after the capture of Fort Donelson had charge of 5,000 prisoners of war. Toward the close of the first day of the battle of Shiloh, where he commanded a brigade, his command occupied a ravine, the defense of which was entrusted to him by General Sherman, who afterward said: «He held it, and I attach more importance to that event than to any of the hundred achievements which I have since heard 'saved the day.'» General Sweeny was commissioned brigadier-general of volunteers 29 Nov. 1862 and was engaged in protecting the Memphis and Charleston Railroad. He was promoted major 16th United States Infantry 20 Oct. 1863 and was present at the fighting at Iuka and the siege of Corinth. In the Atlanta campaign he commanded the second division, 16th Corps, Army of the Tennessee. He participated in the battle of Resaca and at Lay's Ferry forced a passage across the Oostenaula River and fought a battle that compelled Gen. Joseph E. Johnston to retreat with his army. He took part in the battles of Dallas and Kenesaw Mountain, the actions at Nickajack Creek, Ruff's Mills, Rome Cross Roads, Calhoun's Ferry and other engagements, and at the battle of Atlanta 22 July 1864 he repulsed the enemy with great slaughter, capturing four battle-flags and 900 prisoners. In 1866 he was engaged in the Fenian invasion of Canada. During this period he was out of the national service, but he was reinstated by the President and ordered to the Department of the South, where he was in command of the post of Augusta, Ga., and, subsequently, that of Atlanta, Ga. General Sweeny was presented a sword by the city of Brooklyn in August 1862 for his services in the Civil War. He was finally retired from active service 11 May 1870 with the full rank of brigadier-general, United States Army. Consult 'Battles and Leaders of the Civil War.'

SWEENY, William Montgomery, son of the foregoing: b. New York, 29 Aug. 1871. He was educated at public and private schools and academies in New York and Augusta, Ga. He has written for the press and contributed biographical articles to 'Officers of the Army (Regular) who served in the Civil War' (Philadelphia 1892); 'History of the Twelfth Regiment, N. G. N. Y.' (New York 1894); 'Journal of the American-Irish Historical Society' (Boston 1899); White's 'National Cyclopædia of American Biography' (New York 1901) and Lamb's 'Biographical Directory of the United States' (Boston). He is the author of the 'Life and Services of Thomas William Sweeny, Brigadier-General, United States Army' (New York 1907) and editor of 'Sweeny's Narrative of Army Service' (1846–53); 'Captain Thomas Cook, a Soldier of the Revolution (1752–1841)' (New York 1909) and 'Some Notices, Genealogical and Historical, of the Cook, Dandridge, Higginbotham, Morrison, Reagan, Refo and Sweeny Families' (in manuscript).

SWEET, Benjamin Jeffrey, American military officer: b. Kirkland, N. Y. 24 April

1832; d. Washington, D. C., 1 Jan. 1874. In the Civil War he was colonel of the 21st Wisconsin regiment. In 1864 he was placed in command of Camp Douglas, Chicago, where 10,000 Confederates were imprisoned and successfully circumvented the efforts of Confederate societies to seize Chicago and liberate their friends. He was made brigadier-general of volunteers in 1865 and in 1872 was appointed first deputy commissioner of internal revenue.

SWEET, Henry, English philologist: b. London, 1845; d. 30 April 1912. He was educated at King's College, London, at Heidelberg University and at Balliol College, Oxford. He devoted himself to the study of phonetics and Old English philology and became one of the foremost authorities on both subjects. His researches into Chinese and Arabic were also of high value. From 1901 until his death he was University reader in phonetics at Oxford University. He edited numerous Old and Middle English works and was author of many papers on philology and of 'A History of English Sounds' (2d ed., 1888); 'Primer of Phonetics' (1890; 3d ed., 1906); 'The History of Language' (1900), etc.

SWEET, John Edson, American engineer: b. Pompey, N. Y., 21 Oct. 1832; d. 8 May 1916. He was educated in the district schools, became a carpenter's apprentice and rose to be a builder and architect in 1850. He was employed in his profession in the South until 1861; engaged as an inventor and mechanical draftsman until 1873; from 1873–79 was professor of practical mechanics at Cornell. From 1880 he was president of the Straight Line Engine Company. He founded the American Society of Mechanical Engineers, of which he was president in 1883–84, and an honorary member. On his 80th birthday in 1912, he was given a banquet by the society. He was government expert and juror on machine tools at the World's Columbian Exposition in 1893 and in 1899–1901 was first president of the Engine Builder's Association of the United States. In 1904 he was given the John Fritz Medal, which is awarded by a board of 16 of the leading members of the Mining, Civil, Mechanical and Electric Engineering Societies. In 1914 Syracuse University conferred upon him the degree of Doctor of Engineering.

SWEET-BAY, the classic laurel (*Laurus nobilis*), or bay-tree of the Mediterranean regions, which becomes a tree of some 50 feet in its native habitat, but is cultivated as a shrub farther north, being often trimmed like box. (See BAY). It has handsome, lanceolate evergreen leaves, dark-green and shining, which have an aromatic odor and taste and are, therefore, employed in cookery and for packing figs. They have also some therapeutic value and yield a thick oil which is incorporated into ointments and liniments. The sweet-bay of America is the small tree (*Magnolia virginiana*) called more frequently swamp-magnolia or swamp-laurel. See MAGNOLIA.

SWEET-BRIER. See EGLANTINE.

SWEET-FERN, a low shrub (*Comptonia peregrina*), with many brown branches and long linear leaves so deeply pinnatifid on either side of the midrib as to appear fern-like. The flowers are diœcious, without perianths, and appear when the leaves expand; the fertile are in globose aments followed by burr-like fruits — bony nuts invested with awl-shaped persistent bracts. The staminate aments are longer and clustered at the ends of branches. The young foliage is pubescent, and the whole plant has a strong aromatic fragrance when bruised or under hot sunshine. It was formerly included in the genus with the spicy-bay-berry and is often found growing with it on sterile soils or on hillsides further inland. The dried leaves are sometimes used as a substitute for tobacco.

SWEET-FLAG. See FLAG, SWEET.

SWEET GALE. See CANDLEBERRY.

SWEET-GRASS, a name given to certain plants, most of which are fragrant, especially in drying. The small *Anthoxanthum odoratum* is the sweet vernal grass and has narrow spike-like panicles of spreading one-flowered spikelets. The leaves are flat. This plant has been introduced from Europe and is found in fields and meadows over nearly the whole of America, adding to the fragrance of newly mown hay. *Savastana odorata* is the vanilla-grass or holy-grass of Europe, which is strewn before the churches and religious processions. It is the material from which the Indians of the Saint Lawrence region weave their thin-walled baskets that, when made of the genuine grass, retain their odor of new mown hay indefinitely. *Panicularia* is a genus of grasses called sweet grass because cattle are said to be fond of *P. fluitans*. Another sweet-grass (*Asperula odorata*) does not in the least resemble grass, having whorls of leaves and white flowers like tiny stars in cymes. When dried it is fragrant, however.

SWEET-GUM, a large American tree (*Liquidambar styraciflua*), reaching its greatest size in the South Atlantic States, where it develops tall, straight trunks, branchless for 70 or 80 feet above the ground. The head is narrowly pyramidal when young, but when old and field-grown the heads are likely to become irregular and rugged. The five-lobed, star-shaped leaves form thick, dark and glossy foliage turning to brilliant hues in autumn, the young saplings especially being gorgeous in large reddish purple leaves, bright-green beneath. The monœcious flowers are inconspicuous and without perianth. They are gathered into erect heads, the pistillate ones being succeeded by odd fruits, globose and spiked with the points of two-beaked woody capsules, which are brown and twisted and allow the scanty fertile seeds to escape through gaping orifices. They hang by long stalks far into the winter. The bark is very rough, and in young branches and saplings is peculiarly winged by numerous gray corky ridges of undulating outline, which have suggested the name of alligator-wood. The wood is smooth and satiny and would be valuable as a substitute for black walnut, were it not so liable to warp and difficult to season. It is filled with a resinous sap, which is used medicinally, and like that of *Liquidambar orientale*, of Asia, might be a source of gum storax. This fragrant sap has prompted the Latin-Arabic descriptive generic name. The sweet-gum is otherwise known as star-leafed gum, liquidambar, bilsted, red-gum or copalm.

SWEET MARJORAM. See MARJORAM.

SWEET PEA, an annual herb (*Lathyrus odoratus*) of the family *Fabaceæ*. It is supposedly a native of Ceylon, Sicily and Sardinia, the original pink-and-white and the red varieties being credited to the first country and the pure white and purple varieties to the other two islands. The known history of the plant begins in 1650, and the first record of its cultivation in 1699, when Father Franciscus Cupani grew it at Panormus, Sicily. By 1730 the seed was commercially known, and about 60 years later five varieties were offered by a London seedsman. Until Henry Eckford commenced experimenting in 1876 for the production of new varieties there were, however, rarely 12 varieties offered in any one year. Largely due to his efforts the list of varieties had risen to 150 in 1898, and the popularity of the flower had vastly extended. It has been estimated that since 1900 the average annual crop of sweet-pea seed is about 100,000 pounds, about one-fifth of which is produced by one company in California, where nearly all the seed used in Europe and America is now grown.

The sweet pea is a hardy annual herbaceous vine with rough, winged stems, tendril-bearing leaves composed of two leaflets borne on long stalks, and fragrant papilionaceous flowers of various shades, ranging from white to blue and red through many tints, and including both double and «hooded» forms. The pods are about two inches long, and contain about six brown seeds. The double varieties are not regarded with favor, being rather unkempt and lacking the daintiness of the single sorts.

For best results in the garden, sweet peas should be planted very early in the spring or even during the previous late autumn. They will thus obtain an early start, and their roots will penetrate more deeply into the cool, moist soil before warm weather arrives, than if sown later. Moderately rich soil of a rather heavy nature generally gives best results; very rich soil tends to grow vine and leaf at the expense of flower; very poor ground is prone to produce small short-lived vines and little flowers which, however, are often pronouncedly fragrant. The seeds should be scattered thinly in trenches about five inches deep and four or more inches broad. The distance between rows should be about three and one-half feet, the seed covered about one inch deep, and as the plants grow the earth should be drawn toward the vines until it forms a ridge two or three inches high. When the plants are well above the surface they should be provided with supports upon which to climb. Brush and poultry netting are generally employed. Throughout the season clean, shallow cultivation should be given and the flowers gathered daily. This last will considerably extend the season since the formation of seed tends to a cessation of growth.

Several closely related species are cultivated for ornamental purposes but are less popular than the above. The best known are probably the following: The Tangier scarlet pea (*Lathyrus tingitanus*), an annual herb which blossoms earlier than the sweet pea and should be planted separately because of its greater strength and its tendency to crowd out the former. The perennial or everlasting pea (*L. latifolius*), an odorless species with many-flowered clusters of diversely colored blossoms. It is popular for planting among rocks, in rough places and for screens, for which its rampant growth and hardiness recommend it. *L. rotundifolius* and *L. grandiflorus* are also called everlasting and are cultivated to some extent, as are also *L. maritimus*, the sea or seaside pea, and *L. palustris*, the marsh or wing-stemmed pea — the latter grown in damp places.

Consult Hutchins, 'All About Sweet Peas' (1894), and 'Sweet Peas Up to Date' (Philadelphia 1897); Bulletins 111 and 127, Cornell Agricultural Experiment Station (Ithaca 1895, 1896); Bailey, 'Standard Cyclopedia of Horticulture' (New York 1916).

SWEET PEPPERBUSH. See CLETHRA.

SWEET POTATO, a tuberous-rooted perennial herbaceous vine (*Ipomæ a batatas*) of the family *Convolvulaceæ*. The plant is of unknown origin but is supposed to be a native of tropical America. It has roundish or angular heart-shaped leaves, and in cultivation rarely produces blossoms or seeds. The flowers resemble those of morning-glory, but are smaller. The tubers, which are borne below the crown of the plant, are without well-defined eyes. The plant was cultivated by the natives before the landing of Columbus. It is now extensively grown in many warm and mild climates, especially in the Southern States, California and the Atlantic Coast as far north as New Jersey. The annual crop aggregates about 50,000,000 bushels, and the yield per acre varies usually between 200 and 400 bushels, though with best management and favorable season 800 bushels or even more are occasionally obtained.

The sweet potato is propagated less by its tubers planted in the field than by sprouts obtained from the tubers in hotbeds, etc. These sprouts or «draws» are transplanted in the field as soon as the weather has become settled and after the land has been deeply and finely prepared by plowing and harrowing. The soil best suited to the crop is a light sandy loam not excessively rich in nitrogenous plant food but not deficient in this respect. Upon heavy soils the tubers are prone to crack because of the uneven growth under varying conditions of moisture and dryness. Plenty of moisture, warm situation and liberal manuring are essential. The ground is kept cleanly cultivated until the vines interfere with tillage. The tubers are dug in the autumn and stored in a great variety of ways, all considered more or less unsatisfactory since the tubers usually decay badly during storage. While the plentiful yield may frequently beg a market in the autumn, the demand from mid-winter onward can rarely be supplied even at advanced figures. These troubles may be considerably reduced by proper care in harvesting. The following practices are recommended: Digging before the tubers start a «second growth,» choosing clear weather when the soil is dry, using padded baskets to reduce chance of scratching the tubers, handling so as to avoid bruising, storing only the perfect specimens and giving perfect ventilation in the storage heaps which should always be located upon knolls or otherwise dry ground. As adjuncts to these practices the beds in which the sprouts are obtained should be made upon clean fresh land with fresh manure and the plants should never be set two years in succession in the same field; three or four years is considered much better. These are all preventive and are thought to be more valuable than special methods of storage in expensive storage quarters.

Consult Georgia Experiment Station Bulletin No. 25 and Farmers' Bulletin No. 26 of United States Department of Agriculture.

SWEET-SOP, the edible fruit of an evergreen shrub (*Annona squamosa*). It is ovate in shape, with a delicious, sweet pulp, enclosed by a thick rind having projecting scales. Although indigenous to America this tree is cultivated for its fruits in all tropical climates, and is also called sweet-apple, or, in India, custard apple — a name which properly belongs to *A. reticulata*.

SWEET SULTAN, a plant. See CENTAUREA.

SWEET WATERS OF ASIA, a river, the ancient Aretas, flowing between Anadoli Hissar and Kandili, on the Asiatic side of the Bosphorus. The Turks call it Ghiok-suyu, "heavenly waters," from the surpassing beauty of its surroundings. The valley is a favorite picnic resort in summer and autumn, when the better class Turkish families may be seen on Fridays (Mohammedan Sabbath) in their private caïques (boats) on the stream or scattered along the shores under luxuriant cypress, sycamore and plane trees.

SWEET WINES. See WINE AND WINE MAKING.

SWELL-FISH. See GLOBEFISH; DIODON.

SWENSSON, Carl Aaron, American Lutheran theologian: b. Sugar Grove, Pa., 25 June 1857; d. Los Angeles, Cal., 16 Feb. 1904. He was graduated from Augustana College, Rock Island, in 1877, and in theology from Augustana Seminary in 1879; was secretary to the General Council of the Lutheran Church of North America in 1885 and its president, 1893–94. He was a member of the Kansas legislature in 1889; founded Bethany College in 1881 and was its president from 1889 till his death. He was the author of hymn books and books of travel in Swedish and English.

SWETE, swēt, **Henry Barclay,** English theologian: b. Bristol, 14 March 1835; d. May 1917. He was educated at King's College, London, and Gonville and Caius College, Cambridge, where he gained several prizes, and was graduated in 1858. He was professor of pastoral theology in King's College, London, from 1882 till 1890, and examining chaplain to the bishop of Saint Albans from 1881 till 1890; and after 1890 was Regius professor of divinity at Cambridge. He was made honorary chaplain to the king in 1911. His published works include 'Early History of the Doctrine of the Holy Spirit' (1873); 'History of the Doctrine of the Procession of the Holy Spirit' (1876); 'Commentary of Theodore of Mopsuestia on the Minor Epistles of Saint Paul' (1880–82); 'The Old Testament in Greek,' according to the Septuagint (1887–94); 'The Akhmim Fragment of the Apocryphal Gospel of Saint Peter' (1893); 'The Apostles' Creed in Relation to Primitive Christianity' (1899); 'Faith in Relation to Creed, Thought and Life' (1895); 'Church Services and Service-books before the Reformation' (1896); 'The Gospel According to Saint Mark, and the Greek Text, with Introduction, Notes and Indices' (1898); 'An Introduction to the Old Testament in Greek' (1900); 'Patriotic Study' (1902), and 'Studies in the Teaching of Our Lord' (1903); 'Works of the Ascended Christ' (1911); 'The Holy Spirit in the Ancient Church' (1912); 'The Last Discourse and Prayer of our Lord' (1913); 'The Holy Catholic Church' (1915). He also contributed articles to Smith and Wace's 'Dictionary of Christian Biography,' (Vols. III and IV, 1882–87), and to Hasting's 'Dictionary of the Bible' (Vols. II and III, 1899–1900).

SWIFT, Gustavus Franklin, American merchant: b. Sandwich, Mass., 24 June 1839; d. Chicago, Ill., 30 March 1903. At the age of 23 he opened a small butcher shop in his native town, but removed to Boston when he was less than 30 years old. He remained in Boston until 1875 when he went to Chicago, where he developed the department of shipping live cattle to eastern markets. In 1877 he evolved plans for the first refrigerator car, and dressed meats, instead of live animals, were shipped to eastern cities. He was the pioneer in this business, and from the small plant started in 1877 developed the great corporation bearing his name.

SWIFT, Jonathan, English clergyman, poet, political writer and satirist: b. Dublin, Ireland, 30 Nov. 1667; d. Dublin, 19 Oct. 1745. Swift was the posthumous son of Jonathan Swift, the neer-do-weel of a prosperous and pretty well-known family which had numbered several preachers in its course since the time of Robert Swifte (16th century) of Yorkshire, the earliest known of Swift's ancestors. The most famous member was Swift's grandfather, Thomas Swift (b. 1595), the famous Royalist vicar of Goodrich. Through Thomas Swift's marriage to Elizabeth Dryden, great-aunt of John Dryden, came Swift's relation to the poet. Swift's mother, Abigail Erick, of Leicestershire was a distant cousin of Sir William Temple and a woman of much character and wit.

Swift's life divides itself conveniently into three periods: to the death of his patron, Temple, in 1699; from that year, when he began to seek ecclesiastical and political preferment, to the close of his brilliant work for the Tory ministry at the death of Queen Anne, in 1714; and from the latter year till his death, during which period he was dean of Saint Patrick's in Dublin, where he almost continuously resided. The story is that he was taken at the age of one year from Dublin to Whitehaven, England, by his nurse, where he lived two years, learning to read in the interval. At the age of six he entered Kilkenny School at the charge of his uncle, Godwin Swift. Entering Trinity College, Dublin, in April 1682, he was graduated four years later without distinction, and the following year was publicly censured for neglect of his studies and for tavern-haunting. At this time he was probably pretty much depressed in spirits and was friendless. His dependence on the charity of his relatives was galling to his pride, and he was unhappy, but his delinquencies were not very serious. Driven from Ireland in the fall of 1688 by the rebellion of Tyrconnel, he and his mother retired to Leicestershire, whence, in 1689, he became secretary to Temple at Moor Park, near London. His position was a somewhat menial one, but his patron's kindness enabled him to take the degree of A.M. at Oxford in 1692. Returning to Temple but finding his position irritating, he refused the latter's offer to obtain for him a clerkship in the Irish Rolls, quarreled with his employer and entered the church. Ordained deacon in October 1694, and priest in January of the following year, he obtained the living at Kilroot, Ireland. Tiring of his position, however, he applied to Temple for reinstatement, and the latter, glad of his help, called him back to a post of greater importance, early in 1696. Here Swift remained till his patron's death in January three years later.

The decade ending with that date is very important to the life of Swift. Intellectually, he was very active and, besides his routine duties, did a prodigious amount of reading. Though he did not always understand his motives accurately, he was nevertheless not far from the truth when he described his temperament in a letter to a friend who had cautioned him to beware of a marriage that his mother feared he was about to make. Protesting that he could have no thought of matrimony until his position in the world was secure, and adding that he was very hard to please, he continued: «How all that suits with my behaviour to the woman in hand you may easily imagine, when you know that there is something in me which must be employed, and when I am alone turns all, for want of practice, into speculation and thought; insomuch, that these seven weeks I have been here, I have writ and burnt, and writ again upon all manner of subjects, more perhaps than any man in England. And this it is which a person of great honour in Ireland (who was pleased to stoop so low as to look into my mind) used to tell me that my mind was like a conjured spirit that would do mischief if I did not give it employment.» (To Rev. John Kendall, 11 Feb. 1691). Whatever may have been the exact truth of the matter, Swift's constitutional restlessness was aggravated by a malformation in the region of the ear, which, resulting in blood pressure, caused the attacks of giddiness and deafness to which he was always subject and which drove him to intense activity for relief (consult Craik, Appendix, XIII, and Collins, p. 237).

His first writings, however, were of no importance. Falling under the influence of Cowley, he produced his first extant poem in May 1689, a very stilted Pindaric Ode to Dr. William Sancroft, and the seven known poems, chiefly odes, which he wrote before 1698 are of no better quality; it was the fourth, 'To the Athenian Society' (1691) that, according to Johnson, caused Dryden's damaging remark, «Cousin Swift, you will never be a poet.» His vein then suddenly changed, and in 'Lines written in a Lady's Ivory Table-Book' (1698) and 'Mrs. Francis Harris's Petition' (1700) he first displayed evidences of the graphic, humorous description and the complete absence of sublimity which distinguish his verse.

Far more striking are the two works which opened his career as a prose writer. Among a probably large amount of writing now lost, he composed, in 1696, 'The Battle of the Books' and 'A Tale of a Tub,' both of which remained unpublished until 1704. The year 1696 may be taken as the date when Swift abandoned his efforts to imitate the writing of other men, and leaped, full-armed, into his own peculiar and inimitable possession, satire. 'The Battle of the Books,' the one piece now read in a once famous controversy, in which Temple had engaged, as to the relative merit of the Ancients and the Moderns, is famous for its satire of affectation, pedantry and obtuseness and for its lively burlesque of the heroic manner. The other book, a much more elaborate affair, by many regarded as Swift's masterpiece, is in its narrative parts a satire against religious abuses and schism, in the persons of Peter, the Church of Rome, Martin, the Anglican Church, and Jack, the Presbyterian sect. This narrative, however, comprises no more than a third of the book; the remainder is taken up with dedications, prefaces and digressions, which variously satirize the vanity, conventionality and affectation of authors, the irreverence and scurrility of the wits of the day, the pedantry, the cheapness and superficiality of contemporary learning, and, in general, fanaticism, unreasonableness, vanity and emptiness. In these two books, written before he was 30, Swift showed himself to be an unrivaled master of irony, burlesque and satire.

In the summer of 1699 Swift became secretary and chaplain to Lord Berkeley, one of the lord justices of Ireland. Disappointed in his efforts to obtain the deanship of Derry, he was made in February 1700 vicar of Laracor, Agher and Rathbeggan, in County Meath, Ireland, livings worth about £200 a year. On the recall of Berkeley in 1701, he went with the latter to London and published his first political pamphlet, 'The Dissensions in Athens and in Rome,' an attempt to show the need of harmony in politics. Though the pamphlet gained the goodwill of the Whigs, Swift's work for the next nine years was wholly in behalf of the Irish clergy. Four journeys to London, of an average duration of over six months apiece, were undertaken chiefly with a view to obtaining remission of the taxes on the Irish livings, and during the same period Swift wrote a number of able pamphlets in support of the established church, of which the masterly piece of irony, 'An Argument to Prove that the Abolishing of Christianity in England may, as things now stand, be attended with some inconvenience, and perhaps not produce those many good effects proposed thereby' (1708), and 'The Sentiments of a Church of England Man, with respect to Religion and Government' (1708), are the most important. During these visits also, Swift came to know the best wits of the time, the chief literary result of which were the famous 'Bickerstaff Pamphlets' (1709–10), a practical satire against false learning in the person of the astrologer Partridge. His principal mission, however, came to nothing; he was put off by the Whig lords, and, personally disappointed because of his failure, owing perhaps to the impression created by 'A Tale of a Tub,' to gain preferment in the Church, he gave his services to the Tory ministry which came into power in 1710.

During the next four years Swift wrote an extraordinary number of political pamphlets; few political writers have ever done a larger amount of brilliant and powerful work. Swift's task was threefold: to show that the cause of the Tory ministry, its desire to obtain a peace with France, was a just cause, and that its members were worthy men; to cast ridicule on the principals and persons of the Whigs; and to restrain the more violent Tories from extreme measures. His first work, after a caustic 'Short Character of Thomas, Earl of Wharton' (1710), was the conduct of the *Examiner*, the Tory weekly, for which he did all the writing between 2 Nov. 1710 and 14 June 1711, contributing a series of varied and able arguments and satires. His position, maintained with singular adroitness, was that the country was crying for a peace and happiness which could be more readily obtained from the Tories than from the Whigs, especially while Marlborough and Wharton were influential. In 'The Conduct of the Allies and of the Late Ministry in Beginning and Carrying on the Present War' (November 1711), commonly regarded as his masterpiece among the writings in support of the Harley administration, his object was to strip the war of its glamor and to render it unpopular by showing that the Allies, with the connivance of the Whigs, had been systematically exploiting England. «After ten years of war with perpetual successes,» he says in his preface, «to tell us that it is impossible to have a good peace is truly surprising — [and] it is natural to inquire into our present condition; how long we shall be able to go on at this rate; what the consequences may be on the present and future ages; and whether a peace, without that impracticable point which some people do so much insist on, be really ruinous in itself, or equally so with the continuance of the war.» Other important tracts were 'The Importance of the Guardian Considered' (1713), a merciless, but not unprovoked attack on Steele, and the savage and fairer answer to Steele's 'Crisis,' the very skilful 'The Publick Spirit of the Whigs.'

Besides his political writing, Swift published many pieces of a miscellaneous kind, including several papers for Steele's *Tatler*, at least one for the *Spectator*, some controversial satires on religious subjects, his historically interesting but philologically unsound 'Proposal for Correcting, Improving, and Ascertaining the English Tongue' (1712), and the well-known 'Journal to Stella.' He had made the acquaintance of Esther Johnson, then a child of eight, during his first residence at Sir William Temple's, and had been the tutor to this ward of his patron. When he got his livings in 1700, she, with her companion, Mrs. Dingley, went to Ireland to live near him, and during his residence in England remained in Ireland. The 'Journal' extends from 2 Sept. 1710 to 6 June 1713, with scarcely a break. The letters, which were dispatched every two or three weeks with an entry for nearly every day, are chiefly the bare narrative, expressed in simple, intimate terms, of what Swift was doing in a social way, and are singularly free from discussion of the politics of the time. They are important as a record of the life and character of a busy and influential man of the time.

As a reward for his great political services, Swift was appointed, on 23 April 1713, dean of Saint Patrick's Cathedral, Dublin, and the following June went to Ireland to take charge of his new office. Returning to London in August of the same year with a view to healing the growing breach between the Tory ministers, Oxford and Bolingbroke, he was unsuccessful and retired to Letcombe, Berkshire. On the fall of Oxford and the triumph of Bolingbroke, he adhered to the fortunes of the former and saw the close of his political career in England. On the death of Queen Anne, 1 Aug. 1714, the downfall of Bolingbroke and the complete triumph of the Whig party, he returned at once to Dublin, where he remained continuously for the next 12 years.

In Ireland he found himself very unpopular, and in his Church had trouble with his chapter and the archbishop, King. For the next six years he lived quietly, busying himself with his duties and writing only a few pieces, chiefly short letters of advice, articles on manners, etc. In 1716 he may have married Stella. The evidence is conclusive neither way, but the probability is against the marriage. At all events, she continued to live near him till her death in 1728, an event which caused him profound sorrow. Of the various, and occasionally heated, discussions that have arisen about this famous love story, the most sensible conclusion is that of Sir Leslie Stephen to the effect that the question is not practically important in determining the character and achievement of Swift.

In 1720 Swift again became active. For the next 18 or 20 years, until he could write no longer, his very voluminous production has three main aspects: that in behalf of the oppressed people in Ireland, both clergy and laity; that for the doctrines and the establishment of the Anglican Church; and the miscellaneous humorous and satirical writing, both in prose and verse, on which his popular literary fame largely rests. Beginning with a 'Proposal for the Universal Use of Irish Manufactures' (1720), he followed this with tracts on other subjects, and in 1724 began his most celebrated piece of polemic writing, 'The Drapier's Letters.' These very powerful, effective, but not wholly fair pamphlets were occasioned by a patent which had been issued to one William Wood to coin £108,000 of copper for circulation as small coin in Ireland. Swift, in the first three letters, addressed the people of Ireland, under various classes, and with much skill in the selection of arguments suitable to each class, advising them to shun the coinage which the English government was trying to foist upon the Irish public. Then, having prepared his ground, he launched forth, in the next three letters, against the general right of the English to exploit and oppress the Irish. He closed the series with a letter, not published till 1735, «An Humble Address to both Houses of Parliament,» in which he powerfully reviewed the woes of Ireland and made proposals for remedying them. The letters caused great excitement: the printer was arrested and a reward was offered by the government for the apprehension of the writer; but they produced their effect and the coinage was refused. Swift became very popular, and his position enabled him to pursue the subject of his last letter in many other tracts. The miserable condition of Ireland is the burden of his political song, in such able pieces as 'A Short View of Ireland' (1727), and 'Maxims Controlled in Ireland' (1728). The most remarkable of these minor pieces is the very extraordinary piece of irony, 'A Modest Proposal for Preventing the Children of Poor People in Ireland from being a Burden to their Parents or Country and for Making them Beneficial to the Public.' No more bitter or intense satire than this exists in literature: for 10 years Swift had been fighting oppression, and this is the highest pitch of his complainings. Nothing that he had previously touched on — the villainy of the landlords, the vanity and foppery of the women, the rigor of the English and the miserable state of the country in general — is left unexposed.

Swift's writings on religious subjects of this period are, on the whole, of less permanent interest than those just considered. They belong to a rather later date, when his interest in the general economic condition of Ireland had spent itself after its most vehement outcry, 'A Modest Proposal.' These writings are on two main subjects, the economic oppression of the minor clergy in Ireland and the efforts of the various sects of dissenters to obtain greater civil rights. Of the former of these the able tract "On the Bill for the Clergy's Residing on Their Livings" (1731–32), is representative. Specifically it is an argument against the plan of the bishops to get more power by compelling the lower clergy to divide their livings and to erect houses thereon at the direction of the bishops. In general, it is an acute comparison between the condition of the clergy in Ireland and in England and an exposition of the wretched condition of the former. It is said to have induced the commons to reject the bill after it had been passed by the lords. The same idea he expressed satirically, as was usually his practice, in 'An Essay on the Fates of Clergymen,' a piece which deserves a place with Hogarth's drawings of the idle and the industrious apprentices. Typical of the latter class is 'The Presbyterians' Plea of Merit' (1730 or 1733), in which he dismembered the claim of the dissenters to meritorious services in the time of the Commonwealth and the Revolution. The same subject he treated in his ablest satirical manner in 'Reasons Humbly Offered to the Parliament of Ireland for Repealing the Sacramental Test' (1733), in which he purported to show that in all respects the Catholics were more deserving than the Dissenters and should, therefore, have religious freedom. In all the many tracts of this latter class, he argued in favor of the actual establishment of the Anglican Church.

The third kind of work of this period consists of his miscellaneous satires, in prose and verse, and on one of these, 'Gulliver's Travels,' his popular fame chiefly rests. The idea may have originated in the days of the Scriblerus Club (see ARBUTHNOT), but took no definite shape till after 1720. The motive of the book is thus expressed in a letter to Pope, 29 Sept. 1725: "I like the scheme of our meeting after distresses and dispersions, but the chief aim I propose to myself in all my labours is, to vex the world rather than divert it, and if I could compass that design, without hurting my person or fortune, I would be the most indefatigable writer you have ever seen, without reading. When you think of the world give it one more lash at my request. I have ever hated all nations, professions, and communities; and all my love is toward individuals; for instance, I hate the tribe of lawyers, but I love counsellor such a one, and judge such a one; it is so with physicians (I will not speak of my own trade), soldiers, English, Scotch, French, and the rest. But principally I hate and detest that animal called man; although I heartily love John, Thomas, etc." The famous book appeared in November 1726, in London, whither Swift had gone in the spring of the same year. It was published anonymously and had instant success. It has since held its place as the most comprehensive and truculent satire and one of the most popular children's books in the English language.

In a letter to Pope, of 12 June 1732, Swift alluded to two pieces of satire which he had in mind and which are the only ones besides 'Gulliver's Travels,' which need be specifically mentioned. 'A Complete Collection of Genteel and Ingenious Conversation,' etc., commonly called 'Polite Conversation,' appeared in 1738; it is a well-sustained satire against cant and affectation in talk. The other, 'Directions to Servants,' a satire against slovenliness, remained unfinished at his death. They are about the last work that he did. During his visits to London he lodged near Mrs. Vanhomrigh, whose daughter Hester fell in love with Swift. She is the Vanessa of Swift's writings. She followed him to Ireland after her mother's death and resided near him at Celbridge. In 1723 she wrote to Stella but received a stinging rebuke from the dean. She died soon after. Her story is, perhaps, even more pathetic than that of the more patient Stella.

Swift's journey to London in 1726 for the sake of seeing his old friends, and one of the following year, on the death of George I, to determine whether the new ruler would aid his work for Ireland, were the only times when Swift left that country after 1714. Thence on he lived in Dublin in growing physical distress, and in 1738–39 his health began to fail seriously. For three years he was tortured with pain, and in 1742 his mind completely gave way, owing to disease which is said to have had nothing to do with his constitutional malady. Up to his death he was almost wholly imbecile.

For a long time a legend was current that Swift was buried in Saint Patrick's in the same coffin with Stella — a legend accepted by the 'Encyclopædia Britannica' and the 'New International Encyclopedia.' As a matter of fact the grave of Swift in Saint Patrick's, Dublin, is several yards distant from Stella's. In 1835 some alterations in the church disclosed Swift's coffin; a society of phrenologists happened to be in session in the city at that time, and obtained permission to examine Swift's skull and that found in a neighboring coffin, not Stella's. The lazy sexton, in returning the skulls, saved himself trouble by poking them both into Swift's coffin. A further exhumation in 1882 disclosed them together, whence the legend. For the disposal of this oft-repeated story consult article by Dr. H. J. Lawlor in the *English Historical Review* (March 1918).

Swift, in his maturity, is represented in the several extant portraits, of which those by Charles Jervas are the most interesting, as a man of large frame and handsome countenance. Contemporary accounts represent him as a man of much distinction of manner and powerful personality. Intellectually he was unquestionably among the greatest of his time, and his influence was uncommonly great. From the time of the 'Drapier's Letters' he exercised a remarkable sway over the affections of the

Irish, and is said to have been the most popular man in Ireland. By his friends he was greatly beloved and the charm which his personality has exercised on most of his biographers has frequently made them protagonists and led them to minimize some evident defects of his character, as his mercilessness to his opponents and his not infrequent coarseness, defects which he shared with many of the ablest men of his time.

Among all the able writers of the age he is surpassed by none in range and power and by none, except Defoe, in voluminousness. His known writings comprise over 230 separate prose titles, varying in length from the 'Meditations on a Broomstick' to 'Gulliver's Travels,' upward of 300 poems and some 500 letters. Within the limits of his style, which may be defined as the simple, intense and unadorned, as opposed to the ornate or the sublime, he is complete master of his medium and his sureness of touch in the large number of varied subjects that he treated, give him a place among the very greatest of English writers. Neither philosophical intricacy nor emotional appeal interested him, but as master of simple, racy English, of irony, humor, burlesque, satire and invective, he is unsurpassed, as he is also in his management of the topics with which he deals. Though he is remembered in literature chiefly for his great satires, nearly all the titles cited in the foregoing columns are models of their kind in writing. See BATTLE OF THE BOOKS; GULLIVER'S TRAVELS; TALE OF A TUB.

Bibliography.— The best editions of Swift's complete writings are still those of Sir Walter Scott in 1814 and 1824 (2d ed.) in 19 vols. The most convenient and accurate modern edition of the prose is by Mr. Temple Scott (begun 1898) in 12 vols. of the Bohn Library. Other editions and selections of his prose and verse are too numerous to mention specifically. The principal early biographies are Orrery's 'Remarks on the Life and Writings of Swift' (1752), Delany's 'Observations' (1754), Dean Swift's 'Essay upon the Life, Writings, and Character of Dr. Jonathan. Swift' (1755), Hawkesworth's 'Memoir' (1755), Johnson's in the 'Lives of the Poets' (1780), Thomas Sheridan's 'Life' (1784), Monck-Berkeley's 'Enquiry' (1789), John Barrett's 'An Essay on the Earlier Part of the Life of Swift' (1808), Sir Walter Scott's 'Memoirs' (prefixed to the edition of the works), all of which tell much the same story. Scott's is the best. Monck Mason's 'History and Antiquities of Saint Patrick's Cathedral' (1819), contains much interesting and valuable matter. The more modern and authoritative lives begin with John Forster's 'The Life of Jonathan Swift, 1667–1711' (1875), unfortunately unfinished. The most complete and accurate life is, on the whole, that by Sir Henry Craik (London 1882). Sir Leslie Stephen's in 'The English Men of Letters' is also good. Other lives are the enthusiastic study by J. Churton Collins (1893), the less interesting 'Dean Swift and His Writings' by G. P. Moriarty (1893) and the introduction to the Bohn Edition by W. E. H. Lecky. Consult also Smith, S. S., 'Dean Swift' (New York 1910); 'Correspondence,' edited by E. F. Ball (ib. 1914) and "The Bibliography of the Writings of Jonathan Swift" (in 'Prose Works,' Vol. XII, New York 1908); *English Historical Review* (March 1918).

WILLIAM T. BREWSTER,
Professor of English, Columbia University.

SWIFT, Joseph Gardner, American military officer: b. Nantucket, Mass., 31 Dec. 1783; d. 1868. In 1800 he entered the army as a cadet and in 1802 became the first graduate of the Military Academy at West Point. In 1807, having attained the rank of captain of engineers, he was appointed to the command of West Point. For meritorious services in the campaigns of 1813 and 1814 on the Saint Lawrence River, and in defense of the city and harbor of New York, he was brevetted as brigadier-general. General Swift was afterward surveyor of the port of New York for nine years, then civil engineer of the Baltimore and Susquehanna Railroad, and from 1829 to 1835, under appointment from President Jackson, superintendent of the harbor improvements on the lakes, removing to Geneva, N. Y. In 1838 he was chief engineer of the Harlem Railroad in New York, and in 1841 was sent by President Harrison on an embassy of peace to the governors of Canada, New Brunswick and Nova Scotia.

SWIFT, Lewis, American astronomer: b. Clarkson, N. Y., 29 Feb. 1820; d. 1913. He was graduated at Clarkson Academy in 1838. He became interested in astronomy, built his own telescope in Rochester, N. Y., and began to make observations. For years he searched the heavens for comets, and discovered the notable one of 1862. In 1869 he observed a total solar eclipse and secured valuable results. Two years later he found another comet, and in 1877-79 discovered other comets, for which he received a gold medal from the Imperial Academy of Sciences in Vienna. In 1882 he assumed the directorship of the Warner Observatory, and later took charge of the Lowe Observatory on Echo Mountain, California. Before the completion of the Warner Observatory, Dr. Swift was presented by the people of Rochester with a 16-inch refractor costing $11,000. With this instrument he discovered 900 nubulæ there and over 300 at Echo Mountain, California, and about a dozen comets at both places. In 1881 he was awarded the Lalande prize of the French Academy, and the Jackson Guill medal and gift of the Royal Astronomical Society in 1897. He also received several comet medals from the Astronomical Society of the Pacific. He wrote 'Lessons in Astronomy' (1888).

SWIFT, Lindsay, American editor: b. Boston, Mass., 29 July 1856. He was graduated at Harvard University in 1877 and became the editor of the Boston Public Library. Author of 'Massachusetts Election Sermons' (1897); 'The Great Debate Between Webster and Haynes' (1898); 'Literary Landmarks of Boston' (1903); 'Benjamin Franklin' (1910); 'William Lloyd Garrison' (1911), etc.

SWIFT, a local name in the eastern United States for the familiar fence-lizard (*Sceleporus undulatus*) in reference to the celerity of its movements. See SCELEPORUS.

SWIFT CREEK, or ARROWFIELD CHURCH, Engagement at. On 9 May 1864 General Butler sent an expedition from his intrenchments at Bermuda Hundred to destroy the railroad between Richmond and Petersburg. With a large part of the 10th and 18th corps Generals Gillmore and W. F. Smith moved out in the morning and destroyed the road from Chester Station on the north to Swift Creek on the south, a distance of six miles. Arriving at the creek and driving the Confederate skirmishers across it, the Federals found that the stream was not fordable and that the bridges were held by Hagood's and a part of B. R. Johnson's brigade, with artillery posted on the south bank. There was a sharp engagement across the stream, with artillery and infantry, in which each side lost about 150 men, and on the morning of the 10th the expedition returned to Bermuda Hundred. Consult 'Official Record' (Vol. XXXVI).

SWIFT-MOTHS, a cosmopolitan family (*Hepialidæ*) of large or medium-sized moths, characterized by brownish or golden wings, exceptionally white; a jugum is present, and the neuration of the fore and hind legs is similar. Their jaws are vestigial in the imago, and no food is eaten by the adults. The caterpillars bore into the stems of plants, live underground, and feed on roots; the "incomplete" pupæ also are subterranean. The hop-moth and the British ghost-moth are typical examples.

SWIFTS, birds of the family *Micropodidæ* (or *Cypselidæ*), noted for the extreme rapidity of their flight. Their proper place in the system of ornithology has been much discussed. Formerly they were universally classed with the swallows, but the usual opinion among ornithologists is that, unlike as are the swifts and humming birds (q.v.) in general aspects, they with the nightjars form a natural assemblage, the order *Cypseliformes*, or its equivalent. The swifts have a generally swallow-like aspect. The bill is very small, flat and weak, but the mouth, which is not provided with bristles, extends far back beneath the eyes, giving a very extensive gape. Just at its base above are the nostrils partly covered by feathers. The feet are very small without any distinct scaly covering or any comb-like claws, and they present remarkable peculiarities in the position of the hallux and the number of phalanges in the different genera. The wings are extremely long, reaching far beyond the tail and crossing, but the length lies entirely in the extremely elongated primary quills, the upper segments of the arm and the secondary quills being unusually small. In the typical swifts the tail is long and forked, in others it is short, truncate and spiny; there are always 12 retrices. Among anatomical characters swifts have the salivary glands remarkably developed and of the mucous type; the lower intestine has no cæca; the skull lacks basipterygoid processes in those which have the palate of the passerine (*ægithognathous*) type but has them combined with the cleft-palate (*shizognathous*) type; the keel of the sternum is remarkably deep and the pectoral muscles correspondingly well developed. Except that they shun the polar regions these strictly insectivorous birds are cosmopolitan in their distribution. There are about eight genera and 75 species divided into the subfamilies of *Micropodinæ* or typical swifts and the *Chaturinæ*, or spine-tailed swifts. The first has the tail feathers normal, the tarsi and toes feathered, the hind toe capable of being turned laterally or forward and the three front toes with only three joints each. Nearly all of the species of this group belong to the Old World, several being South American, and one belonging to the United States. In *Cypselus* all four toes are directed forward. To this genus belong the common swift of Europe (*C. apus*) and the Alpine swift (*C. alpinus*). The only representative of this group occurring within the United States is white-throated or rock swift (*Aëronautes melanoleucus*), found in the southwestern region north to Wyoming and in winter in Mexico and Central America. The hind toe is directed laterally, not forward, and the toes are only partially feathered. The colors are black above with some white markings and white below; the length about seven inches and the closed wing the same. This species is gregarious and nests in extensive colonies in holes and on ledges of inaccessible cliffs. Like the European swift its flight is incredibly rapid. Among exotic species of true swifts, none are of greater interest than palm swifts (*Tachornis*) of Africa and the tropical Orient and the aberrant tree swifts (*Macropteryx*) of India and Ceylon, which nest in trees.

The subfamily *Chæturinæ* has the feet more normal, but the hind toe is more or less versatile and the phalanges of the front toes, though not reduced in number, are extremely short; the feet are unfeathered and the tail feathers have the vane wanting at the end, the produced shaft forming a stiff mucronate tip. The common chimney swift (or erroneously swallow) (*Chætura pelagica*) is an example, and is too well known to require a description. It is a migratory species and one of the very latest birds to appear in summer. It breeds as far north as Labrador and winters southward to southern Mexico. Its western limit is the central plains. This is one of the birds which has been reputed to hibernate at the bottom of ponds and not a few circumstantial accounts of the manner in which they entered the mud have been published. Several patient, truth-loving, zoologists have carefully investigated these reports with the expected result that they proved baseless. The nests of this swift are interesting structures of twigs glued together with a thick coating of hard varnish-like dried saliva, which also serves to attach the saucer-like structure to the inside of an unused chimney, which at the present time are the almost exclusive nesting and sleeping sites of these birds. Formerly they occupied hollow trees and still do in unsettled parts of the country. The eggs are pure white and number four or five. Most of the life of these birds is spent in flight, and many and remarkable are their aerial performances. The only other swifts of this subfamily inhabiting the United States are *Chætura vauxii* of the Pacific States, there replacing the eastern chimney swift, and the black swift (*Cypseloides niger*) of the Rocky Mountain region and westward from British Columbia to Central America. It ascends to great altitudes. Several species of the latter genus occur in South America. *Callocalia* includes the edible birds'-nest swifts (q.v.) of which a number of species occur from southeastern Asia to Madagascar and the Marquesas.

Consult, besides the articles referred to above, and the standard works on American

Ornithology, especially Hartert, 'Catalogue Birds British Museum' (Vol. XVI, London 1892) and 'Cambridge Natural History' (Vol. IX, New York 1907).

SWIMMING, the art or practice of locomotion or mode of progression in the water by using the arms and legs as paddles. According to the best authorities, all animals, excepting man, monkeys and, perhaps, the three-toed sloth (*Bradypus Tridactylus*), either swim naturally or go through the motions of swimming when suddenly immersed in water. There are, however, a number of animals that, although they swim naturally, drown as they swim. This is the case with rabbits, mice, moles and the smaller cats. Drowning appears to be the result of the fur being saturated. Tigers, cheetahs and lions, the larger cats, are fine swimmers. It is noteworthy that the mole and the rat are equally strong swimmers, the former, however, drowns in a short time, while the latter has considerable endurance in the water and is credited with many feats of long-distance swimming.

The conditions under which an animal will swim well are those in which the wetted surfaces are large and, therefore, afford the greatest power of resistance, and where the specific gravity of the object is a little greater than that of water and consequently subject to the least disadvantageous displacement. Almost all of the larger quadrupeds, especially the deer and the horse, are exceptionally fine swimmers. They simply walk in the water, the motions which serve to support and propel them in that medium being very similar to those employed to progress on land.

On the other hand, in the swimming of man, it is necessary to consider a semi-artificial mode of progression, which is, however, subject to and regulated by the general laws governing aquatic locomotion in relation to the medium, the body immersed therein and to the forces exerted by that body to propel itself. The human body with a normal amount of air in the lungs is very slightly lighter than water and the movements of the limbs produce various effects, according to the direction of the effort. When they are moved horizontally and downward they tend to support and propel the body. When they are moved in an upward direction, as in diving, the body is given a tendency to descend. As to the immersed surfaces, their direction tends to either float or sink the body. When a man wishes to float in the water he assumes a flat position resembling the natural position of the lower swimming forms and for purposes of propulsion and support employs the "dog paddle," in which the motions of the hands are exactly similar to those of the forepaws of a dog in swimming or in walking; a method of swimming employed naturally by almost all land animals.

Although a man's initial efforts to swim result in positions of the body and motions of the limbs which closely approximate to those of the lower animals that swim naturally, he has adopted and developed artificial methods by the use of which he surpasses them in speed and endurance.

These methods involve motions of the limbs which may be conveniently designated as the breast or front stroke, the side stroke, the overhand stroke, swimming on the back, diving, floating and treading. In general, so long as the arms and legs move in any direction, the forces exerted tend to propel the body.

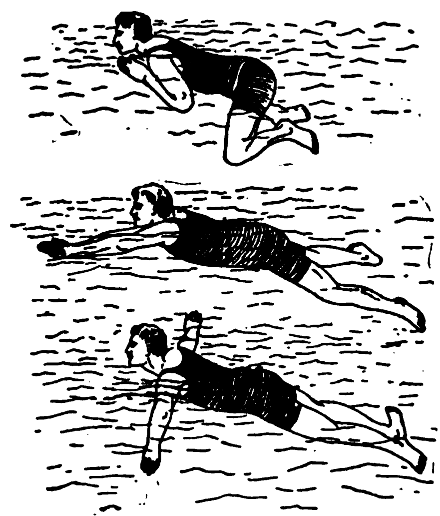

FIG. 1.— Breast Stroke.

The breast stroke consists of a broad sweep of the arms in a horizontal plane, accompanied by a frog-like motion of the legs. It is commenced by placing the hands with the backs upward, the wrists being bent sideways so that the fingers point to the front and the inner sides of the wrist joints touching the breast about four inches below the surface of the water. The arms are then pushed gently forward, the palms being kept flat and the fingers closed. When the arms have been extended to their full extent, the palms of both hands are turned outward and a strong outward sweep is made by each arm, horizontally, through an angle of 90°. The arm movement is completed by bending the elbows backward and inward until they are brought close to the sides of the body and then the hands are carried edgeways, to their original position in front of the body. Simultaneously with the extending of the arms to the front, the feet are struck out backward and spread wide apart and as the arms are swept around, the lower limbs are stiffened and brought firmly together so as to grasp the water by the whole leg, thus imparting a forward movement to the swimmer and also finishing in a straight line behind the body. Then, when the arms are bent and the hands are being brought to their original position in front of the body, the knees and toes are turned outward, the heels are kept close together and the feet are carried up to the body to repeat the movements.

The breathing is effected in a natural and unrestrained manner. A full breath is taken at every stroke and regulated so as to avoid gasping on short heavings, by exhaling as the arms are being extended and inhaling as they are being swept around.

In swimming with the side stroke, the body may be turned upon either side and by changing from one side to the other the swimmer rests his muscles somewhat. In side swimming, the deeper immersion of the head reduces its weight and relieves, somewhat, the strain of its support from the muscles of the neck. If on the right side the right arm is thrown out in front with the palm of the hand turned downward and kept level with the under side of the head. It is then pushed out to its full extent, kept rigid and without bending either

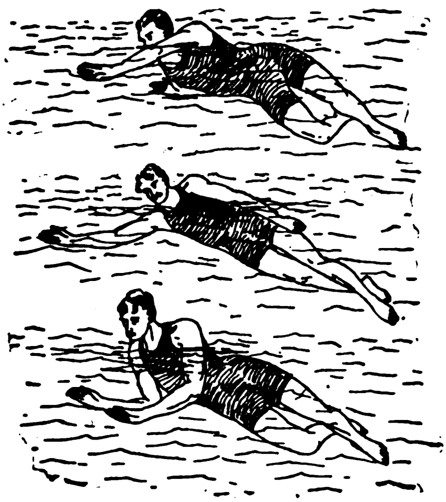

FIG. 2.— The Side Stroke.

the wrist or the elbow, is brought down through the water in a strong movement until the hand at full stretch comes between the legs. It is then brought up along the body to the chin and the stroke repeated. The left hand, formed into a scoop, is turned outward by the wrist at right angles to the forearm and the left arm, with elbow bent, is thrown outward and executes a straight pulling stroke to the left hip. The arms act alternately and when one is executing the positive, the other is at the negative part of the stroke. The action of the legs should be long and powerful and coincident with that of the arms and shoulders. When the right arm finishes its downward stroke and the left arm is extended in front, the legs are drawn up to the body. When the left arm pulls downward, the legs are opened wide, swung around and closed, in one continuous motion. Care is taken never to cross the legs, make any effort to raise or sink the head, or exert any sudden pull at any part whatever of the complete stroke.

In the overhand stroke, all the movements excepting those of the upper hand and arm, are similar to those of the side stroke. The left or upper arm is brought forward and extended as far as possible out of the water in front of the head, then dipped and pulled through with a strong propelling stroke. The method gives a more lengthened reach and when properly acquired, is the most useful and easy of all the various methods of swimming; but the side stroke is the one generally employed in long-distance racing.

One of the fastest strokes for short-distance swimming is the Trudgeon stroke, introduced into England a few years ago from the South Pacific. The action of the arms consists of alternate overhand strokes, while the legs made a frog kick simultaneously with one of the arm strokes, with the body swimming on the belly. A modification of this style was introduced a few years ago by Meffert, the American mile champion, and has been adopted by some of the best American swimmers. In it the head and the forearm are kept submerged when the body is being pushed forward and

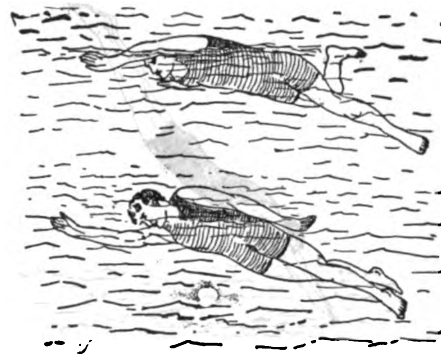

FIG. 3.—Bracing Stroke.

the face is brought out of the water to breathe, by a turning action of the waist as the forward movement checks between the strokes. This style prevents a cramped position of the head and also allows a freer action of the body. Many racing swimmers take a breath only every other stroke, keeping the face half under water half of the time.

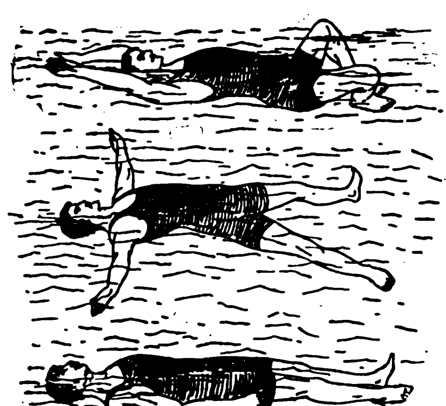

FIG. 4.—Swimming on the Back.

Swimming on the back is accomplished by lying in the water back downward, the hands resting on the waist, the elbows directed outward, the breath held and the chest expanded. To propel, the legs are bent and the feet are drawn up close to the trunk, the knees being directed outward with the heels close together. The legs are now struck out as wide apart as possible and then brought closely together until the great toes, inner ankles and the inner sides of both legs meet along their entire length. Greater speed may be obtained by extending the arms outward and on a level with the body, the palms facing downward and using them as sculls.

Diving, when well performed, is a very graceful feat. The dive may be a standing or a running one. To make a good dive, the feet line and legs are kept close together, the chest inflated and the arms are swung back and forth two or three times. The lungs are then charged

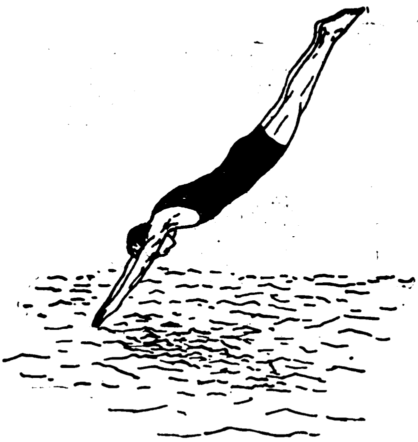

FIG. 5.—Diving.

with a long, deep breath, and the dive is made just a moment before the arms and hands are raised over the head. In springing off, all the power of the legs is used, and in mid-air the body is straightened out like an arrow from the tips of the fingers to the toes. The arms are then declined so as to enclose the head, the chest is contracted for an instant and the water is entered noiselessly and without a splash, fingers first. The moment the body is covered, the head and arms are thrown up, which brings the diver to the surface. The eyes, which instinctively close as they enter the water, should be opened under the water, in order to avoid accidents.

Floating is the position assumed by a swimmer to rest. It is accomplished by holding the forehead below and the mouth and chin above the surface of the water. The arms and legs may be stretched out as far apart as possible, as in the «spread eagle» position or the body may be held rigid and straight with the legs crossed, the lower part of the face and the toes peeping above the water and the arms either lying at the sides or above the head with the thumbs locked.

Treading water is a method employed to maintain a perpendicular position in the water, the head being kept above the surface. It is accomplished by paddling with the hands and working the legs and feet as if going up stairs, with the soles of the feet acting as sustaining surfaces. It is the only branch of the art that approaches natural conditions and if resorted to in cases of accidental immersion, would prevent 75 per cent of the deaths due to that cause.

Expert swimmers are capable of dispensing with the use of the arms, and when treading for display, or in competitions, either hold their arms and hands above the surface or fold them across the chest. They are also capable of floating with both legs or both arms out of the water; spinning like a top while maintaining a sitting position; taking off the clothes on the body; taking off the stockings, and cutting the toe nails, all of which illustrate man's command over the attending artificial conditions.

Aids to increase speed may be employed in the form of wooden plates which are attached to the palms of the hands and the soles of the feet. The most effective are those invented by R. H. Wallace Dunlop and introduced in England in 1876. Other helps, for sustaining purposes, have been employed from very early times. They were generally in the form of flat surfaces of wood, tin and water-proof fabrics, but their use is not recommended.

The Amateur Athletic Union of the United States holds championship swimming competitions in various places every year. The Hawaiian Association has a very large following and holds numerous contests. There are also intercollegiate, metropolitan and many local competitions.

A general idea of the speed and endurance of swimmers may be obtained from a few of the best performances on record: 100 yards — P. McGillivray (American amateur), 54s. (in bath); D. P. Kah'oku (American amateur), 53s. (in open water); A. Wickham (Australian professional), 1m. 4⅘s. (in open water).

One mile — D. Billington (English professional) 24m. 11⅗s. (in open water); B. Kieren (Australian amateur), 23m. 16⅘s. (in bath); G. R. Hodgson (Canadian amateur), 23m. 34½s. (in open water). Woman's record — Fannie Durack (Australian), 26m. 8s.

Long-distance swimming — Webb, 40 miles with tide, 9h. 57m. 00s.; Mercardier, 20 miles with current, 4h. 59m. 46s.; Miss Agnes Beckwith, 20 miles with current, 6h. 25m. 00s.

Long immersions — Webb, 20 miles, increased to 35 miles by tides, crossing the English Channel, 21h. 45m. 00s.

Bibliography.— The literature on swimming is quite extensive. The following-named works are among the best on the subject: Thevenot, 'The Art of Swimming' (trans. London 1699); Bermordi, O. de, 'Schwimmkunst übersetz' (Vienna 1797); Frost, J., 'The Art of Swimming' (New York 1818); Rompelman, H., 'Het nut der Zwemkunst' (Amsterdam 1830); Fontenelle, Julia de, 'Manuel des Nageurs' (Paris 1838); Forrest, George, 'Handbook of Swimming and Skating' (London 1865); Leahy, John, 'The Art of Swimming in the Eton Style' (London 1875); 'Spaulding's Athletic Library,' Nos. 20–30 (New York 1894–95); Dalton, Capt. Davis, 'How to Swim' (New York 1899); *American Physical Review* (Vol. IV, Cambridge, Mass., 1899). Consult also Austin, H. R., 'How to Swim' (London 1914); Brewster, E. T., 'Swimming' (Boston 1910); Dalton, F. E., 'Swimming Scientifically Taught' (New York 1912).

SWIMMING BLADDER, AIR-BLADDER, or SOUND, an internal sac-like organ in fishes by which they regulate their relative buoyancy. See FISH.

SWINBURNE, Algernon Charles, English poet: b. London, 5 April 1837; d. 10 April 1909. He was the son of Admiral Charles Henry Swinburne, of an old Northumbrian family, and Jane Henrietta, a daughter of the 3d Earl of Ashburnham, a woman of high culture who exercised a marked influence on the intellectual development of the poet during his earliest years. From Eton he went to Balliol College, Oxford, where his time was chiefly given to the study of Greek poetry and in less degree of the literatures of France and Italy. He wrote, also, for the *Undergraduate Papers*, a student publication, and seems to have produced a considerable body of verse which, however, he later characterized as worthless. He left Oxford in 1860 without taking a degree and traveled for a short time on the Continent, visiting Walter Savage Landor in Florence, for whom he entertained a great admiration. The year of his leaving Oxford was marked by the publication of 'The Queen Mother' and 'Rosamond,' which, written in the Elizabethan manner, revealed little metric talent and aroused practically no attention. In 1862 Swinburne settled in London, in the house of Dante Rossetti. In 1865 appeared his first and, according to many, his masterpiece, 'Atalanta in Calydon,' which was hailed as giving promise of a poetic genius of the highest rank. In the 'Atalanta' Swinburne displayed for the first time that magical mastery of metrical form in which, in all English literature, he is equaled by Shelley and Milton alone, if by them. In the celebrated choruses of the poem the English language is molded to an exquisiteness of lyric melody which might almost have been deemed impossible in a vernacular dominated by the stiff *imperium* of the Iambic verse. 'Chastelard,' a play dealing with an incident in the life of Mary Stuart, appeared shortly after 'Atalanta,' but was received with marked disappointment. The next year, however, came the 'Poems and Ballads,' which made Swinburne at once a figure of national and international note and the centre of a hurricane of criticism aroused by what might be called the ethical tone of the volume. The 'Poems and Ballads' showed the art of the author of 'Atalanta' at its best, but they sang of themes abhorred by middle class Anglo-Saxon morality, in a manner undeniably thorough. The animal side of sexual passion was therein depicted with a fervidness of tone and a wealth of fleshly imagery which subjected the poet to the most virulent denunciation as a glorifier of pre-Christian morality. As a matter of fact the 'Poems and Ballads' were chiefly intended as a protest against English Philistinism and do not in any way represent the ethical standards of the poet, whose mind on the contrary turns most often to the contemplation of love idealized, however much material beauty may inspire him. The taint of Anacreontism has nevertheless lingered in Swinburne's reputation and is possibly the most salient characteristic of his work to the casual reader. 'A Song of Italy' which appeared in 1867 definitely marks Swinburne's entrance into the field of political lyricism. He sang liberty with the same passionate utterance, though not with the same poetic success, with which he had sung of earthly love, and the theme is continued in his 'Ode on the Proclamation of the French Republic,' 'Songs before Sunrise' (1871) and 'Songs of Two Nations.' About this time he fell under the influence of Victor Hugo, whom he regarded with a feeling amounting almost to adoration, and indeed, in the various phases of his development, the want of measured restraint is striking. 'Bothwell' (1874) is the second part of a trilogy dealing with the fortunes of the unhappy Scottish queen, of which the first part is the 'Chastelard,' already mentioned, and the last, 'Mary Stuart,' published in 1881. In 1876 came 'Erechtheus,' a tragedy formed after Greek models and revealing, as 'Atalanta' had done, his marvelously sympathetic insight into the ancient Hellenic spirit. A second series of 'Poems and Ballads' appeared in 1878 and 'Songs of the Springtides' in 1880. 'Tristram of Lyonesse' (1882) contains some of Swinburne's happiest harmonic effects; the heroic couplet is there freed from its almost mathematical rigidity and precision and made to assume a vague softness of cadence that brings it near to the more flexible forms of lyric verse. Swinburne's work after 1882 shows no artistic progress as a whole. In all the perfect manner is apparent and the poet's resources never fail — and in some there are passages and sketches of an exquisite beauty equaling his best work; but beyond the height which he had earlier attained, he does not go. These works are 'A Century of Roundels' (1883); 'Marino Faliero,' a tragedy (1885); 'Locrine,' a tragedy (1887); 'Poems and Ballads,' 3d series (1889); 'The Sisters' (1892); 'Astrophel' (1894); 'The Tale of Balen' (1896), and 'Rosamond, Queen of the Lombards' (1899); of these Balen perhaps ranks nearest to the great works of his earlier period.

Swinburne also wrote much prose, in the field of criticism, possessing many of the characteristics of his verse, vehemence, imagery and lack of self-restraint. Although he possessed the gift of the illuminative phrase and displays at times a profound insight, his critcism as a rule shows no refinement of judgment. It was his avowed conception of the mission of criticism not to weigh narrowly and to examine minutely, but generously to praise. But though Swinburne was so far untrue to his position in that he sometimes hated as well as loved, he hated and loved with unrestrained passion. He wrote eulogies on 'Charlotte Bronte' (1877), 'Shakespeare' (1880); 'Victor Hugo' (1886), and 'Ben Jonson' (1889). To Robert Buchanan's assault on the 'Fleshly School of Poetry,' including Swinburne, Rossetti and Morris, the first replied in his scathing 'Under the Microscope.' Among his other works of criticism are 'Essays and Studies' (1875); 'Miscellanies' (1886), and 'Studies in Prose and Poetry' (1894). Mention should also be made of 'The Modern Heptalogia,' a volume of parodies on contemporary poets, which appeared anonymously in 1881 and has not been, as yet, officially acknowledged as a work of Swinburne. His it was, however, by common consent and that in spite of the fact that among the most amusing burlesques is the one on himself. Swinburne's position in English literature is to be assigned him on his merits as a master of verse form and poetic rhetoric. With no especial profundity of thought, with no definite theory of life, with no deep insight into human character, he stood pre-eminent as a molder of exquisite melodies. It is his manner that should give him a permanently high rank among English poets. (See ATALANTA IN CALYDON). Consult Wrateslaw, Theodore, 'Algernon Charles Swinburne, a Study' (London 1900); Shepherd, R. H., 'The Bibliography of Swinburne' (ib. 1887); Mackail, J. W., 'Swinburne' (Oxford 1909); Thomas, Edward, 'Swinburne' (New York 1912); Drinkwater, John, 'Swinburne: An Estimate' (ib. 1913); Woodberry, G. E., 'Swinburne' (ib. 1905).

SWINDON, England, in Wiltshire, 29 miles northeast of Bath and 76 miles west of London, consists of two parts — old and new Swindon. The older section on a hill is picturesque and its principal buildings comprise the parish church, town-hall, assembly rooms and corn exchange. The new town on reclaimed lowland contains a mechanics' institute, theatre, etc., the railroad shops of the Great Western Railway employing several thousand men and an extensive park connected with these works. The town is an important railway junction. Pop. 50,751.

SWINE. General Information.— Swine are of immense importance in the commerce of the world. In the United States alone there are some 65,000,000 of swine on the farms and in the hamlets. This figures some two-thirds of a hog for every human being in this nation.

Swine products are many and various,— fats, particularly lard, is one of the chief productions. A real fat hog produced on corn in the pastures of the corn belt may yield as much as 50 pounds of fat in every hundred pounds of his live weight; hams which are eaten fresh, boiled, fried, cured with hickory and other smokes, are relished the world over; bacon, the toothsome breakfast dish of Anglo-Saxons, has no substitute; sausages; spare ribs; pepsin extracted from pigs' stomachs for the medicinal doctoring of human stomachs; the bristly coat is used for brushes and as filler for cushions; the bones are ground for fertilizer; the hide is made into leather; in truth every ounce is utilized, nothing goes to waste.

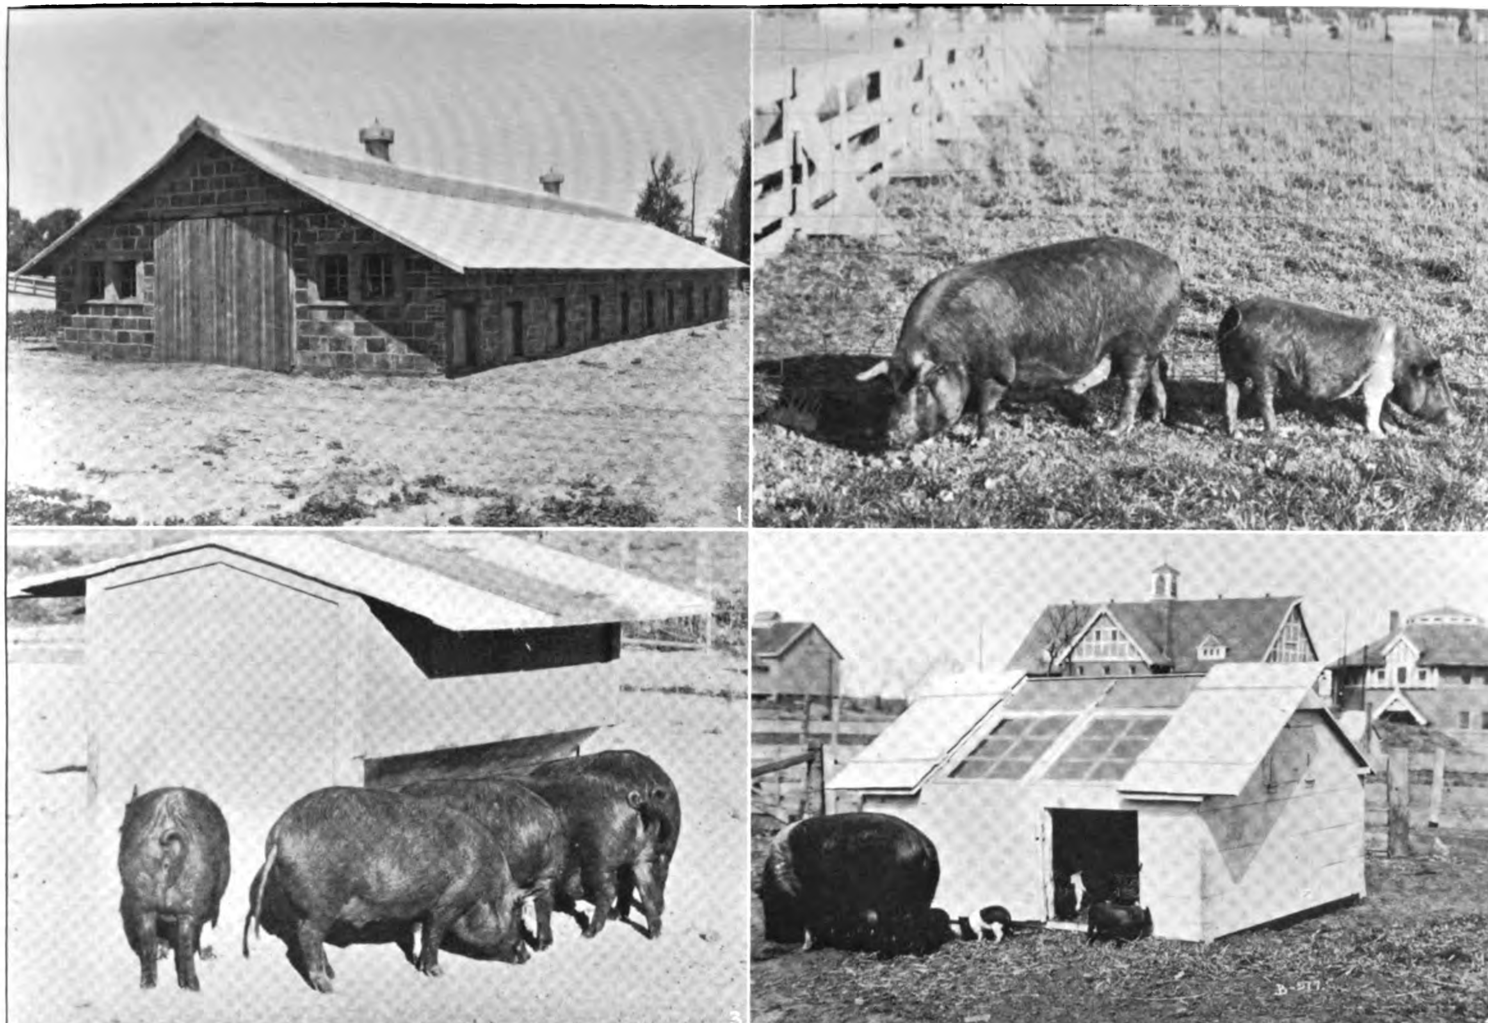
The source of the hog is shrouded in considerable mystery, although the true swine, the wild boar and his kind (*Sus scrofa*), probably developed in the Asiatic continent. Fossil remains have been found in Europe and India although not on the North American continent. The Peccaries found in Mexico and other southern countries are not to be confused with the true domesticated hog that is of such great commercial value. The Peccary is of American origin. The historic swine, therefore, that gave rise to the present day common hog may be basically considered as the wild boar (*Sus scrofa*) with which was infused in the early days the swine of China, Japan and eastern Asia (*Sus Indicus*). An eminent Chinese scholar estimates that swine were domesticated in eastern Asia about 2900 B.C., whereas the European records indicate a period of domestication about 1500 B.C. To these early efforts of the human race we owe much for the improvement and development of the now-a-day swine.

The flesh of swine has been used by all peoples apparently who came in contact with them. The Greeks and the Romans were adepts of the fine art of preparing and serving pork.

Pork is of particular advantage to civilized peoples in that it can be preserved by salting, smoking and other forms of cures so that it may be kept in edible condition for many years. Hams rightly cured appeal more and more to the epicure as the years unfold, so that hams five and six years from the "killing" are particularly appetizing. In the ordinary consumption of pork, however, hams seldom reach their first birthday before being eaten. Salt pork and smoked meats from the pig are shipped all over the world and many a nation owes considerable of its prosperity to its pork commerce.

Types and Breeds.— The domestic hog is entirely different from his wild progenitors. And yet domestic swine are widely different even among themselves as regards their general body conformation. Swine have been produced to meet the demands of the market as well as to fit into certain environments so as to utilize the home-grown feeds to the greatest advantage. We have, therefore, two great predominating types developed to their highest efficiency in Europe and particularly America,— these being the so-called bacon and lard types. Naturally the bacon hog is fine for bacon and lean meat in general, while the lard hog is best for fat (lard) and fatty sausage. The bacon hog flourishes in those sections where there is an abundance of small grains such as barley, oats, wheat and plenty of milk, whereas the lard hog is primarily of American origin, developing simultaneously with Indian corn or maize, a feed most excellently adapted to the production of fat, being highly concentrated and composed of these materials, namely the starches and fats, that are converted through the pig's metabolism into the lard and corn belt pork sausages. Denmark, England and Canada are all good bacon type regions,— Denmark principally because of her milk by-products and England because of her excellent pastures and cereals and Canada because of her cereal grains and milk products.

Contrast the original wild hog with the every-day American lard hog. The wild hog is narrow, more like one's hand viewed edgewise, but the lard hog is wide, certainly chubby in contrast; the former is relatively small in comparison. In short, the lard hog is not only wider and larger, but longer, better "hammed," shorter nosed, shorter "legged," more compact in body, shorter tusked and not nearly so ferocious and speedy of foot. Too, the lard hog has a better quality of meat and a much higher proportion of those most highly prized cuts of meat in proportion to the total weight, this being marked in the development of hams and loins, taken from the rear parts. Persistent selection of these animals for breeding purposes that most nearly approached the desired type has made it possible in the long years of endeavor to develop such a contrast in type. The development of this lard type is all the more remarkable in that the very characteristics which make up this type are supposedly inimical to the best health and bodily interests of the hog. Too much fat decreases vigor and vitality, and we are not surprised to find that the bacon types are much more active and virile, because they are not unduly fattened, in truth the general selection in this bacon pro-

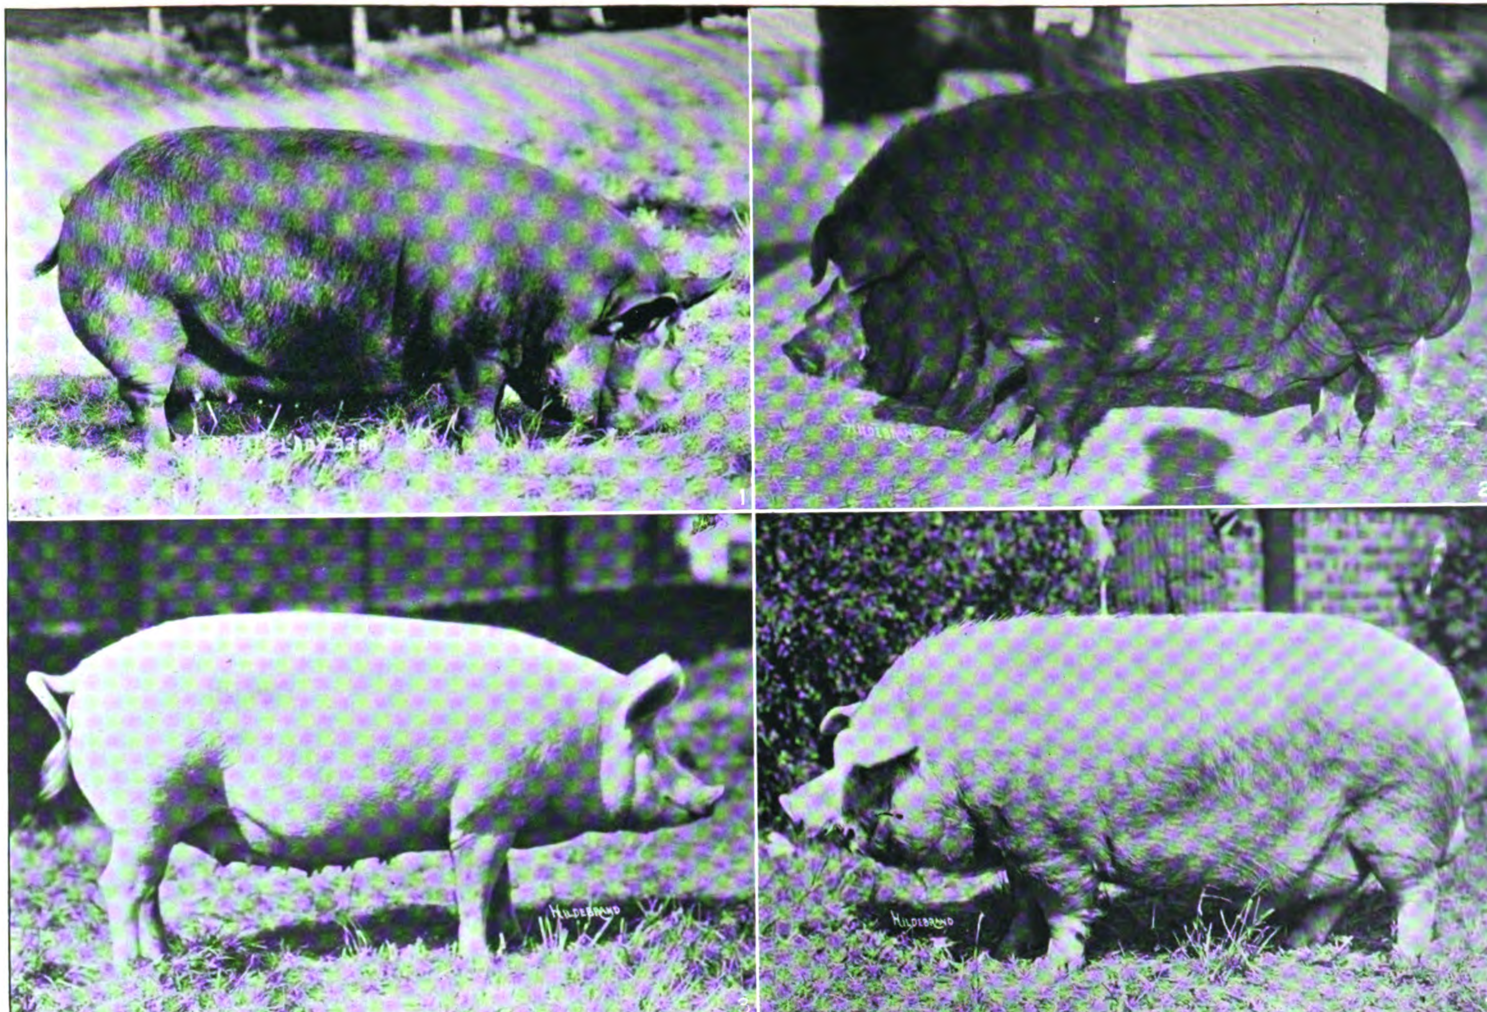


1 The Iowa Community Sunlit Hog House. Here is a new kind of hog house — one substantially but economically built for swine. It is a sanitary, economical and serviceable house of pleasing appearance

3 The Self-feeder method of feeding grains is efficient

2 The system of feeding is responsible for the difference in size — the large shote had all the corn he wanted on alfalfa pasture, and the little one only one-fourth of a full ration. It pays to feed swine liberally

4 The Iowa Movable Sunlit Hog House, well lighted, sanitary, convenient, economical, serviceable and durable



1 A Lard type — the Chester White — a white breed
3 A Bacon type — Yorkshire Gilt — a pure white breed

2 A Lard type — Poland China Boar. Note black color and white markings
4 The General Purpose type, both for bacon and for lard as shown in Berkshire breed by a sow

ducing business has been to develop muscular tissue, the chief emphasis being placed on its proper distribution with some, not too much fat, to make the most acceptable slab of bacon and the nicest "trimmest" hams, hams that do not require "too much trimming away of the fat."

The typical bacon breeds are Tamworths and Yorkshires. The Berkshires may be so classed because they yield the highest quality of bacon, but the Berkshire is sometimes placed in the general purpose class, good for bacon and good for lard. Then there is the Large Black of England.

The typical lard type breeds are Poland China, Chester White, Duroc Jersey, Victoria, Cheshire, Essex and Suffolk.

The general purpose breeds may be classed as the Berkshire, Hampshire, Mule-Foot and possibly the Middle White.

The score card method of teaching judging is in vogue in all of our leading agricultural colleges. A hundred points make up the total or the ideal, and the relative emphasis to place on the different parts is indicated by the number of points as given for perfect. Below are given representative score card values as used by the Iowa State College at Ames, covering the bacon and lard types in the barrows. The relative descriptions show where the emphasis is placed in each type.

BACON HOGS.

SCALE OF POINTS — FOR BARROW	Perfect score
General appearance:	
1. Weight, 170 to 200 pounds, the result of thick cover of firm flesh	6
2. Form, long, level, smooth, deep	10
3. Quality, hair fine; skin thin; bone fine; firm covering of flesh without any soft bunches of fat or wrinkles	10
4. Condition, deep, uniform covering of flesh, especially in region of valuable cuts	10
Head and neck:	
5. Snout fine	1
6. Eyes full, mild, bright	1
7. Face slim	1
8. Ears, trim, medium size	1
9. Jowl, light, trim	1
10. Neck, medium length, light	1
Forequarters:	
11. Shoulders, free from roughness, smooth, compact and same width as back and hindquarters	6
12. Breast, moderately wide, full	2
13. Legs, straight, short, strong, bone clean, pasterns upright; feet medium size	2
Body:	
14. Chest, deep, full girth	4
15. Back, medium and uniform in width	8
16. Sides, long, smooth, level from beginning of shoulders to end of hindquarters. The side at all points should touch a straight edge running from fore to hindquarter	10
17. Ribs, deep, uniformly sprung	2
18. Belly, trim, firm, thick without any flabbiness or shrinkage at flank	10
Hindquarters:	
19. Hips, smooth, wide; proportionate to rest of body	2
20. Rump, long, even, straight, rounded toward tail	2
21. Gammon, firm, rounded, tapering, fleshed deep and low toward hocks	8
22. Legs, straight, short, strong; feet medium size; bone clean; pasterns upright	2
Total	100

LARD OR FAT HOGS.

SCALE OF POINTS — FOR BARROW	Perfect score
General appearance:	
1. Weight, score according to size	6
2 Form, deep, broad, low, long, symmetrical, compact, standing squarely on legs	10
3. Quality, hair silky; skin fine; bone fine; mellow covering of flesh free from lumps and wrinkles	10
4. Condition, deep, even covering of flesh and fat over all parts of the body	10
Head and neck:	
5. Snout, medium length, not coarse	1
6. Eyes, full, mild, bright	1
7. Face, short, cheeks full	1
8. Ears, fine, medium size, soft	1
9. Jowl, strong, neat, broad	1
10. Neck, thick, medium length	1
Forequarters:	
11. Shoulder, broad, deep, full, compact on top	6
12. Legs, straight, short, strong; bone clean; pasterns upright; feet medium size	2
Body:	
13. Chest, deep, broad, large girth	4
14. Sides, deep, lengthy, full; ribs close and well sprung	6
15. Back, broad, straight, thickly and evenly fleshed	10
16. Loin, wide, thick, straight	8
17. Belly, straight, even	4
Hindquarters:	
18. Hips, wide apart, smooth	2
19. Rump, long, wide, evenly fleshed, straight	2
20. Ham, heavily fleshed, plump, full, deep, wide	10
21. Thighs, fleshed close to hocks	2
22. Legs, straight, short, strong; bone clean; pasterns upright; feet medium size	2
Total	100

There are a great many swine terms that need defining. A few of the important ones used in swine husbandry are given:

Swine: General name for any or all of the domesticated, omnivorous, suoid mammals supposedly descended from the *Sus scrofa* or *indicus*, or infusion of the two, more specifically known as Duroc Jerseys, Poland Chinas, Chester Whites, Berkshires, Hampshires, Tamworths, Yorkshires and other established breeds with their various cross-bred and mongrel breedings. Untamed wild animals are referred to preferably as "Wild swine."

Hog: May be used synonymously with the term "Swine" but refers preferably to marketable animals.

Gilt: Young, immature, prospective swine mother.

Sow: Female swine after producing young.

Boar: Well-developed male swine suitable for breeding service.

Boar Pig: Young male swine under breeding age, usually under six months old.

Stag: Swine castrated ("desexed") after the noticeable development of the secondary sexual characters such as tusks, shields, enlarged sheath, crest and others. Stags are docked 70 pounds on the large markets.

Barrow: Swine castrated before the sexual characters develop to a noticeable extent.

Pig: May be used synonymously with swine but preferably in America refers to those under three months of age. In England, Canada and Australia, pigs are swine of any age or weight.

Shote: Immature swine of either sex, except boar pigs, usually weighing from 60 to 175 pounds.

Weanling Pigs: Young pigs after weaning time.

Suckling Pigs: Young pigs following their mother and yet unweaned.

Pork: The dressed meat of swine used for food.

Management and Handling.— In the housing due attention must be paid to these essentials: Warmth, they do not thrive in real cold and freezing quarters; dryness, if kept in damp quarters contract various ills such as rheumatism and stiffness; abundance of diffused light; much direct sunlight, appropriately so for the new-born offspring to give them strength and stamina; shade, especially in the very hot months; ventilation, to insure fresh pure air; sanitation, to prevent diseases; safety; comfort; convenience, this being true not only for the swine but for the caretaker. Swine should not be compelled to unnecessarily exert themselves, unless it be at certain time when particular advantages are to be gained thereby for the herdsman; serviceability; sufficient size to shelter advantageously; durability; reasonably low first cost; minimum cost of maintenance; and pleasing appearance so as to harmonize with the general surroundings adding by all means to the artistic and architectural beauty of the community.

In the feeding, the ration must be well balanced else the swine will not thrive. Corn alone in dry lot, even though plenty of water be supplied, together with salt, is deficient, in that it does not supply all of the nutritional factors necessary for the growth and well being of the pig. To illustrate, well-nourished swine eight months of age can be made to weigh 300 pounds, but they must have a balanced ration to do this,— such as corn, maize and milk (skim, butter or whole); or corn and alfalfa or clover or rape pasture together with a little meat meal; or corn and meat meal, both being fed in separate open containers, same being kept filled with feed and before the swine at all times. «Corn-alone fed» pigs at eight months old fed by the Iowa Experiment Station weighed 57 pounds, and yet the first three months of this feeding time the pigs had a good ration. Similar pigs fed on corn and meat meal from the packing houses weighed 225 pounds. The corn pigs required 1,447 pounds of corn for 100 pounds of gain, but the ones receiving meat meal in addition needed only 366 pounds of corn plus 48 pounds of meat meal, a total of only 414 pounds of concentrated feed. Less than a third as much feed was required where the properly balanced ration was fed. It is wise and proper to vary the ration, giving equitable feeds in the right proportions and thereby giving the pig a chance to develop properly. Both the art and the practice of swine feeding are learned only by much experience mellowed with keen insight into the psychology and the nutrition of interesting but oftentimes perplexing animals.

The costs of production that enter into the making of marketable hogs centre around these import items: Feed, such as the grains; pasture; equipment covering houses, troughs, fences and other details; man labor; horse labor; interest on the capital invested, and general miscellaneous or overhead expense. To give a comprehensive idea as to the distribution of these costs in the heart of the swine-fattening and producing region, namely the corn belt, there is presented herewith the distribution of the total cost, or 100 per cent among the mentioned items:

	Per cent
Feed grains grown and purchased	84
Pasture to supplement grains, also lot rent	4
Man labor	4
Interest on the investment or capital	4
Horse labor	1
Equipment upkeep	1
Overhead expense	2
Grand total expense	100

The Swine Commission of the United States Food Administration in the year 1917 found that it took the equivalent value of 12 bushels good number two corn grain to produce for market the average hundred pounds of marketable hog, delivered to the Chicago, the basic and general controlling hog market of all the world. This counts the costs of all items entering into the keep of the herd. Definitely, therefore, this means that if number two corn grain is worth a dollar a bushel at Chicago that the farmer who ships to that market will not on the average make any money unless he gets over $12 a hundred pounds for the live hogs. The good farmer will of course produce them more cheaply, but when the costs can be put down to the 11-bushel basis that is very good indeed. Of course the man who feeds garbage, the kitchen waste from the cities and towns, can produce hogs more cheaply than the man who feeds high-priced grains. It takes from six to nine pounds of garbage to produce as much pork as a pound of mixed balanced grains.

The best forage crops and pastures for swine are alfalfa, red clover, dwarf essex rape, blue grass, rye, wheat, soy beans, cow peas, and sweet clover. All of the clovers are especially good.

The best grains are Indian corn, barley, rye, wheat, sorghum seed, kaffir corn, milo maize, oats, peanuts, soy beans, cow peas, and other of similar nature.

The best balancers of the ordinary grains are the milks, meat meal, packing house tankage, linseed oil meal, wheat middlings, corn oil cake meal, blood meal, peanut meal, velvet bean meal, gluten feed, together with the green, preferably leguminous and tender pastures.

To secure the greatest success in the feeding and management and marketing of swine, one must look to these essentials:

First.— Locate the business where the conditions are favorable to pork production, this usually being where there is an abundance of cheap grains and other feeds suitable for swine, and where the markets are relatively good and easily accessible. Go to those sections where hogs are making their owners money.

Second.— Select good, sound, healthy, prolific foundation stock of the right market as well as the right farm type.

Third.— Have an ideal and work toward it in your feeding and breeding operations.

Fourth.— Feed a properly balanced ration, one that will supply the essential nutrients at the right time.

Fifth.— House the animals in sanitary, well-lighted, comfortable convenient quarters.

Sixth.— Keep the animals healthy by sensible methods, use preventive measures to avoid cholera, the scourge of swine husbandry, this being done by immunization, using the anti-hog cholera serum perfected by the government, and purchaseable most everywhere.

Seventh.— Be a good manager, keeping everything and everybody "lined" up so that the whole scheme harmoniously work to a common ideal of doing the right thing, in the right way, at the right time. There are many corners to watch, as in all good businesses, hence the vigilant watchful spirit is to be assiduously cultivated.

Eighth.— To be most successful in the swine business one must like it, put his heart into it, yes, and live with it.

JOHN M. EVARD,
Professor of Animal Husbandry, Iowa State College.

SWING, David, American Presbyterian clergyman: b. Cincinnati, Ohio, 23 Aug. 1830; d. Chicago, Ill., 3 Oct. 1894. He was graduated from Miami University, Oxford, Ohio, in 1852 and was for a while principal of the classical school of that institution. He afterward studied theology and in 1866 became pastor of the Fourth Presbyterian Church in Chicago. In 1874 he was tried for heresy but was acquitted by the presbytery. He, however, withdrew from the denomination and becoming an independent minister was pastor of the Central Church in Chicago for the rest of his career. He was a pulpit orator of much power and during his long pastorate of the Central Church constantly attracted large congregations. He was an editor of *The Alliance* and published 'Club Essays' (1880); 'Truths for To-day'; 'Motives of Life' and other works. Consult Newton, J. F., 'David Swing, Poet-Preacher' (Chicago 1909; reprint, New York 1914).

SWINGLE, Walter Tennyson, American botanist and agriculturist: b. Canaan, Pa., 8 Jan. 1871. He was graduated at the Kansas State Agricultural College in 1890. He was appointed special agent of the division of vegetable physiology and pathology of the United States Department of Agriculture in 1891. He studied in Europe in 1895–96 and again in 1898; was appointed agricultural explorer of the Department of Agriculture in 1898 and since 1902 has been in charge of crop physiology and plant breeding investigations for the department. He has visited the countries of southern Europe, Asia Minor, China, Japan and the Philippines in the course of his investigations. He introduced the fig insect into California, which permitted the raising of Smyrna figs there, and had charge of the introduction of date, pistachio nut, Egyptian cotton and other useful crops into America. Author of numerous papers and reports.

SWINOMISH. See SALISHAN INDIANS.

SWINTON, John, American journalist and author; brother of W. Swinton (q.v.): b. Salton, Scotland, 12 Dec. 1830; d. Brooklyn, N. Y., 15 Dec. 1901. He came to the United States in 1845, was educated at Williston Seminary, Mass., and entered the New York Medical College, but did not graduate. In 1860–70 he was chief of the editorial staff of the New York *Times,* in 1869–74 was on the staff of the *Tribune;* and chief of the staff of the New York *Sun* until 1883. He then started *John Swinton's Paper,* a weekly labor and reform journal, which he continued to edit until 1887; later was again on the editorial staff of the *Sun.* His active work in the labor movement began in 1874, when he was a workingmen's candidate for mayor of New York, but polled only a few hundred votes; after that time he was prominent as a writer, speaker and organizer in trade union and reform movements. He published 'The New Issue, the Chinese-American Question' (1870); 'A Eulogy on Henry J. Raymond' (1870); 'John Swinton's Travels' (1880); 'An Oration on John Brown' (1881); and 'Striking for Life' (1894); a defense of the American Railway Union and the Pullman strike.

SWINTON, William, American educator: b. Salton, Scotland, 23 April 1833; d. New York, 25 Oct. 1892. He came to Canada in 1843, where he studied at Toronto and then to the United States, where he continued his studies at Amherst College. He subsequently taught at Greensboro, N. C., and in New York and during the Civil War was war correspondent of the New York *Times.* From 1869 to 1872 he was professor of English language and literature in the University of California. His writings include 'Rambles Among Words'; 'Twelve Decisive Battles of the War'; 'Campaigns of the Army of the Potomac'; 'Word Analysis'; 'Studies in English literature,' and 'Outlines of the World's History.'

SWISS FAMILY ROBINSON, The, a famous romance by J. R. Wyss, which was begun by his father and published as 'Der Sweizerische Robinson.' It was translated into French and afterward into English. It is an entertaining tale written for young people, after the style of 'Robinson Crusoe,' from which the author is supposed to have derived many of his ideas, and has been cleverly parodied by Owen Wister in 'The New Swiss Family Robinson' (1882.)

SWISS GUARDS. Swiss companies served in France from the time of Louis XI, who paid particular attention to cultivate the friendship of the cantons. In 1571 Charles IX created the charge of Colonel-General of the Swiss for Montmorency, who commanded all the Swiss in the kingdom, except the 100 guards of the king. The institution of the Swiss guards as a complete regiment dates from 1616. In 1714 it was composed of 12 companies, some of which had two captains. Louis XIV gave it five officers to each company. All the officers and men were Swiss, and the companies mounted guard before the king according to the rank of the cantons to which their captains belonged. The Swiss guards followed in order of precedence after the French guards. They enjoyed liberty of worship. According to the arrangement with the Cantons, the Swiss guards could not be obliged to serve against Germany beyond the Rhine, against Italy beyond the Alps, or against Spain beyond the

Pyrenees. This convention was often broken. The attachment of the Swiss guards to the king made them obnoxious to the people during the Revolution. They were repeatedly banished and recalled, and on and after 10 Aug. 1792, when they had to defend the Louvre against the mob, they were massacred without mercy. The Lion of Lucerne was designed by Thorwaldsen in memory of their heroism. At the Restoration, a Swiss Guard was formed to guard the person of the worthless Bourbon, but it was dispersed by the Revolution of 1830. The Vatican Palace, Rome, the residence of the popes, is guarded by a company of Swiss, who are termed the Swiss Guard. Consult Stephens, H. M., ‹History of the French Revolution› (2 vols., New York 1891) and Ternaux, ‹Histoire de la Terreur› (8 vols., Paris 1863–81).

SWISS LAKE DWELLINGS. See LAKE DWELLINGS.

SWISSHELM, Jane Grey, American reformer and author: b. Pittsburgh, Pa., 6 Sept. 1815; d. Swissdale, Pa., 22 July 1884. She was among the earliest advocates of woman's rights; an ardent opponent of slavery, and while editing the Saint Cloud (Minn.) *Visitor* had her office and press destroyed by a mob for advocating abolitionism. She was among the first to become a nurse in the Union army. Besides voluminous contributions to current periodicals, she published ‹Letters to Country Girls› (1853), and an autobiography ‹Half of a Century› (1881).

SWITCH GRASS. See GRASSES IN THE UNITED STATES.

SWITCHBACK, an inclined railway in which the progress of the train or car on the descending route is effected partly or wholly by gravity, the car first running down a steep incline and by its momentum surmounting a lesser incline, alternate ascents and descents continuing to the end of the course. Switchback railways are constructed also by curving a track alternately backward and forward along the side of a hill thus obtaining practicable grades for descent. The switchback method is popularized in the circular switchback railways, a common feature at pleasure resorts. The Mauch Chunk «Switchback» in Pennsylvania is one of the best known of these «gravity railroads.» It was formally used to carry the coal from the anthracite mines to the valley; the coal is now transported through a tunnel, and the «switchback» is reserved for the amusement of visitors. See RAILWAYS, ELEVATED.

SWITCHBOARD. See ELECTRICAL TERMS.

SWITCHMEN'S UNION OF NORTH AMERICA. See RAILWAY LABOR ORGANIZATIONS, *Lesser Organizations.*

SWITHIN, or SWITHUN, Saint, bishop of Winchester (about 852–862). He was tutor to King Egbert's son Ethelwulf, a zealous builder of churches, and of conspicuous devotion. He is credited with many miracles and when he died asked to be buried where «passers-by might tread on his grave and where the rain from the eaves might fall upon it.» When a century later his body was to be exhumed for the purpose of being deposited in the Cathedral, on the day appointed for the translation (15 July) it rained and for many days after so as to delay the ceremony. Hence, it was believed, originated the popular saying that if it rain on Saint Swithin's day it will be wet weather 40 days after it.

SWITZERLAND, Fr. La Suisse; It. La Svizzera; Ger. Die Schweiz; Lat. Helvetia: An ancient federal republic of Central Europe, extending between 45° 49′ 2″ and 47° 48′ 32″ N. latitude and 5° 57′ 26″ and 10° 29′ 40″ E. longitude. The superficial area is approximately 15,983 square miles; greatest length, 226 miles; greatest breadth, 136 miles. The country is a confederation of 19 entire and six half cantons, the whole divided into 187 administrative districts. It is bounded on the north by Baden, with the Rhine as frontier; northeast of Bavaria and Württemberg, separated from them by the Lake of Constance; east by Lichtenstein and the Tyrol, with the Rhine and the Grison Alps intervening; south by Italy, where the Alps and the Lake of Geneva form natural boundaries; and west and northwest by France, where the Jura Mountains and the River Doubs form the line of demarcation. The following table shows the cantons, their areas and population, and the areas in which they joined the confederation:

CANTONS	Area in sq. miles	Population
Zürich (1351)	666	534,250
Berne (1353)	2,659	660,640
Lucerne (1332)	579	172,500
Uri (1291)	451	22,730
Schwyz (1291)	351	59,210
Obwalden (1291)	183	17,650
Nidwalden (1291)	104	13,980
Glarus (1352)	266	33,570
Zug (1352)	92	28,940
Fribourg (1481)	644	142,690
Solothurn (1481)	305	121,240
Basel-Stadt (1501)	13	142,870
Basel-Land (1501)	163	78,550
Schaffhausen (1501)	113	47,270
Appenzell Ausser-Rhoden (1513)	93	58,670
Appenzell Inner-Rhoden (1513)	68	14,860
Saint Gall (1803)	779	315,160
Grisons (1803)	2,754	119,860
Aargau (1803)	542	236,860
Thurgau (1803)	381	140,540
Ticino (1803)	1,088	160,680
Vaud (1803)	1,244	327,870
Valais (1815)	2,026	130,750
Neuchâtel (1815)	312	134,910
Geneva (1815)	107	160,960
Total	15,983	3,877,210

Nearly all the cantons have alternative names in French and German. Thus, Lucerne is Luzern in German, while Obwalden and Nidwalden are known in French as Unterwalden-le-Haut and Unterwalden-le-Bas respectively. Zug has a French equivalent in Zoug; Solothurn in Soleure; Grisons in Graubünden in German; Neuchâtel is Neuenburg; Ticino, Tessin; Vaud and Valais are Waadt and Wallis, and Geneva, Genève or Genf.

Topography.— Embracing the highest and most mountainous land on the Continent, Switzerland has aptly been styled the fortress of Europe. Its frontiers are mainly natural ones, composed of mountains, rivers and lakes. Those great mountain ranges and the large number of easily-blocked tunnels by which alone it is possible for troops to cross them may be said to make the country absolutely impregnable in the hands of a determined garrison. During the European War, Switzerland stood as a solid rock in the midst of a turbulent sea, with four nations at war on all the four sides of it. That "fortress" was the strategic key to the mid-European battle-ground; its possession would have had an enormous military value for any one of the belligerent nations. Besides the lofty ranges there are gigantic glaciers, magnificent lakes and wild, romantic valleys. Though Switzerland contains the highest ranges of the Alps and the greater portion of the Jura chain, the highest peaks of both systems belong to France. Physically the country falls into four natural divisions, the High Alps, the Outer Alps (Voralpen), the Jura, and the intervening plain which makes up the rest of the territory. The High Alps, generally called "the Alps," contain the loftiest mountain-chains, lying chiefly in the south and east. They divide the warm south from the colder north and present an imposing spectacle of towering masses of granite, mica and gneiss capped with eternal snow. An apparent labyrinth of mountains possesses a remarkable nucleus or central junction in Mount Saint Gothard (10,500 feet), which forms a kind of starting-point radiating four mountain-chains to the north, south, east and west. In like manner it unites the principal watersheds of Europe and sends its waters into four large basins — north by the Rhine to the North Sea, southwest by the Rhone to the Mediterranean, southeast by the Po to the Adriatic, and east by the Danube to the Black Sea. The other great range, the Jura (q.v.), is linked to the Alps by the small range of the Jorat. The longest and most important valleys follow the same direction as the main ranges. They are formed by the upper courses of the Rhone and the Rhine in Switzerland, besides those of the Inn and Salza, Enns and Mur, Drave and Save, farther east. The upper Rhone traces its course through the valley bounded north and south by the principal chains of the Alps, the Bernese Alps in the north, and the Pennine and Lepontine ranges in the south. The transverse valleys are shorter and more abrupt; they lie athwart the main line of the ranges and are distinguished by a regular succession of narrow gorges and level mountain glades. The largest are formed by the river Reuss in Switzerland, the Adige (Etsch) in the Tyrol, the Rhine between Coire (Chur) and Lake Constance, and the Rhone between Martigny and the Lake of Geneva. The glaciers (of which there are over 1,000) slide down in solid masses of snow and ice from the upper regions; some continue their courses for 20 or 30 miles, forcing their way through the deep channels of the huge ravines by which the mountain sides are furrowed. The Alpine passes depend on the configuration of the valley systems. Several of those passes are partially the result of human labor. Some of them communicate between valleys confined to the north or Swiss side of the Alps, and of these the most celebrated are the Grimsel and Furka passes at the head of the Rhone valley, connecting it respectively with the Haslithal or upper part of the Bernese Oberland, and the Urserenthal, or head of the valley of the Reuss, and the Gemmi or Daube Pass (7,265 feet), a remarkable piece of engineering skill, forming the only lateral communication between the Bernese Oberland and the Rhone valley. Other passes connect Switzerland with Italy, the most important being that of the Great Saint Bernard in the Pennine Chain, that of the Simplon in the Lepontine Alps, the Saint Gothard (q.v.) at the head of the valleys of Reuss and Ticino, and those of Bernardino, Splügen, Bernina, Septimer, and others leading from the Grisons southward. Altogether about 40 commerical highways pierce the Alps, besides a larger number of natural passes unprovided with roads. Of the great pass-roads connecting Italy through Switzerland with southern Germany the most important in Roman times and in the Middle Ages was the Septimer Pass (7,580 feet), connecting the head of the Val Bregaglia with the Rhine valley above Chur by way of the Oberhalbstein and the Albula. The Saint Gothard was not known to the Romans, but was frequented by pilgrims in the 13th century. The Simplon pass (6,600 feet) was a paved Roman road; the railway tunnel which runs under it was opened in 1906. The Great Saint Bernard pass (8,110 feet) connecting Switzerland with Italy starts on the Swiss side at Martigny in the valley of the Drance, and ends at Aosta in the Dora Baltea valley. The famous hospice of Saint Bernard is mentioned in documents of the 10th century.

The avalanches of Switzerland are famous for their destructive propensity, but on their record, year by year, they do not cause any appalling loss of life or property. The mighty forces of nature, in storms at sea, inundations and cyclones, cause probably a much greater proportionate loss of life and property than do avalanches. Though they fall all the year round in Switzerland, spring is the great time for avalanches. During that period some of them descend with remarkable regularity in particular places and at recognized spots. The snow piled up during the winter on the grass slopes below the (summer) snow-line, gradually loses its cohesion as the spring melting advances and glides down to its appointed place according to the trend of the ground. In places where huge masses of snow are collected above steep declivities terminating in narrow outlets the avalanches descend with terrific roar and pressure against the lines of defence — the forests. For this reason the forest laws of Switzerland are very strict. Everything is done to preserve the natural rampart afforded by a mass of pines, and no one is allowed to fell a tree on his own ground with government consent. Where avalanches fall regularly every year, stone galleries are built or tunnels are mined out of the solid rock to protect roads. Many protective devices are employed to arrest the torrents of ice, snow and slush so that the danger from them has largely diminished. The so-called *Staub-Lawine* or Dust-Snow avalanche is the most dangerous on account of its suddenness, and the most difficult to provide against. This is a collection of loose, freshly-fallen snow which has been caught up in one of those sectional tornados that spring up on the mountain slopes, and is driven down on the wings of the wind to the valley below. The *Schlag-Lawine* or Stroke-Avalanche is the usual spring variety, which pour down the slopes like a swiftly-flowing river. This is the type that can be more successfully regulated. It has a secondary form in the *Grund-Lawine* or ground avalanche, which carries earth and rubbish with it and performs a beneficial task in bringing down soil from the heights to the plains. Whereas the avalanche is snow in quick movement toward the valleys, the glacier is snow (pressed into ice) in slow movement. See GLACIAL PERIOD; GLACIER.

Rivers and Lakes.— Owing to its mountainous nature Switzerland is naturally a land belonging to many river systems, though none of the rivers acquires such a size within its limits as to become of much navigable importance. Its position as the centre of the principal watersheds of Europe has been referred to. Great rivers take their origin in Switzerland and attain their chief development in other countries. Both the Rhine and the Rhone rise here, as well as the Po and the Danube. The first three spring from the Saint Gothard mountain mass, but the Rhine is formed by the junction of three distinct head-streams, the Vorder, Mittel and Hinter-Rhine. It flows north into the Lake of Constance, and thence west to Schauffhausen, where it forms the celebrated falls of that name, the largest in Europe in volume. It is navigable for vessels at Coire in the canton of Grisons for vessels of 150 tons, but its navigation properly begins below the falls. Its principal affluent in Switzerland is the Aar, which, after traversing the Lakes of Brienz and Thun, winds across the Swiss plateau to join the main stream about midway between Lake Constance and Basel. The Rhone, said to be the most rapid of the larger rivers of the world, rises in the Rhone glacier (Valais), flows northwest into the Lake of Geneva, issues thence at the town of Geneva under the name of the Arve, and quits Swiss territory about 10 miles below. The waters which the Po receives from Switzerland are carried to it by the Ticino, and thereby to the eastern bay of the Mediterranean; those which the Danube receives are carried to it by the Inn and taken thence on to the Black Sea. The lakes and mountains form a more important hydrographical feature than the rivers. The former are remarkable for their number, size, depth and the grandeur of their scenery. The largest lake, that of Geneva (also known as Lake Leman), has an area of about 220 square miles; Lake Constance, in the northeast, has 208 square miles. Both of these, as well as Maggiore on the south side of the Alps, belong partly to other countries; but within the limits of Switzerland, and not far from its centre, are Lake Neuchâtel (93 square miles), with Morat and Bienne in its vicinity. Thun with its feeder Brienz, Lucerne or Vierwaldstättersee, Sempach, Baldegg, Zug, Zürich and Wallenstättersee. All these internal lakes belong to the basin of the Rhine. The greatest depth of Lake Geneva is 1,015 feet, placing the bottom at about 200 feet above sea-level; the bottoms of the lakes on the southern side of the Alps are below the level of the sea. Rapid mountain torrents feed nearly all the Swiss lakes, entering their upper ends thickly charged with sediment, which is deposited when the rivers enter the lake, to leave it at the lower end as clear streams. Thus the lakes filter and regulate the rivers, thereby protecting nearly all the lower valleys of the country from serious floods. The Aar formerly overflowed its banks, but this has been remedied by the construction of a canal to divert the river into the Lake of Bienne, by which the lower course of the stream is regulated.

Geology and Minerals.— The most remarkable feature in the complicated geological structure of Switzerland and of the Alps generally is the extent to which the flanks of the Alps have been folded, contorted and inverted by the tremendous forces that led to the elevation of these mountains. A typical example is presented by the Saint Gothard, where the central core crops out at the summit of the ridge, and the strata on each side of it, north and south, dip inwards toward the base, so that when seen in section they would present the appearance of the ribs of a fan radiating from a single point. All the loftiest Alpine ranges have a nucleus of granite, on which gneiss and mica-slate recline generally at a high angle. On the west of the plateau the Jura give their name (Jurassic) to the rocks of which they are composed; the mountains on the east are mainly formed of gneiss and mica-schist with various slates in places, especially in the Grisons. The Swiss plateau, stretching from southwest to northeast between the Geneva and Constance lakes, may be described as an area of Tertiary (principally Miocene) deposits separating the two mountain regions composed chiefly of rocks of more ancient date. Switzerland is not rich in minerals; iron ore is found and worked at various places. Asphalt, sulphur and salt occur in certain districts, and formerly argentiferous copper and lead ore were extracted in the canton of Grisons. A profitable source of national wealth is provided by an abundance of mineral springs. Thermal and medicinal baths are dotted all over the country. Baden (q.v.), the chief of the bath centres, enjoys a most salubrious climate and its hot springs have been celebrated since Roman times. Other celebrated health resorts are those of Schinznach in Aargau, Pfeffers in Saint Gall, Leuk or Loueche and Saxon in Valais, Saint Moritz in the beautiful Engadine, with Bernhardin, Fideris and Schuls-Tarasp, Alveneu and Serneus; Blumenstein, Weissenburg and others in canton Berne; Weissbad near Appenzell, Stachelberg in Glarus, Seewen in Schwyz, and Schwendi-Kaltbad in Unterwalden. Altogether there are close on 400 health resorts in Switzerland, many containing luxurious hotels, Kurhäuser, casinos, clubs and theatres, with numerous attractions for devotees of winter sports and tennis lawns. Native industry and initiative have so successfully exploited the gifts of nature that Switzerland has become the "playground of Europe" — if not of the world.

Climate.— The crest of the Alps forms a huge dividing-wall between the polar and the equatorial winds, the latter of which frequently deposit their moisture in the form of rainfall on the southern side of the range. The best-known wind is the *Föhn*, a warm, moist south wind that blows with great velocity in eastern

Switzerland and the upper valleys of the Rhine, Reuss, Rhone and Linth, and is frequently followed by heavy rain. On its approach the thermometer rises and the barometer falls rapidly; presently a fierce storm breaks out. The *Föhn* is calculated to blow for 17 days in spring, five days in summer and 16 days in autumn. The cold north-northeast wind, known by the French name of *bise*, blows in the direction of Geneva between the Bernese Oberland the Jura, but is little noticeable in summer. Various local winds prevail at the higher levels and are of great importance to invalids, e.g., the uniform morning wind, blowing down-hill, in regular alternation with the evening wind, blowing up-hill. The higher inhabited regions of Switzerland may be divided into three zones. The lowest of these, the hill region, between the elevations of 1,300 and 2,600 feet above sea-level, embraces the banks of the lakes in northeast and central Switzerland and the adjacent mountain slopes. Great heat often prevails here in summer, though a pleasant relief is afforded by the lake baths. Lake Constance is the warmest of the inland waters, with a temperature of 68° to 75° F. The second, or mountain region, extends from 2,600 to 3,900 feet, a district of numerous towns and villages. The third, or Alpine region (3,900 to 6,550 feet), presents a much lower temperature and dry, clear weather suitable for certain classes of invalids suffering from lung disease. At Sils-Maria, in the upper part of the Engadine valley, the mean January temperature is 17½° F.; mean July, 53°, and the mean of the whole year 34°. In general the valleys have a severer winter than mountain peaks of equal elevation, as the colder and, therefore, heavier air steadily sinks down to the bottom of the hollows. At places north of the Alps, such as Zürich and Berne, the normal winter temperature is about 30° F., the summer temperature from 50° to 64° or upwards; at Geneva the corresponding temperatures are as high as 33° and 66°. Some of the high-lying valleys, especially those that are open to the east and closed to the west, are facetiously said to have nine months' winter and three months' cold.

Flora and Fauna.— The differences of elevation affect equally the climate and the natural productions of the soil, hence few countries in Europe, even of larger extent, can boast of a more varied vegetation than Switzerland. The flora of the Alps is one of peculiar interest. Like all great mountain ranges the Alps harbor a considerable number of plants found nowhere else, and of those which are found elsewhere the majority do not reappear in the plains and valleys below, but in distant mountains or in the Arctic regions. Out of upwards of 800 species belonging to the Alps, but not to the adjoining lowlands, nearly one-fourth are absolutely restricted to these mountains, and nearly a fifth are found also in the Arctic regions, these being what are hence known as Arctic-Alpine plants. As the elevation ascends there is a gradual change in the aspect of the vegetation, which has been divided into seven regions. In comparison with adjacent countries, Switzerland possesses few forests, and these have little effect in increasing the atmospheric moisture or in moderating the extremes of temperature. In the valleys at the base of the mountains chestnut and walnut grow freely even on the north side, while in the valleys opening toward the Mediterranean lies a zone occupied by these trees while still at a considerable elevation. Higher up is the zone of the beech, maple and other ordinary foliage trees reaching to about 4,000 feet, and then the zone of firs and pines rising about 1,000 feet higher. This region is followed by one of Alpine shrubs, among which rhododendrons («Alpine roses»), heaths and whortleberries are conspicuous, along with larches and two species of pine, the dwarf-pine and the cembra-pine, remarkable for its edible seeds and peculiar to this zone. The shrubs cease to grow at about the height of 7,000 feet, but the Alpine plants that cover the pastures intermingled with the shrubs ascend to the snow line, and even beyond in places too steep for snow to lie. Heer collected about 100 different species of flowering plants above the snow limits on the peaks of the Grisons at about 8,500 feet; 24 species have been observed on the Grands Mulets on Mont Blanc at a height of from 9,800 to 10,600 feet; and the sides of the Pizzo Centrale on the Saint Gothard have been known in August to spread to a considerable distance the fragrance of the flowers which covered them in patches. The celebrated edelweiss, which all Alpine tourists eagerly collect, is the most retiring of these snow region plants. Of utility plants the characteristic product of the plain and lower regions is the vine, which grows up to about 1,800 feet above sea-level. The hilly or lower mountain region up to 4,000 feet produces good crops of barley and oats and excellent pastures. Above this, in the Sub-Alpine region, up to 5,500 feet, no regular crops are grown; in the upper Alpine region the vegetation becomes more stunted and the variation of the seasons is lost. Beyond lies perpetual snow. Many parts even of the lower parts of the country are stony and sterile, but no spot that can be turned to good account is left unoccupied. Though chiefly an agricultural country, Switzerland cannot grow enough crops to support its population, so that the majority of the foodstuffs have to be imported. The productive land is cut up among some 300,000 peasant proprietors who raise, besides the crops already mentioned, wheat, spelt, rye, potatoes and tobacco, and manufacture cheese, condensed milk and wine. Nearly 30 per cent of the entire area is unproductive and about 36 per cent is under grass and meadows. Considerable quantities of fruits are grown. Among domestic animals the first place belongs to the horned cattle. At the last census there were in the country 136,613 horses, 1,615,645 cattle, 171,635 sheep, 550,000 pigs and 358,000 goats. In the summer the cattle are fed on the numerous mountain pastures or «alps,» but of their winter fodder a large proportion has to be imported. In several cantons bee-keeping and silkworm culture are carried on. Among the wild animals are bears, wolves, chamois, goats, boars, stags, badgers, foxes, hares, otters, squirrels; birds of prey of large dimensions; the snipe, heathcock, cuckoo, blackbird and woodpecker. The lakes and rivers produce a varied abundance of fish.

People.— The Swiss are a mixed people as to race and language. The bulk of the population is of Teutonic race, but the Latin race (partly French, partly Italian) compose nearly three-sevenths of the whole. The Swiss Teutons belong to the Alemannic stock and still speak a difficult Alemannic dialect usually called Swiss German or simply Swiss. They occupy the whole of the upper Rhine valley, as far as its extreme western angle at Basel, consequently the whole of the Helvetian highlands lying north of the Central Alps, besides the upper Rhone valley down to Sion or Sitten, under the Bernese Alps. The rest of the upper Rhone valley and the western slopes of the Jura are French, comprising the cantons of Valais, Vaud, Geneva and Neuchâtel. The Italian portion is made up of those parts which belong to the basin of the Po — the whole of the canton of Ticino and the valley of Poschiavo in the Grisons. Along the head streams of the Rhine, in the valleys of the Grisons, and in the region between these rivers and the banks of the upper Inn, and even still farther eastwards, in some Tyrolese valleys beyond the Swiss frontier, are scattered the Rumonsh-speaking people, whose language at first sight seems like a sort of connecting link between German and Italian. These are the interesting Rhæto-Romance tribes, which had long failed to receive the attention of the scientific world. Critical research has since established that Rumonsh is an entirely independent Neo-Latin tongue, standing on the same level as Spanish, Portuguese, Italian, Langue d'Oc, Moldo-Wallachian (Rumanian) and Langue d'Oïl. Rumonsh has two main dialects — the Overland dialect or Rumonsh proper, divided into two sub-dialects, the Sur-Selvian and Sub-Selvian, and the Engadine or Ladin dialect (see RHÆTIA). Yielding to the pressure of the vigorous Teutonic tribes, the Rhæto-Romance races became at last confined to the solitary upland valleys, where they still continue to eke out a laborious existence. Their speech is also steadily yielding to encroachments and is gradually being supplanted either by German or Italian. As the Swiss races differ in origin and language, so also do their temperamental characteristics vary. The French Swiss is active and vivacious; the Italian Swiss, fiery and irritable; the German Swiss, calm and thoughtful. Yet with all their racial and spiritual divergences, a fervent patriotism is common to all of the Swiss people. Independence and liberty are the keynotes of their existence. There is no desire among the German, French or Italian Swiss to be united with their neighbors of corresponding nationalities. It has been said that the Swiss as a people often suffer in the judgment of tourists by failure to live up to their reputation as a «mountain people»— to a glorious «Alpine» character. In truth, however, the idea that dwelling in a mountain region has an ennobling influence on the human character is mostly fallacious. The Swiss are expected by the traveler to carry themselves in all things with the pride and dignity of people who are born and bred in the original home of European liberty. But civilizations and traditions of human freedom have always begun on the plains — by seashore and river bank. If all the facts are taken into account, it is rather a handicap than an advantage to a race to inhabit a mountain country, for in the earlier stages of civilization the mountain fastnesses have imposed upon them the duty of sheltering alike fleeing patriots and criminal fugitives from justice. In later stages, again, mountains interfere greatly with development of the machinery of civilization. It has been facetiously pointed out that mountain air sharpens the appetite more than the wits, and there are some diseases attacking particularly the brain which are almost peculiar to mountain districts. The one favorable national circumstance of the Swiss is that their central position in regard to the great plains of Europe has put them in the track of all the chief currents of civilization. What they have achieved in spite of the handicap of their mountains is one of the marvelous stories of the human race. To these massive barriers they owe in the main their sense of national unity.

Industries; Chief Towns.— The Swiss depend for their support on various branches of industry, to which much attention has been given of late years. There are now large silk and cotton factories, while the watch-making industry established in Geneva since the end of the 16th century has long been famous. Other industries are: Embroidery, musical boxes, chocolate (Suchard, Cailler, etc.), shoemaking, straw plaiting, wood carving, aniline dyes, pottery and aluminum. Asphalt is worked by an English company at Val de Travers and Neuchâtel. In the lowlands the chief occupations are agriculture, horticulture and wine growing. In the highlands almost the sole industry is the rearing of livestock. The principal imports are cereals, fruits, vegetables, colonial produce, animal food substances, iron and mineral products. Being an inland country, Switzerland has direct commercial intercourse only with the surrounding states; but the trade with other countries, especially Great Britain and the United States, is very important. A source of enormous profit is the catering for the thousands of tourists who invade the country. Switzerland is noted for its hotels, and it is no exaggeration to say that the Swiss are the most expert artists in hotel-keeping. The large modern establishments at Geneva, Vevey, Zürich, Lucerne, Interlaken, etc., are models of comfort and organization; the smaller hotels are often equally well conducted, and indeed a really bad inn is rarely met with in French or German Switzerland. In normal times the prices are extraordinarily moderate. A flourishing occupation is that of the professional guide, who is indispensable for expeditions among the higher mountains, especially on those which involve the passage of glaciers. As a class, these guides are intelligent and respectable men, well versed in their duties and thoroughly acquainted with the people and resources of the country. The town life of the Swiss is strongly affected by the hotel life of the tourists. The inhabitants are generally well educated and proficient in languages. Offering asylum as it does to political and social rebels of all countries, Switzerland is a kind of international clearing house for thought and theory. For many years it has been the free and open laboratory in which the schemes of anarchists, Bolsheviki, Nihilists, Young Egyptian and Young Turkey exiles were hatched. During the European War the country was the mecca of diplomats, conspirators and high-born refugees. The Gallic, the Teu-

tonic and the Slav new thought of the day are all understood and discussed in Switzerland, and the Swiss book stores are the most cosmopolitan and representative in the world. There are few important towns, the chief being Zurich, Basel, Geneva, Bern (the federal capital), Lausanne, Saint Gallen, Chaux-de-Fonds, Lucerne, Biel Winterthur and Neuchâtel. Geneva, the home of the Red Cross, was designated the capital of the League of Nations by the Allied Peace Conference of 1919.

Communications.— The state railroads of Switzerland have a length of 3,670 miles, while there are 32 miles of foreign railways within the confederation. Owing to the heavy capital charges ($465,000,000) the state railways do not show a profit. In the last normal year (1913) they carried 91,546,639 passengers. The cars on most of the lines follow the American plan. On the waterways and lakes 22 companies operate 170 steamers and barges. The organization of the post office is highly efficient. Tourists' baggage may be transported very cheaply by parcel post; delivery is prompt and reliable. There are over 2,000 post offices; 2,135 miles of telegraph lines and 2,390 telegraph offices. Every year there are constructed new funicular railroads and tramways leading up the mountain sides; these produce a good profit — over 3 per cent, and are usually privately owned. In June, 1918, the Swiss National Council adopted a project of Federal subvention of a port on the Rhine at Basel, which will open that river to commercial traffic between Germany and Switzerland. To counteract the possibility of drawing the republic within the sphere of German economic influence, an alternative was proposed, by which Switzerland could be placed into direct communication with the Mediterranean via the Rhone. This river could be made navigable for the 20 miles between Geneva and Lyons by the construction of a lock at Genissiat, just below Geneva. By this route Switzerland could obtain all the products necessary for its existence. In April 1919 it was announced that Switzerland had acquired 28 vessels, of 105,000 tons total tonnage, to be attached to the port of Cette on the French coast (Gulf of Lyons), with which a special line will connect with the Swiss railways. The installation of a central warehouse is projected at the Etang de Thau.

Religion and Education.— There is complete religious liberty in Switzerland. According to the last census there were 2,107,814 Protestants, 1,593,538 Roman Catholics and 18,465 Jews. The order of the Jesuits is not allowed within the confederation. In 12 of the cantons the Protestants form the majority; the Catholics in 10. The latter have the larger number of clerics, some 6,000, under five bishoprics, those of Basel and Lugano, Chur, Saint Gallen, Lausanne and Geneva. The Protestant Church is Calvinistic in doctrine and Presbyterian in form; it is under the supervision of the cantonal magistrates. No one is called on to pay taxes specially appropriated for the support of a creed which he does not adhere to. The foundation of religious orders or new convents are prohibited.

The Swiss educational system is both generous and practical, with compulsory attendance (at nine years) enforced and free instruction, books and materials provided. The elementary school classes are mixed and contain up to 45 children. The curriculum assures to boys and girls a general elementary education including a knowledge of French, while considerable time is also devoted to physical exercise, carpentry, needlework and cookery. After a four years' course the scholars enter the secondary schools, where they remain till 15. After a five years' advanced course in the secondary school the scholars have the option of ultimately entering the gymnasium or the industrial and commercial schools. Up to the age of 15 instruction is free; after that the annual fees amount to 60 francs ($12). There are great universities in the chief cities, which are much frequented by foreign pupils. The Swiss technical schools are second to none in the world; they teach everything from waiting at table to watch-making and science. In mountain villages the schools are kept open only during the long Alpine winter. All through the summer the boys work in the fields, while the masters and teachers attend to their own farms. From the primary schools to the universities there are splendid facilities for learning. In the 4,690 primary schools there are about 530,000 pupils annually under 12,023 teachers. The cost of these institutions is little over $10,000,000 a year. In the 642 higher schools there are about 60,000 pupils annually under 2,000 teachers. The cost of these is about $1,500,000 a year. Besides these there are schools of agriculture, dairying, commerce, etc., while continuation commercial schools give further instruction to some 10,000 pupils yearly, who attend vacation and evening classes. In the seven universities, Basel, Zürich, Bern, Geneva, Lausanne, Fribourg and Neuchâtel, there is an average of 9,000 students a year, of whom fully a third are foreigners. An average of 15,000 children a year are treated in the correctional schools, and some 1,300 in 28 schools for the feeble-minded. There are 14 special schools for deaf-mutes, with an average of 700 pupils a year. Special attention is paid in all Swiss educational institutions to gymnastics and physical culture.

Government.—As already stated, Switzerland is a confederation of 19 entire and six half cantons, which have been united for federal purposes since 1848. The present constitution, which dates from 29 May 1874, vests supreme legislative and executive authority in two chambers — (1) a State Council (Ständerath) of 44 members, chosen two for each canton and one for each half-canton for three years; and (2) a National Council (Nationalrath) of 167 delegates of the Swiss people, chosen also for three years by direct manhood suffrage, one deputy for every 20,000 of the population. Among the various forms of government developed in Europe that of a federal republic has been achieved by Switzerland alone. That country may claim to possess the only truly democratic government in the world. The Swiss have produced great results with small resources; they have shown what the plain man can do in the way of government without the help of a ruling class, of gentlemen of leisure, of millionaires or of professional politicians. An ideal democratic constitution should make it impossible for political representatives to impose on the country laws which the people do not want. It should also be difficult, if not impossible, for a small majority to impose constitutional changes to which nearly one-half of the electors are opposed. Yet these obvious requirements are conspicuously absent in democratic countries, for it is often uncertain how far laws, which are easily carried through a parliament or congress, are really wanted by the people, and whether, if put to the popular vote, they would have even a bare majority in their favor. The expression of the will of the people as an aim of government is altogether lost sight of and party necessities become the sole motives of political action. Another requirement of democratic government is that the political machine should work as smoothly as possible, and for this end care should be taken so as to constitute the legislative and executive bodies as to avoid as far as possible the political crises consequent upon sudden changes of government and to minimize the turmoil and excitement produced by elections. The Swiss have solved these difficult problems with ingenuity and originality; they have evolved a political machine in which the frank and sure expression of the popular will and the smooth working and stability of government are obtained to far greater extent than in any other country.

Though the cantons are united together as a confederation or "Eidgenossenschaft" for mutual defense, each retains its individual independence and governs itself according to the constitution best suited to its own requirements. In these various constitutions there are gradations from the fullest democracy to the purest representative forms; but pure non-representative democracies have been adopted in the smaller cantons only, such forms of government being in fact impracticable except among small populations. The united chambers form the Federal Assembly, to which is confided the supreme government. The executive authority is deputed to a Federal Council (Bundesrath) of seven members, elected for three years by the Assembly, the president and vice-president of which are elected annually, and are the first magistrates of the republic. The Council sits at Bern, which is the headquarters of the federal administration. Though ranking only fourth in point of population, Bern owes its status as capital (since 1848) partly to its central position in the Swiss tableland and partly to the historical importance of the canton, which is itself a result of that position. The principles of the referendum and of the initiative are in force. By the former, if a petition is presented by 30,000 citizens for the alteration or revocation of a measure passed by the legislature, or eight cantons demand it, the law in question must be referred to the direct vote of the nation. The latter signifies the right of any 50,000 citizens to demand a direct popular vote on any constitutional question. The federal government alone can contract treaties or declare war; it also controls the army, postal system, finance and customs. The cantonal authorities have jurisdiction over civil and criminal law, justice, police, public works and schools. The president is elected annually and receives a salary of $2,700; he is usually succeeded by the vice-president, whose salary is $2,400, the same remuneration paid to the other five members of the Bundesrath. These seven officials act as ministers: (1) Foreign Affairs; (2) Interior; (3) Justice; (4) Military; (5) Finance; (6) Agriculture and Industry; (7) Posts and Railroads. The 44 members of the State Council receive about four dollars per day, more or less, as stipulated by the cantons which elect and pay them. The 167 members of the National Council are paid from federal funds at the rate of four dollars for each day of attendance and an allowance for traveling expenses. Clergymen are not eligible as deputies; every citizen over 21 has the vote and is eligible for election. The Swiss are keen politicians and go industriously to the polls for the election of representatives and for the settlement of the numerous questions referred to their decision by direct vote. Out of 839,114 electors in 1912, no fewer than 529,000 recorded their votes in a referendum held that year on the new insurance law against sickness and accidents.

Under the operation of the federal constitution the Swiss executive, unlike the British Cabinet, is not renewable all at once, but only gradually as the term of office of each member comes to an end. Nor is it dependent for its existence (and this is a highly important point) on the vote of a majority in the Federal Assembly. Yet the Swiss executive, like the British Cabinet, but unlike the American Cabinet, has the right and duty of initiating legislation; but if a measure introduced by it, or having its support, is rejected by the Assembly, that measure merely disappears for the time being. Nothing else happens. There is no political crisis and no general election. A Swiss election causes no uproar. It has become the habit of the Assembly to elect members of the Federal Council to the presidency in the order of their seniority on the Council, and for years past Swiss presidents have succeeded each other as noiselessly and as surely as if they followed each other by right of heredity. With some difference, the State Council is obviously modeled on the United States Senate, but has not the power of ratifying treaties. By means of the referendum the whole body of the electors throughout the country acts as a check upon the elected representatives in the Federal Assembly, and the electors can, by means of the initiative, if necessary also act as a spur. Swiss representatives have far greater freedom of action than those in other countries bearing a party label. They are not bound to any party and may speak and vote like free men, since the rejection of government measure entails no political crisis nor an election, as would be the case elsewhere. In America, where the executive is not dependent for its existence on a vote of a majority, party feeling is nevertheless as predominant as in England: the loyal party man hopes to receive his reward in the shape of some office for himself or patronage for the benefit of friends. All such considerations are entirely absent in Switzerland, where, although party names and organizations have not altogether disappeared, their meaning and importance are negligible, and no organization, however influential and wealthy, can control politics. The referendum and initiative have broken political despotism and party government in Switzerland.

Local government is entirely in the hands of the cantonal authorities. In some of the smaller cantons there is no special administrative machinery; all the male citizens assemble in the open air at stated periods and transact the public business. These assemblies are called Landesgemeinde. The administrations differ in the larger cantons and are carried on by popularly elected representatives; in most of them the referendum exists, while some have also the popular initiative.

Judicial System.— The Federal Tribunal or Bundes-Gericht is stationed in Lausanne and is composed of 24 members with nine supplementary judges appointed by the Federal Assembly. Their term is six years, and they may be re-elected. The president and vice-president hold office for two years and are not eligible for re-election to those posts. The president is paid $3,200 annually; the others $3,000. Divided into three divisions, the tribunal has final jurisdiction in all national suits; private suits in cases where the value in dispute is not less than $600, and in appeal cases involving not less than the same amount. National suits are such in which constitutional or legislative matters are concerned, intercantonal disputes, or appeal against the decisions of federal authorities. It tries treasonable offenses against the confederation, the jury being popularly elected and paid two dollars a day. For ordinary civil and criminal cases each canton has its own judicial system. Capital punishment was abolished in Switzerland by the new constitution of 1874, but since 1879 several cantons have reintroduced the death penalty, which now exists in the 10 cantons of Appenzell-Inner-Rhoden, Fribourg, Lucerne, Obwalden, Schaffhausen, Schwyz, Saint Gall, Uri, Wallis and Zug. Nevertheless, capital punishment is not referred to in the Swiss penal code.

Finance.— Switzerland derives its revenue from the alcohol monopoly, customs, railways, posts, telegraphs, state property and investments, and military service exemption taxes. The revenue gathered for federal purposes amounts, normally, to about $32,500,000, about half from the customs and almost the rest from the public services. The production and sale of alcohol is a federal monopoly and produces nearly $2,000,000. a year profit. The bulk of the proceeds of this latter are divided among the canton governments, who have to expend one-tenth of the amount received in combating alcoholism. The revenue for 1913 (the last normal year) amounted to close on $20,000,000, and the expenditure to $21,062,000. Owing to cost of mobilization and enhanced prices under war conditions the expenditure for 1917 rose to $38,645,140 and the revenue to $35,316,400. The estimates for 1918 stood at over $50,000,000 expenditure. For mobilization the government issued loans for 80,000,000 francs in 1914; 115,000,000 in 1915; 200,000,000 in 1916; 100,000.000 in 1917, and 150,000,000 in 1918. The public debt amounted 1 Jan. 1918 to $149,010,000; including the floating debt the total was $42,578,000. In 1914 there were 385 savings banks with 446,247 depositors and $315,000,000 in deposits. In 1917 the total state property was valued at nearly $29,000,000. The cantons separately raise about $27,500,000 a year, while the total taxation of the country is normally about $60,000,000 annually. The salt monopoly produces about $7,500,000 a year. At the beginning of 1918 there were in circulation 10,880,000 gold coins of the face value of $40,520,000; 58,376 silver coins, face value $11,460,000; 143,700,000 nickel coins, face value $2,774,000 and 102,500,000 copper coins, face value $270,000 — a total face value of $55,024,000. The national bank, opened in 1907, has the exclusive right to issue bank notes, of which it had in circulation on 30 March 1918 to the value of $139,125,860. Switzerland is a party to the Latin Monetary Union with France, Belgium, Italy and Greece. The franc is the unit of currency; its value in terms of United States money is $0.225, roughly 20 cents, or five francs to the dollar.

Swiss Army.— Compulsory universal service has been the root-principle of Switzerland's military system for centuries. Since the reorganization completed in 1912 the army has been brought to a high state of efficiency. The striking force of the Swiss army consists of about 300,000 men, divided into the Elite (20 to 32 years), the Landwehr (33 to 40) and the Landsturm (40 to 48), which number respectively 117,530, 108,900 and 68,000 men. The supplementary services (men of from 20 to 48, who for various reasons are not entirely fit), number 205,000, and the grand total of the whole army is slightly under half a million or one-eighth of the entire population. There are few exemptions except for physical disability and those excused or rejected pay certain taxes instead of rendering service. Liability extends from the 20th to completion of the 48th year; service is distributed as follows: 12 years in the Elite or «Auszug,» eight years in the Landwehr and eight years in the Landsturm. The longest periods of training are the recruits' courses which every man goes through in his first year of service — 65 days for the infantry, 75 for the artillery and 90 for the cavalry — besides which there are compulsory courses in shooting. The younger men (the first line) do seven other annual trainings of 11 days each (14 days in the artillery) before passing into the Landwehr, when they are called out for 11 days every four years; the Landsturm are only called up in time of war. Men convicted of grave offenses are not allowed to join the army and officers and men whose private life is unworthy of their rank and standing are court-martialed and dismissed. In the strictest sense a democratic service, the Swiss army is a model institution, unique in that every would-be officer starts as a private with the ordinary recruits' course, and promotion to the commissioned and non-commissioned ranks is by merit and not by seniority, except that it is conditional on four years' service in each rank. Although officers naturally have to do more work and pass through longer courses of training than the privates, instances of shirking in order to escape promotion do not occur. On the contrary, all through the army both officers and men do a large amount of extra voluntary work. In peace time there are no generals; these are appointed only on mobilization or outbreak of war. The system of promotion from the ranks has the advantage that it obviates any danger of militarism, which always springs from antagonism between people and officers as a class;

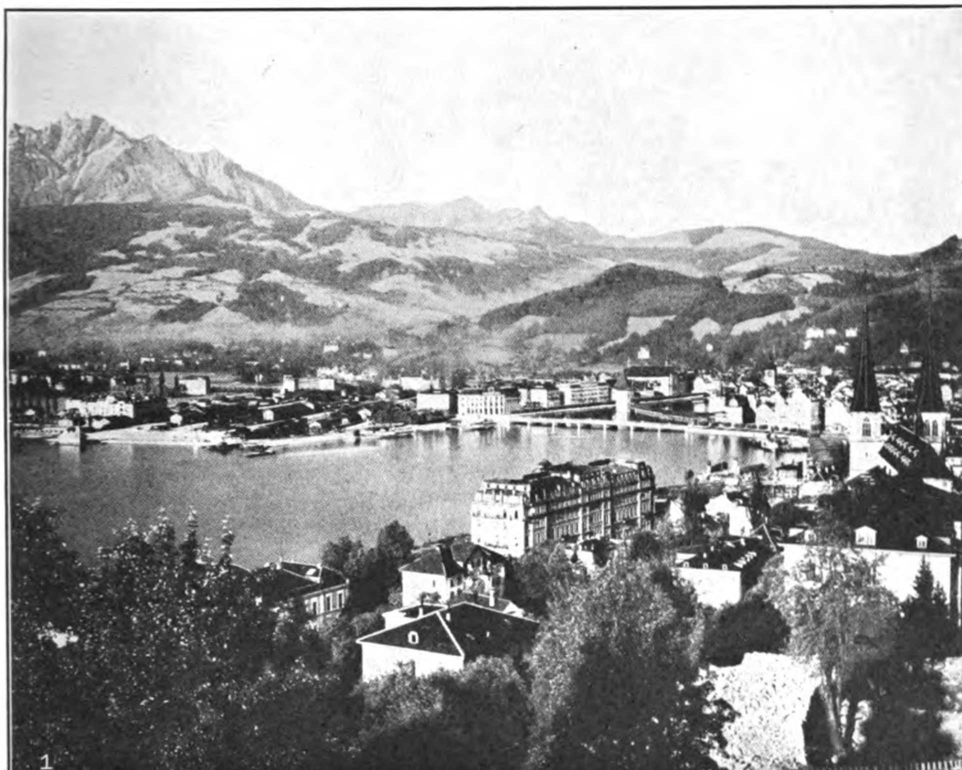
in Switzerland officers as well as men either belong or feel that tney belong to the people, and there is consequently no friction between them. The system also makes physical training obligatory, for it is preceded by compulsory gymnastic training in all the schools and supplemented by a large amount of voluntary gymnastics, drill and shooting practice, which last is the principal cause of the high standard of marksmanship throughout the Swiss army. But apart from target exercise (which is encouraged, while at the same time mobilization is accelerated by the fact that every soldier when he is not out training keeps his rifle and equipment in his own house) the institution of annual trainings tends to produce a high state of physical efficiency throughout the nation.

The composition and organization are thoroughly modern and complete. The infantry (traditionally known as Fusiliers and Carbineers, but for practical purposes are divided into field and mountain infantry) is the main arm. The cavalry consists of dragoons and guides, the former being ranged in independent divisions under the direct orders of the commander-in-chief and the latter brigaded with those divisions. There are altogether 106 battalions, 72 field batteries, 12 howitzer batteries, nine mountain batteries, eight cavalry regiments and 12 squadrons of guides, besides the usual accompaniment of engineers, cyclist, railway and pontoon corps, telegraph section, etc. The fortifications on the southern frontier for the defense of the Saint Gothard pass and the Rhone valley are manned mainly by the Landwehr, which is organized in 56 battalions and 36 squadrons. There are six divisions in the army, each of which belongs to one of the six divisional districts into which the country is divided and each can be worked as a separate army corps. The first consists entirely of French-speaking Swiss, recruited from the cantons of Geneva, Valais, Vaud and Neuchâtel. In the second division three-quarters of the men are French-Swiss, from Fribourg, Neuchâtel and the French Jura. The third, fourth and fifth divisions consist entirely of German-speaking Swiss from the cantons of Bern, Lucerne, Soleure, Basel, Argovie, Saint Gall, Zürich and Schaffhausen. The sixth division (Italians and Rumonsh) is recruited from Ticino, the Grisons and Saint Gall. At the beginning of the European War all six divisions were mobilized so rapidly that in the first week of August 1914 Switzerland was able to post on its frontiers over 250,000 fighting men, well armed and well drilled. The infantry are armed with the Swiss repeating rifle. The field artillery consist of 75's and 120's (howitzers); the mountain artillery of 75's (1906 model) and the heavy artillery of 120's, firing a shell of about 39.68 pounds.

This national militia, which is not a standing army, is administered partly by the cantonal authorities, who have power to promote officers up to the rank of captain. The higher appointments rest with the federal government, which has charge of all general matters of importance. The Swiss consider it an honor to serve in the army and a misfortune to be rejected. Considering its efficiency and the fact that it is raised by conscription, the Swiss army is a comparatively cheap one. The expenditure is 11 francs ($2.20) per head of the population, while 23 francs ($4.60) per head is spent on education. All men rejected on account of physical defects or exempted, such as teachers, clergymen, police, etc., pay a military tax according to income up to the age of 40. Service being the same for all, it is, therefore, a handicap for none. It interferes neither with personal liberty nor with the country's prosperity; it imposes little burden on the national treasury and no burden at all on the national content. In proportion to population Switzerland is one of the richest countries, although it has not an inch of territory beyond its borders. The yearly value of Switzerland's commerce amounts to about $162 per capita of the population, as compared with $107 in England, and the country not only bears the compulsory system, but regards with pride and affection the army which is its result. Owing to its inland position Switzerland has no navy, and no need of one. Yet a "Swiss admiral" did once exist, an Englishman named Colonel Williams, who in 1799 was in the service of the Zürich government and commanded a small fleet on Lake Zürich, with which he was ordered to oppose the French army. When the latter, under Masséna, routed the Austrians and Russians, Williams calmly watched the battle from the lake. Then, enraged at his own inaction, he discharged his crews, scuttled his vessels and took to flight.

History.— Switzerland is believed to have been first peopled by the Rhæti, who were driven from the plains to the mountains by the Helvetii (q.v.), a Celtic tribe. The latter are the oldest inhabitants of the country mentioned in history; they were conquered by the Romans in 58 B.C. and A.D. 10, while the Rhæti were subdued by the same conquerors in 15 B.C. The Romans built military roads over the Great Saint Bernard to Basel and over the Julier Septimer and Splügen to Bregnez and thence to Basel. The chief settlements were Aventicum (Avenches) in the canton of Vaud; Vindonissa, which in the early centuries of the Christian era was the headquarters of a Roman legion with its Rhætian cohorts at the confluence of the Reuss, Aare and Limmat; Augusta Rauracorum (Kaiser Augst) on the left of the Rhine near Basel; and Curia Rhætorum (Coire) in the Grisons. East Switzerland as far as Pfyn in Thurgau and Pfin (*ad fines*) in the Upper Valais, belonged to the province of Rhætia, while Western Switzerland formed part of Gaul. Under Roman dominion Helvetia enjoyed a flourishing trade which covered the land with cities and villages. A trace of that period still exists in the Romanic dialect spoken in some parts of Switzerland. The name Helvetii had become extinct even before the reign of Constantine. About 400 A.D. a great wave of barbarians poured through the peaceful valleys of the Alps, and Huns, Burgundians, Alemanni and Ostrogoths in succession settled in different parts of the country. The Alemanni occupied the whole northern part, where German is now spoken; the Burgundians the western part, where French is spoken; and the Ostrogoths occupied the south, where Italian and Rumonsh are the languages to-day. These races were gradually subdued by the Franks, and by the year 534, under the successors of

SWITZERLAND



1 Lucerne

2 Thurn and the Bernese Alps

Clovis, Switzerland had become a part of the Frankish Empire, which did not take possession of the country with its own nationals, but governed it through appointed officials. Christianity was introduced during this period and the monasteries of Disentis (now a school); Saint Gallen (named for Saint Gallus, an Irish monk, and now a bishop's residence), and Einsiedeln (now one of the most famous pilgrim resorts in the world), were founded, and dukes and counts were appointed as vicegerents of the Frankish kings. Under the successors of Charlemagne, Switzerland was divided: the eastern half was united with the duchy of Alemannia or Swabia (Schwaben), and the western part with the kingdom of Burgundy (912). After the downfall of the latter in 1032 the whole country fell to Germany, which governed it through vicegerents, the dukes of Zähringen. These governors in succession conducted themselves as princes, assumed the name of their castles, and compelled the free inhabitants of their *Gaus* (districts) to acknowledge them as their lords. They were in perpetual enmity with the Burgundian nobles and consequently favored the inhabitants of the towns. They also founded several new towns, such as Bern, Frieburg (Fribourg) and Burgdorf. Throughout the Middle Ages, Switzerland and the Swiss were always in the eye of Europe. At times they presented the spectacles of a patriot people repelling the tyrant and invader with an unearthly courage and good luck; at other times it was that of a warlike clan, safe in the great mountain fastnesses, offering their fighting abilities to the highest bidder and rendering for pay as high a courage and stubborn a fidelity as was ever inspired by love of country. Almost every European nation felt their prowess as enemies or allies. The Swiss was found at every court in some capacity. Peter of Savoy, Prince of West Switzerland, built the great Savoy palace in London, part of which survives to-day as the Savoy Chapel, built on the site in 1505–11; he also built the famous Castle of Chillon on Lake Geneva, immortalized by Byron, and kept great affairs going in both those far-apart countries. It is recorded that Machiavelli prophesied that the Swiss would some day be masters of all Italy, a prediction reasonable enough then in the light of the remarkable military virtue and energy of the Swiss.

As the power of the German emperors declined, the nobles and priests grew ambitious of independence and eager to enrich themselves at the expense of their neighbors. Those of the Swiss towns and smaller communities which had preserved their freedom were compelled by considerations of safety to conclude treaties with the feudal lords of the soil. At the beginning of the 13th century the three forest cantons of Uri, Schwyz and Unterwalden were subject to the then unimportant counts of Hapsburg, who, although they were properly only imperial bailiffs (Vögte), yet regarded themselves as sovereign rulers. This claim the three cantons constantly refused to admit, and eventually (1291) leagued themselves together to oppose the usurpations of the house of Hapsburg. Tradition says that on the night of 7 Nov. 1307, 33 representatives, with Fürst of Uri and his son-in-law Tell, Stauffacher of Schwyz, and Arnold of Melchthal in Unterwalden at their head, met at Rütli, a solitary spot on the Lake of Uri, swore to maintain their ancient independence, and projected a rising of these cantons for 1 Jan. 1308. On the day fixed the rising took place, and the Austrian governors were deposed and expelled. But the events related of Tell are purely legendary. (See TELL). A few years later the three cantons were invaded by the Hapsburgs; but the signal victory at the pass of Morgarten on 15 Nov. 1315, secured the independence of the cantons. The three united cantons were joined by the cities of Lucerne (1332) and Zürich (1351), the cantons of Glarus and Zug (1352), and the city of Bern (1353). Austria, which claimed jurisdiction over three of the newly-added members, namely, the city of Lucerne and the cantons of Glarus and Zug, again invaded the territory of the confederation, but was completely defeated at Sempach (where Arnold of Winkelried is said to have sacrificed his life for the sake of his fellow-countrymen) in 1386, and in 1388 at Näfels. The canton of Appenzell joined the confederation in 1411, and Aargau was wrested from the Austrians in 1415. The third war with Austria terminated in 1460, in favor of the confederation, which obtained Thurgau, Austria being thus deprived of all its possessions in the regions over which Switzerland now extends. Hapsburg Castle still dominates the canton of Argau — a monument of Swiss independence. In 1474, at the instigation of Louis XI of France, the Swiss turned their arms against Charles of Burgundy, invading his country and defeating his army near Héricourt. Charles, in revenge, invaded Switzerland, but the Swiss inflicted severe defeats upon the Burgundians at the three battles of Grandson in Vaud, Morat (Murten) and Nancy in 1476 and 1477, in the last of which Charles was slain. They admitted Freiburg and Solothurn into the confederation in 1481, and about the same time they concluded defensive alliances with several of the neighboring states. Their prosperity rose to such a height that all the courts around, even Austria, sought their friendship and alliance. The last war with Austria broke out in 1498. The Swiss had to undergo a severe struggle, but, victors in six sanguinary battles, they were, by the Peace of Basel in 1499, practically separated from the empire, a separation to which formal and international sanction was given in 1648. That peace ended a triumphant struggle of two centuries. After this war they had no longer any enemy to fear, and their future wars were waged on behalf of foreign powers. In 1501 Basel and Schaffhausen, and in 1513 Appenzell (which had long been an ally), were admitted into full federation. The number of the cantons was thus brought up to 13, at which it remained till 1798. The town and the abbot of Saint Gall and the town of Bienne had seats and votes in the diet without being in full federation; and there were besides six allies of the confederation not enjoying these privileges — the Grisons, Valais, Geneva, Neufchâtel, Mühlhausen, and the bishopric of Basel. In 1516 France gave up to Switzerland the whole of the present canton of Ticino. An alliance between the two countries was formed which lasted until the French Revolution.

In 1518 the Reformation began to make its way into Switzerland, chiefly through the efforts of Zwingli at Zürich. He fell at Kappel (1531), but his work was carried on by Calvin at Geneva. The effect of the Reformation for long was to divide Switzerland into separate camps. Aristocracy and democracy, Protestantism and Catholicism, struggled for the superiority. Internal dissensions, religious and political, continued for nearly 200 years. The last time the two great parties met in arms was at Willmergen in 1712, when victory declared itself for the Protestants. The period of tranquillity that followed was alike favorable to the progress of commerce, agriculture and manufactures, and to the arts and sciences. In almost every department of human knowledge the Swiss of the 18th century, both at home and abroad, acquired distinguished reputation. In the last years of the century the ferment of the French Revolution spread to Switzerland; and in 1798 the ancient confederation was replaced by the Helvetian Republic, founded on the ruins of the ancient liberties of the nation, which lasted four years. In 1803 Napoleon I organized a new confederation, composed of 19 cantons, by the addition of Aargau, Grisons, Saint Gall, Ticino, Thurgau and Pays de Vaud. In 1815, by the Federal Pact of Zürich Neufchâtel, Geneva and Valais were admitted into the confederacy, and the number of the cantons was thus brought up to 22. This confederacy was acknowledged by the Congress of Vienna, which proclaimed the perpetual neutrality of Switzerland, and the inviolability of its soil. Again in 1830 and in 1848, Switzerland was affected by the revolutionary movement in France, and a new federal constitution was introduced in the latter year. During the revolutionary commotions of 1848 Neufchâtel set aside its monarchical form of government and adopted a republican one, and in 1857 it was put upon the same footing with the other cantons. Since that time the annals of Switzerland have little to record beyond the fact of constant moral and material progress. A revision of the federal constitution was adopted after a protracted agitation on 19 April 1874, from which time the cantons gradually adopted the referendum and the initiative. While this agitation was going on several of the individual cantons set the example of revising their constitutions. In this proceeding Zürich led the way, appointing a special council for the purpose in January 1868. It was followed by Bern, Aargau, Thurgau, Solothurn, and other cantons. All the modifications made were in a democratic direction. The chief opposition to the project of a revision of the federal constitution proceeded from the French cantons and the Ultramontane party, the former fearing that in consequence of a revision of the constitution in the direction aimed at, that of giving more power to the central authorities, they would be gradually Germanized, the latter believing that the influence of their party in those cantons where it was numerically strong would be curtailed. But in spite of this opposition the Federal Assembly, on 21 Dec. 1869, adopted the principle of a revision, and elected a committee to prepare a scheme for the purpose. The project of revision drawn up by this committee was laid before the Federal Assembly in the session of 1871–72, and after being accepted there was submitted to the people on 12 May 1872, an article of the constitution then in force requiring that any proposed alteration of it must, before being adopted, be sanctioned by a majority of the people and of the cantons. On this occasion the project was rejected by a small majority; but a new one was drawn up and accepted on the date already mentioned, 19 April 1874. The new constitution gives more homogeneity to the confederacy by assigning to the federal authorities more power in matters relating to law, the army, the church, and education. The laws of the various cantons are partially assimilated; the management of the cantonal contingents to the army is no longer left entirely to the cantons themselves; the ecclesiastical authorities are completely subjected to the civil power; and primary education is made compulsory and secular. Since then two or three partial revisions have been carried out. A constitutional modification, for instance, was passed by the National Council in 1890 to the effect that in future when a revision of the federal constitution, or the admission into it of a new article, is proposed by popular initiative, this proposal must be supported by the votes of at least 50,000 citizens possessed of the right of voting, and not 30,000 as previously. In 1891 the 600th anniversary of Swiss nationality was celebrated.

The more important events in Swiss history of recent years may be briefly summarized. On the last day of 1898 Switzerland was admitted by the United States as a favored nation. In 1900 the nation rejected the «double initiative,» a scheme to elect members of the National Council by proportional representation. The new palace of the Swiss parliament was opened in 1902. In the same year a brief rupture with Italy occurred. Agreements were arrived at during 1903 for the construction of the Jura and Simplon tunnels; a new army bill was passed in 1907, when a British military commission arrived at Basel to study the Swiss army system. In 1908 the sale and manufacture of absinthe were entirely prohibited in the country. During 1909 and 1910 serious damage was caused by floods and avalanches. Progressive industrial development calls for a large supply of labor which Switzerland is unable to supply; becoming every year less of an agricultural country, large quantities of food have to be imported, while the number of factory hands has more than doubled in 25 years. The population of the country districts shows little increase; that of the towns is growing rapidly, mainly due to foreign immigration from Italy, France and, above all, from Germany. During the European War the position of Switzerland was one of extreme difficulty. Need of coal and iron compelled the republic to enter into agreements with the Central Powers to supply them with foodstuffs. Besides maintaining its army on a war footing for the duration of the war, Switzerland became a clearing-house for the refugees, wounded and prisoners of all the belligerents, while international diplomats and exiled rulers made it their headquarters. A noteworthy statement of Swiss policy was made in a memorandum presented in February 1919 by the Federal Council to the Peace Conference in Paris. In this document special emphasis is laid on Swiss neutrality, which «is not chosen according to circumstances, but is permanent»

— a fundamental principle of the Swiss state since the beginning of the 16th century. «As in the past, so in the future, Switzerland must remain the faithful guardian of the passes of the Alps. . . . When all relations between the belligerents were broken off, Switzerland was able, thanks to its neutrality, to undertake the grateful task of carrying out a philanthropic activity which saved the world from an accentuation of its sufferings.» Switzerland welcomed the creation of a League of Nations and, as the oldest of existing republics, «would deem it an honor to bring into the League of Nations the experience acquired in the course of centuries.» The determined insistence on neutrality by Switzerland — except in case of self-defense — places that country in a peculiar position with regard to the League of Nations. As pointed out by Professor Borgeaud in a pamphlet, 'La Suisse et la Société des Nations' (Geneva 1919), neutrality implies sovereignty, a principle inconsistent with the general spirit of the League — unless, indeed, the League itself concedes this privilege for special international reasons. In a remarkable speech delivered before the National Council in August 1918 President Calonder first called attention to this point; though supporting intervention to end the war, he declared that Swiss neutrality prevented Switzerland from forcing itself as a peacemaker. Sturdy independence, freedom of action and avoidance of foreign entanglements or obligations is the keynote of the Swiss Republic. In a state paper dated 15 Nov. 1690 occurs this passage (in French): «The Swiss have two religions in their country, which divide them at times; but they have only one liberty, which they cherish above all: this reunites them always, and will reunite them for ever.»

Henri F. Klein,
Editorial Staff of The Americana.

SWORD, The, a weapon used in personal combat for cutting or thrusting, one of the most ancient and highly esteemed of all weapons. No sooner had the art of working metals been discovered than it made its appearance, replacing almost at once the crude axe of the Stone Age. The earliest swords, of which any authentic records exist, were those of the Assyrians, the Gauls and the Greeks. These swords were double edged, straight or leaf-shaped, and were made of bronze, the art of tempering steel not having then been discovered. The Roman sword, which was made of steel, was short, straight and double edged, having its point cut at an obtuse angle. The swords of the Franks were straight, about 30 inches in length with a tapering point. None of these swords appear to have offered much protection to the hand.

During the Middle Ages the sword was lengthened, while still retaining its general Frankish shape and quillons (cross-pieces) were added for the protection of the hand. A narrow-bladed sword called the estoc, used principally for thrusting, was often carried attached to the saddle by mounted men, the heavy sword being worn upon the person at the same time. A dagger called the miséricorde (dagger of mercy) was worn on the right side by knights, and used to dispatch their fallen foes.

The German lansquenets, or mercenary foot soldiers, used a two-handed sword some six feet in length. On the march this ponderous weapon was worn slung over the back. In wielding the heavy swords of the Middle Ages, the forefinger was often hooked over the right quillon to strengthen the grasp. This forefinger being unprotected (except by the gauntlet) was frequently injured and so, for its protection, a little ring was placed in front of the quillon through which the finger was passed. For the sake of symmetry another ring of the same kind was added to the left quillon, the two rings being termed the «pas d'ane.» Side rings were next added for the protection of the hand and the right quillon was curved upward so as to form the «knuckle bow.» A thumb ring was also sometimes added, the Germans being especially fond of this device. During the 16th century the sword became much lighter, the striking of heavy blows having become less of a necessity owing to the discarding of armor on account of the invention of gunpowder. A cup-shaped guard was added to the quillons (which were generally straight, the knuckle bow being retained as a separate piece) and the weapon became a rapier, the point of which rather than the edge was used in making an attack. With the early rapier a dagger was worn, which when fighting was held in the left hand and used for parrying. Later a cloak was used for the same purpose. As the science of fence became better understood, however, all secondary protections were discarded, and the rapier became a weapon of both offense and defense. Rapiers were often highly ornamented and the guards were frequently of fanciful design. The best of them came from Spain, Toledo being especially noted for the excellence of her blades.

Shortly before the beginning of the 18th century the rapier was supplanted to a great extent by the colichemarde, a weapon with a hilt like our modern small sword, the marked peculiarity of which was that its blade was wide for about half its length and narrow for the other half. About 1760 the colichemarde gave way to the small sword, a very light weapon, having a small circular guard, a knuckle bow and a narrow straight blade. The foil used in fencing which represents the small sword is about 33 inches in length with a quadrangular blade and a bell or ring guard. Italian foils have quillons, French ones do not. The duelling sword is a heavier kind of foil, having a triangular blade tapering to a very fine point. A broadsword is a sword that has a cutting edge. It may be either straight or curved, single or double edged. It is essentially a military weapon and is in use in all armies. In the United States army a form of sabre is used varying from 30 to 34 inches in length. In the European War the sword has come into disuse among infantry officers owing to the lack of opportunity for its employment in trench warfare and the dangerous distinctiveness which it gives to those who bear it.

The sabre which is the best known form of broadsword is single edged. Its blade, which is usually somewhat curved, is thickest at the back, from whence it becomes gradually thinner toward the edge. Its guard consists of a strong knuckle bow often terminating in a solid piece, which amply protects the hand. The scimetar, a light form of sabre having a very pronouncedly curved blade is the favorite weapon of the East. Damascus was formerly noted for the excellence of her scimetar blades. The cutlass is a short heavy broadsword which is in use in most of the navies of the world. The machete, a weapon much used in Cuba, is shorter than the cutlass and lacks the protecting guard for the hand. The claymore, which may be called the national weapon of Scotland, is a heavy straight broadsword having a very elaborate basket hilt.

The schlaeger, the weapon used by the German students in their university duels, is a long straight sword with a very sharp edge, having a solid metal guard which completely encases the hand. The sword bayonet is a short sword adapted for use either with or without the rifle.

The long sword of the Japanese is a weapon some two and a half to three feet in length, with a heavily backed blade, a sharp cutting edge, a long handle and a small round guard. Their short sword is like the other but only about half as long. In olden times both of these swords were worn together thrust through the girdle by the samurai, a privileged fighting class corresponding to the knights of the Middle Ages. It was with the short sword that hara-kiri (self dispatch) was committed in order to avoid the disgrace of dying at the hands of the public executioner, the samurai being accorded this right. When fighting, the short sword served as an extra weapon in case the long sword became lost out of the hand, or broken. (See FENCING). Consult Lacombe's 'Arms and Armour'; Castle's 'Schools and Masters of Fence'; Hutton's 'The Sword and the Centuries.'

FRED GILBERT BLAKESLEE,
Late Swordmaster First Regm't C. N. G.

SWORD-DANCE, a dance in which swords and movements made by them form an important part. In the modern sword dance as practised among the Highlanders of Scotland, the performer shows his ability and skill by dancing among the blades without cutting himself.

SWORD FERN. See *Filicales*, under FERNS AND FERN ALLIES.

SWORD-LILY. See GLADIOLUS.

SWORDFISH, an enormous mackerel-like fish (*Xiphias gladius*), representing alone the world-wide family *Xiphiidæ*. It has an elongate mackerel-shaped body which may equal in size that of the largest sharks, and whose muscles are astonishingly strong. A powerful forked tail, a lofty, sail-like dorsal fin, usually divided in adults, but continuous in the young, and other strong fins, give the creature a power and speed in swimming equaled by few oceanic animals. The skin is naked, more or less rough, and the flesh red in color and rich in flavor is greatly enjoyed when eaten. These fishes are predatory, obtaining their food by fierce forays upon flocks of lesser fishes. Their strength and sharp teeth are supplemented by the prolongation of the fore part of the skull into a horizontally flattened «sword,» composed of the consolidated vomer, ethmoid, and premaxillary bones. The excellence of this weapon and the power of attack is attested by the frequent piercing of boats and even of large wooden ships, through which the sword has been deeply thrust before breaking off. Although occasionally seen in the Pacific, the swordfish is characteristic of and numerous only in the North Atlantic, the Mediterranean Sea, and about the Antilles, where in summer it approaches the shore, in pursuit of schools of spawning fishes, and itself becomes the object of a profitable fishery, especially in Italian waters. Along the northern seaboard of the United States this is regarded as a prime summer sport. The fishermen cruise a few miles from the coast in small schooners, having at the extremity of the bowsprit (from which the jibboom has been removed) a small platform supporting a belt-like rail of iron at the height of a man's waist, within which a harpooner may stand securely while his arms are free. Having sighted a swordfish, visible by its projecting backfin, the vessel is steered up to it and a barbed harpoon is thrown to which is attached a rope by which the catch is hauled aboard. Consult Goode, G. B., 'Fishery Industries' (Washington 1884).

SWORDS, Order of. See ORDERS (ROYAL) AND DECORATIONS.

SYBARIS, sĭb'ạ-rĭs, an ancient Greek city and colony of Lower Italy, in Lucania, on the Gulf of Tarentum, not far from the site of the later town of Thurli. Tradition ascribes its building to a colony of Achæans and Trœzenians about 720 B.C. It rapidly rose to a high degree of prosperity, but enervated by the mildness of the climate, the richness of the soil and their great wealth, the inhabitants became proverbial for their luxury and voluptuousness. In a war with Crotona the city of Sybaris is said to have brought into the field 300,000 men, while the forces of the former amounted to but 100,000. The Crotonians, however, were victorious and totally destroyed Sybaris by turning the waters of the river Crathis against it (510 B.C.). The inhabitants of the town dispersed themselves for the most part over the other Greek cities of Lower Italy. Sybarite is still used to signify an effeminate voluptuary. In 1879 and in 1887 excavations revealed two great cemeteries but the true site of the city remains undetermined. Consult *Notizie degli Scavi* (Rome 1879–88) and Orsi, P., 'Atti del congresso di scienze storiche' (Vol. I, Rome 1904).

SYCAMORE, sĭk'ạ-mōr, Ill., city, county-seat of DeKalb County, on the Chicago and Great Western and the Chicago and Northwestern railroads, about 55 miles west of Chicago. The city was founded in 1836. It is in an agricultural and stock-raising region and has considerable manufacturing interests. The chief manufacturing establishments are flour mills, insulated wire works, brick and tile works, soap factories, wagon and carriage works, agricultural implement works, varnish and furniture factories, canning establishments and creameries. There are large establishments for preparing fruit and vegetables for shipment. There are 12 churches, a young ladies' seminary and public graded schools. The national bank has a capital of $50,000; there is also a private bank. Pop. about 3,800.

SYCAMORE, a name applied originally to *Ficus sycomorus,* a tree known in biblical times and places, and the legendary one chosen by Zacchæus to climb into for a sight of the Saviour. It is a species of fig, an evergreen timber tree, flourishing in Egypt, which supplied an inferior coarse-grained wood for ordinary purposes and for mummy cases. A famous Egyptian statue of an old man was carved out of a block of sycamore wood about 4000 B.C. The thick foliage, resembling that of the mulberry, makes the sycamore a desirable shade-tree and it is still planted for this reason in Egypt. The fruit is borne directly on trunk and branches, edible and sweet-flavored and is a large item of food among the lower classes. The ripening of the figs is hastened by making incisions in the apexes. In the Middle Ages a European maple, *Acer pseudo-plantanus,* was selected to represent the tree of Zacchæus in the old miracle plays, on account of its dense foliage. It is a tall, very handsome tree of quick growth and living for perhaps 200 years. The leaves are large and have acute lobes, somewhat resembling those of the plane, and the yellowish flowers droop in terminal racemes. The bark is smooth, often peeling off in large flakes, leaving patches of lighter shade, the sap is saccharine and the wood is hard and white, although with a brownish heart, and takes a fine polish, being used by wheelwrights, turners, cabinet-makers and wood-carvers and for musical instruments. Sycamore endures sea and mountain winds better than most timber trees and is, therefore, planted for its shade in exposed places. Certain of these trees in Scotland were known as dool-trees, or grief-trees, because they formed informal gibbets on which to hang the enemies of powerful barons.

Perhaps because of the likeness in foliage and the stripping of the bark, the name of sycamore has been again transferred to the American plane-tree (*Platanus occidentalis*) better called buttonwood. This is one of the largest American trees with awkward, twisted, wide-spreading limbs which, however, when the tree is fully leaved out, forms a broad pyramidal head. The bark is smooth, that of the upper portion flaking off in pieces each year, leaving whitish patches, which are very conspicuous in winter. The large leaves range from simple coarse-toothed to distinctly deltoid and three-lobed blades. The flowers are clustered in compact round balls, with from three to eight minute petals and sepals; the fruit-heads retain this globose form and are composed of obpyramidal nutlets, having long, nearly erect hairs at the base. They are usually solitary and swing on long peduncles during the winter, only falling apart in the early spring. The reddish-brown wood is chiefly useful for cigar-boxes and is compact and difficult to split or to work.

The Australian sycamores are *Sterculia lurida* and the white sycamore *Cryptocarya obovata,* one of the native nutmegs, and a large tree yielding serviceable white timber. *Melia azedarach* is the false sycamore, the large tree more commonly known as the pride-of-China tree.

SYCEE (sī-sē') **SILVER,** the fine silver of China, cast into ingots weighing commonly rather more than one pound troy. They are marked with the seal of some banker or assayer as a guarantee of purity.

SYCOSIS, a pustular disease of the skin of the bearded face. It is often called barbers' itch (q.v.) and may be regarded as a form of that disorder. The usual treatment consists of application of carbolic acid, zinc ointments, ichthyol, sulphur or oil of cade.

SYDENHAM, Charles Edward Poulett Thomson, 1st BARON, British statesman and governor-general of Canada: b. Wimbledon, Surrey, 13 Sept. 1799; d. Kingston, Canada, 19 Sept. 1841. He was the son of a London merchant and spent some time in Russia in connection with his father's business. He was elected to the House of Commons in 1826 and in 1830 became a member of the Grey Cabinet as vice-president of the board of trade, of which he in 1834 became president and treasurer of the Navy. He became a recognized authority on financial matters and he was an earnest supporter of free trade. He was appointed governor-general of Canada in 1839 and it was under his administration that the union of Upper and Lower Canada was effected and a new constitution established. For his services in connection with this difficult undertaking he was in 1840 granted a peerage. He was preparing to return to England when he met his death through a hunting accident. Consult Poulett-Scrope, G. J., 'Memoirs of Charles, Lord Sydenham' (1843).

SYDENHAM, Thomas («THE ENGLISH HIPPOCRATES»), English physician: b. Wynford Eagle, Dorset, 10 Sept. 1624; d. London, 29 Dec. 1689. He entered Oxford University in 1642 but his studies were interrupted by service as an officer in the Army of Parliament. He was graduated bachelor of medicine at Oxford in 1648 and was elected a fellow of All Souls College, but his medical studies were again interrupted by military service. He began practice at Westminster about 1655, for some time still giving much attention to politics. He was licensed by the Royal College of Physicians in 1663 and took his M.D. at Cambridge University in 1676. While his medical studies were much interrupted and his early practice was without a medical license he made remarkable progress. He developed powers of diagnosis amounting to genius and he followed the method of Hippocrates in watching the progress of the patient and assisting nature in its effort to throw off disease. His theories were backed by his notable success in treating patients; and by his strong sense and plain manner of dealing with matters hitherto cloaked with professional mystery. He also kept mainly to simple prescriptions instead of the involved sort in vogue. He received recognition from abroad comparatively early in his career, his fame being largely augmented by his writings; but he made many enemies in the medical profession at home, although he also enjoyed the loyal support of many notable members of his profession. He made important contributions to medical science in his study of gout, of which he was a victim; his observations of epidemic diseases through a number of seasons and distinguished several that were formerly confused; introduced the cooling method of treating smallpox; was the first to use a tincture of opium, laudanum; and initiated the use of Peruvian bark in treating malaria. His scorn for dogmatic theories was intense and he was known in the case of a patient whose strength had been vitiated by the weakening processes of the day to prescribe food instead of medicine — an unheard-of procedure. His doctrines came into full recognition in the early part of the 18th century and it was then that the custom of designating him the «English Hippocrates» was inaugurated. However, while he felt keenly the antagonism evinced toward him by many members of his profession, he enjoyed a uniformly successful career and never suffered the ostracism endured by many pioneers in new theories of medicine. Author of 'Observationes medicæ' (1676); 'Tractatus de podagra et hydrope' (1683); 'Schedula monitoria de novæ febris ingressu' (1686); 'Processus integri' (1692), etc. The best edition of his works is that of the Sydenham Society, edited by W. A. Greenhill (2d ed., 1844). Little is known of his personal life, but of the numerous sketches of his career appended to editions of his works the most interesting is his own account of his theories and practices in the introduction to 'Observationes medicæ' (1676). Consult also Picard, F., 'Sydenham, sa vie, sa œuvres' (Paris 1889); Payne, J. F., 'T. Sydenham' (London 1900).

SYDNEY, sĭd'nĭ, Australia, capital of New South Wales, on Port Jackson, was the first city founded in Australia, by British colonists. Its selection was due to the beautiful site and the advantages offered by streams and adjacent bays. The principal streets are lined by handsome residences and commercial houses. The important buildings include the government offices — of white stone in Italian style; — the magnificent town-hall, with a high tower and fine organ; banks; post and telegraph offices; government house, a castellated building of fine Gothic architecture; the university, a vast edifice, also Elizabethan Gothic; together with the associated colleges, including the Woman's College, Saint Mary's Cathedral (Roman Catholic), a Byzantine synagogue, exchange, custom-house, mint, parliament houses, hospitals, asylums, and the Queen Victoria Market. Domain, Hyde Moore, and Centennial parks and the Botanical Gardens are extensive; the racecourse comprises 202 acres. The Australian Museum, founded in 1836, is the oldest institution of the kind in Australia. Its erection cost £59,000. It contains a very large botanical garden, a technological exhibit, and a library, which, together with other libraries in the city, numbers 240,743 works. The slaughter-houses and water-supply system are owned by the city and the tramway system is owned by the state. There are manufactories of glass, pottery, wagons, boots and shoes, stoves, hardware, tobacco, etc.

The University of Sydney dates from 1852, receiving its royal charter in 1858. Women students have been admitted since 1881. Port Jackson is of vast proportions, and accessible to the largest vessels, penetrating the country for 20 miles, and sending out branches in all directions. The shores present a bold and rugged aspect. Four companies operate ferries to and from Sydney over the waters of Port Jackson, which carry nearly 24,000,000 passengers annually. This service and equipment — the best boats are double-ended screw-boats — are said to be the equal of any in the world. Sydney is near a coal-formation extending over several hundred miles in East Australia, and is the centre of trade for the pastoral and mineral regions of the western districts, connected with an extensive railway system. The various manufacturing industries are well represented in the city, and its trade is large and growing. Sydney was founded in 1788. The discovery of gold in 1851 stimulated its development. On 1 Jan. 1901 the installation of Earl Hopetoun as first governor-general of the Australian Commonwealth took place here, consummating the federation of Australia.

An outbreak of bubonic plague in 1900, supposed to have been due to the introduction of plague-stricken rats brought in foreign vessels

SYDNEY, AUSTRALIA

1 Sidney, looking east from George street into Bridge street

2 The beautiful residence suburb of Sydney. The house at the left of the flag-staff, near the centre, is "Cranbrook," the home of the Governor of New South Wales

from afflicted ports, led, in 1901, to the formation of a board of port overseers, called the Sydney Harbor Trust. This commission assumed control of all the wharves, docks and harbors, and considerably improved shipping at Sydney. Sydney has 103¾ miles of electric tramways, mostly under municipal control. Pop. 648,746.

SYDNEY, Canada, city, chief port of entry of Cape Breton Island and capital of Cape Breton County, province of Nova Scotia, situated on the southwest arm of Sydney harbor, 285 miles northeast of Halifax; and on the Intercolonial and the Sydney and Louisburg railroads and on the Sydney and Glace Bay Electric Railway. Of these the most important is the great works of the Dominion Iron and Steel Company, employing 3,000 men and turning out 500 tons of steel rails daily. The shipping of coal is also an important industry employing great numbers of men. Among other industries are chemical works, iron and brass foundries, railway repair shops, slag cement works, wood factories, brewery and bottling works. The value of its manufactures reach about $11,000,000 annually. There are five banks located in the city. The chief publications are two daily and three weekly newspapers, one of which the *Mac Talla* is published in pure Gælic. There are 13 churches in the city, branches of the Y. M. C. A. and the Salvation Army, and a Catholic Young Men's Club. Among the public institutions are the county insane asylum and a large public library. The most prominent public buildings are the customs building, the new courthouse, city hall and the new county academy. The educational facilities include a high school, Sydney Academy, School of Mining and Engineering, Catholic convent schools, and a business college. Sydney was founded in 1784 by United Empire Loyalists. It became an incorporated town in 1885 and chartered as a city in 1904. Municipal affairs are administered by a city council consisting of a mayor elected every year, and 10 aldermen, representing five wards and elected for a term of two years. The city owns and operates its waterworks. Pop. 17,723.

SYDNEY MINES, Canada, town in Cape Breton Island and County, province of Nova Scotia, on the northern arm of Sydney Harbor, three miles north-northwest of North Sydney, and connected with that city by electric railway. The town owes its existence to the Nova Scotia Steel and Coal Company, whose mines are the oldest in Canada, coal having been mined there as early as 1785. A large steel plant is also located there, and these two industries employ 2,500 persons. The town government consists of a mayor, elected yearly, and a council of eight members elected every two years. Pop. 7,470.

SYENITE, as at present understood in petrography, a notocrystalline rock in which the chief feldspar is orthoclase, and in which quartz is absent. Originally it was used for a hornblendic granite such as occurs at Syene (now Assuan), Egypt, where it was quarried for obelisks. Typical syenite contains orthoclase and hornblende; those with biotite are called mica syenites. Some plagioclase is always present, and besides this, magnetite, apatite and zircon are invariable. See NEPHELITE.

SYKES, Frederick Henry, American college president: b. Queensville, Ontario, 13 Oct. 1863; d. Cambridge, Mass., 14 Oct. 1917. He was graduated at Toronto University in 1885, and in 1891–95 was student, scholar and Fellow at Johns Hopkins University, where he took his Ph.D. in 1894. He engaged in teaching and in 1903 became professor of literature and director of extension teaching at Columbia University; and he was professor of English and director of technical education at Teachers' College, Columbia, in 1903–13. From its organization in 1913 until 1917 he was president of the Connecticut College for Women. He was general editor of Scribner's 'English Classics Series'; and author of numerous textbooks on English composition and of 'French Elements in Middle English' (1899); 'Syllabus of Lectures on Shakespeare' (1903); 'Lectures of the History of English Literature in the Nineteenth Century' (1904), etc.

SYKES, George, American soldier: b. Dover, Del., 9 Oct. 1822; d. Brownsville, Tex., 9 Feb. 1880. He was graduated at the United States Military Academy in 1842. He was engaged in the closing scenes of the Seminole War and later in Texas, and served through the Mexican War. He was afterward on duty at western army posts and engaged in Indian warfare, and in 1855 was promoted captain. He was commissioned major of the 14th United States Infantry soon after the outbreak of the Civil War, participated in the battle of Bull Run, was commissioned brigadier-general of volunteers 28 Sept. 1861 and major-general 29 Nov. 1862. He commanded the Fifth Army corps at the battle of Gettysburg, and in April 1864 was transferred to duty in Kansas. He was brevetted brigadier-general in the regular army in 1865 in recognition of his services at Gettysburg and throughout the war. He became colonel of the 20th Infantry in 1868, and spent the remainder of his life at different western army posts. Congress appropriated funds for his burial at West Point, where a monument was erected to him.

SYLLABUS, a document issued by Pope Pius IX, 8 Dec. 1864, which condemned 80 current doctrines of the age as heresies. It is a summary or collection of errors previously reprobated in various allocutions and encyclicals. It is a condemnation of the intellectual, social, and religious heresies, characteristic of modern times as these are in opposition to Roman Catholic doctrines. It was divided into 10 chapters each containing several propositions with reference to their previous condemnations under the following general heads: (1) Pantheism, Naturalism and Absolute Rationalism; (2) Moderate Rationalism; (3) Indifferentism and Latitudinarianism; (4) Socialism, Communism and Secret Societies; (5) The Assertion of the Supremacy of the Civil Power over the Church; (6) The right of the State to interfere in Spiritual things; (7) Morality independent or religious sanction; (8) The Sufficiency of merely Civil Marriage; (9) the Denial of the Temporal Independence of the Papacy; (10) Falsely styled "Liberalism." The *Syllabus Errorum* was the occasion of much controversy and was seized upon by the German government as a pretext of the famous May Laws against the Roman Catholic Church in that country. The syllabus reasserts all the claims of the mediæval papacy. It provoked conflicts between the papal and the civil power in Prussia, Austria and Brazil. «Syllabus» is the name also used for a decree of Pius X (1907), condemning modernism in 65 propositions.

SYLLOGISM, *in logic,* an argument stated in full logical form, so that its conclusiveness is manifest from the structure of the expression alone, without any regard to the meaning of the terms. A perfect syllogism comprises three and not more than three propositions, the third being the one to be proved; this is called the «conclusion»; the other two, called the «premises,» contain the means by which the conclusion is arrived at. A syllogism may be represented thus in symbols,

All A is B,
All C is A,
∴ All C is B.

Or with words instead of symbols:

All metals are elements,
Lead is a metal,
∴ Lead is an element.

This syllogism is valid, because the conclusion logically follows from the premises. For the «figures» and «moods» of the syllogism and the rules for the construction of syllogism see LOGIC.

SYLPHS, in ancient mythology, the name given to the elementary spirits of the air in the polytheistic-pantheistic system of the Paracelsists. The sylphs, like the other elemental spirits — the salamanders or spirits of fire, the gnomes or spirits of earth and the undines or spirits of water — form the link between immaterial and material beings, for though, like men, they eat, drink, speak, travel, sicken and beget children, they resemble the more elevated spirits in the litheness and transparency of their bodies and their rapidity of movement; they also know more of the present and the future than man does. They have no soul, and consequently suffer annihilation after death. Consult Paracelsus, ‹Liber de Nymphis, Sylphis, Pygmæis et Salamandris et Cæterio Spiritibus› (Basel ed., 1590).

SYLT, sĭlt, Germany, an island in the North Sea, near the coast of Schleswig-Holstein. It is 22 miles in length, and has an area of 40 square miles. It consists largely of sand dunes with some cliffs,— especially near Kampen. The Friesian inhabitants are chiefly occupied in agriculture, stock-raising and duck-trapping, and are renowed as stalwart sailors. The dialect is peculiar, but German is the school and church language. The principal town is Keitum; the port is near Munkmarsh, connected by rail with Westerland. Lighthouses stand between Wenningstadt and Kampen and on the northern point of land. There is good sea-bathing. Pop. about 5,000.

SYLVANITE, a native telluride of gold and silver, containing 24.5 per cent gold and 13.4 per cent of silver. It usually occurs massive, but is often seen in curious skeleton crystallizations, due to twinning, and somewhat resembling the written Hebrew characters, giving rise to the name, «graphic tellurium.» Individual crystals are rare and of highly complex, monoclinic forms, with perfect clinopinacoidal cleavage. It is brittle; fracture uneven; hardness only 1.5 to 2; specific gravity very high, 7.9 to 8.3; lustre brilliant, metallic; color usually silver-white or slightly yellowish; streak gray. It is an important ore of gold and silver in Transylvania (whence its name), Colorado and California.

SYLVANUS, sĭl-vā'nŭs, in Roman mythology, a rural deity, who is represented as half a man and half a goat.

SYLVESTER, James Joseph, English mathematician: b. London, 3 Sept. 1814; d. there, 15 March 1897. He was of Jewish parentage and was educated at Cambridge University, where, however, his religion prevented his taking his degree until after the passing of the Tests Act in 1872; but he took his degree at Trinity College, Dublin, in 1841. He became professor of natural history at the University of London in 1837; and in 1841 was called to the chair of mathematics at the University of Virginia. He remained there but a short time, his frank expression of his opinion of the slavery question making his stay impracticable. He was connected with a firm of actuaries in London in 1845–55, meantime writing brilliantly on mathematics. In 1855–70 he was professor of mathematics at the Royal Military Academy, Woolwich. In 1877–83 he was professor of mathematics at the newly-established Johns Hopkins University; and while in America founded and was the first editor of the *American Journal of Mathematics.* He was called in 1883 to the Savilian chair of geometry at Oxford University and retained it until his death, although he was not on active duty from 1892, when his sight failed. From 1870 he was recognized as one of the leading mathematicians of the world. He published a vast amount of original work, chiefly in the form of contributions to scientific periodicals and to learned societies. His researches dealt principally with algebraic forms, although he also made contributions to analytical and pure geometry, mechanics, optics and astronomy. He exerted a profound influence upon the study of higher mathematics in America as well as in Europe, and his genius as an inventor of mathematics was accompanied by remarkable facility in instructing and inspiring his students. He was also an able linguist and was deeply interested in verse making, although he failed to make a name in that field. He wrote in this connection ‹The Laws of Verse› (1870). He was elected a Fellow of the Royal Society in 1839 and was the recipient of many honors from universities and learned societies both at home and abroad. His mathematical works were edited by Baker, H. F., ‹Collected Mathematical Papers› (2 vols., New York 1904–10).

SYLVESTER, sĭl-vĕs'tẽr, **Joshua,** English poet: b. 1563; d. Middleburg, Holland, 28 Sept. 1618. He is remembered by reason of his translation into English of the ‹Divine Weekes and Workes› of Du Bartas, a French Huguenot nobleman. It was especially popular with the Puritans in both the Old and New World, and was one of the sources of inspiration for Milton's ‹Paradise Lost.› Anne Bradstreet, the New England «Tenth Muse,» was an enthusiastic admirer of Du Bartas, known to her through Sylvester's version, and modeled her literary style upon Sylvester's somewhat exaggerated version of the strained pedantry of the original. Sylvester, in order to gain the favor of James I, whose dislike of tobacco was well known, published in 1615 an anti-tobacco tract, 'Tobacco Battered and the Pipes Shattered.' His works were edited by A. B. Grosart (2 vols., London 1878).

SYLVESTER. See SILVESTER.

SYLVITE, native potassium chloride, KCl, isomorphous with halite or common salt, crystallizing in the isometric system. Its habit is cubic, the crystals often modified by the octahedron. It usually occurs in granular or columnar masses, or compact. The crystals have perfect cubic cleavage; fracture uneven; brittle; hardness, 2; specific gravity, 1.98; lustre vitreous; usually colorless or white; transparent when pure. It is soluble in three parts of water and tastes slightly more bitter than common salt, like which it is highly diathermanous. It is mined in Galicia and very extensively at Stassfurt and Leopoldshall in Prussia, the production in 1902 amounting to 181,341 metric tons. It is used in the manufacture of potassium salts, especially the nitrate (saltpetre) and the carbonate (potash). It is also called sylvine and sylvinite. See POTASSIUM.

SYLVIUS, Jacobus (Latinized name of JACQUES DUBOIS), French anatomist: b. Amiens, 1478; d. Paris, 14 Jan. 1555. He early devoted himself to mathematics and the learned languages, but in middle life turned to medicine and took his degree at the University of Montpellier, later entering the University of Paris at the age of 51. He taught anatomy at the college of Tréguier, and later at the University of Paris. He is generally credited with the invention of the use of injection in dissection, but while he taught it evidence points to its being known before he used it. He appears to have been an ardent disciple of Galen rather than an original investigator, but gained a great name in his profession. The Sylvian fissure, the Sylvian aqueduct and the Sylvian artery were named for him.

SYMBIOSIS, a biological term introduced by De Bary to denote intimate and complementary partnerships between different organisms, as between the algoid and fungoid elements in lichens, or between unicellular algæ and radiolarians. A great number and variety of cases of symbiosis have been recorded among the lowest plants, but botanists find the subject more and more obscure and their decisions are by no means general. The effort to differentiate symbiosis from commensalism and parasitism has proved most baffling in many cases. The term «social symbiosis» has been given to the association of insects found in the communities of ants, bees, termites, etc., where many small aphids, beetles, etc., not at all related to their hosts, dwell in peace and in some cases seem to contribute to the general welfare as well as receive benefits. The subject has been discussed mainly in Germany. Consult Brandt in *Archiv für Anatomie und Physiologie* (Leipzig 1882); Hertwig, Oskar, 'Die Symbiosis' (Jena 1883); Keeble, Frederick, 'Plant-Animals: A Study in Symbiosis' (Cambridge 1912).

SYMBOL, a word of various meanings, derived from the Greek word *symbolon,* «a sign,» or *symbole,* a composition. In the early period of Christianity the word was often applied to the Creed and is still so applied in Latin countries. It is also used to indicate, either in a religious or profane sense, an emblem, figure or type, something which specially distinguishes one regarded in a particular character, or as occupying a particular office, or holding a special place in legend or mythology, as, for instance, the trident which is the symbol of Neptune. See SYMBOLS, ASTRONOMICAL; SYMBOLS, CHEMICAL; SYMBOLS, MATHEMATICAL.

SYMBOLIC LOGIC. See LOGIC, SYMBOLIC.

SYMBOLISM. The word symbol is derived indirectly from the Greek *symbolon,* a sign or token. Symbolism is the art and doctrine of symbols; it is the knowledge of the treatment of symbols or of deciphering the occult intent of signs or symbols and especially in reference to things spiritual, invisible or unable to be pictured, as an idea, a quality, etc. To the Greeks the word *symbolon* meant signs of such clearness that the allusion and the object were practically coincident. Among the Greeks their hospitality ended in giving their guests, or exchanging with them, a memorial of the visit in the form of a wooden tablet, a die or a ring, broken into two pieces. The host retained the other half, and in case of a future meeting presentation of the halved token was a sure identification, as one half fitted exactly into the fracture of the other half of the *symbola.* It is claimed by authorities that the origin of symbolism is traceable to the hieroglyphics or pictorial writings of the ancient Egyptians and was transmitted from them to other nations by the Jews. The Egyptians symbolized their gods with animal forms or combinations of both human and animal form; thus Horus, the sun-god, took the form of a sparrow-hawk, the disc was the hieroglyph of the sun, hence the winged disc (*Mir*), derived from the Assyrians, has its clear definition, and expressed also the victory of good over evil. The snake (*uraeus*) was symbol of death, hence, used as an attribute of the Egyptian kings, meant power over capital punishment, just as the handled cross (*ankh*) seen held by gods and kings signified life. The staff (*uas*) was the Nile kings' symbol of authority and has retained that significance with most nations ever since. From insect life also the Egyptians obtained such important symbols as the scarab (*Scarabæus sacer*), the «sacred beetle,» which they worshipped as a symbol of divinity, carving its form on finger rings containing inscriptions to be carried as an amulet. As to the mythology of the ancient Greeks and Romans it is not clear to us whether at first they looked upon their gods as symbolic of the elements of the world surrounding them; certain it is that they embody a very perfect system of the symbolism of Creation. With Uranus, god of the heavens above them, wedded to Gæa, the broad-chested earth, bringing forth Cronus, god of the harvests, and Zeus, the light of heaven, springing forth from the heaven god; with the storm-besieged mountain top of Olympus dedicated as seat of the lightning god and realm of the divine brood, poetic symbolism could get no closer to the human accounting of nature. Contemporary writers appear to show the acceptance of the theogony as allegoric if not symbolic, and symbolism played a big rôle in the mysteries and in orphism. And the Neo-Platonists under Plotinus, Porphyry, Proclus and the Emperor Julian were forced by the ridicule and logic of the Christian apologists to acknowledge that Saturn, Jupiter, Mars, Minerva and Venus were but symbols under which with other myths they represented divine attributes and manifestations. Leaders in the modern schools of learning begin to see that it is symbolism that is expressed in the mythologies of Egypt and India as well as of Greece and Rome. But the most universally practised worship has been that of the sun-god, whose symbol, the swastika, dates back earlier than the Sanscrit, and which symbolic cross has always been a sacred sign and known as the «Wheeling cross» or «wheel of the law» with Buddhists. Representing the sun, when its hands point to the right, on its westward orbit, and symbol of the earth's revolution in easterly direction when the hands point to the left (sometimes then termed suavastika), it is found as an ancient symbol all over the American continent on pottery of our prehistoric races. In a slightly varying form this swastika, known as the *fylfot,* appears among the ancient Celts as a favored symbol, occurring very frequently among the Scandinavian nations of early days. Variables such as the *triskelion, tetraskelion,* etc., are interesting but belong to the subject of symbols, not symbolism now under discussion. The Chinese live in an atmosphere of symbolism, every decoration having symbolic motifs as the chief characteristic, and even the shapes of the vases and jugs are symbolic. Scattered all over their pottery, porcelain, bronzes and enamels we find such symbols as those of longevity: *Kylin* (unicorn), *kwei* (tortoise), *ho* (crane), *luh* (deer). Their mystic number eight (*Pa*) shows forth in the *Pa-pao* or eight «precious things»; the *Pa-kwa* or eight mystic trigrams, the astrologers' symbols; the *Pa-chi-siang* or eight Buddhist symbols, etc. From the vegetable kingdom they find symbolism in the peach (*tao*), token of marriage and longevity, while the latter condition is also symbolized in the gourd (*hu-lu*) and the fungus (*chi*); and the bamboo (*chuh*), pine (*sung*) and plum tree (*mei*) are symbol of three friends. With the Japanese symbolism is a large part of their life. Among such we find: A plum, bamboo, orchid and a chrysanthemum symbolize the «four wise men» of Confucius; a pine twig, wisp of straw and a red lobster are a New Year symbol combination; a moon, snow flake and a flower in conjunction are symbols of the changing conditions of nature.

Jewish Symbolism.— Like all other Oriental peoples the Jews practised their system of symbolism. Many symbolic rules and formulæ occurred in the building of Solomon's Temple, if the result of the researches of the Freemasons can be relied on. The rending of Jeroboam's garment by the prophet Ahijah implied the separation of Israel from Judah; the rainbow presented a sign or symbol of the pact between God and the earth; the law of circumcision was a symbol of the covenant of the body. Josephus writes that the high priest's vestments were in every detail of symbolic intent, the coat symbolizing the earth; the upper garment, heaven; the bells and pomegranates, thunder and lightning; the ephod, the four elements, and the interwoven gold, the glory of God, the 12 jewels in the breastplate, the signs of the zodiac, etc. Other instances of symbolic significance are the blood of the Paschal lamb, the shearing of the hair of the Levites, washing and bathing and anointing as a ritual, the laying on of hands, etc.

Christian Symbolism.— While the primitive Christians in the Roman Empire used a symbolic language of signs, this was not done as a matter of choice but of necessity The persecuted sect could not safely, even in the Catacombs, express themselves in their depictions on sarcophagi or chapel walls with open comment; they had to hide their epitaphs and other written or depicted statements in forms that would not draw down destruction on them. Any originally conceived system of symbolism specially created for giving expression to Christian doctrine would have brought suspicion among the authorities as to the intent of such strange symbols. Therefore we find these early worshippers of the cross using an eagle, Roman symbol of Jupiter; they borrowed from the signs of the zodiac, from symbols appearing in the pantheistic mysteries, etc. And when they, later, used the sign of the cross it was half hidden in combination with an anchor, a symbol used by the pagans. A crude form of a fish (now called a *vesicle* or a *mandorla*) became symbol of Christ referring to a similarity of sound, *ichthus* the Greek word for fish, or from the fact that the letters therein would serve as the Greek initials of the words: Jesus, Christ, Son of God, Savior. The vine (attribute of Bacchus) was adopted as a symbol of Christian promise. The lamb, the palm, the Good Shepherd, would all be understood by the heathen contemporaries in a different sense than that given to these symbols by the early Christians. Greater safety in the use of symbols was afforded the Christians from the fact that there were other persecuted sects within the Roman Empire, who, for their forbidden cults, initiated a well-developed system of symbolism for use in public communications to their fellows, a language undecipherable to the uninitiated. Inscriptions of these symbolic expressions are found cut in the vast rock temples in Egypt, in Syria, Asia Minor, Sicily, Greece, on the Rhine and in France. A method of inculcating a knowledge of this sign language, together with the cult, was carried on unbeknown by their persecutors. They formed themselves into literary societies, guilds, burial unions, schools, etc., all under license as legal corporations, but secretly active as congregations of doctrine propaganda instead of the supposed secular gatherings. Among the systems of symbolism adopted by the early Christians were those belonging to the Pythagorean and Platonic doctrines and the sacred number systems among them. But from 325 A.D. such usage became a state offense. Augustine made war on the symbolic language and declared it a characteristic of the Gnostics. This latter sect, coming into existence when Christianity was first preached openly, endeavored to combine its principles with the Greek philosophy. Under such teachers as Saturninus, Basilides and Valentine a very extensive symbolic language was created in the Byzantine period and practised by these Gnostics, but the full intent of the expressions of this cult is lost to us at this day. Byzantine art discloses a considerable proportion of their symbols, such as the *Abraxas*, etc. As a matter of fact there is a close connection between Byzantine Christianity and Mithraism, from which much was derived, even if in changed form. And Byzantine art is built up entirely of symbolism, even to its very architecture, and its frequent lack of beauty from an artistic point of view is caused by its occultism in form and manners. Unlike the pagans, the Christians in their practice of symbolism always clearly distinguished the conventional signs from the divine and sacred essence they represented in their ceremonies or sacraments. In covering the catacombs with such depicted figures as fish, lamb, shepherd, grapes, fountain and hart, ship sailing safely on rough seas; with their $\overset{P}{X}$ Chi Rho («sacred monogram»), Alpha and Omega, etc., they set up no figures for idolatrous worship, but simple allegorical symbols. Leading authorities on ecclesiastical symbolism were Hugo of Saint Victor, Richard of Saint Victor, Vincent of Beauvais, Durandus, bishop of Mende, Languedoc, Honorius of Autun, Sicardus of Cremona, etc.

Symbolism attained its apogee in the Middle Ages, when animals, colors, plants, lines and attitudes had their hieratic significance. Candles, symbolic of the Light of the World, found ubiquitous use in all rituals; the vestments of the clergy, besides the ritual itself, were symbolic. The Church also had its representation in a woman crowned and majestic, bearing the banner of victory and the chalice, while Judaism, as unbelieving, took the form of an aged woman holding a cracked staff, the tables of the law falling to earth, her eyes bandaged and her crown toppling from off her head. Art was fond of depicting the universality of life's uncertain tenure by illustrating, under the title of «The Dance of Death,» a human skeleton calling, as unwelcome visitor, on king, queen and humble peasant. The books of «Bestiaries» afford us an insight into the allegorical or mystical significance of the most grotesque mythical animal creations of those days of superstitions. They figure on the gargoyles and in the moldings of Romanesque and Gothic structures. Much of the beauty of Gothic architectural traceries is found in the disposition of the trefoil and quatrefoil, having their symbolic intent of the Trinity and the four Evangelists. And the four Evangelists themselves enter the language of symbolism either as the «four rivers,» or Matthew being represented as an angel, Mark as a lion, Luke as a winged ox and John as an eagle. The 12 Apostles were given each their symbol for recognition in art depiction; Saint Peter bearing a key, Saint Jude a cross, Saint Matthew a wallet, Saint Thomas a spear, Saint Simon Zelotes a saw, and so on. Alchemy, from which our science of chemistry arose, was largely a science of mysticism and symbolism. It was probably derived from the Egyptians, not the Arabs as was formerly supposed, and Hermes is, after all, likely to have been the originator. At first the view evidently was that metals in their changeable forms (reactions) had body and soul like human beings, hence lead was called Osiris and considered by the Egyptians as the soul, or «prima materia» of all metals. Later it was supposed that quicksilver (mercury) was the soul of metals. And in the final determining the alchemists (probably through the Babylonians) used the planetary names for the metals thus:

Planet	Symbol	Metal
Saturn	♄	Lead
Jupiter	♃	Tin
Mars	♂	Iron
Sun	☉	Gold
Venus	♀	Copper
Mercury	☿	Quicksilver
Moon	☽	Silver

And from the hermetic books sprang our first knowledge of chemistry, in which the chemical contents wrap up in philosophy and religion the search for gold and the philosopher's stone. And we learn from these students that the stone was «the world in little, microcosm, man: one, a unity; three, mercury, sulphur and salt, or spirit, soul and body.» And we find the alchemists speaking of men as metals and reading such an ancient authority as Isaak Hollandus, it is difficult to differentiate between mankind and lead (which is called Saturn), but we are told by his interpreters that he must not be understood to speak of common lead but the lead of the philosophers. Great symbolists were the Rosicrucians, if we may believe what we read about them. From those who claim the origin and existence of the Rosicrucian fraternity as a probable existence of the past we are informed that the writings, 'Fama' and 'Confessio,' of the early 17th century in mentioning therein the gold which they alchemistically created it was «not the gold of the multitude but it is the living gold, the gold of God.» Symbolism, therefore, pure and simple. And later the brotherhood (in England) under Frizius and Fludd transform the ritual into Freemasonry and its symbolism is stated in the «Summum Bonum.» The Renaissance and Reform arrested the science of symbolism.

The science of heraldry is largely one of symbolism and the numerous crosses have in past days had authorities who deciphered the symbolic intent of their variants, as well as the meaning of many other «charges.» Symbolism has been applied to a language of flowers, as well as to colors, numbers, etc. And each of these fields of application have been more or less adopted by the Christian Church in its symbolism.

The term «symbolism» is used in the technique of psychoanalysis to define a certain brain reflex action, as in dreams, etc. In the science of psychoanalysis there are two spheres or states of the mental process; they are designated the «preconscious» and the «unconscious.» Much of the *unconscious* brain action is what the psychoanalyst terms «archaic,» meaning what is known to the lay world primitive or animal. Symbolism in this teaching has a very broad aspect as is disclosed by such an authority as Wm. A. White in the following expression: «For what after all is a word but a symbol of an idea and an idea but the symbol of a thing.» «Whether or not we see the symbolism of a given expression, for example, depends upon the closeness of analogy between the sign and the thing signified. The closer the analogy the less the symbolism and the less evident the analogy the more pronounced the symbolism.» «Ferenczi uses the term symbol to apply only to likenesses that have one member of the equation repressed in the unconscious.» «The idea symbolizes in mental imagery the thing in the outside world and the word symbolizes the idea. From this point of view our thinking takes place by the use of symbols.» In its action, we are told, the symbolism of a word may assume dynamic force (energy). In such dynamic symbol words are included *flag, patriotism*, etc. This medical conception and theory of symbolism is claimed to be of assistance in indicating the true inwardness of certain neuroses, as hysteria, etc.

CLEMENT W. COUMBE.

SYMBOLISTS, the name of a group of French writers and their imitators in other countries whose school arose in the eighties and at first was supposed to indicate a reaction against Parnassianism and realism. The school or rather style was inaugurated by Philippe Auguste Mathias Villiers de L'Isle-Adam (1838–89) whose play 'Axël' remains the typical drama of the Symbolists. The Symbolists are so called from their habit of introducing an object or being merely as an expression of an idea. Dreams, mythology, music, are their favorite subjects, which they commonly interpret in lyric verse. Form and expression count more with them than substance. Their characters are often degenerate, their themes repulsive, their wit redolent of the gutter and their notions of art rather subversive of morality than otherwise. They were frequently called Décadents, especially the earlier followers of Baudelaire. Jean Moréas (1856–1910) was at first one of the defenders of the principles of the Symbolists, defending them from the appellation of decadent and justifying their innovations as the natural development of the prosody of Baudelaire, Mallarmé and Verlaine. Later he returned to the older forms of versification and to the classical tradition. Other prominent figures among the Symbolists were Gustave Kahn, Catulle Mendès, De Régnier, the Belgians Mæterlinck and Rodenbach, the Americans Vielé-Griffin and Stuart Merrill, the Irishmen John M. Synge and William Butler Yeats and the Englishman Aubrey Beardsley, whose unwholesome pictorial productions certainly classify him with the Symbolists. The most beneficial innovation of the Symbolists lay in their attempts to break away from the formality and stiffness of French versification in their attempts at rhymed prose or *vers brisés*. They abandoned rhyme and the fixed traditional forms and reveled in assonance, repetition and generally attempted to make their lines the visible counterpart of their themes. (See FRENCH LITERATURE). Consult Barre, André, 'Le Symbolisme' (Paris 1911); Gourmont, Rémy de, 'Le livre des masques: portraits symbolistes, gloses et documents sur les écrivains d'hier et d'aujourd'hui' (2 vols., ib. 1914); Kahn, Gustave, 'Symbolistes et décadents' (ib. 1902); Pellissier, G., 'Etudes de littérature contemporaine' (ib. 1898); Symons, Arthur, 'The Symbolist Movement in Literature' (London 1899).

SYMBOLS, Astronomical, signs or symbols some of them very ancient, which conveniently represent astronomical objects, phases of the moon, etc., and astronomical terms. They are:

SYMBOLS OF THE HEAVENLY BODIES.

Sun	☉	Juno	⚵
Mercury	☿	Vesta	⚶
Venus	♀	Jupiter	♃
Earth	♁ or ⊕	Saturn	♄
Moon	☾	Uranus	⛢ or ♅
Mars	♂	Neptune	♆
Ceres	⚳	Comet	☄
Pallas	⚴	Star	✱

The asteroids, except the four given here, are represented by a circle with a number, thus, (64), designates Angelina, the sixty-fourth asteroid, in order of discovery.

LUNAR PHASES.

● Moon in conjunction, or *new*.

☽ Moon in eastern quadrature, or *first quarter*.

○ Moon in opposition, or *full*.

☾ Moon in western quadrature, or *last quarter*.

SIGNS OF THE ZODIAC.

Aries	♈	Libra	♎
Taurus	♉	Scorpio	♏
Gemini	♊	Sagittarius	♐
Cancer	♋	Capricornus	♑
Leo	♌	Aquarius	♒
Virgo	♍	Pisces	♓

PLANETARY POSITIONS.

Ascending node	☊	Eastern Quadrature E	□
Descending node	☋	West. Quadrature W	□
Conjunction	☌	Trine	△
Sextile	✱	Opposition	☍
Quadrature	□		

ASTRONOMICAL CONTRACTIONS.

Right ascension, R.A. Æ, or a.
Declination, Dec. or δ.
North polar distance, N.P.D.

SYMBOLS, Chemical, letters or symbols used in chemistry to designate the various chemical elements. They are merely the first letters of the names of these elements (not in every case of their English name); or when the names of two or more elements begin with the same letter, two letters are used as the symbol, one of which is always the first letter of the name of the element. Generally speaking the letters comprising the symbol are taken from the English name of the element; but in some instances, specially in the cases of metals which have been long known, the symbols are derived from the Latin names: thus we have *Hg*, symbol for mercury, from the Latin *Hydrargyrum; Fe*, from the Latin *Ferrum*, for iron; and so on. In a few cases the symbols are deduced from the old German names: thus *K*, the symbol for potassium, is the first letter of the old German word *Kalium*, and *Na*, the symbol for sodium, is from the German *Natrium*. However derived, whether from English, German, Latin or French, the symbols of the chemical elements are universally the same. For a considerable time French chemists employed the symbol *Az* to represent nitrogen, from the name *Azote*, which was given to this element in reference to the fact that it alone could not support life (Greek, *a*, privative, and *zoē*, life); but this symbol is now almost entirely superseded by the letter N. The symbols of chemical compounds are constructed by placing together the symbols of their constituent elements, a number being attached to each signifying how many atoms of the element enter into the composition of the amount of the compound expressed by the entire symbol. For it must be understood that chemical symbols have a quantitative as well as a qualitative meaning. When a chemist meets in a chemical treatise with the symbol *O* he knows that this signifies not only oxygen but a certain definite amount by weight of oxygen, *O* always means 16 parts by weight of oxygen, so *Fe* means 56 parts by weight of iron; and so also the compound symbol Fe_2O_3 means $(56 \times 2) + (16 \times 3) = 160$ parts by weight of oxide of iron. For a further account of the uses and modes of formation of chemical symbols see the article CHEMISTRY.

SYMBOLS, Mathematical, signs or abbreviations used in mathematical operations for the sake of brevity and to facilitate expression. In arithmetic and algebra there are four general kinds of symbols used; namely, those of quantity, operation, relation and abbreviation. Quantities are generally represented by letters. Known quantities are represented by the leading letters of the alphabet, or by the final letters with one or more accents, thus: x', x''', y'', etc. Unknown quantities are represented by the final letters of the alphabet, as x, y, z, etc. Besides the English letters, those of the Greek alphabet are often made use of. Certain letters have come to represent certain quantities. Thus, π generally stands for the ratio of the diameter to the circumference of circle, or the number 3.1416; e denotes the base of the Naperian system of logarithms, or the number 2.718281828; M denotes the modulus of any system of logarithms. The symbol ∞ denotes an infinitely great quantity.

Of the symbols of operation the sign +, *plus*, when written between two quantities, signifies that the second is to be added to the first; as, $a + b$. The sign —, *minus*, when placed between two quantities, denotes that the one on the right is to be subtracted from the one on the left; as, $a - b$. The sign ×, when placed between two quantities, denotes that the one on the left is to be multiplied by the one on the right; as, $a \times b$. Multiplication may be indicated by placing a point between the factors when they are both expressed by letters; as, $a.b$. This method is not applicable when the factors are numbers, because, in that case the indicated product would be confounded with a mixed decimal fraction; thus, 5.6, instead of being read, product of 5 by 6, would be read 5 and 6-tenths. There are cases, however, where the sign is used between numerical factors, as in series where the factors follow a law which it is desirable to keep before the eye: thus the general term of the binomial formula is

$$\frac{m\cdot(m-1)\cdot(m-2)\ .\ .\ .\ (m-n+1)}{1\cdot 2\cdot 3\cdot 4\ .\ .\ .\ .\ .\ n}\, a^n x^{m-n}\ .$$

The sign ÷, placed between two quantities, indicates that the one on the left is to be divided by the one on the right; as, $a \div b$. Division may also be indicated by writing the quantities in place of the points; as, $\frac{a}{b}$, or $a:b$, or a/b, $\underline{a|b}$ . . . . $x^{-n} = \frac{1}{x^n}$. The sign ~ denotes the difference between two quantities, without implying which is to be subtracted from the other; as, $a \sim b$. The sign $\sqrt{\ }$ is called the radical or evolution sign, and when placed over a quantity indicates that its root is to be taken; as, $\sqrt{a}$: the degree of the root is indicated by a number written over the sign, which is called the index of the *root* or *radical;* thus $\sqrt[3]{a}$, $\sqrt[4]{a}$, etc. The sign $\sqrt{\ }$ indicates the square root. A vinculum —, bar |, brackets [], { }, parenthesis (), etc., indicate that the quantities enclosed by them are to be regarded together; as, $(a+b)\,x$, $\left.\begin{matrix}a\\+b\end{matrix}\right|x$, etc. The symbol Σ denotes that the algebraic sum of several quantities of the same nature as that to which the symbol is prefixed is to be taken, thus,

$$\sum \frac{q}{n(n+p)} = \frac{1}{p}\left[\,\Sigma\left(\frac{q}{n}\right) - \Sigma\left(\frac{q}{n+p}\right)\right]$$

is a formula, in which p being constant and q and n arbitrary, signifies that of the algebraic sum of any number of terms deduced by attributing values to q and n is equal to $\frac{1}{p}$ multiplied by the difference of the algebraic sum of the terms, which are deduced by attributing the same values to q and n in the expressions $\frac{q}{n}$ and $\frac{q}{n+p}$. Of the symbols of relation f, F, ϕ, written before any quantity, or quantities, separated by commas, as $F(x)$, $f(x, y)$, $\phi\ (x, y, z)$, etc., denotes quantities depending upon the quantity or quantities within the parenthesis, without designating the nature of the relation. The sign of equality, $=$, between two quantities, denotes that those quantities are equal to each other. The sign of inequality, $>$, placed between two quantities, denotes that the one placed at the opening of the sign is greater than the one placed at the vertex of the sign; thus, $a > b$, a is greater than b, but $a < b$, is read: a is less than b; also, $a \not> b$, a is not greater than b; $a \not< b$, a is not less than b. The sign $\neq$ is a negation of equality; as, $a \neq b$, a is *not* equal to b. The signs of proportion :, : :, :, placed between quantities, taken two and two, show that the quantities are in proportion; thus, $a : b :: c : d$, is read, a is to b as c is to d. The first and third signs are signs of ratio, and the second the sign of equality, so that the above might be written

$$\frac{b}{a} = \frac{d}{c}.$$

Of the symbols of abbreviation the sign $\therefore$ stands for *therefore* or *hence* and $\because$ stands for *since* or *because.* Other algebraic and mathematical symbols are % for *per cent* or ‰ *per thousand;* $\int$ the symbol of integration; the Decimal, as in 5.6 (America), 5·6 (Great Britain), 5,6 (Continental Europe), meaning 5 and 6-tenths; identity $\equiv$.

Geometry borrows most of its symbols from those of algebra just explained. Magnitudes are represented pictorially; the symbols $\angle$, $\measuredangle$ are pictorial representations of *angle, angles.* $\parallel$ means *parallel to;* $\perp$ *perpendicular to;* $\triangle$, ▲, represent pictorially the terms *triangle* and *triangles* respectively; while ⊙, Ⓢ, represent *circle, circles;* □, ▣, *square, squares;* ▭, ▣, *rectangle, rectangles;* and ▱, ▱., represent *parallelogram* and *parallelograms.* Arc is represented by the symbol ⌒ and $\acute{a}$ designates radians; $\sim$ means *congruent to* and $\sim$ *similar to.* See NOTATION and consult Cantor, M. B., 'Vorlesungen über Geschichte Mathematik' (Leipzig 1910); 'Vorschläge zur Vereinheitlichtung der Mathematischen in Schilunterricht,' in 'Schiften des deutschen Ausschusses für den mathematischen und naturwissenchaftlichen Unterricht' (ib. 1913). This contains an extended list of symbols.

SYME, sīm, **James,** Scottish surgeon: b. Edinburgh, 7 Nov. 1799; d. 26 June 1870. He was educated at the university of his native city, and studied anatomy under Barclay and Liston, visiting also Paris and Germany. In 1829 he opened Minto House Hospital, which he carried on for four years with great success as a surgical charity and school of clinical instruction; and in 1833 was appointed professor of clinical surgery in Edinburgh University. In 1847, on Liston's death, he accepted the same professorship in University College, London; he soon, however, returned to his former chair in Edinburgh, and continued to hold it till his death. Among his numerous writings are a 'Treatise on the Excision of Diseased Joints'; 'Principles of Surgery'; 'Diseases of the Rectum' (1838); 'Pathology and Practice of Surgery' (1848); 'Stricture of the Urethra' (1849). Consult Paterson, R., 'Memorials of the Life of James Syme' (Edinburgh 1874).

SYMEONIS («SIMMONS»), **Henry,** the hero of the most persistent and unique feud in history: Oxford University having for nearly 600 years (till 1827) required every candidate for the baccalaureate to swear war, not even against Symeonis' posterity, but against allowing himself, centuries dead, to be «reconciled.» The only explanation hitherto given in a cyclopædia is an incredibly silly guess of Brian Twyne in 1608, that Symeon had feigned baccalaureacy before attaining it. Such a trifle would never have gibbeted him for the ages. In fact, the cause was precisely his not being a student at all. He was a wealthy citizen of Oxford, who about 1242, in the first historic «town and gown row,» killed a student and fled into exile from the vengeance of the others. Against their protest Henry III allowed him to compound for £80 (some $5,000 now) and return to stand trial. The university seems to have fought this off for nearly 20 years; and when overborne in 1264, they made this at least one grievance for most of them removing to Northhampton. Simon de Montfort on mastering the king in that year recalled them; presumably, therefore, Symeonis' permit was rescinded. At all events, the university exacted an oath from all degree men thereafter not to consent to his «reconciliation» — that is, peaceable residence in their town. It was retained after his death *in terrorem,* as a warning to all who might molest Oxford students; and at last mummied as part of a set of historic victories not to be canceled, though this one was long forgotten.

SYMINGTON, William, British engineer and inventor: b. Leadhills, Scotland, 1763; d. London, 22 March 1831. He was educated at the universities of Edinburgh and Glasgow, studying for the ministry, but abandoned that profession to become a civil engineer. In 1787 he took out a patent for an improved form of steam-engine, and in 1802, after years of futile attempts, he succeeded in propelling the tug-boat *Charlotte Dundas* by means of steam-engines with which he had fitted her. He gained the patronage of the Duke of Bridgewater, but the death of the duke in 1803 left him without the financial aid necessary to the promotion of his venture, and being unable to gain it elsewhere, he drifted from place to place, finally dying in poverty.

SYMMACHUS, Pope (498–514): b. Cardinia (?); d. Rome, 19 July 514. He was baptized at Rome, entered the ranks of the clergy and was ordained deacon. He was elected and consecrated Pope 22 Nov. 498, succeeding Pope Anastasius II. However, a minority of the Church, of Byzantine learnings, met on the same day and elected the Roman archpresbyter Laurentius as Pope, and a bitter dispute ensued. The matter was carried to Theodoric, the Gothic ruler of Italy, who decided in favor of Symmachus as having been elected first and by a majority. The Byzantian party, persisted in its efforts to seat Laurentius, established him in Rome and gained control of severr churches. It brought various charges against Symmachus, but after many sittings and much controversy the Synod reached the momentcus decision that the Pope is above temporal authority. In 505 or 506 Theodoric ordered Laurentius to surrender the churches held by him and his followers and the dispute came to an end. The remainder of Symmachus' reign was uneventful, except in the way of quiet progress. He formulated rules for the sale of Church property which were of great benefit to the Church; and his name is connected with the building or decoration of various churches in Rome.

SYMMACHUS, sĭm'ą-kŭs, **Quintus Aurelius**, Roman statesman of the 4th century. He was educated in Gaul; and after serving as quæstor and prætor became corrector of Lucania and Brutii (365) and proconsul of Africa (373) and member of the pontifical college. His petition to Gratian, urged on the Senate's behalf, for the restoration of the altar of Victory, proved unavailing (382), as did the extant letter addressed by him when præfect of the city (384) to Valentinian. The failure led him to side with the pretender Maximus (387), and for so doing he was impeached of treason, but pardoned and raised to the consulship (391). There remains of his works 10 books of letters and fragments of orations. These are contained in Seeck, ‘Monumenta Germaniæ Historica: Auctores Antiquiesini’ (Vol. VI, Berlin 1883). Consult Dill, S., ‘Roman Society’ (London 1899); Dimsdale, M. S., ‘History of Latin Literature’ (New York 1915).

SYMMES, sĭmz, **John Cleves**, American soldier and author: b. Sussex County, N. J., about 1780; d. 1829. In 1802 he entered the United States army as ensign and served through the War of 1812, reaching the rank of captain in 1813. At Niagara and the Fort Erie sortie he won distinction. After the war he lived at Newport, Ky., and passed his time in propounding his own planetary theory, which comprised the belief that planetary bodies, including the earth, consist of hollow concentric spheres open at their poles. The inside of the earth he believed to be inhabited, and he imagined an aperture (known since as “Symmes' Hole”) in the earth's crust, near latitude 82° N., communicating with the interior of the planet, where he fancied plant and animal life to exist, and which he described as being lighted with two subterranean suns, Pluto and Proserpine. Humboldt stated that he and Davy had repeatedly been invited by Symmes to descend through this hole to the earth's interior. In 1822 and in 1823 Symmes petitioned Congress for an expedition to test his theory. Jules Verne is said to have made this idea the basis for his story, ‘A Journey to the Centre of the Earth.’ Symmes advocated his views in lectures and pamphlets, and in a work entitled ‘Theory of Concentric Spheres’ (1826). Consult *Atlantic Monthly* (April 1873, ‘Symmes' Theory of the Earth’).

SYMMES' HOLE. See SYMMES, JOHN CLEVES.

SYMMETRY. From the Latin *symmetria*; proportion, symmetry; which, in turn was derived from the Greek *symmetria*, meaning agreement in dimensions, proportionate. In its present-day intent the word symmetry in the language of the laity can be defined as harmony or balance in the proportions of parts as to the whole.

Geometry.— Two points are said to be symmetrical with respect to a straight line, when the straight line bisects at right angles the straight line joining the two points. Thus in Fig. 1 the two points P and P' are symmetrical with respect to the line $M\ N$, if $M\ N$ bisects $P\ P'$ at right angles. In such a case the line $M\ N$ is termed the *axis of symmetry*. Two figures are said to be symmetrical with respect to an axis when every point in one figure has its symmetrical point in the other. Thus in Fig. 2 the figures $A\ B\ C$, $A'\ B'\ C'$

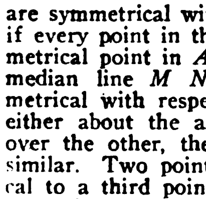

FIG. 1.

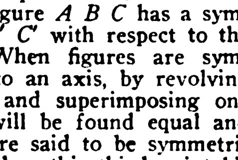

FIG. 2.

are symmetrical with respect to the axis $M\ N$, if every point in the figure $A\ B\ C$ has a symmetrical point in $A'\ B'\ C'$ with respect to the median line $M\ N$. When figures are symmetrical with respect to an axis, by revolving either about the axis and superimposing one over the other, they will be found equal and similar. Two points are said to be symmetrical to a third point, when this third point bisects the straight line joining the two points. Thus in Fig. 3, P and P' are symmetrical with respect to A, if the straight line $P\ P'$ is bisected at A. And the point A is called *the* *centre of symmetry*. Two figures are said to be symmetrical with respect to a centre, when as in Fig. 4, the triangles $A\ B\ C$, $A'\ B'\ C'$ are

FIG. 3.

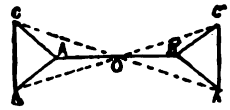

FIG. 4.

symmetrical to the centre O, and every point in the triangle $A\ B\ C$ has a symmetrical point in $A'\ B'\ C'$. A figure is symmetrical with respect to an axis when it can be divided by that axis into two figures symmetrical with respect to the axis. And a figure is said to be symmetrical with respect to a centre when every straight line drawn through that centre cuts the figure in two points symmetrical with respect to this centre. In solid geometry when two planes intersect they are said to form a *diedral angle*. When three or more planes meet in a common point, they are said to form a *polyedral angle* at that point. Two polyedral angles are symmetrical, when the face and diedral angles of one are equal to the face and diedral angles of the other each to each, but arranged in *reverse order*. As example the triedral angles $S\ A\ B\ C$ and $S'\ A'\ B'\ C'$ (in Fig 5) are symmetrical when the face-angles

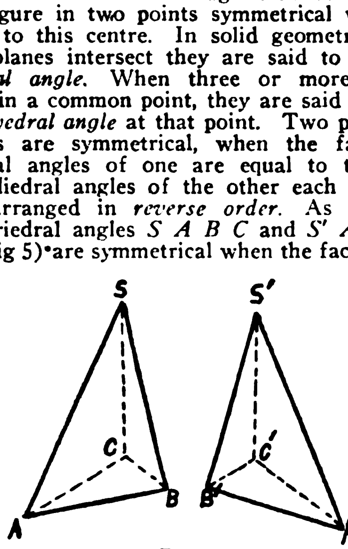

FIG. 5.

$A\ S\ B$, $B\ S\ C$, $C\ S\ A$ are equal respectively to the face angles $A'\ S'\ B'$, $B'\ S'\ C'$, $C'\ S'\ A'$ and the diedral angles $S\ A$, $S\ B$, $S\ C$ to the diedral angles $S'\ A'$, $S'\ B'$, $S'\ C'$.

Symmetrical spherical triangles are those in which the sides and angles of the one are equal respectively to the sides and angles of the other, but arranged in the reverse order. Thus the spherical triangles $A\ B\ C$ and $A'\ B'\ C'$ (Fig. 6) are symmetrical when the vertices of

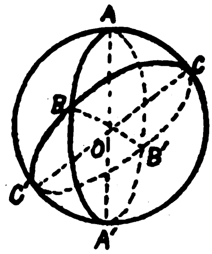

FIG. 6.

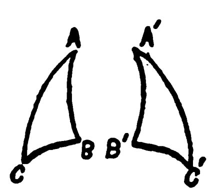

FIG. 7.

the one are at the ends of the diameters from the vertices of the other (antipodal). Two symmetrical triangles are mutually equilateral and equiangular; yet in general they cannot be made to coincide.

In algebra «a function of several quantities which is not changed when any two of the quantities are interchanged, such as Σa, a_2, is called a symmetric function of the quantities. Such a function of the roots of the equation has been designated by enclosing the exponents in brackets, expressing the repetition of a number by an exponent: thus Σa^3, $a^3_2 a^3_3 a_4 a_6 — a6$ is written $[3^2 2\ 1^3]$. In particular, a symmetric function of the form $[K] = a^{k_1} + a^{k_2} + \ldots . a^{k_n}$ is called an elementary function» (Decker).

Physiology.— In the science of biology animals are distinguished as *Radially* symmetrical; *bilaterally* symmetrical; *serially* symmetrical; *assymmetrical*. This is a division according to their structure internally and externally. In a *radially* symmetrical animal such as a jelly-fish, the body can be halved by a number of vertical planes — it is symmetrical around the median vertical axis. In other words it is of the same conformation all round possessing neither right or left side. In a *bilaterally* symmetrical body, such as that of the human, it is possible to equally divide the body in halves through one plane only. In some animals the body is marked off in transverse grooves creating a series of similar parts like the joints of the human finger or of the bamboo. This is a process termed in biology *metamerism* or *serial symmetry*, closely associated with the worm family. Biologists teach the theory that the evolution of these different symmetrical functions are in accordance with the proportionate inertia or energy inherent in the different animals. Thus in the simple sponges, *Cœlentera* (see SEA-ANEMONES; JELLYFISH), and in the *Echinoderms* (sea-urchins, etc.), we find radial symmetry, also it is characteristic of the very common embryonic stage known as the *gastrula* (an oval or thimble-shaped sac which constitutes two layers of cells). Thus radial symmetry belongs to the sedentary animal life, the life without motive energy, often floating and drifting. Whereas the animals of bilateral symmetry have the advantages of mobile activity in the search for food, as well as power of escape from their enemies by energetic motion in definite directions. In plant life we also find symmetrical qualities in the organism but only rarely in the strict sense as in animal life. It approaches the true condition most nearly in many flowers, leaves and stems with decussating whorls. Two, three, four or a large number of symmetrically dividing planes often pass through one member, as a shoot or root, all of which intersect in the axis of growth. These members are termed *polysymmetrical*. The characteristic is found in the so-called «regular flowers,» in stems with alternating whorls and in most roots. Ferns, etc., can be divided bilaterally. showing a repetition of similar parts on either side, but the symmetry is not exact.

Mineralogy.— One of the most important branches of the science of mineralogy is crystallography which deals with the angular construction of crystals. The *faces* or outer surfaces of crystals are arranged according to certain laws of symmetry and, based on these natural laws of symmetry, crystals are divided into groups and systems. As in geometry, the relationships of the planes to one another are brought under the heads of the *plane of symmetry;* the *axis of symmetry* and the *centre of symmetry.* All may be combined in the same crystal, some have neither characteristic. Study of the conditions has brought the conclusion that there are 32 natural groups among crystals based upon their symmetry. As to *planes of symmetry* in crystals, these occur when for each face, edge or solid angle there is another similar face, edge or angle which has a like position with reference to this plane. Thus in a crystal of amphibole it is symmetrical with reference to a central plane of symmetry and, in ideal cases, it is called the *right symmetry,* having for every point on one side of the plane of symmetry its corresponding point at equal distance on the other side. Each half is a *mirror image* of the other half. In some crystals may be found as many as nine planes of symmetry, three of one set and six of another; this is exhibited in the cube. As to *axes of symmetry,* these occur in crystals when, as in geometry, a solid can be revolved through a certain number of degrees about some line as an axis and, as a result, it again occupies precisely the same position in space as at first. There are four different kinds of axes of symmetry in crystals, each defined according to the degrees in angular revolution needed, in other words according to the number of times the crystal repeats itself in a complete revolution of 360°. Thus the axes are *binary, trigonal, tetragonal,* etc. As to the *centre of symmetry,* most crystals have besides planes and axes of symmetry or without either, a symmetry with reference to a point, its *centre,* as in the triclinic crystal in which every face, edge and solid angle in one half has a face, edge and solid angle in the other half. In such crystal form the geometrical conditions are termed *compound symmetry* with reference to an axis of binary symmetry and a plane normal to it, if the crystal is calculated as divided into two similar halves by a plane parallel to any one of its faces and one half be revolved 180° about an axis normal to this face. Crystals are said to exhibit *pseudo-symmetry* when their angles apparently approximate in symmetry to the requirements of a system higher in symmetry than that to which in fact they belong. The micas show this tendency, being truly monoclinic in crystallization yet in angle appearing, at times, rhombohedral or orthorhombic. Grouping crystals according to their symmetrical forms crystallography creates the following divisions: Isometric system; tetragonal system, hexagonal system, orthorhombic system, monoclinic system and triclinic system. See CRYSTALLOGRAPHY.

Symmetry in Art.— In this subject, as in all art matters, we have to go back to the classic Greeks, from whom, as we have seen, the word symmetry itself is derived. And in art circles for numerous generations the term has been the subject of much controversy, hence, according to the evidence introduced and the strength of the theory advanced, the intent of the word among art experts has changed from period to period. As Viollet-le-Duc says, it used to mean "precise relation between the measurements, harmony, moderated relations, calculated, in view of resulting satisfaction for the mind and eyes. . . . Symmetry to-day says, in the language of architects, not a ponderation, harmonious relations of the parts of a whole, but a similitude of the opposed parts, the exact reproduction on the right side of an axis of that on the left." The Roman architect Vitruvius (1st century A.D.) wrote: "As to symmetry it is a proper accord of the members, of works among one another, and of separated parts, the relation of each of the parts with the whole, . . ." Vitruvius defines the Greek *symmetros* as "qualitas eurythmiae." But eurythmy means harmony, just proportion, more precisely "correct rhythm." This is the Greek sense of the word *symmetria,* but the great superiority of Greek over all other art has been claimed to be the artists' subjection to symmetry through the *modulus* used as a yard-stick. No doubt, both in their architecture and sculpture, the Greeks had a *system,* for comparative measurements absolutely prove this, but, as Viollet-le-Duc claims, the Greeks had no idea of symmetry as "a kind of decalcomania or counterpart"; theirs was altogether a different idea. It was "a harmony of measures, and not a similitude or repetition of parts." Their symmetry was "a relation between established measurements and adopted rhythm." In architecture of great public edifices in which the Greek classic orders figure there is generally a *centre of symmetry* found, as in a bisection from the apex of the pediment of the temple forms, or an axis of symmetry revolvable around the centre of the boss above the roof of the choragic monument of Lysikrates, etc. The decorative features must, therefore, in harmony follow the similar restricted spaces framed in the right and left ends by the angles of the pediment, by opposed recumbent figures or other triangular designs. But these Attic artists and sculptors showed a freedom from mathematical preciseness that pleases and rests the eye while leaving an appearance of the closest exactitude to measure. Treated from the æsthetic viewpoint, symmetry of geometric accuracy in art palls on the senses and, with our modern love of freedom and revulsion against restrictions, we find the periods in art fluctuating from the stern lines of classic masters and taking flights into fantastic opposed methods as in the case of the rococo style or the baroque orgy of unfettered freedom and degraded license and symmetry thrown to the winds. Symmetry is imposed on the designer of wall papers; landscapes (at times), and gardens to this day show tendencies to symmetry imitative of Dutch method of treatment of past days. And in interior decorative and furniture arrangement we find the idea of symmetry prevalent, chairs and other seats as well as mantle ornaments being in *sets.* Lovers of untrammeled art look to the Far East, and especially Japan, for the breach from symmetry in art. There we find symmetrical arrangement, outside of that necessitated in architecture, altogether absent. In the realm of Occidental painting we find the great masters freely grouping their personages in genre work, though in religious work the main figure (we had almost said the *central* figure) is liable to appear in the rather exact middle point, and the surrounding figures are apt to be divided about equally on either side, giving symmetrical balance, probably a habit formed through the many years in which such depiction was *arranged* to cover spaces in churches. To sum up, symmetry would seem to have a dubious place in art, outside of architecture, according to recent ideas. The asymmetric art methods of the Japanese have produced a powerful reaction in our Western æsthetic tastes and the severities of geometric proportion in art design have lost their hold on the minds of this century's artists and patrons. The conception that symmetric balance smacks of *patterns* quite popularly prevails and recent schools are revolutionary in accord with the times.

CLEMENT W. COUMBE.

SYMONDS, sĭm'ŏndz or sī'mŏndz, **E. M.** (GEORGE PASTON), English novelist. She has published 'A Modern Amazon' (1894); 'A Study in Prejudices' (1895); 'The Career of Candida' (1896); 'A Fair Deceiver' (1897); 'A Writer of Books' (1898); 'Little Memoirs of the 19th Century' (1902); 'Sidelights on the Georgian Period' (1902); 'George Romney' (1903); 'The Pharisee's Wife' (play, 1904); 'R. R. Haydon and his friends' (1905); 'Clothes and the Woman' (play, 1907); 'Lady Mary Wortley Montagu and Her Times' (1909); 'The Pope: His Life and Times' (1909); 'The Naked Truths' (play, 1910); 'Nobody's Daughter' (play, 1910).

SYMONDS, John Addington, English author and critic: b. Bristol, 5 Oct. 1840; d. Rome, 19 April 1893. Graduated from Balliol College, Oxford, in 1860, he was elected Fellow of Magdalen in 1862, undertook but abandoned legal studies, and entered literature as a profession. For many years he was compelled by ill-health to reside at Davos-Platz, canton of the Grisons, Switzerland. His studies were largely concerned with the Renaissance and the representative personages of that period. His chief work is the 'Renaissance in Italy' (1875–86), a historical narrative with mingled criticism. Its scholarship is very accurate and comprehensive, and its insight into the spirit of the time and movement is notably acute. If it fail in well-roundedness and system some excuse may be found in the complexity of the subject and some reparation in the brilliancy of individual passages. Other volumes in this general field are 'An Introduction to the Study of Dante' (1872); 'Shakespere's Predecessors in the English Drama' (1884), an excellent contribution to the history of English literature; lives of Sidney (1887) and Jonson (1887) in the 'English Men of Letters' series; of Michelangelo (1893) and Boccaccio (1895); and English renderings of the 'Sonnets of Michelangelo and Campanella' (1878) and the 'Autobiography of Benvenuto Cellini' (1888). Others of Symonds' works are 'Studies of the Greek Poets' (1873–76), designed for the popular reader and approaching Hellenic literature through the individuality of the authors; 'Sketches in Italy and Greece' (1874); 'Sketches and Studies in Italy' (1879); 'Essays, Speculative and Suggestive' (1890); 'In the Key of Blue,' essays (1893); 'Walt Whitman' (1893); and three books of verse, 'Many Moods' (1878); 'New and Old' (1880), and 'Vagabunduli Libellus,' a collection of sonnets (1885). Symonds' critical work is marked by a finished style and a distinctive note of liberal culture. Consult the 'Life' prepared from correspondence by H. F. Brown (1895); Herbert Warren in Miles' 'Poets and Poetry of the Century'; Brooks, V., 'J. A. Symonds: A Biographical Study' (New York 1914).

SYMONS, sĭm'ŏnz, **Arthur,** English poet and critic: b. Milford Haven, Wales, 28 Feb. 1865. He has written 'Introduction to the Study of Browning' (1886); 'Days and Nights' (1888); 'Silhouettes' (1892); 'London Nights' (1895); 'Studies in Two Literatures' (1897); 'The Symbolist Movement in Literature' (1899); 'Collected Poems' (1901); 'Cities of Italy' (1907); 'The Romantic Movement in English Poetry' (1909); 'Knave of Hearts' (1913); 'Figures of Several Centuries' (1915); 'Tragedies' (1916); 'Tristan and Iseult' (1917). He has edited the essays of Leigh Hunt, the plays of Shakespeare, etc.

SYMONS, George Gardner, American artist: b. Chicago, 1865. He received early training at the Art Institute, Chicago, and at Paris, Munich and London. His work was awarded numerous medals and prizes, and he was elected National Academician in 1914. He is represented by 'The Opalescent River' in the Metropolitan Museum, New York City, 'Sorrow' in the Cincinnati Museum, 'Snow Clouds' in the Corcoran Gallery, Washington, and 'The Winter Sun' in the Art Institute, Chicago.

SYMPATHETIC STRIKE. See STRIKES AND LOCKOUTS.

SYMPATHY, is in itself feeling felt, and became possible only after human reason began its operations. As feeling, its discussion belongs to psychology; as a sociogenetic power, its consideration is sociological; as a "motive principle of judgment" (Höffding), it is the concern of the moralist. In any article such as this, it is almost unavoidable to discuss the subject, without at one and the same time involving all three approaches to the consideration of the meaning of sympathy; and here no attempt will be made to avoid such a union. As feeling, sympathy is a secondary, it is a representative pain. It is an echo in one's self of the pains of others. Hedonism of all forms misconceives the relation that obtains between pleasure and pain as being analogous with that which obtains between heat and cold; and indeed in some respects pain and pleasure are counter-parts. But they are not like heat and cold in so far as the one is not the same as the other, differing only in degree. There obtains here a difference which is one of a kind, not merely of degree.

That sympathetic pain depends for its possibility upon the human rational powers admits of no doubt. For the syllogism of sympathy is this: (a) A given influence produces pain or pleasure in me. (b) You are like me. (c) Therefore, the same influence will produce pain or pleasure in you. True, this reasoning in and of itself, is feelingless. But to constitute a motive to activity, such as sympathy developed into altruism may exhibit, there must be first developed a reflex responsiveness, such that previously experienced sensations of pain or of pleasure caused by one influence shall be remembered and revived, shall be repeated as part of a series of sensations that are caused by the influence itself.

It might be an idle speculation to attempt to ascertain the very earliest form of sympathy. However, one may feel certain that it is the reverse of Herbert Spencer's idea which is that sympathy grew out of «love of the helpless.» It is, however, quite probable that «love of the helpless» was one of the earliest manifestations of sympathy, just as light sometimes is evidence of electricity. Perhaps sympathy was first felt in the heart of woman as mother with her strong motive love for her offspring, which natural love, though in itself an entirely different faculty, early enough blended with or helped to create a derivative reason-born sympathy. Altruism differs from sympathy in another way. Sympathy is not necessarily a desire. It is simply a feeling, even though a feeling depending on the rational process, for its existence. True: it naturally enough suggests action. But being a pain, like other pains that are *not desires*, it naturally but not necessarily gives rise to a desire to act in such a way as to cause relief from pain. As such it is the concern of the sociologist. And as said before, it involves an intellectual operation, a knowledge of how one should act to attain an end. Altruism is complex, it is sympathy to which is added desire for activity. It is not only painful feeling, it is also motive. David Hume treated the passions as an essential part of «human nature,» making much of sympathy, as was likewise done both by Ferguson and Adam Smith, later by Bentham, and in more recent times by Professor Höffding, each from his own special point of view. Not a few ethical students conceive of sympathy as the parent of most all the moral sentiments; and sympathy is then in turn derived from love of kindred. Sympathy has it seems its seat in the general emotional tracts, in the great sympathetic plexuses, of which there are so many, and of such very wide distribution in the human system. It is, however, as yet impossible to locate these plexuses, and assign to them particular sentiments — a localization which of course assumes the hypothesis that the system has attained a sufficient degree of specialization to localize sentiment at all. Altruism, in so far as it is not purely biological, is without doubt rooted in sympathy. This latter, as has often been noted, is not seldom conceived in its turn as the bases of all morality excepting race morality. One may well believe that without sympathy all moral reform would be impossible. Just as «Love of the helpless» can only be experienced by a highly rational being, so its root (not its blossom), which is sympathy, is a product of a high rational power of intellectual activity capable not only of representing to self the painful states of others, but also of experiencing the reflex of such representations in one's self as a form of pain. For it requires a power of putting one's self in the situation of another, to represent to one's self the pains of others. When once such power is acquired, it causes a reflex of the represented pain to self and this reflected pain felt by one representing it becomes more and more sharp and unendurable as the representation becomes more vivid, and as the general organization of a human being becomes more delicate and more refined. Such high degree of differentiation was, one may be sure, far from being attained at an early stage of human development, a fact, which, it may be mentioned, explains such vicious and abnormal institutions as the savage subjection of women. Civilization has been, and may indeed be, measured by the capacity of men for suffering representative pain or sympathy and by their efforts to relieve it. For in the merely animal kingdom it may be suspected that there is scarcely any, if there is any, sympathy with suffering at all. And yet as the fine painting by Landseer of a «Sick Monkey» illustrates, one may well hesitate to pronounce that feelings of sympathy are entirely alien to the animal world.

SYMPHONY, an elaborate musical composition for a full orchestra, consisting usually, like the sonata, of three or four contrasted yet inwardly related movements, as an andante followed by an allegro, another andante varied or an adagio, a minuet with its trio or a scherzo, the whole composition closing with a lively rondo or rapid finale. The symphony, which may be regarded as the highest kind of musical composition, was unknown in its present form before the time of Haydn, who with Mozart, Mendelssohn and Beethoven are the most successful composers of this class of compositions. The nine symphonies of the latter are generally recognized as being the noblest works of their kind. The term symphony is also frequently applied to short introductory or closing instrumental passages in compositions which are predominantly vocal. See MUSIC; ORCHESTRA.

SYMPIESOMETER, a kind of barometer in which the weight of the air is indicated by the compression of gas in a tube, the lower part of the tube being filled with some oily fluid and the gas occupying the upper portion.

SYMPOSIUM, The. In the 'Symposium' Plato tells the story (in the main fictitious, no doubt) of a banquet given by Agathon in celebration of a tragic victory on the stage. Instead of the usual diversions over their cups the guests propose to entertain themselves with successive encomiums of Eros, the god of love; and of these speeches is formed the bulk of the dialogue. The most notable of the earlier discourses is that put into the mouth of Aristophanes, the comedian, in which occurs the humorous myth (not without deep significance) of the creation of man as a rounded whole, with four arms, four legs, etc., and of his slicing afterward by Zeus into two half-beings, male and female, who are driven by love to endeavor to reunite themselves once again into a perfect whole. When called upon last, Socrates, with his customary irony, protests his ignorance, but consents to regale the company with a tale he pretends to have heard from a certain wise woman of Mantinea. According to this prophetess, Eros is the offspring of the god Poros («Plenty») and the mortal Penia («Poverty»); he is thus not properly a god, but a mighty daemon, or intermediary being, whose office it is to form a link between the eternal bounty of heaven and the conscious imperfection of mankind. Love, the allegory would say, is not the happiness of possession — for such happiness belongs only to the gods — but the unsatiated longing to possess. By its creative power it is man's substitute for immortality; for if the individual must perish, yet he is permitted by love to continue his existence in his children. It is the source of art, leading men to satisfy by the creation of beautiful forms their innate longing for the absolute beauty they can never possess. It is also the cause of philosophy. He is not a philosopher, but a god, who knows the truth; nor is he a philosopher who is unaware of his ignorance; rather, the philosopher is he, who, being aware of his ignorance, is driven on ever by the soul's thirst for the truth, to learn and to raise his life into one continual communion with the world of ideas. Whether later in date of composition or not, the 'Symposium' is logically a sequel to the mythological portions of the 'Phædrus.' In the earlier dialogue Socrates tells how in some remote age the soul of man, in its winged chariot, followed the procession of the gods to the summit of the celestial vault, and from there beheld the everlasting ideas of truth and justice and beauty and the like, of which things true and just and beautiful in this world are the shadowy transient images. And so, when a man sees some fair object or person, love is awakened in his soul as a reminiscence of that half-forgotten vision. In the 'Symposium' the mythical nature of love as a reminiscence is less emphasized, but its dynamic and philosophic function is developed in splendid imagery. Without this emotional quality, as it is worked out here and as it is suggested in other dialogues, the ideas of Plato would be a curious theme for the metaphysician; with the introduction of love as the force driving us to participation in their divine nature, the philosophy of Plato is transformed into something that has enthralled poets and artists and entered largely into the rapture of the saints; it has become one of the molding influences of civilization. But it cannot be said that this influence has been entirely for good. From this source has come the popular notion of «Platonic love,» which has acted as a befuddling and enervating ferment in society. It is fair to add that Plátonic love, as most of the poets have understood it, is the very reverse of what Plato himself had in mind. Petrarch, for instance, would absorb the universe into his passion for a woman; Plato would forget the woman in his pursuit of ideal beauty. It is right to remember also that the conclusion of the 'Symposium' contains the extraordinary confession of Alcibiades, in which, as if Plato was concerned to remove any misunderstanding of his doctrine, Socrates is pictured as the stalwart soldier and as a lover, proof against every seduction of the flesh, a man of iron character above all. Nevertheless Plato's language, when dealing with the passion of beauty, is sometimes unguarded. The 'Symposium' is commonly regarded as Plato's most perfect literary production, as perhaps the most perfect piece of prose composition of any age or in any tongue.

PAUL ELMER MORE.

SYMPTOMS, *in medicine,* the phenomena from which are inferred the existence and nature of disease. Symptoms have their seat in the functions which are affected by the disease so as to be raised above their usual activity, or depressed below it, or even to become changed in the nature of their action. The organs themselves are often changed in their appearance, structure, size, etc. Symptoms may be perceptible by the patient alone (for example, pain and all change of sensations), or by the physician also (for example, all diseased movements). The more a function or an organic system is extended through the body, the more frequently will it be the seat of morbid phenomena. The nervous, the vascular and the cutaneous systems, for instance, are affected in most diseases; hence also irritability, the power of nutrition, etc., which extend through the whole organization, are so easily affected by diseases, and thus afford symptoms. If the latter are in the organs originally affected they are called idiopathic; but if they are caused by sympathy with other and distant parts, they are called consensual or sympathetic. The temperament, age, sex, mode of living, etc., of the patient produce a considerable variety in the symptoms of every disease. When they are indubitable signs of a particular disease, symptoms are called pathognomonic.

SYNAGOGUE. See JEWS AND JUDAISM.

SYNAPTA, a genus of a group of holothurians distinguished by the non-development of an *ambulacral system.* Locomotion in *Synaptæ* is effected by the muscular contractions of the body, aided by the presence in the skin of anchor-shaped spicules of lime, which these animals use to fix one portion of the body, while the other portion is pulled forward. These animals live in muddy coasts and form mud-cases. See HOLOTHURIA.

SYNCHRONIZER, an instrument in common use in electric-generating stations employed to indicate the relation between the frequency of two or more alternating current generators and especially to show when a generator is operating at the same frequency as others with which it is the desire of the engineer to connect it, in the same circuit. A variety of the instrument is also employed to determine when the voltages of two circuits are in phase with each other. A common form of the instrument is a small motor the armature of which is connected to one generator and the field-windings to another. By an arrangement of armature coils a rotating field is produced which turns the armature in one direction or the other according to the difference in phase between the circuits. A pointer turned by the armature shows which generator is fast and which slow. Another form consists of two incandescent lamps connected in the two circuits in such a manner that they light up or remain dark when circuit is closed. Consult Jansky, C. M., 'Electrical Meters' (New York 1913) and Edgcumbe, K. W. E., 'Industrial Electrical Measuring Instruments' (ib. 1908).

SYNCHRONOGRAPH. See TELEGRAPH

SYNCHRONOUS MOTOR. See ELECTRICAL TERMS.

SYNCLINE. See FOLD.

SYNCLINORIUM. See FOLD.

SYNCOPATION, *in music,* an alteration of the rhythm, by driving the accent to that part of a bar not usually accented.

SYNCOPE. See FAINT.

SYNCRETISTIC CONTROVERSY, the name given in church history to the disputes which attended prolonged and repeated efforts in the 17th century to bring about the union of all Protestant churches. George Calixtus, professor of theology at Helmstadt, was the author of the proposition, which was brought forward at intervals from 1645 to 1686, when the discussion was finally abandoned. See LUTHERANISM.

SYNDIC, (1) in government and commerce, an officer in various countries entrusted with the affairs of a city or other community, company of art or trade, etc., who calls meetings, makes representations, etc. (2) Also a person appointed to act in some particular affair in which he has a common interest with his constituents, as when he is one among several creditors of the same debtor. Mayors of Italian towns bear the title of syndic.

SYNDICALISM, a political and industrial doctrine which demands that the means of production, distribution and government shall be turned over to all those workers who are actively useful and necessary in the community. There are many different views on the subject, held by the opponents and believers in the movement, but a general description is aimed at here. It is antagonistic to every other form of control, whether by government, existing labor unions or by capital. The motivating and regenerating force of syndicalism is to come from the enthusiasm of the workers themselves. It distrusts organization, delegates and all forms of leadership except that of the propagandists. Force is the basis of society, and this weapon is to reform the world. The first objective aim is to eliminate the present owners of production. The means to accomplish this vary in the theories of different exponents of the doctrine, but they may be generally outlined here. Sabotage, boycotting, strikes (qq.v.) and disturbances of all kinds are legitimate. They propose first, by anti-militarist propaganda, to avert the possibility of armed suppression, and then to use their ultimate weapon, "the general strike." This demands the stoppage of every activity and the consequent crippling of the entire government, which, bereft of armed force, will be compelled to capitulate to the working class. This having been accomplished, they then propose to abolish property and masters; level the reward of all work; and carry on trade, production and education by trade unions and local organizations. Syndicalism differs from socialism in that the former demands social revolution through incited labor to abolish capital; whereas the latter expects to work reform through political agitation by gaining majorities in existing governments. Furthermore, Socialism aims at further centralization of government control and depends on rich unions with capable leaders, while Syndicalism prefers poor unions and actual leveling of authority. It differs from the I. W. W. movement in that in its constructive policy it aims at decentralization of trade power, instead of one tremendous all-embracing union of workers, modeled on the lines of capitalistic organization. The movement began in France in 1892, where prior to the European War there were 600,000 avowed Syndicalists. From France it spread to Italy where it was taken over chiefly by the agriculturists who at the same period owned 200,000 acres of tillable lands farmed on the co-operative plan; and the entire railway system was under the influence of Syndicalists.

The movement has a large following in England, some 60,000 being present at a conference held before the war. In America a similar movement began under the direction of the I. W. W. Russia has many different classes of labor agitators,— the Bolsheviki embody many Syndicalist principles. Traces of it are found also in Spain, Greece and Latin America. Consult Brooks, T. G., 'American Syndicalism' (1913); MacDonald, 'Syndicalism' (1913); Lewis, A. D., 'Syndicalism and the General Strike' (Boston 1912); Clay, Sir Arthur, 'Syndicalism and Labor' (London 1911); Challaye, F., 'Syndicalisme revolutionnaire et syndicalisme dans l'evolution sociale' (Paris 1908); Harley, J. H., 'Syndicalism and the Labor Unrest' (in the *Contemporary Review*, March 1912); Kleinlein, Andreas, 'Der Syndikalismus in Deutschland' (Brussels 1912); Lanzillo, A., 'Le movement ouvrier en Italie' (Paris n. d.), and the works of Georges Sorel.

SYNDICATES, a name given in the United States to those combinations of capitalists organized for the purpose of controlling production and raising prices. The term is also used of associations which buy a literary or artistic product outright from the author and market it to subscribers simultaneously in non-contiguous parts of the country. Perhaps the most familiar example of this is the colored Sunday Supplements which appear in different journals on the same day at points throughout the continent from the Atlantic to the Pacific.

SYNDROMES, Endocrinous. The conceptions concerning the push that lies behind the metabolism of the human body even in recent years have been all too elementary and simplistic. They have, however, slowly and gradually undergone modification until the importance of a number of overlooked structures have forced themselves within the past 10 years (1910–20) almost with a rush upon the medical horizon. These structures are the endocrinous glands or the hormonopoietic system. Their study now constitutes an enormous specialty.

As early as 1828 Parry called attention to the relationship between enlarged thyroid and rapid heart beat, since which time the works of Johannes Müller, Addison, Gull, Brown-Séquard, Marie and many others have served as starting points for the building up of a rich structure which is amply recorded in a score of monographs. The chief of these are Biedl, 'Internal Secretions' (bibliography of 4,000 titles, 1913); Falta, 'Ductless Glands' (1915); Parhon et Golstein, 'Les Sécrétions Internes' (1909); Levy and Rothschild, 'Endocrinologie' (1913); Gley, 'Les Sécrétions Internes' (1914); Sajous, 'Internal Secretions'; Pende, 'Endocrinologia,' and the special articles in Lewandowsky's 'Handbuch der Neurologie' (1913). In addition to these a large number of special monographs upon the individual organs have been written all of which may be found in the works here quoted in the *Bibliography*.

Out of this prodigious development, much of which is evanescent and hastily constructed, a large amount of solid substance remains and a number of permanent acquisitions have been made. The net result has been to show much more essentially than ever before the fundamental physicochemical foundations of biological metabolic processes as they are utilized in the upkeep of the animal machine. The viewpoint has been attained that a marked degree of chemical interrelationship takes place between the different organs of the body. That this is automatically regulated through the vegetative nervous system (the old sympathetic) chiefly, apparently in some cases, though this is by no means clear, solely through chemical regulation. The disorders of this adjustment now constitute a special department of vegetative neurology, and are most conveniently grouped under the terms endocrinology, or the endocrinopathies.

In the earlier period of the study of these endocrinopathies individual disease groups, uniglandular syndromes, were isolated. Among the most accentuated of these were Addison's disease, diabetes mellitus, myxedema, cretinism and acromegaly, but of recent years it has been increasingly emphasized that whereas a certain group of symptoms, which may be linked to plus or minus activities of one or another gland may be most prominent, nevertheless other glandular modifications are bound up in them and are not to be neglected. Hence has arisen the viewpoint that most of the endocrinopathies are, strictly speaking, poly- or pluri-glandular syndromes.

For many years, even back to the earliest days of primitive animistic magic, it has been held that every living tissue yields a chemical product which will act upon other tissues. The early alchemistic studies, those of Paracelsus, to the latter work of Hahnemann, and the isotherapists, are all attempts to co-ordinate a host of empirically observed facts. They are all worth rereading if the reader will put himself in sympathy with them through a comprehension of the now strange symbols then used.

Endocrinous glands for the present purposes are those structures which yield products termed hormones and chalones having some definite or specific action related to, yet different from, enzyme activities. These structures are developed from different embryological formations. The hypophysis (posterior lobe) and chromaffin tissues (suparenal chiefly) are nervous; the thyroid and pituitary (anterior lobe) come from the buccal cavity; the pancreas and mucosa of the small intestine from the intestine, the parathyroids and thymus from the branchial arches (old gill slits of fishes), the gonads (testes and ovary) and the interrenal bodies from the genital ridges. Some of these, in humans, merge into one structure, as thyroid and parathyroid, as chromaffin and interrenal cells in the suprarenals, as hypophysis (posterior lobe) and pituitary (anterior lobe).

The present article will attempt to sketch only the general outlines of the various uniglandular and pluriglandular syndromes. The more radical French school is followed, but at the same time attention should be called to the fact that the French school presentations contain gross fallacies, and should be read *cum grano salis*. Still the clinical suggestions of these writers are so rich that it is felt to be a better course to call the attention of the physician to possible relationships rather than to take the more conservative attitude of directing attention only to that which can be indubitably proved. This whole subject is still so largely empirical that the principle of putting the hypotheses to a test will be found to be more advantageous than that of believing only the obvious. The former attitude may result in gaining useful therapeutic truths, the latter becomes monotonous and frequently encourages stupidity.

The more recent suggestive and extreme summaries of Biedl, Falta, Laignel-Lavastine, Levi and Rothschild are therefore here summarized.

Uniglandular Syndromes.— *Thyroid.*— Myxedema.— The chief symptoms are arrest of development, dwarfism, infantilism, infiltration of skin and mucous membranes, mental torpor, slow ideation, defective memory, apathy, laziness, slowness, sleepiness, taciturn, awkwardness. The pulse is usually small, rapid and irregular, at times increased tension. There are constipation, diminished urination, hypothermia and chilliness of the skin. Reflexes diminished. The voice is frequently nasal, slow, monotonous and raucous. Headache is frequent and at times epileptic attacks occur. These are all symptoms of diminished secretion.

Exophthalmic Goitre.— A more or less complete catalogue of findings for a lot of cases will include tachycardia, arrhythmia, anxiety, pulsations in the neck, exophthalmos, epiphora, v. Graef's, Stellwag's, Möbius' symptoms, facial paresis, cramps, tremors, neuralgias, chiefly frontal and ocular, colic, hot flashes, profuse sweats, thermophobia, engorgement of the skin, dermographism, transitory edemas, pigmentation, urticaria, alopecia, diminution of electrical resistance, albuminuria, polyuria or glycosuria, anorexia, bulimia, vomiting, ptyalism, hyperchlorhydria, diarrhea, dyspnea, amenorrhea, atrophy of mammæ, loss of flesh, agitation, emotional instability, volubility, insomnia, anxiety, excessive anger or reverse, maniacal excitement, marked depression, cyclothymic variations, confusion, epileptic attacks. Eppinger and Hess have endeavored to separate a vagotonic and sympathicotonic type.

In the vagotonic type the more prominent signs are decreased lacrymation, less exophthalmos, with enlargement of the palpebral fissures, v. Graef's sign, abundant sweating, diarrhea, mild tachycardia, no alimentary glycosuria, pilocarpine and oculocardiac reflexes positive. In the sympathicotonic types there are exophthalmos, dryness of eyes, violent tachycardia, glycosuria, oculocardiac reflex reversed or absent, increased reaction to adrenalin. Most cases are mixed in type. In all save infectious forms psychical influences are striking and psychotherapy is extremely valuable in the early stages, less so in chronic cases. Money worries bulk large in the etiology of the psychogenic cases.

Thyroid insufficiencies, other than those of myxedema, are infantilism, obesity, Dercum's syndromes, pseudolipomata, alopecia, precocious loss of hair, scleroderma, urticaria, pruritus, recurring herpes, transitory edemas, migraine, asthma, constipation, mucous enterocolitis, acrocyanosis, Raynaud's syndrome, localized erythemas, rhinorrhea, glucose tolerance, genital instability, chilliness, mammary hypertrophy.

Thyroid Instability (Levi and Rothschild).— From dyshypothyroidism: chilliness, baldness, headaches, depression, crying, giddiness, passing edemas, neuralgic pains, suffocations, shivering, hot flushes, at menstrual period. With predominant dyshyperthyroidism: thinness, increase of eyebrow development, hot flashes, palpitation, intestinal spasms, irritability, emotionalism, phobias, inquietudes, migraine, asthma, hyperidrosis dysidrosis, tremors. Mixed cases: chilliness, shivering, migraine, frequent urination, neuralgic pains, distractable reddening of eyebrows, catamenia; neuralgias, anxiety, dilatation of palpebral fissures, swelling of feet, variations in volume of the feet, tremors, nervous crises, hysterical attacks.

Parathyroids.— Tetany.— This syndrome is unquestionably related to parathyroid loss or deficient Parkinson's syndrome(?). The viewpoint of Lundborg and of Gauthier is that this syndrome belongs here, and is a hyperfunction disorder, but it rests on very unstable foundations.

Thymus.— Vagotonic Symptoms of Basedow Syndrome(?): Profuse sweating, palpitation, lymphocytosis, eosinophilia, sensation of weakness.

Myasthenia of Erb-Goldflam(?): Headache, ptosis, external ophthalmoplegia, fixed or transitory palsies principally of the face, the neck, myasthenic electrical reaction.

Thymus Loss: Idiocy of Klose and Vogt.

Tetany(?): Basch.

Suprarenals.—Addison's Syndrome and Suprarenal Insufficiency: Asthenia, arterial hypotension, morning nausea and vomiting, lumbar pains, melanoderma, white lines on the skin, amyotrophy, abulia, depression. At times myoclonus, epileptic attacks, tetany, periodic palsies, delirium, mental confusion, sudden death.

Suprarenal-genital Syndrome: External feminine pseudo-hermaphroditism with virile secondary sexual characters; suprarenal virilism; amenorrhea, gynecomasty, adiposis with easy bruising, all signs of feminine maturity; hypertrophy of the clitoris, hypertrichosis of masculine type, masculine voice, muscular and nervous hyperasthenia, active and violent sexual inversion; arterial hypertension, arteriosclerosis; glycosuria.

Sympathetic Paraganglia.— Chromaffin cells of the solar plexus, aortic paraganglion of Zuckerkandl, cardiac paraganglion of Wiesel and Wiesner, Luschka's carotid and coccygeal glands, tympanic paraganglia. The syndromy of the affections of these glands is entirely obscure.

Pancreas.— Diabetes Mellitus: Glycosuria, polyuria, polyphagia, polydipsia; neuralgias, pruritus, impotency, constipation, dry mouth, dry skin, diminished perspiration, atrophy of the testicles, abolition of the tendon reflexes, arterial hypertension, asthenia, headache, susceptibility to cold, perforating ulcer of the foot, syncopies, comatose or apoplectiform attacks, paralyses, vertigos, asthmatic dyspneas, pseudo-angina, narcolepsy, depression, apathy, hypochondria and coma.

Hypophysis.— Froehlich's Genital Adiposity Syndrome: Adiposity, arrest of development or regression of the genital glands, of the genital organs and the corresponding secondary sexual characters; somnolence.

Syndrome of Hypophyseal Insufficiency of Rénon and Delille: Tachycardia, instability of the pulse, arterial hypotension, insomnia, anorexia, distressing sensation of heat, exaggeration of sweat secretion.

Acromegaly: «A simple hypertrophy, not congenital, of the upper and lower extremities and also cephalic,» headache, amenorrhea, tendon reflexes increased, arrhythmia, syncope, perspiration, polyuria, glycosuria, sensitiveness to cold, neuralgias, acroparesthesia, cramps, lancinating pains, lassitude, irritability, depression.

Gigantism: «Acromegaly of the subjects in the epiphyseal cartilages which have not yet ossified,» impotency, amenorrhea, indolence, infantilism, abulia, asthenia, glycosuria, polyuria.

Diabetes Insipidus(?): Polyuria, polydipsia.

Pineal.— Genital Macrosomia: Abnormal increase in height, premature genital and sexual development with secondary sexual characters, hypertrichosis, exaggerated mental precocity.

Pineal Adiposity: Diffuse obesity.

Choroid Plexus.— Hydrocephalus: Hypertension of the cerebrospinal fluid, rapid development, nervous and mental syndrome of ventricular hypertension, obnubilation, idiocy.

Ovaries.— Infantilism: Amenorrhea, absence of secondary feminine characters, obesity, deficiency of hair, childishness.

Acquired ovarian insufficiency: (*a*) Peripheral vasodilatation, subjective crises of heat, sweating, continuous or paroxysmal tachycardia, palpitations, arterial hypertension, insomnia, severe headache, facial neuralgia, lumbago, neuromuscular asthenia, memory instability, irritability, enervation, hysterical crises; exaggeration of the sexual instinct(?), more often absent or inverted; obesity, restlessness, anxiety, phobias, impulsions, gastrospasm, constipation, vomiting, vertigo, syncope.

(*b*) «Vagotonic crises» before the menses and at the beginning of pregnancy, pallor, tendency to syncope, nausea, vomiting, constipation, diminished arterial tension, pulse rather slow, oculocardiac reflex positive, Samogyus' sign, psychic depression particularly connected with the development of the corpus luteum. These crises occurring before menstruation or at the beginning of pregnancy must not be confused with the reactionary dyshyperthyroidism of the menopause marked by flashes of heat, sweating, hypertension, paroxysmal tachycardia, palpitations, anxiety.

«Hyperovaria» (Dalché): Precocious puberty, copious menstruation, pain before and during the first days of the period, intermenstrual leucorrhea, developed sexual instinct, well-marked eyebrows, thinness, pallor, small breasts, large pelvis, rounded lower limbs contrasted in size with the upper ones, arterial hypotension, craving for movement and action, enervation, tendency to loquacity, erotic crises.

Testicles.— Infantilism: Defective development of the male genital organs, absence of secondary sexual characters, obesity, deficiency of hair, length of the lower limbs, small cranium, childishness.

Acquired Testicular Insufficiency: Increase in height, diminution of the pilous system, glabrous state of the body, tendency to obesity, gynecomasty, frigidity, impotency, senility, arterial hypertension(?), asthenia.

The types of testicular insufficiency according to Rebattus and Gravier are: (*a*) The sterile. (*b*) Eunuchoid gigantism, because the internal secretion of the testicle is established late. In this case there is a prolonged infantilism. (*c*) Eunuchism by castration characterized by gigantism and infantile appearance. The secondary sexual characters do not appear. (*d*) The reversive infantilism of Gandy, where simply a sort of asexual condition is noticed, with attenuation of secondary sexual characters and a certain degree of obesity, with late testicular difficulty in the adult.

Dyshyperdiastematia: Lower limbs short and cranium very large, pilous system well developed, especially the mustache, thinness, persistence of youth, a degree of arterial hypertension, virile character, activity, moral and physical energy.

Prostate.— Prostatic Insufficiency: Asthenia, diminution of potency, neurasthenia, at times suicide.

Hypertrophy of Prostate: Arterial hypertension, retardation of the heart, cerebral hemorrhages, genital excitation.

Pluriglandular Syndromes.— Basedow's disease with thymic hypertrophy and vagotonic symptoms; sclerodermia and tetany, amenorrhea; Addison's syndrome; acromegaly, etc.

Myxedematous with Thymic Hypertrophy. Tetany, acromegaly, Addison's syndrome, amenorrhea, infantilism, mammary hypertrophy, etc.

Acromegalic or ovarian insufficiencies with various disturbances, psychic, nervous, vasomotor, trophic, etc., connected at one time with the myxedematous, at another with the Basedowian series.

Ovarian Predominance.— Thyroid Reaction to Ovarian Insufficiency: Tachycardia, palpitations, perspirations, nervous irritability, vertigo, scanty urination, trembling, anxiety, etc.

The differences between these nervous manifestations and the picture of the attenuated forms of exophthalmic goitre are very slight, says Laignel-Lavastine. This pathogenic conception permits of important therapeutic results; one may ask, for example, whether the anti-Basedowian therapy with hematothyroidin would not be of advantage in the nervous and psychic disturbances of the normal menopause which repeat one feature after another of the Basedowian series.

Dyshyperovaria of the Hypothyroid: Anticipation, prolongation and copiousness of the menses, menorrhagia, metrorrhagia.

Thyro-ovarian Disturbances of the Same Significance.— Either ovarian insufficiency in the myxedematous series, or the dyshyperovarian in the Basedowian series; in either case the nervous disturbances of the dysthyroid are modified by all the factors of the ovarian rhythm, whatever they may be.

Hypophyseal Predominance.— Infantile giants, with their clinical varieties: feminism, eunuchism, cryptorchidism, feminine pseudohermaphroditism, mental infantilism.

Acromegalics with deficiency syndromes, myxedema, infantilism, amenorrhea, obesity, asthenia.

Acromegalics with syndromes of hyperactivity, more or less vicious, synergetic or substitutive; simple or exophthalmic goitre, arterial hypertension and atheroma, lacteal secretion.

Suprarenal Predominance.—Addisonian with amenorrhea, impotence, chilliness, tetany or, on the other hand, exophthalmic goitre.

Very often Basedowians, acromegalics, giants, with spontaneous glycosuria, alimentary or merely adrenal, the latter making it possible in certain cases to suppose a certain degree of suprarenal hyperactivity.

Without Marked Predominance.— The case of Claude and Gougerot is an example: Loss of sexual characters, countenance old-looking, skin thickened, wrinkled, pigmented; chilliness, absence of perspiration, asthenia, arterial hypotension, tetany; testicular, prostatic, suprarenal, thyroidal and perhaps parathyroidal atrophy. Consult Jelliffe and White, 'Diseases of the Nervous System' (3d ed., 1919; chap. III, 'The Endocrinopathies').

SMITH ELY JELLIFFE, M.D.

SYNERGISM, the co-operation of man with God in the act of his conversion; the term was first employed to designate the relation of man to the Holy Spirit in the work of conversion, as defined by Melanchthon in the 'Interim' (1548). Luther, in his commentary on Genesis, allows to man no part whatever in this act: «In things spiritual and divine which relate to the salvation of the soul, man is like the pillar of salt into which Lot's wife was transformed; nay he is like to a block and a stone, a lifeless statue which has no use of eyes, mouth, of any of the senses, or of the heart.» Melanchthon's doctrine (which, however, he soon retracted) was that «God does not deal with man as with a block, but draws him so that his will co-operates»; it was this term of co-operation that gave to Melanchthon's doctrine the title Synergism.

SYNESIUS, sĭ-nē'shĭ-ŭs, Neoplatonist philosopher: b. Cyrene, 370 A.D.; d. about 415. He studied in Alexandria, where he was the friend and pupil of Hypatia (q.v.). In 409 he was baptized in the Christian Church and the following year consecrated bishop of Ptolemais, in North Africa. His philosophical views are expounded in his writings,— homilies, letters, hymns and other literary works. In these he exhibits multifarious learning, keenness of intellect and a glowing style. The Christian dogmas which seem to conflict with his philosophical views he explains allegorically. Consult Migne, 'Patrologia Græca' (Vol. 66, 1859); Volkmann, 'Synesius von Kyrene' (1869); Crawford, W. S., 'Synesius the Hellene' (London 1901); Gardner, A., 'Synesius of Cyrene' (ib. 1886).

SYNGE, sing, **John Millington,** Irish dramatist: b. Newtown Little, near Rathfarnham, 1871; d. 24 March 1909. He received his education at Trinity College, Dublin, where he was graduated in 1892. For about seven years he studied music in Germany and languages in Germany, Italy and France. He spent several years in the Latin Quarter of Paris where he gave his attention to the study of decadent French literature, especially to Baudelaire. He accomplished little in Paris but being meanwhile interested in Ireland, in 1899 William Butler Yeats persuaded him to abandon his efforts as a French literary critic and study the social types, manners and customs of the inhabitants of the Aran Islands, a people who still retained their primitive Celtic culture. He finally settled in Dublin where he became one of the literary advisers to the Abbey Theatre and where he produced his dramas. These are remarkable for the angry protests and discussions which they provoked when produced in Ireland and in the United States. His first play was 'In the Shadow of the Glen' (1903); followed by 'Riders to the Sea.' 'The Tinker's Wedding,' although written in 1902, was not produced until 1909. 'The Will of the Saints,' a tragic-comedy (1905), was performed in German at Berlin in 1906. In 1907 appeared 'The Playboy of the Western World,' about which there arose violent discussion and protest. Some critics hail it as the best comedy in English since Sheridan, while in Ireland it is regarded as a savagely ironical treatment of a situation more frequently found in Baudelaire than in contemporary peasant life in Ireland. These plays have a wonderful diction and set the fashion for that peasant drama which became the most prominent feature of the Abbey Theatre. In design and substance, however, Synge's dramas are of the Gallic decadence. 'Riders to the Sea,' perhaps the least objectionable, is, *mutato nomine,* Pierre Loti's 'Pêcheurs d'Islande,' in an Irish setting. The dominant idea of 'The Well of the Saints' (1905) is from a play of Clémenceau's. The story of 'The Shadow of the Glen' is found in Voltaire's 'Zadig,' and the notorious 'Playboy of the Western World' is merely a dramatization of a work of Baudelaire. The form and tone of the plays of Synge are no less foreign than the substance; there are frequent sneers at the morals and religious practices of the Irish, and in 'The Playboy' are several blasphemous utterances; the characters of the latter are devoid of all semblance of good, and their sole moral motive is «fear of Father Reilly.» In short, Synge is «much Maeterlincked, Baudelaired and Ibsenized, but Gaelicized not at all.» As regards their dramatic and literary value, however, it is admitted that these plays possess a certain beauty. The talk of the Irish peasant is at times shot through with a queer poetic imaginativeness. It abounds in quaint terms, idioms and images unknown to English. These peculiarities Synge has reproduced and accentuated. And it is little wonder that to audiences strangers to the Gaedhaltacht his work should appeal with a sense of delighttul freshness and originality. Synge's peasants are viewed through a distorted medium. He himself had admitted in private life that the Connacht peasant whom he put upon the stage was not the peasant as he existed in real life, but the writer's own literary fancies set amid Connacht surroundings. Consult article by D. J. O'Donoghue (in *Irish Daily Independent,* 21 Aug. 1911) in which he points out the foreign sources of Synge's plots; O'Neill, George (in *Irish Catholic,* 23 Dec. 1911); *America* (New York, issues September-October 1911); Yeats, J. B., 'J. M. Synge and the Ireland of His Time' (New York 1912). See Irish Literary Revival; Playboy of the Western World; Riders to the Sea.

SYNGENETIC, a term applied to ore deposits that have been formed at the same time as the enclosing rocks, as for example the interbedded iron ores of the Birmingham region in Alabama, which were formed as sediments during the Clinton (q.v.) epoch. Epigenetic deposits, on the other hand, were introduced after the enclosing rocks were formed. Any vein of ore would then obviously be epigenetic. See Ore Deposits; Economic Geology.

SYNGNATHIDÆ. See Pipe-fishes.

SYNNÖVE SOLBAKKEN, sĭn'nė-vę' sôl-bäk'kĕn, a peasant-romance by Björnstjerne Björnson, was published in 1857. Without any knowledge of Auerbach's 'Schwarzwälder Dorfgeschichten' or George Sand's country tales, Björnson introduced this very type of the short story in Norwegian literature. His thorough knowledge of the peasant class and his study of the old sagas furnished the material on which his peasant stories are based. 'Synnöve Solbakken' met with instant acclaim and has been translated into most European languages. Thorbjörn, the hero of the story, is a peasant's son, and Synnöve, the heroine, is a peasant's daughter. Thorbjörn has a fiery temper, in fact, he is something of a savage and must, therefore, pass through a hard ordeal before he can become a fit husband for the gentle and lovable Synnöve. This bitter experience tests the devotion of the young people for one another and contributes to bring everything to a happy conclusion. Björnson idealized the peasants of his country. This is due partly to his fondness for the old sagas, partly to his own poetic temperament. His peasant types are decidedly above the average in poetic endowment. They are often able to express their feelings in beautiful poetry, as Synnöve did when she received Thorbjörn's letter written on his sick-bed. Björnson's peasants are noted for terse speech and this trait, too, is in imitation of the saga style, for Björnson wanted to show that the peasants of to-day had more faithfully than any other class in modern society preserved the traditions of a historic past. Consult Jaeger, Henrik, 'Illustreret norsk Literatur historie' (II, 589–639 and 711–768); Brandes, Georg, 'Det Moderne Gjennebruds Maend' (pp. 1–69, trans. by Mary Morison in a volume entitled 'Henrik Ibsen. Björnstjerne Björnson. Critical Studies, by Georg Brandes,' 1899).

Joseph Alexis.

SYNOD, an ecclesiastical deliberative and legislative assembly. The word is synonymous with council, but œcumenical assemblies are commonly called councils and minor ecclesiastical assemblies synods, though these are also styled councils. A diocesan synod is composed of a bishop and the clergy of a diocese; a provincial synod, of an archbishop (or metropolitan) and the bishops suffragan to him; a national synod of all the metropolitans and bishops of a nation. In the Presbyterian Church synods are courts of review immediately superior to the presbyteries and consist of all the ministers and elders who are members of a number of contiguous presbyteries; the supreme council of the Presbyterian Church is the General Assembly.

SYNODICAL PERIOD, is the period between two successive conjunctions or oppositions of a planet with the sun, as observed from the earth. A synodical month is a lunation, being the period from full moon to next full moon or from new moon to next new moon. A synodical month is 29 days, 12 hours, 44 minutes, 2.37 seconds.

SYNONYMS, words of the same language which are the precise equivalents of each other; in popular acceptation, words sufficiently alike in general signification to be liable to be confounded, but yet so different as to require to be distinguished are synonyms. The following pairs of words are pairs of synonyms: teacher, instructor; resemblance, similarity; supposition, hypothesis; beginning, commencement. But words commonly regarded as synonymous are seldom perfectly so, as is seen in works on synonyms. There is always going on in a language a process of «desynonymization» which tends to restrict one member of a synonymous pair to one meaning, the other to another. For example, «wave» and «billow» originally meant precisely the same thing; but «billow» is now restricted to poetical use, while wave is used chiefly in practical matters. The study of synonyms is a valuable intellectual discipline in itself, apart from consideration of its high importance as a guide to the right use of words. «The habit of thorough investigation into the meaning of words, and of exact discrimination in the use of them, is indispensable to precision and accuracy of thought, and it is surprising how soon the process becomes spontaneous, so that one often finds himself making nice and yet sound distinctions between particular words which he has never made the subject of critical analysis.» Consult Crabbe, George, 'English Synonyms' (new ed., New York 1891); Fernald, 'English Synonyms and Antonyms' (ib. 1896); Ordway, E. B., 'Synonyms and Antonyms' (ib. 1913); Roget, P. M., 'Thesaurus of English Words' (new ed., ib. 1914); Smith, C. J., 'Synonyms Discriminated' (3d ed., 1908).

SYNOPTIC GOSPELS, those called of Matthew, Mark and Luke, which regard events generally from the same point of view and present strong resemblance to each other. Four hypotheses have been offered to account for the correspondences of the synoptics: (1) Derivation from some common written original. (2) Priority of one of the three and recurrence to that by the authors of the other two. (3) Derivation of all three from the same source in oral tradition. (4) Derivation of all three from the oral tradition, but consultation of Matthew's gospel by Mark; of Matthew and Mark by Luke. See BIBLE.

SYNOVIAL MEMBRANE, the membrane lining the various joints or articulations and which secretes a peculiar fluid — the synovial fluid — for the due lubrication of the joint. See JOINT; MEMBRANE; ARTHRITIS.

SYNOVITIS. See ARTHRITIS; JOINTS.

SYNTAX, *in grammar*, proper arrangement of words under established rules and according to the best usage in order to express ideas. A word expresses a single notion, but by itself is little more than an articulate sound intimating, like the cry of animals, a wish or a feeling. A succession of such sounds, properly arranged and connected for the expression of ideas, becomes language. The art of constructing sentences is, therefore, not less important than the power of speech; it is indeed the intellectual part of language and a characteristic of reason. The first step in syntax is the analysis of sentences; a clear perception of the mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths and in most cases superfluous. See GRAMMAR; PHILOLOGY.

SYNTHESIS (Lat. *synthesis*, from Gk. σύνθεσις, combination, composition), the combination of individual objects or elements of thought into a whole. Thus, by synthesis, separate propositions are combined into a system, or simple concepts into compound and complex ones. In this manner one recognizes that various properties, taken together, constitute the characteristics of some one object. The process, however, does not destroy the identity of the component parts, but merely correlates them into a unity. It is, therefore, the opposite, or complement, of analysis (q.v.), which is the process of distinguishing within some given object the various characteristics of that object, without, however, destroying its unity. Hence, the name synthesis is applied in mathematics and philosophy to a process of reasoning working to a conclusion from propositions that have already been demonstrated, or principles that have previously been assumed or established.

SYNTHESIS, Chemical. The building up or formation of chemical compounds from their elements or groups of their elements. The opposite of analysis, one meaning of which is the breaking up or decomposition of a chemical compound into its elements. Thus the formation of water from its elements hydrogen and oxygen is synthesis, while the decomposition of water into hydrogen and oxygen is analysis. Many of the most important manufacturing processes are synthetical. The synthesis of compounds from their individual elements is of great scientific but of little technical interest. However, the recent synthetical process of uniting moist nitrogen and oxygen to form nitric acid by use of the electrical discharge bids fair to be of great interest to mankind because of the use of nitrates as fertilizers. The synthesis of compounds from groups of their elements is of very great industrial importance. Sometimes only a single and simple chemical reaction is required, as, for example, the action of water on quicklime to form slaked lime, while others, such as the manufacture of indigo from naphthalene, require many and complicated changes. There is a great difference as to the ease with which elements or groups of elements unite to form compounds. Some unite readily under ordinary atmospheric conditions of temperature and pressure, while others may require the action of heat, light, electricity, presence of water, etc. Phosphorus and iodine unite the moment they come in contact. Phosphorus and oxygen unite slowly at ordinary temperatures but with violence if the temperature is raised; sulphur and iron do not act at all at room temperature but do so when heated highly; hydrogen and chlorine do not act in the dark at ordinary temperatures but do so with explosive violence if exposed to the light; ammonia and hydrochloric acid or the mixture of bicarbonate of soda and cream of tartar used in baking powder do not react when dry but do so in the presence of water.

Up to 1828 it was thought that all organic chemical compounds, those formed in or produced by animals and plants, could not be prepared in the laboratory by synthetical processes. The action of a «vital principle» or «vital force» was thought to be necessary. Wöhler showed this to be not true when (1828) he prepared urea, an organic substance produced by animals, from ammonium cyanate. Since that time an immense number of other organic substances have been prepared by synthetic processes. Some of the well-known ones are oil of wintergreen, indigo, caffeine, alizarine, etc. The processes used in synthesis have been so thoroughly studied that the chemist has only to find out the exact chemical structure of a compound to be able to prepare it in the laboratory. Sometimes these laboratory processes are too costly to be of technical importance, but often they are of great commercial value. See INDIGO; ALIZARIN.

Many substances are prepared by synthesis that never existed in any plant or animal. They are purely laboratory products. To this class belong most dyestuffs, many valuable medicines and a large number of perfumes and flavoring substances. Consult Berthelot, P. E. M., 'La synthèse chimique' (Paris 1876); Posner, Theodor, 'Lehrbuch der synthetischen Methoden' (Leipzig 1903); Lassar-Cohn, 'Arbeitsmethoden für organisch-chemische Laboratorien' (2 vols., Hamburg 1907).

SYPHILIS. This is a general infectious disease, chronic in character, which may be communicated through inoculative contact or transmitted by inheritance. In the acquired form, it first produces at the point of inoculation a specific lesion termed the chancre, followed by a gradual infection through the communicating lymphatic vessels and eruptions upon the skin and mucous membranes. Later, there may develop in the connective tissue, or in any part of the body, adventitious new growths which may undergo suppurative or destructive changes.

The history of syphilis is shrouded in obscurity; certain writers have sought to trace its origin back to a remote antiquity. It is claimed that syphilis was well known to the ancients, and that descriptions of morbid conditions applying to this disease are found in the Bible, in Egyptian papyri, Assyrian and Babylonian inscriptions, as well as in the ancient Chinese and Japanese literature and the books of the Vedas. The evidence which connects syphilis with these ancient historic records is vague, indefinite and inconclusive. Our actual knowledge of syphilis dates from the appearance of the disease in Europe about the year 1494, and there is much evidence to show that the disease was native in South America and was brought to Europe by Columbus' sailors. There can be no question that gonorrhœa and ulcerative affections of the genital organs resulting from sexual debauch and uncleanliness were well known and frequently spoken of by ancient writers. With the irruption of syphilis in Europe toward the close of the 15th century, and its widespread extension, the identity of gonorrhœa was swallowed up in the greater importance of this newer and more formidable disease. During a long period all diseases of the genital organs were regarded as identical in origin and nature. This doctrine reigned practically supreme for more than three centuries and was not definitely overthrown until 1838. At the present time we recognize that under the general term «venereal» are comprehended three distinct diseases, independent in origin and nature, namely, gonorrhœa, chancroid and syphilis.

Cause.— Since 1905 the cause or etiology of syphilis has assumed an entirely new phase. Previous to that time it was very strongly suspected, especially by those who had followed the development of the science of bacteriology, that the cause must be associated with some variety of specific micro-organism, as was the case with so many other infectious diseases. The history and clinical phenomena of the disease all pointed in that direction. Everything seemed to favor such a theory and there was apparently nothing from the bacteriological point of view which could be urged against it. In 1905, after careful investigation of the primary and secondary lesions in 70 successive cases of syphilis, Schaudinn announced that he had succeeded in finding in each of them a spirillum or spirochæte which he named spirochæta pallida. (This organism is also known as Treponema pallidum). This should be classified as a protozoon. When regarded as a protozoon it is described as one of the flagellated mastigophora which is characterized morphologically by a long slender body with numerous corkscrew-like coils and a flagellum at each extremity. Upon the protozoon supposition it is the pathogenic parasite of syphilis.

The findings of Schaudinn were confirmed by Hoffman and others, and additional investigations were made by Metchnikoff at the Pasteur Institute. Some of the higher apes were successfully inoculated with the organism, the results being especially satisfactory with the chimpanzee. Various methods of staining have been used with this organism. In the Levaditi method the spirochetæ appear as dark spirals upon a pale yellow background, and when a weak counterstain is used they can frequently be detected in great numbers in the liver cells. They have also been found in the tissues of the lungs, spleen and heart.

General Course and Character of the Disease.— Syphilis bears a certain resemblance to the infectious fevers, as smallpox, measles, etc., in its incubation, mode of development and the appearance of a characteristic eruption. In the majority of cases the phenomena of syphilis develop with a certain order or regularity which admits of its division into periods or stages, known as the primary, secondary and tertiary stages. After the introduction of the virus there is no appreciable evidence of its action during a period more or less prolonged, from two to five weeks, on the average 28 days. This period is termed the period of primary incubation or the incubation of the chancre. At the expiration of this period there appears at the point of entrance of the virus the chancre, which is termed the initial or primary lesion of syphilis. This primary lesion constitutes for a time the sole sign, the unique expression of the disease. After the appearance of the chancre there ensues a period of six to seven weeks, termed the period of secondary incubation. During this period, the lymphatic glands nearest the chancre undergo an indolent enlargement, constituting what is termed the bubo of syphilis. After the second incubation the disease is said to become constitutional, although it is not definitely known at what precise time generalization of the virus takes place. Not infrequently there is, during this period, some evidence of constitutional disturbance — headache, neuralgia and febrile disturbance, more or less pronounced — which ushers in what are recognized as the constitutional signs of syphilis, in the shape of eruptions upon the cutaneous surface or the mucous membranes.

The *secondary* stage of syphilis is usually from 18 months to two and a half years in duration. The secondary eruptions are not continuously present, but come out in successive crops. The completion of this stage may mark the definite end of the disease, or there may succeed the tertiary stage, characterized by the appearance of gummatous formations which may affect the sub-cutaneous tissues, the periosteum, the bones and the internal organs of the body. The duration of this stage is practically indefinite. The tertiary lesions may continue to recur for 5, 10 to 15 years, or even during the lifetime of the individual. This division of syphilis into stages is somewhat artificial. It does not always pursue this regular and methodic course with an orderly procession of secondary and tertiary lesions; there is not always a sharp limitation between the stages. Secondary manifestations may continue to recur for several years.

Syphilis, as we comprehend it to-day, has a much graver significance in its relation to the health of the individual than was formerly supposed. Our conception of the range of its pathological action has been gradually enlarged with increasing knowledge of the vast complexity and far-reaching character of its morbid processes. While it was formerly known that syphilis was a constitutional disease and capable of causing changes in the internal organs, these systemic complications were regarded as few in number and of only occasional occurrence. The secondary manifestations visible upon the surface of the body were thought to constitute practically the entire expression of the disease. At the present day, these secondary manifestations are regarded as of subsidiary importance, since they rarely compromise the integrity of any important organ. The tertiary manifestations of the disease — cerebral, spinal, vascular, ocular, pulmonary, intestinal, hepatic and renal affections — constitute the chief significance, as well as the individual danger of the disease. The tertiary lesions of the brain and cord occupy the first rank in frequency as well as in gravity. Of all the menaces to the life and health of the individual from syphilis, lesions of the nerve centres are the most to be feared. The pathological field of syphilis has been greatly enlarged by the inclusion of a group of affections badly termed parasyphilitic, which, though of syphilitic origin and nature, are extremely refractory to specific treatment and practically incurable. As types of this group may be mentioned locomotor ataxia and general paralysis. It has been stated that every hemiplegia occurring in a man less than 40 years of age addicted to alcohol or affected with lesions of the circulatory system is, in nine cases out of 10, of syphilitic character. Practically all cases of paresis and tabes dorsalis are due to syphilis, and the spirochete has been found in the brain spinal cord in these diseases.

Syphilitic Heredity.— From a strictly socio-biological standpoint, the hereditary consequences of syphilis are of the greatest significance. Its pernicious effects upon the offspring give to syphilis an especial importance as a factor in the degeneration and depopulation of the race. Syphilis is recognized as the perfected type of a hereditary disease. No other disease is so susceptible of hereditary transmission, so pronounced in its influence and so destructive to the offspring. The hereditary influence of most other diseases is manifest in the transmission to the offspring of a constitutional protoplasmic state, characterized by a feeble organization and diminished resistance to disease. In tuberculosis and leprosy, for example, the influence of heredity is limited to the creation of a predisposition to disease, from an enfeebled capacity of resistance of the organism, which renders it readily susceptible to the action of the germs of disease. In syphilis there is a direct transmission of the specific qualities contained in the sperm or germinal cells, with the result that the normal processes of nutrition are vitiated and the produce of conception is blighted in its development or destroyed. No disease has such a murderous influence upon the offspring as syphilis.

Syphilis may be transmitted by indirect inheritance through the specifically infected sperm or ovule at the time of impregnation or through the utero-placental circulation in the course of pregnancy. Post-conception syphilis is applied to cases where the mother — or even both parents — may be healthy at the date of conception; the wife is infected during the course of pregnancy and she in turn transmits the disease to the child in utero through the vascular channels of the utero-placental circulation.

Syphilis may be transmitted directly from the father, the mother remaining healthy, although in most cases the mother is infected by the fœtus in utero. It may be transmitted directly by the mother, the father being healthy. The paternal hereditary influence is comparatively restricted; the influence of maternal heredity is much more certain and pronounced. When both parents are syphilitic, the infection of the child is almost inevitable — especially, when the disease of the parents is recent and active. The percentage of deaths from mixed heredity varies from 60 per cent to 86 per cent. The quality of hereditary transmissibility is not impressed upon the syphilitic organism permanently. As the disease grows older there is a progressive enfeeblement of the transmissive power, until it finally becomes extinct. The influence of heredity is rarely manifest after the fourth year; still, there are many well-authenticated cases in which it may be prolonged five or six years or even longer. The attenuating influence of time upon syphilitic heredity is shown in a series of successive pregnancies. The first pregnancies terminate in abortions, which occur at a later and later period; then, still-born children, or children living at birth but which soon die; then, syphilitic children, surviving but showing evidences of specific taint; and, finally, healthy children, free from all signs of the paternal disease. Specific treatment also exercises a powerful corrective influence upon heredity. It frequently happens that if syphilitic parents undergo active treatment before the time of pro-creation the child is born healthy. If this treatment is now suspended, the next pregnancy may result in a syphilitic child. Treatment seems, then, not to entirely extinguish, but rather to hold in abeyance, the transmission capacity.

Hereditary Syphilis.— Death of the child in utero is the most habitual expression of hereditary syphilis. More than one-third of all syphilitic children born alive die within the first six months of their existence. An analysis of statistics from authenticated sources shows that only one child finally survives out of four syphilitic pregnancies. In the immense majority of cases infants with syphilitic taint begin to show signs of the disease from the second week to the second or third month. It was formerly thought that if there were no evidences of contamination within the first year it might be assumed that the child had escaped. It is now known that even if the syphilitic child has escaped the early manifestations of the disease it may be doomed to the lesions of late hereditary syphilis, which are especially liable to appear at the period of second dentition, the period of puberty, from the 20th to the 30th year, or even later.

When a child the subject of inherited syphilis is born alive it may be apparently healthy and present no positive evidences of specific taint. Very often lesions of the osseous system are the only evidences of inherited disease manifest at birth. After a certain period, usually within a few weeks or months, the child may begin to show the stigmata of the parental disease. The surface manifestations of inherited syphilis, like those of the secondary stage of the acquired form, are at first generalized and diffuse. Later, they become more discrete, with a tendency to localize themselves in certain regions. Lesions of the internal organs often coexist with the earliest cutaneous manifestations. Hereditary syphilis is further differentiated from the acquired form by certain lesions which are its exclusive products. They are not in their essential nature syphilitic, but rather the result of changes impressed upon the fœtus in its formative or developmental stage. They present the characters of dystrophies or degenerations due to perversions of nutrition. These dystrophies may affect the entire body or be limited to a single organ or a system of organs.

The influence of hereditary syphilis is often manifest in a native debility or inherent incapacity for life. Many syphilitic children are endowed with a feeble vitality, so that they succumb to slight causes of disease. They die at an early age, often with no obvious signs of disease but simply from an inability to support life. They are the subjects of what may be termed «sudden, inexplicable death.»

In another class of cases there is an arrest or retardation of development; the children are stunted or dwarfed; they develop slowly physically and mentally; they are often feeble-minded or idiotic. The term «infantilism» has been employed to express the sum total of these characteristics. In other cases there are presented anomalies or marked deviations from the normal development, seen in the bones of the cranium and in the long bones, producing malformations of varied types, such as incurvation of the tibia, pigeon-breast, deformity of the thorax, curved spine, deformed pelvis, etc. These dystrophies may be expressed in such marked deviation from the normal type that the result is a monstrosity.

Heredo-Syphilis.—The effects of hereditary syphilis are not limited to the immediate descendants, but they in turn are capable of transmitting these dystrophies and organic defects to the third generation. Observation shows in the most positive manner that the influence of heredo-syphilis in determining abortions, still-born children and various organic defects is scarcely less marked than that of syphilis directly acquired. It would seem that while the contagious activity of the disease is entirely extinct, the nutritive disturbances set up in an organ or system of organs of the progenitors may be handed down to their offspring.

Syphilis as a Social Danger.— It is now generally recognized that syphilis, with alcoholism and tuberculosis, are the three great plagues that afflict modern humanity. Owing to its wide prevalence and the dangers to the personal health and life of the individuals affected, syphilis constitutes a serious menace to the public health. The amount of morbidity from this cause in any country or community is an unknown and unknowable quantity, since owing to its secret and shameful character cases of this disease are not subject to official registration. The spread of syphilis is favored not only by the fact that its contagious activity and transmissive power persist during a prolonged period but because it is exceedingly prolific in its sources and modes of contagion. While it is commonly propagated through sexual relations, syphilis is not necessarily so contracted. It may be conveyed by accidental inoculations, in the ordinary relations of life, in various industrial and professional occupations. Kissing is a very common mode of infection and a very large number of cases of contagion occur in this way. A syphilitic infant may infect a healthy nurse, or a healthy infant may receive infection from a syphilitic nurse in the act of suckling. Syphilis may be transmitted through the intermediary of any object upon which the secretions of the syphilitic have been accidentally deposited. It may be conveyed by drinking vessels, spoons, knives and forks, household effects, pipes, toilet articles and other objects too numerous to mention. Certain occupations favor the spread of syphilis, especially that of glass blowing, where the infected blow-pipe is passed from mouth to mouth. Syphilis is not infrequently communicated in barber shops, through razor wounds or through the use of shaving brushes, soap or towels. Infections in professional life are not uncommon. Physicians and accoucheurs have acquired syphilis in the examination and treatment of syphilitic patients. Every syphilitic individual is the source of possible danger to persons with whom he comes in intimate contact. A case of syphilis in a family may be the origin of many innocent infections. The syphilitic child may infect the nurse and members of the family; these in turn may affect others. Veritable endemics of syphilis, amounting to 10, 15, 20 or more infections, have originated in this way. It is this quality of expansiveness, this capacity of morbid irridiation through family and social life, that gives to syphilis its superior significance as a social danger.

It is especially, however, in its relation with marriage that the ravages of syphilis as a social plague are of the highest interest and importance. By its inhibitory influence upon the productive energy of the family, syphilis may seriously compromise or entirely defeat the social aim of marriage — the raising of children. When it does not destroy the product of conception, it may blight its normal development. The subjects of inherited syphilis that survive are stamped with inferiority and compelled to pass through life bearing the stigmata of degeneration or disease. A syphilitic man should not marry so long as he is capable of carrying contagion to his wife or begetting syphilitic children. Since the contagious and transmissive power of the disease is gradually exhausted, syphilis constitutes only a temporary barrier to marriage, which may be removed by time and treatment. It may be formulated as a general rule that a syphilitic man should not marry until after a certain period (on an average four years) has elapsed since the date of his infection, during which time he should receive sufficient specific treatment. A still longer period of probation would afford an additional guarantee of safety. It is to be observed, however, that there may be contra-indications to marriage which arise from risks to the personal health of the individual by reason of his disease. The syphilitic man may be exposed to dangers, the consequences from his disease, which unfit him for the responsible position of head and support of a family. The possible existence of such disqualifying conditions must always be taken into consideration when the question of marriage is concerned.

Diagnosis.— The chancre or indurated ulcer which appears upon that portion of the body where inoculation has taken place, which may be at any point where the skin or mucous membrane has been broken or injured, has been regarded since the time of John Hunter as the distinguishing evidence that syphilis is present. The discharge or secretion from such a sore, as well as the blood of the individual who has the sore, both of which contain the germs of the disease are the media by which the disease is communicated, while the period during which such communication is possible may continue through several years if the disease remains untreated. These germs produce a specific antigen, by their action upon the blood and tissues, and this forms the basis for the Wassermann test in the diagnosis of syphilis. This test works upon the theory of deviation of the complement by antigen substances contained in the syphilitic fluid blood or cerebro-spinal fluid and prevents or fails to prevent the lytic action of the hæmolysing fluid, according as syphilis is present or absent.

The Wassermann test is made in the following manner. Certain definite quantities of tissue, representing the antigen, are taken from the liver and spleen of a syphilitic fœtus, together with a definite volume of the blood serum of the individual upon whom the test is to be made. They are mixed in a test tube and fresh normal guinea-pig serum which contains the complement is added to them. The tube is then placed in an incubator, at the temperature of the body, for one hour, after which its contents are poured into a second test tube which contains a mixture of red blood cells of a sheep, or other suitable animal, suspended in a physiological salt solution plus the serum of a rabbit which has been immunized to the before-mentioned red blood cells of the sheep. If the individual whose serum was placed in the first test tube actually has syphilis there will be no hæmolysis of the red blood cells in the second tube after it has been kept in the incubator for the required period of one hour. In other words there is fixation of the complement and the reaction is said to be positive. If, on the other hand, hæmolysis of the red blood cells takes place the reaction is negative and the individual presumably does not have syphilis, or has it in a quiescent condition. Various errors may occur with the Wassermann test, so that it is not regarded as absolutely reliable. This has resulted in the development of various modifications of the test, the one which has been regarded as most satisfactory being known as the Noguchi nodification. The Wassermann test or the Noguchi modification must be repeated at intervals of a month or two for a year or more, even though it should be negative on each occasion, to determine whether the disease has been entirely eradicated.

Treatment.— Mercury and the iodide of potassium have until a very recent date formed the basis of most of the successful treatment of syphilis. A great deal of enthusiasm was excited by the first published results of the use of salvarsan or "606"— results which unfortunately have not been confirmed by a more extended experience. While there is no question of the incontestable efficacy of this remedy in causing the earlier lesions of syphilis to disappear, and even certain intractable lesions of a later stage, yet relapses are the rule and even more common, it would appear, than after the use of mercury. The effect of a remedy in preventing the dreaded manifestations of the disease upon the nervous system and the organs essential to life is the crucial test of its curative value. It will be necessary to wait several years before we can estimate its curative efficiency as determined by the ulterior evolution of the disease. There is reason to doubt whether any chronic infectious disease like tuberculosis, leprosy and syphilis can ever be expelled by therapeutic violence. The most refractory and difficult form of syphilis to treat is neurosyphilis, or syphilis of the nervous system. Neurosyphilis may give rise to a great variety of different types of disease, so great that the general practitioner can hardly bear them all in mind. Special methods of treatment are essential in these forms of syphilis. Consult Jelliffe and White, 'Diseases of the Nervous System' (3d ed., 1919).

SYR, or **SIR DARYA**, sēr-dār'yä, Turkestan, (1) A river (the ancient Jaxartes) rising in the Thian-Shan Mountains on the boundary of East Turkestan and flowing west and northwest into the Aral Sea. It traverses the districts of Ferghana, Samarkand and Syr Darya and has a total length of about 1700 miles. In its upper course it receives numerous tributaries. After leaving the mountain regions in a series of rapids it flows for the rest of its course over the vast arid plains of the Syr Darya district, where it is broad, deep and tranquil, but receives few affluents. It here repeatedly divides itself and numerous irrigation canals lead from it into the surrounding country. The river is navigable for 600 miles, but the proposed line of steamers has not yet been installed. (2) A district of Turkestan with an area of 194,853 square miles. The capital is Tashkend; pop. about 150,000. The population of the district is 1,990,000.

SYRA, sē'rā, Greece, (1) An island in the Ægean Sea, the largest of the Cyclades, 13 miles south of Andros, with an area of about 32 square miles. The surface is rugged and bleak and the coast indented by numerous bays and inlets. The diversified landscape includes fertile valleys with some barren patches. The chief products are wheat, barley, cotton, wine and figs, but crops are inadequate to the demand and provisions are largely imported. Syra remained neutral during the War of Independence, thus becoming an important centre of commerce. The climate is salubrious. Pop. 26,856. (2) Syra, or Hermupolis, the capital, is built in terraces rising from the bay. It is the seat of government for the Cyclades, the see of a bishop and residence of foreign consuls. Its trade with the Levant is considerable. It is the commercial emporium of the Ægean Sea, imports provisions, coal, etc., and exports emery, tobacco, sponges, valonia, etc. Pop. about 20,000.

SYRACUSE, sĭr-a-kūs, N. Y., city and county-seat of Onondaga County, situated on the New York Central and the Delaware, Lackawanna and Western railroads, almost exactly midway between Albany and Buffalo, 148 miles either way, in lat. 43° 9' W. The New York State Barge Canal reaches it through Onondaga Lake.

Topography.— The city is at the foot of the Onondaga Valley, through which and the city the Onondaga Creek flows into a lake of the same name north of the city, five miles long and one and one-half miles wide. The southern part is flanked by hills at the northern ends of the ranges on the east and west of the valley and extending considerable distance southward; while the northern part is upon ground which slopes upward from the Erie Canal to the northern boundary. There are several hills of volcanic formation and of geological interest. A considerable part of the city is situated upon silt brought down from the Onondaga Valley, to a depth at one point of at least 179 feet, as proved when at that depth a salt drill passed through a cedar log. Perhaps there is no section of the State of New York which possesses more of geological interest than Syracuse and Onondaga County, and this is certainly true of their Indian history. The streets are generally regularly laid out, though some of the principal streets have independent courses creating triangular divisions of blocks. Many are 99 feet in width, but the majority are 66 feet. There are 570 streets, with a total length of 250 miles. There are nearly 114 miles of paved streets, mainly with brick and asphalt, and 209 miles of sewers. The area of the city is 19.18 square miles.

Transportation.— Syracuse is an important railroad point, its roads being to its centre like the spokes of a wheel to the hub. Passenger trains to the number of 100 arrive in and depart from the city daily. Abundant freight facilities are offered by competing lines and important advantages can also be had from the improved New York State waterways. Diverging from the city are the following railroads: New York Central, West Shore, and Delaware, Lackawanna and Western. These roads not only thread some 20 counties in central New York, but several of them extend, with their connections, to the extremes of east, west, north and south. Of street railways, the trolley system embraces 95.72 miles of single track. This includes the mileage of track within the city of Syracuse, also to East Syracuse and Minoa, Eastwood, Liverpool, Solvay and Rockwell Springs. The New York State Railways operate to Utica and intermediate points; the Empire United Railways to Oswego and intermediate points; the Rochester and Syracuse to Rochester and points beyond, such as Buffalo and Lockport. All these lines carry freight and express. Motor truck lines operate from Syracuse to Utica, Watertown, Oswego, Auburn, Cortland and Rochester.

Commerce and Industry.— Syracuse ranks fourth among the cities of the State in the number and variety of its manufacturing plants; there are 760 industrial establishments, with an approximate invested capital of $63,957,000, and an annual production valued at $52,226,000, employing 25,000 persons. The manufacture of typewriting machines has taken on large proportions, the combined interests representing at least $8,000,000 in popular value. The product is large and constantly increasing. Automobiles are produced in large numbers, and among other manufactured articles are soda ash, tool steel, candles, automobile gears, farming implements, tools, clothing, chinaware, furniture, cement, chemicals, mining machinery, etc. The former leading manufacture of salt is still carried on at the brine springs on the shores of Onondaga Lake, and the extensive chemical works of the Solvay Process Company employing 5,000 hands are in a western suburb. (See *History* in this article). The printing industry is also extensive, more than 60 newspapers and periodicals being published, several of them devoted to the arts and sciences. The wholesale trade supplies hundreds of small dealers in the surrounding country in a radius of many miles. The retail trade involves an area of 38 mile radius and conservatively speaking brings 5,000 shoppers to the city each week.

Banks and Banking.— Six banks have a combined capital of slightly more than $6,600,000 with a large surplus. Two savings banks have 85,000 depositors and $48,000,000 of assets.

Buildings.— The business section is compactly built up of brick and Onondaga limestone mainly; there are a number of exhibits of present-day architecture and construction, such as the Onondaga County Savings Bank building, the University buildings, City Bank building, University Club, Young Men's Christian Association, Keith Theatre building, First Trust and Deposit building, Syracuse Trust Company, the Hunter-Tuppen Company and

Dey Brothers and Company's department stores, the high schools, courthouse, library and others. There are many stately and handsome business and public buildings, and fine private residences are seen in large numbers on all of the principal avenues. James street, it is very generally conceded, is second to no avenue in this country in point of attractiveness. The buildings of the Syracuse University, particularly the John Crouse College of Fine Arts, are all models of good architecture, and the Hall of Languages is a fair example of the excellence of Onondaga limestone, which exists in such vast quantities for building purposes.

Education.— The public schools are under the direction of eight commissioners, who appoint a superintendent at a salary of $4,000 per year. There are 38 public school buildings, having a valuation of $3,444,838. The number of pupils registered in the public schools for the year ended 1 July 1918, was 22,344, and in the high schools 3,358. The buildings are of brick, substantially constructed and supplied with the most modern sanitary appliances and heating apparatus. The course of study is according to the most advanced ideas, and a graduate of the high school is quite as well equipped as were graduates of most colleges half a century ago. Teachers' meetings are held monthly under the direction of the superintendent, not only to preserve uniformity in the system, but also for the instruction of teachers in their general as well as special duties. The Syracuse University (q.v.), embracing the colleges of liberal arts, fine arts, law, medicine, forestry and applied science, is situated on the highlands in the southeastern part of the city and has an ample campus of 100 acres. The property, including endowments, is valued at $3,156,711. There are 3,540 students in attendance; the professors and instructors number 344. It is under the control of a chancellor and board of trustees and allied religiously to the Methodist Church, though very liberal in this respect. The library comprises over 99,000 volumes and 43,000 pamphlets. An observatory is one of its essential fixtures. In the tower of the buildings of the College of Fine Arts is a chime of bells, and on an upper floor in the Hall of Languages building the Central New York Weather Observation Bureau is located and maintained by the United States government. All of the athletic sports are maintained, and the secret societies all have fine fraternity houses. There are 12 parochial schools and two non-parochical under Roman Catholic control, with 122 teachers and 5,400 pupils. They are under the general supervision of the bishop of the diocese, and are mainly intended for academic instruction.

Libraries.— The Syracuse Public Library system including three branches and 34 stations centres in the Carnegie Building which was completed in 1905 at a cost of $268,000. The library contains about 140,000 books and in 1918 had a circulation of 556,437 among 43,921 borrowers. The main library is the centre of many public activities, including the Americanization work of the city. The servce of the library is free. The library of the Court of Appeals in the Court House is one of the three best libraries of the State, by which it is maintained. The general library of Syracuse University is housed in a building donated by Mr. Carnegie and is rich in certain lines of research material. The State College of Forestry connected with Syracuse University maintains a special library for forestry students. The College of Medicine has a well-equipped library for physicians and surgeons.

Religion and Charity.— Of churches and missions there are 116, of denominations as follows: Methodist, 23; Roman Catholic, 17; Presbyterian, 12; Baptist, 10; Episcopal, 8; Lutheran, 8; Jewish, 7; Congregational, 6; Evangelist, 2; Reformed, 2; Church of Christ, 1; Unitarian, 1; Universalist, 1; Scientist, 1; Seventh Day Adventists, 1; missions, 16. There are 13 cemeteries, of which Oakwood stands first because of its rolling surface, its shading oaks, impressive entrance way and costly memorials. Burials were made within the present enclosure of one of these cemeteries nearly a century ago. There are five principal hospitals, namely, the Good Shepherd, Saint Joseph's, Homeopathic, Memorial and Crouse-Irving. Each hospital has its own training school for nurses. The Syracuse Free Dispensary affords medical relief to suffering people and ministers to the need of more than 3,828 people annually, giving 20,373 treatments and 8,584 prescriptions. It is wholly supported by voluntary contributions. The Onondaga Orphan Asylum, the Saint Vincent De Paul Orphan Asylum and the House of Providence are the three principal homes for orphans or homeless children, the first being under Protestant patronage, the others having Roman Catholic support. The State Institution for Feeble-Minded Children is situated on an elevation on the western boundary of the city and is under the supervision of a superintendent and board of trustees. A small farm is connected with the institution which not only gives easy employment to a certain class of inmates, but produces a considerable quantity of supplies. The buildings are of good architecture and the grounds in their vicinity covered with a variety of shade trees and shrubs. The unfortunate children are of all ages, and while the condition of the mentality of most of them is hopeless a few manifest some improvement after long and patient effort on the part of the teachers.

Public Utilities.— Water is brought from Skaneateles Lake, 20 miles away, at an elevation of 440 feet above tidewater. The lake is 16 miles long, averaging 2 miles in width and is mainly supplied by springs. The immediate supply is from a reservoir of 17 acres 220 feet above the main level of the city, which give a hydrant pressure of 95 pounds. Almost every part of the city is supplied; the water bureau bears the cost of connections between mains and curbs. There are 226 miles of mains and 3,042 fire hydrants. The bonded debt for the waterworks is $4,100,000. The fire department comprises five gasoline pumping engines and hose carts; two triple gasoline pumping engines and chemical hose cart; four steam-fire engines — tractor drawn; six gasoline combination chemical hose wagons; two horse-drawn combination hose wagons; four hook and ladder trucks — tractor drawn; one hook and ladder truck, horse drawn; one water tower;

four district chiefs' auto runabouts; one chief's car; one motor-supply wagon; one horse-drawn supply wagon. It is under the command of a chief, assistant chiefs and the respective captains of the several companies. The police force comprises 250 men and a special force of detectives, all under officers of grades from chief to sergeant. The inspections and parades of the body show good drill and discipline and the force is rated as of the best. The sanitary conditions are under the observation of a board of health, the health officer being salaried. Garbage is collected by day labor and is burned in a crematory at a certain contract price. The mortuary statistics show an average annual death rate of 13.1 per 1,000 of population.

Government.— The municipal government is organized under the uniform charter for cities of the second class of the State, the executive and administrative control being vested in a mayor and common council composed of 19 aldermen, representing the same number of wards, and with the mayor elective every two years. A president of the common council, comptroller, city treasurer, four assessors and eight members of the board of education are also elective. The commissioner of public safety, having control of the fire, police and public health departments and of the bureau of water; the commissioner of public works, the city engineer, the corporation counsel and commissioner of charities are appointees of the mayor. The mayor, corporation counsel, commissioner of public works, comptroller and city engineer constitute the board of contract and supply, which makes all municipal contracts and furnishes all supplies to the various departments. The mayor, president of the common council, corporation counsel, comptroller and city engineer constitute the board of estimate and apportionment, which makes up the annual expense budget and fixes the salaries of city officers, subject to the action of the common council. The Municipal Court is presided over by two judges and its cases often number more than 3,000 a year. It is invested with considerable power and authority.

History.— The territory now occupied by Syracuse, also territory both north and south of it, was known to white men, as early as 1620, by the French, and subsequently by the English, who came up what are now the Oswego and Seneca rivers through Onondaga Lake, from Lake Ontario, and left present traces of their invasions throughout the central and northern parts and some in the southeastern part of Onondaga County. Possession of the territory was seriously and successfully contested by the Indians (mainly the Onondagas), and here and there abundant evidence of the fierceness of battles has been shown by the quantities of stone arrow points and hatchets found. The Iroquois were more or less involved in the invasions, but the brunt of resistance was with the Onondagas, who were in real possession of the lands. The League had been formed probably about 1580, which bound the Six Nations (q.v.) included in it to mutual assistance and some was given. The council fire was with the Onondagas, they being the strongest of the Six Nations, and it has always remained with them. By treaties with friendly native white people and the State, the Onondagas from time to time were induced to surrender their possessions, until finally they were allotted a "reservation" a few miles south of the city where they were to occupy permanent homes and makes the best of the rocky hills constituting most of their land. There the Onondagas, to the number of about 425, still exist, wedded to their habits and traditions. Many of them speak English and a few attend the Methodist or Episcopal mission and a goodly number of the children attend a school supported by the State. The religion of most of them is essentially pagan, and many of those who profess to be converted to the Christian faith find it difficult to divest themselves of pagan leanings. When emigrants began to come to the locality from New England as early as previous to the Revolutionary War, they were received kindly by the Indians, even if they recognized the fact that they were in a sense trespassers, so that when the county was created in March 1794 there was a considerable settlement scattered over most of it. As early as 1789 the Salt Springs, long known to the Indians who had produced salt from them, became known to white settlers, and they, in a crude manner, began the manufacture of salt and sent quantities of it to the Eastern market. The State assumed control of the Springs in 1797 (20 June) and leased lots and privileges to whomsoever might desire them; during the remainder of that year 25,474 bushels of salt was produced and inspected by the State officials, the lessees being required to pay a royalty or tax per bushel produced. The annual product increased rapidly so that in 1810 452,050 bushels were made; (1820) 458,329 bushels; (1830) 1,435,446 bushels; (1840) 2,621,-305 bushels; (1850) 4,268,919 bushels; (1870) 8,748,115 bushels. About 1890 the annual product began to diminish, mainly because of competition at Warsaw and in Michigan. It was estimated that at one time the Springs gave employment, directly and indirectly, to one-half of the population of the city; but with their decadence, more and more attention was given to the development of manufacturing industries, which have now become very numerous, having vast capital and being the main support of the wage-earners of the city. Principal among these is the Solvay Process Company, whose extensive works are situated just across the west line of the city, on the State Barge Canal and New York Central Railroad. The company also has branch works at Delray, Mich., near Detroit, which have a capacity of about 500 tons of alkali per day. The amount of capital invested at Syracuse is estimated at $6,000,000 and about 5,200 men employed. The principal products are soda ash, bicarbonate of soda, caustic soda and crystals, of which the daily output is estimated at 1,000 tons. This company also makes coke, tar, ammonia, carbolic acid, picric acid and some other coal-tar products. Here again salt becomes both indispensable and profitable, for it is an essential element in the production of alkali, by the so-called ammonia process, which is employed here. The company obtains its brine from wells which it sunk near Tully, some 20 miles south of the city, and brings the brine to its works through iron pipes. It was in the sinking of these wells that the source of the brine which for so many years has been utilized in Syracuse was found, in a mass of solid salt, extending, no doubt, for many miles east and west. It was found necessary to discharge fresh water into some wells, when it would become saturated and then pumped from other wells to the pipes leading to the works. Experiments made at this point in the belief that the discovery would verify the source were justified. The supply is supposed to be absolutely inexhaustible, but singularly enough the brine is not suitable for the best quality of salt, which is still produced from local wells to the extent of nearly 2,000,000 bushels per year. The company procures its limestone from Split Rock, several miles southwest of its works, bringing the material in by means of large buckets suspended on overhead wires and moved by steam power. They run in close connection and continuously and are capable of transporting 1,000 tons in 12 hours. A vast excavation has been made in the great layer of rock, of much breadth and thickness. Much of the building stone came from this quarry before it was converted to its present purpose. The «waste» product of the works has been used to fill surrounding low lands until hundreds of acres have been covered to great depths and places of deposit are now so limited that Onondaga Lake will henceforth be used as the place of discharge. The material is white and like marl and possesses no sustenance for vegetation.

The State Fair is always a feature of the social life of Syracuse, as well as entertainment for thousands of people from abroad. The grounds, situated on the western border of the city, consisting of 100 acres, quite covered with buildings for various purposes, embracing a very costly speeding track, are owned by the State, under an act of the legislature making the establishment permanent. Several clubs of large membership, the Century leading and much the oldest, are centres of sociability and places for business conferences among men, while there is one woman's club, the Kanatenah, and many other social organizations.

Population.— When the county was created in 1794 the county-seat was established at Onondaga Hill, four miles southwest of the present city centre; but the construction of the Erie Canal and development of the salt works caused a change of the county-seat to Syracuse in 1827, when the population of the village created in 1825 had increased to about 2,000 and to 6,829 in 1830. The population of Syracuse has increased steadily and very rapidly, as follows: 1850 (city incorporated in 1848), 22,271; (1860), 28,119; (1870), 43,051; (1880), 51,792; (1890), 88,143; (1900), 108,374; (1910), 137,249; (1919), estimated 160,000.

FREDERICK E. NORTON,
Secretary, Syracuse Chamber of Commerce.

SYRACUSE, ancient **SVIAGOSA,** Sicily, a city and seaport on the southeastern extremity of the island, 80 miles southwest of Messina. It has an excellent harbor but has greatly declined from its ancient magnitude and splendor when it had a population of 500,000 inhabitants. Ortygia, once an island, now a peninsula, at the southeastern portion, contains all that remains of the ancient city. Here are seen ruins of a Greek temple, dedicated to Diana or Apollo, a castle, remains of ancient baths and mediæval palaces, a cathedral built within the columns of a Doric temple to Diana or Minerva. There is also a museum containing valuable antiquities, coins, etc. In the southern portion of the town is the fountain of Arethusa, called la Parruca by the inhabitants, whose water became salty after an earthquake. Parts of the walls of the ancient city are preserved, which formerly enclosed the entire city on the mainland, also of the two great aqueducts; a Roman amphitheatre of the age of Augustus; a Greek theatre of the 5th century B.C.; a temple to Ceres and extensive catacombs; the massive towers of the fortifications of the castle Euryalos in the northwest, subterranean passages hewn through solid rock, etc., with endless ramifications in all directions. The Ear of Dionysius, a deep grotto with a wonderful echo, is 170 feet long, 60 feet high and 20 to 35 feet wide. Syracuse was founded by Greek Corinthians in 734 B.C. Its early political history is obscure; it is known that it thrived and itself sent out other colonies, becoming the largest and wealthiest city of the Old World. It had at one period a democratic government. In 215 B.C. it was invested by the Romans and defended by Archimedes, resisted for three years, but finally surrendered 212 B.C., remaining in possession of the Romans till the downfall of their empire. Theocritus and Archimedes were natives of Syracuse. An increasing export trade is carried on in olive oil, lemons, oranges, etc. Pop. 27,352. Consult Baedeker, C., 'Southern Italy and Sicily' (16th ed., Leipzig 1912); Freeman, E. A., 'History of Sicily' (4 vols., Oxford 1894); Cavallari and Holm, 'Topografia archeologica di Siracusa' (Palermo 1883, 1891).

SYRACUSE UNIVERSITY, located at Syracuse, N. Y., was chartered in 1870. The collegiate department, which was first opened in 1871, was the continuation of Genesee College, founded at Lima, N. Y., in 1849. In 1872 the Geneva Medical College, founded in 1835, was moved to Syracuse and became the College of Medicine of the university and in 1873 the College of Fine Arts was organized. This latter was an experiment in American education and has proved eminently successful. The College of Law was added in 1895, the College of Applied Science in 1901, the Teachers' College in 1906, the Library School in 1896, the Summer School in 1901, the Graduate School in 1911, the New York State College of Forestry in 1911, the College of Agriculture in 1910, the School of Oratory in 1914. The Hospital of the Good Shepherd became a part of the university in 1915. The College of Liberal Arts offers one course leading to the degree of A.B. The course includes certain required studies, one major subject (six hours a week for two years), one minor subject (three hours a week for two years) and free electives to complete the required number of hours. Instruction in Bible study is a part of the curriculum but the courses are elective. The Graduate School provides for work leading to the degrees of A.M., M.S. and Ph.D. The College of Fine Arts offers a four years' course in architecture, leading to the degree of B.Ar., a four years' course in painting, leading to the degree of B.P., four-year courses in piano, vocal, organ and violin, leading to the degree of B.Mus., a course in *Belles-lettres* leading to the degree of B.L. These courses include instruction in general history, philosophy, etc., as well as in theory, history and practice of the arts. The College of Medicine offers a four years' course, leading to the degree of M.D., and the College of Law a three years' course, leading to the degree of LL.B. Two years must be spent in a college of liberal arts before the medical course is undertaken and one year before the course in law can be undertaken. Students can so arrange their electives as to complete the college and medical courses in seven years, the college and law courses in six years. The College of Applied Science offers courses in civil, electrical, mechanical and chemical engineering, leading to the degrees of C.E., E.E., M.E. and B.S. in chemical engineering. The students maintain literary, historical and scientific associations and the Greek-letter fraternities are well represented. Physical training is a regular part of the collegiate course and there is a general interest in athletics. All business of the athletic teams is in the hands of the athletic governing board, which includes representatives of the faculty, the students, the alumni and interested business men of the city. Dormitories for women include Winchell Hall, Haven Hall, Reid Hall and eight cottages. Sims Hall is the dormitory for men. Many of the students live in their fraternity houses. The campus contains 100 acres situated on a hill overlooking the city and surrounding country. The university farm is located a mile from the campus. The buildings of the university include (1916) the Hall of Languages, the Charles Demarest Holden Observatory, the Carnegie Library, the John Crouse Memorial College (for the College of Fine Arts), the College of Medicine, the College of Law, the Archbold Stadium and Gymnasium, the Women's Gymnasium, the Esther Baker Steele Hall of Physics, the Lyman Cornelius Smith College of Applied Science (containing shops for metal and wood work), the Administration Building, Lyman Hall of Natural History, Bowne Hall of Chemistry, New York State College of Forestry building, the Photography building, the free dispensary, Margaret Olivia Slocum Teachers' College, the Joseph Slocum College of Agriculture, nearly a block of hospital buildings and the University block, one of the largest commercial buildings in the interior of New York State, erected for investment purposes. In 1902 the United States government established a weather observing station with complete equipment in the Hall of Languages. The library contains over 100,000 volumes, including the general library, the historical library of Leopold von Ranke, purchased in 1887 and other special libraries in economics, science, etc. The Syracuse City Library and the law library of the State Court of Appeals are open to students. The students number over 4,000, of whom 1,500 are in the College of Liberal Arts, and the faculty, 325.

JAMES R. DAY,
Chancellor.

SYRIA, a country of western Asia, geographically and anthropologically a kind of peninsula of the Mediterranean, forming a bridge between north and south, connecting Asia Minor and Mesopotamia with Arabia and Egypt, and bounded by the sea on the west and by the desert, only some 60 miles inland (at the narrowest part) on the east. The name «Syria» is rather a geographical expression than a geographical fact, for the region which bears that name on our maps has been arbitrarily thus delimited by modern (Christian) geographers. The name was originally of much wider application than it is now, while even to-day, strictly speaking, it includes Palestine. The subjects of the Assyrian Empire, from the Black Sea to the Mediterranean, were known in ancient times as Assyrians or, in the abbreviated form, Syrians. These two names came at a later period to have different applications: Whereas «Syria» once meant all the Assyrian Empire and also Mesopotamia, it became usual with the Greeks and Romans to apply that name to the more western of these regions, but including Palestine. Later on, Christian sentiment created imaginary boundaries out of existing landmarks and separated the «Holy Land» from a part of itself, a proceeding that gave birth to the prevalent erroneous impression that Syria and Palestine are two distinct countries. Geographically and geologically they cannot be separated; the mountains of Palestine, both on the western and eastern sides of the Jordan, are, respectively, the terminations of the Lebanon and Anti-Lebanon Mountains. The Jordan Valley is a continuation of the Buka Valley, and three out of the four sources of the river Jordan itself are in Syria. The district we describe as Palestine no longer means as once «the land of the Philistines,» and always has included much which the Philistines never held; it was never entirely held by the Hebrews for any length of time. Its boundaries correspond with the idealized limits of Canaan as divided among the 12 tribes, with the possessions of the Hebrew kings in the days of their greatness, and with the Palestine of New Testament history.

Syria, under Turkish rule, was divided into four vilayets and two «independent sanjaks» as follows: Aleppo, 33,430 square miles, pop. 1,500,000; Syria, 37,020 square miles, pop. 1,000,000; Beirut, 6,180 square miles, pop. 533,500; Lebanon, 1,190 square miles, pop. 200,000; Zor, 30,110 square miles, pop. 100,000; Jerusalem, 6,600 square miles, pop. 341,600. The last two are «sanjaks»; the whole of Palestine was included in that of Jerusalem and the vilayet of Lebanon. Total area, 114,530 square miles; pop. 3,675,000. Of the area, not more than 12,000 square miles comprise Palestine, to which also belong between 600,000 and 700,000 of the population. The ancient inhabitants called the country «Aram,» of which name the Biblical «Syria» is a translation. The Arabs called it esh-Shâm (the left) north of Mecca and Medina; and Yemen (Yamin) to the right of those cities. Damascus, believed to be the most ancient city in the world, was the capital of the Aramaic kingdom. While the modern inhabitants use the ancient inclusive name Suriyya, the Arabs call both Syria and Damascus esh-Shâm; the Turkish name is Suria (also Shâm); the Persians call it Soristán.

Topography.— Regarded in the ordinary sense of the name, Syria is the long and narrow district on the eastern shore of the Mediterranean, extending from the Taurus range on the north, separating it from Asia Minor, to Egypt on the southwest, between 36° 5′ and 31° N. lat. and long. 33° 30′ and 39° E. The Euphrates forms the northeastern border; the Syrian Desert the eastern limits, and Arabia on the south and southwest. The Mesopotamian plains are separated by the desert from the Mediterranean coast region, which stretches nearly in a straight line from the Sinai Peninsula northward to Anatolia. The desert forms a chalk and limestone tableland rising gradually to an altitude of over 2,000 feet above sea-level, stretching away southward into the Arabian Peninsula, but on the west sinking abruptly down to the long, deep and narrow depression of El-Ghor, which forms the eastern limit of the southern section of the coast region known as Palestine. Farther north the desert merges imperceptibly in the plains of Damascus and Aleppo and thus presents no natural well-defined limits to Syria on the east. Elsewhere the boundaries are sufficiently clear. The total length north and south is variously estimated at between 370 and 430 miles, with a mean breadth of 100 miles, narrowing in the south to 60 and expanding northward to 150 miles. Palestine is cut off by the Lower Orontes (Nahr el-Asi) and Mount Hermon from Syria proper, measuring from this point to the southern end of the Dead Sea (Bahr Lût, i.e., Lake of Lot) about 160 miles, with an average breadth of 70 miles. Geologically, Syria is a great desert-plateau only differentiated from the North Arabian Desert by a picturesque mountain-wall, split in the north into two parallel chains — the Lebanon and Anti-Lebanon, the latter falling gradually northward down to the plains of Upper Mesopotamia, while the former is continued by the less elevated Jebel-Nusarieh as far as the plain of Antioch, about the 36th parallel. North of this plain the Jebel-Nusarieh is continued by the Giaour-Dagh and Akma-Dagh to the Taurus above the Gulf of Alexandretta. These ranges condense the vapors from the sea and remain snow-clad till late in summer, giving the 10 to 16 miles' breadth of the Syrian seaboard its luxuriant subtropical vegetation and Palestine its fertility as far as its southern borders. The Lebanon range runs for about 90 miles southwest and approaches at some points to within 8 or 10 miles of the Mediterranean, presenting to seaward the appearance of bare, rocky walls surmounted here and there by a few snow-decked peaks, Dahr-el-Kodib (10,200 feet) and Jebel-Makmal (10,020 feet). From these is derived the name of Lebanon (white mountains), which was already current in the time of Moses. Despite its rugged appearance the Lebanon contains many fertile slopes and valleys, well cultivated and thickly populated. Eastward it is cut off from the Anti-Lebanon by the still more fertile plain of the Beka'a (Coele-syria), whose bald, rocky ramparts present more varied outlines than the coast range. The southern extremity of the Anti-Lebanon rises in the Jebel-esh-Sheikh (Mount Hermon) to an altitude of nearly 10,000 feet, the culminating point of the Syrian highlands, about 30 miles southwest of Damascus, the capital of Syria. The offshoots of the Lebanon range also stretch southward, with slight interruptions, throughout the whole of Palestine. Where it enters that country the upper part approaches the sea and at Mount Carmel sends forth a lateral branch, which farther south is separated from the sea by a fertile plain. Within this region are situated the oldest and most famous places in Palestine, including the mountains of Naphtali, and of Ephraim and Judah. It is this range which prevents the Jordan from flowing toward the sea and compels it to follow a southern course until it loses itself in the Dead Sea. Excluding the southeastern flanks of Hermon, both the Lebanon and Anti-Lebanon ranges are of limestone formation; the former is a single ridge deeply marked from the effects of erosion by water, while from the latter five ridges diverge northward. The spaces between them is taken up by a plateau of from 4,000 to over 5,000 feet above sea-level. The depression of El-Ghor, referred to above, is the deepest in the earth's crust, falling about 13,000 feet below sea-level, or more than 4,000 feet lower than the Beka'a plain. The four main streams — the Jordan, Leontes, Orontes and Abana — rise in the neighborhood of Baalbek, under the 34th parallel. They flow in four opposite directions, south to the Dead Sea, southwest and northwest to the Mediterranean, and east to the Bahr-et-el-Ateibeh, some five hours' journey beyond Damascus. The Euphrates, breaking the Taurus in a succession of cataracts and rapids, flows south and southeast, separating Mesopotamia from Syria and the deserts of Syrian Arabia, and is joined by the Tigris at Kurna. In the course of the Jordan are the lakes of Merom (El-Huleh) and Tiberias, and at its mouth is the Dead Sea. There are few perennial streams in Syria; the rain is quickly absorbed by the stony ground. Some of the old river-beds (wâdy) are deeply eroded. The mountain chains divide Syria into three regions — a western, consisting of a narrow belt of lowland extending between the sea and the mountains, sometimes sandy, but generally fertile; a central, occupied by the principal mountains of the chain; and an eastern, consisting for the most part of a bare, arid, sandy plateau, occasionally relieved by a few oases. Above all towers Mount Hermon, visible from almost all parts of Syria and forming a valuable landmark for the guidance of caravans. The «Little Ghor» or plain of Gennesareth stretches west of Lake Tiberias. On the eastern border of Syria extends the interior of the country, a fertile steppe, which when artificially watered yields the most luxuriant produce. This region, which is called the desert on account of its lack of water, stretches at a mean level of 1,900 feet to the vicinity of the Euphrates. It is inhabited by independent, nomadic Bedouins and frequently traversed by caravans. Beyond the Jordan, not far from Mount Hermon, rise the volcanic hills of Tulûl. To the south of Damascus lie the ancient wheat-bearing plains of Haurân and the mountains of that name, a region in which numerous ancient inscriptions are to be found. Farther south extend the mountains of Gilead, partially wooded. The mountains of Moab form an extensive tableland separated from the desert toward the east by a low range of hills. Between the Haurân and the Oasis of Damascus there stretches a broad expanse of volcanic hills, the Eastern

Trachonitis (Tulûl-es-Safa), toward the northern verge of which stand the stupendous ruins of Palmyra (Tudmur), supposed to have been built by Solomon. The Ala region between the vilayets of Damascus and Aleppo forms an extensive basaltic upland tract for many miles east of the Orontes. Here are the ruins of many ancient cities. In the extreme north the great inland plateaux of Aleppo, Umk and Aintâb occupy all the space between the bend of the Euphrates and the coast range, and are thickly inhabited by Turkoman and Armenian agriculturists. This region marks the extreme limits of both of these races toward the southwest. West of the Umk plateau lies the Bahr-el-Abiad (Lake of Antioch), a fine sheet of water, eight miles by six, formed by the junction of several steppe streams and draining to the Orontes.

Flora and Fauna.— Vegetation is much more varied and luxuriant in the north than in the south. The fertility of the soil of Syria is extolled by many ancient writers as well as in the Bible. Even the Syrian «desert» consists, not of sand, but of excellent soil, which after the early rain produces a rich crop of grasses and flowering herbs, affording most valuable pasture. The whole coast-district belongs to the region of the *Mediterranean Flora,* which extends around the basin of that sea, reaching inland as far as the lower hill country. This vegetation is, therefore, similar to that of Spain, Algeria and Sicily, with some modifications in the direction of Egypt. Among the principal products are corn, cotton, fruit in almost endless variety, indigo, sugar cane, grapes, oranges, mulberries, olives and tobacco. The tobacco especially of the Latakia district facing Cyprus is noted for its powerful, aromatic flavor. What still remains of the historic cedars of Lebanon is now found only at a solitary spot a few miles below Tripoli; farther south, the rose of Sharon is still cultivated. Inland, as the higher ground of the interior is approached, the vegetation changes to that of the Oriental type, a great variety of species with a dry and thorny undergrowth and stunted trees. The vegetation of the Jordan Valley somewhat resembles that of Nubia on the verge of the tropics. Considerable quantities of raisins are grown round Damascus and Es-Ṣalt. Pistachios are raised in northern Syria and nuts in central Syria, while in the desert near Damascus and east of the Jordan *kali* or saltwort is grown extensively. The *gall apples* produced by the oaks of the north are largely exported to Europe for dyeing purposes. Other products are licorice, alizari or madder, the bark of the pomegranate tree (used in tanning) and sumach, figs, citrons, pomegranates and almonds, cucumbers, onions, artichokes, egg-plant and truffles. While the cedar and cypress is growing rare, the pine is common; tamarisk and the poplar willow are frequently met with, as well as the terebinth or turpentine tree and the Valonia oak.

Among wild animals the chief are the Syrian bear, the hyæna, jackal, boar, panther and ounce. A connecting link between the domestic and the wild animals is formed in Syria by the dog and the cat. Each town and village is infested with masterless dogs who subsist on the refuse. There are two species of the fox and the wolf is not uncommon in the Lebanon Mountains. Gazelles are hunted in eastern Syria. The numerous caverns harbor several varieties of bats; there are four species of hares and numerous rodents, among them the graceful jumping mouse of the desert. The domestic animals include a small but hardy race of horses; camels and mules are also used as beasts of burden, especially in the trade between the coast and the interior. Fat-tailed sheep are plentiful, but the transplanted Angora breed soon degenerates. Pigs are practically unknown. The domestic hen is very common, but ducks are only to be found in a wild state. Partridges occur on all the hills and quail in the cornfields of the plains. The eagle and vulture are found about the Dead Sea, while storks, cranes and becassins frequent different localities. Among the few singing birds the nightingale (bulbul) is the most notable. Fish abounds in the Jordan and Lake Tiberias as well as in almost all the perennial streams. Both Syria and Palestine are rich in «creeping things» and insects. Crocodiles have been seen (though very rarely) in the marshes between Haifa and Kaisariyeh on the Palestine coast, where the climate resembles that of the Nile Delta. The common chameleon, the harmless little gecko and numerous snakes, many of them poisonous, are found, as well as the land tortoise and the small-tailed water tortoise. Among the mountains occurs the dark-colored khardon of the Arabs, with its prickly tail and back. Mosquitos, wasps, wild bees, hornets, grasshoppers (or locusts) are common. Locusts are the plague of farmers, often devouring whole crops; they are eaten only by the Bedouins. North of Beirut sponges are found on the coast, where there is a large fishing industry.

People.— The inhabitants of Syria present a conglomeration of races united by one common language, Arabic. They are mainly members of the great family named Semitic, a purely conventional term used to designate the group of peoples who are ethnographically allied by their languages — those of a peculiar construction and similar in character to the Hebrew. The dwellers of Syria consist chiefly of descendants of the ancient Syrians, Arabs, Turks, Greeks and Jews; among the most celebrated tribes are the mysterious Druses and Maronites, while several other nomadic tribes such as the Turkomans, dwell in the north; Kurds, on the banks of the Euphrates, and Bedouins in the Syrian Desert. Greeks, Romans and European crusaders have all blended with the ancient Semitic stock to produce the Syrians of to-day.

From the most remote times Syria was inhabited by Semitic stock; the Philistines and Hittites were the only exceptions. The former, whatever their origin, were soon merged with the primæval inhabitants, adopting both language and religion. In like manner the non-Semitic branch of the Hittites was absorbed. The Arab invasion in the 7th century introduced a new factor. All the people of Syria, as well as Egypt and Mesopotamia, became unified by a vigorous conquering race which left an ineradicable mark on the language and culture of the Christian and Jewish natives, to whom they were racially related, though of a different faith — Islam. That religion was even an eclectic compound of popular Christianity and Judaism. Their language, Arabic, was most properly spoken in all Syria, while an Arabic Christian dynasty had existed in Damascus even before the invasion. These vigorous sons of the desert brought about a double process of assimilation. They learned eagerly from the natives, from the Persians and the Greeks. They were apt pupils who in many cases were not only able to improve upon the wisdom of their teachers, but also to absorb and mold all this foreign learning into the Arabic language, even to the extent of applying Arabic equivalents for the technical words of science or philosophy instead of using the Greek forms. That process of acclimatizing foreign ideas and culture is still prevalent among Syrian writers to-day. The Mohammedan invaders absorbed many of the old customs and religious traditions of the soil and adopted the old shrines of saints in different communities and gave them Mohammedan names. Through their language they impressed their own poetry, national heroes and saints upon the people with the result that the most modern Syrian writers echo the voices and thoughts of Arabian bards and philosophers. In the Syria of to-day the Christions, Mohammedans and Jews possess a common heritage of proverbs, legends, parables and superstitions. Indeed, it is no exaggeration to say that the modern Syrians are one people with the same fundamental outlook on life, despite their different religions and sects, characteristics, clannish traits and various dialects. In this happy blending of races the natural endowments of the people are favorably exemplified by the Christian section of the population. They form a highly intelligent people with a remarkable capacity for adopting European ideas. The admixture of Greek and Arabic blood seems not to have impaired the good qualities of their Phœnician and Aramæn ancestors. The inhabitants of the coast districts are still Phœnicians in their enterprising spirit, commercial skill and love of travel. In Marseilles, Liverpool and Manchester, Syrian merchants are settled who promote the interests of their native land, extending their trading relations to Scandinavia and North America. Intelligent industry is responsible for the prosperous condition of the Beirut Christians. Here proverty is rare, and everyone is engaged in some branch of industry or trade. Family life is simple and patriarchal. The women are thrifty housewives and devoted to their families, associating little with the outside world. The Druses and Turkomans (qq.v.) are alien races; the old Syriac or Aramaic tongue is spoken only by the Nestorians of Kurdistan; the Turkish officials and soldiers under the old régime spoke their own language.

Education and Religion.— Under Turkish rule elementary education was nominally compulsory for all children of both sexes, while the Ministry of Public Instruction provided for the inspection of schools maintained by non-Moslem communities. In Syria there are many native schools and other educational institutions maintained for foreign missions. In the numerous girls' schools instruction is limited mainly to the study of French and English. The «Sisters of Charity» conduct an excellent training school where woman's work is taught and native teachers are trained. The rival houses of the «Sisters of Nazareth» and of the «Prussian Deaconesses» are highly praised for their labors, while the American missionaries aim especially at practical objects of education.

In religion the bulk of the inhabitants are Mohammedans; the Christians make up one-fifth of the total, and are divided into Orthodox Greeks, United Greeks, Maronites (q.v.), Roman Catholics, Nestorians and Protestants. The number of Jews is estimated at about 200,000. Protestantism is making rapid progress in Beirut (where that denomination maintains a fine church, several schools and a printing establishment) and in the Lebanon. In the latter region also dwell some Bedouin «Ishmaelites,» descended from the murderous sect of «Assassins,» who have given a familiar word to most European languages. Quite recently large settlements of Moslem Circassians, driven from their homes by their objection to living under Christian Russia, have been established east of the Jordan.

Towns.— In Syria many of the most venerable cities in the world, such as Damascus, Aleppo, Emessa, Beirut and Jerusalem, still flourish and retain their ancient names in modified but recognizable forms. Tyre, Palmyra, Baalbek and some other famous places have either disappeared or shrunk into obscure hamlets. The principal seaports of Syria are still found on the coast of what was once Phœnicia, the home of the most famous navigators of antiquity. Beirut is the chief port and next to Smyrna the largest and most flourishing seaport in the Levant. Two other northern ports are Latakia and Tripoli; the southern ports, Sidon, Tyre, Acre, Cæsarea (Kaiseriyeh) and Ascalon, have lost their trade and importance during the centuries since the Crusades and are now little more than fishing villages with small local traffic. Jaffa (Joppa) has recovered all its former prosperity owing to the orange industry and the Jerusalem Railway. Alexandretta (Iskandrun), in the extreme north, contains the finest harbor on that coast, but is the most fever-stricken spot in that region. Swedea (Seleucia), about 30 miles south of Alexandretta, also has a fine natural harbor. A peculiar feature of this district is that practically all the inhabitants are afflicted with the «Aleppo Button» or the «Baghdad Date Mark,» each the result of a boil that always lasts a year before healing. Europeans contract these diseases often during only a few days' stay. Sidon (q.v.), now called Saida, is of considerable historical interest.

Communications.— Of the three great routes which have been the main thoroughfares between Europe and Asia — namely the Red Sea, the Euphrates Valley and the Caspian — the Euphrates is the most ancient and most direct. From remotest antiquity it has been the main channel by which the riches of the East have flowed to the West, and to possess this Indo-Syrian trade route has been the desire of all great European powers, for the region it traverses is the pivot of European domination in Asia. The first great traffickers between East and West were the Phœnicians, whose success in commerce was probably largely based on their trade connections across the Syrian Desert with the Persian Gulf. Trade continued to flourish from the 6th to the 12th centuries, the Arab irruption causing but little interference. Then the Mongol avalanche burst into the Euphrates Valley and Europe lost her hold on Asia, for the land route was severed. On the heels of the Mongols came the Turk, who laid the foundations of the Ottoman Empire on the bridge between Europe, Asia and Africa, completely strangling all Indo-European intercourse. The establishment of the British Levant or Turkey Company in the 16th century gave the first impulse to the revival of the old Euphrates route until, in 1750, the Indo-Syrian caravan tracks came again into a brief period of comparative prosperity. But for the discovery of an unbroken waterway to India and the cutting of the Suez Canal, this route would have remained the highway of the East. Even in the early part of the 19th century, despite the preference for sea-borne trade, the prospects of a revival of the old land-route were encouraging. The proposed Euphrates Navigation Company and Railway were outward signs of a great need which Great Britain was slow to recognize, but which Germany eventually took up and attempted to realize in her road to the East. It is not improbable that future historians, delving in the diplomatic records of the past 25 years, will assign a prominent place among the «causes» of the Great War to the silent struggle for the command of the Mediterranean and the bridge between East and West. From Alexandretta to Aleppo the road is now accessible to wheeled traffic. From this point the pilgrims' route to Mecca and Medina is superseded by the railroad following the Orontes Valley by Hamah and Homs to Damascus, running thence through the Haurân southward to Arabia. Geographically, the Syrian railways form a sort of southern prong of the Bagdad Railway. In Syria railway enterprise began with a roundabout line of 54 miles, running from Jaffa to Jerusalem, opened in 1892. Since then great progress has been made, and altogether about 1,400 miles were in operation in 1914, with electric street cars in Damascus and Beirut. Since the end of 1906, when the section Aleppo to Hamah was opened, a French line has united the former town with Rayak on the line from Beirut to Damascus, with a total length of about 206 miles and a big bridge over the Orontes at Hamah. The same company owned a line from Homs to Tripoli, which was taken up to use the material elsewhere. North of Rayak the lines have the normal or «continental» gauge; all those to the south of this point are narrow guage. Here also is the junction of the French system, a line of about 155 miles, connecting Beirut with Damascus and Mezeril. Starting from Beirut Harbor, the railway climbs up the Lebanon (by cogwheel) for about 5,000 feet to a point just above Ain Sofar, winding thence down to the valley of the Bekaa, in which Rayak junction lies. From there the line runs southeastward across the plain and crosses the Anti-Lebanon to Damascus, to the south of which city the line (which was taken up during the war) ran almost parallel to the west of the Hedjaz Railway. The Hedjaz line was built by the Turks with the assistance of foreign engineers, mainly for the use of pilgrims, and was opened for traffic as far as Medina (820 miles) in 1908. Starting from Damascus, it was never completed to Mecca or prolonged to the Red Sea coast as proposed. It has a branch (22 miles) connecting Bosra with Deraia, as well as a line to Haifa, northwest of Nazareth, and a 25-mile feeder from Amman to Es-Salt. From Beirut a steam tramway runs along the coast 10 miles north to Yunie.

History.— From Egyptian records in stone and papyrus it seems that, at the earliest times known to us, Syria, or at any rate Palestine, was at times a dependency of Egypt. As regards commerce, manufactures and agriculture the country had reached a considerable degree of civilization. A record of the days of Rameses II (1300–1280 B.C.) mentions 38 fortified places in Palestine and 18 more north of Tyre. At an early period Syria became part of the Assyrian Empire, and afterwards passed to the Persians under Cyrus, and the Greeks under Alexander, who conquered the country after the battle of Issus in 333 B.C. Ten years later Ptolemy took possession of Syria and Palestine, and in 312 B.C. began the era of the Seleucides, when Antioch was founded. The Seleucide dominion lasted 248 years, when the conquering Romans made Syria a Roman province in 64 B.C. At this period the Aramaic language was chiefly spoken throughout Syria, although the Greek language and culture were gradually being introduced. Under the Greek and the later Roman supremacy there sprang up, even in remote parts of the country, numerous buildings of great splendor. About the beginning of our era Palmyra was particularly noted for the magnificence of its architecture. The whole of Christian Syria, including Palestine, was wrested from the Eastern Roman Empire by the Persians in A.D. 611–614. Nomadic tribes of Arabs had from time immemorial ranged over the Syrian plain as far as Mesopotamia, and certain Arab tribes from the Yemen were settled in Syria, particularly in the Haurân. For centuries before the rise of Islam the Arabs were everywhere a disturbing element to the Byzantine Empire. The new religion promulgated by Mohammed produced extraordinary results. As by magic, long-standing intertribal feuds among the Arabs disappeared — they became a united nation galvanized by religious enthusiasm. Shortly after the death of the Prophet the Arabs defeated the Byzantines, and Syria fell into their hands (636). It was governed by caliphs till 883, and then passed under various masters till it was conquered by the Seljuk Turks, who gradually obtained possession of the whole country (1070–85). The first Crusade began in 1096; Antioch fell to the Crusaders in 1098. By 1118 the kingdom of Jerusalem had been established and the Franks had taken Cæsarea, Tripoli and Beirut. The next 140 years included the romantic period of Richard Cœur de Lion and Saladin, the latter becoming master of the whole of Syria except the Frankish possessions (1183). North and central Syria were conquered by the Mongols in 1259–60; in 1291 the Mamelukes ended the Frank rule in Palestine and later united Syria with Egypt. After this period the history of Syria presents few points of interest; internal strife continued between the Mamelukes, Circassian sultans and Mongolian governors. In 1400 came the Mongol invasion of Tamerlane, when great numbers of the inhabitants were massacred.

War broke out in 1516 between the Ottoman Turks and the Mamelukes; the latter were defeated by Sultan Selim, and in the following year the whole of Syria was incorporated in the Turkish or Ottoman Empire — a connection destined to be severed 400 years later by the Great War. The more important events in the modern history of Syria are its conquest by Mehemet Ali of Egypt in 1833, and its subsequent restoration to Turkey in 1840 by the intervention of the great European powers; and the disturbances that broke out in the Lebanon district in 1860 between the Maronites and the Druses. A Maronite monk was found murdered, and suspicion fell upon the Druses. The latter made a general attack on the Maronite villages near Beirut and a large town under Mount Hermon. With a promise of protection the Turkish commander ordered the Maronites to lay down their arms. On this being done, they were abandoned to their enemies, who thereupon swarmed into their villages and massacred all men, women and children. So far from rendering the promised protection, Turkish troops were said to have assisted in the butchery. France and Great Britain intervened; a French expedition was dispatched to the scene. Its active services, however, were not required. As a result of that intervention the Lebanon district was created an independent sanjak, the governor of which was required to profess the Christian religion.

During the European War in June 1917 Syria was invaded by a British force under General Allenby who captured Beersheba 31 Oct., Geza 7 Nov., and Jaffa 17 Nov. The victorious troops entered Jerusalem 9 Dec., and Palestine, separated from Syria, was created an independent sanjak under British administration.

HENRI F. KLEIN,
Editorial Staff of The Americana.

SYRIAC LANGUAGE AND LITERATURE, one of the members of the Semitic family of languages. It is a variation or dialect of the *Aramaic* tongue, which covered the districts of Mesopotamia, northern Syria, Damascus and eastern Palestine southward to Arabia Petræa. The language of Syria, especially in its earlier form, differs very little from Chaldee or eastern Aramaic. The Latin equivalent of the name which is *Syriacus* and its Greek equivalent mean of or pertaining to Syria or its language.

Language.— When Syriac first appeared within the view of history it must have been undoubtedly quite an ancient tongue, since its grammatical forms had assumed great definiteness, though it was subject to constant linguistic influence from the powerful and highly organized peoples by which it was surrounded. In later days it continued to be affected by Greek and still later by Arabic, the latter of which contributed to it many words. There was undoubtedly a very considerable body of pre-Christian Syriac literature; but this seems to have disappeared before the iconoclastic and missionary zeal of the Christian priests, though some of it may still be recorded from the ruins of very ancient Syraic cities. Syriac differs very considerably from Hebrew, more especially in its vocal system which is much more condensed than that of either Hebrew or Arabian. In the Aramaic the prefixed definite article does not exist; it is replaced by the ending "a" emphatic, but no longer definite in the sense that the prefixed article is definite. Both Hebrew and Syriac have 22 letters and these are identical in use and form, the dialectic difference of the two tongues being taken into consideration and allowed for. The Syriac tongue possesses 10 vowel sounds (ā a ē e ī i ō o ū u) which were used during the living period of the language, rudicaled in the same manner as in the Semitic tongues. Later on, when it was rapidly becoming a dead speech, two distinctly different methods of representing these vowels came into use. The West Syrians borrowed their's from the Greek alphabet, applying them in a somewhat indefinite manner; while the East Syrians made use of a series of dots by which they secured a much more effective vowel designation. The close relationship of Syriac to Hebrew and Arabic is evidenced by the fact that words having the same root in these three tongues have for the most part the same fundamental vowel sounds, with occasional interchange of letters and some slight and regular modifications indicative of the existing dialectic differences. In Hebrew the accent has a much greater tendency to lengthen the vowel than it has in Syriac, and the latter has a more primitive vowel system than the former. The pronominal suffixes to be found in all the members of the Semitic group of languages effect fewer modifications or changes of the vowels in Syriac than in Hebrew and some of the other members of the group. Syriac possesses no neuter gender, has only two numbers, singular and plural, and had early attained to much more flexibility of construction than Hebrew; and this flexibility the Christian writers steadily increased. The Syriac verb is more regular than the Hebrew form, but it is noticeable for the lack of the original passive forms which have been replaced by distinct grammatical inventions. Syriac has also contributed to its own flexibility by the invention of true tenses with the use of an auxiliary, thus attaining a decided superiority over Hebrew. The use of conjunctions and prepositions shows that Syriac was working steadily in the direction of an analytical construction. Its choice as the tongue in which so much early Christian literature was written was fortunate, since it gave very much greater facility to the expression of thought and the presentation of ideas of so many kinds which has already begun to knock incessantly at the door of a new world of religious and philosophical imagination and reason.

Literature.— The Syriac language is of great importance as the medium of literary expression of so much of the activities of the early Christians and because of the numerous versions of the Bible or parts thereof written in it. The Syriac writers showed all the literary activity of their ancestors and of the Semitic races by which they were surrounded. There is no doubt but that this activity was the legitimate result of long years of literary practice during their pre-Christian life; but unfortunately this early pagan literature has disappeared. But there is plenty belonging to the Christian period still in existence. This covers every avenue of the activities of a people, philosophy, law, science, legend, story, religion, biblical lore, poetry, church government, canonical law, liturgy, biography, historical, romance and theology in all its many forms. Like the Hebrew, Christian Syriac literature shows the ever-present, ever over-brooding spirit of the religious thought which had early in the Christian era obtained such a hold upon the imagination and the affection of the Syrians. The use of Syriac in literature was spread pretty well over the centres of population of the area covered by the language itself as indicated previously in this article. Almost every Syriac city at some time in its career became more or less active in a literary way previous to the Arabic conquest of Syria (636–37) and the body of literature thus produced was large and varied within a certain field limited only by the activities of the people themselves physically and mentally. In fact the Syriac literature is very largely a chronicle of these racial activities. Hence it is not great in a poetical sense. The style and manner of expressing thought is frequently excellent; but Syriac imagery and imagination never rise to the sublime heights of the Hebrew writers. Syriac literature is at its best when it is dealing with all the phases of the Christian religion, history, biography, devotional works and the lives of the saints. Edessa seems to have been the earliest seat of the Christian-Syriac literature which spread rapidly to other parts of the country. This literary activity began probably in the 2d century though legend claims that it had begun in the time of the Apostles. It is in fact quite probable that the translation into Syriac of the Old Testament was made in the 1st century by Syriac Jews; and in the 2d century a compilation of the first four gospels is reported to have been made by Tartian (q.v.) about 180. Many compilations and translations were made from the Old and the New Testaments during the following five centuries. Among the early Syriac writers is Bardesanes, the Gnostic (d. 222). Historian, philosopher and poet, he is reported to have written 150 hymns and to have been an authority on astronomy. Most of these hymns have been lost; but some of them have been preserved in the Hymns of the Soul, in the 'Acts of Thomas.' His 'Dialogue on Destiny.' which is still extant, gives a good idea of his imagination and his clearness of thought. To the following century belong Aphrates the author of homilies popular in his day and for years afterward; Ephraem (d. 337), the most famous commentator, poet and writer of exegetical discourses; and Aba, Balæ, Zenobius and other disciples of the latter who filled much the same field as he. The following century was one of great activity in the Christian Church for it witnessed the separation of the Mesopotamian Christian Church from that of Rome and the division of the former into two sects, the Monophysites (q.v.) and the Nestorians. This led to great literary activity throughout Syria within the body of the Christian society so that the 4th century marks the beginning of the great Syriac literary period which continued active until the Arabian conquest. One of the most noted writers of the 5th century was Isaac of Antioch (q.v.), abbot of a convent. He wrote many hymns and poems and 191 metrical homilies have been credited to him. He denounced the current abuses and luxury of his times much in the mood of the Hebrew prophets of an earlier age in a forceful manner and in a style rich in imagery and marked with imagination. A hundred or more of his poems still exist. Another writer of force belonging to this period was Narses of Maalletha. To the same century belong Ibas, bishop of Edessa, who was deposed from office on account of his Nestorian writings; Dadhisho, commentator; Narsai, "Harp of the Holy Spirit," poet and theological writer, many of whose poems survive; Jacob of Serugh, poet, and Philoxenus of Mabbogh, an excellent prose writer. Among the Syriac writers of the 16th century are John of Tella; John bar Aphtonya, commentator, poet, hymn writer and biographer; Sergius of Rasain, scholar, translator and grammarian; John of Ephesus, noted church historian; Moses of Aggel, translator and writer; Marutha of Seleucia, commentator, sermon, hymn and epistle writer of note; Bodh, logician and translator of Persian tales, and Hannana of Hedhaiyabh, commentator, controversialist and general writer of great activity. Among the historical works of interest written in Syriac are 'Chronicle of Edessa,' 'Chronicle of Dionysius of Tell Mahre' and the semi-religious works of Zacharias of Metylene. The whole body of translations made into Syriac was very large and embraced works from most of the great literatures of the day. This translation continued on into the period of Arabic domination; but Syriac after the middle of the 7th century began to be a dead language. After this period it became the vehicle of the Church and of scholars much as Latin was regarded in Europe. Therefore, the works written in Syriac during the period of Arabian domination are for the most part of a learned nature and the literature tends to run largely to matters ecclesiastical, historical, philosophical and scientific. Among the most noted of the classical Syriac writers are Thabit ben Korrah (9th century); Theodor bar Choni (10th century); Dionysius bar Salibi (12th century), who wrote the 'History of the Crusades'; Michael of Melitene (12th century), 'History of the World'; Abulfar of Gregory (13th century), commentator, grammarian and historian, and Abhdisho (14th century), critic, historical writer and author of a careful work on Syriac literature.

JOHN HUBERT CORNYN,
Birmingham Southern College.

SYRIAC VERSIONS OF THE BIBLE, entire or in part, are numerous. The most important is the Peshitto (q.v.) or "plain" version of the Old Testament, made probably in the 2d century, and in great part from the Hebrew text, while some of the books are rendered from the Septuagint; originally the Peshitta Old Testament contained only the books of the Hebrew canon; the deutero-canonical books as found in the Septuagint were added later. The New Testament books in the Peshitta Version are the four Gospels, Acts, Epistles of James, 1 Peter, 1 John and 14 Pauline epistles; the early Syrian Church did not receive the other apostolic epistles nor the Apocalypse. In the 2d century Tatian compiled a *Diatessaron* or harmonized compilation of the four Gospels, the greater part of which is extant; for a time the Diatessaron displaced the four Gospels in the Syrian Church. The Monophysites in the 4th century, dissatisfied with the Peshitta, made a complete new version from the Greek texts of the Septuagint and the New Testament. Another translation of the Septuagint was made in the 7th century by Paul, bishop of Constantia; copies of this are extant in the British Museum and in the Ambrosian Library at Milan. Another version of the whole Bible is that used by the Malkites (or Melchites) in Palestine; it is written in an Aramaic dialect more akin to the language of the Jewish Targums than to the Syriac of the Peshitta. See BIBLE.

SYRIAN CHURCHES, those churches in Syria, Mesopotamia and adjoining countries which use a Syriac liturgy; but with them is usually classed the Melchite Church, whose liturgy is Greek. The principal Syrian churches are: (1) That of the Jacobites or Monophysites; they are supposed to number 45,000 families in Syria, Mesopotamia and Chaldæa; they are presided over by two patriarchs. (2) The Syrian Catholic Church, a secession from the preceding in the year 1546; it is constantly gaining accessions from the Jacobites. (3) The Nestorian Church in Kurdistan, Chaldæa and Mesopotamia; its adherents are estimated at 150,000 and are presided over by two patriarchs. (4) The Chaldæan Church in communion with the See of Rome is a secession from the Nestorian Church, and is constantly gaining strength by new accessions from that body. (5) The Maronite Church, with its principal seat in the Libanus, has been in communion with the See of Rome since the 13th century; it is the most flourishing Christian community in Syria. (6) The Melchite Church, in communion with the Orthodox Greek Church. (7) Finally, the United Melchite, or Melchite Catholic Church, in communion with the Church of Rome.

SYRIAN PROTESTANT COLLEGE, an undenominational institution of higher learning at Beirut, Syria, opened in 1866, and the largest American educational institution outside the United States. It was chartered by New York State in 1863 and is controlled by a board of 12 trustees in New York, the faculty conducting the local government. It was the outgrowth of a mission, and is now an independent organization. There are seven departments, preparatory, collegiate, commerce, medicine, pharmacy, training school for nurses and Biblical archæology. It has 18 stone buildings, a 40-acre campus, nine well-equipped laboratories, an anatomical observatory, a hall of science, and hospitals for women and children and for eye diseases. The library contains about 15,000 volumes. There are about 900 students and 70 instructors. The Syrians predominate among the students, but there is a wide representation of nationalities, usually not less than 12. Instruction is in English.

SYRINGA, any of several shrubs. Popularly this name has been applied to the mock orange (genus *Philadelphus*) which has long been cultivated in gardens for its handsome flowers; generically, however, it is the name of the lilac. These two genera belong to different families, the *Saxifragaceæ* and the *Oleaceæ,* respectively. This confusion is a legacy from the old herbalists who united jasmine, mock orange and lilac under the one genus *Syringa,* a feat which also accounts for the use of the name jasmine for *Philadelphus,* among the Germans. Jasmine belongs with lilac in the family *Oleaceæ.* The French, on the other hand, adopt *Seringa* as the popular name for *Philadelphus.* See JASMINE; LILAC; PHILADELPHUS.

SYRINX, si'rinks, in ancient mythology, a nymph beloved by Pan, and who turned into reeds when flying from him. The god is said to have constructed his pipes from those reeds. See MUSICAL INSTRUMENTS.

SYRPHUS-FLY, a fly of the family *Syrphidæ,* smooth or hairy insects, often seen hovering almost without motion over flowers, some of them looking like bees. The species are numerous and the larvæ diverse in habits. Most of the latter feed on the roots or bulbs of plants, or live in decaying wood, mud or sewers, or in the water, or as parasites in the nests of wasps and bumble bees, or crawling over plants in quest of aphides; hence they are sometimes called aphis-lions. The family is very numerous.

SYRTIS, sėr'tĭs, two gulfs of the Mediterranean Sea, on the coast of Africa; the Lesser Syrte, or Gulf of Gabes, is on the east coast of Tunis, between the islands of Dschebado and Kerkenah. The Greater Syrte, or Gulf of Sydra, southeast from the latter, between Tripoli and the plateau of Barka. They form together the most southerly part of the Mediterranean. The navigation of the Syrtes was anciently considered very dangerous, their shores being full of quicksands and their waters impeded by sandbanks, shallows and sunken rocks. The only harbor is Bengasi.

SYRUP, a saturated solution of sugar in water, either simple, flavored or medicated. In preparing syrups the best refined sugar should be used, and either distilled water or filtered rain water; they will thus be less liable to spontaneous decomposition, and will be transparent without undergoing the process of clarification. When vegetable infusions or solutions enter into the composition they should be made perfectly transparent by filtration or clarification before being added to the sugar. The proper quantity of sugar for syrups is about two pounds for every pint of water. It is of great importance to employ as little heat as possible, as a solution of sugar, even when kept at the temperature of boiling water, undergoes slow decomposition. Syrups should be kept in a moderately cool though not a cold place. See SUGAR GROWING AND SUGAR MAKING.

SYRUS, sī'rŭs, **Publius,** Roman author who flourished about 43 B.C. After Laberius he reigned supreme on the stage, and his mimes were full of shrewd epigrammatic wit. About 200 apothegms are still extant, under the title 'Witticisms of Publius Syrus.'

SYSTEM, the term applied to the rocks of a given period; thus we say that the Cambrian system of rocks was laid down during the Cambrian period, the Tertiary system during the Tertiary period, etc.

SYZRAN, sĭz-rāny', Russia, a river-port near the right bank of the Volga, 90 miles southeast of Simbirsk. It has nine churches, a monastery, convent, grammar school, technical school and banks. The manufactures include leather goods and iron-wares. Trade depends upon grain, fish and salt, great quantities of grain being exported. It lies on the Rjashsk-Batonki Railway. Pop. 46,234.

SZABADKA, sŏ'bŏd-kŏ, Hungary, in the county of Bács-Bodrog, 25 miles southwest of Szegedin and 110 miles southeast of Budapest. The fashionable summer resort of Lake Palics lies within its confines. Its chief points of interest are the schools, hospitals, almshouse and music school. Agriculture is the chief occupation. It has considerable trade in fowls, fruit, cattle, horses, hides, wool, corn and tobacco. Linens and shoes are manufactured. Pop. 94,600.

SZECHUAN, sā-choo-ăn', China, the largest province of the republic, in the west, with Tibet on the northwest and Yun-nan on the southwest; area, 218,480 square miles. It is traversed and watered by the Yang-tse-Kiang and its affluents, is hilly throughout, mountainous in the west and rich in natural products, including coal, iron and other minerals. Opium, silk, salt, sugar, medicines, tobacco, hides, musk, rhubarb and white wax (produced by an insect) are exported to the annual value of $25,000,000; and European cottons and woolens are imported to the value of $15,000,000 annually. The capital is Cheng-tu, the chief commercial town Shung-king, which was opened to foreign trade in the end of 1889. Ichang was thrown open in 1877. Pop. of province 54,500,000. (See CHINA). Consult Baber, 'Travels and Researches in Western China' (London 1882); Bishop, 'The Yang-tse Valley and Beyond' (New York 1901); Hosie, 'Three Years in Western China' (ib. 1890).

SZE-MA KWANG, sĕ'mä' kwang', Chinese statesman and author: b. 1009; d. 1086. He is renowned as the author of 'The Comprehensive Mirror of History,' in 294 books, the labor of 19 years. It covers a period from the beginning of the 5th century B.C. to A.D. 960. Sze-ma is also the author of 'Ki-ku-lu' or 'Investigations into Antiquity,' which brings her history down to 1066 A.D. He also wrote a dictionary and numerous essays are ascribed to him. Consult Giles, H. A., 'History of Chinese Literature' (New York 1901), and Rémusat, 'Nouveaux mélanges asiatiques' (2 vols., Paris 1829).

SZE-MA TS'IEN, sĕ'mä' chĕn', Chinese author: b. 163 B.C.; d. 89 B.C. Born in Lungmun, Honan, in 110 B.C. he succeeded his father, Sze-ma T'an, as grand recorder and astronomer, and took up the historical work begun by him. It was finished in 91 B.C. and was named 'Shiki,' or 'Historical Records.' It covers the period from 2697 to 104 B.C. He is also noted for reforming the calendar. The chronology settled by him still prevails in China. Consult Giles, H. A., 'History of Chinese Literature' (New York 1901), and Hirth, F., 'Ancient History of China' (ib. 1911).

SZEBEN, sĕ'bĕn, **NAGY,** nŏd'y, or **HERMANNSTADT,** hĕr'män-stät, Rumania, the capital of a county of the same name in Transylvania. It lies amid beautiful surroundings, among which there are several noted health resorts. The city, which is built partly on a hill, partly on a small river-plain, has handsome, well-paved streets and a large market place. Among the principal buildings are a large Gothic church dating from the 13th to the 16th century and now used by a Lutheran congregation, the city hall, the communal hospital, several large barracks and the palace of Bruckenthal containing a library and collections of art and antiques. There are five institutions for higher education in the city, besides a cadet school, trade schools and a number of minor schools. The principal industries are the manufacture of cloth and blankets, soap, spirits, glue and horn articles, and there are many machine shops, tanneries and two large breweries. The inhabitants are chiefly German Protestants. The formerly important trade with the East has declined. Nagy-Szeben was the capital of Transylvania, and from the 15th to the 17th century was very strongly fortified. It was a city of Hungary until under the Peace Treaty of 1919 with part of Transylvania it was included in Rumanian territory. Pop. about 31,000.

SZEGEDIN, sĕg'ĕd-ēn, Hungary, capital of the county of Csongrad, on the Theiss, 100 miles southeast of Budapest. It lies in a marshy district. It has suffered the ravages of flood and fire, and is now modern in construction and buildings. Its public buildings are prepossessing and include municipal buildings, courts, barracks, theatres, Franciscan monastery with a large and valuable library, museum, etc. There is a fine quay and embankment affording protection against further inundations. The river is spanned by fine bridges for railway and general traffic. The manufactures are soap, paprika, liquor, soda, tobacco, coarse cloth, etc. There is an important trade in wood, corn, wool, cattle, salt and tobacco. Many river boats are built in the yards of Szegedin. In 1526 it was taken by the Turks, who held it until 1686. Pop. 118,300.

SZENTES, sĕn'tĕsh, Hungary, in the county of Csongrad on the left bank of the Theiss, 29 miles northeast of Szegedin. It contains many good buildings, among which is a Protestant church with a fine tower, other churches and a town house. The trade depends upon corn, cattle and wood, in which it has a large trade as also in wine. It has a system of municipal tramways. Pop. 31,590.

SZOLNÓK, sŏl'nŏk, Hungary, a river port and market town in the county of Jázygia, on the right bank of the Theiss. It is the seat of the government courts, a steamboat station and the junction of four railways. Its buildings include a Turkish mosque now used as a chapel, the ruins of a citadel and a Franciscan monastery. It carries on an extensive trade in fruit, grain, cattle, salt and wood — especially the latter. It was the scene of a Hungarian victory over the Austrians on 5 March 1849. Pop. 28,900.

T

T, the 20th letter of the English alphabet and the 16th consonant, is a sharp mute consonant to which *d* answers as a sonant. Its earliest form both in Greek and Latin was but little different from that which it still has; but in some Umbrian and Etrurian inscriptions it is an upright stroke with a small stroke at the top slanting right or left: in early Phœnician and in Hebrew rock inscriptions it has the form + or × or ᚠ. *t* is usually classed as a surd or voiceless dental, but in English pronunciation it might be classed with the cerebrals, being made with the tongue on the hard palate. In French and other languages of Continental Europe the *t* is a true dental, for in pronouncing the letter in those languages the tongue comes in contact with the teeth. The same difference exists between English and those other languages in the pronunciation of *d*. The digraph *th* has two valves in English, namely, the voiceless dental fricative value which it has in *thank, throw,* and the voiced dental fricative value in *that, then*: these two sounds were represented in the Anglo-Saxon alphabet by two different characters, namely þ for *th* in *thank, throw* and ð for *th* in *this, that*: but in Old English manuscripts there was little consistency in the employment of these characters. In some variations of the Irish pronunciation of the digraph *th* in *thin, thorn, through,* etc., is a true aspirate rather than a fricative, the tip of the tongue is pressed against the upper gums and the breath emitted with force; but in correct English pronunciation of this *th* the tongue is brought against the back of the front teeth, with very slight contact, and the breath emitted between tongue and teeth; and there is a similar difference between the Irish and the English pronunciation of *th* in *that, then, this,* etc.; in the Irish pronunciation the tongue is brought into full contact with the teeth. *Ti,* unaccented, before a vowel is usually pronounced as *sh: nation, nashun, motion, moshun; t* before the diphthongal *u* (as in *use*), has the value of *tsh; nature, natshur.*— In the corresponding words of English and the languages akin to it there is interchange of *t* with other letters; examples: Eng. *three,* Ger. *drei,* Goth. *thrais;* Lat. *tres,* Gr. *treis;* Eng. *thatch,* Ger. *Dach,* Lat. *tectum,* Gr. *tegos;* Eng. *brother,* Ger. *Bruder,* Goth. *brothar,* Lat. *frater;* Eng. *dew,* Ger. *Thau;* Eng. *thank,* Ger. *Dank.* Very usually *t* in an English word is represented by *z* in the kindred German word: Eng. *two,* Ger. *zwei;* Eng. *toll;* Ger. *Zoll.*

TNA, is an explosive substance having the formula $C_6H(NO_2)_4NH_2$ which is derived from aniline and has the scientific name of tetranitroaniline. Flürscheim, who, in 1910, proposed to use it as a commercial explosive as it was more powerful than any substance then in use, manufactured it from commercial dinitrobenzene by treating the latter with a solution of sodium bisulphate and then nitrating the product thus obtained with mixed acids at 70° C. or lower. The TNA separated in yellow crystals which when washed and dried had a specific gravity of 1.867 and, when heated at the rate of 5° C. per minute, a melting point of 216° C. and an explosion point of 260° C. Its rate of detonation is 5,500 meters per second. It is an efficient agent for re-enforcing detonators and as a booster, but its stability is questioned.

TNT or **TRINITROTOLUENE.** See TRINITROTOLUENE.

TNX, an explosive substance having the formula $(CH_3)_2C_6H(NO_2)_3$ and whose scientific name is trinitroxylene. It is produced by nitrating the aromatic hydrocarbon known as xylene with mixed acids and fuming nitric acid. Several different compounds having the same percentage and radical composition may be formed but the one produced in largest amount and the one most sought is the trinitrometaxylene. This when pure crystallizes from alcohol in milk-white lamellæ which when slowly heated melt at 176°–177° C. TNX is used either alone or in admixture with ammonium nitrate, as a bursting charge for high explosive shells. It has also been used as a component of blasting explosives such as monachite.

T-RAIL. See RAILS AND STRUCTURAL SHAPES, MANUFACTURE OF.

T-SQUARE, a ruler used by draftsmen, made similar to the common L-shaped square, but of wood, and in the form of a T. It is often graduated in the edges and is convenient for ruling lines at right angles to a base. Sometimes the long arm is made adjustable, so that it may also be used for drawing angles.

TA-KU, tä'koo', China, a small, fortified town situated near the head of the Gulf of Pe-chi-li, southeast of Tien-tsing, and about 80 miles southeast of Peking. It is important as guarding the entrance to the Yung-ting River. It has been the scene of several engagements and was captured by the Allies in 1900, and after the war remained garrisoned by German troops.

TA-LIEN-WAN, tä'lĕn'wän', Manchuria, a bay on the east side of the extremity of the Liao-tung Peninsula, about 40 miles northeast of Port Arthur. The British fleet occupied it in 1860. It is within the territory leased to Russia in 1898. At its head is the northern port of Dalny (q.v.) which was opened to foreign trade in 1901. The construction of a Russian naval station was well advanced when the Russo-Japanese War broke out in 1904 and the bay became the scene of war operations. The adjoining territory passed to Japan in 1905.

TAAFFE, tä'fĕ, **Eduard Francis Joseph von,** Austrian statesman: b. Prague, 24 Feb. 1833; d. Ellischau, 29 Nov. 1895. He was of Irish descent and a Baron of Ballymote as well as Viscount of Austria; was educated at the University of Vienna and entered the civil service. Promotion followed rapidly and in 1867 he became Minister of the Interior. In the following year he also served as acting Minister-President. He had entered politics as a German liberal, but manifested a growing tendency toward Federalism, which he regarded as the only means of reconciling warring factions. In 1870 he joined with two of his colleagues in urging upon the emperor a policy in the direction of Federalism with autonomy, but being defeated in this endeavor, he resigned. In 1871 he became governor of Tyrol and Vorarlberg. In 1879 he was again made Minister of the Interior, formed a new Cabinet and remained at its head until 1893. Devotion to the cause of the emperor was Taaffe's strongest trait, and as this involved the consolidation of the antipathetic nationalities of Austria, he bent every effort in that direction. He worked not through one party, but with any party which by opportune measures could be brought to support his policy, and he relied mainly upon private efforts, for in public he was an inferior speaker. In 1893 he was defeated in his purpose to extend the franchise and his retirement from public life directly followed.

TAAL, tä-äl', Philippines, pueblo, province of Batangas, Luzon, on Balayan Bay at the mouth of the Pansipit River, 13 miles northwest of Batangas, and about 50 miles south of Manila. It is named after an older town on Lake Taal that was destroyed in the volcanic disturbances of 1754. The people are mostly Tagalogs. It is connected with Batangas and other towns by highway, has a well-sheltered anchorage and carries on an important coastwise trade. Agriculture, stock-raising and fishing are also important industries of which Taal is the centre, and sulphur deposits are found in the vicinity. The town is well built on a terraced hill, is an important military station and one of the largest municipalities in the province. It has good schools. Pop. about 36,000.

TAAL, Philippines, a lake. See BOMBON.

TAAL, Philippines, a volcano on Bombon Island in Lake Bombon or Taal, province of Batangas, Luzon, about 40 miles south of Manila. The island from which it rises is 14 miles in circumference; its greatest height is to the southwest, 1,067 feet above the level of the lake; from this point it descends and then rises to a height of 780 feet to the north. The crater is oval and the walls steep; at the base are two steaming lagunas. It supplies large quantities of sulphur. The last eruption recorded took place in 1911; eruptions also occurred in 1709, 1715, 1716, 1731, 1747, 1754, 1808, 1873 and 1911.

TABACO, tä-bä'kō, pueblo, province of Albay, Luzon, on Tabaco Bay, east coast, 15 miles north of Albay, the provincial capital. It has the deepest and best-sheltered harbor in the province and carries on a large trade with Manila, being third port in Albay in the importance of its shipping. Pop. about 25,000.

TABARD, in the times of the Tudors, a tunic-like garment, worn over the armor, covering the body before and behind and reaching below the loins, but open at the side from the shoulders downward; it had wide sleeves or flaps reaching to the elbow and was generally embroidered with the arms of the wearer or if worn by a herald, with those of his lord or sovereign.

TABARI, tä-bä'rē, **Abu Jafar Mohammed Ibn Djerir,** Mohammedan theologian and historian: b. Amul, Taberistan, 839; d. Bagdad, 923. During the first half of his life he widened the area of his learning and experience by traveling from one centre to another of Moslem religion and speculation between eastern Persia and Egypt, devoting himself to the perusal of the Koran and the acquisition of all the lore which jurisprudence, tradition, history and philology had contributed to the elucidation of the Mohammedan scriptures. In about 881 he settled at Bagdad and employed the fruits of his investigation as a teacher and writer in Arabic. His principal works are the ‹Tefsir› or ‹Exegesis,› which contains a complete collection of the existing and independent commentaries of all interpreters of the Koran, with large additions, original and compiled, from abstruse sources. It filled 25 large manuscript volumes and was published in 35 numbers of the *Zeitschrift der Deutschen Morgenländischen Gesellschaft* (1881). His other work is somewhat less important, being a history of the world (‹Annals›) from creation to 914 A.D.

TABASCO, tä-bäs'kō, Mexico, a state situated at the head of the Gulf of Campeachy and bounded by the states of Vera Cruz, Chiapas and Campeche. It is one of the smallest states of the Confederation, its area being 10,072 square miles. The surface consists almost entirely of a great flat, sloping gradually to the sea, but in many parts so low that it is subject to inundations. The streams, though numerous, are short and shallow and are generally obstructed at their mouths by sandbars. The Tabasca, or Gsijalva, River, however, is navigable for 90 miles and the Usmacinta for 175 miles. The climate is excessively hot, particularly along the coast, and in the marshy districts very unhealthful. A large portion of the state is still covered with primæval forests. The principal cultivated crops are cacao, coffee, dye-woods, vanilla, indigo, tobacco and sugar. The inhabitants are chiefly Indians. The capital is San Juan Bautista. Pop. of the state about 190,000.

TABASHEER, or **TABASHIR,** a remarkable substance occasionally found in the hollow joints of certain species of bamboo and other large grasses. It is ordinarily sought for by splitting open those bamboo stems which give a rattling sound when shaken. It is especially apt to be found in the *Bambusa arundinacea* of Indian and other related species of Japan, China, Java and the Andes Mountains. During the rapid growth of the bamboo shoots, their solid joints become hollow and are partially filled with water containing silica in solution. The development of the foliage leads to active transpiration; the water absorbed from the soil quickly disappears and tabasheer is the residue. It is at first jelly-like, but gradually solidifies into small milky-white masses. Physically and chemically these are practically identical with the hydrophane variety of the mineral opal. It is an open question whether tabasheer should be registered as belonging to the mineral or the vegetable kingdom. It is essentially a hydrous silica, the lime and potash which are often present being doubtless simply impurities. Its optical properties are most remarkable. According to Brewster, it has a lower index of refraction than any other solid or liquid, its refractive power being not only lower than water, but so much lower as to be almost intermediate between water and air. The material is isotropic, opalescent and remarkably phosphorescent. It becomes transparent when saturated with water and is remarkably porous. It probably possesses greater absorptive power than any other mineral, Brewster claiming that the pores occupy two and one-half times as much space as the silica itself, notwithstanding the fact that they are invisible even under very high powers of the microscope. From time immemorial it has been highly esteemed in the Orient for its supposed medicinal properties. A knowledge of the substance was introduced into Europe by the Arabian physicians and its name is of Arabic origin. Much so-called tabasheer in Turkey and Asia Minor is artificial. Consult *Nature* (Vol. XXXV, p. 488, 1887).

TABB, John Banister, American poet: b. Amelia County, Va., 22 March 1845; d. 1909. After private study, he was appointed in 1862 captain's clerk to the Confederate blockade-runner *R. E. Lee*, but in 1864 was captured and held prisoner for seven months at Point Lookout, Md. He studied music in Baltimore, taught there, and at Racine College, Michigan, and after courses at Saint Charles College, Ellicott City, Md., and Saint Mary's Seminary, Baltimore, was ordained in 1884 to the priesthood of the Roman Catholic Church. Later he was professor of English at Saint Charles. He privately printed a book of 'Poems' in 1884, and from that time wrote largely for the magazines, gathering his contributions at intervals in various collections. His volumes are 'Poems'; 'Lyrics'; 'An Octave to Mary'; 'Rules of English Grammar'; 'Poems Grave and Gay' (1899) 'Two Lyrics' (1900); 'Later Poems' (1910). Ingenious in matter, compact in form, his favorite length is the quatrain distinguished by an effectively simple diction.

TABBY, a variety of rich watered silk which has undergone the operation of tabbying or being passed through a calender, the rolls of which are made of iron or copper variously figured, which, bearing unequally on the stuff, renders the surface unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABBYITE, a variety of asphalt, semi-brittle, semi-waxy, containing a small percentage of ceresin; readily fusible, freely soluble in carbon disulphide; used in making paint, varnish, rubber substitute and pavings. Occurs with other bitumens in Wasatch County, Utah.

TABERNACLE (from Lat. *tabernaculum*, a tent), the tent in which the Ark of the Covenant was deposited during the wanderings of the Israelites in the wilderness and subsequently in Palestine until the erection of a permanent building at Shiloh. When this building was erected does not appear in the Scriptures, but 1 Samuel iii, 3, clearly shows that it existed in the early days of the prophet. The building in which the Ark was is there spoken of as a temple. The sanctity which attached to the Jewish tabernacle led to the use of the word by Christians to designate places considered peculiarly sacred and in the Roman Catholic Church the name is given to the receptacle in which the consecrated elements of the Eucharist are retained. This is a small structure of marble, metal or wood, placed over the high altar and reserved exclusively for the Eucharist. Tabernacle is also in occasional use as a designation of Protestant churches. See ARK; PYX.

TABERNACLES, Feast of, one of the solemn yearly feasts of Israel, directed by the Lord, as set forth in Leviticus, ch. xxiii. It is there commanded that the 15th day of the 7th month shall be the Feast of Tabernacles, to last for seven days. On the first day there should be a holy convocation and no servile work should be done therein. «Seven days ye shall offer an offering made by fire unto the Lord; on the eighth day shall be a holy convocation unto you, and ye shall offer an offering made by fire unto the Lord: it is a solemn assembly, and ye shall do no servile work therein.» The Israelites were further directed to take boughs and branches of trees and willows and to dwell in booths seven days, to remind them of the time when they dwelt in booths in the exodus from Egypt. All orthodox Hebrews observe the Feast of the Tabernacles, which comes in the latter part of September. See JEWS AND JUDAISM.

TABES DORSALIS, an affection of the nervous system akin to locomotor ataxia and paralysis. It is characterized by a lack of power in harmonizing the action of certain muscles, the absence of such co-ordinating power being apparent first in the lower extremities, making the gait straggling and unsteady. There is no true paralysis, but sensitiveness is diminished; the loss of power proceeds and the later stages of the malady are marked by such symptoms as disordered vision, incontinence of urine and exhaustion. The duration of the disease varies from a few months to several years. Its causes are obscure. A peculiar change in the posterior columns of the spinal cord and in the posterior or sensory roots of the spinal nerves accompanies it. Prolonged exposure to cold and damp, drunkenness, sexual excesses, masturbation, etc., have been regarded as causes. Many authorities believe that it is, in many instances, or even exclusively, a remote result of syphilis. It is alleged to be more common in men than in women and subjects between the ages of 30 and 50 are said to be most liable to it. The patient has an unsteady gait and walks like a drunken person, but soon recovers his bearing in some degree. A difficulty in carrying out the intents of the will is experienced and in picking up an object one hand is employed to steady the other. When the eyes are shut the patient walks with extreme difficulty. Tabes dorsalis may be distinguished from disease of the cerebellum by absence of the characteristic pain at the back of the head, and of vomiting. The progress of the disease may be retarded, but the prospect of cure is nearly hopeless. The treatment is limited to improvement of the general health: warm clothing, nutritious food and rest are the chief items. Salvarsan is sometimes injected directly into the spinal column with good results. Consult Osler, William, 'Practice of Medicine' (New York 1912).

TABLAS, tä'bläs, Philippines, the largest and most western island of Romblón province, 15 miles north of the island of Panay; length, north and south, 40 miles; width, 13 miles; area, 320 square miles. The island is mountainous; the highest peak, in the extreme northeast, has an elevation of 2,405 feet; the coasts are mostly abrupt; on the west coast are several good anchorages for small craft; Loog has the best harbor. There are no good roads and few trails; communication between the towns, which are all on the coast, is by sea. The chief industries are agriculture, stock-raising and fishing; but these are almost entirely for domestic purposes. The island is heavily wooded, but lack of communication with larger islands has prevented the development of the forest resources. Pop. about 26.000

TABLE-LAND, or **PLATEAU**, an elevated flat tract of country of considerable area. In ordinary usage the term is applied to such flat areas elevated above 1,000 feet from sea-level. The level character of the plateau may be due to the horizontality of the strata composing it, the surface being formed by a resistant stratum, or it may be due to subaerial or marine denudation of a flexed and folded mountain region, the erosion having proceeded so far as to reduce the region to a nearly level tract or peneplain, which is then elevated bodily. Any portion of the ancient mountain system not worn away will rise as a peak or mountain range above the peneplain surface, and constitute a *monadnock*. A plateau of this type — that is, an elevated peneplain — may be readily recognized by the disagreement of the slope of the strata composing it with the level surface of the peneplain, the two not infrequently making an angle of 90 degrees with each other. When a young plain of deposition with horizontal strata is elevated into a plateau, and the rivers begin to cut their channels down into it, it is in the beginning of its first geographic cycle. If it remains stationary at the altitude to which it was raised, the rivers will eventually incise their channels to such a depth that their bed from ocean to head is almost perfectly graded. Then lateral erosion will widen the valley bottoms, and reduce the portions of the plateau between the river valleys until finally these separating remnants of the plateau have dwindled to such an extent that they appear as ridges or peaks rising from a level plain, which latter is the result of the confluence of all the river valleys cut into the former plateau. This is the beginning of the peneplain stage, and continued erosion will bring the surface nearer to a perfect plain not far above sea-level. If this is reached, the first cycle of geographic development is complete. The second cycle is inaugurated by a re-elevation of the land into a new plateau, when the whole process will be repeated. In like manner a folded mountain region may be worn down to a peneplain, and re-elevated to enter upon the next cycle of erosion. Most plateaus are probably elevated peneplains, either of horizontal strata or of more or less strongly folded and truncated strata. Into these the present drainage has incised itself more or less successfully. Thus the New England region is a peneplain plateau, of inclined strata, whose surface, moderately redissected by streams, slopes gently toward the coast. Southern New York, western Pennsylvania, Ohio and other districts are part of a plateau in which the strata are nearly horizontal and which has been more or less strongly dissected. This extends southward into Tennessee where it is known as the Cumberland plateau. It is probably past its first cycle of erosion, and appears to have been a peneplain.

Among other noteworthy plateaus of North America are the «High Plateaus» of southern Utah, which range in elevations from 7,000 to 9,500 feet above the sea, their elevation being connected with that of the Wasatch Range of mountains. Between the Rocky and Sierra mountains extends a broad plateau from Mexico northward through British America. It averages from 3,000 to 5,000 feet in elevation, and is deeply dissected by the cañons of the Colorado, the Columbia and other rivers. The portion included between the two rivers named is called the Great Basin. It is bounded on the east by the Wasatch Mountains, and on the west by the Sierra Nevada and Cascade ranges, and has a width of nearly 500 miles, with an elevation of 4,000 to 5,000 feet. It has no outside drainage, and hence the streams are short, and the water bodies saline. Great Salt Lake and Mono Lake in California are respectively on the eastern and western side of this plateau, and the surface between is arid and more or less desert. Similar conditions exist in the Mexican extension of this plateau. A higher type of table-land — to which the name intermont plateau has been applied — is found in the great plateau of Tibet between the Himalayas and the Kuen-lun Mountains. Its altitude is about 13,000 feet, while the enclosing mountains rise from 25,000 to 29,000 feet in height. It is 1,200 miles long from east to west, and half as wide. The plateau of Quito is 10,000 feet above sea-level and surrounded by lofty peaks rising 20,000 feet or more. That of Bolivia has an elevation of 12,900 feet with Lake Titicaca at 12,830 feet, and the city of Potosi at 13,330 feet elevation.

The plateau of Spain averages 2,250 feet in elevation, that of Auvergne, in France, about 1,100 feet. Bavaria is a plateau rising 1,660 feet. Persia is another from 2,000 to 4,000 feet above the sea. The Abyssinian plateau in Africa averages 7,000 feet above the sea, while much of the Sahara region is about 1,500 feet above sea-level. The table-land character of all these regions appears only in a general view. Owing to the dissection of the plateaus they appear as a rule anything but level to the traveler unless a comprehensive view from a summit is obtained. Many of the larger plateaus are also traversed by mountain ridges.

TABLE LAWN-TENNIS. See PING-PONG.

TABLE MOUNTAIN, Cape Colony, Africa, a flat-topped mountain with nearly perpendicular sides, situated just south of Cape Town. Its height is 3,540 feet.

TABLE TURNING, in psychical phenomena, the tipping or moving of a table at a séance, usually at gatherings of believers in spiritual manifestations. A number of persons form a circle round a table, on which their outstretched fingers lightly rest. They assume a passive state, usually sitting in a dim light, and sometimes listening to soft music. After a time the table begins to move, and on some occasions to answer questions either by tilting or rapping at appropriate letters as the alphabet is repeated. Faraday was of opinion that a rotary impulse was unconsciously imparted to the table by those who stood around it, and it has been pointed out that pushing may take place without any distinct consciousness on the part of those who push, and that expectant attention is known to produce such a state of the muscles as would occasion this unconscious pushing. The principle involved is the same as in planchette and the ouija board, and has been investigated exhaustively by the Psychical Research Society. Consult Podmore, F., 'Modern Spiritualism' (London 1902). See SPIRITUALISM.

TABLEAUX VIVANTS, tăb'lō vē'vän (French «living pictures»), are representations of scenes from history or fiction by means of persons grouped in the proper manner, placed in appropriate postures, and remaining silent. They are supposed to have been first introduced by Madame de Genlis, instructress of the children of the Duke of Orleans.

TABLES, Lunar. See LUNAR TABLES.

TABLINUM, in Roman antiquity, an apartment in a house in which were deposited the genealogical records and archives, and all documents commemorating the exploits which had been performed by members of the family, or which were connected with the high offices which any of them had filled. It was usually located opposite to the entrance.

TABOO, or TABU, a word of very extended meaning used by South Sea Islanders, to denote something consecrated, sacred, forbidden to be touched, or set aside for particular uses or persons. It is applied both to persons and things, and both to the object prohibited and to the persons against whom the prohibition extends. Thus a consecrated piece of ground is taboo, the act of consecrating it is called taboo, and the persons who are excluded from entering are also said to be tabooed. It is taboo among certain tribes, for any inferior to touch the body of a chief living or dead, or anything belonging to him; to eat in his presence, or anything he has touched; to cross his threshold otherwise than on the hands or knees, or to mention his name. A particular article of food is sometimes tabooed at a certain season in order to preserve it against a season of scarcity, etc. In the case of a serious infringement of the taboo the punishment is death; in less heinous cases a sort of outlawry, the neighbors being permitted to appropriate or destroy the offender's goods.

The word «taboo» has been adopted into English to designate similar customs among races, apart from those from which the term was derived; and has assumed a colloquial sense which is altogether non-religious and negative, though the word was originally used more to designate definite religious ceremonies that were obligatory upon the tribe or upon the individuals composing it. These ceremonies were observed at certain stated times and under certain conditions, generally in connection with important undertakings. In many Indian tribes of America, the warrior who succeeded in killing an enemy was required, on his return to his home, to undergo certain purification ceremonies before he could again resume his former relations with the members of his tribe. Until these ceremonies had been performed, not only were these former relationships tabooed to him, but he was himself tabooed to the tribe; and any one violating the conditions of the taboo became himself tabooed. Always during the period of duration of the taboo, the individual or individuals subject to it are denied the exercise of certain privileges. The taboo may be temporary or permanent; it may be ceremonial, belonging to a fixed and definite period in life, or it may be occasional. Most ancient races had a particular taboo connected with birth, puberty, marriage, death, and even with periods previous to birth and after death; with the assumption of public office and with almost every undertaking in life. Probably most of these customs had their origin in the fear of the superior power of certain deities or evil-disposed spirits and a desire to propitiate them. But in time many of them came to be of a more or less religious and formal nature, and thus many religious observances were formerly taboo in character. Very numerous are the things which have been subject to taboo; but they may be classed under a few more or less definite heads of a general nature. These include objects unclean in their nature, or through mythical, superstitious or religious association; things supposed to belong to, to be possessed by, or to be influenced by spirits or beings feared on account of their mysterious power; strange or unknown objects or customs which it is the part of good sense to propitiate beforehand in case they should prove powerful and ill-disposed. The dread power of priests and rulers was especially feared for it was held little inferior, if any, to that of ghosts, witches, and the supernatural people in general, and superstitious animals.

Opposed to those taboos of fear were those inspired by a desire of personal advantage. Of this nature were the offerings and prayers offered to household gods and to certain deities before undertaking any enterprise of a personal nature. The priest, as the representative of the tribe or the nation, performed the same ceremonies for them and with the same end in view. In connection with these ceremonies there were certain taboos. On opening a cask or bag of wine, the first cupful was tabooed to all but the gods of growth and fertility who made the production of the wine possible. The firstlings of the flock were given to the protector of the herds, the ancient god of hunting; the first fish caught by the fisherman, the first game taken by the hunter, the first ripe fruit and vegetables grown by the husbandman were all, in like manner, tabooed to their possessors. There was not a movement or interest in life without its taboo of a similar nature. Not infrequently the two ruling motives of fear and hope of personal gain are found combined in the same taboo, for a much feared and suspected superior being might, if propitiated, become a valuable ally and helper in time of need.

Taboo associations had much to do with totems and every totem had its taboo. Among many American Indian tribes, a hunter might not kill the animal represented by his totem. Among certain others only a part of such animal was tabooed. The moon being the goddess of fertility, her power was greatest when her full face looked toward the earth. Hence among many races, the planting of grain was tabooed except at the full of the moon. Yet potatoes and bulbous plants could be planted only when she showed the least of her face, for it was feared she might make the part above the ground grow at the expense of that beneath it. Among the forest tribes of the eastern United States and Canada the killing of the ground squirrel was tabooed because he was credited with the discovery of medicines or their introduction to man. Among the Algonquins the white rabbit was tabooed to the hunter because the great culture god Nanabozho frequently assumed the form of a white rabbit. The white dog could not be eaten by the plains Indian because he was reserved as an offering to the great spirit. Among many primitive peoples the names of the dead were tabooed for a certain length of time lest the pronouncing of them might call their spirits back to earth or incite them to unfriendly action. To such a length was this fear of the dead carried that some tribes buried the name with the departed and in its place bestowed another by which the dead was afterward referred to and remembered. Sometimes tabooes were as wide as the tribe or the nation; and many of these ancient tabooes have survived in the shape of national feeling against the use of certain objects.

The custom of making certain places sacred to certain deities arose out of the practice of setting apart such places for the worship of these deities, or through the fact that certain places were believed to be the abode of all powerful beings. This belief tabooed such places to all but the powerful beings who it was claimed had already pre-empted them. (See NATURE WORSHIP; AMERICAN MYTHOLOGY). G., 'The Golden Bough' (London and New York 1907–13); Gennep, 'Tabou et totemisme á Madagascar' (Paris 1904); Waite, Gerland, 'Anthropologie der Natur-Völker'; Smith, W. R., 'Lectures on the Religion of the Semites' (New York 1907); Sumner, W. G., 'Folkways' (Boston 1907); Taylor, 'Te Ika A Mauri, or New Zealand and Its Inhabitants' (London 1870).

JOHN HUBERT CORNYN,
National University of Mexico.

TABOR, Horace Austin Warner, American miner and capitalist; b. Holland, Vt., 30 Nov. 1830; d. Denver, Colo., 10 April 1899. He learned the stonecutter's trade in Massachusetts; removed to Kansas in 1855, and four years later to Colorado, and settled in California Gulch, a place he later named Leadville. In 1878 he with his partners struck a rich deposit of silver in the mine later known as Little Pittsburg. In 1879 he sold his interest in this mine for $1,000,000, with which sum he engaged in speculation and increased his fortune to $9,000,000 in 10 years. He became mayor of Leadville and gave large sums, both to this place and to Denver, for the erection of public buildings. Leadville, accordingly, when hardly more than a mining camp, was given an opera house costing $500,000. In 1878 he was elected lieutenant-governor of Colorado, and from February to March 1885 was United States senator in place of Henry M. Teller, who had entered the Cabinet. From that time his fortunes began to decline and by 1897 his entire accumulations had been swept away. He returned to mining on a small scale, and in 1898 was made postmaster of Denver.

TABOR, Palestine, now called *Jebel et Tûr* or *Jebel Tor*, "the Mountain," a remarkable hill, eight miles east of Nazareth, rising abruptly in the shape of an almost perfect cone from the northeastern arm of the plain of Esdraelon to a height of nearly 1,000 feet, or 1,840 feet above sea-level. It is well-wooded; the dark green of the walnut, the rose bushes, the yellowish-white styrax blossoms, the pistacia and oak trees — all these and many others beautifying the path to the summit, where a view is obtained, embracing Galilee, Samaria, Peræa, and reaching as far northward as the snow-crowned Hermon. The coverts afford a shelter for wolves, wild boars, lynxes and various reptiles. The isolation of this mountain doubtless led to its being made by the earlier ecclesiastics the scene of the Transfiguration. Historical data, however, shows that the summit was occupied as a stronghold from the times of Antiochus Magnus (218 B.C.) until the destruction of Jerusalem under Vespasian. Architectural remains still exist on the summit. Consult Baedeker, 'Palestine and Syria.'

TABOR COLLEGE, located at Tabor, Iowa. It was chartered in 1854 as Tabor Literary Institute, and an academic department opened in 1857; the collegiate department was established and the name changed to Tabor College in 1866. It is non-sectarian in control; but owes its foundation and support largely to the Congregationalists, and is endorsed by the Congregational Conference of Iowa; a committee from this conference examines the work of the college each year. In addition to the regular collegiate courses, there is an academic department with a three years' course, and a conservatory of music. The college work is arranged according to the group system, all groups leading to the degree bachelor of arts. Diplomas are granted to graduates from the academy and the conservatory of music. The college is coeducational.

TABORITES, a group of the followers of John Huss, who was condemned as a heretic by the Council of Constance, and burned at the stake, 6 July 1415, and his ashes strewn on the river Rhine. Others of the faith were known as Hussites. These exasperated followers took cruel revenge on priests and monks of the Church. King Wenceslaus of Bohemia pacified them by granting them religious freedom and the use of some of the churches. After the death of the king in 1419, the Pope issued a command for the conversion or suppression of the Hussites, and the latter took up arms and assembled under the leadership of John Ziska on Mount Tabor. They captured Prague, burned the monasteries and defeated the imperial troops. Their success was continuous for about 15 years until the division between the more radical branch known as Taborites, who acknowledged the Scriptures as the only source of authority, and the Calixtines, who leaned to Roman Catholic principles of faith, became acute. The Calixtines came to an understanding with Rome, and the Taborites, left to fight alone, were signally defeated in 1434. The struggle with the empire terminated, however, in the concession of civil and religious freedom to Bohemia by the Emperor Sigismund in 1436, but civil war raged at intervals in Bohemia until 1485, when King Ladislas confirmed the imperial grant. See HUSS, JOHN.

TABRIZ, tä-brēz', or **TAVRIS,** tä-vrēs', Persia, a city in the extreme northwest, about 50 miles from the Russian border, capital of the province of Azerbaijan, on the left bank of the Aji, 36 miles above its entrance into Lake Urumiah. It is situated at the inner extremity of an amphitheatre, about 4,000 feet above sea-level, with hills on three sides, and an extensive plain on the fourth. It is surrounded with a wall of sun-dried brick, with bastions, and is entered by seven or eight gates. A large portion of the population resides outside the walls, and the plain around is covered with gardens, producing the finest fruits in great abundance, particularly grapes. The citadel is the most conspicuous building in the city. It was originally a mosque, and is 600 years old. It consists of a lofty edifice of brick, and though much damaged by earthquakes, is still a noble structure. Within the walls of the citadel there are a cannon-foundry and barracks. The most interesting building in the town is the fine ruin Kabúd Masjid (Blue Mosque), which is about 300 years old, and is partly covered with arabesqued tiles. A considerable trade is carried on in the import of European goods and sugar, the former consisting mostly of cotton manufactures, principally British, petroleum from Russia, and woolen goods, chiefly from Austria and France; and in the export of raisins and other fruits, leather, carpet, silks, skins, cottons, shawls, tea, etc., principally to Russia and Turkey. The imports and exports in normal years total over $10,000,000. Though still a considerable city, Tabriz has diminished in importance from what it was in ancient times; the descriptions of old travelers, who speak of its splendid cafés and its hundreds of caravansaries and mosques, being no longer applicable; while its ancient population of 550,000 had dwindled to about 165,000 in 1881, although in 1918 estimated at 200,000. The city has been repeatedly devastated by earthquakes, the most destructive being those of the years 858, 1041 and 1721; on the last occasion 80,000 persons are supposed to have perished. During the World War the city was occupied first by the Turks and later by the Russians.

TABULAR STANDARD OF VALUE, a project for giving fixity to the value of money by varying from time to time the amounts of gold to be paid according to the changes in its purchasing power. The practical object which those who advocate the adoption of this standard of value proposed is the attainment of a perfectly stable currency for the payment of rents or other deferred contracts. A tabular standard, therefore, if adopted would be simply an official index number. (See INDEX NUMBER). According to Jevons it is proposed that a considerable number of commodities, say 100, should be chosen with special regard to the independence of their fluctuations one from another, and then the geometrical average of the ratios in which their gold prices have changed would be calculated logarithmically. The system involves the proposition that these average prices should constitute the legal standard for settling contracts expressed in money — thus, if a note was signed in 1915 pledging the payment of $1,000 in gold in 1920, and it appeared that in 1920 that $1,000 would then buy upon the average of all commodities one-fourth less than it would have bought in 1915, the debtor should be compelled to pay $1,333 to the creditor in 1920 in full satisfaction of the debt; since in 1920 the sum of $1,333 will purchase only what $1,000 would purchase in 1915. It is claimed by its advocates that such a standard would add a wholly new degree of stability to social relations, securing the fixed incomes of individuals and public institutions from the depreciation which they have often suffered. Speculation, too, based upon the frequent oscillations of prices, which take place in the present state of commerce, would to a large extent be discouraged. The great obstacle to its adoption is the difficulty of getting economists to agree upon the precise manner of fixing the standard and calculating the averages of the several commodities, and even agreeing upon the inclusion of the latter. The idea of a tabular standard appears to be due to Sir George Evelyn who advocated «a standard of Weights and Measures» before the Royal Society in 1798. Joseph Lowe further elaborated the idea in 1823 in his ‹Present State of England.› Scrope followed Lowe and nearly all economists of the 19th century were interested in the tabular standard. W. S. Jevons brought the matter into prominence in 1865, and further elaborated it in his later works. Consult Palgrave, ‹Dictionary of Political Economy›; Anderson, B. M., ‹The Value of Money› (New York 1917); Price, ‹Money and its Relation to Prices› (London 1896); Walker, ‹Money› (New York 1878).

TABULARIUM, in Roman antiquity, a depository of public records; specifically, a building for the preservation of such records which stood on the slope of the Capitoline Hill in Rome facing the Forum. It was built (78 B.C.) by the consul Quintus Lutatius Catulus. The masonry of many of its great vaults and columns is still intact, although another structure has been erected on the old walls.

TACAMAHAC, the name of various oleoresins allied to elemi, exuded by different species of trees. East Indian tacamahac, yielded by *Calophyllum inophyllum* of Réunion and Madagascar, is a dark-green balsamic resin of specific gravity 1.032, melting at 75° C. A yellow variety is produced by an African tree (*Amyris tacamahac*), and another kind comes from the Brazilian *Icica heptaphylla*. The balsam poplar (*Populus balsamifera*) of the United States yields a similar resin.

TACANÁ, Guatemala, a volcano on the Mexican frontier, which rises to a height of 12,400 feet. It is one of several neighboring volcanic peaks of the Cordilleras, and is second in height to Tajumulco which reaches an elevation of 12,600 feet.

TACCA, the typical genus of the family *Taccaceæ*. It is represented by perennial herbs with tuberous or creeping rootstocks, large radical leaves, and dense umbels of flowers, brown, purple, or greenish in hue. These terminate a naked scape and have an involucre of bracts, the inner being filiform and pendulous, the outer herbaceous or colored. The fruit is a berry, usually three-angled or six-ribbed. *Tacca pinnatifida* is the South Sea arrowroot, or pia-plant, found in Polynesia and southeastern Asia. It is a low plant, with dissected horizontal leaves and an umbel of greenish flowers.

TACHÉ, Alexandre Antonin, Canadian Roman Catholic archbishop: b. Rivière-du-Loup, Quebec, 23 July 1823; d. Winnipeg, Manitoba, 22 June 1894. After graduating from the College of Saint Hyacinth and studying theology at Montreal, he became a member of the Order of the Oblate Fathers. He then started out as a missionary for the Northwest and there began the charitable work among the Indians of the Red River country which made him famous. He was consecrated (1850) bishop of Arath, and (1863) bishop of Saint Boniface. When the bishopric of Saint Boniface became a metropolitan see in 1871 Taché was appointed its first archbishop. In 1870 while bishop of Saint Boniface at the urgent request of the Canadian government, he performed the service of pacifying the Métis of Manitoba, who had rebelled. Among his published works are 'Vingt années de missions dans le nord-ouest de l'Amerique' (1866); 'Esquisse sur le nord-ouest de l'Amerique' (1869), etc.

TACHÉ, Sir Etienne Paschal, Canadian politician: b. Saint Thomas, Quebec, 5 Sept. 1795; d. there, 29 July 1865. He practised medicine until 1841, when he became a member of Parliament; from 1848–49 was commissioner of public works; and from 1856–57 was speaker of the legislative council. He published 'Du developpement de la force physique chez l'homme' (1829); 'Reflexions sur l'organisations des volontaires' (1863).

TACHEOMETRY, tăk-ȩ-ŏm'ē-trĭ, quick measuring, applied in surveying to a method which does away with the practice of measuring distances by a chain or tape-line and ascertaining difference of level by a separate instrument, the relative position, both horizontal and vertical, of points on the earth's surface being determined by one observation. A theodolite, or a specially constructed tacheometer, of which a telescope is an important part, is employed, and along with it a staff similar to a leveling-staff, 12 feet or so in length, and suitably marked. See SURVEYING.

TACHINA-FLIES, flies of the family *Tachinidæ*, a large and important group resembling house flies and noted for their parasitic habits. They are usually of medium or rather large size and gray, more or less striped; the wings clear, the bodies bristly; and have a disposition to fly in the sunshine with a buzzing noise. All are parasitic and are especially fond of laying their eggs upon the backs of caterpillars. For many interesting features in the life of these flies consult Howard, 'The Insect-Book' (New York 1901), and the special papers there cited.

TACHYGRAPHY. See SHORTHAND.

TACITUS, tăs'ĭ-tŭs, **Marcus Claudius,** Roman emperor: b. about 200 A.D.; d. Tyana, Cappadocia, April 276. He was descended from Tacitus, the historian, whose works he deposited in all the public libraries and caused them to be transcribed 10 times a year at the public charge. On the death of Aurelian he was called to be emperor by the Senate, although against his will (275), having gained the confidence of the supreme council by his mildness, rectitude and moderation. During his short reign he prescribed many needed reforms and endeavored to restore the power of the Senate. At the age of 75 he undertook a campaign against the Alani, assuming after his victory the title «Gothicus Maximus.» He was assassinated by his own unbridled soldiers; his brother Florianus Tacitus, who succeeded him, shared a like fate.

TACITUS, Publius Cornelius, in the judgment of many competent critics the greatest Roman historian. Neither the time nor the place of his birth is known, but certain statements in his own works and in the letters of the younger Pliny (the two chief sources of our information about him) make it probable that he was born about 55 A.D. His education, marriage and political career all point to a family of equestrian rank, and his father was not improbably that Cornelius Tacitus who, according to the elder Pliny ('Natural History,' VII, 76), was procurator of Gallia Belgica. He married in 78 the daughter of Gnæus Julius Agricola, the illustrious governor of Britain. He enjoyed the official favor of Vespasian and Titus, and, at least at first, of Domitian, under whom, in the year 88, he presided, as prætor and as a member of the ancient college of the Quindecimviri at the celebration of the secular games. After his prætorship, he was for four years absent from the capital, and was thus prevented from being present at the death of Agricola, which took place in Rome in 93. During these years he was probably acting as prætorian legate in a province, and may have gained at this time some personal knowledge of Germany. In 97 (possibly 98) he was appointed consul to succeed Verginius Rufus, over whom he pronounced an eloquent funeral oration. He was an intimate friend of the younger Pliny, a few years his junior, with whom he was associated, in 100, in the successful prosecution of Marius Priscus, accused of extortion by the province of Africa. According to an inscription discovered in 1890 at Mylasa, in Caria, Tacitus reached, perhaps in the year 112–13, the highest post open to a senator, the pro-consulship of Asia. The date of his death is not known, but, inasmuch as the extension of the empire to the Persian Gulf, which was accomplished by Trajan in 115–16, is mentioned in 'Annales,' Vol. II, 61, and several years were presumably required for the completion of that work, he may have lived into the reign of Hadrian, which began 117 A.D.

His earliest work is the 'Dialogus de Oratoribus,' written probably under Titus, 79–81. The scene of the conversation is laid in the house of the poet Maternus, in the year 74–75, and a charming discussion of the relative merits of poetry and oratory leads up to the main theme, the decline of eloquence in modern times. The treatise abounds in true and striking reflections, and exhibits the same power of subtle analysis that marks the later works. But the style is distinctly Ciceronian, and in its rounded smoothness, so different from the abrupt incisiveness of the 'Histories' and 'Annals,' shows the influence of Quintilian, who was then preaching a return from the style of Seneca to that of Cicero. For this reason the great Justus Lipsius, in 1574, attributed the 'Dialogus' to Quintilian, and since then it has been ascribed to Suetonius, Pliny and others. But the weight of evidence is decidedly in favor of the Tacitean authorship.

During the 15 years of the reign of Domitian, years whose horror finds sombre expression in the opening chapter of the 'Agricola,' Tacitus published nothing. But early in 98 there appeared, in rapid succession, the 'Agricola' and the so-called 'Germania.' The former, the story of the life of his father-in-law, whom he evidently loved and reverenced, is a masterpiece of biographical writing. The style is no longer Ciceronian but Sallustian, rapid, terse and piquant, rising at the close to sustained sublimity. The second monograph is commonly known as the 'Germania,' but its exact title is differently given in the important manuscripts and cannot be determined with certainty. It falls into two parts. The first 27 sections deal with the physical characteristics of Germany and the institutions, beliefs and customs of the inhabitants as a whole; the remaining 19 describe the individual peculiarities of the separate tribes. The treatment is rhetorical and ethical rather than simply scientific, so that the purpose of the essay has often been questioned and the credibility of its statements attacked. But it is regarded as on the whole a trustworthy account of German lands and peoples, though the geography is weak and the description of the tribes in the interior may have been based upon insufficient evidence. The Germans were then the object of much interest (Trajan was in Cologne at the time of his accession) and Tacitus, writing to satisfy this curiosity, pointed out at the same time to his countrymen, the contrast between their own corrupted civilization and the vigorous simplicity of these Northern tribes, and gave a warning of possible danger.

In the introduction to the 'Agricola,' Tacitus announced his intention of composing *memoriam prioris servitutis ac testimonium præsentium bonorum*. The first part of this plan was realized in the years 104–10 by the publication of the 'Historiæ,' consisting originally of 14 books, or possibly only of 12, covering the period from the death of Nero in 68 to that of Domitian in 96. But, instead of adding the reigns of Nerva and Trajan, he then wrote the 'Annales,' in 16, or possibly 18 books, from the death of Augustus in 14 ('*Ab excessu Divi Augusti*' is the actual title of the work) to the point at which the 'Historiæ' begin. Of this remarkable achievement, the continuous history of the empire for 82 years, there is extant about one-half. Of the 'Annales' we have books I–IV with the beginning of V and the greater part of VI, and, with a gap at the beginning and also at the end, books XI–XVI, that is, we have lost almost entirely the years 29–31 of the reign of Tiberius, the whole of the reign of Caligula, the first six years of Claudius, and the last two of Nero. The extant portion of the 'Historiæ' ends in the middle of book V and describes the eventful year 69 and part of 70. The treatment is obviously much more minute in the 'Histories' than in the 'Annals,' and this is due to the fact that Tacitus is here dealing with occurrences which came well within his own lifetime. The loss of the reign of Domitian is especially to be regretted.

Interesting as are the minor works, it is in the 'Histories' and the 'Annals' that the real genius and literary art of Tacitus are revealed. His methods are essentially scientific, though he does not use archives and original sources as much as would a modern historian. But he strives conscientiously to ascertain the facts and to determine the sequence of cause and effect. A thorough aristocrat and lover of the old republic, he yet bows to the inevitableness of the empire and appreciates the enlightened rule of a Trajan. But the reign of Domitian permanently embittered his soul. He was gifted by nature with a marvelous power to trace the hidden springs of thought and action and experience of life bred distrust and made him an expert in the analysis of human weakness and guilt. His portrayal of Tiberius, for instance, though certainly prejudiced and unjust, is extraordinarily subtle and brilliant. The style, which we may see in process of formation in the 'Agricola' and 'Germania,' is characterized by pregnant brevity, leading sometimes to obscurity, by deliberate avoidance of balance in the structure of the sentences and by poetic phraseology. The influence of Virgil is marked. See GERMANIA.

Bibliography.— The standard text is that of Halm (Leipzig 1907). The 'Dialogus' has been admirably edited by Peterson (Oxford 1893) and by Gudeman (Boston 1894); the 'Agricola' (Oxford 1896), and also the 'Germania' by Furneaux (ib. 1894); the 'Historiæ' by Spooner (London 1891); the 'Annales' by Furneaux (2 vols., Oxford 1891, 1896). There is a fine special lexicon by Gerber and Greef (Leipzig 1903). There is an excellent translation of all the works by Church and Brodribb (London 1905); of 'Annales,' I–VI by Ramsay (London 1904); of the 'Histories' by Fyfe (Oxford 1912); of the 'Dialogus,' 'Agricola' and 'Germania' by Fyfe (Oxford 1908) and by Peterson and Hutton (Loeb Classical Series, New York 1914). Consult also Boissier, 'Tacitus and Other Roman Studies' (New York 1906).

NELSON G. MCCREA,
Anthon Professor of the Latin Language and Literature, Columbia University.

TACKLE, among seamen an arrangement of two or more blocks, with suitable ropes, for raising or lowering weights. The combination is usually designed to increase the capacity of the available power. One block is fixed while the others are movable. Tackles are termed luff and watch, single and double Spanish burtons, Bell's purchase, luff upon luff, etc., according to the arrangement of the bearings, pulleys, etc. See BLOCK; PULLEY.

TACKS. See NAILS.

TACLOBAN, tä-klō'bän, Philippines, pueblo, capital of Leyte Island; on the east coast at the southern entrance to the San Juanico Strait, on the northwest extremity of San Pedro Bay. It is the northern terminus of the east coast highway, has an excellent port, with four large wharves. Pop. about 12,000.

TACNA, täk'nä, Chile, (1) a province occupying the northernmost extremity of the country. Area, 8,686 square miles. The main ridge of the Andes runs just within the eastern boundary and a lower range runs along the coast. Pop. about 30,000. (2) Its capital, a city of about 14,000 population, of local importance. The Chileans defeated the Peruvians in a battle here in 1880.

TACOMA, tȧ-kó-ma, Wash., third city in Washington, seaport, county-seat of Pierce County, on Commencement Bay, 38 miles south of Seattle and 25 miles north of Olympia. Its phenomenal growth has given the city the name «The City of Destiny.» It is also called the «City of Beautiful Homes» and the «City with a Snow-Capped Mountain in its Dooryard.» It is situated at the head of navigation on Puget Sound and is the western terminus of the Northern Pacific and the Chicago, Milwaukee and Saint Paul railroads, both of which maintain large ocean docks and car repair shops. Tacoma is also the American terminus for the Osaka Shosen Kaisha, a Japanese steamship line with headquarters at Osaka, Japan. Tacoma's harbor is one of the greatest deep sea harbors in the world and because of its similarity to the Italian city, Tacoma is often referred to as the «Naples of America.»

Topography.— The Puyallup River empties into Commencement Bay within the city limits and is one of five waterways that help make up this modern port. The city is built on rising ground which reaches an altitude of 418 feet above the river. The best residence portion of the city is on a plateau, elevated about 200 feet above the blue waters of the beautiful harbor, and from any portion of this section may be seen stretches of gleaming water losing themselves among the wooded islands; beaches, white, gray and brown, and frowning headlands. The Olympic Mountains stretch along to the west, rugged, snow-flecked and mysterious, while to the east rises Mount Rainier, here known as «Mount Tacoma.» «The Mountain that was God,» as one author calls it, an eternally snow-capped peak, 14,520 feet high. It is but «four hours from Tacoma to the Glaciers,» from tidewater to mountain elevation. The streets of Tacoma are level and paved, and so generously and wisely is the city laid out that it has not a street less than 60 feet wide, while it has several noble avenues 100 feet wide and a few 120 feet. Nearly every home — that of banker, merchant, manufacturer, wage-earner — is surrounded by beautiful lawns, and pretty gardens. The climate is noted for its equableness and mildness, the mean annual temperature being 50.6°; the mean maximum, 58°; and the mean minimum, 43.3°. Rainfall is 43 inches, with little or no snow.

Trade and Commerce.— Because of her strategic position, Tacoma has always commanded a huge water-borne commerce. In 1918 1,666 arrivals from foreign ports were recorded, with cargoes of 2,103,656 tons, while clearances for foreign ports numbered 1,803 with a tonage of 2,103,595. The total value of imports and exports was $318,613,938. Flour exports alone totaled 2,160,474 barrels, valued at $22,747,555. The daily capacity of the flour mills is 9,000 barrels. Tacoma's wheat warehouses have a storage capacity of 8,584,300 bushels. From the time in 1869 when a schooner-load of lumber from the old Hansen mill was shipped to San Francisco, Tacoma has been the leading lumber manufacturing city of the Pacific Coast. There are 52 mills in the district in addition to many allied lumber industries. In 1918 the lumber exports totaled 93,500,000 feet. The principal steamship lines operating to the Orient are the Osaka Shosen Kaisha of Osaka, Japan, and the Pacific Steamship Company's Admiral line. Dodwell's Blue Funnel, among other lines, also operates to Tacoma. Already possessing superior facilities for economical handling of cargoes, including large coal bunkers, electrically operated, a port commission of three, elected by the city following the creation of a port district in 1918, plans the expenditure of millions in construction of new waterways and improving present port facilities. The hub for the southwestern counties of Washington, Tacoma possesses a huge wholesale and jobbing trade. Her jobbing trade in 1918 totaled $160,000,000; retail trade $65,000,000.

Manufactures.— With 1,850 business enterprises, including over 300 manufacturing plants, Tacoma has approximately 58,116 wage-earners, with a monthly pay-roll averaging $6,783,000. The value of manufactured output in 1918 was $152,000,000. Of this amount $27,900,000 represents the value of eight steel vessels and 42 wooden ships launched in the year by six shipyards. In the shipyard industry a maximum of 15,000 men were employed. The Todd Drydock and Construction Corporation alone employs about 8,000 men, and is one of the largest and best laid out steel shipyards in the country. The Tacoma Smelter employing 1,000 men had an output of 156,000,000 pounds of copper valued at $40,000,000 in 1918. This plant refines one-twelfth of the world's copper output. Next in importance, come lumber and its allied industries, including the manufacture of woodware, box shooks, baskets, furniture; and meat packing, flour and cereal milling, candy and food products, marble, iron and steel products, including machinery, boilers and marine engines.

Most of Tacoma's industries are centred on 1,500 acres of tidelands extending the width of the southern boundary of the harbor, the

Banks and Banking.— Tacoma has six national and State banks. At one time there were 10, the decrease being due to mergers of the largest institutions. The deposits 1 Jan. 1919 totaled $38,139,781. The clearings for 1918 were $243,973,348, while the bank transactions amounted to $775,311,157. Postal savings deposits were $1,135,732. The clearing house was established in 1889, and includes all the banks in the city, which own the buildings in which they are located.

Government and Finances.— The city adopted the commission form of government in 1910. Five commissioners, one of them mayor, all popularly elected, serve four-year terms. The city controller is the only other elective official. The police and fire departments are well organized, the fire department being completely motorized. The city owns and operates a $2,000,000 hydro-electric power plant of 32,000 horse-power capacity; a $2,300,000 gravity water system with a 42,000,000 gallons daily capacity; a municipal freight and passenger dock, and a municipal street car line on 11th street serving the industrial district. The total length of paved streets is 110 miles; improved streets, 307 miles; cement sidewalks, 408 miles; sanitary sewers, 224 miles; storm sewers, 339 miles. Assessed valuation (50 per cent of the true valuation) is $59,508,611. The bonded indebtedness, $3,394,000. City power rate is .45 of a cent to two cents per kilowatt, according to load factor, cheapest rate in the country. Private power companies have plants with a capacity of 72,000 horse power, with practically identical rates. The streets of the city are electrically lighted. A single gas plant supplies Tacoma consumers; also those in the city of Olympia. The parks and playgrounds are administered by the metropolitan park board, members of which are elected by popular vote. The acreage of parks is 1,200, including Point Defiance Park and Zoo, 662 acres, and Wright Park, 40 acres. In addition are park areas outside of the city limits surrounding Spanaway Lake, Steilacoom Lake, American Lake, and Gravelly Lake. There are four golf clubs with 18-hole courses.

Public Buildings and Clubs.— Most prominent of public buildings are Federal building (United States Post Office, custom office, internal revenue, and federal court), Pierce County Court House, City Hall, Tacoma building (owned by Tacoma Commercial Club and Chamber of Commerce and Weyerhaeuser Timber Company), National Realty building, 16 stories; Fidelity building, 12 stories; Tacoma Theatre, Jones Block (Pantages Theatre), William L. Davis building, Perkins building, *News-Tribune* building, Tacoma Hotel, Olympus Hotel, Northern Pacific Headquarters building, Rhodes building, Provident building, National Bank of Tacoma building, Bank of California building, Scandinavian-American Bank building, Elks Club. Prominent clubs include Elks, Union Club, University Club, Moose, Rotary Club, Kiwanis Club, all but last two owning their own buildings; Automobile Club, Y. M. C. A., Y. W. C. A., Commercial Club and Chamber of Commerce, Tacoma Country and Golf Club, Lakeside Country Club, Lochburn Golf Club, and Meadow Park Golf Club, Tacoma Yacht Club, Tacoma Tennis Club, Soldiers and Sailors Club.

Transportation.— Six railroads have terminals or connections in the city. The Northern Pacific and Chicago, Milwaukee and Saint Paul railways have their western terminals in Tacoma, including car repair shops, and ocean docks. The Great Northern and the Oregon and Washington (Union Pacific) railroads operate in the city, and the Great Northern has connections with the Canadian Pacific and the Chicago Great Western railroads. Electric interurban trains operate between Tacoma and Seattle on a half-hour schedule; also between Tacoma and Puyallup. There is a total of 143 miles of track operated by the local traction company. Automobile stages on regular schedules operate on a dozen paved highways to every city and town in Pierce County and adjoining counties, including the cities of Seattle, Olympia, Aberdeen and Hoquiam, and Chehalis and Centralia. Local steamers operate to all points on Puget Sound, including Victoria and Vancouver, British Columbia, and to Pacific Coast and Alaskan ports.

Camp Lewis and Rainier National Park.— The largest permanent army mobilization and training cantonment in the United States is Camp Lewis, just south of Tacoma's city limits. The cantonment contains 76,000 acres and is 18 miles long and 12 miles wide. Citizens of Tacoma and Pierce County (the city pays 80 per cent of the taxes) voted $2,000,000 in bonds to purchase the land donated to the government for military purposes. In consequence, a full division of troops will be maintained at the camp permanently. Paved highways with auto transportation lead from the city to the camp. There is also steam and electric railway transportation.

From Tacoma automobiles convey a tourist in four hours over one of the finest paved highways in America to the Glaciers of Rainier National Park and to matchless Mount Rainier (or Tacoma, its local name), 14,520 feet high. The park is the most popular of those supervised by the United States government. Attendance in 1918 was 50,000, exceeding that of any other national park. There is transportation to the park over the Tacoma Eastern to Ashford from Tacoma, giving rail transportation to within a few miles of the park entrance.

Education.— Tacoma is the seat of the College of Puget Sound (Methodist), Pacific Lutheran Academy (Lutheran), Annie Wright Seminary (Episcopal), Academy of the Visitation and Aquinas Academy (Roman Catholic). There are eight parochial schools, six commercial or business schools, and in the public school system two magnificent high schools and 32 grammar schools. The total enrolment of the public schools is 18,904, including 2,000 attending night schools. There are 645 teachers employed. The Stadium High School has a Greek amphitheatre called Stadium which has a normal capacity of 32,500 persons, which can be increased to between 40,000 and 50,000. The Carnegie Library, with two branch libraries and branches in the high schools and grammar schools, has 85,598 volumes with a net circulation in 1918 of 338,237. The total value of library property is $200,000, and the number of registered borrowers 18,111. Overlooking the Stadium and opposite the high school are the Ferry Museum, with a large collection of Indian curios and pioneer relics, and the stately home of the Washington State Historical Society.

Churches and Charities.— Nearly every religious sect or denomination has a house of worship in Tacoma, the city being particularly well equipped with beautiful churches, the total number reaching 135, the principal denominations being Methodist Episcopal, Presbyterian, Lutheran, Episcopal, Congregational, Roman Catholic, Baptist, Christian Science, Christian, Jewish, Evangelical, Friends, Adventist, United Presbyterian and Universalist; also Salvation Army and Volunteers of America.

Charitable institutions include the Northern Pacific Hospital, County Hospital, Tacoma General Hospital, Saint Joseph's Hospital, City Contagious Hospital, Western Washington Hospital for the Insane at Fort Steilacoom, a suburb; the Children's Home, City Rescue Home, Parkland Children's Home.

History.— Tacoma city was originally within the boundaries of the first ward, popularly known as Old Town, now called Old Tacoma. The city was laid out in 1868 by Gen. M. M. McCarver. In July 1873 the Northern Pacific Railroad established its Pacific Coast terminus on Commencement Bay, giving it the name New Tacoma. The city was also called Commencement City. In 1880 the new town became the seat of Pierce County, and in 1883 Old Tacoma and New Tacoma were consolidated and incorporated as a city. Since that time additional territory has been annexed on four different occasions, giving the city a total of five taxing districts. The present area of the city is 25,168 acres of land and 2,752 acres of water, or 39.81 square miles. The distance from northern to southern boundary is seven miles. The 35 wharves and docks have a lineal frontage of six miles.

Population.— Government census (1880) 720; (1885) 1,100; (1890) 36,006; (1900) 37,714; (1910) 83,743; (1 Jan. 1919, local estimate) 142,447.

Edward P. Kemmer,
Managing Secretary of the Tacoma Commercial Club and Chamber of Commerce.

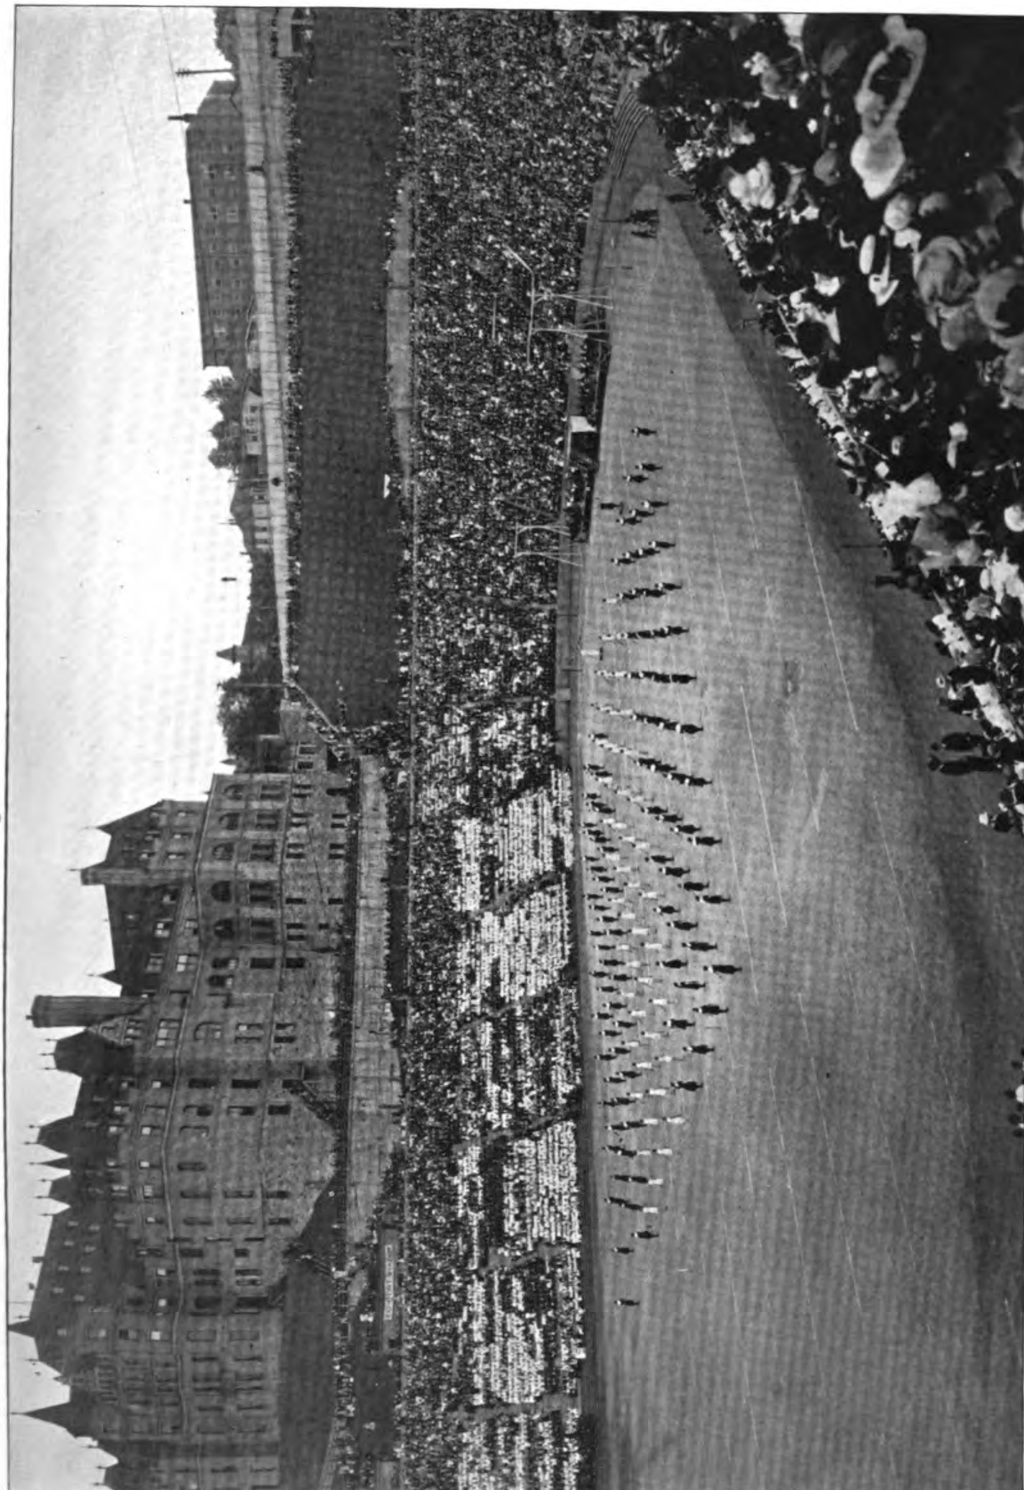
TACONIC (tą-kŏn'ĭk) **MOUNTAINS**, a range extending nearly north and south, uniting the Green Mountains of western Massachusetts with the Highlands of the Hudson. The highest peaks are Equinox in Vermont, 3,847 feet, and Greylock in Massachusetts, 3,305 feet. The Taconic system, in geology, was named from the characteristic strata of this range, a metamorphic rock, believed to be older than the Silurian system.

TACONIC SYSTEM, a term applied by Prof. Ebenezer Emmons, in 1842, to certain azoic and palæozoic rocks occurring in the eastern part of New York and western parts of Vermont and Massachusetts. These he believed to be the equivalents of the Cambrian rocks of England. Subsequent investigations have shown that Emmons misread the geological structure of the regions studied by him, and his arrangement of the strata has, therefore, been set aside. The subject has given rise to much discussion among American geologists. Consult Emmons, 'Geology of New York,' 'American Geology,' and 'The Taconic System'; Marcou, 'On the Use of the Name Taconic'; Walcott, 'Taconic System of Emmons'; Winchell, 'Some Objections to the Term Taconic'; Dana, 'History of Taconic Ideas' (in *American Journal of Science,* 3d ser., Vol. XXXVI, 1888).

TACTICS. Tactics has regard to the evolutions of an army in the actual presence of an enemy, and may be defined as the strategy of the battlefield or the science of manœuvring and combining those military units which drill, discipline and the regimental system have brought to the perfection of machines. It was admirably described by Napoleon as *the art of being the stronger* — that is, of bringing an overwhelming force to bear on any given point whatever may be the relative strength of the entire armies opposed. The earliest records of battles are those of mere single combats, in which the chiefs, fighting either on foot or in chariots, performed great deeds; and the commonalty, who apparently were without discipline, were held in profound contempt. With the growth of democracy arose the organization of the phalanx, the advance of which was irresistible; and its firmness equally so, if charged in front. It, however, changed front with great difficulty; was much deranged by broken ground; and failed entirely in a pursuit, or if attacked in flank. Far lighter, more mobile was the Roman legion. Among Roman tactics was also the admirable intrenchment, which they scarcely ever omitted as an additional source of strength for their position.

Events reproduce themselves in cycles; and with decay of Roman civilization came again the mail-clad heroes and cavaliers — mounted this time on horses — who monopolize the honors of battle, while the undisciplined footmen had an undue share of the dangers. Later in the feudal period, this disparity between knight and footmen was diminished by the employment of bodies of archers, whose shafts carried distant death. The adoption of gunpowder for small arms altogether neutralized the superiority of the armored knight. This change brought infantry into the front place in battle, and threw cavalry into the status of an auxiliary. The French Revolutionary Wars tended much to the development of artillery as a field weapon and Napoleon employed this terrible engine to its fullest extent, a practice followed by the best modern generals, who never risk a man where a cannon ball can do the work. Frederick the Great was considered an innovator for fighting with infantry four deep. During the French war, the formation of three deep became general. Before the battle of Waterloo, the British leaders had acquired sufficient confidence in their troops to marshal them in a double line.

In the battles of Gravelotte and Sedan, the turning tactics came prominently forward. At Sedan the turning movement was complete. The losses of the tenth German division at Wörth prove what a serious matter it is to make a direct attack against the breech-loader. They amounted to about 4,000 men. It was of course necessary to make vigorous attacks on some points of the French position, so as to take



Tacoma High School Stadium, built of solid concrete. Seats 40,000 persons. View taken during Stadium Day exercises

off their attention from the circular enclosing movement of the Germans. Although they (the Germans) were frequently obliged to make front attacks, the principle of the turning movement always asserted itself. In any case, however, a direct infantry attack should always have been undertaken in sufficient force. But this was too often not the case, so that weaker forces exposed themselves to suffer great losses in long-continued doubtful conflicts, gaining at the same time but little ground.

On the defensive the shooting-tactics of the Germans consisted simply in firing at short range, a practice which always had the best results. The main position selected was generally strongly occupied in first line. It was rightly judged that a strong development of fire at the commencement of an action was necessary and advisable. Separate strong masses in reserve, not a great many little reserves, were formed. If there was sufficient time, the position was divided into sections and prepared for defense as well as possible. On the approach of the enemy the artillery was at once deployed into a connected line. The cavalry, having at first been pushed forward to check the enemy's advance was then withdrawn behind the line of defense.

To sum up the characteristic points of the infantry battle-tactics of 1870–71, it will be necessary in doing so to mention in the first place what we did *not* see. That is to say, *no* volleys in battle; *no*, or at least a very few, attacks by troops in close order; if, however, a compact body ever did attack, it was always a small one, never amounting to a battalion column. But we *did* see great deployments of skirmishers on both sides; long continued gradually advancing musketry fights, often rolling backwards and forwards; at last the flank of one party turned or else one side exhausted; the other side pressing on in consequence, or a rush of dense clouds of skirmishers who endeavor at any price to dislodge their opponents; not forgetful that, in case of failure and retreat, they are *dead* men. On both sides great dispersion; intermingling of troops and particularly in broken ground; hence the leader's control diminished. With the Germans — more steadiness and the habit of reserving their fire. With the French — more hurry and the habit of firing at long ranges. However great the effect of the artillery; however enormous was the loss of the French by shells, there was still no example of a really great result being due specially to artillery. Even the plateau of Floing, which was cannonaded from all sides, had to be stormed by infantry. And the same may be said of Saint Privat.

The instances which have been given are the principal assaults in the first half of the war; they present many points of resemblance. In nearly every case the troops were drawn up in two lines of company columns and a reserve. The skirmishers were sent forward, the first line followed at 150 or 200 paces distant and then the second line. In no instance, however, does it appear that there was more than one line of skirmishers; behind them the troops marched with dogged bravery, in solid line of two ranks, shoulder to shoulder, or in company columns with platoon fronts far inside the line of rapid effective fire; and they continued this march until the fire caused a break in their lines and a retreat, or until they reached the work after enormous losses and held it as the result of a hand-to-hand fight. The skirmish line was so small in comparison with the main force that it really amounted to nothing and the attack was in fact made in solid line. The attack and the forward movement were not distinguished. This *defective* formation was the principal cause of the heavy losses.

In offensive tactics we may consider three general modes of attack, one of which the commander of a combined force must select as the most suitable for his purpose. (1) *Frontal attack*, which would mean a direct advance upon the whole of the enemy's line or position. As a general rule, this form of attack is unadvisable, as even in case of success the result is not decisive; the enemy's line of retreat being unassailed, he simply falls back to a position more to the rear. There may, however, be situations when the nature of the ground prevents any other mode of operation, or where the frontal attack may be made use of to feel the enemy and ascertain his exact dispositions, in preparation for a concentrated attack upon one of his weak points, as soon as they are discovered. (2) *Combined attack upon front and flank*. In this case the enemy is attacked in front at the same time that a portion of the force is directed at one of the flanks. An attack upon the flanks by itself unaccompanied by a front attack is not advisable, except in the case of small detachments acting against one another, or unless the attack can be effected by surprise, in which case the enemy is unable to meet it in time by a change of front. Were a strong force in position attacked solely on the flank it would quickly form up its reserves to a new front, the troops of the original front coming up in support. For a flank attack, therefore, to succeed, it must, as a general rule, be accompanied by a frontal attack, sufficient to hold the enemy to his original position. An attack upon both flanks combined with a frontal attack can only be tried under circumstances of great superiority of numbers, without which it would become a most dangerous operation, enabling the enemy to give the counter-stroke of a weak point of a straggling line and beat the assailants in detail by cutting their force into two. In engagements where the numbers are small the flank attack may be made alone. (3) *Concentrated attack upon a weak point*, to break through the enemy's line or force his position. This mode of attack, if the most difficult of execution, is undoubtedly in case of success the most decisive, the enemy being broken into fractions which can subsequently be beaten in detail. The enemy's line of retreat may also thus be arrived at, and his communications cut before he can recover himself. The attack must always be made with force sufficient to resist a counter enveloping attack on the part of the enemy; which might otherwise be disastrous in its results. The increased range of modern guns and rifles has made this attack more hazardous than ever, for a concentrated fire-action can now be brought to bear on the assailant, not only from all parts of the defense in his immediate front, but in most cases from either flank as well.

Unless, therefore, the ground covers the movement in a great degree it should not be attempted.

In addition to the above primary modes of attack, a *turning movement* may also be considered. This might be looked upon as almost a form of flank attack were it not that it differs from it in some essential particulars. The turning movement is more often a *menace* than an *attack* for it threatens the enemy's line of retreat so as to force him to change front or shift his position before he enters the combat. The manœuvre differs also from a flank attack inasmuch as it removes the scene of combat from the position held by the enemy, while the flank attack takes place on one of the flanks of the position itself. The turning movement may be made, either with a portion of the force at command, or with its whole strength. In the first case, the conditions should render it improbable if not impossible that the enemy could act offensively in turn upon each fraction of the divided force. Otherwise the separate movement should not be attempted, as it must end in disaster. When the ground permits, or is favorable, cavalry and horse-artillery are specially suited to the turning movement. They should, therefore, nearly always form a portion and sometimes the whole of the troops employed in the service, both because they can by rapid advance produce the moral effect of surprise, and because they can more easily avoid destruction by a superior force.

The commander of a small force of the three arms should have no difficulty in preparing his plan of attack and issuing his orders, upon receiving reports of the strength and dispositions of the enemy and of the nature of the ground upon which he must act. In ordinary cases when small forces are engaged, the cavalry, which reconnoiters in advance, will bring in sufficient information for the purpose; but if the enemy should be covered by advanced troops, it may be necessary to make a special reconnaissance, sometimes supported by guns, in order to arrive at a knowledge of his strength and intentions. With large forces this would probably be carried out by the advanced guard the artillery of which, re-enforced where necessary from the main body, would take up what may be called a *preliminary artillery position* and open fire at long range to cover the advance of the troops employed in the reconnaissance. The information required being obtained, the commander would issue his orders. In the case of very small operations or of a sudden encounter with the enemy these would be given verbally; under other conditions orders should, if possible, be written. Should the force, as it probably would, consist of detachments under various commanders, it would be necessary that there should be a *general order* for all, and also a *special order* addressed to each commander where separate action is required. The general order should be clear, precise and complete, and as short as quick compliance with these requirements will permit. It should contain:

1. The conditions or circumstances of the intended action with what is known of the enemy.

2. The mode of action determined upon, and how to be undertaken; thus for instance, to attack the enemy when he is touched on in direct advance, or, to attack the whole, or a certain part of a position.

3. The strength, composition and general division of the attacking force, with names of commanders; this may be given more in detail in the margin of the order if thought necessary.

4. The preliminary positions to be taken up by each distinct part of the force with their directions of attack.

5. The hours at which these positions are to be assumed, and at which the forward movement or attack is to be commenced.

6. The position where the commander of the troops will be found during the action, to which all references or reports are to be made or sent.

These clauses would be sufficient for a small force, but in operations of greater magnitude it would be necessary to add:

7. The positions of the ambulance and field hospitals, and the order of march of the trains of the various columns.

It must be understood that the dispositions of the troops thus indicated are only intended for the first phases of the engagement, for, until the enemy's counter-plans are developed, the final movements which depend thereon cannot be defined. The special orders addressed to separate commanders should contain nothing that may tie their hands too much in matters of detail. As a rule, they should be told the thing to do, not the manner of doing it, and within safe limits, to be named, they should be allowed free action.

For the purpose of watching the phases of the combat, the position which the commander should assume during the engagement ought, if possible, be on an eminence, from which he can perceive the principal portion of the ground over which the troops are to work. He should not quit this post (duly announced in the "order") without exceptionally good reasons, and if he is obliged to do so, an officer should be left behind to direct all reports or messengers to the new station of the commander.

The orders which are necessarily transmitted during an action by the commander of the troops are of much importance and should be given with great care. They should, if possible, be in general harmony with the original plan of attack, although certain modifications may become necessary. They should not descend to details which are better left to commanders of corps, nor should the commander of the troops interfere in the execution of his orders, further than to assure himself that they are carried out. He should be satisfied on this point by means of constant reports and communications which must be kept up without interruption during the action between him and the commanders of separate corps and detachments. When the reports cannot be sent by an officer, they should be written, and in such case be numbered and dated with the exact hour and minute of dispatch. Above all other matters it is most important that the commander of the troops should be immediately informed when circumstances render it impossible for a subordinate commander to carry out the orders or instructions, as the failure to execute these may necessitate modifications and fresh orders to replace the former ones.

By the end of the third stage it may be presumed that the enemy has been forced to show his hand sufficiently for the purposes required of determining the best method of finally attacking him, and the commander's main dispositions are either directed to be carried out in their original design or else modified to suit new ascertained conditions.

The artillery, which up to this time has continued from its first position to support the general advance, by endeavoring to silence the enemy's guns and to draw off his fire from the infantry, is now directed to deliver barrages and to concentrate its fire upon the intended point of attack in order to prepare the way for the infantry assault. The moral effect of this fire upon the defenders will probably be very great, even if the physical effect upon troops partly behind cover of ground and obstacles be comparatively trifling.

Whenever the ground will admit, the infantry are supported on the flanks by cavalry, which advances under cover in small columns, with strong supports close at hand, and losing no opportunity of attacking any advanced troops of the enemy and warding off adverse attacks in return. The very fact of the cavalry occasionally showing itself on the flanks gives confidence to the attacking infantry and demoralizes the defenders, especially if they are themselves deficient or weak in that arm.

The fourth stage is now commenced, by the infantry being firmly launched at the selected points of attack, and it comprises the whole of the real action up to the moment which immediately precedes final success or failure.

The infantry here plays the principal part. It is fairly committed to the fight and having received its final impulse in the desired direction from the commander of the force, no power can alter or recall it, for good, during the remainder of the engagement. Its development of fire-action should rapidly increase as it nears the point of attack, for upon its weight of fire depends its success.

The cavalry on the flanks should be on the watch, not only to protect the infantry flanks of its own troops extended in the advance, but also to seize opportunities of approaching unseen the flanks of the opposing infantry or artillery, and of throwing them into disorder or demoralizing them, if not inflicting serious injury. If repulsed and in its turn disordered, it must rally under the protection of other arms, and again return to exercise similar functions. But cavalry at this stage can only play a minor part, unless the ground be more than usually favorable to its action; with the exception, therefore, of strong supports to the cavalry acting on the flanks, the remainder of this arm would still be kept in reserve, but not so far to the rear that it could not be brought up quickly if required to make a diversion or demonstration on either flank.

The artillery, which during the former stages has been of first importance on account of its long range, now falls into the second place. The circumstances of the case must determine whether it shall keep up its fire on the enemy's guns to relieve its own infantry, or whether it shall fire on the enemy's troops. As the rule to be followed is, that it shall fire on that arm of the enemy which is for the time the most important, the enemy's infantry will in all probability be now the object. In either case, a moment may arrive during this stage when a second position more in advance is necessary for the guns, on account of their fire becoming masked by their own advancing infantry. If a portion or the whole of the guns can, in such case, be advanced rapidly and placed in a good position (especially on a flank, whence they can add their own fire to that of the advancing troops, which are at the moment absorbing the whole attention of the defending infantry), the proximity to the enemy's line, of this *second principal artillery position,* must not be too much limited by ordinary rules of caution. When the attack and defense are nearly matched, it is clear that the addition of a close artillery fire on either side may turn the scale and compensate by decisive success for any loss sustained. As this close action of guns may in case of repulse lead to confusion, it would perhaps be advisable that the whole of the available artillery should not take up this second advanced position, but that a portion be held in reserve, massed in a favorable position, and be kept in action all the time in support of the advanced battery.

If the attack is successful and the enemy retires either before the demoralizing influence of the last steady advance, or broken by actual assault, the position he occupied is quickly assumed by the artillery and a heavy fire brought to bear on the retreating troops. The reserve cavalry, which by this time has been brought up from the rear, and probably posted on the weaker flank is now launched in pursuit accompanied by horse-artillery, the superior mobility of both rendering their use peculiarly well suited to this service. The commander of the troops would move forward from his station, and take his post upon the position lately occupied by the enemy, for further direction of the movements. The infantry meantime would recover from its first confusion, reform its ranks broken by the assault, and then furnish from its freshest troops, in all probability the reserves, a force to aid in the pursuit. The field-batteries will also push forward and harass the enemy with their fire, when he gets out of range of the position or becomes masked in his retreat by the interposing troops in pursuit.

If, on the other hand, the final assault of the position has been unsuccessful, the attacking force must retire, covered, in open ground by the cavalry and artillery, in close ground by the least disorganized portion of the infantry supported by the artillery. The latter arm now plays an important part. It must run every risk to enable the retreat to be safely effected, until a rearguard can be organized to protect the movement. With this view, the first position where a stand can be made close to the field of action must be taken up by the freshest of the infantry, and the guns must be posted in such manner as not only to support the infantry, but further to cover all the necessary dispositions for conducting the retreat in good order.

Should a commander of a force of the three arms decide to stand on the defensive, he should take up the position most suitable for his purpose without delay, as the superiority to be attained by this course of action must result in great measure from the advantages attendant upon choice of ground. A good position should be such, from a tactical point of view, that the different arms could be disposed for defense in the manner most suitable to their action and that there should be facilities for concealing their strength, composition and posts from the view of the enemy, and of preserving them more or less from his direct fire during the attack. It is also of the highest importance that the front of any position selected for defense should be clear for view and fire, as should also be the flanks, unless they rest on impassable obstacles.

The first stage of the defense which was commenced with the reconnaissance of the enemy would thus comprise the selection and occupation of the position by the defenders, as well as the advanced action, if any, of the artillery, already alluded to. Upon the selection of the ground most suitable for the artillery of the main position, will in great measure depend the exact trace of the fighting line for the infantry, the positions for the guns so much depending upon the circumstances of each case, and more especially upon the configuration of the ground. The guns of the position should, however, if possible, be so placed as to bring the enemy's columns under fire at long range, and hence they ought to command every distant approach. They should also be able to pour a concentrated fire upon the probable positions which will be assumed by the attacking artillery, and be stationed so as to sweep the ground in front of the position from the earliest to the latest moment of attack. The defense of the flanks in the case of large forces must be specially provided for.

It would, therefore, appear that, unless the ground is peculiarly favorable for posting guns in flanking positions, where without being exposed to enfilade they can bring a cross fire to bear upon the main attack, and a flanking one to protect the immediate front, the required conditions can only be fulfilled by the guns being placed in the front line and preferably at the salients, should an irregular contour mark the front of the position. The general distribution of the infantry would probably be in three lines; the first or fighting line of defense, the special supports, and the reserves. If time for hasty fortification is permitted some sort of entrenchment should be always prepared for the batteries, as even a low parapet of earth gives protection to the gunners. Great care should, however, be taken that the newly broken earth is concealed or covered in such a manner from the enemy's view, that it shall not serve as a mark for their artillery more distinct than would otherwise be presented by their guns alone. Shelter-trenches may also be prepared for the infantry in the fighting and supporting lines. Neither the places prepared for the batteries nor the shelter-trenches should be occupied by the guns or troops till the proper moment for action arrives.

In making these arrangements, it is of the utmost importance to secure the artillery of the main position against the fire of the enemy's advanced skirmishers or marksmen; and with this view, the batteries ought to be covered in their immediate front by a line of extended riflemen, placed either in trenches or pits or behind natural cover, at a distance of from four to five hundred yards in advance of the guns which they defend. If the battery is on a flank, this protection should also be extended for a similar distance to the flank. The infantry thus posted would remain as long as possible in position, and only retire when, at the final stage, they are driven back by the overwhelming advance of the assailants. Besides their principal function, of keep-off the enemy's skirmishers from too early approach to the batteries of the defense, these advanced infantry could often bring an irritating fire to bear upon the attacking artillery at its first principal position, and perhaps serve to prevent the guns from approaching to the most telling ranges. This possible action would of course depend much upon the features of the ground.

It is impossible to lay down any rule for the exact position of the artillery of reserve. High ground near the exposed flank, provided facility of movement therefrom in case of necessity is presented by its features, would often be suitable. The guns should, however, in any case be well up to the front, so as to lose no advantage of range from the commencement of their fire. A position in rear which entails not only a sacrifice of some hundreds of yards range, but the necessity of firing over the heads of the defending infantry, greatly to their discomfort and demoralization, does not appear to present commensurate advantages of safety to the guns. It is evident that artillery so placed would be comparatively useless during the later stages of the defense, when once the attacking infantry has advanced so close that the fire of the retired batteries would be masked by the ground, or by the defending infantry lining the position. Guns so placed might be useful in defending an inner line, or for supporting a counter-stroke delivered inside the position after the assault has been made, but their action would be lost almost altogether during the period immediately preceding the final attack of the position. The previous knowledge of ranges and distances, possible to the artillery of the defense, presents a great advantage; but if circumstances have not permitted the gunners to ascertain them during the preliminary arrangements, by aid of range-finders, aeroplanes, or other means, the earliest portion of the artillery action must be utilized to obtain correct estimates of the ranges to all important points, by means of trial shots.

There are certain points or portions of all positions, the possession of which would assure the assailant the greatest tactical advantages. In many cases also the conformation of the ground appears to limit the movements of an enemy to certain lines of operation. The defense should, therefore, occupy these parts of the position in force, with supports in close proximity, while still preserving the general line. Under the second condition the force should be prepared to resist advance by rapid re-enforcements at any of the possible points of approach. The reserves of the third line should be placed so as to be available for strengthening the most likely points of attack and to be able to protect the line of retreat. Most of the cavalry, and some horse-artillery if it can be spared, would be placed with the reserves. Sometimes a portion of this force is placed in the second line for the purpose of joining in forward movements and flank attacks upon the assailants, or of covering the retreat of the troops engaged in these counter-attacks if unsuccessful.

The second stage generally commences with the opening of fire at long range from the main batteries of the position, upon the heads of the enemy's infantry to quit its order of march and deploy. The attacking artillery will probably now reply from its first principal position, and as the artillery of the attack is at this time the most important arm it must be answered by the guns of the defense. In this artillery duel the defenders should have the advantage, as knowing accurately the ranges to the various points which must be occupied by the enemy in his advance, and as being moreover entrenched while the assailants are all comparatively exposed. During the second stage the infantry of the defense are brought up into position and open long-range fire upon the advancing enemy with more or less effect.

In the third stage the advance to effective rifle range of the attacking infantry has forced the defense to show more clearly the positions for the real attack, the direction of which it is now the object of the defending commander to discover, by every means in his power. As the supports and reserves of the assailing infantry come clearly into view, they should receive the concentrated fire of part of the artillery of the defense.

In the fourth stage the real point menaced by the attack being made clearly apparent, the commander re-enforces it to meet the assailants with a superior fire, and the artillery of the defense is directed at the opposing infantry; which now has become the principal arm in the attack. Should a counter-attack be projected it takes place during this stage, unless it is to be delayed until after the assault. Resistance to a flank movement of the attacking troops would also now have to be made. In the case of a counter-stroke being delivered by the defense, part of the cavalry and horse-artillery might be employed in support of it. Cavalry also should generally move forward on the flanks at this part of the action to seek for opportunities of throwing the flanks of the attacking infantry into disorder, or of taking guns too rashly advanced.

The fifth or last stage comprises the final repulse of the attack upon the position or the defenders' enforced retreat therefrom. In either case pursuit by the victors may ensue. Immediately before and during the final advance or assault every gun of the defense should concentrate its fire upon the attacking infantry, in order to check their advance, and should the assailants retire, the guns must continue to fire upon them, until masked by interposing troops sent forward in pursuit. Should the defenders, on the other hand, be forced to fall back, guns must cover the movement and enable the infantry to disengage itself.

The underlying idea of all infantry tactics is to close with the enemy as soon as possible and with all the units well in hand. The ideal conditions would be those making possible a quiet, quick and orderly advance without halting to open fire, but this is impossible with the highly developed weapons of to-day, and even though some of the attacking infantry managed to close with the enemy, there would be too few left for a bayonet fight. Therefore in order to make a successful assault, the infantry must move up under covering fire. To provide this protecting fire, it has equipped itself with the pistol, bayonet, and high-powered rifle, the one-pounder, trench mortars, the effective hand and rifle grenades, and has called to its assistance its supporting arm — the artillery. The enemy, attempting to protect himself from the terrific fire he knows will precede the infantry attack, has prepared deep dugouts and bombproofs, in which he often hides until the last possible minute.

Despite the fact that all of the above preparations are simply to give the bayonet man a chance to use his weapon (and to kill as many of the enemy as possible while doing it), it follows that fire action is more important than shock action, for without the fire the shock would be impossible. Therefore, the bayonet men must know how to shoot their rifles and to co-operate with the machine gun, the grenade, and the artillery, and must be so formed that during the assault they can deliver an effective rifle fire, present a solid front to the enemy in the bayonet charge, and be close enough to furnish mutual moral and physical support.

The wave attack that has been used so much in France was produced in order to furnish the greatest amount of mutual support among automatic riflemen, grenadiers, the one-pounders and riflemen, and at the same time to allow the greatest number of riflemen (bayonet men) to close with the enemy in the best formation possible. All of the conditions so far discussed make it imperative that the assaulting troops be perfectly organized and that they follow their covering fire (barrage) as closely as possible.

Consulting Military and Civil Engineer.

TACTICS, Naval. See NAVAL TACTICS.

TACUBAYA, tä-koo-bä'yä, Mexico, a city in the federal district, situated three miles southwest of Mexico City. It is the principal pleasure resort of the valley of Mexico, and has many fine buildings and gardens. The national observatory is situated here, as well as the castle of Chapultepec. Pop. about 40,000.

TACULLI, an American Indian tribe of the Athapascan family, residing in British Columbia, at the headwaters of the Peace and Fraser rivers. They numbered about 750 in 1918 and lived on various small reservations. The majority of them are Roman Catholics, having been converted by French missionaries.

TADEMA, tä'dĕ-ma, **Laurence Alma.** See ALMA-TADEMA, LAURENCE.

TADOUSAC, tä-doo-zäk', Canada, a town in Chicoutimi and Saguenay County, Quebec, situated at the confluence of the Saguenay River with the Saint Lawrence. It is a summer resort, and noted as being the oldest settlement in Canada. It was one of the early centres of the fur trade, and the home for a time of Father Marquette. Remains are still visible of one of the early Jesuit establishments. Pop. 2,500.

TADPOLES. See FROG.

TAFILET, tä-fē-lĕt', or **TAFILELT,** Morocco, an oasis on the southern border of Morocco and northwestern border of the Sahara region, 200 miles south by east of Fez. It covers about 530 square miles, and has a population of about 125,000, distributed among about 150 villages, of which Abuam is the most important. The date-palm is cultivated, and silks and rugs are manufactured.

TAFT, Alphonso, American jurist: b. Townshend, Vt., 5 Nov. 1810; d. San Diego, Cal., 21 May 1891. He was graduated from Yale in 1833, became a tutor there and was admitted to the bar in 1838. In 1840 he settled in Cincinnati and took part in politics, being a member of the Republican convention in 1856. In 1865 he was appointed judge of the Superior Court of Cincinnati, serving until 1872, when he resigned to resume his law practice. On 8 March 1876 he was appointed Secretary of War but after two months was transferred to the post of Attorney-General. During 1877–82 he practised law in Cincinnati, and in April of the latter year was sent as Envoy Extraordinary and Minister Plenipotentiary to Austria. From 1884 to August 1885 he was Minister to Russia.

TAFT, Charles Phelps, American lawyer and editor, half-brother of President Taft: b. Cincinnati, Ohio, 21 Dec. 1843. He was graduated at Yale University in 1864, and later studied at the universities of Heidelberg, Berlin and Paris. He was admitted to the bar of Ohio in 1866 and in 1869–70 was engaged in practice in Cincinnati. In 1879 he became the principal owner of the Cincinnati *Times* which in 1880 he consolidated with the *Star* as the *Times-Star,* of which he has since been editor. He was a member of the Ohio House of Representatives in 1871 and served in Congress in 1895–97. He was presidential elector-at-large from Ohio in 1904, and president of the Ohio electoral college in January 1905.

TAFT, Henry Walters, American lawyer, brother of President Taft: b. Cincinnati, Ohio, 27 May 1859. He was graduated at Yale University in 1880 and later studied at the Cincinnati and the Columbia Law Schools. He was admitted to the bar in 1882 and engaged in practice in New York, where he is a member of the firm Cadwalader, Wickersham and Taft. He was special assistant to the Attorney-General of the United States in the tobacco trust investigation. He was a member of the New York board of education in 1896–1900; a trustee of the College of the City of New York in 1903–05; and since 1908 has been a trustee of the New York Public Library. In 1907 he was appointed chairman of the Permanent Legal Advisory Board for Greater New York under the selective service regulations.

TAFT, Lorado, American sculptor: b. Elmwood, Ill., 29 April 1860. Of English ancestry, settled about 1679 in Mendon now a part of Uxbridge, Mass., his father was Don Carlos Taft, professor of geology, University of Illinois (1872–82), later banker in Hanover, Kan. He graduated B.S. 1879, and M.L. 1880 at the University of Illinois; and studied at the École des Beaux Arts, Paris (1880–83). He opened a studio in Chicago in January 1886; from 1886–1907 was instructor and since lecturer at the Art Institute of Chicago University, extension lecturer University of Chicago (1892–1902) and since 1902 professional lecturer on the history of art. He won the designer's medal at the Columbian Exposition, Chicago (1893); silver medal, Pan-American Exposition, Buffalo (1901); gold medal, Saint Louis Exposition (1904); silver medal, Panama-Pacific Exposition (1915). His work and lectures exercised a wide influence and in 1913 he received the honorary L.H.D. degree from Northwestern University. He is the author of 'The History of American Sculpture' (New York 1903), and of 'Sculpture of the Nineteenth Century' (1919) in the encyclopedia. Among his notable works are 'Sleep of the Flowers'; 'Awakening of the Flower'; Decoration of Horticultural Building, Columbian Exposition; 'The Eternal Silence,' Graceland Cemetery, Chicago; 'Solitude of the Soul,' Art Institute, Chicago; 'Blackhawk,' Oregon, Ill.; 'Washington,' Seattle, Wash.; 'Paducah,' Paducah, Ky.; 'Trotter Memorial Fountain,' Bloomington, Ill.; 'Columbus Memorial Fountain,' Washington, D. C.; Ferguson, 'Fountain of the Great Lakes,' Grant Park, Chicago; Ogle County 'Soldiers' Monument,' Oregon, Ill.; James Whitcomb Riley medal; 'The Fountain of Time,' Chicago; Thatcher Memorial Fountain, Denver, Col.; 'Alma Mater' for University of Illinois.

TAFT, William Howard, 27th President of the United States: b. Mount Auburn, Cincinnati, 15 Sept. 1857, son of Judge Alphonso (q.v.) and Louisa M. (Torrey) Taft. After graduating with honors from Yale (1878) he studied law in Cincinnati, being admitted to the bar in 1880. From 1881 to 1883 he was assistant prosecuting attorney in Hamilton County, Ohio, and for a time Collector of Federal Internal Revenue. From 1883 to 1887 he practised law in Cincinnati, after 1885 being assistant county solicitor. In 1886 he married Miss Helen Herron. In 1887 Governor Foraker appointed him to fill an unexpired term as judge of the Superior Court. He was later elected for a full term; but in 1890 he was appointed solicitor-general of the United States by President Harrison. In 1892 he was made a Federal judge of the sixth circuit, a position for which by temperament and training he was admirably fitted, and the work of which he found most congenial.

On 12 March 1900 President McKinley chose him to head a commission to establish civil government in the Philippines, and on 4 July 1901 he became first civil governor. Taft accepted both appointments at the expense of his personal preference for a career on the bench, being influenced by a deep sense of responsibility toward and a genuine affection for the Filipinos. In 1902 Roosevelt twice offered him an appointment to the Supreme Bench of the United States, but he put aside what has been his chief personal ambition because he felt his immediate duty was to continue in the islands. As an executive his work was highly successful. In 1902 he conducted at Rome the important negotiations for the purchase of the Catholic Friars' lands. To a remarkable degree he won the confidence and affection of the Filipinos, though he disappointed many by his frank statement that in his judgment it might be two

WILLIAM HOWARD TAFT

Twenty-seventh President of the United States

generations before they would be ready for complete self-government. He believed in «The Philippines for the Filipinos,» and opposed exploitation primarily in the interest of American capital. He urged tariff concessions for Philippine products.

On 1 Feb. 1904 he became Roosevelt's Secretary of War, and for over four years was engaged in such important enterprises as the building of the Panama Canal. In 1906, when disorders called for American intervention, he was sent to Cuba, and for a time acted as provisional governor. In 1907 he visited Cuba and Panama, and later Japan and China, going to the Philippines for the opening of the legislative assembly, and returning by way of Russia. In 1906–13 he acted as president of the reorganized American Red Cross.

By 1907 Roosevelt was exerting his influence to secure the Republican nomination for his Secretary of War, whom he described as possessing «a standard of absolutely unflinching rectitude on every point of public duty, and a literally dauntless courage and willingness to bear responsibility,» besides a knowledge of men, tact and kindliness. Nominated on the first ballot, June 1908, Taft resigned as Secretary. The campaign with Bryan was fought largely on the issue of continuing the «Roosevelt policies,» the President declaring that Taft was «the man who I feel is in an especial sense the representative of all that in which I most believe in political life.» With this recommendation, and on the strength of his ideal training for the office, Taft was given 321 electoral votes to Bryan's 162.

As President he lacked the magnetism and dramatic force of his predecessor. In general he took a moderate position on public questions. «We middle-of-the-road people,» he said (1911), «who are not extremists are, we believe, the real Progressives, because you do not make progress by great strides; you make progress step by step.» His position on important issues may be summarized as follows: (1) In connection with the Payne-Aldrich Tariff Bill he used his influence in favor of downward revision to a protective basis, just sufficient to cover the difference in cost of production between here and abroad. Though not satisfied with some provisions, he signed and defended the law as the best ever passed. He favored further revision on the basis of reports to be made by a tariff commission; and he vetoed later revisions of several schedules largely because they were not based on such reports. He worked for reciprocity with Canada. (2) On conservation his fundamental views were not so different from those of the Progressives as they seemed to believe. He hesitated, however, to stretch the executive power, and Congress was slow to give him the power he requested. Unfortunately his support of Secretary Ballinger against Roosevelt's friend, Pinchot, appeared to place him in opposition to the policies of his predecessor. (3) In the matter of railroad and trust regulation he favored strict enforcement of existing law and his administration secured the dissolution of the Standard Oil and Tobacco trusts. He urged the clarification of the Sherman law and favored Federal charters for corporations doing interstate business. (4) He was opposed to the more radical schemes of direct popular government, in particular the «recall of judicial decisions.» (5) He favored and extended civil service reform, worked for efficiency and economy in government, especially urging a budget system and advocating pensions for Federal employees. (6) In foreign affairs he worked heartily for peace, negotiating treaties for arbitration and the judicial settlement of international difficulties, which were rejected by the Senate. By «dollar diplomacy» the administration sought to secure opportunities for trade and the investment of capital. This policy was denounced by some as leading to imperialistic interference in the affairs of weaker nations, and making government diplomacy a mere agent of big business.

Some of these views were too progressive to suit the old leaders, and yet it was not long before the insurgent Progressive-Republicans were denouncing the President as too friendly with reactionary party bosses and big business, and a deserter from progressive standards. Believing in the necessity of party government, the President did feel it necessary to work with and through the party majority in Congress. For a time he withheld patronage from insurgent senators and representatives, and when he changed his policy the damage had been done. The defense of the Tariff Bill, the dismissal of Pinchot, the repeated vetoes of later tariff reduction bills, the veto of the grant of statehood to New Mexico and Arizona because of radical provisions in their constitutions, all increased his unpopularity. The elections of 1910 gave the Democrats a majority in the House and showed a popular discontent with the old Republican rule and a drift toward Progressive Republicanism or toward the Democratic party. In Congress the insurgent Republicans often joined the Democrats to defeat the regular Republicans. In 1910 Roosevelt returned from Africa, and before long was openly taking issue with the policies of his successor. By 1911 the Progressive Republicans were planning to prevent the renomination of Taft. At first La Follette was to be their candidate, then they turned to Roosevelt. Early in 1912 he agreed to accept the nomination. In the States having direct primaries Roosevelt made a much better showing than Taft; but the control of the party machinery by the regulars brought about the President's renomination. The Progressives started a new party, ensuring the overwhelming defeat of the President in November and the election of Wilson.

The outstanding feature of the administration was the conflict between conservative and progressive forces; but the confusion and recrimination should not obscure important developments during these four years. Among these were the reform of the rules of the House of Representatives (1910); the corporation tax (1909); increased powers of the Interstate Commerce Commission; Postal Savings Bank (1910) and Parcel Post (1912); Children's Bureau (1912) and Department of Labor (1913); publicity for and limitation of campaign contributions (1910–11); submission of amendments on income tax and direct election of senators.

Since 1913 Mr. Taft has been Kent professor of law at Yale University, lecturing on constitutional law in the college and the law school. He has continued to take an active interest in promoting international peace and a League of Nations. During the World War he was joint chairman of the National War Labor Conference Board.

With the calming of factional bitterness, Mr. Taft has gained again in the public esteem and confidence, and the accomplishments as well as the mistakes and difficulties of his administration appear in a better perspective.

ARTHUR P. SCOTT,
Assistant Professor of History, The University of Chicago.

TAGABAWAS, tä-gä-bä'väs, a Philippine people living on both sides of Dávao Bay, Mindanao, a mixture of several Malay tribes.

TAGACAOLOS, tä-gä-kä'ō-lōs, a Philippine tribe, whose settlements are scattered among other tribes along Dávao Bay, Mindanao.

TAGALS, tä-gäls', **TAGALOGS**, or **TAGALOS**, a Philippine people of Malay origin, inhabiting chiefly Manila, the provinces of Cavite, Bataán, Bulacán, Batangas, Infanta, Laguna, and Mindoro, and scattered among other tribes in several other provinces. They are Christians and one of the leading peoples of the archipelago, both in numbers and in culture; they possessed an alphabet and considerable civilization before the arrival of the Spaniards. They were the leading element in the last insurrection against Spain, and proved troublesome after American occupation. They are, however, intelligent, shrewd and generally industrious; and when once comprehending American ideals prove trustworthy. See PHILIPPINE ISLANDS.

TAGANROG, tä-gän-rŏg', Russia, a town in the government of Ekaterinoslav, on a lofty promontory on the Sea of Azov, opposite the mouth of the Don, 28 miles west-northwest of Azov. There is a monument to Alexander I, who died here; also churches, exchange, gymnasia, etc. It has manufactures of candles, leather, tobacco, macaroni, etc. The harbor, though the deepest in the Sea of Azov, is shallow, not admitting vessels which draw more than 10 feet; but its situation secures to it a considerable trade. The principal exports are wheat, rye, barley, oats, linseed, rapeseed, wool, oil-cake, caviar and butter; the imports include fruit, oil, machinery, hides, petroleum, dry goods, wine, etc. The annual exports previous to the World War averaged over $50,000,000. Pop. 71,000.

TAGBANUAS, tąg-bä'noo-as, native tribes of the Philippine Islands inhabiting the island of Palawan. They may be classified into five groups, some more civilized than others, according to the nature of the locality and the extent of contact with the coast tribes. The Tagbanuas Apurahuanos have a peculiar writing and alphabet. They have an elaborate system of government, laws for the regulation of morals and feast days. Their god is Diwata, whose principal officer and representative on this earth is called the Babailan, who may be of either sex. Consult Venturello, M. H., 'Manners and Customs of the Tagbanuas and Other Tribes of the Island of Palawan, Philippines' (in 'Smithsonian Miscellaneous Collections,' Vol. XLVIII, p. 514 et seq., Washington 1907).

TAGBILARAN, täg-bē-lä'rän, Philippines, pueblo, capital of the province of Bohol; on the southwest coast. Opposite the town is the important dependent island of Panglao, separated from Bohol Island by a strait one mile in width. The chief industries are agriculture and turtle fishing. Pop. 11,000.

TAGES, tä'gĕz, in early Italian mythology, son of a minor local deity, or genius, and grandson of Jupiter. He taught the Etruscans the arts of augury and divination, and was said to have sprung forth from a clod of earth freshly turned up by a husbandman named Tarchon, in the neighborhool of Tarquinii.

TAGGART, Marion Ames, American writer for young people: b. Haverhill, Mass., 7 May 1866. She has published 'The Blissylvania Post Office' (1897); 'Aser, the Shepherd' (1899); 'The Wyndham Girls' (1902); 'In the Days of King Hal' (1902); 'Nut-Brown Joan' (1904); 'Pussy Cat Town' (1906); 'Betty Gaston' (1910); 'Nancy the Doctor's Little Partner' (1911).

TAGGART, Thomas, American congressman: b. County Monyhan, Ireland, 17 Nov. 1856. He came to the United States in 1861 and settled at Xenia, Ohio. He engaged in the hotel business at Indianapolis in 1877, and since 1886 has been active in politics. He was chairman of the Democratic State Committee in 1892–94; mayor of Indianapolis in 1895–1901; and in 1916 was appointed to fill the vacancy in Congress caused by the death of B. J. Snively. He was elected to Congress in 1912 and in 1914.

TAGISH, a tribe of American Indians formerly residing about the headwaters of Lewis River, Alaska. A remnant of the tribe still exists.

TAGLIONI, täl-yō'nē, **Maria**, Italian ballet dancer: b. Stockholm, Sweden, 23 April or 18 March 1804; d. Marseilles, France, 23 April 1884. Her father was Philippo Taglioni (b. Milan, 1777; d. 1871), a ballet master at different opera-houses successively in Europe. She was rigorously trained by her father and developed a marvelous grace, so that she became the admiration of Europe in her day. She made her début at Vienna in 1822; appeared at Paris in 1827, and at Berlin, London and other capitals later. Her style was termed «ideal»; was chaste and refined in distinction to the «realistic» dancing of her predecessors, Gardel and Vestris. Her great successes were 'La Bayadire,' 'La Sylphide,' composed for her by her father, and 'La Fille du Danube.' In 1832 she was married to Count Gilbert de Voisins, and in 1847 retired from the stage. She is frequently mentioned in contemporary literature, particularly by Balzac and Thackeray.

TAGORE, tą-gôr, SIR **Rabindranath**, Hindu poet: b. Calcutta, 1861. His father Maharshi Devendranath Tagore was a famous spiritual leader who belonged to a family distinguished for many generations throughout India. He was educated chiefly under private tutors and at the age of 17 visited England. By this time he was writing verse, largely imitative of the old Vaishnava poets. When he was 18 years old he published 'Sandhya-Sangita' ('Songs of Sunset'), and 'Pravata-Sangita' ('Songs of Sunrise'). In these he arises to the height of neo-romanticism in Bengali poetry. In 1884 he was married and went to

Shilaida on the banks of the Ganges to manage his father's estate. There he came into touch with the real life of the people and wrote poems, tales, parables and dramas dealing with their everyday affairs. His best known works of this period perhaps are 'The Crescent Moon,' 'The Gardener,' 'Gitanjali' and 'The Hungry Stones and Other Stories.' This second or Shilaida period of his life, which lasted 17 years, had a sad ending, as he lost in rapid succession by death, his wife, daughter and the younger of his two sons. At the age of 40 in 1901 he began work at Bolpur, which centred around his school, 'Shanti Niketan,' or translated, 'Abode of Peace.' Beginning with two or three boys it had grown in four years to 60, and in 1919 numbered over 200 boys. This school, while strictly Indian in its characteristics, embodied in itself, in forms modified to environmental conditions, the most advanced educational ideas of the world to-day, while retaining also the best traditions of the ancient Indian garden and forest schools. It is interesting to Americans to note that the self-government of his school is largely modeled after that of the George Junior Republic. Here Tagore brought the power of his personality to play upon an increasing number of young men who are making the India of to-morrow. The award of the Nobel prize in literature in 1913 brought him into world fame, and in 1915 he received the honor of knighthood. He has published in Bengali over 30 poetical works and 28 prose works, including novels, short stories, essays, sermons, dramas, etc. With a fine appreciation of the value of the English language he has made his own translations and published in English 'Chitra' a play; 'The Crescent Moon: Child-Poems'; 'The Gardener'; 'Gitanjali'; 'Personality'; 'The King of the Dark Chamber'; 'Reminiscences'; 'Songs of Kabir'; 'Sadhana: the Realization of Life'; 'The Hungry Stones and Other Stories'; 'The Post Office'; 'Fruit Gathering'; 'Stray Birds'; 'The Cycle of Spring'; 'Sacrifice and Other Plays'; 'Nationalism'; 'Mashi and Other Stories'; 'Lover's Gift and Crossing.' Consult Rhys, E., 'Rabindranath Tagore' (1914); Pearson, W. W., 'Shantiniketan: The Bolpur School' (1916); Roy, B. K., 'Rabindranath Tagore: The Man and His Poetry' (1916).

TAGUS, tā'gŭs (Spanish, *Tajo*; Portuguese, *Tejo*), the largest river of Spain and Portugal, rising in the mountains of Albarracin, on the frontier of New Castile and Aragon, a little more than 100 miles from the Mediterranean. Pursuing first a northwesterly and then a southwesterly course, it passes by Aranjuez (a little south of Madrid), Toledo, Talavera and Alcantara, enters Portugal, and passes by Abrantes, Santarem, below which it begins to broaden into its fiord-like and expanding estuary, contracting again below Lisbon, and 10 miles farther down flowing into the Atlantic. Total length, 565 miles. The tide reaches nearly to Santarem, and regular navigation of the river begins at Abrantes. It flows through a mountainous country and its current is much broken by rocks and cataracts. Its principal affluents are the Jarama, Guadarrama, Alberche, Tietar, Alagon, Elja and Zezere on the right bank; and the Guadiela, Almonte, Salor, Sever and Sorraia on the left.

TAHITI, tä-hē'tē, formerly **OTAHEITE**, the largest of the Society Islands, situated in the southern Pacific Ocean, in lat. 17° 40' S., and long. 149° 30' W. It consists of two mountainous, volcanic and roughly circular parts, united by a low, narrow neck of land, and abounds in magnificent scenery. The greatest dimension is northwest and southeast, 28 miles; the total area is about 400 square miles, and the highest point 7,320 feet above sea-level. The climate is very agreeable. The natural vegetation is extremely beautiful and luxuriant, but cultivation is limited to the coastal plain, where also nearly all the population is located. Copra, pearl-shell, cotton, vanilla and oranges are the chief exports, whose value in 1902 amounted to $860,000. Papeete, on the northwest coast, is the French administrative capital for all the French possessions in Polynesia. The native Tahitians were once a splendid race, noted for their simple, idyllic life. (See TAHITIAN LITERATURE). The vices introduced by contact with civilization soon brought about moral and physical degeneration, and the native inhabitants are rapidly diminishing in number. The island was discovered by a Spanish navigator, Quiros, in 1605, and visited by Captain Cook in 1769. In 1842 it came, as a native kingdom, under French protection, and in 1880 was declared a French colony. Pop. about 12,000. See SOCIETY ISLANDS.

TAHITIAN (tä-hē'tĭ-an) **LITERATURE.** As mentioned under Tahiti, the natives of this southern Pacific island were once a beautiful race, living a natural, simple and idyllic life, as expressed in the accounts of Tahiti by Wallis, Bougainville, Cook and others, and idealized in the works of Melville, 'Omoo' (The Rover); Stoddard, 'Idylls'; and Loti, 'Marriage.' Notwithstanding their physical and moral degeneration since the introduction of European civilization, the evidences of the aboriginal state of existence, outside the recitals of early explorers, are to be found in their traditions and legends preserved in the native songs and poems of the existing Teva family, of royal lineage, descended from Hototu, first queen of Vaieri, who married Temanutunu, the first king of Punauia. The songs, generally of love, war and lamentation, locally called *himenes*, are sung as a kind of choral chant with a monotonic buzzing bass, on which a high shrill cadencing is repeated indefinitely, ending always in a long iee-i-é-e. The longer poems recite the history of the family, the various forms of etiquette and addresses for visits; shorter poems consist of soliloquies, laments, reproofs and ceremonial topics. Among favorites of which English translations have been made are the 'Coronation Song of Pomare'; 'Lament of Aromaiterai': 'Soliloquy of Teura, a beauty asked to wed Punu, an old chief'; and 'Song of Reproof, at the beginning of the Wars between Teva and Purionu, in 1768.' Consult La Farge, 'Tahitian Literature' (p. 14389, Vol. XXIV); 'Warner's Library of the World's Best Literature.'

TAHLEQUAH, tä-lē-kwä', Okla., town, former capital of the Cherokee Nation, in the valley of the Illinois River, about 18 miles east of Port Gibson, and 25 miles northeast of Muskogee, on the Saint Louis and San Francisco Railroad. It is in a fertile agricultural region. It contains two public high schools, the Cherokee National Female Seminary and the Cherokee National Male Seminary. The latter was founded in 1847. There are two mission schools, the Baptist and the Presbyterian, and two school libraries. There is one bank and four weekly newspapers. The manufacturing is increasing, and there are grain elevators, cotton gins and flour mills. Pop. (est.) 3,000.

TAHOE, tä-hō', a lake at the base of the Sierra Nevada, on the boundary between California and Nevada, part in Placer County, Cal., and part in the counties of Douglas and Ormsby, Nev. It is about 20 miles long and from 8 to 12 miles wide, and has an altitude of 6,275 feet, and an extreme depth of 1,650 feet. The outlet is Truckee River. Lake Tahoe is noted for its beauty and the picturesque surroundings. It is a favorite and unique summer resort, on account of the cool and healthful climate and the beautiful scenery.

TAHPANHES, or **TEHAPHNEHES,** an ancient city of Egypt, mentioned in the Bible (Jer. ii, 16; xliii, 7), usually identified with the Daphnæ of the Greeks, situated in the northeastern part of the Delta, about 30 miles southwest of Pelusium. In 1886 the site was explored by Petrie (q.v.), who gives an account of the work in his 'Tanis,' Part II (1887).

TAHR, tär, a wild goat (*Hemitragus jemlaicus*), found on steep tree-covered slopes along the whole range of the Himalayas from Kashmir to Bhutan. The horns are about a foot long, flattened, with a notched anterior margin; body fawn-brown; the hair of the neck, chest and shoulders hangs to the knees; the female is lighter in color with smaller horns. Its nearest relative is the nilghiri goat of central India.

TAI-CHU, tī'chow', the former capital of Formosa (q.v.). See Tainan.

TAI-NGNAN-FU, tī'ngän'foo', China, a city in the province of Shantung, situated 35 miles southeast of Tsi-nan, on the railway to Yichau. It has a temple covering a large area, which draws many pilgrims bound for Mount Tai, which is regarded as sacred. Pop. about 75,000.

TAI-TOU, empress of Abyssinia: b. 1853; d. Addis Abeba, 11 Feb. 1918. She was a daughter of the king of Gondar and took an active part in the troublous politics of Abyssinia, and was concerned in all the civil wars and intrigues which ended in the raising of Menelik, whom she had taken for her fifth husband in 1883 when he was simply king of Shoa, to the position of Negus-Negusti (emperor) in 1889. At Adowa where the Italians suffered a crushing reverse, she accompanied Menelik to battle headquarters and put her own hereditary troops in the field. During Menelik's long illness she practically governed the country and kept it from internal disorders. On Menelik's death in December 1913, his grandson, Lidj Jeassu, a youth of 18 and no blood relation of the empress, became emperor, but failed to maintain order, and largely on Tai-Tou's initiative he was deposed in September 1916, and his aunt, Zauditu, Menelik's older daughter, was proclaimed empress.

TAI-YUAN-FU, tī'wän'foo', China, the capital of the province of Shan-si, situated near the centre of the province, 260 miles south of Peking. It consists of a Chinese and a Tatar city separated by a high wall. The city has served as the residence of the emperors and contains a number of magnificent mausoleums. The surrounding region is very fertile and contains rich coal deposits. Pop. over 200,000.

TAIHOKU, Formosa, capital of the island. It has progressed rapidly since it came under Japanese government in 1898. Systematic colonization was begun in 1909, and in 1916 the population was over 100,000. See Formosa.

TAILFER, Patrick, American colonist: lived in the 18th century. He was a physician and emigrated to the newly-founded colony of Georgia in 1740. Later he removed to Charleston, S. C. He is remembered for his joint authorship of 'A True and Historical Narrative of the Colony of Georgia from the First Settlement thereof Until the Present Time' (1741). It is a severe arraignment of Gen. James Oglethorpe's method of governing the colony and accuses the general of undue exercise of arbitrary authority and of putting his personal interests before those of the settlers. The work has been the subject of much discussion as to whether it was justified or was merely the expression of a group of malcontents.

TAILLON, Sir Louis Olivier, Canadian statesman: b. Terrebonne, Quebec, 26 Sept. 1840. He was educated at Masson College and was called to the bar in 1865. He engaged in practice at Quebec in 1882 and became one of the leaders of the bar. He served in the Quebec assembly from 1875; was speaker in 1882–84; Attorney-General in 1884–87; and in January 1887 he formed an administration, but resigned in two days and until 1890 was leader of the Opposition. He was appointed Minister without Portfolio in December 1891; was Prime Minister in 1892–96; and Postmaster-General in 1911. He was knighted in 1916 some years after his retirement to private life.

TAILOR-BIRD, an East Indian warbler (*Orthotomus* or *Sutoria sutoria*), one of many species in a large genus which exhibit a close similarity in structure and habits. They inhabit cultivated districts, are dressed in plain tints, feed chiefly on insects, and are peculiar mainly in their nest-making. They either sew a dead leaf to a living one or join two neighboring leaves together, so as to form a kind of hanging pouch, which remains attached to the branch by the leaf-stalk of one or both leaves. The threads which they use consist generally of twisted vegetable fibres or of actual cotton threads, the bill serving for a needle in puncturing holes in the leaves and in drawing the threads through. Occasionally, if a large enough leaf be found, the nest may be formed by joining together the free edges of the leaf. The lower part of the pouch contains the nest, which is a cup of soft materials and is entered from above. The actual structure of this ingenious cradle has never been scientifically observed, although tailor-birds are common. The best information is contained in Hume, 'Nests and Eggs of Indian Birds' (London 1890).

TÁIN BÓ CÚALNGE, THE CUALNGE CATTLE-RAID. The mediæval Irish scholars catalogued their native literature under several heads, to one of which they gave the name Táin, by which they meant a "reaving" or a "driving" of cattle. The most important tale belonging to this class is the subject of this article. The professional Irish story-tellers also arranged their epic tales according to cycles, one of which was known as the Ulster cycle, because the scene is always laid in Ulster; as the cycle of Conchobar (Connor), the king round whom the Ulster warriors mustered; as the Red Branch cycle, from the name of their banqueting hall; and, finally, as the Cuchulainn cycle, from the name of the champion round whom the saga pivots. The 'Táin Bó Cúalnge' has always enjoyed the reputation of being the most celebrated story of Irish antiquity.

The following is the argument of the Cualnge Cattle-Raid: One night a dispute arose between Queen Medb of Connaught and her husband, Ailill, as to the amount of their respective possessions. On matching their wealth, they were found to be equal, except that among the king's herds was a lordly bull called "the Whitehorned." Thereupon Medb dispatched her courier to Daré mac Fiachna, a rich landowner in Cualnge (Anglicé Cooley), in Ulster, to ask for the loan of his wonderful bull, called "the Brown of Cualnge." Daré at first granted the queen's request but, incensed at a remark made by one of the envoys, he withdrew his promise and swore that never would he hand over the Brown Bull of Cualnge.

Medb straightway gathered a formidable army composed of allies from all parts of Ireland wherewith to undertake the invasion of Ulster and to carry off Daré's bull by force.

Now it happened that the expedition took place while the Ulstermen suffered a debility which lasted all winter and the burden of defending the province fell on the shoulders of a stripling of 17 years of age, namely Cuchulainn, who was exempt from the curse which had befallen the remainder of the champions of Ulster.

Cuchulainn confronted the foe and agreed to allow them to continue their march on condition that every day they send one of their champions to meet him in single battle. When he shall have killed his opponent, the host shall halt and pitch camp until the following morning. Queen Medb agrees to abide by those terms. In each of the combats which ensue, the heroic youth is victorious and slays many of the most celebrated warriors on the side of Connaught. The severest of all those single fights was the one which lasted four days and in which he had as antagonist his early friend and foster-brother, Ferdiad. After the death of Ferdiad, Queen Medb, impatient at these delays, broke the sacred laws of ancient Irish warfare and overran Ulster with fire and sword.

By this time the Ulstermen have come out of their debility and gathered their forces. In the final battle Medb's army is repulsed and retreats in flight into Connaught. But she had the satisfaction of carrying off with her the prize and the cause of the war, the Brown Bull of Cualnge.

The events which the 'Táin Bó Cúalnge' relates and its personages are ascribed by the Irish annalists to about the time of the birth of Christ, that is to about 300 years before the introduction of Christianity into the island, and such has been the constant Irish tradition. It belongs to a period when agriculture was almost unknown, when land was plenty and when the possession of kine to place upon it was of first importance and when cattle-raids were of frequent occurrence. The general condition of culture described in the saga corresponds in a remarkable way with the earlier part of the age to which archæologists have given the name La Tène, or Late Celtic, and which terminated at the first century of our era.

The 'Táin Bó Cúalnge' even carries us back to one of the earliest and most widespread beliefs of the great linguistic family to which we belong, to one of the most primitive aspects of a world-wide nature-myth. Its great protagonist, Cuchulainn, gives us the impression of a god, who appears to personify warmth and light struggling against the powers of cold and darkness. In the earliest version of the story, he is the son of the supreme god Lug and a mortal woman. Hence the curious combination that we find in him: On the one hand he acts like a brave and courtly warrior; on the other, his supernatural exploits exceed the course of ordinary human existence. By the time the tale had been given an historical framework and had been consigned to writing, the mythological idea from which it had sprung was, at most, but dim and uncertain. The story-tellers and their hearers regarded Cuchulainn and the other characters of the saga as real Irish men and women, and, although we are not to look for historical accuracy in the saga in every particular, it is very likely that, in the main, the events narrated really took place and the protagonists really existed.

The whole spirit of the 'Táin Bó Cúalnge' is strongly pagan, which is another proof that the tale was committed to writing very early in the Christian period. It is not the work of any one man, but the epic of all Ireland, the accumulated work of generations, the last stage of a slow evolution. Its arrangement in literary form may have taken place as early as the 5th century and its shaping, substantially as we have it, dates from the first half of the 7th century, if not earlier. The earliest manuscripts containing it probably disappeared during the Viking invasions, with the result that the oldest extant version dates from the year 1100. From that date till the middle of the last century a score or more of manuscripts have preserved it. Consequently, the 'Táin Bó Cúalnge' is the most ancient epic tale of western Europe and its composition antedates by a wide margin the epic tales of the Anglo-Saxons, the Scandinavians, the Franks and the Germans. Furthermore, it is entirely original and contains not the slightest hint of any foreign derivation.

The 'Táin Bó Cúalnge' is in prose interspersed here and there with verse and is not a work of art like the 'Iliad' or the 'Odyssey'; it is not a finished epic, but an epic in the making, showing better perhaps than any other work in literature the development of popular tradition through more than a thousand years and the earlier stages of an epic. It affords a picture of an old barbaric civilization, with all its inherent imperfections and roughness, wild phantasy and extravagance of deed and description, as it arose and developed among the people, unvarnished by poetic art. Withal it evinces poetic worth and contains some passages which are not surpassed in any literature.

The 'Táin Bó Cúalnge' is a great tale, one of the greatest and most curious in the world, and of the utmost importance to the philologist, the folklorist, the archæologist and the historian. For the first time in Europe it brings to light a high and romantic chivalry. It is a tale that is worthy of any literature in the world and no other race with which the Celts may be compared is able to produce any such ancient indigenous literary monument.

Bibliography.— The text of the Táin, from the most important manuscripts, has been published by Ernst Windisch, 'Die Altirische Heldensage, Táin Bó Cúalnge,' Irische Texte, Extraband (Leipzig 1905), which contains complete apparatus, introduction, notes and vocabulary; Faraday, L. W., 'The Cattle-Raid of Cualnge' (London 1904) is a translation based on one manuscript; Hull, E., 'The Cuchullin Saga' (London 1898; contains a translation by Standish H. O'Grady); Hutton, M. A., 'The Táin, An Irish Epic Told in English Verse' (Dublin 1907) is a paraphrase, as is Gregory, Lady A., 'Cuchulain of Muirthemne' (London 1903); Dunn, J., 'The Ancient Irish Epic Tale, Táin Bó Cúalnge, The Cualnge Cattle-Raid' (London 1914) is the first complete version in English and (pages xxxii–xxxvi) contains a full bibliography on the subject.

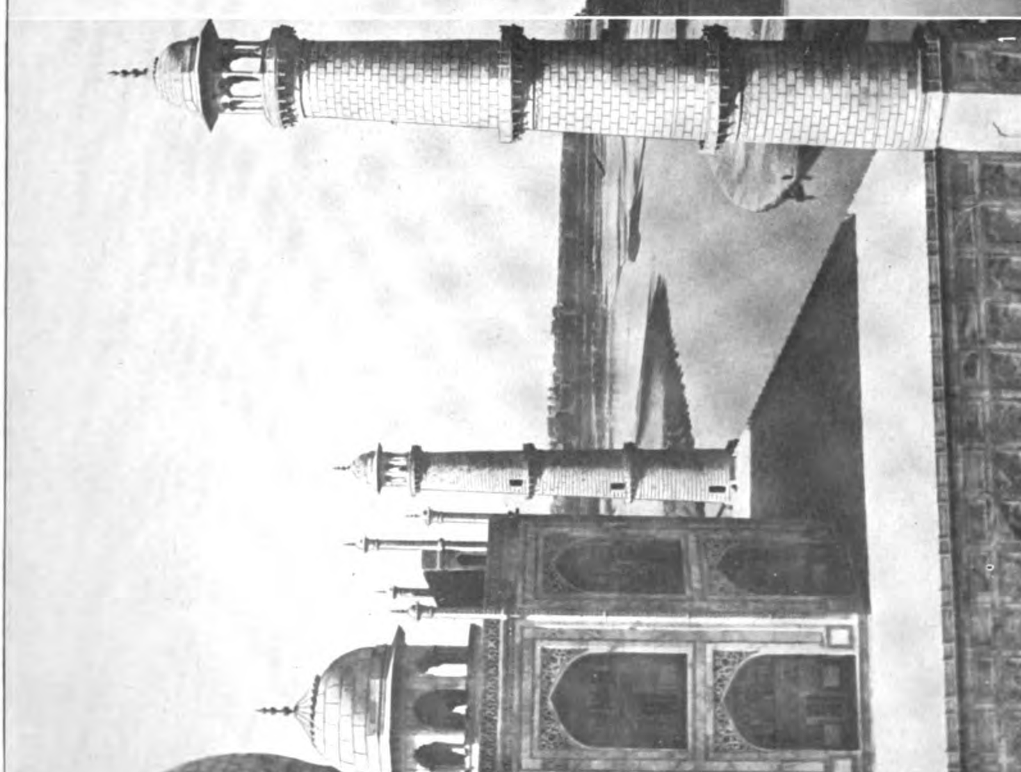
JOSEPH DUNN,
Professor of Celtic Languages and Literatures, The Catholic University of America.

TAINAN, tī'nän', Formosa, Japan, a city situated on a small river near the southwest coast of the island. Until 1896 it was the capital of the island. A canal connects it with Formosa Channel. Under the Chinese and Japanese régimes it has had the status of a treaty port. There are a rice mill and several sugar mills. Pop. 53,790.

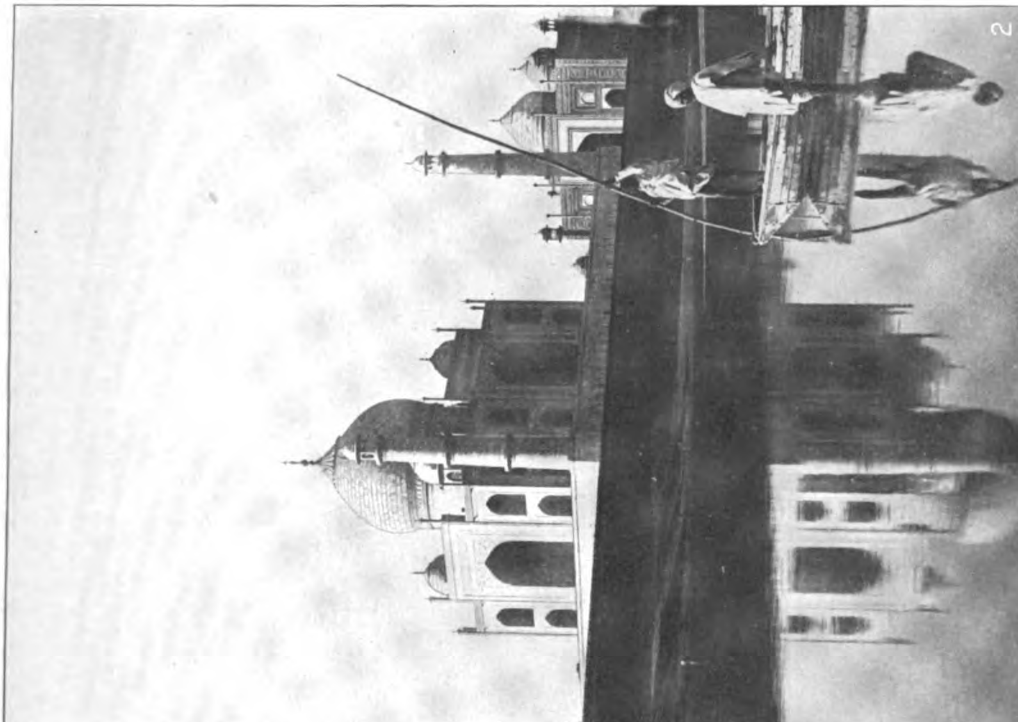
TAINE, tān, **Hippolyte Adolphe,** French critic and historian: b. Vouziers, Ardennes, 21 April 1828; d. Paris, 5 March 1893. He was educated at the Collège Bourbon and the Ecole Normale, Paris, was assigned by the government, which thought his talent dangerous, to a provincial post as instructor, but resigned this and devoted himself to literature, writing in quick succession 'Essai sur La Fontaine' (1853; rev. ed. 1860), 'Essai sur Tite Live' (1854) and 'Philosophes Français du XIXe Siècle' (1856). In 1864 he was appointed to a professorship in the Ecole des Beaux-Arts, where his series of lectures on the history of art were patterns of philosophical criticism. The dissolution of the empire and the attendant troubles directed him to the study of the philosophy of history and in connection therewith he wrote his 'Origines de la France contemporaine' ('Ancien Régime,' 1876, 'Revolution,' 1878–84, 'Régime Moderne,' 1890 — unfinished), a work of great erudition, in which he condemns the royalists, but finds their gravest faults repeated by the republicans and makes his bitterest attack on Napoleon. Thus he alienated all parties, holding all responsible for the disasters of the "Terrible Year." A work more familiar to readers in the United States and England is his 'Histoire de la littérature anglaise' (1864; Eng. trans., by Van Laun). The brilliancy of this performance is unquestioned, but the justice of its method has been much discussed and while Taine became the founder of a cult in France, he found in England and America no imitators of importance. Literary criticism, æsthetics and psychology were to him sciences as exact as chemistry; he treated them with a laboratory style of analysis and deduction. "Little facts, well-chosen, important, significant, amply substantiated, minutely noted" — such, in his own words, he made his material. "The whole world," said Bourget, "seemed to Taine matter for intellectual exploitation." Taine judged all products of the human mind by the three inflexible standards of race, epoch and surroundings and these he manipulated as if they were mathematical formulæ. He quite disregarded the factor of individuality and reduced everything to that rigorous systematization which drew protest from Amiel. He succeeded in pointing out certain things which no other historian had noted, but dogmatized to a degree no longer regarded as permissible. (See ORIGINS OF CONTEMPORARY FRANCE). Taine's other published works include 'Essais de critique et d'histoire' (1857); 'Ecrivains actuels de l'Angleterre' (1863); 'Idéalisme anglais' (1864), a study of Carlyle; 'Positivisme anglais' (1864), a study of John Stuart Mill; 'Nouveaux essais de critique et d'histoire' (1865); 'Philosophie de l'art' (1865); 'Philosophie de l'art en Italie' (1866); 'Voyage en Italie' (1866); 'Notes sur Paris, ou vie et opinions de M. Frédéric-Thomas Graindorge' (1867); 'L'Ideal dans l'art' (1867), lectures delivered at the Ecole des Beaux-Arts; 'Philosophie de l'art dans les Pays-Bas' (1868); 'Philosophie de l'art en Grèce' (1870); 'Du suffrage universel' (1871); 'Notes sur l'Angleterre' (1871), a work of considerable value; 'Derniers essais de critique et d'histoire' (1894) and 'Carnets de voyage: notes sur la Province' (1897). Taine was created honorary D.C.L. of Oxford in 1871 and in 1878 he was elected a member of the French Academy. Consult Monod, 'Les maitres de l'histoire' (1894); Lemaitre, 'Les contemporains'; De Margerie, 'H. Taine' (1894); Boutmy, M. E., 'Taine, Scherer, Laboulaye' (Paris 1901); Giraud, V., 'Hippolyte Taine' (ib. 1901); Aulard, A., 'Taine, historien de la Revolution française' (Paris 1907); Gummere, F. B., 'Democracy and Poetry' (Boston 1911).

TAINTER, Charles Sumner, American inventor: b. Watertown, Mass., 25 April 1854. He has invented the graphophone and was the associate inventor of the radiophone. In 1874 he was a member of the United States expedition sent to the South Pacific to observe the transit of Venus. In 1881 he received the gold medal at the Electrical Exhibition, Paris, for his inventions in connection with the radiophone and in 1889 was given the French Academy decoration, 'Officier de l'Instruction Publique' for the invention of the graphophone; in 1900 he received the John Scott medal in Philadelphia for this same invention.

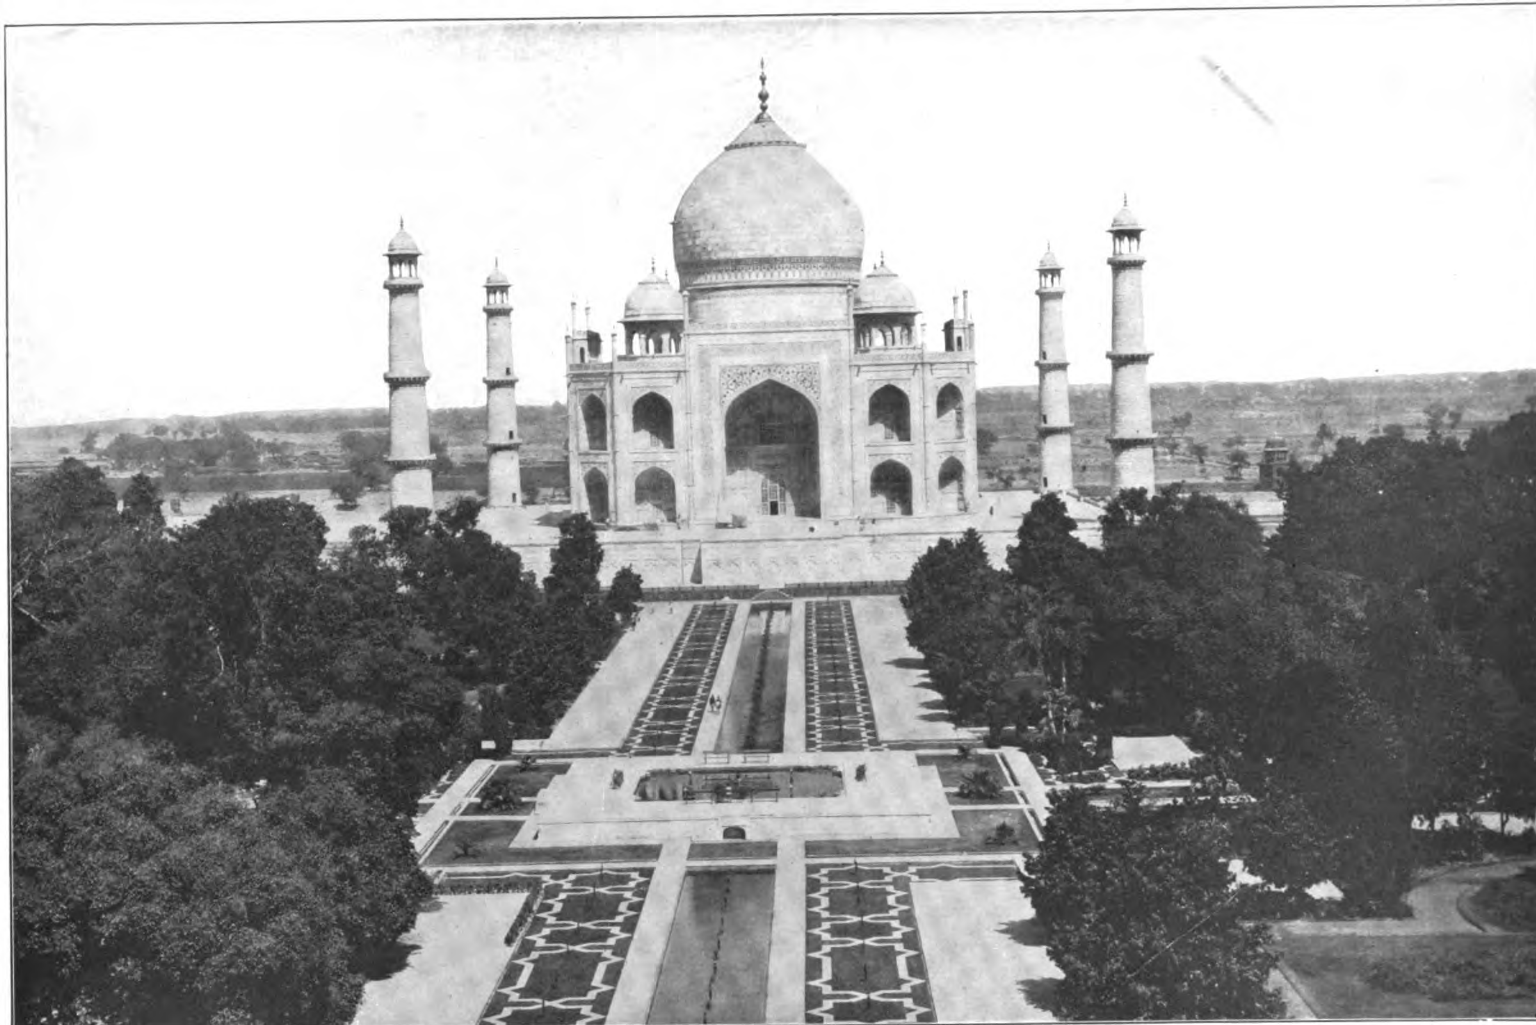
TAIPINGS, tī'pĭngs', the name given by foreigners to the insurgent followers of Hung



1 View from the Taj Mahal up the Jumna River to Agra



2 The Taj Mahal (built 1629-51), Tomb of Mumtaz Mahal, favorite wife of Shah Jehan



THE TAJ MAHAL

Hsiû-ch'wan, who raised a formidable rebellion in China in 1851 and who until his suppression in 1864, was looked upon by his disciples as emperor of the dynasty of Taiping — signifying Grand Peace, and the T'ien Wank — Heavenly King, of the T'ien Kwo — Kingdom of Heaven.

TAIT, tāt, **Archibald Campbell,** English prelate, archbishop of Canterbury: b. Edinburgh, 21 Dec. 1811; d. Addington, 1 Dec. 1882. Brought up a Presbyterian, he received his education in the schools of his native city. He entered the University of Glasgow in 1827, and having gained a Snell exhibition he matriculated at Balliol College, Oxford, in 1830, becoming about the same time a member of the Church of England. He was graduated with a first in classics in 1833, elected a Fellow of his college in the following year, ordained in 1836, and was active as tutor of Balliol for seven years. While several of his intimate friends joined the Tractarian movement, he himself kept aloof from it, and joined in the protest against Tract XC. He succeeded Dr. Arnold in the headmastership of Rugby School in 1842, and retained this post till 1850, when he was appointed dean of Carlisle. He took an active part in the work of university reform at Oxford, and in 1856 he was appointed to the see of London. He declined the archbishopric of York in 1862, and in 1869 was appointed archbishop of Canterbury. He at first opposed the bill for the disestablishment of the Irish Church, but on being appealed to personally by the Queen he accepted the inevitable. He was also instrumental in securing the enactment of the Public Worship Regulation Act of 1874. His mind was of a calm statesmanlike cast, and he acted with coolness and dignity in the critical events of his time, such as the Essays and Reviews controversy, the Colenso case and the legal prosecution of Ritualists. He was looked upon by the High Church party as a mere Erastian; they accused him of unfairness, but in his latter days he vindicated his sincerity in professing charitable tolerance with unmistakable clearness. Consult Davidson and Benham, 'Life of Archibald Campbell Tait' (1891); Dangin, 'English Catholic Revival in the XIXth Century' (London 1914).

TAIT, John Robinson, American painter: b. Cincinnati, Ohio, 14 Jan. 1834; d. 1909. He was graduated at Bethany College, Va. (1852), and studied in Florence, Italy (1853–56); in Dusseldorf (1859–71); and in Munich (1873–76). He was for several years the art critic of the New York *Mail and Express.* Among his writings are 'European Life, Legend and Landscape' (1859) and 'Dolce far Niente,' poems (1859).

TAIT, Sir **Melbourne McTaggart,** Canadian jurist: b. Melbourne, 20 May 1842. He was educated at Saint Francis College, Richmond, and was graduated at McGill University, Montreal, in 1862. He started practice as lawyer in 1862 at Richmond, then joined the late Sir John Abbott (1870), remaining his law partner many years. He was created K.C. in 1882 and was elected treasurer of the Montreal bar. In 1887 he was appointed puisne judge to reside at Sweetsbury, province of Quebec, removing to Montreal in 1889. In 1906 he was made chief justice of the Supreme Court. He was knighted on the occasion of the Queen's Jubilee (1897). A founder of the Children's Memorial Hospital, he has been its president since 1905.

TAIT, Peter Guthrie, Scottish physicist: b. Dalkeith, 28 April 1831; d. Edinburgh, 4 July 1901. He was educated at the Edinburgh University and at Saint Peter's College, Cambridge. Elected Fellow of Peterhouse in 1852, he became professor of mathematics at Queen's College, Belfast, two years later, and held that office till his appointment in 1860 to the chair of natural philosophy in the University of Edinburgh. He published 'Dynamics of a Particle' (1856); 'Quaternions' (1867); 'Thermo-Dynamics' (1868); 'Recent Advances in Physical Science' (1876); 'Heat' (1884); 'Light' (1884); 'Properties of Matter' (1885); 'Dynamics' (1895); 'Newton's Laws of Motion' (1899), etc. He was joint-author with Lord Kelvin of a well-known 'Treatise on Natural Philosophy'; and also collaborated with the late Balfour Stewart in 'The Unseen Universe.'

TAIWAN, tī-wän', the native name for Formosa (q.v.).

TAJ MAHAL, täzh, mạ-häl', India, a celebrated mausoleum in a beautiful garden, outside the city of Agra, about a mile east of the fort. It was built by the Emperor Shah Jehan for himself and his favorite wite Mumtaz Mahal, who died in 1629. Tavernier, who saw the building in process of construction, says that 20,000 men were employed upon it continually for 22 years. It is an octagonal building 70 feet high, with sides measuring 130 feet; and is surmounted by a dome giving an additional height of 120 feet; total height, 190 feet. At the four corners of the platform centred by the mausoleum are minarets 133 feet high. The whole is built of white marble, and the interior decorations are of sumptuous magnificence. The screen surrounding the chamber containing the cenotaphs of the emperor and his consort, above the sepulchral vault, is composed of 12 kinds of stones, chief of which is the valuable lapis lazuli; the arabesque mosaic and inlaid work is described as of unsurpassed beauty. The cost of the mausoleum is variously estimated to have been from $10,000,000 to $50,000,000.

TAJURA, or **TAJURRAH,** tä-joo'rä, northeast Africa, a bay and seaport in the French Somali Coast protectorate or territory of Obok, on the Gulf of Aden. It was ceded to France in 1884. The rising French seaport of Jibutil is at the entrance of the bay, on the south side, whence a railway extends since 1902 to Harar. See Abyssinia.

TAK-I-KESRA. See Ctesiphon.

TAKAHASHI, tä'ka-hä'shē, **Korekiyo,** Baron, Japanese financier: b. Sendai, 7 July 1854. He studied English in Japan, then, for one year, in America. In 1875 he was appointed principal of the Osaka English School, becoming (1881) official in the Department of Agriculture and Commerce. In 1892 he entered service of the Bank of Japan, becoming the following year director of its western section. In 1895 he entered the Yokohama Specie Bank as manager, becoming, successively, director (1896), vice-president (1897), and was then appointed vice-governor of the Bank of Japan, returning (1906) to the Yokohama

Specie Bank as president while retaining his former position. From 1904–06 he negotiated important loans from England and America. He was created baron in 1907.

TAKAHIRA, tä'kạ-hē'rạ, **Kogoro,** Baron, Japanese diplomat: b. Iwate, 1854. He was appointed attaché to the legation at Washington in 1879 and became secretary in 1881. Later he was made chargé-d'affaires at Korea, then consul-general at Shanghai and (1887) New York, following which he was successively appointed Minister-Resident to Holland and Denmark, Minister-Plenipotentiary at Rome, Vienna and Berne. From 1901–05 he was minister at Washington, in the latter year signing, with Baron Komura, the Peace Treaty at Portsmouth, N. H. He was Ambassador at Rome (1907), then transferred to Washington the following year, serving till 1909.

TAKAMINE, tạ'kạ-mĭn, **Jokichi,** Japanese-American chemist: b. Takaoka, Japan, 3 Nov. 1854. He was graduated in chemical engineering (1879) at the Engineering College of the Imperial University at Tokio, becoming Japanese government student at the Glasgow University and Andersonian University, Glasgow, from 1879–81. From 1881–84 he was head chemist of the Department of Agriculture and Commerce, Tokio, then (1884–85) Imperial Japanese Commissioner to the Cotton Centennial, New Orleans. In 1887 he organized and erected the first super-phosphate works at Tokio. He came to America in 1890 where he brought a fermentation process to practical use producing diastatic enzyone, now used in starch factories. He established a research factory in New York, and with others, formulated a process of extraction of the active principle of the suprarenal glands on a commercial scale, producing "adrenalin."

TAKAMATSU, tä'kä-mät-soo, Japan, the capital of the prefecture of Kagawa, situated on the north coast of Shikoku. Pop. 40,000.

TAKAOKA, tä'kä-ō'kä, Japan, a town in the prefecture of Toyama near the west coast of central Hondo. It manufactures dyes and hardware. Pop. about 40,000.

TAKASAKI, tä-kä-sä-ke, Japan, a town in the prefecture of Gumma, situated nearly in the centre of Hondo, 60 miles northwest of Tokio, with which it has railroad connection. It has cotton and silk manufactures. Pop. 34,900.

TAKATA, tä-kä'tä, Japan, a town in the prefecture of Niigata, near the west coast of central Hondo. It has extensive manufactures of cotton goods. Pop. 32,600.

TAKIGRAPHY. See Shorthand.

TAKILMAN FAMILY, a tribe of American Indians occupying the country along the Rogue River in Oregon. In 1860 there were some 17 villages of this tribe but it is now scattered or extinct.

TAKOW, tä-kow', or **TA-KAO,** tä-kä-ō', Formosa, a port on the southwest coast, connected by rail with Tainan. Its principal export is sugar. Pop. 15,000.

TAKU, a tribe of North American Indians, residing in the vicinity of Taku Inlet, Alaska. They number about 300.

TALACOGAN, tä-lä-kō'gän, Philippines, a settlement of Moros, province of Surigao, Mindanao, on the Agusan River, seven miles north of the outlet of Lake Pinayat, and 96 miles south of Surigao, the provincial capital. Pop. 11,590.

TALAMANCA, täl-ā-män'kä, Panama, a name formerly applied to the Atlantic Coast region of western Panama and Costa Rica. At the time of the Discovery the region was inhabited by numerous tribes with a peculiar civilization of their own. They manufactured a great variety of ornaments of gold, in which the country was very rich. By the encroachments of the whites they were driven into the forest and mountain recesses. Here a tribe known as Talamancans still lives in practical independence and wholly unaffected by modern civilization, within a short distance of the Panama Railroad.

TALAVACHI, a mysterious poison formerly manufactured by the Aztecs, and by them handed down to the Mexican Indians. Skilfully administered, it is said to destroy the mind while leaving slight effects on the body. The peculiar effect of the poison seems to be to induce monomania or epilepsy.

TALBOT, Arthur Newell, American engineer: b. Cortland, Ill., 21 Oct. 1857. He was graduated (1881) at the University of Illinois, receiving his civil engineer's diploma in 1885. He has been engaged in engineering work on railways, sewerage, waterworks and other public utilities as well as in the investigation of construction material. Since 1890 he has been professor of municipal and sanitary engineering, having charge of theoretical and applied mechanics for the University of Illinois. In 1918 he was elected president of the American Society of Civil Engineers. He has written 'The Railway Transition Spiral' (1901); 'Tests of Concrete' (1906); 'Tests of Columns' (1912); 'Tests of Reinforced Concrete Buildings under Load' (1913).

TALBOT, Ethelbert, American Protestant Episcopal bishop: b. Fayette, Mo., 9 Oct. 1848. He was graduated from Dartmouth College 1870, and from the General Theological Seminary in 1873. He was ordained to the priesthood in the year last named and was rector of Saint James, Macon, Mo., 1873–87. In 1887 he was consecrated missionary bishop of Wyoming and Idaho, and in 1897 was translated to the see of Central Pennsylvania. After administering the diocese of central Pennsylvania for seven years he accomplished its division into the diocese of Bethlehem of which he remained bishop with residence at South Bethlehem, Pa. and the diocese of Harrisburg. He is the author of 'My People of the Plains,' of 'A Bishop Among His Flock' and 'Tim: an Autobiography of a Dog.' Besides these books he has published various sermons, addresses and tracts, etc.

TALBOT, Henry Paul, American chemist: b. Boston, 15 May 1864. He was graduated (1885) at the Massachusetts Institute of Technology and obtained Ph.D. diploma at Leipzig in 1890. He has served successively as assistant (1885–87), instructor (1887–88 and 1890–92), assistant professor (1892–95), associate professor (1895–98) and professor of analytic chemistry (1898–1902) at the Massachusetts Institute of Technology, where he has since had charge of the department of chemistry and chemical engineering. He has written 'Introductory Course of Quantitative Chemical Analysis' (1897); 'The Electrolytic Dissociation Theory,' in collaboration with A. A. Blanchard (1905); besides numerous articles published in the scientific journals.

TALBOT, John, 1st Earl of Shrewsbury: b. about 1380; d. Castillon, France, 17 July 1453. He was appointed lord-lieutenant of Ireland by Henry V in 1414. Five years later he began a long career in the French wars, being present at the siege of Milan in 1420, and at that of Meaux in 1421. He returned to Ireland as lord-lieutenant in 1424 and was knighted in 1426, but in 1427 went again to France. After the raising of the siege of Orléans he determined to save the town of Beaugency; but hearing that the place had already been evacuated, he retreated northward toward Patay, where he was overtaken by the French and captured (1429). He regained his freedom by exchange in 1433. In 1436 he became marshal of France, and by 1439 had become governor and lieutenant-general of France and Normandy. The capture of Harfleur in 1440 was largely due to him. In 1442 he was created Earl of Shrewsbury. In 1445 he conducted Queen Margaret to England, and that year went for the third time to Ireland, where to his titles were added those of Earl of Waterford and Lord of Dungarvan. In 1448 he crossed the channel again as lieutenant of Normandy. In 1453 he went to the assistance of the besiegers of Castillon, and fought against great odds until he was killed.

TALBOT, John, American Protestant Episcopal missionary: b. Wymondham, Norfolk, England, 1645; d. Burlington, N. J., 29 Nov. 1727. He entered Christ's College, Cambridge, became Fellow of Peterhouse in 1664, rector of Freetherne, Gloucestershire, in 1695, and entered the employ of the English Society for the Propagation of the Gospel in Foreign Lands in 1702. He came to America, founded Saint Mary's Church, Burlington, N. J., and was its rector 1704–22. His later loyalty to the Episcopal Church appears to have fallen into question. For the two sides of the controversy consult Hills, 'History of the Church in Burlington' (1876), and Perry, 'History of the American Episcopal Church' (1885).

TALBOT, Silas, American naval officer: b. Dighton, Bristol County, Mass., 1751; d. New York, 30 June 1813. Upon the breaking out of the Revolutionary War he was commissioned captain in a Rhode Island regiment, and after participating in the siege of Boston, accompanied the army in 1776 to New York. For the skill with which he directed certain operations against the British shipping in the harbor he received from Congress a major's commission. He participated in the memorable defense of Fort Mifflin, November 1777, and in 1778 rendered valuable assistance to General Sullivan by transporting the American forces from the mainland to the upper end of the island of Rhode Island. A dashing exploit of the war was his capture in 1778 of the British floating battery *Pigot*, of 22 guns, anchored in one of the channels commanding the approach to Newport. In 1779 he was commissined captain in the navy, and, after cruising with success against British commerce, was captured by a British fleet and confined in the Jersey prison ship 1780. He was afterward removed to England, and in 1781 was exchanged. Upon the reorganization of the navy 1794, he was again called into the public service, and superintended the construction of the frigate *Constitution* (*Old Ironsides*), which in 1799 was his flagship during a cruise in the West Indies. He resigned his commission in 1801, and passed the remainder of his life in New York. Consult Tuckerman, 'Life of Commodore Silas Talbot' (1851).

TALBOT, William Henry Fox, English photographer and scientist: b. Lacock Abbey, near Chippenham, England, 11 Feb. 1800; d. there, 17 Sept. 1877. He was graduated from Cambridge in 1821, and represented Chippenham in Parliament 1833–34. Scientific research being more attractive to him he gave up politics, and, devoting himself to the study of the chemical action of light, made important discoveries in photography. In 1839 his invention of photogenic drawing was explained by Faraday to the Royal Institution, and in 1841 he patented the calotype process. He is still referred to as an authority whose statements are sound. Subsequently Talbot devoted himself to antiquarian research, being one of the first decipherers of the cuneiform inscriptions from Nineveh. His publications include 'Chemical Changes of Color' (*Phil. Magazine* 1828); 'Legendary Tales' (1830); 'Hermes, or Classical and Antiquarian Researches' (1838–39); 'The Pencil of Nature' (6 vols. on photography 1844–46); 'Assyrian Texts Translated' (1856), etc.

TALBOT, or OLD SOUTHERN HOUND, a race of dogs, probably extinct, which seems to have been the original stock from which the various breeds of hounds sprang. The color was pure white; large head, very broad muzzle, long pendulous ears and rough hair on the belly. Talbot is the family name of the English house of Shrewsbury which has a talbot for badge and two talbots for supporters.

TALC, one of the commonest and most important of the non-metallic minerals. It is usually massive or foliated, the laminæ being flexible but not elastic. It is number one in Mohs scale of hardness, and like most very soft minerals it has a greasy feel. Its lustre is pearly and glimmering, and its usual colors are green, gray or white. Foliated varieties are often quite transparent, while the massive is translucent. It is of average specific gravity, about 2.7. It is acid magnesium silicate, $H_2Mg_3Si_4O_{12}$. Talc, like the related mineral serpentine, is of secondary origin, having been formed by the alteration of various magnesian minerals such as tremolite, pyroxene and enstatite. It occurs in metamorphic rocks all over the world, being the most prominent mineral in the rock known as talcose schist, and sometimes forms extensive beds, occurring thus in most of the Atlantic Coast states. Although very soft, it is almost indestructible, not being attacked by acids nor injuriously affected by intense heat. Its common, massive form, popularly known as "soapstone," is the "steatite" of mineralogy. Some soapstone is, however, a massive pyrophyllite (q.v.) and the term soapstone is applied loosely by miners to almost any soft rock or mineral with a greasy feel. Talc is used in the arts either powdered as "flour talc," or in sawed pieces. Flour talc is employed as a base for fireproof paints, in boiler and steampipe coverings, and foundry facings, for electric insulators, in the manufacture of dynamite, and of wall papers to which it imparts a glossy surface; it is very extensively used in the manufacture of toilet powders, and cheap soaps, for dressing leathers and skins, and as a base for lubricants. About half a million dollars' worth of «fibrous talc» is produced annually in the single county of Saint Lawrence in New York. This material is a mixture of talc and fibrous tremolite and is used in making paper. When ground the fibres cause the retention of the flour talc in the paper pulp, thus adding materially to the strength and weight of the paper. The supply of pure, compact soapstone, the most valuable variety of talc, comes largely from western North Carolina and Virginia. It is sawed into slate pencils and crayons and is manufactured into the tips of gas burners. The chief uses of soapstone are for stationary washtubs, sinks, acid tanks, hearth-stones, fire bricks, mantels, griddles and many other articles of everyday use. «French chalk» is a fine-granular talc used as a crayon by tailors. In China and Japan a fine compact talc is carved into various ornaments, household gods and pagodas, though considerable of the material thus used is agalmatalite (q.v.) or pyrophyllite. See MINERAL PRODUCTION OF THE UNITED STATES.

TALCA, täl'kä, Chile, the capital of the province of the same name, on the Rio Claro, about 180 miles south of Valparaiso, on the railway from Curico to Concepcion. It is a fine city, with handsome churches and a lyceum. Weaving is the chief manufacturing industry. Pop. (1916) 41,618. The province has an area of 3,864 square miles and the population is 131,058.

TALCAHUANO, täl-kä-wä'nō, Chile, a seaport in the province of Concepcion, situated 260 miles south of Valparaiso, and eight miles west of the city of Concepcion, with which it has railroad connection. It has a lighthouse, a new custom-house, a wireless station, and large warehouses and docks. The harbor is being fortified. It is the principal export town for wheat in southern Chile. It suffered severely from earthquake in 1835, but was rebuilt. Pop. 21,876.

TALE OF A TUB, A, and THE BATTLE OF THE BOOKS. Swift's 'A Tale of a Tub' was written for the most part about 1696, but was not published till 1704, when it appeared in a volume with 'The Battle of the Books.' The author wittily dedicated it to Prince Posterity, and to this day it has generally been regarded as one of the two or three great prose satires in English. Not the least interesting parts of it are the digressive chapters on critics and criticism and on madness, in which the theory is advanced that happiness consists in being well deceived. Its most fruitful fancy is of the sect who took the tailor for their idol, and held the universe to be a large suit of clothes — the germ of Carlyle's 'Sartor Resartus.' The allegorical narrative presents the fortunes of three brothers, Peter, Martin and Jack, standing respectively for the Roman, the Anglican, and the Dissenting churches. Their father on his death-bed bequeathes them each a coat with two virtues: «One is, that with good wearing they will last you as long as you live. The other is, that they will grow in the same proportion with your bodies.» For a time the boys wear their coats in accordance with their father's will. Later they come up to town and fall in love with the three ladies then most in reputation, the Duchess d'Argent, Madame de Grands Titres and the Countess d'Orgueil. Desiring to be in the fashion they violate their father's will, covering their coats with shoulder-knots, silver fringe and figured embroidery. Peter becomes dictatorial and insists on being addressed by his brothers as Mr. Peter, Father Peter and finally as My Lord Peter. Martin and Jack revolt from his authority, and, in token of repentance, attempt to remove the embellishments from their coats, in which process Martin, reforming with moderation, restores his garment to something like its original state, but Jack in a fanatical fury rends his from top to bottom. Swift asserted that he had written as a good churchman, ridiculing only Popery and Dissent. The wits were delighted with his attack; but sober Anglicans were alarmed at its implications; and it is undeniable that its disgusting coarseness and brutal levity were inimical to every form of religious reverence. The satire was assailed and explained by William Wotton; but his explanations were maliciously seized upon and made to serve as annotations in subsequent editions. As an old man Swift is said to have exclaimed: «Good God, what a genius I had when I wrote that book.»

'The Battle of the Books,' written about 1697, was Swift's contribution to the famous literary controversy of the 17th century regarding the relative merits of ancient and modern writers. In England the discussion was rendered rather insignificant by the curious confusion of the champions, the wits of the day appearing as defenders of the ancients, and the great classical scholar of the age as a leader of the moderns. The conflict was opened over the 'Letters of Phalaris,' which Sir William Temple, in his 'Essay Upon the Ancient and Modern Learning' (1692), declared «have more of grace, more spirit, more force of wit and genius than any others I have seen, either ancient or modern» — yet the 'Letters of Phalaris,' said Temple, is one of the two most ancient books in prose that we possess. William Wotton, championing the moderns, replied in 1694 with 'Reflections Upon Ancient and Modern Learning.' In 1695 Charles Boyle brought out an edition of the extolled *Letters*, in behalf of the ancients. In 1697 Wotton published a second edition of the 'Reflections,' including an essay by the learned Richard Bentley, showing that the 'Letters of Phalaris' were forgeries and, relatively, *modern*. At about this point Swift comes in with his 'Battle of the Books,' written for the defense of the ancients and in support of his patron, Temple, the immediate object being to turn the laughter of the town upon Wotton and Bentley. Swift was on the wrong side with respect to the Phalaris question and with respect to the scholarship of the enemy. But he releases a flight of nicely pointed arrows against pedantry and sour-tempered criticism and the vanity and egotism of the modern spirit. In the course of the dispute between the Spider and the Bee he strikes out an idea and a phrase which Matthew Arnold adopted and popularized

as the epitome of his gospel of culture — "sweetness and light." Consult lives of Swift by Samuel Johnson, Sir W. Scott, J. Forster, H. Craik, L. Stephen, P. M. Simon, etc.; also Saintsbury's 'History of Criticism'; Spingarn's 'Critical Essays of the Seventeenth Century'; 'Cambridge History of English Literature' (Vol. IX). STUART P. SHERMAN,
Professor of English, University of Illinois.

TALE OF TWO CITIES, A, published in 1859, was the second of Dickens' historical novels and is to-day more popular than the author's earlier novel of the same kind, 'Barnaby Rudge' (1841). The reason lies partly in the fact that the French Revolution is a more permanently interesting historical event than the anti-Catholic agitation and the Gordon riots in London. The chief purpose of the novel is to give an impression,— in this case a very English impression with its roots in the anti-Napoleonic tradition,— of the days of the old Régime and the French Revolution, in which cynicism, arrogance and cruelty, on the one hand, and uncouthness, violence and guillotining, on the other hand, were the prominent features. No account is suggested of the intellectual causes of the Revolution. It is a picture of action. The turbulence of Paris compared with the dignified and law-abiding ways of London give the book its title. The story is the account of the escape from France of the emigré, Saint Evremonde, or Charles Darnay, of his return to France, his arrest, condemnation through the unwitting evidence of his own father-in-law, Dr. Manette, and his final escape through the self-sacrifice of Sidney Carton. This last is the most famous part of the book, both ethically and episodically. Sidney Carton, the real hero, takes advantage of his resemblance to Charles Darnay to mount the scaffold in place of the latter, who is meanwhile hurrying disguised to England with his family. The story is a moving one and is almost wholly lacking in the usual humorous scenes and characters of the author. It has been successfully dramatized. Certain of the scenes, as notably the flight from Paris, the death of Carton, and the women knitting indifferently at the executions, have become famous. WILLIAM T. BREWSTER.

TALENT, the name of a weight and denomination of money among the ancient Greeks, and also applied by Greek writers to various standard weights and denominations of money of different nations; the weight and value differing in the various nations and at various times. The Attic talent as a weight contained 60 Attic minæ or 6,000 Attic drachmæ, equal to 56 pounds, 11 ounces, British troy weight. As a denomination of silver money it was equal to $1,220. The great talent of the Romans is computed to be equal to $500, and the little talent to $375. A Hebrew weight and denomination of money, equivalent to 3,000 shekels, also receives this name. As a weight it was equal to about 93¾ pounds avoirdupois; as a denomination of silver it has been variously estimated at from $1,500 to $1,880.

TALES OF THE ARGONAUTS, The. 'The Tales of the Argonauts' is a volume of short sketches collected and published by [Francis] Bret Harte in 1875; but the title is sometimes loosely applied to all this author's stories of early California. Nothing in the 'Tales of the Argonauts' proper quite equals in merit 'The Luck of Roaring Camp,' 'The Outcasts of Poker Flat' and 'Tennessee's Partner,' which had appeared in an earlier collection; but 'An Iliad of Sandy Bar,' 'How Santa Claus Came to Simpson's Bar,' and some others have been deservedly popular. The Argonauts are of course the gold-seekers of 1849 and the years immediately following. These adventurers came from all quarters of the globe and all ranks of society, and they had in common only the possession of the strength and determination necessary to reach the new Colchis. Here they lived, at first, wholly free from the conventional restraints imposed by an organized society, and each man showed himself for what he was. Many of these primitive social conditions still existed when Harte went to California in 1854, and they made a great impression on the observant boy. He did not use them in literature, however, until he was able to look back on them in the light of a man's experience. Californians objected that his pictures were unreal; but they give the impression of essential truth to life — an impression not spoiled by his persistent habit of showing the good elements in even the lowest and most debased characters. Harte occasionally seems to have adopted some of the less fortunate devices of Dickens, but his manner was chiefly his own. He lacks literary finish, though he was painstaking in regard to style; but in these early tales he has a sure command of humor and pathos, and a complete mastery of his unique material.
WILLIAM B. CAIRNS.

TALES OF THE CRUSADERS, two novels by Sir Walter Scott, respectively entitled 'The Talisman' and 'The Betrothed.'

TALES OF A GRANDFATHER, a collection of stories dealing with the history of Scotland, by Sir Walter Scott, and published in four series in 1827–30.

TALES OF HOFFMAN (*Les Contes d'Hoffman*), Opera comique in prologue and three acts by Jacques Offenbach (libretto by Barbier), first produced at Paris, 10 Feb. 1881, several months after the composer's death. In spite of the unparalleled success which Offenbach had achieved with his light-hearted, clever and unfailingly melodious *operas bouffes,* he evidently desired to bequeath to posterity a work of more serious artistic import; and he spent his most ambitious efforts and years of his life on the 'Tales of Hoffman.' As his end approached, he begged the manager to produce it in time for him to witness the première. While he did not live to see it, the public took to the work no less heartily than to the operettas and it will undoubtedly outlive them. The story is novel and cleverly put together. The prologue shows Hoffman and his fellow students in Luther's Inn at Nuremburg; he is persuaded to tell of his three love encounters and these form the three succeeding acts. The opera ends as it began, Hoffman acclaimed a hero by his admiring friends. Inspired by its romance and fantasy, Offenbach has written a genuinely attractive score, which displays his talent for melody-making and ingenious characterization at its best. The barcarolle, in the second act, once heard, is never to be forgotten. Alone it would have made the opera, but there are many other numbers worthy of recall — the burlesque ballad of Kleinzach, sung by Hoffman in the prologue and epilogue, Nicklausse's song of the doll, the automaton's song, «Les oiseaux dans la charmille,» Antonia's romance, «Elle a fui,» and the trio finale of the third act. Offenbach's treatment of the dramatic situations is always clever and at times subtle. The orchestration, while simple, is refined and the general artistic level of the work greatly above that on which he was usually content to stand. In Europe, 'Tales of Hoffman' has been pursued by superstitious fear on the part of the managers owing to the fact that its first performance at the Ring Theatre in Vienna was the occasion of a conflagration which caused great loss of life. Its revival in New York by Oscar Hammerstein in 1907 proved that its original appeal is still potent.

LEWIS M. ISAACS.

TALES OF MY LANDLORD, a name applied to four series of Scott's novels, the first embracing 'Old Mortality' and 'The Black Dwarf'; the second, 'The Heart of Midlothian'; the third, 'The Bride of Lammermoor,' and 'A Legend of Montrose'; and the fourth 'Count Robert of Paris,' and 'Castle Dangerous.'

TALES OF A TRAVELLER, a well-known work by Washington Irving, published in 1824. It is a delightful medley of humorous and tragic elements and the author himself declares them to be «moral tales,» with the moral «disguised as much as possible by sweets and spices.»

TALES OF A WAYSIDE INN. The 'Tales of a Wayside Inn,' by Henry Wadsworth Longfellow, was published in three parts, in 1863, 1872 and 1873, respectively. The poet followed the old plan of presenting a series of stories as told by different persons — in this case by friends of the author who, though they were not named, were so plainly characterized as to be easily recognizable. Among those of wider fame are Ole Bull, the violinist, and Thomas William Parsons, the poet and translator of Dante. The «Wayside Inn» was the old Red Horse Inn at Sudbury, 20 miles from Cambridge — a favorite resort for parties from Harvard College. Each of the three parts has a *prelude* and a *finale*, and there are *interludes* which link together the tales and introduce the narrators. Most of the stories were derived by Longfellow from his wide reading — many of them from the legends of continental Europe, a few from American sources. The 'Birds of Killingworth' was developed from so slight a hint that it may fairly be said to be of the poet's own invention. Longfellow, while not a poor story-teller, was hardly at his best in narrative, particularly in narrative with vigorous action, and the 'Tales of a Wayside Inn,' taken as a whole, is not to be listed among his most distinguished works. A few of the Tales have, however, won a place for themselves. Among these are 'Paul Revere's Ride,' told by the Landlord, and 'King Robert of Sicily,' which is ascribed to the Sicilian.

WILLIAM B. CAIRNS.

TALESMAN. From the Latin *talis*, such, or of such a kind and quality. A talesman is a juror summoned to fill up a panel for the trial of a particular case. A default of jurors appears to have but one immediate remedy in common law, that is to select *tales de circumstandibus* (those bystanders who are competent) in sufficient number to make up the jury. A number of statutes forbid summoning bystanders but the procedure is maintained in most jurisdictions, and the method is considered legal unless forbidden by statute. There appears to be no set limit as to the extent of the emergency requiring talesmen beyond that of the panel being exhausted and deficiency of jurors existing. Talesmen can only be summoned for a single trial, not for a circuit. Talesmen are considered strictly as *additional* jurors, not called to form a new panel. In some States it has been held that the jury may be made up entirely of talesmen when all the panel has been discharged or taken on to some other case or when a «challenge to the array» has been sustained, but such right of action has been denied and the usual method employed is to issue a new venire.

TALFOURD, tâl'fẽrd, SIR **Thomas Noon,** English poet: b. Reading, 26 May 1795; d. Stafford, 13 March 1854. He was called to the bar in 1821, but in early life mainly supported himself by literary labors, as a contributor to various periodicals. In 1835 and 1837 he was returned to Parliament as one of the members for Reading; and between these years produced at Covent Garden his tragedy of 'Ion.' The tragedies subsequently written by him were 'The Athenian Captive'; 'Glencoe, or the Fate of the Macdonalds'; and the 'Castilian.' None of these had the same success as the first. As a dramatist his excellence lies more in beauty of language and sentiment than in power of dramatic action. In 1849 he was raised to the bench in the Court of Common Pleas and knighted. He died suddenly while charging a grand jury. Besides the dramas above referred to, he was the author of 'Life of Charles Lamb' (1837); and the same in a much enlarged edition (1848).

TALIAFERRO, tŏl'ĭ-vẽr, **William Booth,** American soldier and lawyer: b. Belleville, Gloucester County, Va., 28 Dec. 1822; d. there, 27 Feb. 1898. He was educated at Harvard and at William and Mary College, being graduated from the latter in 1841. He then studied law, and was engaged in the practice of his profession until 1847, when he became captain in the United States infantry; later he was promoted major; and in August 1848 was mustered out and resumed his law practice. At the outbreak of the Civil War he became colonel in the provisional army of Virginia; in 1862 he was promoted brigadier-general in the Confederate army and in 1865 major-general. He commanded at Gloucester Point, Va., took part in most of the battles of the Army of Northern Virginia until March 1863, when he was given charge of the district of Savannah, Ga. In July 1863 he was in command of the troops and defenses on Morris Island, and gallantly defended Fort Wagner (q.v.) against a combined land and naval attack. Later he was in command of the district of South Carolina. After the war he was elected to the State legislature and served 10 years during the Reconstruction period. He was prominent in the Masonic fraternity and was Grand Master of the Masons of Virginia in 1876–77.

TALIESIN, British bard or minstrel of the 6th century. To him are attributed about 56 poems, which many critics consider of later origin. Consult Skene, 'Four Ancient Books of Wales' (1868); Guest, 'Mabinogion' (1877).

TALIM, tä-lēm', an island of the Philippines, in the centre of the Bay Lagoon, Luzon, separated from a peninsula on the southern coast of the province of Rizal by a channel about half a mile wide; length from north to south, 10 miles; width, four miles; area, 20 square miles. A central mountain range traverses the island from north to south; there are villages along the coast on each side. Building stone is obtained in the mountains and sent to Manila.

TALIPOT, a palm (*Corypha umbraculifera*) of Ceylon and India, remarkable for possessing the largest inflorescence of any plant. The straight, cylindrical trunk takes over 50 years to attain its full height; during 30 of those years the leaves spring from near the ground, but afterward the palm grows rapidly until it is 70 feet tall. It then sends up from the centre of the crown a gigantic, pyramidal flower-panicle, with a main rachis over 30 feet long, and a dozen branches reaching so far out that the base of the panicle also is about 30 feet across. These branches terminate in many branchlets and twigs, and are covered with possibly 100,000 greenish-yellow, diœcious blossoms, which have so powerful and disagreeable an odor that the tree is often cut down at this stage. As soon as the tree begins to bloom the leaves fade, and by the time the flowering period (about a month) has ended, they have often all fallen off, leaving the bare, ringed trunk crowned only by the inflorescence. After a year's time the fruits, which are inedible, are matured and fall in great quantities, and the whole tree dies down, having lived to produce only this single exhausting crop.

The leaves also are gigantic, one alone being capable of sheltering 10 persons comfortably. They have prickly stalks six or seven feet long and are more or less circular, with radiating ribs of the texture and strength of rattan, and plaited, narrow segments which are joined together nearly to the tips, and can be folded like a fan. They can be easily marked with a metal point and are used as writing material to some extent by the natives and Buddhists. They are of coriaceous texture when dry, and are valuable for thatching houses, for umbrellas, fans and basketry, and are carried before Singhalese of rank. In times of famine the trunks are felled, for the sake of their pith, which produces a kind of sago.

TALISAY, tä-lē'sī, Philippines, pueblo, province of Cebu, on the east coast, six miles southwest of Cebu, the provincial capital. It is on a short branch of the coast highway connecting it with towns to the north and south. Pop. 19,000.

There are also two smaller pueblos of the same name: (1) in the province of Ambos Camarines, Luzon, two miles northwest of Daet; pop. 3,560; (2) in the province of Batangas, Luzon, on the north shore of Lake Bombon (Taal), 26 miles north of Batangas; it is near a pass from Batangas to Cavite; the chief industry is fishing; pop. 8,200.

TALISMAN, a small object presumed to possess an astrological or mystical charm that may protect or guard the owner in some way. It was usually of stone or metal and bore an engraved figure, and gained its suggested value because of certain ceremonies, at some particular moment, as at the culmination of a certain star or at the conjunction of certain planets. The talisman was supposed to exercise supernatural influences over the bearer or owner, particularly in averting disease. The nature of the talisman has been very different among different nations. The Egyptians made use of images of their gods and of sacred animals, such as the ibis and the scarabæus; the Jews used the phylacteries inscribed with passages from the Old Testament (a section of the cabala is devoted to teaching the construction of talismans); the Greeks used little tablets having written upon them various magical words, such as the Ephesian words, or those written on the feet, the girdle and the crown of the statue of Artemis at Ephesus; the Romans employed various idols, which they suspended upon the body by chains; the Arabians and Turks made use of sentences from the Koran; and we also find in the East medals of particular metals struck under a particular constellation and marked with magical signs. In the Middle Ages astrology and the knowledge of the virtues of talismans and amulets formed an important part of medical science; and the quacks of modern times sometimes have recourse to similar means. The talisman differs from the amulet, in that it does not require to be worn or carried, but like Aladdin's lamp will work wonders. See FETISH.

TALKING MACHINE. The wonderful, though natural, growth in popularity of the talking machine has caused its manufacture and sale in the few years that have passed since its perfection to become a truly great industry. Its utility for entertainment purposes in the home no doubt aids in the absorption of most of the instruments constructed in the competing factories, but the use of talking machines in commercial life (dictaphone perhaps in particular), greatly aids the numerical demand and it is found a valuable aid in teaching foreign languages. History mentions talking machines as early as the 13th century, when Albertus Magnus, the philosopher and scholar, is said to have produced a mechanism that reproduced the human voice. A queen of Sweden is said to have had a head which talked automatically in Hebrew, Greek, Latin and French. The Reverend John Wesley writes in his journal at date 26 April 1762, that he saw an invention at Lurgan, Ireland, of startling capabilities. It was "an automaton of an old man in a case over against a clock . . . Every time the clock struck he opened the door with oue hand, drew back the curtain with the other, turned his head, . . . then said with a clear, loud articulate voice, 'Past one, two, three' and so on." The invention was contrived by a man named Miller. But so many visitors called from foreign parts to see this wonder, and no one offered to purchase it, that it took up his time so much he nearly failed in business and he "took the whole machine to pieces." This Miller told the preacher later he had made very successful experiments and could make a man who could talk and sing hymns, but he was too busy on other work. In 1783 Abbé Mical presented to the French Academy of

Sciences an invention that talked, but he later broke it up, having religious scruples.

In 1877 Thomas Alva Edison brought out his first talking machine. The contrivance was of the simplest, being merely a steel point fixed to the centre of a flexible disc and a revolving cylinder behind the point. It was first displayed in Paris. The invention was enclosed in a little box about a foot square and the record was made on a piece of tin-foil. As a wonderfully clever toy sold at small expense it created great admiration. In 1888 Edison constructed his phonograph with its diaphragm having the lateral movement instead of the cylinder and the sheet of tin-foil was discarded in favor of a cylinder of wax, the vibrations being recorded with a tiny chisel. Edison is said to have gained his incipient conception of a talking machine while working with automatic telegraphs operating at high speeds. He made some experiments with embossed strips impressed with dashes and dots thereon which were moved rapidly beneath a stylus to vibrate it. He observed the stylus made audible sounds while vibrating, and as the great inventor never passed by mechanical facts, however trivial they might appear to the ordinary investigator, he became interested in this curious sound phenomenon. He was about this time working on telephone experiments and the idea of a new sound developer occurred to him as a possibility. The conception of developing a talking machine soon grew in his mind and under his expert hands he soon had his first talking machine — getting his first patent 19 Feb. 1878, No. 200,521, with its tin-foil records.

The graphophone was an outcome of much experimentation by laboratory experts and at its inception the sewing machine was becoming a highly popular home machine. Therefore the manufacturers at first used the sewing-machine stand (frame, treadle and table top) in their first output, as motive power which was manufactured in the East Bridgeport vacated building of the Home Sewing Machine Company. It met with poor success and the spring motor was invented which made it portable and sales grew rapidly. Next the cylinder form of record was discarded for the disc form of record. The listener had been using a pair of tubes for the ears. these gave way to the horn for the dissemination of the sound leaving the ears naked and the sound audible at a distance. Later again the ungainly horn and all the mechanism was enclosed in a box or a cabinet.

Emil Berliner invented the gramophone aparatus in 1892 with a smoked disc and stylus to produce sound vibrations. See GRAMOPHONE, GRAPHOPHONE, PHONOGRAPH, etc.

TALL OAT-GRASS. See GRASSES IN THE UNITED STATES.

TALLADEGA, tăl-ạ-dē'gạ, Ala., city, county-seat of Talladega County, on the Southern, the Birmingham and Alabama, the Louisville and Nashville and Atlanta, Birmingham and Atlantic railroads, about 70 miles east of Birmingham and 100 miles north of Montgomery. In the place where the city now stands, General Jackson had an encounter in 1813 with a large band of Cherokee warriors. Jackson was victorious. The city is in a fertile agricultural region, in which there is also considerable mining. The chief industrial establishments are three cotton factories, two machine shops and grist mills, the $200,000 chemical plant, cottonseed-oil mill, three lumber and planing mills. There is considerable trade in grain and cotton. The educational institutions are the Synodical Female College, Alabama Academy for the Blind, Alabama School for the Deaf-Mutes, Alabama Institution for Deaf, Dumb and Blind Colored Children, Talladega College (colored), opened in 1869, under the auspices of the Congregational Church, and public schools. There are several churches and one orphanage. The two national banks have a combined capital of $150,000, State bank $50,000, deposits over $1,000,000. Pop. about 5,854.

TALLADEGA, Battle of, in the War of 1812. On 7 Nov. 1813, four days after the battle at Tallishatchee Jackson learned that 160 friendly Creek Indians in Lashly's Fort at Talladega, about 30 miles south of Fort Strother, were besieged by 1,080 hostile warriors and were in danger of capture. Accordingly, with 1,200 infantry and 800 cavalry, he set out and on the 9th had approached within 80 yards of the Indians before he was discovered. Jackson arranged his plan of battle so that the Indians would be surrounded, but in the fight three companies of militia gave way and allowed many Indians to escape. Jackson's victory was decisive, 290 of the enemy being found dead on the field while his own loss was 15 killed and 85 wounded. Jackson returned to Fort Strother 10 November where he was forced to remain idle until the battle of Emuckfaw (q.v.). Consult Brackenridge, H. M., 'History of the Late War,' pp. 190–191; Lossing, 'War of 1812,' pp. 763–766; Wiley and Rines, 'The United States,' Vol. V, pp. 448–449; biographies of Jackson by Parton (Vol. I, pp. 440–444); Buell (Vol. I, pp. 306–310) and Frost (pp. 142–346).

TALLADEGA COLLEGE, located at Talladega, Ala. It is open to all persons without regard to color or race, but is practically for the education of the negro race, and its work is arranged to meet their needs. It was founded in 1867 by the American Missionary Association (Congregational), aided by the Freedman's Bureau; and was the first college open to colored pupils in Alabama; the charter was obtained in 1869. A farm was bought in 1877, additions to it were made in 1887 and 1902 until the land owned by the college includes about 800 acres. The college is coeducational and aims to secure the best development of social character by the association of students of both sexes under the same general discipline and careful supervision. The college organization includes seven departments. The theological department offers three courses, the classical course including the study of the Bible in Hebrew and Greek, leading to the degree of D.D.; the English course, the same as the classical without the study of the Bible in the original languages; the Bible training course, of two years, including almost entirely special study of the Bible without the other studies of the usual theological course. The college department offers two courses, the classical and the scientific, leading to the degrees of A.B.

and BS.; and the college preparatory department has two corresponding courses of three years, differing only in the last year. The normal course requires four years' work beyond the grammar grades, the first year being the same as the first year of the college preparatory; it includes practice work in the primary and intermediate grades. In the department of music singing lessons are a part of the curriculum in all grades, in addition to which there is more advanced work in vocal music and in pianoforte. Industrial training has always received attention at the college. Students do the greater part of the work on the farm and in the care of the dormitories, laundry, etc., some give the day to this work and study in night classes. There are also printing and carpentry work provided; student labor has had a part in the erection of most of the buildings. Different groups of girls in the college department have entire charge of the housekeeping in Foy Cottage, the girls' industrial house. In addition to this instruction is given the boys in the third to seventh grades in woodworking and drafting, in the eighth grade in forging, and to the girls in the third to seventh grades in sewing and dressmaking and in the eighth grade in cooking. Instruction is also given to students in the preparatory and normal departments in agricultural subjects and in nurse training. The college buildings are situated on high ground about half a mile from the city; they include Swayne Hall (the main college building), Graves Hall (theological building), Foster Hall (women's dormitory), Stone Hall (men's dormitory), Cassedy School (primary and intermediate grades), Foy Cottage (girls' industrial house), the Slater Shop (for boys' industrial work), a library building, the De Forest Memorial Chapel, also the laundry, printing office and houses for teachers. The college ranks among the leading negro educational institutions in the South, and has won the respect and confidence of the white men of the community. Its productive funds in 1917 amounted to $256,000; it is also assisted by the American Missionary Association; the library contained 16,500 volumes; the students numbered 707, and the faculty 40.

TALLAHASSEE, tăl-a̤-hăs'ē, Fla., city, capital of the State, county-seat of Leon County, on the Dixie highway and the Old Spanish Trail highway, on the Georgia, Florida and Alabama and the Seaboard Air Line railroads, 205 miles east of Pensacola, Fla., and 163 miles west of Jacksonville. It is in an agricultural, stock and fruit-growing region and ships considerable fruit. The chief industries are cotton compresses, cotton gins, railroad shops, novelty works and cigar factories. There are 10 churches, six of which are for the colored people. The educational institutions are Florida State College for Women which has a teachers' normal school attached, founded in 1857; West Florida Seminary, University, founded in 1884, separate public schools for white and colored children. There are three libraries. Tallahassee has five banks, three State banks and two private banks, capital $220,000; surplus $56,250. The water-supply, for domestic purposes, comes from artesian wells. The city owns the gas, water and electric light plants. Franchise for an electric street and interurban railway was granted in 1916. Temperature in summer ranges from 82° to 98°. Tallahassee is 21 miles from Saint Marks on the Gulf, where there is fresh and salt water fishing; much large game still abounds in this section. Pop. about 7,000.

TALLAHATCHIE, tăl-a̤-hăch'ĭ, a river which has its rise in Tippah County, in northern Mississippi, flows southwest, and unites at Greenwood with the Yocona to form the Yazoo River. It is about 220 miles long and navigable for 100 miles.

TALLAHATCHIE, Battle of, in the War of 1812. When news of the massacre at Fort Mims (q.v.) 30 Aug. 1813 reached Nashville, Tenn., Gen. Andrew Jackson (q.v.) collected 2,500 infantry and 1,000 cavalry, crossed Tennessee into what is now Alabama, on 23 Oct. 1813 established a camp called Fort Deposit and early in November reached the headwaters of the Coosa. Learning that the Indians had posted themselves at Tallishatchee on the south side of the Coosa, about 13 miles distant, Jackson sent Col. John Coffee with 920 troops to destroy them. By a rapid march Coffee reached the Indian camp 3 November and was boldly charged by the Indians but repulsed them and killed all, about 200 in number, with a loss to himself of 5 killed and 41 wounded. Jackson then moved toward Talladega (q.v.). Consult Brackenridge, H. M., 'History of the Late War,' (p. 190); Fay, H. A., 'Official Accounts' (pp. 143–145); Lossing, 'War of 1812' (pp. 758–763); Wiley and Rines, 'The United States' (Vol. V, pp. 447–448); biographies of Jackson by Parton (Vol. I, pp. 430–438), Buell (Vol. I, pp. 302–304) and Frost (p. 132 et seq.).

TALLAPOOSA, tăl-a̤-poo'sa̤, Ga., city in Haralson County, on the Southern Railroad near the Alabama line, about 53 miles west of Atlanta. It is in an agricultural region, in the vicinity of pine forests. There is considerable iron ore in the vicinity and near the city are large vineyards. Its industries are connected with the culture and shipping of grapes, with cotton, farm and lumber products, and mining. There are banking facilities and newspapers. Pop. 3,000.

TALLAPOOSA, a river which has its rise in Paulding County, Ga., and flows southwest into Alabama. It unites with the Coosa about five miles north of Montgomery and forms the Alabama River. It is about 245 miles long and navigable for 40 miles.

TALLEGALLA. See MEGAPODES.

TALLEYRAND-PÉRIGORD, tăl-ā-rôṅ (Eng. tăl'ĭ-rănd) pā-rē-gōr', **Charles Maurice de**, French diplomatist: b. Paris, 13 Feb. 1754; d. there, 17 May 1838. Although the eldest of three brothers he was, in consequence of lameness, prevented from entering the army and destined, against his will, for the priesthood. He commenced his studies at the College d'Harcourt, continued them at the Seminary of Saint Sulpice and at the Sorbonne, and completed them at Rheims, where an uncle of his was archbishop. His life of restless activity is naturally divided into three parts: namely, from his consecration as bishop (1789) to his banishment by the Convention; from that period to the Peace of Paris 1815; and from the return of constitutional government to his death. In 1780, when only 26, he was appointed general agent to the clergy, and in 1789 he was consecrated bishop of Autun. As he found his spiritual functions inadequate to satisfy his ambition, he attached himself to Mirabeau, then connected with the Minister of Finance, Calonne. Here his political career began Mirabeau recommended the abbé to the Minister. Hitherto Talleyrand, at the court of Versailles, had displayed all the qualities of a polished, witty and gallant courtier. But he now left the court party and joined the Republicans, and on the meeting of the States-General was elected deputy for Autun, and voted soon after they opened for merging the three estates into one national assembly. In vain the court tried to stop him in his career. After the storming of the Bastille he was chosen by the national assembly one of the committee which was to issue an account of their proceedings. His popularity was greatly increased by the leading part which he took in urging the confiscation of clerical property. At this time he founded, in concert with Lameth, Barnave, Lafayette, Mirabeau, Siéyès, and Sailly, the Society of the Friends of the Constitution, out of which the Jacobin Club afterward arose. He soon retired from it, however, as too extreme, and in 1789 founded the society known as the Club des Feuillants. Here he exerted himself for a monarchy, surrounded by democratic institutions. On 16 Feb. 1790, he was elected president of the national assembly, and on 14 July of that year, the first anniversary of the fall of the Bastille, presided in that capacity at the memorable solemnity of national federation in the Champ de Mars. About this time he was the author of various important administrative proposals, a registration scheme which was adopted, and forms the basis of that still in force in France, and a plan of a system of public education which was of great service to the subsequent assemblies which took up the problem. When the civil constitution of the clergy was framed he gave his adhesion to it and he ordained the first constitutional clergy. For this he was immediately excommunicated by a Papal brief, and embraced the opportunity to renounce his episcopal functions (April 1791). On two occasions in 1792 he was sent to London charged with diplomatic functions, although bearing no official position. After his return on the second occasion (August 1792), he was accused of cherishing royalist sympathies, but Danton rescued him and sent him back to London (September). But the charges against him gained strength; and by a decree of the Convention he was placed on the list of emigrants, which precluded his return to France. His power under the Directory was now forever lost, although by the intervention of Madame de Staël the decree against him was recalled in 1795. After his arrival in Paris the opposition which he met with from Carnot prevented him from being employed, and kept him in bad odor. At last, by exerting himself in the Constitutional Club, he succeeded in 1797 in gaining the Ministry of Foreign Affairs; but being suspected of keeping up an understanding with the agents of Louis XVIII he was obliged to resign in July 1799, and his downfall as a republican was complete. But he had early recognized Bonaparte as the coming man in France and after the latter's return from Egypt did much toward bringing on the critical event of the 18th Brumaire (10 Nov. 1799), when the Directory fell and the Consulate began. Appointed Minister of Foreign Affairs, he took the lead in the negotiations for the Treaties of Luneville and Amiens. In 1803 he married a Mrs Grand, with whom he had been living for some years. They separated in 1815. He became an uncompromising promoter of the Napoleonic idea, was a chief instigator of the murder of the Duc d'Enghien in March, and after the establishment of the empire in 1804 was appointed to the office of grand-chamberlain. In December 1805, after the conclusion of the campaign against Austria, he negotiated the Peace of Presburg, and in the following year exerted himself for the elevation of Louis Bonaparte to the Dutch throne. On 6 July 1806, he was created Prince of Benevento. After the battle of Jena he was very active, and concluded the Peace of Tilsit with Russia and Prussia (July 1807). From this time, from what cause is not well known, a coolness arose between him and Napoleon, and became more and more marked. In 1808 he secretly joined a Royalist committee, and in conjunction with Fouché began to intrigue for Napoleon's downfall. On the first news of the unsuccessful issue of the Russian expedition, he placed himself in communication with Louis XVIII, joined the Congress of Chatillion, received the Emperor of Russia into his hôtel, and on 1 April 1814, established a provisional government, placed himself at the head of it, and procured Napoleon's abdication. He afterward exerted himself very effectually in re-establishing Louis XVIII on the throne of his ancestors. He was at the Congress of Vienna when news arrived that Napoleon had landed from Elba. He took part in the declaration then issued characterizing Napoleon as a disturber of the peace. When in 1815 the Allies again entered Paris he again became president of the council with the portfolio of Foreign Affairs; but as he refused to sign the second Peace of Paris he gave in his resignation.

With the commencement of constitutional government in France and the internal struggles connected with it Talleyrand's principal career was properly concluded. In the first years of the Restoration he often appeared at the palace and gave good counsel, of which the reigning party made no use. In the house of peers he often voted with the opposition, defended the freedom of the press, and condemned the Spanish campaign of 1823.

When he saw the rocks on which the Restoration would be wrecked he retired to Valençay, keeping open house, and giving a welcome reception to all who had distinguished themselves either by literary or political service. In his social intercourse Talleyrand always exhibited the grandee of olden times. Naturally indolent he worked as little as possible, but he was well acquainted with the art of turning others to account and getting them to work for him. In ordinary business he managed with ease, and skilfully skimmed the surface of things, but he did not possess the talent of speaking on the spur of the moment on important emergencies. Probably this defect led him to the adoption of one of his fundamental axioms, never to explain one's self at the moment. He was accustomed to say, what however had been often said long before him, that language had been given to man to enable him to conceal his thoughts. On the occasion of the July Revolution of 1830 he at first kept entirely aloof. Louis Philippe, however, before accepting the throne, asked his advice, and received the short answer that he should take it. When, by the revolutions in Belgium and Poland, in connection with other circumstances, the July throne became endangered, Talleyrand at last came forward, and finally abandoning the old dynasty and his own work united with Louis Phillippe for the maintenance of the peace of Europe. In September 1830 he went as Ambassador to London, and made all kinds of exertions calculated to show off the peaceable intentions of the July dynasty. To him mainly was it owing that Austria and Prussia joined the conferences of the three powers which had decided the fate of Greece, and that after endless protocols the powers united in their views with regard to Belgium. After these results he turned to what had long been his favorite idea, the formation of a combination of France, Britain and Austria against Russia. The plan was partly successful when in 1834 he subscribed the quadruple alliance (the parties to which were France, England, Spain and Portugal), which was intended above all to guard the constitutional principle in Western Europe. He returned from London in 1835, and repeatedly made his appearance at the court of the citizen-king, where he was received with great distinction, and revered by the ladies as an oracle. It is said that before his death he was reconciled with the Church. The principal part of his immense property, estimated at about 18,000,000 francs, he left to his niece, the Duchess of Dino. He left memoirs in manuscript which were to remain unpublished till 30 years after his death. They have proved of little value. Consult 'Correspondence Between Talleyrand and Louis XVIII' (1881); Lamartine, 'Mémoires Politiques'; Blanc, 'Histoire de Dix Ans'; Guizot, 'Mémoires', and Blennerhasset, 'Talleyrand' (1894); McCabe, Jos., 'Talleyrand' (London 1906).

TALLIEN, Jean Lambert, zhŏṅ läṅ-băr ta-lē-ăṅ, French revolutionist: b. Paris, 1769; d. there, 16 Nov. 1820. He first made himself widely known by publishing a revolutionary journal called *Ami du Citoyen*. He soon became one of the most popular men of the revolutionary party, and was concerned in the commotions of 10 Aug. 1792. Nominated a deputy to the Convention from the department of Seine and Oise, he distinguished himself in that body by his violence in the process against Louis XVI, even objecting to the king's being allowed counsel to defend him. He took part in most of the sanguinary proceedings which occurred during the ascendency of Robespierre, and in 1794 was sent on a mission to Bordeaux. Here he was checked in his sanguinary career by the influence of Madame de Fontenay, a woman remarkable for her beauty, who, having been imprisoned at Bordeaux as she was going to join her family in Spain, owed her life to Tallien. He took her with him to Paris, whither he went to defend himself before the Convention against the charge of moderation. After the fall of Danton and his party, Tallien perceived that he should become one of the next victims of Robespierre if he did not strike the first blow. Accordingly, at the sitting of the Convention of the 9th of Thermidor (27 July 1794) he vehemently assailed Robespierre, and it was mainly by his influence that the latter with his friends was brought to the guillotine. At this period he married his *protégée*, Madame de Fontenay. Having been nominated a member of the committee of public safety, he used all his influence against his former associates, Fouquier-Tinville, Carrier, Lebon, etc., and demanded the suppression of all the revolutionary committees. In 1795 he was sent as commissioner of the Convention to the army of Hoche in Brittany. He subsequently became a member of the Council of Five Hundred, but his influence gradually declined. In 1798 he accompanied Bonaparte's Egyptian expedition. The vessel in which he sailed to return to France was captured by the British, and he was taken to London. On finally reaching France he found his importance altogether gone, and was glad to accept the office of French consul at Alicante. The last five years of his life were spent in poverty in Paris.

TALLIS, or TALLYS, Thomas, English composer of cathedral music: b. about 1514; d. 23 Nov. 1585. He was the author of some of the finest chants in the cathedral service of the English Church, and filled the position of organist of the chapel royal in the reigns of Edward VI, Mary and Elizabeth. William Byrd, the distinguished musician, was his pupil, and the two published in 1575 a collection of motets and hymns. Tallis composed settings to the 'Venite Exultemus,' 'Magnificat,' the 'Nunc Dimittis' and other canticles and to the 'Te Deum' as used in the English service, and his works fill a large space in the church music catalogue of Novello.

TALLMADGE, tăl'măj, **Benjamin,** American soldier: b. Setauket, N. Y., 25 Feb. 1754; d. Litchfield, Conn., 7 March 1835. He was graduated from Yale in 1773 and became principal of a high school in Wethersfield, Conn. He enlisted at the outbreak of the Revolution and rapidly attained the rank of major. In 1779 he crossed Long Island Sound and captured 500 Tories at Lloyd's Neck, L. I., and in 1780 successfully planned the capture of Fort George at Oyster Bay. He was given the custody of Major André and had charge of his execution. Later he settled in Litchfield, Conn., and he was member of Congress from 1801–17. Consult 'Memoirs' by his son (1859).

TALLMADGE, Nathaniel Pitcher, American legislator: b. Chatham, N. Y., 8 Feb. 1795; d. Battle Creek, Mich., 2 Nov. 1864. He was graduated (1815) at Union College, then studied law and (1818) was admitted to the bar. He commenced practice at Poughkeepsie, and was sent to the assembly in 1828, serving as State senator from 1830–33, when he was elected to the United States Senate. He was appointed by President Tyler governor of the Territory of Wisconsin in 1844, retiring within a year from office and practising his profession at Fond du Lac. His last years were spent at Battle Creek, Mich.

TALLOW, a somewhat indefinite mixture of the harder and less fusible fats, which is chiefly prepared from the natural fat of sheep and oxen. It consists mainly of stearin, olein, and palmitin, and it is nearly colorless and taste-less when pure, although the commercial product is commonly yellow. Until the cellular tissues are removed it is termed suet. In the manufacture of tallow the animal fats are cut into pieces and boiled with water, the fatty matter then melting and rising to the surface, whence it is removed by skimming. The cellular tissues of the natural fat remain behind, sensibly unaffected; but they are afterward treated by great pressure, to express whatever tallow they may have retained after treatment by the boiling process. The whiter and purer portions of the tallow are used in the manufacture of candles, and the softer and yellower grades are used in the manufacture of soap, as well as for dressing leather, and as a lubricant for heavy machinery. The melting point of tallow varies with the composition of the substance, commonly ranging from 100° F. to 120° F. The specific gravity is usually about 0.93.

TALLOW, Mineral, a waxy solid formed of a mixture of the higher hydrocarbons, usually of the paraffin or methane series. Commonly called ozokerite, earth wax or hatchettite. It may be considered a solid petroleum. It occurs in irregular seams and masses in the earth, in Galicia, in the Caucasus, and in Colorado. After purification it gives a product called ceresine, very similar to beeswax in physical properties. It is used in the manufacture of candles, of insulating materials, of bottles to contain hydrofluoric acid, and as an adulterant for beeswax.

TALLOW TREE, any of several trees which yield rather dense fatty substances used like tallow for making candles and soap. The tallow tree or butter-and-tallow tree of Sierra Leone (*Pentadesma butyracea*) is a member of the family *Guttiferæ;* the oil obtained from its fruit is used like butter. The tallow-tree of Malabar (*Vateria indica*) belongs to the family *Dipterocarpaceæ* and is noted for its large leathery leaves sometimes 10 feet long, its panicles of fragrant white flowers, for the hard, white, scentless tallow of its seeds, and for the «East Indian copal» which is obtained from incisions made in its large trunks. The candle-nut (q.v.) is often called tallow tree. In America the tallow tree of China (*Sapium sebiferum*), a member of the family *Euphorbiaceæ,* is probably best known. It has become naturalized in the Southern States, having been introduced in the vicinity of Charleston and Savannah whence it has extended. It is a large tree with long-stemmed, smooth, ovate pointed leaves, about two inches long; inconspicuous flowers in straight terminal spikes; and hard, smooth, brown three-celled capsules about half an inch in diameter. The hemispherical seeds are covered with a white waxy tallow, and after the capsule bursts, hang by threads among the bright red leaves of autumn. They are gathered by the Chinese, crushed and boiled (the capsules also), and the tallow skimmed off. Wax is often added to increase the consistency, about three pounds to 10 being the usual proportion. For ages this tree has furnished the Chinese with their candles. Vermilion is often added to color the otherwise white wax.

TALLQVIST, tal'kvist, **Knut L.,** Swedish Orientalist: b. Kyrkslätt, 16 March 1865. He studied at the Swedish Normal Lyceum and the University, Helsingfors, then at the universities at Leipzig and Berlin. Student from 1883, he was candidate in philosophy (1887), licentiate (1890) and regular doctor in 1894. He was docent of Assyriology and Semitic languages (1891–99) becoming professor of Oriental literature in the latter year. He wrote ‹Die Sprache der Contracte of Nabunaid› (1890); ‹Babylonische Schenkungsbriefe› (1891); ‹Die assyrische Beschwörrungsserie Maqlû› (1895); ‹Arabische Sprichwörte und Spiele› (1897); ‹Ibn Sa'id Kitab almugrib, Book IV› (1899); ‹Neubabylonisches Namenbuch› (1905).

TALLY, a stick divided longitudinally through the middle, formerly in general use as a medium for recording accounts. One-half was kept by the debtor and one by the creditor, and when any debt or payment was recorded the two halves were adjusted together, and a notch or some other mark made on them both. This method, however inconvenient in other respects, was an excellent security against forgery, since it would be difficult, if not impossible, for a person to make a false tally correspond with the counter-tally, in all respects in which the forger wished them to correspond, so accurately as not to be detected as false. When a debt was entirely cleared off, the creditor's tally was given to the debtor. Tallies were in use till the 18th century for keeping accounts in the exchequer of England. In modern usage any mark made to record a score may be termed a tally. A common method of keeping such a tally, as in counting votes, is to make a stroke for every vote, and draw every fifth stroke across the preceding four, to separate the strokes into groups of five, for easy counting. Such a group of marks is also called a tally.

TALMA, Francois Joseph, frăn-swă zhō-zĕf tăl-mä, French tragedian: b. Paris, 15 Jan. 1763; d. 19 Oct. 1826. In 1787 he made his début at the Theatre Français in the character of Séide in Voltaire's ‹Mahomet› and was received with applause. Talma rendered an important service to the French stage by introducing dressing in accordance with the time and country of the character represented. Chenier's tragedy of Charles IX, or Saint Bartholomew's, was brought forward in 1789, and Talma, after studying the character of Charles in history, and his person in medals and portraits, exhibited them with such truth and life that his reputation as the first French tragedian was established beyond dispute. The principal parts which he created, or carried to the highest perfection, were Séide, Othello, Hamlet, Sylla, Regulus, the grandmaster of the templars, Charles IX, Charles VI, Manlius and Orestes. He did not generally excel in comedy, but appeared in 1823 with great success in the character of Danville in Delavigne's ‹Ecole des Vieillards.› Talma was the great favorite of the Emperor Napoleon and accompanied him to Erfurt in 1808 and to Dresden in 1813. He was the author of a small but very interesting work, entitled ‹Reflections sur Lekain et sur l'Art Théâtral,› and of an autobiography afterward edited and published by Dumas (1849–50).

TALMAGE, James Edward, American geologist and theologian: b. Hungerford, England, 21 Sept. 1862. In 1876 he emigrated to Utah with his parents who had embraced the faith of the Latter-day Saints. He was a student at Lehigh University 1882–83; at Johns Hopkins University 1883–84, and was graduated as B.S. in chemistry from the former in 1891 and received honorary D.Sc. from the same institution in 1912; also honorary D.Sc. and didactics from Church of Jesus Christ of Latter-day Saints 1890. He was professor of chemistry and geology, Brigham Young University 1884–88; president Latter-day Saints University, Salt Lake City 1888–93; president University of Utah 1894–97; professor of geology and mineralogy, University of Utah 1894–1907; consulting and mining geologist 1907–11; director Deseret Museum, Salt Lake City, since 1891. He was one of two delegates from the Royal Society of Edinburgh to International Geological Congress, Russia, 1897. In the Church of Jesus Christ of Latter-day Saints he was ordained deacon 1873, teacher 1877, elder 1880, high priest 1884 and as one of the council of the 12 apostles of the Church 1911. He is a life fellow of American Association for the Advancement of Science; Royal Scottish Geographical Society; Royal Microscopical Society, London; Geological Society, London; Geological Society of America; Royal Society of Edinburgh; life associate of Philosophical Society of Great Britain. He is the author of 'First Book of Nature'; 'Domestic Science'; 'Tables for Blowpipe Determination of Minerals'; 'The Great Salt Lake Present and Past'; 'Account of the Origin of The Book of Mormon'; 'The Articles of Faith'; 'The Story and Philosophy of Mormonism'; 'The Philosophical Basis of Mormonism'; 'The Great Apostasy'; 'The House of the Lord'; 'Jesus the Christ,' etc.

TALMAGE, Thomas De Witt, American Presbyterian clergyman: b. Bound Brook, N. J., 7 Jan. 1832; d. Washington, D. C., 12 April 1902. He was graduated from the New Brunswick Theological Seminary in 1856 and was ordained pastor of the Reformed Dutch Church, Belleville, N. J., in that year. He held Reformed (Dutch) pastorates in Syracuse, N. Y., in 1859–62, and Philadelphia, in 1862–69; was a chaplain in the Union army during the Civil War, and in 1869 became pastor of the Central Presbyterian Church in Brooklyn, N. Y. His congregation erected in 1870 a new church known as the Brooklyn Tabernacle, which was burned in 1872. It was rebuilt in 1874, but twice again was destroyed by fire. After the third fire in 1894 Dr. Talmage resigned his pastorate and traveled abroad. In 1895 he accepted a call as associate pastor of the First Presbyterian Church of Washington, D. C., later becoming full pastor, a charge which he resigned in 1899 in order to devote himself to literary work. He was editor of *The Christian at Work,* New York, in 1873–76, of *The Advance,* Chicago, in 1877–78, of *Frank Leslie's Sunday Magazine* in 1879–89, and of the *Christian Herald,* New York, from 1890. For 30 years his sermons were printed weekly in religious and secular papers, and in 1901 it was estimated that they were published in 3,600 newspapers in various languages. He also appeared weekly for many years as a lyceum lecturer. Among his many publications are 'The Almond Tree in Blossom' (1870); 'The Brooklyn Tabernacle' (1884); 'From the Pyramids to the Acropolis' (1892); 'From Manger to Throne' (1894), etc. Consult Adams, 'Life and Sermons of T. DeWitt Talmage' (1902); Wilkinson, W. C., 'Modern Masters of Pulpit Discourse' (1905).

TALMUD, a code or digest of Jewish laws and opinions. See JEWS AND JUDAISM; THE TALMUD.

TALON, ta'lôn, **Jean Baptiste,** French Canadian administrator: b. Picardy, France, 1625; d. 1691. In 1663 he was made chief officer of justice, police and finance in the French possessions in America. He encouraged trade by building ships and sending exploring parties to Hudsons Bay and the Upper Lakes. Three of his seigniories were erected into baronies and he assumed the title of Count d'Orsainville. His memoirs form a valuable source of information with regard to early Canadian history. Consult Talon, 'Memoire à sa majesté sur l'état present du Canada' (1667).

TALTAL, täl-täl', Chile, a seaport in the province of Antofagasta, situated near the southern boundary of the province. It has railroad connection with the mining regions of the interior, and exports considerable quantities of nitre and some metals. Pop. about 7,000.

TÁLÚK, ta-look', or **TALOUK,** a term applied to land tenure in India, and having different meanings in different parts of the country, but generally describing an estate subject to some control intermediate between the government and the proprietor. The word itself in Arabic signifies dependence, and this indicates the usual sense of the term as applied to land. In Bengal it is an ownership subordinate to the Zemindars, who were originally tax-farmers for native princes, but whom the British authorities in India elevated to a sort of lordship over the property whose taxes they gathered in. In the Northwestern Provinces it is an inferior estate, or part of an estate, paying revenue through a superior proprietor. In Oude and Madras the word means a district set off for revenue purposes, evidently a derivation from the old meaning of an estate held under tax-farmers. One who administers such a district is a talukdar.

TALUS, accumulations of debris at the foot of steep slopes or cliffs. It may be material broken off by frost, by gravity, or by any other agency. It accumulates at the foot of the slope as a result of gravity. These talus slopes or cones are often of enormous size and consist mostly of coarse angular blocks. When cemented together this forms Talus Breccia. See BRECCIA.

TAM O'SHANTER. Composed, it is said, in the course of a single day, 'Tam o'Shanter' was written at Ellisland in 1790, while Burns was struggling with the difficulties of farming and the duties of exciseman. In no other poem does his peculiar genius find fuller expression. Scott said of it: «I verily believe 'Tam o'Shanter' to be inimitable.» Inimitable it is in its imaginative audacity: the vivid realism of the alehouse «bousing»; the weird terrors of Tam's midnight ride; the grim grotesques of the Kirk-Alloway revels, with «auld Nick — a towsie tyke»; the triumphantly serio-comic dénouement. And blent with this fantasy there is the keen, humorous sympathy of his characterizations: of «our sulky, sullen dame, nursing her wrath to keep it warm»; of Souter Johnny, «his ancient, trusty, drouthy crony»; of Tam himself, «the blethering, blustering, drunken blellum.» And as in 'Tam o'Shanter' the imagination of Burns is unmarred by the moralizing and sentimentalizing that so often beset him, so the style, terse, racy, picturesque, illustrates his mastery over his native idiom. Burns himself said of this poem that it «shewed a finishing polish» that he «despaired of ever excelling.» And we may echo his verdict that the unique quality of 'Tam o'Shanter' is one that he never did excel. Consult Henderson, T. F. (in 'Cambridge History of English Literature,' Vol. XI, and bibliography).

FRANCES W. CUTLER.

TAM-SUI, tăm-soo'ē, Formosa, a seaport on the northern coast of the island at the mouth of the Tam-sui River, 10 miles northwest of Tai-pe, the capital. It is the chief export town of the island, and the principal staples are tea, rice, sugar, coal, jute, camphor, etc. Pop. about 7,000.

TAM-TAM, tăm tăm. See TOM-TOM.

TAMA, tä'mạ, Iowa, city in Tama County; on the Iowa River, and on the Chicago, Milwaukee and Saint Paul, and the Chicago and Northwestern railroads, about 63 miles northeast of Des Moines and 18 miles east by south of Marshalltown. It is in an agricultural and stock-raising region. An Indian reservation (Sac and Fox) is nearby. The chief manufacturing establishments are flour mills, paper and lumber mills, broom factories, machine shops and cigar factories. The shipments consist chiefly of flour, brooms, poultry, livestock, eggs, vegetables and grain. There are seven churches, public and parish schools, two banks and a library. Pop. 2,800.

TAMAGNO, Francesco, Italian operatic tenor: b. Turin, 1851; d. Varese, 1905. His début on the operatic stage occurred (1873) in 'Un Ballo in Maschero,' at Palermo. Under Abbey he first appeared on the New York stage in the season 1889–90 when his name in Europe was a word to conjure with among his patrons. Under Abbey and Grau, season 1894–95, he was again on the boards in New York at the Metropolitan Opera House and Americans were treated to his rendering of 'Othello' his greatest rôle, which had made such fame in Milan. He retired from the stage in 1902.

TAMANDUA. See ANT-EATER.

TAMANOIR, the great ant-eater (q.v.).

TAMAQUA, tạ-mä'kwạ, Pa., borough in Schuylkill County, on the Little Schuylkill River, and on the Philadelphia and Reading, and the Central of New Jersey railroads, about 35 miles north of Reading and 15 miles west of Mauch Chunk. It is in a region noted for the quantity and quality of coal deposits. It was settled in 1799, and became a borough in 1833. The chief manufacturing establishments are flour mills, foundries, machine shops, a powder mill and planing mills. It has large coal yards. There are about 70 factories, paying wages of over $300,000 annually, with products of over $1,000,000. There are 12 churches, a high school, elementary schools, a business college and a library. There are several banks and newspapers. Pop. 10,000.

TAMAR, tā'mạr, (1) a southern river of England, flowing between the counties of Cornwall and Devonshire; and emptying through the Hamoaze into Plymouth Sound, two miles above Plymouth; length about 60 miles. (2) A river of Tasmania, formed by the union of the North and South Esk, and flowing into Bass' Straits at Fort Dalrymple.

TAMARACK. See LARCH.

TAMARAO, a sturdily built dwarf buffalo (*Bos mindorensis*) of the Philippines, which stands about three and one-half feet high at the shoulders and has coarse, thick, blackish brown hair. «The horns,» says Lydekker, «although massive, are comparatively short, and rise upward in the plane of the face with a lyrate curvature; they are distinctly triangular, with the largest face in front, and are somewhat roughened. In its massive horns, thick legs and uniform coloration, this species comes nearer to the Indian buffalo than to the anoa.»

TAMARIN. See MARMOSET.

TAMARIND, a leguminous tree (*Tamarindus indica*) and its fruit. It is supposed to have originated in eastern tropical Africa, but is now universally cultivated in the tropics. It reaches a height of 80 feet, and has a crown of widespreading branches and thick foliage. The leaves are abruptly pinnate, the flowers fragrant, red and yellow, with three perfect petals, and four sepals and colored caducous bracts. They are gathered in terminal racemes. The bean-like fruits are indehiscent flattened pods, and have a brittle brown shell. The seeds are flat, angular and shining, and are embedded in a dark-hued fibrous juicy pulp, which is pleasantly acid, laxative and cooling. This fruit is used to prepare tamarind fish, to make acidulous cooling drinks, and is also an article of commerce, with or without being preserved in sugar. Every part of the tree is used for medicinal purposes, except the yellowish-white, purple mottled wood, which is valuable for turnery, being hard and heavy. The seeds are astringent, the leaves are employed for curries and for a yellow or red dye. Velvet, or brown, or black tamarinds, are the product of a small leguminous tree (*Dialium guineense*), of Africa. It has pinnate leaves on slender branches, and downy black pods, of about the size and shape of a hazel-nut, containing seeds embedded in an edible, farinaceous pulp. The tamarind of New South Wales is a slender sapinaceous tree (*Cupania anacardioides*) of Australia, has an acid fruit and coarse-grained, whitish wood. Wild tamarind is a large tree of Jamaica (*Pithecolobium filicifolium*), having twice-pinnate leaves; *Pithecolobium dulce* is the sweet-pulped Manila tamarind. Certain leguminous trees of Central America and the West Indies, *Pentaclethra filamentosa* and *Acacia villosa*, are respectively the wild and the yellow tamarind.

TAMARISK, any member of the genus *Tamarix*, which is represented by shrubs, also called «flowering cypress,» inhabiting warm arid regions, but not hardy in America as far north as Massachusetts. They are salt-loving plants, often growing so near the sea that the spray of high breakers dashes over them, and are.

therefore, admirable for maritime planting. Like some other plants living near salt-water, or on arid steppes, certain species of *Tamarix* bear foliage with a punctate appearance, caused by minute pits. These leaves excrete saline solutions, which in rainless seasons serve to attract moisture during the cool nights, and facilitate its absorption by special cells at the bottom of the tiny cavities. In the daytime, the dried salts cover the leaves with a crust, which protects the plants from excessive evaporation under the desert sun. The tamarisk salt-tree (*T. articulata*) of the Indo-Chinese region is a bush or small tree looking somewhat like a conifer, which secretes enough salt to be useful in a culinary way; it is also the source of tamarisk-galls employed for medicine and for dyeing, since they contain 50 per cent of tannin; also an astringent bark.

Tamarisks are generally planted for ornament but are sometimes killed in hard winters quite to the ground. They are of unusual feathery aspect, with widely spreading, somewhat wand-like branches, crowded with small leaves like scales. In the axils of these are many dormant branch-buds, so that the plant readily sends out new shoots. The flowers are small and pink, in close spike-like racemes which are often panicled, and are softened by the many protruding stamens. One of the most widely known (*T. gallica*) reaches 15 or 20 feet in height, with panicled racemes blooming in late summer; it is very easily propagated and furnishes good fire-wood. A species of the Levant (*T. mannifera*) when punctured by a scale-insect (*Coccus manniferus*) exudes honey-like drops of sap that harden in the morning coolness; this is gathered and sold to Syrian pilgrims as manna (q.v.). The German tamarisk is *Myricaria germanica*. It has wand-like branches, bluish foliage, and many racemes of light pink flowers, terminating lateral branches.

TAMATAVE, tä-mä-täv′, the capital of Madagascar, situated on a peninsula slightly north of the middle of the east coast. It is the principal port of the island and has a good harbor protected by a natural breakwater, and fortifications. A railroad connects it with Antananarivo, which was the capital up to 1902. There is also canal transportation. Hides, gold dust, rice and rafia fibre are the leading articles of export. There is cable communication with Mozambique, Mauritius, Reunion and Aden. There are good banking facilities. Pop. 8,647.

TAMAULIPAS, tä-mow-lē′päs, Mexico, a state on the Gulf coast, occupying the northeastern corner of the country. Its area is about 32,128 square miles. The southwestern part of the state is traversed by the eastern Sierra Madre, but the greater portion belongs to the tertiary coastal plain, and is a rolling country, sloping gradually to the coast. The latter is lined with lagoons and sand-bars. The state is traversed by several large streams, and the Rio Grande forms the northern boundary. The climate on the coast is hot, and the northeastern plains are semi-arid. The population is chiefly centred on the lower mountain slopes, where the rain is sufficient. There are three railway lines. Agriculture and grazing are the chief industries. Cotton, sugar and cattle products are exported. Tampico (q.v.) is the chief seaport, whence steamships connect with Pensacola, Baltimore, New York and Havana. The capital is Ciudad Victoria. Pop. 249,641.

TAMAYO Y BAUS, tą-mą′yō ē bą-oos, **Manuel**, Spanish dramatist: b. Madrid, 1829; d. 1898. His parents were actors and the boy traveled about with them and early learned to play his parts on the stage; and thus early gained an insight into the nature and structure of the drama. The natural result was that he soon began writing dramas himself. His first dramatic production, an adaptation of 'Genevieve de Brabant,' was produced successfully when he was only 11 years of age. In this play his mother and himself took leading parts, the first production taking place in Granada. From this time on he continued to write for the stage and to acquire an increasing reputation as a dramatist. At the age of 29 he was elected a member of the Spanish Royal Academy, and for the last 14 years of his life he was director of the National Library and chief of the board of archivists, librarians and antiquarians. Among his best-known dramas are 'La locura de amor' (1855); 'Lances de honor' (1863); 'Un drama unevo' (1867). The latter, which has been translated into English under the title of 'A New Drama' by J. D. Fitz-Gerald and T. H. Guild (New York 1915) is considered his best drama. Consult Cotarello y Mori, E., 'Historia Literaria' (Vol. I, Madrid 1901); Sicaras y Salvado, N., 'Manuel Tamayo y Baus' (Barcelona 1906); Tonnenberg, Boris de., 'L'Espagne litteraire' (Paris 1903).

TAMBERLIK, tăm-bĕr-lēk′, **Enrico**, Italian operatic singer: b. Rome, Italy, 16 March 1820; d. Paris, 15 March 1889. He began his career at Naples as tenor singer in 1841, and in 1850 went to England, where he enjoyed great popularity for 24 years. He visited the United States in 1857. After his retirement from the stage he lived in Madrid, where he engaged in the manufacture of small arms.

TAMBOBONG, tăm-bō′bŏng, Philippines, pueblo, province of Rizal; in the northwestern part of the province, near the coast of Manila Bay; five miles north of Manila. It has a large sugar refinery and a cigar factory; the weaving of cotton cloth and the fisheries are also important industries. It is connected with Manila by steam tramway, and carries on a considerable trade. Pop. 25,000.

TAMBOUR-WORK, a species of embroidery introduced into Great Britain in the 18th century, now little used. A single tambour worker usually sits at a low circular frame, over the top of which the silk, linen or muslin is stretched by means of a hoop, much in the same way as the head of a drum is tightened. A frame of different construction is used when several workers are employed on the same fabric, consisting principally of two rollers, which, when properly fixed, stretch the linen, etc., to the necessary degree of tension. As the work proceeds the finished part is wound over one roller, while a fresh surface is at the same time unwound from the other. The needle, which is about one-half inch in length, terminates in a small hook with the point curving inward. This is fixed in a handle of bone, ivory or wood, of the thickness of a quill, by means of a small screw on the side. The worker, holding the thread on the under side of the frame, passes the needle through the muslin, etc., from the upper side, and by a continued series of loops interwoven together, succeeds in producing a verv minute and beautiful chain line, with which she traverses the outline of any pattern previously sketched upon the fabric she is employed to ornament.

TAMBOURA, the name applied in Persia and Turkey to a musical instrument of the guitar type, with strings of wire struck with a plectrum. The neck is long and the body, of gourd-shape, is often beautifully ornamented.

TAMBOURINE, tăm-boo-rēn', a musical instrument of the drum type, much used among the Italian peasants and negro minstrels. It consists of a piece of parchment stretched over the top of a broad hoop, which is furnished with little bells. It is sounded by sliding the fingers along the parchment or by striking it with the back of the hand or with the fist, elbow, etc.

TAMBOV, tăm-bŏf', Russia, capital of the government of that name, on the left bank of the Tzna, at the confluence of the Studenetz, 263 miles by rail southeast of Moscow. It was founded in 1636 and was then fortified, and is yet surrounded by a dilapidated rampart, and is built chiefly of wood. It has a gymnasium, military school, ecclesiastical seminary, female institute, house of correction and infirmary; is the residence of a governor, the see of a bishop and the seat of several important courts and public offices. There are breeding studs, manufactures of woolens and sailcloth, leather, soap, tallow, alum and vitriol, and a considerable trade with Moscow and Petrograd in tallow, leather, wool and provisions. Pop. 71,400. The government or province is 25,710 square miles in area and the population (1915) is 3,555,000. It is a rich agricultural region.

TAMERLANE, tăm-ẽr-lān'. See Timur.

TAMIL, or TAMIR, a branch of the Dravidian stock to which the original inhabitants of India belonged. They inhabit the extreme south of India, and have remained comparatively free from admixture with the Sanskrit-speaking Indo-Europeans and other invading races of subsequent arrival. Retaining their own tongue they adopted and developed the civilization of their conquerors and are much more enlightened than other races of Dravidian stock. The Tamil language is spoken over a large section in the extreme south of India; it is spoken to a great extent in Ceylon; it is spoken also by a majority of the Indian settlers in places farther east, as Pegu, Penang, etc.; and in many parts of southern India, even where it is not the vernacular, it is spoken by the better class of Hindus. The structure of the language is very simple. It has two dialects: the higher (Shen-tamil), now used in poetry, is the more ancient of the two; the lower (Kodun-tamil) is the language of common life. The literature of the Tamil language, the earliest extant works of which are supposed to be as old as the 9th century of our era, embraces nearly every branch of the knowledge of northern India. Consult Pope, 'First Lessons in Tamil' (Oxford, 7th ed., 1904). See India.

TAMING OF THE SHREW, The. 'The Taming of the Shrew' has been the most permanently popular of Shakespeare's minor plays and is still notably successful on the stage. There is little agreement regarding either the date at which it was composed or the extent of Shakespeare's concern in it. It was first printed in the 1623 folio, but a separate quarto edition in 1631 shows its continued appeal at a time when few but the very greatest of the Shakespearean plays justified individual republication. This drama is a refashioning of one of the best pre-Shakespearean comedies, 'The Taming of A Shrew,' printed in 1594. The characters are renamed (except Kate) and the lines wholly rewritten, but the general conduct of the plot is not radically altered, more change in the last regard appearing in the story of Bianca than in that of Katharine. Since the effort to ascribe to Shakespeare the original 'Taming of A Shrew' is invalidated by the fact that the former play belonged to Lord Pembroke's company and by its ridiculous purloinings from Marlowe, legitimate speculation is limited to discussion of the extent of the poet's revisionary work in preparing 'The Taming of the Shrew.' That the Katharine-Petruchio scenes were recast by him is agreed, but many critics refer the scenes dealing with the lovers of Bianca to an unknown second reviser. No particular reason for the last assumption exists beyond the unwillingness to credit Shakespeare with work not manifestly beyond the abilities of his contemporaries. This, of course, is a correct criterion only where it is clear that the author is exerting his full power. In the case of the present play it is logical to suppose that the entire revision was done by Shakespeare, who handled the main plot with enthusiasm and retouched the subordinate scenes with independence and adequacy, but in a somewhat perfunctory spirit. The notable Induction, with the character of Sly, is not primarily Shakespeare's contribution; it occurs in the earlier version, where indeed Sly continues on the stage through the entire performance and offers frequent comments like those of Revenge and Andrea's Ghost in 'The Spanish Tragedy.' Shakespeare, apparently in the interests of simplification, allows him to be forgotten after the first scene of Act I, but he has made the Induction peculiarly his own by the insertion of Warwickshire place names and allusions. On 26 Nov. 1633 'The Taming of the Shrew' was acted at Saint James' Palace before Charles I and the queen. It is noted that the play was "liked." Two nights later it was followed by a performance of Fletcher's sequel, 'The Tamer Tamed,' in which Petruchio's second wife turns the tables. Various adaptations of Shakespeare's play were popular in the 17th and 18th centuries. In 1754 Garrick produced a three-act abridgment called 'Katherine and Petruchio,' which for a century or more supplanted the original. The complete play was revived by Augustin Daly in 1887 with deserved success. John Drew played Petruchio, Otis Skinner Lucentio and Ada Rehan Katharine. One hundred performances were given between 18 January and 13 April.

Tucker Brooke.

TAMMANY HALL. See TAMMANY SOCIETY.

TAMMANY SOCIETY, or COLUMBIAN ORDER, The, was founded 12 May 1789 by William Mooney, ex-Revolutionary soldier (two weeks after the national government was established), as «a fraternity of patriots solemnly consecrated to the independence, the popular liberty and the federal union of the country.» It had for its objects (1) the perpetuity of democratic-republican institutions; (2) benevolent care of Revolutionary soldiers and others of its members, «their widows and orphans, and others who may be proper objects of their charity.» The membership was composed of those who were known before the Revolution as «Sons of Liberty» and «Sons of Saint Tammany»; societies formed to promote the cause of independence. The society was opposed to the Saint George, Saint David and Saint Andrew societies, whose Tory members openly proclaimed fealty to George III. After the Revolution, Alexander Hamilton (q.v.) removed the political disabilities of these Tories (1787) and they became the foundation of the Federalist party, and being rich and influential fought corruptly for Hamilton's scheme of a Federal President and Senate, to hold office for life, who should appoint the State governments and dominate Congress. Many of these Loyalist Tories were elevated to office immediately on their enfranchisement. This enraged the «Liberty Boys» who fought England's soldiers, and suffered repeated betrayal by these same Loyalists whose plots were many against the patriots. Many of these Tory conspiracies were successful and sent numbers of patriots to the charnel prison ships to meet death; others failed, as when the Tory mayor of New York, Mathews, plotted to kidnap Washington and assassinate his staff. The hatred bred by these and kindred infamies was fanned to flame by the disfranchisement of Revolutionary soldiers whose means and property were meagre. In 1777 the constitutions drafted and operative in New York State gave the right to vote only to those who owned «freehold to the value of 100 pounds, free of all debts.» This gave full political power to the rich Loyalist Tories who monopolized trade and banking privileges, while it disqualified the bulk of those who fought in the patriot army and those who were punished by poverty for nobly sustaining the Revolutionary cause. The founding of the Society of the Cincinnati (q.v.) augumented the existing bitterness and hatred. Jefferson and others pointed out its menace to the liberties of the people and its monarchial plan to found an order of hereditary nobles, with militarism as a basis. The Tammany Society was founded as a crowning protest to these portentous happenings and to discredit Alexander Hamilton's prophecy that the democratic-republican scheme of government was doomed to disastrous failure.

Early History.—The Tammany Society was divided into 13 tribes corresponding to the 13 original States. The Society adopted Indian titles and ceremonials and the forms and usages of the aborigines to the fullest extent practical. The wigwam was the term applied to the Society's place of meeting. Indian symbols and mottoes were used to designate the 13 tribes, as follows:

The Eagle Tribe, New York State.
The Otter Tribe, New Hampshire.
The Panther Tribe, Massachusetts.
The Beaver Tribe, Rhode Island.
The Bear Tribe. Connecticut.
The Tortoise Tribe, New Jersey.
The Tiger Tribe, Delaware.
The Rattlesnake Tribe, Pennsylvania.
The Fox Tribe. Maryland.
The Deer Tribe, Virginia.
The Buffalo Tribe, North Carolina.
The Raccoon Tribe, South Carolina.
The Wolf Tribe Georgia.

The 13 sachems (or trustees) annually elected a grand sachem or president. The *kitchi okeinaw,* or great grand sachem, was an honorary office conferred upon the following Presidents of the United States: Washington, John Adams, Jefferson, Madison, Monroe, John Quincy Adams and Jackson. The office was abolished after General Jackson's incumbency. The Sagamore was the master of ceremonies and the Wiskinskie the sergeant-at-arms. According to the true Indian fashion the year was divided into seasons and these subdivided into moons. The era began with the discovery of America by Columbus and included the year of the Declaration of Independence and of the founding of the Society. (New York City, 3 Dec. 1903, is written by the Society thus: Manhattan Season of Snows, 12th moon, year of discovery 411th, of Independence 127th and of Institution 114th). The Society motto is «Freedom our Rock.» The following toasts at the 4 July 1789 banquet illustrate the Society's sentiments from its formation. Thirteen cannon shots followed each toast. These are the two first toasts: (1) «May honor, virtue and patriotism ever be the distinguished characteristics of the Sons of Saint Tammany.» (2) «The head men and chiefs of the Grand Council of the Thirteen United Fires — may they convince our foes not only of their courage to lift, prudence to direct, and clemency to withhold the hatchet, but of their power to inflict it in their country's cause.»

Achievements.— The national government repeatedly failed to conclude a treaty of peace with the warlike Creek Indians whom the Federal government was anxious to placate. The Tammany Society undertook the conciliation. The Celtic half-breed chief McGillivray, who led the Creek tribe of Indians, with 28 of his chiefs and warriors were brought to New York by Tammany and given a banquet 2 Aug. 1790. The Tammany braves were in full Indian costume when they escorted McGillivray and his warriors to President Washington. The treaty was signed 13 Aug. 1790. The Society in June 1790 founded a museum for «the preservation, collection, and study of Indian relics, etc.» In 1791 the Society, under the direction of John Pintard, its first sagamore, founded many educational and progressive institutions which later developed great efficiency under the Society's fostering care. Two of these institutions have since merited national recognition, namely, New York Historical Society (q.v.) and the Academy of Design (q.v.). In 1793, when France in desperation struggled to overthrow feudal oppression, the Tammany Society's sympathy and moral support was prompt, enthusiastic and enduring. Sentiments and sympathies of political and other associations were usually expressed by toasts at a banquet specially held for that purpose. Until about 1840 these «public dinners» were the chief means of announcing the policies, booms and sentiments of political and social bodies. On 12 May 1793 the Tammany Society, at its annual dinner, gave the toast, «Success to the Armies of France, and wisdom, concord, and firmness to the Convention.» This was greeted with roars of applause for many minutes. The society suffered a flood of vituperation, abuse and threats of grave harm from the Tories and Federalists. In 1800 the society bought real estate collectively to comply with the property qualifications imposed on the voter. On 13 April 1808 the society marched in a body to Wallabout («Wallabocht») Bay, where the foundation stones were laid by them of the receiving vault, for the bones of 11,600 patriots, victims of England's brutality. The society collected 11 hogsheads of bones along the beach of Wallabout Bay of those who died of hunger, disease and cold in the awful English prison ships. Tammany interred these bones in a tomb near the present navy yard with imposing military and civil ceremonials. In 1812 the Tammany Society loudly called for war with England, pledging «their lives, fortunes and sacred honor» in support of the government for the waging of «that just and necessary war.» At every stage of the conflict the Society gave full and loyal support. Tammany Hall in Nassau street became the headquarters of the war party where they hoisted the flag to proclaim each victory and celebrated the success of the American forces in loyal manner. Tammany also gave a fighting force to the nation, which developed later three able generals and a colonel. In August 1814 about 1,200 members of Tammany Hall went in a body to Brooklyn and erected earthworks and other defenses. On 29 June 1814 members of the Tammany Society mobbed a large Federalist meeting gathered to celebrate the return of the Bourbon dynasty to the throne of France. In 1817 the Society with high patriotic speeches and ceremonial made imposing interment of General Montgomery in Saint Paul's churchyard. On 23 Feb. 1819 Tammany gave a banquet in honor of Gen. Andrew Jackson at which they launched a boom in his behalf for the Presidency.

Manhood Suffrage.— From the moment of its foundation in 1789, the Tammany Society fought for manhood suffrage and against «imprisonment for debt.» On 1 Dec. 1820 a Tammany Hall mass meeting resolved: «That the distinction of the electoral rights; the mode of appointment to office and the union of the judiciary and legislative functions were objectionable and highly pernicious.» The meeting urged the legislature to pass the reform measures they advocated and when the legislature overwhelmingly advocated the extension of the suffrage, Tammany celebrated the victory for reform 14 June 1821, at Tammany Hall with democratic jubilation. The sentiment dominant at this gathering is tersely expressed by one of their members: «We would rather be ruled by a man without an estate than by an estate without a man.»

On 4 March 1822 a banquet was given at Tammany Hall for the purpose of expressing their utmost joy at «the extension of the right of suffrage and the abolition of those cumbersome relics of old centralizing methods, the Council of Appointment and the Council of Revision.» The function of the former was expressed in its title; that of the latter was to give final approval or disapproval of all legislation. The «Toasts» at this banquet appropriately express the Tammany sentiment of the participants. Here are two illustrations: «The right of suffrage — corruption in its exercise most to be apprehended from its limitation to a few.» This was another: «The young and rising politician — may integrity and principle guide him — studying the public good, not popularity.» The extension of the suffrage greatly increased the voting power of Tammany and augmented its political prestige. In 1820 manhood suffrage in full became a fact; Tammany's political power having vastly increased, in this year Tammany succeeded in abolishing the last vestige of property qualification to the right of suffrage by an overwhelmingly large popular vote. In 1826–27 Tammany forced the fight for the five-year limitation for the acquisition of citizenship. In 1827 a Tammany delegation visited General Jackson at New Orleans to present an anniversary address on the famous battle in which he humbled England, and to urge his candidacy for the Presidency in the coming year. Martin Van Buren (who was a member of the Tammany Society) visited New York later in the year and organized the sentiment of the Society for Jackson. To offset this sentiment and the large alien vote of Tammany, the «Native American Party» was formed, whose battle cry was «Political privileges should belong exclusively to the natives of the country.» In 1828 Tammany gave General Jackson nearly 6,000 majority in a total vote of nearly 25,000. This was the first national election held wherein the State of New York chose Presidential electors by popular vote.

Mid-Century History.— On 26 Nov. 1830 Tammany Hall held high festival in honor of the French Revolution. President Monroe, though in feeble health, reviewed the Tammany parade and later presided at the banquet at Tammany Hall. Patriotic speeches for democracy were delivered and elaborate fireworks concluded the celebration. In 1831 Tammany abolished «imprisonment for debt,» where the debtor was a resident by New York City. On 3 March 1831, Tammany, by a unanimous resolution, declared the renomination of General Jackson and the nomination of its Grand Sachem of the Eagle Tribe, Martin Van Buren, for Vice-President. In 1832 Tammany gave General Jackson 5,620 of a majority in a total vote of 30,474, despite the flagrant corruption and frauds openly used to defeat Jackson in this national election. The United States Bank and allied financial interests denounced Jackson as a «Revolutionist,» whose «despotism» would spread throughout the nation «the fearful consequences of anarchy.» The bank officials publicly gave $6 a vote, and as their resources seemed unlimited, raised the bribe in particular cases, yet failed to defeat Jackson. On 13 June 1833 General Jackson exhibited his gratitude to Tammany Hall by a ceremonious visit to the wigwam, accompanied by Governor Marcy, Vice-President Van Buren, the Secretary of State Woodbury and the mayor and common council of the city. In 1833, through Tammany's persistence, sustained by the public opinion which it aroused, the State legislature was forced to pass as a reform measure an act permitting New York City to elect its mayor. In 1834 Tammany Hall for the first time in United States history elected a mayor by popular vote. Tammany's candidate was Cornelius W. Laurence. The United States Bank and the combined money powers of the period bent every energy to defeat Laurence. All the newspapers were subsidized, and alarmed the citizens with inflammatory editorials predicting "Universal disaster," "general destitution," "trade paralysis" and "appalling panic." Agents of the banks hired thugs and bred riots. Serious disorder and daily scenes of violence preceded the election. Every form of coercion was employed on the business element and actual trade suspension was artfully produced. Yet, despite all these artificial and real terrors and their influence on the timid and greedy, Tammany elected her candidate and gave an enduring argument for the spread of manhood suffrage throughout the nation. In June 1861, Grand Sachem William D. Kennedy took to the front a regiment composed of members of Tammany Hall, which had been raised and equipped by the Tammany Society. This regiment, the 42d New York Infantry, distinguished itself for valor in 36 battles and engagements. In 1864 Tammany presented General McClellan's name at the Chicago convention as the Presidential candidate of the Democratic party. General McClellan received, in the ensuing election, from Tammany's efforts, a majority of over 37,600 in a total vote of about 110,000. In 1870 Tweed, having gained an ascendancy in Tammany Hall, committed the organization to many extravagant expenditures, thus bringing much scandal upon the wigwam. He was forced to retire from his leadership and was driven out of the country, a prey to ruin and disgrace. Since that time Tammany has ceased to stand for high policies and has become emblematic of boss rule and policies for "what there is in it."

Later History.— In 1872 the reform of the organization was undertaken by a group of Democrats under the guidance of Samuel J. Tilden. Tammany came to the front again with John Kelly as its leader. It became a factor in city, State and national politics. Under Mr. Kelly, Tammany largely regained the confidence and respect of the Democracy. Upon his death, in 1886, Tammany was governed by a committee consisting of Richard Croker, James J. Martin, Hugh J. Grant and Thomas F. Gilroy. This government eventuated in the absolute leadership of Richard Croker. Under the influence of Mr. Croker, Tammany in 1888 won a series of brilliant political victories, establishing democracy firmly in the city and State. It was due to Mr. Croker's skilful management that all of the so-called Democratic organizations in opposition to Tammany Hall were put out of existence and Tammany left the sole representative of Democracy in this, the greatest city in the United States. In 1900, after the defeat of the Democracy in the country at large, Mr. Croker ceased to take an active interest in Tammany affairs. He resigned his leadership after the municipal defeat in 1892, and the Hon. Lewis Nixon, a protégé of Mr. Croker's, was placed in command. Mr. Nixon's training had been for the navy. His knowledge of politics was purely academic, and his leadership was naturally very brief. The organization then drifted along under the leadership of a committee consisting of Daniel F. McMahon, Louis F. Haffen and Charles F. Murphy. In 1903 Mr. Murphy assumed the leadership upon the vote of the executive committee. Mayor George B. McClellan and the entire Tammany ticket were elected in November 1903.

He was re-elected, and in 1910 William J. Gaynor was elected by Tammany. While Mr. Gaynor was markedly independent, yet Tammany held its grip on most of New York's political activities. In 1913 the fusion candidate, John Purroy Mitchell, beat the Tammany forces, and there was a partial return to Republican rule. However, notwithstanding Mitchell's acknowledged ability and popularity, Tammany beat him in 1917, with an almost unknown candidate, John F. Hylan. Tammany maintains in Manhattan probably the strongest and best organized political machine in the world. While there are Democratic organizations and leaders in the outlying boroughs, they are known to be subservient to Tammany, and the assembly districts all have Tammany leaders — the very name of Democratic organization is lost. Permanent headquarters and leaders exist in each of the 23 assembly districts and subordinates handle the details like a great army. They are in business all the year around and every day in the year, aiming to maintain their hold in all the political offices and all the expenditure of public moneys that they possibly can. The fact that they have been able to place many judges on the bench as well as to control most of the executive offices has at times been the subject of great scandal. Yet membership in the organization includes very many men of high character and patriotism, and their influence at times is apparent.

Tammany for many years has catered to and largely held the votes of the poorer classes — charity has been dispensed widely from the district offices; bureaus are maintained to give work to those who can be depended upon to vote with the organization; excursions, parties and dances are given freely; those who have a bad habit of getting into jail for small offenses are systematically bailed. Notwithstanding that, members and followers have been charged time and again with catering to vice, even discussing it and trafficking in it; with dishonesty and wastefulness of public funds; with placing and keeping incompetents in office, and the entire list of political mistakes, weaknesses and crimes, yet after every exposure and temporary reform, the same old Tammany comes back to power and dominates the politics of the world's largest city. Consult Breen, 'Thirty Years of New York Politics' (1899); Lewis, 'Richard Croker' (1901); Riordon, 'Plunkett of Tammany Hall' (1905); Forrest, J. W., 'Tammany's Treason' (Albany 1913).

TAMMERFORS, tăm'mĕr-fŏrs (Finnish, TAMPERE), Finland, a town in the government of Tavastehus, about 80 miles northeast of Abo, on the railway from the Gulf of Finland to the Gulf of Bothnia. It is the third largest town in Finland, and the principal manufacturing centre. Its industries include cotton and linen spinning and weaving, and the manufacture of paper, iron and steel mills, locomotive works and shipyards. Pop. 45,213.

TAMMUZ, tăm'ŭz, a Babylonian deity, worshipped by Jews who drifted into idolatry, and mentioned in Scripture, in Ezekiel viii, 14: «Then he brought me to the door of the gate of the Lord's house which was toward the north; and, behold, there sat women weeping for Tammuz.» According to Sayce (in Hastings' Dictionary of the Bible) Tammuz was originally the sun-god, and was a Babylonian deity whose worship was early imported into the West, the name being in Sumerian *Dumu-zi*, «the son of life.» In Canaan Tammuz was addressed as Adonai, «my lord,» whence the Greek Adonis; and as Tammuz was originally associated with the Babylonian goddess Istar (Astarte), so Adonis was associated with Aphrodite. The Vulgate agrees with this explanation by its rendering of Tammuz as Adonis. This worship was much practised among the Phœnicians, and was celebrated chiefly at the Phœnician town of Byblus. The ceremonial was prolonged through different scenes. Adonis was supposed to have been killed by a boar; search was made for him, a wooden image being provided to represent Adonis, and on his being found, wild and licentious orgies began, and the burial of the idol terminated the first portion of the pageant. The river of Adonis, or Nahr Ibrahim, at the season of the year at which this worship took place, becomes discolored from the heavy rains on Lebanon, and in the popular superstition the stream was stained by the blood of Adonis.

The resurrection of Adonis next followed in the ritual, and was celebrated with frantic rejoicings. This idolatry appears to have been originally symbolical, connected with the sun's decline in the winter and his returning strength in summer, or with the death of nature and its revival in spring. The festival seems to have been held at the summer solstice. Movers and Hitzig place it at the autumnal equinox; but Tammuz is with the Jews the name of the fourth or midsummer month. Jerome also asserts that the anniversary of the death and resurrection of the fabulous Adonis was celebrated in the month of June. It was, however, in the sixth month that Ezekiel's vision happened. The period of celebration might perhaps vary, or the time of the prophet's vision might not be coincident with the actual celebration of the festival. The worship of Adonis was suppressed by Constantine. Consult Langdon, S., 'Tammuz and Ishtar' (Oxford 1914).

TAMPA, Fla., city, port of entry, county-seat of Hillsborough County, at the mouth of Hillsborough River at its entrance to Tampa Bay, and on the Atlantic Coast Line and Seaboard Line railroads, being the Gulf terminus of both, about 29 miles from the Gulf of Mexico. It has a harbor, the best on the western coast of Florida, and it has regular steamer connection with all the large Gulf ports, large ports of the West Indies and with New York and a number of other Atlantic ports. In the vicinity are large mines of phosphate. Lumber and naval stores are largely produced and shipped.

Manufacturing.— The chief manufacturing industry of Tampa is connected with tobacco products. In 1914 the number of factories was over 200 (three-fourths of them being cigar factories), the capital invested $9,858,000, and the value of the product for the year $14,039,000. The wages paid to workmen are more than $6,500,000 annually. The tobacco used in the factories is nearly all imported from Havana, Cuba. The manufacturing of tobacco in Tampa is largely done by Cuban immigrants. The Sumatra «wrapper leaf» grown in Florida is said to be superior in quality to that grown in Sumatra, and is used to some extent.

Commerce.— The amount of tobacco leaf imported into the port of Tampa from Havana has for several years exceeded that of any other United States port except New York. The internal revenue paid by the city exceeds $1,000,000 annually, and the custom collections for the district are about $9,000,000. Phosphate comes next after tobacco, and over $3,000,000 is sometimes shipped abroad in a single year. The quantity of fruits and vegetables which are being shipped to Northern markets is increasing.

Buildings and Municipal Improvements.— Since 1886, when Tampa was made a port of entry, it has grown rapidly. To accommodate its late number of winter guests, many large and beautiful hotels have been erected. Other fine public buildings are the custom-house, the churches, the schools, the banks and many of the business blocks.

The electric car lines connect the suburban sections with the different parts of the city. The water supply comes from springs; the daily use is 7,000,000 gallons. The pumping capacity of works is 10,000,000 gallons.

Churches, Schools, Etc.— There are 18 church buildings. There are 12 public school buildings, including the Hillsborough County High School, established in 1886. Another high school is in charge of the Sisters of the Holy Name, who conduct three parish schools in Tampa and one in each of the nearby suburbs, West Tampa and Port Tampa. There is a college for boys, under the management of the Society of Jesus, and five private schools. There are three daily and five weekly newspapers. The six banks have a combined capital of $1,000,000, and deposits amounting to over $6,000,000.

Government.— The government is vested in a mayor and a city council, elected by the people for terms of two years. The council has 11 members, three being elected at large. There are police, sanitary and public works departments, including a board of health with ample powers to protect the city's interests.

History.— Tampa is the historical landing place of Narvaez and De Soto, of ill-fated early Spanish expeditions. Its first settlement began with the establishment of the United States military post of Fort Brooke, during the wars with the Seminole Indians. It was the seat of small shipbuilding and salt works during the Civil War, and was captured by Federal gunboats. Its recent rapid growth dates from the coming of railroads and cigar factories in 1886. Pop. (1910) 37,782; (1919) 52,000.

TAMPA, a bay on the west coast of Florida, an inlet of the Gulf of Mexico. The northern part is divided into an eastern arm, Hillsboro Bay, and a western arm, Old Tampa

American Scarlet Tanager (Pyranga rubra), with a female (below) and immature males (above)

Bay. The harbor is protected by a line of keys forming barriers against the west winds. A point of land extending south almost closes the inner harbor. The bay is about 35 miles long and from 5 to 15 miles wide. At the entrance, on Egmont Key, lat. 27° 36′ N., long. 82° 45′ 15″ W., is a lighthouse nearly 90 feet in height. This was the landing place of the Spanish explorers De Soto and De Narvaez. On its shore the United States government maintained Fort Brooke for many years previous to the Civil War. During the Spanish-American War this bay was the principal point of embarcation for United States troops to Cuba.

TAMPAN. A poisonous tick found in Angola and other parts of southern Africa. It is about the size of a pea and when filled with blood is dark blue in color. It usually bites the parts between the toes or fingers and causes a disagreeable itching which gradually ascends the limbs till it reaches the abdomen when vomiting or fever occur.

TAMPICO, tăm-pē'kō, Mexico, a town in the state of Tamaulipas, situated in the southeastern corner of the state at the mouth of the Panuco River. It is an old Aztec city, built in a low, unhealthful locality, surrounded by lagoons and marshes. The streets are broad and regular, with large market places, and there are several fine buildings. The harbor has been improved by jetties and a breakwater, and the town rivals Vera Cruz as a commercial port. Its development during recent years is largely due to the finding of petroleum near by. It is the terminus of two railroads, and the commercial outlet for all the Northeastern States, all steamship lines of the vicinity making this port. The exports are petroleum, mining and grazing products, wood, honey, wool and hemp to the total of nearly $100,000,000 annually. The imports are of about one-half this value, being mostly manufactured articles from the United States. Pop. about 36,000.

TAMPICO FIBRE. See Istle.

TAMWORTH, Australia, an inland town of New South Wales, in the northeastern part of the state, on the railroad from Sydney to Brisbane. It is the centre of an agricultural and mining district. Pop. about 7,750.

TAMWORTH, England, a borough of Staffordshire, on the Tarne River, 110 miles northeast of London; the site of interesting old ruins, dating from the 8th century. Pop. 7,500.

TANA, tä'nä, British East Africa, a river rising on the slopes of Mount Kenia, and flowing southeast into the Indian Ocean. It is navigable for light-draught vessels about 350 miles to Hameye, just below the Hargazo Falls.

TANA. See Tree-shrew.

TANA, Lake. See Dembea.

TANAGER, a family of perching birds (*Tanagridæ*), allied to the finches. They are distinguished by the bill being of triangular shape at its base and arched toward its tip. The upper mandible may exhibit a notched appearance; the wings are pointed and of moderate length; the feet short and slender. The hinder toe is strong and elongated, all the digits being provided with strong curved claws. These birds are chiefly found in the tropical parts of America and include several genera and many species, all of brilliant coloration and usually capable of fine singing. One of the best known is the organist tanager (*Euphonia musica*) of the West Indies, so named from the pleasing and varied nature of the song. The Antilles possess several peculiar species. Three or four species of the genus *Pyranga* are regular migrants to the United States in summer, one, the scarlet tanager, or black-winged fire-bird (*P. rubra*), being familiar at that season throughout all the Northern and Eastern States and southern Canada. It is of less size than the robin, and a bird of the woods and orchards rather than of open lands, and almost never seen upon the ground. The male is everywhere rich scarlet except his wings and tail which are pure black. This full plumage is not acquired, however, until the fourth year, the young males being dull yellow, more or less reddened according to age; while the females are always clothed in an inconspicuous dress of mottled green. The song of the male is loud, vigorous and merry, and is heard later in the summer than that of most other birds. The nest is a rather rude structure placed in a tree, and containing greenish, brown-spotted eggs. In the Southern States another species, the summer redbird (*P. æstiva*) is of more pinkish and glowing hue than the scarlet tanager, and lacks the black on wings and tail; it has a Western variety (*Cooperi*). The males of another Western species, the Louisiana tanager (*P. ludoviciana*) are yellow and black, with the head red; and a fourth darker species (*P. hepatica*) is mainly Mexican. Consult Ridgway, ‹Birds of North and Middle America,› Part II, (Washington 1902), and standard books on American birds.

TANAGRA, tăn'a-gra, Greece, an ancient town of Bœotia, on the left bank of the Asopos, 15 miles east of Thebes, the scene of a battle in 455 B.C. between the Athenians and the Spartans, in which the latter were victorious. Tanagra, now called Gremada, is a scene of ruins. Excavations since 1873 have brought many interesting objects to light, especially the beautiful painted terra cotta draped female figures from six to nine inches in height, known as Tanagra figurines.

TANANARIVO, tä-nȧ-nä-rē'vō. Capital of the island of Madagascar. Its most prominent building is the royal palace which is located at the top of a hill. The place has no commerce but has a few industries and many new buildings, among which are two cathedrals, a mosque, several colleges and hospitals and a number of churches. Pop. about 95,000.

TANARO, tä-nä'rō, a river of Italy known anciently as Tanarus. It rises in the Ligurian Alps, in northwestern Italy, flows northeast past Asti and Alessandria, and empties into the Po 10 miles northeast of Alessandria; length 125 miles.

TANAUAN, tä-nä'wän, Philippines, (1) Pueblo, province of Batangas, Luzon, in the northeastern part of the province, 24 miles north of Batangas. It is on the main road to Manila, and was wiped out by a volcanic eruption of Taal, in 1754, but rebuilt. It is the centre of sugar and tobacco raising and fruit growing country, and has large markets. There are good schools. Pop. 20,040. (2) Pueblo, province of Leyte, on the northeastern coast, on

San Pedro and San Pablo Bay, nine miles south of Tacloban. It is on the coast road. Pop. 18,510.

TANCHEL, or TANQUELIN, a fanatic who arose in the Netherlands about 1115, who proclaimed himself Son of God, and had many followers. He was killed at Antwerp in 1125 and those who believed in him, known as Tanchelmians, or Tanquelinians, were converted back to the Roman Catholic faith.

TANCRED, tăng'krĕd, soldier and Crusader: b. about 1068; d. 5 Dec. 1112. His father was a Sicilian or Italian marquis named Odo or Ottobonus; his mother the sister of the celebrated Norman, Robert Guiscard, whose eldest son, Bohemond, was the friend and brother-in-arms of Tancred. (See GUISCARD). In 1096 the two heroes embarked for Epirus, and thence marched to Macedonia. At the siege of Nicæa (1097) Tancred first appears among the heroes who directed the course of events, and he also took a conspicuous part in the battle of Dorylæum (July 1097). He now advanced, with Godfrey's brother Baldwin, over the Taurus toward Jerusalem. Tancred first pentrated through the passes of the mountains, and obtained possession of Tarsus by capitulation. The perfidious conduct of Baldwin caused a quarrel between him and Tancred, but it terminated in the reconciliation of the chiefs, who now joined the main army which was then marching upon Antioch. On the march to Jerusalem, Tancred had command of the advance guard, and he was the first to storm the walls of the town. During the scenes of horror which attended the capture of Jerusalem (July 1099) he conducted himself with humanity. The Sultan of Egypt advanced to attempt the recovery of Jerusalem, but was totally defeated by Godfrey of Bouillon and Tancred before Ascalon (12 August). Tancred captured Tiberias, besieged Jaffa and, after the death of Godfrey, endeavored to effect the election of Bohemond as king of Jerusalem; but the unworthy Baldwin obtained the throne. Tancred subsequently conducted the defense of Antioch, and after Bohemond's death in 1111 obtained that principality. He is represented by Tasso in the 'Jerusalem Delivered' as a brilliant and blameless hero. He is also celebrated in Rossini's opera 'Tancredi' (1813). Consult Guizot, 'Collection des Memoires-Gesta Tancredi'; Delabarre, 'Histoire de Tancrède' (1822).

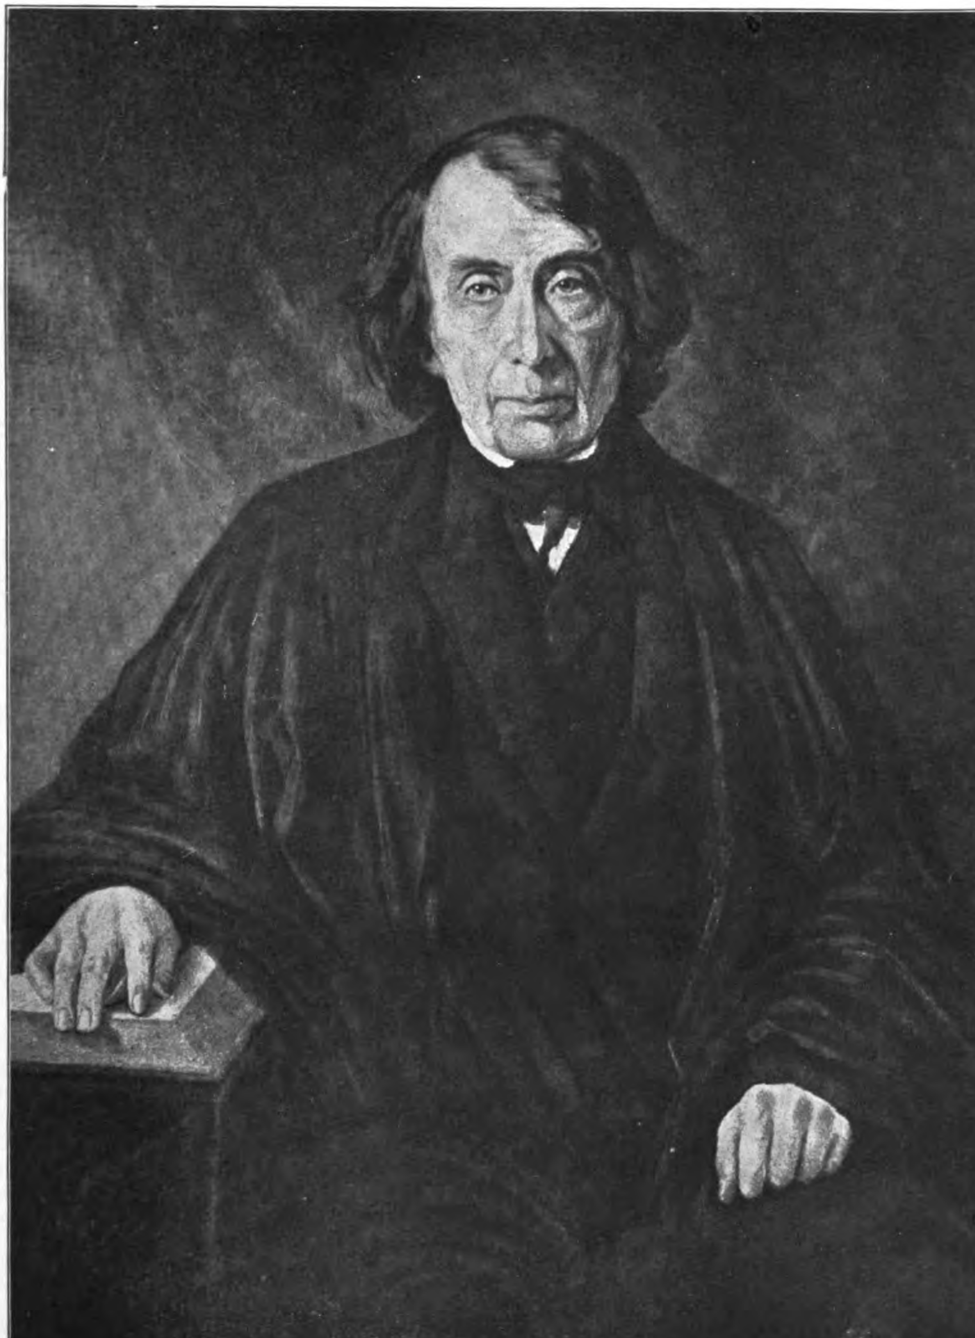
TANDOLANOS, tăn-dō-lä'nōs, a wild Philippine tribe of Malay origin living on the west coast of Palawan, between Punta Diente and Punta Tularan.

TANDUBATO, tăn-doo-bä-tō', Philippines, one of the smaller islands of the Tawi Tawi group, of the Sulu Archipelago, lying off the northeast coast of the island of Tawi Tawi; length, north and south, six miles; greatest width, five miles. The island is mountainous, Tandubato peak being the highest point. See TAWI TAWI.

TANDY, James Napper, Irish patriot: b. 1740; d. Bordeaux, France, 1803. As a Protestant leader of the popular movement he took zealous action in corporation politics, free trade agitation and volunteering affairs, and was elected the first secretary to the United Irishmen of Dublin. In 1792 he sent a challenge to the solicitor-general, Toler, and was condemned to prison till the close of the session by the House of Commons. As the viceroy had offered a reward for his arrest, he raised a formal action for illegality against him and his privy-councillors, which was dismissed at the final hearing. For distributing in County Louth a seditious pamphlet, he was about to be tried in 1793, when the government discovered that he had met the Defenders and taken their oath, with the view of effecting a coalition between them and the United Irishmen. Tandy fled to the United States, but crossed to France in 1798, where he was raised to the rank of a general of division in the French army. He joined the ill-fated invasion of Ireland, and made a futile landing at Rutland Island 16 Sept. 1798. He escaped to Hamburg, the senate of which city handed him over to the English government. On 12 Feb. 1800, he was put on trial at Dublin, and acquitted. He was again put on trial (1801) for the treasonable landing on Rutland Island. This time he was sentenced to death, but, from motives of policy, was permitted to make his way to France, where he spent the rest of his days. He was the hero of the familiar Irish song, 'The Wearing of the Green.'

TANJEFF, Serge Ivanovitch, Russian composer: b. 1856; d. Petrograd, 20 June 1915. He was son of a Russian government official and, while quite young, was studying the pianoforte at Moscow Conservatory under Lange. He was next sent to the public school but later it was decided to continue his music studies under Nicholas Rubinstein. He studied fugue under Hubert, leaving the conservatory (1875) with the award of the first gold medal. He played in Paris 1877–78, then performed through the Baltic provinces, next returning to Moscow, where he was appointed professor of instrumentation, succeeding Tschaikowsky (q.v.). On Rubinstein's death he became professor of the pianoforte but displayed his talents rarely before the public. He composed 'Oresteia' a trilogy in eight acts (1895); 'John of Damascus,' a cantata (1884), many choruses, some symphonies and quartets. He arranged for the piano works of Tschaikowsky, Glazounoff, Arinsky and others.

TANEY, tâ-nĭ, **Roger Brooke,** American jurist: b. Calvert County, Md., 17 March 1777; d. Washington, D. C., 12 Oct. 1864. He was descended from a leading Roman Catholic family, was graduated in 1795 from Dickinson College, read law in Annapolis, began practice in 1799 and was immediately elected to the house of delegates as a Federalist. Defeated in 1801 and again in 1803, he returned to the practice of law. He was married in 1806 to Anne Phœbe Charlton Key, a Protestant, the sister of Francis Scott Key. Though a Federalist, he supported the government during the War of 1812 and was an unsuccessful candidate for Congress. In 1816 he was elected to the State senate. From 1815 to 1831 as one of Maryland's leading lawyers he was engaged in many of the important cases that came before the United States Supreme Court. After the break up of his party, he became a Democrat. In 1827 he was attorney-general of Maryland; and in 1831 was appointed Attorney-General of the United States and was the trusted adviser of Jackson.



ROGER BROOKE TANEY

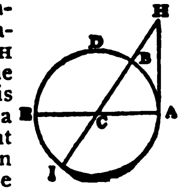
Chief Justice of the United States Supreme Court, 1836-1864

During the Bank controversy the Secretary of the Treasury refusing to remove the government deposits from the United States Bank, Taney, who had advised the removal, was transferred (1833) to the office of Secretary of the Treasury. He then removed the deposits and for this was fiercely criticised as being a «tool» of Jackson, the Senate in 1834 refusing to confirm his nomination, the first instance of the rejection of a Cabinet officer. In 1835 Jackson nominated him for associate justice of the Supreme Court, but again the Senate refused to confirm. In 1836 the personnel of the Senate having changed, Taney was nominated and confirmed as chief justice to succeed John Marshall, but not without strong opposition from Henry Clay and others. Taney at once showed tendencies toward strict construction and reversed several of Marshall's decisions. This angered the associate justices, some of whom threatened to resign. Taney was a strict constructionist rather than a States rights lawyer and judge. In the case of Prigg v. Pennsylvania the chief justice for the first time declared a State law unconstitutional. This was one of the «personal liberty» laws. In 1850, a similar law of Wisconsin was declared invalid. These decisions of the Supreme Court called forth States rights expressions from Northern legislatures. Taney's best-known decision was made in the Dred Scott case. The only point really decided was that Dred Scott was a slave, but the opinion of the court written by Taney also declared: (1) that negroes had not been regarded as citizens by the framers of the Constitution and hence could not become citizens of the United States nor have a standing in Federal courts; (2) that the Missouri Compromise was unconstitutional because Congress was bound to protect property, and the Constitution having recognized slaves as property, Congress was bound to protect slavery in the Territories. During the Civil War the Supreme Court ceased to have influence. Taney in the Merryman case (1861) denied the power of the President to suspend the writ of habeas corpus, and during the next three years opposed with no effect the arbitrary methods of the administration. As a lawyer, Taney never avoided the unpopular side. In 1811 he made himself disliked by defending Gen. James Wilkinson. In 1819 he defended a Northern Methodist minister indicted for inciting slaves to insurrection. During the trial of this case he said: «A hard necessity compels us to endure the evil of slavery for a time; yet while it continues it is a blot on our national character.» He emancipated his slaves, providing for their welfare. As chief justice, he brought system into the procedure of the Supreme Court which it had lacked under Marshall. Weak sight and bad health made writing difficult for him and the opinions of the court were usually written by one of his ambitious associates. He retained his mental powers to the last, in spite of wretched health. In person he was tall and thin, with an appearance of great physical weakness; in disposition quite, cheerful and studious, devoted to his family and friends. Consult Van Santvoord, 'Sketches of the Lives and Judicial Services of the Chief Justice of the United States' (1853); Tyler, S., 'Memoir of Roger Brooke Taney' (1876). Taney wrote an autobiography, which ended with 1801 and forms chapter I of Tyler's Memoir.

WALTER L. FLEMING,
Professor of History, West Virginia University.

TANGANYIKA, tä-gän-yē'kä, central Africa, a large lake on the boundary between the Kongo Free State and what was German East Africa, touching with its southern extremity on British Rhodesia. It lies in the Great Rift Valley, is over 400 miles long, 30 miles wide, and extends in a south-southeast direction from lat. 3° 20′ to 8° 44′ S. The shores are somewhat irregular but there are few islands or reefs. The lake is hemmed in on both sides by lofty, precipitous mountains, through a break in which the water is discharged by the Lukuga into the Kongo, when the water is high, but in low years there is little or no discharge. Nearly all the surface is navigable, and soundings at some points have gone below 2,000 feet. The sudden storms of the locality are, however, a real danger to navigation. The water is slightly brackish and swarms with fish, crocodiles and hippopotami and some marine mollusks, whose presence suggests former connection with the ocean. English and German steamers ply on the lake; Ujiji is the principal trading station on the shores. The lake was discovered by Speke and Burton in 1858, and later explored by Livingstone and Stanley. It was mapped by E. C. Hore about 1880, and the outline considerably corrected by later explorers. The first steamship was the *Good News*, launched by the Londan Missionary Society in 1884, and a half dozen now ply the waters. Consult Burton and Speke, Livingstone and Stanley's works; Hore, E. C., 'Lake Tanganyika' (London 1892); Moore, J. E. S., 'The Tanganyika Problem' (London 1903); files of the *Geographical Journal*, and 'Proceedings of the Zoological Society' (London 1906).

TANGENT, a straight line of indefinite length, which touches but does not cut a curve; also the length of a straight line which touches a curve measured from the point of tangency to the point where it meets a diameter of the curve; one of the trigonometrical functions. Tangent to a curve is the limiting position of a secant. Suppose a straight line as cutting a curve in two points near to one another, and then suppose the line to move so that the points approach each other; at the instant when the points coincide the line is a tangent to the curve. Let A B be any arc less than 90°, draw A H touching the arc at A; from the centre C draw C B H, cutting A H in H; the length A H is the tangent of the arc A B. It is now considered best to make a distinction between the tangent of an arc and the tangent of an angle. An arc is a curved line of certain length; an angle is not measured by the length of arc, for the measure of a certain angle is so many degrees, whatever may be the length in inches of the circular arc subtending it. The tangent of an angle is called a trigonometrical ratio, because it is the fraction formed by dividing the number representing the length of one side of a right-angled triangle by that repre-



Tangent.

senting the length of the other side. Consider the triangle H C A, the tangent of the angle H C A is $\frac{AH}{CA}$; this fraction is the same whatever the lengths of A H and C A. (See TRIGONOMETRY). A plane is said to be tangent to a curved surface when three points of the plane coincide with three points very close together of the surface. A list of the properties involving tangents may be obtained from works on analytical geometry.

TANGHIN, a poison yielded by the seeds of *Cerbera* (*Tanghimia*) *veneniferà*, a tree of Madagascar, which is itself called tanghin. The oblanceolate smooth leaves are crowded at the ends of the branches, whence spring also cymes of small flowers. The smooth, roundish, yellow fruits contain a fibrous nut, enclosing a poisonous kernel about the size of an almond. This was employed as an ordeal nut by the natives of Madagascar, to detect witch-craft, or to determine whether or not an accused person were innocent. The seed was pounded and administered to him; if it acted as an emetic, his innocence was established, and no great harm ensued; if he retained the poison he died quickly — a sufficient evidence of his guilt. It has been said, however, that the issue was arranged beforehand, and a strong emetic was given to the suspected criminal not doomed to death.

TANGIER, tăn-jēr', or **TANJA**, tăn'jä, Morocco, a seaport town on the Atlantic Ocean, near the western entrance of the Strait of Gibraltar, southeast of Cape Spartel. It stands on a height near a spacious bay, and presents a striking appearance when approached from the sea. It is surrounded by walls, and is defended by a castle and several forts; but consists mostly of wretched houses, huddled together in narrow, dirty lanes. The residences of the European consuls, and those of a few wealthy merchants are exceptions, and the gradual introduction of good hotels, European stores, electric lighting, etc., is effecting a notable change. The principal building is the castle, occupying a commanding height, but in a very dilapidated state. The total value of the imports, chiefly from Great Britain, France (and before the war Austria and Germany), in 1914 was $4,260,000; of the exports, $2,825,000, chiefly to Spain, Great Britain, Egypt, France and the United States. The principal articles of export are eggs, oxen, slippers, wax, woolens, goat skins and carpets. The internal traffic is chiefly with Tetuan and Fez. In the time of the Roman Empire, Tangier, under the name of Tingis, was the capital of western Mauretania. It afterward came into the possession of the Vandals, Byzantines and Arabs in succession. From the last it was taken by the Portuguese in 1471, and in 1662 was annexed to the English Crown as part of the dowry of the Infanta of Portugal. In 1684 it was abandoned by the English on account of the expense necessary to keep it up. It was bombarded by the Spaniards in 1790, and by the French in 1844. Pop. estimated at 40,000, including over 9,000 Jews, and about 10,000 Europeans.

TANGIER, a sandy island of Virginia about five miles long, in Chesapeake Bay, southeast of the mouth of the Potomac River. Tangier Sound, which washes the north shore, is noted for its large oyster beds.

TANGLEWOOD TALES, a volume of juvenile stories published by Hawthorne (1853). The narrations are based on Greek mythology and are told by a certain Eustace Bright, the supposed narrator of the stories in Hawthorne's 'Wonder Book.'

TANGUAY, tăn'gä, **Cyprien**, Canadian clergyman and genealogist: b. Quebec, 1819; d. 1902. He was graduated (1839) at Quebec Seminary and ordained to the Catholic Church in 1843. In 1860 he founded Rimouski College and the Notre Dame Convent at Saint Germain. He was appointed (1867) by the Canadian government to make researches in Paris as to Canadian history, and again, in 1887, to search Europe's archives for Canadian data. He was one of the earliest Fellows of the Royal Society of Canada. He compiled 'Dictionnaire généalogique, des familles canadiennes' (1871–90, 7 vols.); 'Le répertoire du clergé canadien par ordre chronologique' (1893, 2d ed.).

TANHAY, tän-hī', town, province of Negros Oriental, on the Tanhay River, about two miles inland from its mouth, 15 miles north of Dumaguete. It is near the south entrance to Tañon Strait, and on the coast road. Pop. 12,410.

TANIS, tā'nĭs (Hebrew, ZOAN), ancient Egyptian city, south of the Delta, before the founding of Alexandria, the chief commercial city of Egypt, capital of the Hyksos kings about 2100 B.C., and of Rameses II and Mereneptah of the 19th dynasty, who built there a great temple to Set, the god of war. It was a great city for probably 2,000 years, but its prosperity was destroyed by the silting up of the Tanitic mouth of the Nile, which was named from it, and it was destroyed for rebellion in 174 A.D. The filling up of the delta has resulted in its being left far inland, so there was no inducement to rebuild it. Numerous excavations have been made of the ruins and 14 obelisks in all were uncovered, as well as enormous temples and much statuary. Tanis has been identified with Zoan, mentioned in Numbers xiii, 22, and also with Rameses. The ruins near the fishing village on San el Hager, near the south shore of the Lake of Manzaleh, were explored first by Mariette in 1860, and in 1883–84 by Flinders Petrie (q.v.). Consult Petrie, 'Tanis' (1885); Breasted, J. H., 'Ancient Records of Egypt' (1907).

TANJORE, tăn-jōr', India, capital of the district of the same name, in Madras, on the Cauvery, about 45 miles from the sea and 170 miles southwest of Madras. It is a junction station on the Great Southern Railway of India. The fortified town, about four miles in circuit, contains the palace of the rajah, numerous pagodas and irregular streets. Outside of it are other quarters, an English church, the British residency and a remarkable pagoda, with a tower 200 feet in height and a sculptured bull, which is one of the triumphs of Hindu art. Tanjore is an educational centre renowned for Sanskrit literature, and has a college, three high schools, a medical school, etc. Manufactures of silk muslin and cotton are carried on to a considerable extent. The town was besieged and taken by the British in 1773. It was afterward restored to the rajah, from one of whose successors it was acquired by treaty in 1799. Pop. 60,341. (2) The district of Tanjore has an area of 3,654 square miles and a population about 2,400,000. It is fertile and is regarded as the granary of the Madras territories. It is for the most part covered with rice-grounds, with cocoanut groves interspersed. It is noted for its good roads. Hindu institutions still prevail here in great perfection.

TANK. An engine of war first used by the British in their attack on the Somme (France) 15 Sept. 1916. It was invented by Maj.-Gen. E. D. Swinton, of the British army, using the propelling principle of the «caterpillar» farm tractor, invented about 1900 by Benjamin Holt, of Stockton, Cal. It was afterward adopted in various forms by French, United States and German armies. Essentially a motor-driven armored vehicle, carrying machine guns or other light pieces, it is capable of traversing muddy ground, trenches, shell craters, etc., and making its way over obstacles such as trees, parapets and débris of buildings. The tank is a land battleship for the protection of attacking troops. Like the ancient Roman testudo, or tortoise, it was invented to overcome the great firing power of defending forces, themselves sheltered from infantry fire. The German general staff had learned the defensive value of the machine gun as demonstrated at Port Arthur and elsewhere during the Russo-Japanese War and had not only accumulated thousands of these weapons but had great numbers ot trained units to handle them. During the first years of the war machine guns, both on attack and defense, proved tremendously destructive to the Allies, and as action settled down into trench warfare their effectiveness was even increased. Hidden underground during the artillery preparation for an attack, they could be brought out at the last moment to take an enormous toll in lives. Major-General E. D. Swinton, of the Royal Engineers, and later of the British War Cabinet, was the famous «Eye-witness» of the early months of the war, officially commissioned to report daily fighting for the press and public. This position gave him exceptional opportunity for observation all along the western front. The «caterpillar» tractor used by the British army for towing huge guns over difficult fields suggested to him the idea of a self-propelled fort heavy enough to withstand all but the heaviest-calibred enemy fire and yet mobile under the worst conditions. During the course of a visit paid Mr. Holt by General Swinton in 1918, the tank inventor told the story: «In July 1914 a friend of mine, a mining engineer, was looking for a cheap system of transportation. He wrote me and said, 'I struck a Yankee machine in Antwerp that they call a Holt caterpillar tractor. This machine climbs like hell.' I had known of soldiers wanting just such a machine ever since the time of Julius Cæsar. I thought, if this tractor climbs *like* hell, what we want is something that will climb to *beat* hell. At the beginning of the war I had a peculiar position, with a knowledge of the needs and the chance of discovering many new things. One thing was that the Germans had secretly armed themselves with thousands of machine guns. The machine gun is the most perfect man-killing gun ever made. The Germans manufactured it in England under a British royalty. For a time before the war broke out they did not pay any royalties or submit any accounts. They knew the war was coming and they started it with 50,000 of these guns ready. They used them like artists. Our men went out against them and were mowed down by thousands.

«It appeared that the idea I had in July 1914 might produce a machine that *would* climb, which was absolutely right. It was obvious that launching assaults on enemy positions unless they were first blown to dust was merely to throw infantry into a maze of barbed wire in which they would be caught helpless, like flies on 'tanglefoot,' and mown down by rifle or machine-gun fire poured in at short range from all directions. We had to have something to go across trenches and over barbed wire.

«The machine gun was proving a disease against humanity. It was invented by the late Hiram Maxim, so you Americans have the credit of producing that disease. But you have the credit of producing the antidote, too — the 'caterpillar' tractor, invented by Benjamin Holt. We started out to make that climbing machine, the machine-gun destroyer. We made a large number of them between August 1916 and March 1917, and kept it a secret. It had been whispered around that they were reservoirs to take water to our troops in Egypt. 'Reservoirs' was good camouflage, but it was a long word, and 'tank' was better. The name stuck. They were a surprise to the Germans. They have taken thousands of prisoners and have saved thousands of lives. Frederick Palmer, the American war correspondent, estimated that they saved 20,000 lives on the Somme and as many more at Cambrai, in 1917. Not only have the tanks saved life by the moral effect of their approach and by the number of machine guns put out of action — they themselves have taken thousands of lives.»

The tanks owe their success to two essentials, first, the internal combustion engine, which has also made feasible the use in war of the airplane, submarine and motorized artillery, and, second, the traction or propelling device developed by Holt and established throughout the world as a commercial success without definite forethought as to its application in war. The main features of this mechanism are a track on either side of the machine, composed of a series of steel shoes suitably linked together, with joints protected from mud and dust; idler pulleys for laying the shoes down in front and driving sprockets for picking them up again in the rear; and uprights on the inner surface of the shoes to form continuous rail-like bands upon which roll the truck wheels carrying the weight of the machine. «Caterpillar» and tank have this much in common, that they lay down their own rails and roll over them. Aside from that their purpose and construction are quite different. The tractor is a towing machine, used in war for the rapid, certain handling of guns and supplies, not completely armored and not intended for trench-line duty. The war tractor is practically a mere duplicate of those used on thousands of farms and industrial locations throughout the world. The British, Russian, French and American armies, however, adopted it as the one feasible means of moving heavy mobile artillery over difficult ground, and over a decade of commercial and military experience together perfected the traction mechanism to the point of making the tank possible. The great weight of the machine is distributed over a long and fairly broad surface resting on the ground, hence the pressure of a 12-ton tractor on the soil is actually less per square inch than that of an ordinary man's shoe, a matter of three to six pounds per square inch. Not only is the effect of weight reduced, but the large area in contact with the ground develops enormous useful friction, or ground-grip, which is intensified usually by corrugations on the shoes or by removable lugs or grouters. The first British tanks, viewed from the side, were rather diamond-shaped, the extreme front being the height of a man off the ground. Since the track belts run lengthwise clear around the body, this shape brings additional track surface into contact with the ground during the ascent from a shell crater or ditch. The earliest type is about 34 feet long, 12 feet wide and 10 feet high, and weighs around 32 to 35 tons. A sleeve-valve motor of 120 horse power furnishes power for a road speed up to seven or eight miles per hour. Close-fitting armor sufficient to turn anything except a direct hit from a big shell protects everything but the track itself. The «male» tanks are equipped with light, quick-firing guns capable of firing shell and are essentially destroyers of machine guns. The «female» carries machine guns only, and is used entirely against enemy personnel. Guns are usually mounted front and rear, but barbettes on the sides of the tank give the widest range of aim to the battery amidships. All available wall space is packed with pigeonholes for ammunition. Six to eight men usually form the crew, an engineer, mechanician, two steersmen and two to four men at the guns, one of whom may be the tank commander. Separate clutches drive the two sides of the track, and steering is done by disengaging the clutch on that side toward which it is desired to turn. The other belt then tends to turn the tank about on a pivot. The tank is grotesque in its movements, lumbering along with little outward show of motion; poking its nose suddenly down into a deep crater and as suddenly rearing upright as it climbs a bank or parapet; wallowing through the mud; tipping at apparently perilous angles; climbing over or through ruined walls, smashing trees, or flattening out machine-gun nests. The noise within the tank is terrific and the heat stifling. The huge shape forms a target which is almost irresistible and draws a hail of bullets which would prove more effective against attacking troops. The tanks were first used on the Somme in a surprise attack at dawn — one without artillery preparation. Their success was instant and complete and their dramatic appearance not only proved the sensation of the war up to that time but gave tremendous encouragement to the Allied forces. A similar attack at Cambrai in May 1917 gave the British forces a crushing victory, which, however, was turned into a severe defeat through no fault of the Tank Corps. The French army adopted in 1917 a tank of quite different type, mounting an armored body on what was virtually the conventional tractor propelling mechanism, only considerably longer than that of the «caterpillar» itself. This type gave better protection to the track than the British machine, and mounted even heavier guns. During the spring of 1918 the British scored another surprise in the form of smaller and very fast tanks, called «whippets,» after the breed of racing dogs. These little terrors attacked like the cavalry of past wars, outrunning and cutting down the fleeing enemy, charging machine gun emplacements, twisting and turning with all the agility of a polo pony and clearing the way for the troops behind. The French followed with even smaller machines, known as the Renault Type, manned by two men each and traveling 10 to 12 miles per hour. A large number of these were built in American factories.

The Germans produced some large tanks, rather copying the French type than the British, but had achieved indifferent success up to the summer of 1918, when the offensive passed to the Allies. Bombs placed in their path were found an easy means of overturning them and putting them out of commission. Captured German tanks were lacking in mechanical refinement, proving that Allied initiative in the matter of tanks carried with it a superiority of inestimable value. The Allied tanks probably did more than any other single factor to offset the advantage in man power and centralized command held by the Central Powers during the second and third years of the war. The engineers who perfected the «caterpillar» as a tractor for the American farmer and industrial user, notably Pliny E. Holt, William Turnbull and E. P. Norelius, together with the resources of the plants which supplied thousands of Holt tractors to the British and French artillery divisions, were placed at the disposal of the United States War Department after America entered the fight. The tractor in Antwerp that «climbed like hell» was only the beginning of a remarkable development that proved to be one of America's great mechanical strokes toward the winning of the war. See TRACTOR, CATERPILLAR.

TANKAGE. Fertilizer produced from the offal of the abattoirs. Waste material such as tendons, intestines, lungs, hair, trimmings of hides, bones, horns, hoofs and some blood are the chief component parts of tankage. Hair and hide trimmings are now barred because they are practically indestructible and retain their form in the soil for years. It is treated with superheated steam under pressure to remove fat and gelatine, then mixed with a little slaked lime to prevent rapid fermentation. It is then dried and crushed. If little or no bone is present the product is termed meat tankage. Tankage varies considerably in its composition, sometimes containing as much as 12 per cent nitrogen in meat tankage and in bone tankage up to 9 per cent nitrogen with 7 per cent phosphoric acid. Tankage is a slow-acting excellent fertilizer; in bone tankage its value as a direct crop-producer is dependent largely on the fineness of the grinding. Of course the nitrogen acts in exactly the same manner on the soil as meat. Comparatively tankage contains less nitrogen than dried blood but more phosphoric acid. The considerable variation in its composition is exposed by the following table, taken from Snyder's 'Soils and Fertilizers,' all from one factory:

	1st Year	2d Year	3d Year
Moisture per cent	10.5	9.8	10.9
Nitrogen " "	5.7	7.6	6.4
Phosphoric Acid " "	12.2	10.6	11.7

In a general way 5 to 8 per cent of nitrogen can be expected and from 5 to 12 per cent phosphoric acid. In its action on the soil it is slower than dried blood. It is an excellent garden fertilizer and is also used for field crops in proper rotation and as a top-screening for sod land. As tankage in its full strength should not be allowed to come in contact with seed it is usually applied several days before planting operations, or else a special fertilizer and seed drill is used which places it near but not in contact with the seed. Two hundred and fifty pounds per acre is computed as a good dressing, but as high as 400 pounds can be safely applied under certain conditions. In dry weather an excessive application (say 800 pounds) will destroy vegetation. Of course the strength of fertilizer advisable must be calculated according to the composition of the soil; where the soil is badly impoverished a larger proportion of tankage can be usefully applied than on one kept up in good quality. Because of its comparatively slow action tankage should be used in as finely ground condition as possible and should be applied to the soil with a view to its permanent benefit rather than as a direct food for a certain crop. Tankage of a certain type and content is also utilized as a hog-feed with good results when mixed with corn or other food rich in carbohydrates or fats but poor in protein content. It is also used for feeding dairy-cows and in preparing beef cattle for market. See FERTILIZERS; LIVE STOCK, THE FEEDING OF.

TANNAHILL, tăn'ạ-hĭl, **Robert,** Scottish song writer: b. Paisley, 3 June 1774; d. there, 17 May 1810. He received little education, having been apprenticed to a weaver at an early age, and wrote some of his songs while working at the loom. In 1802 he made the acquaintance of Robert Archibald Smith, a Scottish composer, who set a number of his songs to music. In 1807 he published the first edition of his 'Poems and Songs'; a second edition being declined by the publisher, Tannahill became despondent and drowned himself. In 1838 appeared a complete collection of his writings, with a memoir by Ramsay.

TANNER, tăn'ẽr, **Benjamin Tucker,** African Methodist bishop: b. Pittsburgh, Pa., 25 Dec. 1835. He was educated at Avery College, Allegheny, Pa., and at Western Theological Seminary. He was editor of the *Christian Recorder* for 16 years, founded and was for four years editor of the A. M. E. *Church Review,* and in 1888 was appointed bishop. He was a delegate to the third Ecumenical Methodist Conference held in London in 1901, and has published 'The Origin of the Negro' (1869); 'The Negro in Holy Writ'; 'The Color of Solomon — What?,' etc.

TANNER, Henry Ossawa, American artist, son of B. T. Tanner (q.v.): b. Pittsburgh, Pa., 21 June 1859. He studied under Thomas Eakins at the Pennsylvania Academy of Fine Arts subsequently removing to Paris he became the pupil of Jean Paul Laurens and Benjamin Constant. In the Salon of 1896 he received honorable mention and a third class medal in 1897. He was awarded the Walter Lippincott Prize, Philadelphia, in 1900; Second Medal, Paris Exposition, in the same year; and medals at the Buffalo, Saint Louis and San Francisco expositions. He is represented by paintings in the Luxembourg, the Wilstach Collection, and at the Pennsylvania Academy of Fine Arts, Philadelphia.

TANNER, James, American lawyer and public official: b. Richmondville, N. Y., 4 April 1844. He enlisted in the 87th New York volunteers and was soon promoted its corporal. Losing both legs in the second battle of Bull Run, he returned to New York, studied law, and was admitted to the bar in 1869. He received an appointment at the New York custom house and became deputy collector. From 1877–85 he was tax collector of Brooklyn and in 1889 was appointed United States commissioner of pensions, but later resigned to become a pension attorney, prosecuting claims against the government 1889–1904. On 1 April 1904 he was appointed register of wills, District of Columbia by President Roosevelt. From 1876 he was deputy-commander of the Grand Army of the Republic, New York, and 1905–06, commander-in-chief.

TANNER, John Riley, American soldier and statesman: b. Warwick County, Ind., 4 April 1844; d. Springfield, Ill., 23 May 1901. He enlisted in the 98th Illinois volunteers in 1863, and was with Sherman's army during its active campaign in Georgia, Tennessee and Alabama. Returning to Illinois after the war, he engaged in farming and selling fruit trees, entered politics in 1870, as Republican candidate for sheriff, was elected, and held thereafter the offices of circuit clerk 1872–76, State senator 1880–83, United States marshal 1883–85, State treasurer 1886–88, assistant United States treasurer, Chicago, 1892–93 governor of Illinois 1896–1900. He was the recognized leader of the Republican party in Illinois, was the first in Illinois to speak openly for a single gold standard, declaring himself thereon early in 1895, and as governor his administration was able, efficient and economical. Immediately after the blowing up of the *Maine* in Havana Harbor, he secured the passage of resolutions in the legislature, tendering to the national government the material and moral support of Illinois in the event of war with Spain, and within 36 hours after the call for troops he had mobilized 10,000 men at Springfield, thus procuring for Illinois the honor of having the first regiment ready for muster into the national service. His vigorous stand against the importation of contract labor under arms at the time of the Virden riots brought about a storm of protests that his acts were without precedent and unconstitutional. These were met with the answer that he would make precedents and construe the Constitution and the law for the welfare of the State.

TANNHAUSER, tän'hoi-zẽr, German minnesinger, probably of Salzburg or Bavaria, who in the 13th century appears at the court of Frederick the Warlike and other princes. He led a wandering and adventurous life, and taking Neidhart (q.v.) as his model, celebrated in song the loves of the Bavarian peasantry. A didactic poem 'Hofzucht' (Court Behavior) is also attributed to him. He is credited with the original tale of Tannhäuser the knight. This chivalrous knight in the course of his wanderings meets a sage named Hilario, who instructs him in secret lore. At the same city a lady called Lisaura conceives a violent passion for him which he returns. Gradually, however, the tales of his instructor regarding spiritual beings lead him to desire association with some beautiful spirit in mortal form. Hilario assures him that he may attain this at Venusberg, a hill near Freiburg, where Venus holds her court in the midst of all delights. Tannhäuser starts for the haunt of the goddess, on hearing of which Lisaura kills herself. For a long time the knight remains in Venusberg, but at last his conscience touches him, he thinks with regret of Lisaura, and listens to the Virgin Mary, who calls upon him to return. The goddess allows him to depart, when he proceeds to Rome to seek from Pope Urban absolution for his sins. The Pope, however, declares to him that it is as impossible for him to obtain the grace of God, as it is for the staff which he holds in his hand to bud and bring forth green leaves. Despairing, the knight retires and enters the Venusberg once more. Meanwhile the Pope's staff has actually begun to sprout, and Urban, taking this as a sign from God that there is still an opportunity of pardon and salvation for the knight, hastily sends messengers into all lands to seek for him. But Tannhäuser is no longer to be found, and never again appears on earth. The Tannhäuser legend has frequently received poetic treatment, and Richard Wagner has adopted it (with modifications) as the subject of one of his operas. Consult Zander, 'Die Tannhäusersage und der Minnesinger Tannhäuser' (1858); Baring-Gould, 'Popular Myths of the Middle Ages.'

TANNING, broadly speaking, the art of converting the skins of animals into leather. The skin of most of the higher animals consists from the tanner's point of view of two layers, the outer containing coloring matter, the roots of the hair or fur, and being cellular in structure; the inner being thicker and of fibrous structure. The outer layer is decomposed much more easily than the inner by the action of alkalis; the latter is only soluble in water after protracted boiling, yielding a solution which gelatinizes upon cooling. Moist skin undergoes putrefaction when exposed to the air for some time. Dried skin is hard and brittle. In preparing leather the object of the tanner is, in the first place, to remove the outer layer of the skin together with all adhering hair, and, in the second place, to bring about such a change in the under layer as shall prevent it from putrefying in moist air, and at the same time render it indifferent to moisture, without, however, altering its tenacity and suppleness. The process of tanning, therefore, divides itself into two parts: (1) Cleansing the skin and removing the outer layer; (2) converting the inner layer into leather. Technically only the second part of this process merits the title of tanning. As supplementary to these there is involved the process of dressing and currying the leather. The skins used by the tanner are principally those of cattle; but the skins of horses, asses, pigs, goats, dogs, alligators and many other animals are also converted into leather. The quality of the hide varies in different species of animals, and also in the same species, depending upon the quality and amount of the food consumed, and to a still greater degree upon the vicissitudes of climate in which they are reared. Wild cattle are said to furnish hides superior to those of domestic cattle.

In the first stage of the process the skins, having been thoroughly washed and trimmed of tails, shanks and pates are soaked in water until they are sufficiently soft to allow of the adhering flesh and muscle being scraped off by means of a blunt knife; this softening process is generally aided by beating the hides with hammers or sticks worked by machinery. It is of great importance that the water be soft, or if necessary softened with borax. If the hides are green, 24 hours are allowed for the first soaking, and an equal period for a second soaking in a fresh bath. They are usually halved lengthwise between the two soakings. Dry hides are soaked 24 hours in water containing sodium sulphide, then halved and run through a dry mill for nearly an hour and then stacked up in piles for another 24 hours. They are then put back into the same bath for 24 hours more, again milled, then fleshed and put into clean, cold water overnight. If the soaking is too prolonged the skin cannot be made into good leather. The hides are now generally placed in pits with milk of lime, whereby the hair and upper layer of skin is gradually loosened. This operation requires about six days, the hides being changed daily to a fresh lime bath. They are then again subjected to the action of the dressing knife. The final process preparatory to tanning consists in bating the hides in a very dilute acid liquid in which a mild putrefactive fermentatation is going on. This bath is commonly made with lactic acid and glucose, the latter furnishing the fermentative ingredient. In this bath, which continues for six days, the lime is entirely removed and the hides are considerably softened and swollen. The prepared hides may now be tanned — that is, enabled to withstand putrefaction without loss of suppleness — by the action of different materials. These materials may be broadly grouped as (1) tannin, (2) metallic salts, (3) oily matters. When tannin is used the process is always called tanning. When metallic salts are used the process is in some localities called tawing; and when oily matters are used, shamoying or oil-tawing.

Vegetable Tanning.— The sources of tannin used in the vegetable tanning processes are chiefly oak bark and hemlock bark. The former is taken from the yellow and red oaks, though all oaks carry a proportion of tannin which may be available in some circumstances. The tannin content of the best oak bark ranges from 9 to 14 per cent. Hemlock bark is in much larger supply, and, therefore, is more largely used. It carries from 7 to 8 per cent of tannin. Chestnut wood is used to a considerable extent in the South, and an extract of this wood is marketed in other parts of the country showing a tannin content of from 28 to 32 per cent. The quebracho wood of South America is one of the largest sources of tannin, the dry wood yielding 18 to 24 per cent. The extract of quebracho, the form in which it is generally marketed, carries from 62 to 65 per cent of tannin. Other important sources are: Sicilian sumac, with 25 to 30 per cent tannin; gambier, a dry extract of the plant, with 60 per cent tannin; myrabolans — the dried fruit of a tree of India — with 30 to 38 per cent tannin; Mexican mangrove bark, 30 per cent, and African mangrove bark, 40 per cent tannin; valonia — the acorn cups of an Asia Minor oak — 30 to 40 per cent tannin; and palmetto extract, from the roots of the palmetto tree, about 20 per cent tannin. The amount of tanning materials which the United States normally imports is shown by the figures for the fiscal year ended 30 June 1916 — before the entry of the United States into the war caused a dearth of merchant shipping. In that year the amount of quebracho was 106,864 tons, valued at $1,598,465; of mangrove bark was 21,186 tons, valued at $582,992; and of all other tanning materials and extracts, a value of $668,166. The annual consumption of domestic tanning materials is about 900,000 tons of hemlock bark, 400,000 tons of oak bark and 500,000 cords of chestnut wood.

Leather tanned with oak bark or its extract is of a light fawn color, regarded as the most desirable. Hemlock produces a reddish leather; quebracho a yellowish tint; chestnut, a brown color; and mangrove a still deeper brown. Hemlock is rarely used alone, being too harsh; it is commonly combined with quebracho, with which it yields a fine, soft and pliable product of superior color. Quebracho and palmetto are used together to advantage in both quality and color of the leather. A highly approved process combines hemlock, chestnut and quebracho extracts for a primary tanning, and quebracho and gambier in combination for retanning. This formula is particularly suitable for large and heavy hides. All hemlock-tanned leather is improved by retanning with gambier, or gambier and sumac combined. Chestnut tannings are much improved by retanning with sumac. Thick and heavy hides are usually tanned «in the bark» as it is termed; thinner hides «in liquor.» In the former process a layer of spent bark is spread upon the bottom of a wood-lined pit, upon this are piled successive layers of hides and fresh bark, the whole is covered with spent bark and the pit is filled with water. After 8 to 10 weeks the hides are removed to a second tank containing less bark, from which, after three to four months, they are again removed to a third tank containing a yet smaller quantity of bark, where they remain for four to five mouths. If necessary the process is repeated several times. The hides increase in weight from 10 to 12 per cent during this process. The total quantity of bark required averages six times the weight of the dry hides. Tanning «in liquor» consists in placing the hides successively in solutions of tannin of gradually increasing strength. The tannin is thus caused to penetrate the hides completely. The thinner hides must be immersed for 6 or 8 weeks, the thicker for 12 or 24 weeks in the tanning liquor. A more rapid process is obtained by combining the tanning agents. A liquor compound with quebracho extract and palmetto extract is one of the quickest, and the leather may be pressed and split and the grains retanned after 18 to 20 days. The modern tanner divides his work into three stages: in the first the hides are colored by immersion for 24 hours in a weak liquor, activated by one part of hemlock to two parts of quebracho; in the second stage the tanning process is carried forward by strenghtening the liquor by fresh additions twice daily until it tests 30° (barkometer); the third stage follows the pressing to remove superfluous liquor and the splitting of the hide into grains, and is a retanning process with a strong gambier and sumac liquor; for about one hour. The entire process may be completed within eight days.

Mineral Tanning.— This process depends upon the action of chromic acid instead of tannic acid. Of very recent introduction the chrome process has extensively displaced the much slower tannic acid processes and its product seems equally durable and acceptable in the industries. After the hides are bated and washed they are pickled with sulphuric acid and salt or with aluminum sulphate and salt. They are then put into a solution of salt in a vat with paddles, and the paddles run for half an hour. The chrome liquor, a compound of potassium bichromate and sulphuric or muriatic acid, is then added until the bath reaches 50° B., the paddles being run for one hour. More of the chrome liquor is then added, and the paddles run for three hours longer. The remainder of the chrome is then added and the hides left until the tanning is complete, which will take about six hours. They are left in the liquor for 12 hours longer and then pressed and placed in a second bath of sulphurous acid and finally washed with a solution of borax, when they are ready for splitting and retanning with gambier or palmetto. This is the process commonly employed in making calfskin, goatskin and sheepskin leathers, though they are often tanned with alum. In the latter case, when the skins have been washed and prepared by being submitted to processes closely resembling those already described they are separately soaked in a tepid bath containing alum and common salt dissolved in water; they are then, without being dried, placed in heaps for a few days, after which they are wrung out and dried slowly by exposure to air. The alum bath for 10 skins is usually prepared by dissolving 0.70 kilos of alum and 0.30 kilos of common salt in 22.5 litres of boiling water. Aluminium chloride is produced by the mutual action of the salt and alum, and is absorbed largely by the skins; the excess of salt appears also to aid in the conversion of the skins into leather. The tawed and dried skins are softened by being damped and stretched between a curved iron and a movable steel plate, after which they are again dried. Heavy hides are sometimes tawed for the use of the saddler by steeping them in a bath containing a larger quantity of alum and salt than that mentioned above, drying them and then rubbing them with tallow before a charcoal fire. A very strong leather may thus be prepared in a comparatively short time. The more delicate kinds of leather — especially that for making kid gloves, kid shoes, etc., are tawed by immersion in a bath containing alum, salt, yolk of eggs, wheaten flour and water. The oil contained in the egg yolks confers upon the leather a great degree of softness, the gluten of the flour seems to aid the skin in the absorption of aluminium chloride. The skins are stretched by hand and rapidly dried in the open air; they are then damped, placed between linen cloths and trodden upon until they become soft. They are finally polished by rubbing with a glass disc smeared with white of egg or a solution of gum, etc.

Oil tawing.— So called wash leather or chamois leather is prepared from the skins of deer, sheep, calves, etc., by tawing them with oil. The skins having been washed, limed, etc., in the ordinary way, are repeatedly rubbed with animal oil, exposed to the beaters of a fulling machine, and dried. The oil employed is turkey red oil, made by treating castor oil with sulphuric acid. Other oils have been employed, but castor oil remains the only oil which has been successfully sulphonated. A small quantity of carbolic acid is sometimes added. The skins are stretched and sprinkled with oil, which is gently rubbed in with the hand; they are then placed in bundles in the fulling machine and exposed to the action of the beaters for several hours. After exposure to the air the skins are again rubbed with oil and again placed under the beaters; these processes are repeated until the fleshy odor of the original skin is no longer perceptible. By exposure to a warm atmosphere a process of gentle fermentation is originated within the skins, whereby the pores are dilated and the oil is enabled to penetrate the mass more thoroughly. The excess of oil is finally removed by washing with a dilute warm caustic lye; the skins are then dried and dressed. Wash-leather is much used for making military belts, gloves, socks, etc., for surgical applications, for cleaning glass and porcelain and for polishing jewelry. A great variety of other processes are in use for tanning, many of them being patented. These formulas call for such ingredients as witch hazel, horse chestnut, poke-root, crane's bill, blackberry roots, persimmon bark, nicotin, formic aldehyde, sodium nitrate, chromium chloride, iron sulphate, zinc sulphate, etc. For specific purposes these may have their uses, but the basic processes of tanning have remained unchanged for many years.

The manner in which tanning is conducted in different establishment varies much in detail, though the general principles are the same. Instead of that uniformity in the commoner processes which might be expected from accurate knowledge, each tanner treasures his secret as to the best process for bringing about the chemical transformation which it is their common object to effect; and these secret methods, the value of which as the result of a limited experience is inevitably overestimated by those whose knowledge is confined to that experience, prevent comparison and the rejection of superfluous and perhaps injurious operations. The trade of tanning may, however, be said to be still in its infancy, and it must be admitted that the chemical processes involved are far from being solved. It was only at the end of the 18th century that scientific methods began to be applied to leather-making, and although not much progress has hitherto been made, considerable activity has been shown in the pursuit of improvement. The extreme slowness of the process of leather making by any of the ordinary processes of tanning has afforded a strong motive for inquiry as to the possibility of hastening it by additional contrivances. Much time has been saved by splitting the leather as it comes from the lime pits, and tanning the thinner splits individually. The necessity of preserving the solidity and tenacity of unsplit hides seems to militate against any rapid method of progress in the passage of the tanning agents through and through them.

TANNINS, or TANNIC ACIDS, are compounds of high molecular weight, widely distributed in the vegetable kingdom. Some varieties are found in diseased vegetable tissues or in abnormal growths, while others are present in the different parts of the healthy plant. Gallotannic acid is present in gall-nuts, caffetannic acid in coffee beans, morringa-tannin in yellow wood, quercitannic acid in oak-bark, ellagitannic acid in pomegranate rind, etc. These tannins are not by any means identical in all their physical properties and their chemical conduct; still they possess some characteristics in common. They are usually amorphous, have an astringent taste, dissolve in hot water, convert animal hide into leather and yield dark-blue or green precipitates with ferric salts. Of these varieties gallotannic acid — the chief constituent of the commercial product — has, more than any other tannin, received the attention of investigators. The statements in this article refer chiefly to this compound.

Gallotannic acid is extracted from powdered galls by treatment with aqueous or alcoholic ether. On standing the liquid separates into an upper layer containing gallic acid and other impurities and into a lower layer, from which crude tannic acid is obtained by spontaneous evaporation. From this product impurities may be further removed by treatment with dry ether in which the acid is insoluble. Ethyl acetate and acetone have also been used quite extensively for the extraction and purification of tannic acid. The compound has further been purified by treating its water solution or suspension with lead acetate. This reagent precipitates a lead salt which is readily decomposed with hydrogen sulphide.

Gallotannic acid is an amorphous substance with an astringent taste, soluble in water, ordinary alcohol, glycerine, ethyl acetate and acetone; almost insoluble in dry ether, chloroform, benzene, carbon bisulphide and petroleum benzine. Its aqueous solution gives an acid reaction with litmus, although its acidity cannot be determined by direct titration, an indicator being practically valueless. With pure *ferrous* salts aqueous solutions of tannic acid give no coloration at first, but a color is soon developed by atmospheric oxidation and a blue-black precipitate is ultimately formed. With *ferric* salts a bluish-black precipitate is at once formed; this reaction is taken as a basis for the use of the compound in the preparation of blue-black inks. Cold alkaline solutions of tannic acid absorb atmospheric oxygen very readily, forming highly-colored oxidation products. Tannic acid solutions form precipitates with many metallic salts, with a number of mineral acids, with nearly all alkaloids and glucosides and with gelatin, albumin and starch. Animal hide kept in a solution of the acid is gradually converted into leather. At 215° C. tannic acid decomposes into water, carbon dioxide, pyrogallol and metagallic acid and with boiling dilute sulphuric acid it is hydrolysed into gallic acid.

Tannic acid is extensively employed in the process of tanning, in the manufacture of gallic and pyrogallic acids, in the preparation of inks and as a mordant in dyeing. With formaldehyde it forms a condensation product which is used in the manufacture of hygienic fabrics. Tannic acid has also found extensive application in medicine. It is recommended as an antidote to metallic poisons with which it usually forms insoluble precipitates. It is employed as an astringent to prevent excessive secretion in ulcers and sores and to check bleeding. Tannigen (tannyl triacetate), tannocol (gelatin tannate), tannalbin and bismuth tannate have been prepared and employed in intestinal catarrh. Mercurous tannate has been used in syphilis, tannochrom in skin diseases, tannobromine in the treatment of scalp diseases.

Although oak-bark, gall-nuts and other natural sources of tannic acid had been used by the ancients, the compound was first isolated and described by Scheele in 1787. Berzilius (1827) assigned to it the formula $C_{18}H_{18}O_{12}$. Liebig (1834) modified this to $C_{18}H_{16}O_{12}$. In 1850 Mulder called attention to the hydrolysis of the compound into gallic acid. Strecker (1852) claimed that tannic acid was a glucoside in which three molecules of gallic acid combined with one molecule of glucose; while others up to the present day have contended that the purified substance contains no sugar. In 1870 Schiff claimed to have converted gallic acid into tannic acid by a process of condensation. He called his product digallic acid and assigned to it the formula $C_{14}H_{10}O_9$, which had also been adopted by some earlier investigators. Schiff's digallic acid formula remained unquestioned for many years, but in 1890 Ph. van Tieghem, C. Scheibler and others made the observation that tannic acid was optically active, a property that rendered Schiff's digallic acid formula improbable. After several years of study Nierenstein (1908) announced the conviction that tannic acid was a mixture of Schiff's digallic acid and optically active leucotannin. While Emil Fischer's researches with the carefully purified substance pointed to the conclusion that tannic acid might be considered as a compound of one molecule of glucose with 10 molecules of gallic acid. The hydrolysis of the compound into glucose and gallic acid, as well as its synthesis, are cited as possible confirmations of this view. At the same time it is frankly admitted that the question of structure has not received its final settlement.

Of late years compounds showing the properties of tannic acid have been prepared by synthetic processes. Of these so-called «Syntans,» Neradol and Neradol D deserve mention. They are obtained by heating phenol sulphonic acids with formaldehyde. It is claimed that the amount of Neradol required to tan skin is less than of any other vegetable tannin.

Lehigh University.

TANOAN, tä'nō-ăn, or **TAHÁNO, FAMILY**, a linguistic stock of American Indians inhabiting a group of pueblo villages in the upper Rio Grande Valley, New Mexico. The chief of the modern villages are Isleta, Jemez, Picuris, Pojoaque, San Ildefonso, San Juan, Sandia, Santa Clara and Taos. They are considered the most representative pueblo group, and are probably the most ancient of the pueblo settlements. The villagers who number about 3,000 have not perceptibly advanced in civilization, from the descriptions given of them by Spanish explorers who first visited the villages over three centuries ago. Deriving their name from Tahano, the Indian name of the chief Tano pueblo, they then inhabited a number of other villages, now in ruins, in Mexico, Texas and Arizona grouped under the names Tano, Tewa, Tigua and Piro. Consult Bandelier, H. F. A., 'The Indians of the Southwestern United States, 1880–85' (Boston 1890–92).

TAÑON, tä-ñōn', a strait in the Philippine Islands between Cebu on the east and Negros on the west; the northern entrance is 20 miles wide and the southern entrance five miles; the length is 103 miles. The shores are steep and generally free from obstructions; there are a number of important towns on its coasts.

TANREC, or **TENREC**, a genus (*Centetes*) of insectivorous mammals, distinguished by the elongated muzzle and the short rounded ears. The body is covered on the upper surface with spines and bristles; no tail exists. These animals inhabit Madagascar, the most familiar species being the *centetes ecaudatus*, while other species are the tendrac or spiny tanrec (*C. spinosus*) and the banded tanrec (*C. madagascariensis*). The *C. ecaudatus* is an animal of about the size of the European hedgehog, but with a larger body, the legs being also more elongated. The quills or spines are yellowish at their bases and black toward the tips. These animals hibernate like the European hedgehogs and live in burrows, which they excavate by means of their strong claws. They do not, however, possess the power of rolling themselves up into a ball-like form for defense. The food consists of insects, reptiles, etc. All three species are eaten by the natives of Madagascar.

TANSY, a composite herb (*Tanacetum vulgare*), introduced into America from the northern Old World. It is a familiar weed of waste lands and roadsides, probably escaped from old herb gardens and maintaining its station with vigor — a characteristic which is said to have suggested the Greek name *Athanasia*, «immortality,» which has been corrupted into «tansy.» It is a handsome plant, with dark-green, deeply cleft and pinnatifid, fern-like leaves, numerous on an erect stem about three feet high, which is topped by somewhat dense corymbs of flat, button-like, gold-colored heads of rayless florets. It has a rank odor and bitter, aromatic flavor, which caused it to be used formerly as a seasoning herb, a practice now practically obsolete. The acid juice contains a volatile oil that is very poisonous, yet tansy was a popular anthelmintic and stomachic drug and still holds a place in materia medica as an aromatic bitter and irritant narcotic; it is employed to relieve the pain of ulcers, bruises and rheumatism. White tansy is the sneezewort, and several other plants of similar aspect are also called tansy; while *Argentina anserina* is the goose-tansy.

TANTA, or **TANTAH**, tän'tä, Egypt, capital of the province of Gharbîeh, in the Delta, about 55 miles by rail north of Cairo. It has large public buildings, a palace of the Khedive, bazaars and three important annual fairs. The centre of education is the Mosque of El Ahmadi where in 1914 2,860 students and 113 professors were registered. Pop. about 59,000.

TANTALITE. A rare mineral consisting of tantalite of iron and manganese, with 72.4 per cent of tantalum when pure. An important source of that metal, at one time used extensively for filaments for incandescent electric lamps; obtained in Black Hills of South Dakota and in Virginia.

TANTALUM, chemical symbal Ta, atomic weight 183, is a rare element found by Ekeberg (1803) in a mineral afterward called tantalite ($FeTa_2O_6$) obtained from Finland. It is also found in the minerals samarskite, yttrotantalite and fergusonite. The other rare element columbium is usually found with it. The metal is obtained by heating the potassium and tantalum fluoride with metallic potassium and extracting the potassium fluoride with water. It is a black substance with a metallic lustre, insoluble in sulphuric, hydrochloric or nitric acids or aqua regia, but soluble in hydrofluoric acid. Like columbium it ignites when heated in the air, forming tantalum oxide, Ta_2O_5. This oxide unites with certain metallic oxides or hydroxides to form compounds called tantalates which may be considered as derived from hypothetical acids called tantalic acids. Tantalum is used in the manufacture of electric lamps. It is found in pegmatite veins in the Black Hills of South Dakota and at other places in the United States. The chief supply comes from Australia and Scandinavia.

TANTALUS, tăn'ta-lŭs, in Greek mythology, king of Phrygia or Lydia; son of Zeus or Tmolus. Tradition does not agree as to the crime by which he forfeited the favor of Zeus and merited condign punishment. According to one account he offended Zeus by his perfidy; according to another he stole away the nectar and ambrosia from heaven, and a third story is that he murdered his own son Pelops and served him up for some of the gods. Homer represents him as standing up to his throat in water, with the most delicious fruits hanging over his head, which, when he attempts to quench his thirst or to appease his hunger, elude his grasp. According to Pindar a great rock is suspended over his head, which constantly threatens to fall and crush him.

TANTIA TOPI, tän'tē-ä tō'pē («the weaver who became an artilleryman»): b. Bithur, near Cawnpore, India, about 1819; d. 18 April 1859. Rebel leader during the Indian Mutiny of 1857. He displayed marked ability; beginning as a lieutenant of Nana Sahib, after the flight of the latter into Nepal, he assumed command and continued the war for months, putting the English to no end of trouble, being the last rebel in the field. He was finally captured, tried and hanged in April 1859.

TANTRA, the name given in Hindu religious lore, to dialogues between the god Siva and his bride in one of her many forms, but chiefly as Uma and Parvati. The Tantrikas or followers of the Tantras, consider them a fifth Veda and attribute to them equal antiquity and superior authority. In them is found instruction in the methods of acquiring six superior faculties, as what would now be termed clairvoyance, second sight, observation on the astral plane, leaving of the physical body, etc. Meditation and its results is dealt with at great length, breathing instructions are given that suggest modern Yogi practice and there is instruction in the languages of animals. Consult 'The Tantra of the Great Liberator' (trans. London 1913). See INDIA.

TANTUM ERGO, tăn-tŭm ĕr'gō, the hymn sung in the Roman Catholic Church at benediction with the Holy Sacrament.

TANZIMAT. See TURKEY, *Government*.

TAO TE KING. Laotze, author of the 'Tao Te King,' «Book of the Way and Virtue,» lived in the 6th century B.C., and was keeper of the archives at the capital of the Chau, where Kongtse (Confucius) visited him. Later many legends, borrowed from Buddhism, gathered around his memory, until he became chief deity of the Taoists and his 'Tao Te King' their chief scripture. (See TAOISM). The 'Tao Te King' treats the world, man, morality and politics in reference to Tao, variously translated Way, Word, Reason, Nature, God. An understanding of the 'Tao Te King' is greatly aided by familiarity with Brahmanic and other mysticism, and Douglas even supposes that Laotze derived his doctrine from India; but if so he thoroughly assimilated it to the Chinese mind, while his references to Chinese antiquity indicate originality. In any case, Tao is distinguished from the ontological Brahma by the characteristic Chinese stress upon its ethical content. Tao is the Absolute which unfolds its mysterious nature into Shangti (the Chinese personal god), the rational world and moral man; and will finally withdraw all three again into itself. After introducing his Tao, Laotze passes from one theme to another without logical sequence, but always meaning to exemplify the working of Tao, limited. as usual with the Chinese, to the moral and political spheres. Laotze was no philosophic dreamer; but, like his great rival, Kongtse, was offering a remedy for the troublous times in which they lived. Laotze's remedy was a return to Arcadian simplicity, such as existed before rules and laws were devised or needed. With this pessimistic rejection of entire human culture, Laotze constantly joins rejection of its base features, such as ambition, pride, loquacity and greed; while he commends its obscure and weak but indispensable elements. In the course of this exposition, many a gem of insight is brought to light, though often embedded in dull earth.

Selections from the 'Tao Te King'.— «Therefore the sage, in the exercise of his government, empties the peoples' minds, fills their bellies, weakens their wills, strengthens their bones. He constantly tries to keep them without knowledge and without desire, and where there are those who have knowledge, to keep them from presuming to act on it. Where there is this abstinence from action, good order is universal.»

«There is no guilt greater than to sanction ambition, no calamity greater than to be discontented with one's lot, no fault greater than the wish to be getting. Therefore the sufficiency of contentment is an enduring and unchanging sufficiency.»

«To those who are good to me, I am good; and to those who are not good to me, I am also good, and thus all get to be good. To those who are sincere with me, I am sincere; and to those who are not sincere with me, I am also sincere, and thus all get to be sincere. The sage does not accumulate for himself. The more that he expends for others, the more does he possess of his own; the more that he gives to others, the more does he have himself.» Consult Legge, J., 'The Texts of Taoism' (2 vols., in 'Sacred Books of the East').

EDMUND BUCKLEY.

TAOISM. Taoism ranks with Confucianism and Buddhism as the three great religions of China, which amount in practice to one religious compound, wherein Confucianism is politico-moral and ceremonial, Taoism is religious and magical, while Buddhism deals in metempsychosis and the future life. Only the priests are exclusive followers of either Taoism or Buddhism. There are even «temples of the three doctrines,» where idols of Buddha and Laotze stand on either side of Kongtze. The Chinese ask about a religion not, «Is it true?» but «Is it moral?» Tested thus, all their religions seem to the Chinese acceptable.

Taoism is the folk-faith of the Chinese, primitive but receiving various accretions through the centuries, such as a corrupted form of Laotze's doctrine of the Tao (from which Taoism takes its name) in the 6th century B.C., a magician deified as Yu Hwang in the 7th century A.D. and Kwanti a soldier deified as War-god only in 1828. Especially in the three centuries B.C., emperors and folk alike, under the leadership of Taoist priests, neglected labor to search for the elixir of life and for power to transmute base metals into gold. Thus Taoism came to include most of the national hero-worship and nature-worship (of a type lower than Confucianism) and most of the divination and magic, the latter including *fangshui*, the Chinese geomancy, according to which the location of a house or a grave depends on supposed magnetic currents, the azure dragon, the white tiger and the like. This folly is strong enough to form the chief obstacle to civil engineering in China, as when a telegraph pole would disturb the *fangshui* of a region or a railway that of a cemetery!

The gods of Taoism furnish a good index to its heterogeneous origin. The San Ching, «Three Pure Ones,» are simply a triplication of Laotze, done to correspond with a Buddhist triplet. But, since these are sunk in contemplation, the superintendence of mundane affairs falls to Yu Hwang Shang Ti, «Gemmeous Sovereign God.» The first elements have souls which rose to become the five planets and thus divine. Many stars are deified. The Dragon-king, a familiar feature of Chinese processions, seen even in America, represents water in its varied forms and, therefore, has numerous temples beside seas and rivers and is discerned among rain clouds. Sun cult survives in the bonfires of the spring festival. Licentious festivals were long ago suppressed in accord with the politico-ethical nature of the dominant Confucianism. Sacred animals are the fox, snake, hedgehog and weasel; sacred trees are the cassia, willow, banyan, pine and peach. To the ancestral tablets and an image or picture of the Kitchen-god (originally a Fire-god) found in every Chinese house the Taoist adds certain other figures according to locality, trade and preference.

Taoism worships also certain culture-gods who preside over various vocations. Thus, students revere Wan-chang (a deified scholar) as God of Letters, soldiers worship a deified soldier as Kwanti the God of War, and tradespeople worship Tsai-Shin, God of Riches. Besides such great gods there are innumerable *shin* «spirits,» of whom Chinese live in dread by day and especially night.

The priests of Taoism are probably cognate with the *shaman* of Siberia, but its monks, nuns, pope, monasteries and temples were copied from Buddhism. These priests conduct the ritual for the city and State gods, purify streets, houses and persons from evil spirits, and prepare paper amulets for pasting on doorways to exclude spirits. Though Taoist priests marry, their vocation is not hereditary, they are recruited from the lowest classes, are ignorant and immoral, and are generally despised by the *literati*, the learned officials of China. From these priest-magicians one must distinguish the monks who observe Laotze's principles by celibacy, seclusion and mystical communing.

The Taoist scripture is far less the recondite 'Tao Te King' (q.v.) of Laotze than «The Tractate of Actions and their Retributions,» an anonymous tract composed about the 11th century A.D., which is universally popular. Its 212 brief statements fall into five sections. The first of these declares that happiness follows virtue as misery follows vice; the second states that «spirits in heaven and earth,» in «the great Bear constellation» and within «men's person» execute this earthly theodicy by deducting some days from a man's life; the third specifies the virtues man must practice and their reward in making him an «immortal»; the fourth, and by far the longest, names the vices he must shun; while the fifth provides for repentance and enacts a new rule of theodicy. The tract is characteristically Chinese, agreeing with Confucianism in its stress upon morality and in its belief in an earthly theodicy; but its doctrine of the immortals probably originated from Buddhism. Another popular religious tract, the «Book of Secret Blessings,» expresses in 541 words brief moral rules with a flavor equally of Taoism, Confucianism and Buddhism, by all of which indeed it is approved. In subsequent centuries Taoism further adopted from Buddhism its doctrine of hells and it exhibits in its temples realistic figures of the damned under torture. Foreigners name such a temple «Chamber of Horrors,» and its gruesome spectacles are well adapted to terrorize the obtuse minds of the Chinese masses.

EDMUND BUCKLEY.

TAPAJOS, tä-pä-zhos', Brazil, a tributary of the Amazon, formed by the confluence of the Arinos and Juruena, which rise on the edge of the Brazilian plateau in the state of Matto Grosso. The main stream is at first hemmed in by mountains and obstructed at intervals by rapids, but after it enters the state of Para it is a broad and deep stream. It enters the Amazon at Santarem in about long. 54° 30′ W. A few miles above its mouth it broadens into a lake-like expansion 12 miles wide and 75 miles long. The river is 1,040 miles long and steamers ply on it for 210 miles.

TAPESTRIES. The *peristromata* of the ancient Babylonians were highly praised by Lucretius, Plautus, Stichus, Martial and Italicus and have been considered as tapestry work of some kind. That they were a costly and greatly admired product is proven by such facts as that Metullus Scipio paid 800,000 sesterces (about $40,000) of their money for such work and Nero 4,000,000 (about $200,000). Homer writes of tapestries of great beauty woven by the Greeks; the Book of Exodus speaks of textile hangings done by the Hebrews. But all these may have been embroideries and not woven on a loom, for it is certain the «Sarrazinois carpets,» made earlier than the 12th century, were of embroidery work, not woven. The walls of many European Continental churches and princely palaces were covered with high warp (*haute lisse*) tapestry hangings by the 13th century. And the tenterhooks are found on the walls of halls in mansions of the 14th century from which the tapestries were suspended. Certain textile fabrics have been unearthed from the remains of the ancient Panopolis (Fayoum) which are true tapestries in our modern sense of the word. The history of their production is in doubt but they have been called «Coptic tapestries.» They date from different periods ranging from the 2d to the 8th or 9th centuries and have always been discovered in the form of narrow strips attached to clothing as a border decoration. These very ancient pieces display crude decorative designs in several colors.

Gothic Tapestries.— By the 13th century, incited by the Oriental works of art brought back by the returning Crusaders, Europe started an era of industrial art work. Flanders progressed most rapidly in the art of weaving tapestries and her «imaged cloths» (*draps imagés*) produced at Arras quickly became famous; so much so that the term «arras» soon became the familiar name for tapestry and still remains so in some languages. Brussels became the next centre of this industry to be followed by Valenciennes and Tournay. From the last half of the 15th century to the middle of the 16th century the richness and pure beauty of the «Gothic» weavings produced have caused the period to be termed the Golden Age of tapestry; it is frequently referred to as the «Gothic-Renaissance.» Arras and Paris were now vieing with each other as the principal centres of production. Every royal court and every baron and knight showed enthusiastic energy in acquiring these lovely coverings to hide the bareness of the stone walls and to act as curtains for the door openings of their castle interiors. The work of the tapestry ateliers was pushed strenuously to meet the great demand; and when Paris fell to the British arms whole Flemish provinces were given over to the industry to meet the still greater demand. But the persecutions of Charles the Bold drove the weavers (1477) from Flanders to bring a more flourishing industry to Brussels and Bruges to the loss of Arras and Liège. The tapestry products dating from 1483 to 1515 are generally considered by connoisseurs as the greatest achievements of the weavers' looms known from the point of pure art. But these beautiful hangings were not confined to the castles of royalty and nobility, for the wealthy merchants acquired them and displayed them from windows and balconies for the admiration of the passing crowd when the streets were decorated in honor of royal and civic processions and fêtes. The lists, at tournaments, were gay with such rich decorations. With the advance of time we find primitive stiffness in depiction, entailed with the Byzantine influence and ecclesiastical demands, gradually pass to the soft curves of naturalistic expression. The great space, formerly divided up into numerous scenes by quaint separating motifs of Gothic columns and arches, now becomes one of scenes blending into one another, later to be given over to one main scenic picture. The backgrounds that in the early Gothic weaves were occupied by dense masses of plant life (an Oriental decorative method, doubtless acquired through the Crusades) and known to us as «verdures,» pass to landscapes and castles lacking in perspective. These *verdures* are known to the auctioneer and his catalogue as «mille-fleurs» on account of the many little blossoms peeping out from the leafage. Another distinctive style was called «à personnages» crowded in the background with *persons* streaming from hills, churches, palaces. Belonging to this early period of unequaled art we find such talented tapissiers as Nicolas (or Colin) Bataille, the Parisian, of the 14th century, who worked in France and Flanders; Jacques Dourdin, who worked under the Duke of Burgundy. A clever tapestry designer was Jan van Room (Jean de Rome) in Gothic-Renaissance style. These figure-decorated pieces are known as «historiated.»

Renaissance.— The decadence of the tapestry art sets in with the 16th century; the textile now attempts to imitate the painted canvas, the weave in wool to simulate brush work in pigments. To get this strictly artificial effect the few simple woolen dyes have to be multiplied into innumerable hundreds of color tones and shades. The genius of a Raphael is called into play to design (1515) the «Acts of the Apostles» set of cartoons for tapestries to adorn the Sistine Chapel at Rome. In about four years Peter van Aelst, at Brussels, had reproduced the great work into color in the loom. They cost Pope Leo over $130,000, in money of that date. This ended the pure method of tapestry treatment in the Flemish ateliers and Renaissance painting in wool takes the place of Gothic, for the weavers of Brussels and other northern centres now got cartoons from Mantegna, Paolo Veronese, Andre del Sarto, Giulio Romano and other Italian artists to follow out on their looms. The «Acts of the Apostles» designs were later reproduced in most European centres. Wilhelm de Pannemaker was noted for his work in this period and style, as were the Pannemaker family. With the enormously increased demand the ateliers grew vastly in numbers and we have centres in Brussels, Arras, Tournai, Bruges, Enghien, Oudenarde, Middlebourg, Lille, Antwerp and Delft. As might be expected with a pressing demand much greater than the supply, haste and deterioration set in from careless execution. Low warp (*basse lisses*) were started. Rubens was making cartoons for the Netherlands now.

Italian Tapestry Factories.— Already in 1420 Johannes Thomae de Francia (French) was managing, at Mantua, an atelier for the Gonzaga family. Succeeding him came Nicolas, Guidone, Adamante (all French). Flemings were employed about 1450 (Rinaldo Boteram of Brussels, and one Rubichetto). Giovanni dei Conradi and Andre Mantegna did cartoons. In Venice looms were started by John of Bruges and Valentine of Arras in 1421. Boteram set up looms also in Siena. Renault de Maincourt (about 1455) did «The Creation of the World» for Pope Nicolas V. In 1441 Ferrara had looms worked by the Flemings Pietro di Andrea and Giacomo de Angelo; while Nicolas and John Karcher worked there with Lucas Cornelisz the designer. Rost and five other Flemings arrived, a school was opened and a local artist, Battista Dosso, designed «Life of Hercules,» «Scenes from Metamorphoses» and other beautiful work. Extant pieces of this school are (in Ferrara Cathedral) «Story of Saint George and Saint Maurelius» and (in Como Cathedral) «Story of the Virgin.» In Florence the Medici established an atelier called «Arrezaria Medicea» (1546–1737), under Karcher and Rost. Johan van der Straaten was director about 1570 and did prolific work. Many pieces are in the Florence Tapestry Museum, including the Karcher and Rost best productions «The Story of Joseph» in 20 pieces. Cartoons were designed by Jacopo Sansovino, Bacchiacca and others. Master weavers (17th century) were Papini, van Asselt, Lefèvre, Pollastri, the two Termini, Bartoli, Manzi, Cavalieri, Bucci. In Rome, Cardinal Barberini (1633) established an atelier with Jean François Romanelli as art director, Giacomo della Riviera director of works, M. Wauters (of Flanders) was a creator. «Scenes from the Life of Christ,» in 11 pieces, in the Cathedral of Saint John the Divine, New York, are from this factory. In the Hospitale Saint Michele, Rome, Pope Clement XI started (1710) an atelier with Jean Simonet of Paris manager, and A. Procaccini art director. Ferloni was manager from 1717 to 1770. In Naples (1737), the Florence Medici factory having closed, its weavers started here and ran till 1799. Under Benedetto da Milano the Vigevano works started (16th century) and produced the «Triulse Months» for Marshal Triulse, now in this family's Milan palace.

German Factories.— Otto-Heinrich had an atelier at Launingen in the 16th century. Peter Candid designed and Hans van de Biest wove (17th century) «The Four Seasons» and «Day» and «Night,» six pieces, in the Munich Museum.

French Factories.—François Premier, after his Italian campaign, started an atelier (about 1535) at Fontainebleau. The «History of Diana» was done in honor of Diana of Poitiers. Under his son (Henri II) it became defunct; but (1551) Henri opened an atelier at the orphan asylum, La Trinité, employing the children on the work. The «History of Mausolus and Artemisia» (15 pieces) were made here by Maurice du Bourg, its chief, from the designs of Larembert and Caron. Other factories have reproduced it. Henri IV started both high and low warp looms in 1597 in faubourg Saint Antoine ateliers, under du Bourg and Daurent; and, about 1601, Flemish artisans were invited to Paris. Frans van den Planken came from Oudenarde and Marc de Coomans from Brussels and started an atelier in Paris with branches in Tours and Amiens. Henri IV decided to accelerate the industry still more by installing du Bourg and Laurent in the Louvre and de la Planche (van den Planken) with Coomans in Les Tournelles palace. The latter works was moved to faubourg Saint Marceau, Paris. Louis XIV patronized the industry and Pierre Lefèvre and his son Jean (Florence weavers) came to Paris in 1647. The high warp looms of Tours got Cardinal Richelieu's patronage. Rheims, under direction of Daniel Pepersack, produced «The Story of Christ» and other works. Fouquet of Vaux let Maincy start an atelier (1658) on his estate and Le Brun drew cartoons for it («The Hunt of Meleager»); Louis Blammaert directed the Flemish weavers. When Fouquet, as successor of Mazarin, fell in disgrace, the Maincy factory was closed, after only three years' operation.

Beauvais Tapestry.— Minister Colbert (1664) persuaded Louis Hinert, owner of Flanders ateliers, to move his looms to Beauvais under such attractions as a subsidy, assurance of Court orders and 30 years' privilege. Hinert was bankrupt by 1684 and was succeeded by Philipe Behagle, who started making full-sized figure pieces. High and low warp looms were operated, but the large pieces showed very little demand. Behagle started a school of design under management of Le Pape and many of the small pieces (low warp), of great beauty, for furniture, came from designs of this class. On Behagle's death his sons failed and the brothers Filleul took over the business only to fail likewise. In 1722 the atelier was run by Sieur de Mérou, who engaged Jean-Baptiste Oudry (from the Gobelins). Oudry's genius in designing cartoons and management made Beauvais noted. Perfect workmanship marks this period; verdures are delightful, cute ducks, pheasants, foxes, dogs charm connoisseurs. Charles Natoire (of Gobelins) used his talent on furniture. Mérou's financial losses brought Nicholas Besnier as successor. Noted designers of Beauvais pieces are François Boucher, Leprince, Casanova, etc. Low warp pieces predominate. Besnier's death in 1753, followed by the death of Oudry two years later, injured art values of future Beauvais pieces although, under the auspices of André-Charlemagne Charron (1753–1780) the factory was quite a success. From 1780 Sieur de Mérou (from Aubusson) was director, and introduced the fabrication of pile rugs (Savonnerie style). The Revolution injured the industry and for one year it was closed but the factory has been kept running ever since. Among extant Beauvais pieces are «Conquests of Louis the Great» (two pieces only) in Florence; Raphael's «Acts of the Apostles» (eight pieces), one set in Beauvais Cathedral, another in the French National Collection; «Adventures of Telemachus» (six pieces) in Royal Spanish Collection, several in Paris; «Battles of Charles XII of Sweden» (four pieces) in Royal Swedish Collection. Oudry's «Fables of La Fontaine» designs for chairs gained great popularity and were reproduced prolifically. In the archbishop's palace at Aix-en-Provence are a set of Natoire's «Don Quixote» (10 pieces). Quite a large number of Boucher's pieces are in the United States.

Aubusson Tapestry.— The origin of this factory is in doubt, but the Duchess of Valentinois' will (dated 1507) mentions the «tappicerie de Felletin,» and Felletin is a town near Aubusson. Henry IV (late 16th century) lent the Felletin and Aubusson ateliers assistance by forbidding Flemish tapestry imports. Savary's 'Dictionnaire du Commerce' (1641) says: «There are also two other French tapestry factories, one at Aubusson in Auvergne, and the other at Felletin in La Marché.» In 1637 Aubusson had about 2,000 operatives, but both material and designs were of a low order as well as the dyes, and weavers were leaving. Colbert promised a talented artist and an expert dyer. But they never came. The king permitted the use of the title «Royal Manufacture» and promised a good painter, who did not appear. Financial conditions at the Court were bad. However, the factory continued. But in 1685 the revocation of the Edict of Nantes set the best weavers in flight, for they were Protestants, much to the injury of the factory. Louis XV in 1731 sent the efficient dyer (Sieur Fizameau from the Gobelins) and the promised painter (Jean-Joseph Dumons). Dumons' designs were a success. Fizameau was soon succeeded by Pierre de Montezert. An ordinance of 1732 enforced the weaving of the initials of the town and weaver into the blue border. The Revolution closed the factory, but ever since it has been running with success. Aubusson looms are all low warp. The product is furniture tapestry.

Savonnerie Tapestry.— The textile produced at this factory is not what is known generally under the name of *tapestry* because it has a velvet-like pile. It is a decorative material which originated in the East and had been called *longue laine* (long wool) or *à la façon Perse*, also *after the fashion of Turkey*. Pierre Dupont and Simon Lourdet started looms for this work in 1627 in the Louvre with royal license «to weave carpets in the style of the Orient, with gold and silver.» The plant was moved in 1631 to the old soap works (*savonnerie*) at Chaillot. Louis XIV permitted (1712) the works to assume the title «Manufacture royale des Meubles de la Couronne et des Tapis façon de Perse et du Levant.» They gained the same privileges as the Gobelins. The king and his successors, Louis XV and XVI, patronized the industry and gave extensive orders. While the process was that of knotted work cut to pile, it has ever been classed as tapestry. Much of the product has been used on furniture as upholstery though properly being a carpet textile. Designs run to branched foliage and architectural motifs with a medallion or other centre.

Other French factories were as follows: Fontainebleau; a tapestry atelier was started here (about 1535) by François Premier with Philibert Babou as manager and Sebastian Serlio (Italian architect) as art director. Le Primatice drew the cartoons. It was discontinued as unprofitable while under the direction of Philibert Delorme during the reign of Henry II. A factory was opened by Raphael de la Planche (son of Frans van den Planken) at rue de la Chaise, faubourg Saint Germain, Paris, on the death of his father. An atelier at Vaux (17th century) had the honor of having to work on the «Story of Constantine» and «Hunts of Meleager» designed for it by Lebrun, director of the Gobelins.

English Tapestries.— An existing piece of tapestry containing the coat-of-arms of the first Earl of Pembroke proves that the industry was established here already in the 16th century. It was woven by Richard Hyckes of Barcheston, who had another atelier at Weston. There are two tapestry maps from this weaver's hands in the Oxford Bodleian Library. The Sheldon family continued the work into the next century. William Benood (1670) had an atelier at Lambeth, London, of whose work Haddon Hall holds the «Vulcan and Venus» set (four pieces). Glenham Hall owns four «Indo-Chinese» pieces from the loom of John Vanderbank (end of 17th century), «manager of the King's Wardrobe,» who also produced «The Elements» (three pieces) at Burley House; his atelier was in Great Queen street, Soho, London. Early in the 18th century Stephen Demay wove the «Hero and Leander» panels and «Acts of the Apostles,» still extant, and Peter Parisot, in the same period, had an atelier at Fulham, London. The name Bradshaw is woven in a sofa covering of this century at Belton House.

Mortlake.— King James I smuggled into England 50 expert Flemish weavers and established, in 1619, a tapestry factory at Mortlake. Sir Francis Crane was the instigator of the movement. Orphans from the «Foundlings

Hospital» were apprenticed under the superintendence of Philip de Maecht, a Fleming. His productions were marked P. D. M. often. Designs were done by Francis Clein (or Cleyn) from Denmark. The king's promised financial assistance was not forthcoming and Sir Francis, having sunk all his capital, made an appeal to his sovereign for cash to pay overdue wages of his weavers. The Prince of Wales gave financial assistance and obtained some funds from the king. On the king's death (1625) his successor, Charles I, aided further (as when Prince) and Crane was repaid his cash losses and given lands, while the factory became a financial success. England produced the finest wool ever used on tapestry work (it was always in great demand in Flanders and France), and now with Italian art designs and Flemish operators Mortlake, for 10 years, brought forth the grandest tapestry pieces the world ever saw. Capt. Richard Crane, on the founder's death (1636) carried on the work unsuccessfully; civil war and the beheading of the king injured the quality and quantity of the work. Sir Gilbert Pickering, under the Commonwealth, became head of the factory. A Hampton Court copy of Mantegna's «Triumph of Cæsar» was duplicated. Cheaper and poorer tapestries from France and the Netherlands were more popular with a war-impoverished people, however, and the factory closed in 1703. Mortlake reproduced Raphael's great «Acts of the Apostles» with border designs by Van Dyck; Rubens' «Story of Achilles» in six pieces; Cleyn's «Story of Vulcan» and «History of Hero and Leander.» «Vulcan's Complaint to Jupiter» is in an American collection (loaned to the Metropolitan Museum of Art, New York); the Swedish Royal collection owns «Hero and Leander» (five pieces); «Vulcan and Venus» pieces are in the French National Collection and in America; «Naval Battle of Soleby» (three pieces) is in Hampton Court; three sets of Mortlake «Acts of the Apostles» are in the French collection.

Merton.— In 1881 William Morris founded the Merton Works, «The Goose Girl,» from a Walter Crane cartoon, being the first production. Designs by Burne-Jones were next carried out. Among the best known Merton pieces are «Story of the Holy Grail» (in Stanmore Hall); «The Seasons» (Victoria and Albert Museum); «Star of Bethlehem» (in Oxford); «Primavera,» «Flora,» «Pomona,» etc. Merton tapestries are of coarse weave, 10 to 16 ribs per inch.

Spanish Looms.—The Santa Barbara (Madrid) atelier opened, in 1720, under patronage of Philip V, with the Jacques Vandergoten family, from Antwerp, as experts. Some of the noted 18th century 92 pieces, woven from 45 designs of Francisco de Goya, are in Escurial Palace, others in the Prado. The factory is still in operation.

Russian Looms.— In 1716 the Imperial Tapestry Works was founded by Peter the Great, with Behacle and Beauvais operators as experts.

Japanese Tapestries are of very delicate and beautiful design, but very rare, hence few are discoverable in connoisseurs' collections.

American Looms.— William Baumgarten, in 1893, started some tapestry looms at 321 Fifth avenue, New York City, with M. Fousadier as manager. After several pieces had been finished (one in the Field Columbian Museum, Chicago), the industry was moved to Williamsbridge, a suburb, and more weavers, from Aubusson, were engaged. A $20,000 set of wall panels and furniture coverings (after Boucher) was produced for P. A. B. Widener of Philadelphia. It took 13 months to execute. Next were some wall panels in the directors' room of the New York Life Insurance Company. Beautiful work has been done for such patrons as Mrs. Sheperd of Scarborough, Jacob H. Schiff, Charles M. Schwab, J. B. Ford, D. G. Reid, etc. Here also are produced floor pieces in Aubusson pile style.

Extant Masterpieces.— Of *Gothic verdures* we have in America (Metropolitan Museum, New York and elsewhere) «Baillée des Roses,» «Capture of Jerusalem by Titus»; Cluny Museum has «Lady of the Unicorn»; Victoria and Albert Museum (London) has four «Hunting Scenes»; before the World War Rheims Cathedral had «Coronation of Clovis,» «Capture of Soissons,» «Story of the Wonderful Stag,» «Victory over Gondebout,» etc. Of *Gothic* tapestries dating from the 12th to 15th centuries there are in the Cathedral at Angiers a set of seven «Apocalypse»; in the Brussels Museum were «Four Philosophers,» «Abraham and Isaac,» «Presentation of Infant Jesus in the Temple»; in Halberstadt Cathedral, «Christ and Apostles»; pieces (fragments) from the Saint Gereon Church, Cologne, are in museums at London, Lyons, Nuremberg. Arras productions of this period, known and identified, had become reduced to a single set before the war; the «Story of Saint Piat and Saint Eleutherius» in Tournay Cathedral. *Late Gothic* examples are in the Louvre, «Last Judgment,» «Combat of the Vices and the Virtues,» «Creation,» «Triumph of Christ,» «Christ Inspiring Faith,» «Scenes» from New Testament, «Creation»; two David tapestries in Brussels Museum; «Story of David» in Cluny Museum. *Transition Gothic-Renaissance* pieces extant: in Rheims were «Story of Saint Remi,» «Story of the Virgin»; «Story of Saint Stephen» (nine pieces) is in Cluny Museum; «Life of Christ» in Aix-en-Provence Cathedral; «Life of Christ» in La Chaise-Dieu (both latter 14 pieces). All are without borders. *Renaissance* pieces are «Acts of the Apostles» in 10 pieces in Beauvais Cathedral, French National Collection, Hampton Court, Dresden Museum, Berlin Museum, Imperial Austrian Collection, Royal Spanish Collection, and in Loretto Cathedral. Many other splendid examples are in private American collections. Fragments of the 15th century Burgundian «Sacraments» (J. P. Morgan donation) are in the Metropolitan Museum, New York.

Tapestry Characteristics.— In identifying the location of the weave special attention is given to the *border,* because special borders were designed for replicas of the noted pieces. The tape border or binding, known as the «galloon» often contains the marks of the weavers, but they are often absent. The primitive design is a characteristic of Gothic tapestry, such as the Byzantine «stiffness» of expression and folds in clothing, the *flatness* or absence of what artists term «atmosphere,» the lack of perspective. Early works (14th and 15th centuries) usually have but a single subject, few personages. Pointed Gothic architecture in the piece places its period, as do the capitals and shafts of columns. Of course, Renaissance tapestries display florid columns. The earliest pieces have no border — these *verdures* have simple flowers filling spaces. To find dates the costume is of great assistance; when armor appears the style affords a good clue. Much may be proven by the makeup of the lettering. Renaissance pieces are devoted to classic subjects, battle scenes, kings, queens and their courts. Borders are a clue; earliest were of woven tape (*galloon*) in a single tone. Then came frames of fruit, flowers, foliage (also ribbons sometimes), they are Gothic. Next we arrive at scenes depicted in square divisions, they are Renaissance. The relative value of the border keeps growing as well as the size, and, by the 18th century, we have the central subject actually crowded for space to make room for the elaborated border subjects. In Louis XV tapestries we arrive at actual gold picture frames in textile, moldings and all.

Tapestry Marks.— The first producers' marks appeared in 1528, when Brussels passed the ordinance by which each piece had to have the town mark, "a heraldic shield between two B's" in either capitals or minuscules. The two B's either face the same way or, sometimes, the left B is depicted backwards. It appears on the galloon and generally in a lighter tone than the body. There was also the merchant's mark. This law only affected those pieces of about 13 feet or over, not the small ones (which were few in early days). In the pieces from the Spanish ateliers of Wilhelm de Pannemaker his W P is found in several confusing combinations, and the number 4 frequently is found combined with the W. The initials J G are said to be the weave mark of Jacques Geubel. The Bruges ateliers used two B's traversed by a crown. A gyronne of four in a shield or circle was the mark of Pierre of Enghien. In the 17th century we find initials frequently, as two C's intertwined for Charles Coomans; A. C. monogram for Alexander Coomans; J. F. for Jean Lefèvre; P with a fleur-de-lis stood for Paris. A fowl roasting on a spit was the Jean Rost sign; Florence used a lily; Mortlake a shield with a cross entire; Tournay a castellated tower; Lille a peculiar shield charged with a lily and side initials L and F; Amiens used a double S entwined; Beauvais a red heart, white pale and two B's; Munich a shield charged with a child standing with arms outstretched on white background (*field*).

CLEMENT W. COUMBE.

TAPESTRIES, Manufacture of. The direct history of tapestries has been studied and written by many European and by a very few American savants. The rise and fall of numerous ateliers and of tapestry-weaving centres have been traced, quantities of marks and monograms deciphered, long lists of master-weavers discovered and the technical processes of weaving at the different eras defined, but the collateral history of these art products remains to a great extent unwritten. In evidence of the interesting results researches in this direction may unfold, the arguments of a learned Frenchman in an essay which appeared some years ago almost tempt one to believe that the tapestries woven by Helen and Andromache, to represent the principal episodes in the siege of Troy, actually inspired the 'Iliad' and the 'Odyssey.' We have become fairly well acquainted with the social position tapestries occupied in different nations since the dawn of civilization, by studying the impressions they made upon the popular taste from age to age and by reading the history of the rôles they filled on hundreds of occasions of pomp and ceremony during many succeeding centuries. We have also become fairly well acquainted with the changes made in their style and character from the infancy to the maturity of the art, and with the alterations in the ideas they expressed throughout the same period, by patient research among documents from the great centres of production, by gleanings from the inventories of princes and other potentates and from newly discovered material concerning individual ateliers the existence of which had been long forgotten, but above all by careful study of the existing specimens wherever they can be found. Guiffrey, Muentz, Pinchart and Wauters have long since proven that tapestries often exhibit the finest and loftiest conceptions of many of the great masters, that at all epochs the most eminent artists designed models for them, and that they frequently constitute the only surviving examples of whole schools of paintings which without them would have been lost to the world. In addition they are as trustworthy interpretations of the characteristics and mannerisms of both schools and individuals as are paintings, and are more faithful exponents of the national ideas and sentiments of the country and era in which they were created, and, therefore, it is no longer possible to separate the history of paintings from that of storied tapestries.

Weaving.— Tapestries, or calling them by their classical name — «Arras» — are decorative pictures or designs in tissue which are made by interweaving variously colored woof threads with undyed warp threads after the latter have been extended either vertically or horizontally upon a loom. This interweaving is done with an implement called a «broche» in French, which is neither a shuttle nor a bobbin, but partakes of the character of both and for which there is no equivalent word in English. The picture represented is developed upon the warp by the different colors of the woof threads. Needles are never used in weaving tapestries. In the process of weaving the woof becomes practically an integral portion of the completed structure. Art tapestries can only be woven by trained artists who, in the best periods of the art, always interpreted and never copied a model. Their work cannot be altered nor improved to any important extent as they go along except by destroying and re-weaving a defective part. There is no similarity whatever in hand-woven tapestries and machine-woven fabrics which masquerade under the same name, since tapestries are woven in an entirely different manner from fabrics; since they have no nap; since each piece possesses a distinct originality and is not a mechanical repetition of the same subject; and since every thread of the warp is so completely encased by those of the woof that the warp is invisible on either side. There are two kinds of tapestries, «haute-lisse» and «basse-lisse.» Translated liberally, the former means «upright warp» and the latter «horizontal warp,» since the first kind are woven on upright and the second kind on horizontal looms. At Gobelins they weave only in haute-lisse, and at Beauvais, Aubusson and Malines, only in basse-lisse. In both kinds the warp threads are stretched on rollers so that they may be kept taut and parallel like the strings of a harp, but naturally very much closed together, as there are usually 22 to 26 of them to the inch. In the process of weaving both kinds about an ell in width of the warp forms a breadth of relay, and the weaver uses as many different broches as there are different tones and shades of color. In haute-lisse one end of a string is attached to every other warp thread in each relay, at a slight distance above the weaver's hands, and the other end is fastened to a crossbar above his head so that all these strings hang in loops within easy reach. By the assistance of these strings called «lisses» he manipulates the warp threads backward and forward with his left hand and passes the broche from right to left between as many or as few of them as he desires with his right hand. In basse-lisse these strings are attached by a mechanical contrivance to pedals at the base of the loom so that the weaver raises and depresses the warp threads with his feet, and having both hands free to pass the broche, he weaves about one-third faster than the weaver in haute-lisse.

Rapidity and Cost of Weaving.— The number of warp threads which are covered by one pass of the broche and one thread of the woof are only as many as are included in a single shade or tone of color. In background scenes and skies the woof-thread may cover at each pass from 30 to 60 warp threads, but when personages or their costumes are represented it rarely covers more than two or three of them. In short, it is the manifold changes in the coloring, the lights and shadows, the half-tones, and so on, which determine how many threads of the warp shall be covered by a thread of the woof at each pass of the broche.

Hatching the Colors.— In high art haute-lisses tapestries, well filled with personages, the artist-weaver can weave only about a yard square in a year. At the Gobelins, to-day, this yard square costs about $880, which does not include taxes, insurance, interest on cost of plant, rental for the apartments of the weavers, etc. The weaver passes from light to dark colors and from one shade or tone to another by weaving in threads of intermediate shades or tones in formations like the teeth of a comb and thus avoids the mosaic effect which would follow weaving two different colors side by side. This process is termed hatching the colors, and is one of the most difficult feats in tapestry weaving. In valuable antique tapestries the colors are usually hatched with such skill that the untrained eye does not readily discover where the different shades of the same color begin or end.

Difficulties of Weaving.— In both haute and basse-lisse the weaver works on the wrong side and the finished part faces away from instead of toward him. Consequently he is unable to criticize the progress of his work unless he walks around to the front of his loom in haute-lisse, and unless he raises it from its horizontal position in basse-lisse. In haute-lisse the cartoon is placed behind the weaver, and in basse-lisse it is placed beneath the warp. The weaver in haute-lisse translates the cartoon by sight, with nothing to direct his eye but the outlines of it that he has traced upon the warp, but he can, by walking round to the front of the tapestry, or by the aid of a mirror while seated take constant note of his work, and even make slight modifications in it. The weaver in basse-lisse, seeing but imperfectly what he translates, as the warp threads hide the cartoon to a certain extent, cannot examine his work, except at considerable trouble, until the tapestry is finished, when it is too late to remedy any defects. Naturally, therefore, the artist in haute-lisse has greater opportunities for noticing the effect of light and shadow and can more readily interpret or idealize the cartoons according to his own conceptions than can his brother in basse-lisse. For these reasons haute-lisse tapestries possess as a rule greater artistic value than basse-lisse. It may be said in a few words that haute-lisse are mostly creations from, and basse-lisse are mostly reproductions of, their respective cartoons.

The precautions taken by the weaver to verify the correctness and excellence of his work are, however, of little advantage if he does not possess the specially developed talents as well as the necessary skill and experience to insure success in his interpretations. He uses dry and supple materials which cannot be manipulated as readily as the semi-liquid colors of the painter, nor can the thickness of these materials be increased or diminished at will as can paints upon canvas. He cannot correct nor alter, nor even materially modify what he has done, nor erase and reproduce it with facility, as can the painter. He cannot varnish his production, nor employ any other of the multiplied accessories of the brush and the palette. His work grows almost imperceptibly and he is, therefore, unable to sieze the general effect of the entire composition in any other way than mentally. He cannot obtain transparency and harmony except by the complicated process of hatching the colors, and must be exact in choosing them and measurably correct in his drawing, although working on the wrong side. He can improve slight faults by packing the woof threads more or less closely together with a special kind of comb, but he cannot change faults in color or in drawing except by unweaving the defective part and renewing it totally. Is it any wonder that it requires at least 12 to 15 years to educate a novice in all the mysteries of the profession and that it took several generations of master-weavers to perfect the art of weaving storied tapestries? The tyro will not be able to tell a haute-lisse from a basse-lisse tapestry, and the amateur even is often at fault unless there should be a manifest defect visible, like a mark, monogram or inscription running backward. Since the cartoon in basse-lisse is placed beneath the warp, it faces the finished tapestry, and its subject is, therefore, reversed in the process of weaving, just as your signature or any other bit of writing is reversed on the blotting pad with which you dry it. No marks, monograms or inscriptions were usually painted upon the cartoon, consequently the weaver often made the mistake of weaving some of them in as he would write them, which naturally made them run backward in the finished tapestry. In basse and haute-lisse interpretations of the same cartoon, the subject faces the spectator in the former in an opposite direction from which it faces him in the latter. To avoid this difference it has been usual for a long time to furnish the basse-lisse weaver with a reversed model of the cartoon so that the scheme of the tapestry when finished should run as it would if woven in haute-lisse. Any one can, however, occasionally detect a basse-lisse tapestry on closely scrutinizing it with a microscope on the wrong side, by finding here and there the hairs from a man's beard. This may seem ludicrous, but the ancient basse-lisse weaver, according to existing illustrations, usually wore a full beard, and when he bent over his work to catch glimpses of the carton beneath the warp, he occasionally caught a hair or two of it between the threads of the warp and the woof. There are a number of embroideries miscalled tapestries, notably the historical Bayeux frieze which many authorities assert was made by Queen Matilda of Normandy, and her maids of honor, although there are many excellent reasons for doubting such assertions. It is needlework, and in no sense a tapestry.

History of Weaving.— The art of weaving tapestries was understood in the remotest ages, and was discovered but little later than the art of painting on walls or wooden panels, for the spirit of decoration manifested itself almost everywhere long before the dawn of civilization. It is a long way from the coarse and crude example used in ancient times by many wandering tribes in the decoration of their tents, to the sumptuous and refined textile paintings universally employed by the rich and noble in the 15th, 16th and 17th centuries to enhance the splendor of their palaces; nevertheless the student will find ample opportunity for serious thought and gratification in everything that elucidates the progressive steps in the prolonged march. In short he will find that the study of tapestries will lead him into fields which were practically closed for 100 years, and that it will open his eyes to new visions of beauty of the existence of which he had scarcely a suspicion. Until recently an ornamental decoration on a Grecian vase representing Penelope at her loom was presumed to be the most ancient visible evidence of the manner of weaving tapestries, but the discovery upon the walls of the hypogeum of Beni-Hassan el-Gadin of a painting finished about 3,000 years before the birth of Christ, upsets all previous calculations, since it represents two persons weaving at a loom very similar in many respects to those now in use at the Gobelins. There is a tradition among the Hebrews that the art was invented by the daughter of Noah; but some of the ancient philosophers and many of the ancient poets claim that the honor belongs to Pamphile, daughter of Apollo. Although Pliny describes in graphic language the sumptuous beauty of the industrial and decorative products of his era, yet he is unfortunately silent upon the manner in which they were woven, and the probable inventors of weaving them. Ovid, on the contrary, is delightfully explicit and not only gives the mythological origin of the art, in his description of the fabulous contest in tapestry weaving between the Lydian maiden and the goddess Minerva, but judging by his technical explanation of the process, one could well believe that he describes the manner in which tapestries are woven at the Gobelins to-day. According to the story Arachne was exceedingly vain of her dexterity in weaving and challenged Minerva to a trial of skill. The outraged goddess accepted, but vowed vengeance on the presumptuous damsel. Each attached the warp to the beam, and passed the slender broches in and out among the threads. Minerva wrought the scenes of her contests with Neptune, and Arachne the love exploits of Jupiter. The goddess could not forbear admiring the handiwork of the maiden, although enraged that a mortal should have dared to compete with an immortal. In her anger she destroyed the tapestry of Arachne, struck the damsel on the forehead with her broche, metamorphosed her into a spider, and bade her weave on forever.

Oldest Tapestries.— The oldest existing mural tapestries are no doubt the fragments from the Church of Saint Gereon in Cologne, which were woven in Europe in the 11th or 12th century. The oldest of all existing tapestries are no doubt those discovered in the Crimea by Stephani, the archæologian, who believes they were woven in Asia 400 years before the Christian era. The oldest I have ever seen are of Coptic origin and were found in the tombs of ancient Panopolis. They were woven in haute-lisse and are presumed to date from the 2d to the 9th centuries. Coptic tapestries were all used, in so far as known, in decorating costumes, as there is no evidence that any were woven to ornament houses. In consequence many have been preserved until this day because they were buried with the bodies of those who had worn them. They are mostly shaped like bands and were sewn around the bottoms of garments or made into chasubles, or worn around the neck and wrists like the lace collars and cuffs of the Hollanders in the Rembrandt and Hale portraits.

As Mural Decorations.—Throughout the history of art from the earliest records, tapestries have ranked as the most magnificent of mural decorations, and the most important factor in crowning with pomp and splendor grand tournaments, funerals of exalted personages, receptions to famous generals or renowned prelates, triumphal entries of sovereigns or distinguished conquerors, royal and princely marriages, and coronations of popes, emperors and kings. Everywhere they occupied the places of honor and were relied upon to create the profoundest effect and arouse the highest enthusiasm. Great generals carried them to the wars, and princes and monarchs did not hesitate to borrow from each other whenever they desired to give an entertainment of unusual magnificence. In patrician homes their rich warm colors brought out in exquisite relief the classical purity of the architecture and the beauty of the statuary, bronzes and gilded furniture. In churches, as Muentz poetically declares, they sifted the sunlight and thereby added to the mysterious shadows of these sanctuaries. When we read of the glorious rôle they played on hundreds of grand occasions, none of which can be referred to in the limited space of this article, we are at first fascinated and then amazed, for the facts so far outrun our liveliest imagination that they prove as thrilling as any romance of chivalric days, and as absorbing as any epic of ancient or modern times.

Nationalization of Weaving.— In no countries of Europe except France and Flanders did the art of weaving tapestries ever become thoroughly nationalized. There were many important ateliers established elsewhere, but nearly all had a comparatively ephemeral existence and rarely survived their founders. All connoisseurs regret the short life of the Mortlake atelier of England, for its «History of Vulcan» ranks among the most important series in existence. The Medicean ateliers of Florence lasted about a century and some of the superb specimens in the Florentine galleries issued from them. Of those founded under the ægis of the popes, that by Cardinal François Barberini was maintained by the family for nearly 50 years and created several magnificent series.

Tapestry Museums.— There are only two museums in Europe devoted exclusively to the exhibition of tapestries and textile products, to wit: the Gobelins in Paris, and the Crocetta in Florence. In all other cities, although some of them possess remarkable collections, their tapestries are displayed either in the royal or imperial palaces, or in the museums among the other objects of art. Those exposed at the Gobelins have been selected with especial care so that each piece shall be an object lesson to the student, enable him to distinguish the modifications in the methods of weaving at different epochs, criticize the results, and become acquainted with the changes from the first foundation of the Gobelins in 1603 to the present day. The most valuable and important state collections of storied tapestries are those in Paris, Madrid, Florence and Vienna. In each collection, except the last named, there are about 600 pieces. That in Paris is largely composed of tapestries woven in France and is unrivaled in its magnificent specimens of Gobelins and Beauvais manufacture. That in Madrid is largely composed of those woven in Flanders, and is remarkable for its wealth of superb Flemish specimens. That in Vienna is not as large nor as valuable as those in Florence, Paris or Madrid, but includes tapestries woven in all the great centres of production, although, as in Madrid, those woven in Flanders are in the majority. That in Florence is composed in nearer equal proportions of the products of France and Flanders than any of the rest, although the Italians claim that almost one-third of it was woven in Italy.

Flemish Art.— The work of the Flemish ateliers, studied in its entirety, constitutes an immense epic in warp and woof, illustrating religious and profane history, mythological episodes, legends of the saints, creations of the poets and novelists and celebrated acts of great men of all ages. Her master-weavers, however, did not confine themselves to these inexhaustible sources, but made admirable representations of nature's models, for, the truthfulness of their landscapes, the repose, softness and veracity of their background scenes, and the purity and reality of their garlands of flowers and fruits have received the unbounded admiration of connoisseurs for generations. Some of the historians of tapestries have failed to award Flanders her just rank as the greatest of all centres of tapestry weaving. For over three centuries she eclipsed all others in the magnificence and excellence of her products and in future ages when the tapestries of the latter part of the 18th and all of the 19th century have passed into oblivion, amateurs and connoisseurs will still recall the glory of her ateliers and still go into raptures over the tapestries which issued from them during the 15th, 16th and 17th centuries. During these 300 years she led the world in the production of practically perfect examples of textile painting, that is, tapestries which are rich in color, strong in decorative effect, graceful in drawing and with subjects adapted to the exigencies of the loom and the æsthetic requirements of wall decorations. Her tapestries of the first half of this period rarely contain more than 30 to 50 different tones and shades of color, the half tints and graduations having been made by hatching one color into another. In the 16th century Flemish tapestries reached their apogee. Her master-weavers, from their profound love of their art, wove as if inspired and painted both grandly and broadly in tissue. By careful and intelligent study they absorbed and interpreted even the motives to which the artists yielded when they designed the models and «often further idealized the latter's ideals.» Naturally, therefore, the productions of Flanders outrivaled those of any other part of Europe, but about the middle of the 17th century she was obliged to bow her proud head to her rival — Paris. As the taste and demand for tapestries grew, most of the sovereigns of Europe determined to establish ateliers for weaving them in their respective territories, but nearly all were obliged to depend upon Flanders for master-weavers capable of carrying their resolutions into effect. France was the only exception of any note, for the art of weaving tapestries had been introduced in that country at probably the same period as in Flanders. Although the French ateliers had languished all through the long years of her wars with England, yet the best of them had not succumbed. Under the fostering succor of Francis I and Henry II they showed renewed signs of life; under the wise policy of Henry IV and Louis XIII they gathered additional strength, and under the magnificent support of Louis XIV they outrivaled all competitors. Nevertheless Henry IV summoned celebrated Flemish master-weavers to France, loaded them with honors and showered inestimable privileges upon them, which Louis XIII and Louis XIV gladly continued and extended. The object of the French kings was to increase the demand for tapestries by introducing the cheaper methods of weaving then known in Flanders, as the lessened cost would bring them within the reach of the middle classes, whereas they had heretofore found purchasers only among the rich and the great. Finally, as these kings expected, French ideas and taste prevailed and the ateliers of France grew in importance and reputation as the character and prestige of those of Flanders faded away, until all the latter were closed, leaving the field entirely to their French competitors. See TAPESTRIES; GOBELINS, etc.

CHARLES M. FFOULKE,
Lecturer and Writer on Antique Art Tapestries.

TAPEWORM. An elongate flattened ribbon-like parasitic worm belonging to the class Cestoda (q.v.) of the phylum Plathelminthes. In the large majority of forms the body is divided tranversely by septa into links, segments or proglottids which are usually conspicuous externally although in a few less common genera such partitions are lacking and there are rare species in which the body consists of but a single joint or section.

The tapeworms are common in all vertebrates and from their considerable size and length are the most conspicuous of all parasites. Three of the 24 species found in man are 10 meters or more in length and yet certain other species are so insignificant that they have long been overlooked. The large human tapeworms were known to the Greek and Egyptian physicians although all were regarded as of one kind and it was 1602 before the famous Basel clinician, Felix Plater, distinguished two kinds of tapeworms from man. The large bladder-worms from various domestic animals were also well known to Greek writers on medicine but were considered as growths until Redi in Italy demonstrated their animal nature. They were, however, placed in a special class (Cystici) until about 1850 Küchenmeister by feeding experiments established their relation as larval or immature forms of certain tapeworms. The proscription placed by Moses on the use of certain flesh had its ground unquestionably in the prevalence in such animals of bladder-worms. Hippocrates writes of the evacuation of pumpkin-seed-like fragments as diagnostic of tapeworm and Aristotle showed that in contrast with round worms which are free the tapeworm is attached to the wall of the alimentary canal by means of its head.

The body of a tapeworm has at one end a bulbous enlargement known as the head or scolex which in other types has a different construction but is oval with two elongate grooves in the fish tapeworm of man and more rounded with four cup-shaped suckers in the beef and

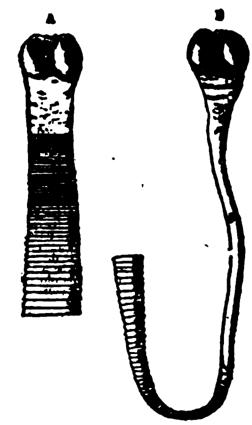

FIG. 1.— The Beef Tapeworm. A, the head; B, head and part of the body.

pork tapeworms of man. (Cf. Figs 1 and 3). Following the scolex comes a very slender region, usually undivided; this is the neck. It changes very gradually into the jointed body which becomes heavier and more conspicuously divided toward the large end where in the full grown intestinal parasites proglottids are being regularly set free and evacuated from the intestine of the host. Since the body is highly muscular and has no hard skeleton, it varies constantly and conspicuously in shape, especially at and near the scolex and neck so that the entire appearance of the anterior may be radically modified. (Fig. 1). The head may be armed with hooks as well as suckers, as in the human parasite often designated the pork tapeworm.

Most tapeworms are found in the intestine and in man this is the only normal location; the reports of their occurrence in the stomach being purely imaginary or due to reversal of the normal movement of the alimentary canal. They have been found in the bile duct and with the scolex embedded in the wall of the intestine, but all such occurrences are rare and rank as abnormal. The effect of this parasite on the host is measured first by the loss of nutriment which must be relatively great as the tapeworm is large and grows with striking rapidity. In the beef tapeworm the growth measures about 72 millimeters per diem which is equivalent to the formation of 13 to 14 proglottids daily. This factor is, however, inadequate to explain the results produced by the presence at times of only a single parasite. These symptoms are prominently of a reflex nervous character and are usually explained on the supposition that the tapeworms produce toxic substances which are absorbed by the host and induce a marked toxemia. One human tapeworm produces a severe anæmia of the pernicious type recognized as characteristic of the presence of this species.

The symptoms of tapeworm disease are rather general and not well defined so that a diagnosis must be made by the demonstration in the fæces of loose proglottids which are discharged either singly or in groups of three or four. The abundance and distribution of tapeworms are not accurately known and statistical data exist only for a few localities and for selected groups such as hospital patients, inmates of public institutions and soldiers.

The French maritime hospitals reported in 1890 about 1.5 per cent of all cases were treated for tapeworm infections and the United States hospital service during the Civil War recorded only 0.012 per cent treated for tapeworm, a record that is certainly much lower than the true degree of infection in this country.

The bladder worm, or larval stage in the life history of the tapeworm, is found encysted in the flesh of a great variety of hosts. It gains entrance to the final host when the flesh containing the cysts is ingested. When set free by digestion the bladder-worm everts the head and neck region which were formed in inverted fashion on the inside of the hollow spherical or oval larva. The bladder itself is digested but the chain of proglottids grows out from the neck.

The beef tapeworm (*Tænia saginata*), also called the unarmed tapeworm of man because the scolex is devoid of hooklets, inhabits the small intestine of man but has not been found in any other host. The bladder-worm (*Cysticercus bovis*) occurs in the muscles and viscera of cattle. As is natural from the cosmopolitan distribution of both hosts this parasite occurs over the entire world but is more common in those regions where the habit prevails of eating beef underdone or rare. It is also increasing in frequency as shown by the statistics of the French maritime hospitals which report 33 cases among 130,927 or 0.2 per 1,000 during 1861–65; and 1886–90, 2,253 were infected among 152,352, or nearly 75 times as many as at the earlier date. Attention has already been called to the head of this tapeworm which with the neck is highly muscular and variable in form. The reproductive organs are not visible except as faint strands of tissue in full grown proglottids; they have the form represented in Fig. 2. The numerous small round masses are the testes which communicate by branching vessels with the common sexual pore at the side. Generally speaking these pores alternate in successive segments. The large bush-like masses are ovaries and the slender flattened structure near the posterior margin is the yolk gland. Between it and the ovaries lies the small spherical Mehlis gland formerly known as the shell gland, but incorrectly designated as such since investigations show that the material for the shell comes from the so-called yolk gland or vitellarium. At this stage of development the uterus appears as a median sausage-shaped receptacle. When the eggs accumulate it is increased in size so greatly that numerous lateral branches are formed extending almost to

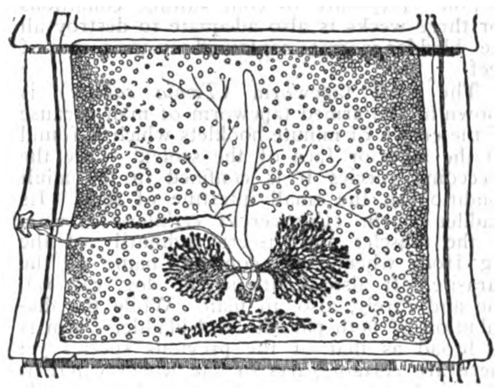

FIG. 2.—Sexual organs in a tapeworm segment (*Tænia saginata*).

the margin of the proglottid, giving the aspect shown in Fig. 3.

The segments of this tapeworm when evacuated are little more than sacs covering the much branched uterus which is crowded with eggs. They possess considerable power of independent movement and are frequently found at some distance from the point of deposit. The eggs have several coverings which

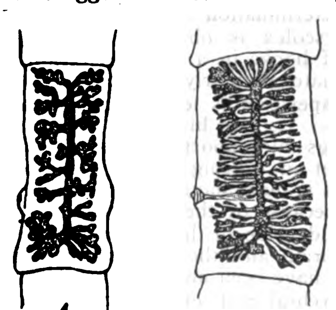

FIG. 3.—Free proglottids of *A*, *Tænia solium*, and *B*, *Tænia saginata*.

serve to protect them even after the disintegration of the proglottid. Distributed by chance an egg reaches the stomach of an ox with the food or drink of the animal. Under the stimulus of the gastric juice the membranes are ruptured and spherical six-hooked larva escape. It bores its way through the wall of the alimentary canal and comes to rest in the connective tissue. When it reaches a suitable location it develops by growth and the accumulation of a considerable amount of fluid in the centre to a bladder-worm. A thickening of the wall of the bladder produces an ingrowth in which is formed in reverse the head of the future tapeworm. Growth is slow and in six months the worm measures only six millimeters or less in diameter. If the flesh containing the bladder-worm is consumed by man while the parasite is still living the head of the bladder-worm is everted and it attaches itself to the wall of the intestine and begins to grow into a mature specimen. This period of growth requires no more than 9 or 10 weeks for the production of mature proglottids. Since a moderate temperature is unfavorable to the bladder-worm well-cooked meat cannot possibly carry the infection. Exposure to cold storage conditions for three weeks is also adequate to destroy all the bladder-worms contained in a piece of beef.

The pork tapeworm (*Tænia solium*) is known as the armed tapeworm of man because of the crown of minute hooklets which is found on the anterior face of the scolex. Like the preceding species it is confined in the adult condition to the small intestine of man. Its bladder worm (*Cysticercus cellulosæ*) occurs in the muscles and viscera ordinarily of the pig from whence the common name of the parasite. It also occurs in the dog, cat, rat, ape and rarely, also, in man. While the distribution of both parasite and bladder-worm is as broad as that of the previous species yet there are certain parts of the world where it is entirely wanting, i.e., among those people who do not eat the flesh of the pig. The species is common in European countries where pork is consumed in the smoked but uncooked condition and is very uncommon in the United States because of the general practice of eating pork well done. The parasite is somewhat more slender than the beef tapeworm. The terminal proglottids (Fig. 3) show that the branches of the uterus are less numerous and heavier than those of that species, but to distinguish between them is not always easy. A positive determination can readily be made when the scolex is obtained because of the presence of hooks in a double circle in which they alternate regularly in size. In general the pork tapeworm is less muscular and more transparent. Its life history is similar except that the eggs find opportunity for hatching and development in the pig rather than in cattle. The species is more dangerous than the preceding form because of the fact that the bladder-worm may develop in the human host. Apparently the brain and the eye are the points in which they have been more frequently observed and the cerebral cysticerci are most dangerous because they produce naturally conditions similar to brain tumors and are not infrequently the cause of sudden death. There are no special symptoms connected with their presence and usually it is not possible to distinguish between them and tumors of different origin. The bladder-worm displays in some situations a marked longevity as the same individual has been followed by means of the opthalmoscope for 20 years in the human eye. Because of the campaign against the use of pork except when well cooked this parasite has grown much rarer within recent years.

The dwarf tapeworm (*Hymenolepis nana*) is the most numerous parasite of this group found in man in North America. It is regarded by some as identical with a species that occurs in rats and mice. On account of its small size it was not discovered until the middle of the last century and while even yet it is frequently overlooked it is present at times in enormous numbers. It may justly be considered cosmopolitan in its distribution. Cases occur in general under unfavorable hygienic surroundings and infection is probably traceable to contamination of food by rats and mice. The worms are usually found in considerable numbers and excite digestive disturbances of marked severity. Diagnosis is made by microscopical demonstration of eggs in the fæces and treatment should be at the hands of a physician. The records of Ransom concerning North American cases indicate the great frequency of the parasite in children and especially in infants.

One of the smallest of tapeworms is *Tænia echinococcus* which is a parasite of the dog. The chain consists of only three or four proglottids. The parasite is important because of the character of its larva or bladder-worm which is known as an hydatid (*Echinococcus polymorphus*). This bladder-worm develops in a very large number of hosts and produces a complex structure with secondary and tertiary bladders in great numbers so that the entire mass assumes enormous proportions. Specimens found in the human host have attained a mass equal to 30 or 40 pounds. The liver is the preferred seat of the bladder worm in man and its serious character depends upon this fact because the tissues involved may be of a character to prevent surgical treatment and bring about the death of the host. In addition to the general practice of removing the hydatid by surgical means other methods of treatment have recently been tried with some success. This and numerous other parasites owe their

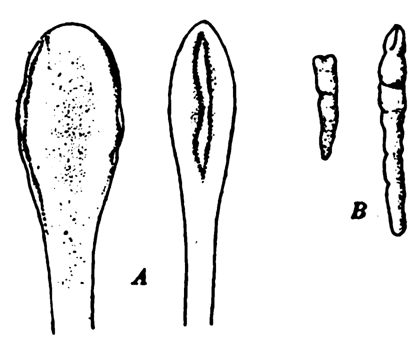

FIG. 4.—*Dibothriocephalus latus*; *A*, Scolex × 15, *B*, Larvæ from fish, in extended and contracted condition.

abundance and distribution to the frequence and movements of stray dogs.

The broad tapeworm, *Dibothriocephalus latus,* is also known as the fish tapeworm of man. The adult occurs in the small intestine of man and of the dog. The larva is found in the muscles and viscera of numerous fish: pike, burbot, grayling and trout. This is the largest common human parasite, reaching often a length of 20 meters. The head (Fig. 4) is provided with a pair of lateral sucking grooves which distinguish it readily from the other forms discussed previously. The uterus forms a rosette (Fig. 5) in the thickened centre of the proglottid and the species is recognized readily by both of these features. The para-

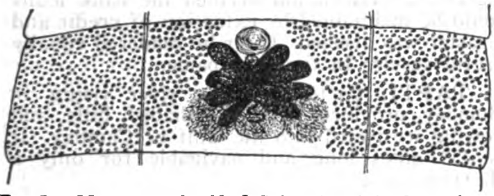

FIG. 5.— Mature proglottid of *Dibothriocephalus latus*, showing female reproductive organs. Note characteristic uterine rosette centre.

site is very abundant about the shores of the Baltic and also occurs in isolated spots as around a lake near Munich and in the vicinity of Lakes Geneva, Neuchâtel and Bienne in Switzerland. Larvæ have been found abundantly in fresh fish from markets near the Baltic and living specimens were obtained from smoked, salted and frozen fish as well as from salted roes used as caviar. The species is common in Japan and perhaps in some other parts of Asia where the larval host is said to be a salmon eaten raw as a delicacy by the natives. It has been introduced many times into the United States and seems to have established itself in small areas around certain lakes in northern Michigan, Wisconsin and Minnesota where an abundant foreign population has introduced from the Old World the habit of eating smoked fish without cooking. For further data consult Nuttall, G. H. F., ‹The Poisons Given off by Parasitic Worms in Man and Animals› (American Naturalist, Vol. XXXIII, 1899, pp. 247–49); Stiles, C. W., and Hassall, Albert, ‹The Inspection of Meats for Animal Parasites› (United States Department of Agriculture, Bureau Animal Industry, Bull. 19); Ward, H. B., ‹Cestodes in Reference Handbook of Medical Sciences› (New York 1913).

HENRY B. WARD,
Professor of Zoology, University of Illinois.

TAPIOCA, a starchy product manufactured from the rootstocks of cassava or manioc (*Manihot manihot*), which belongs to the family *Euphorbiaceæ*. The plant is a perennial herb or shrub which grows about three feet tall, bears long-petioled, deeply lobed leaves, and axillary panicles or racemes of monœcious flowers followed by three-celled capsules containing three seeds. The fleshy, cylindrical rootstocks are often three feet long and weigh 25 or more pounds. In the tropics, especially of South America, where the plant is native, manihot is extensively cultivated, and in Florida and other parts of the Southern States it is also grown. The usual practice in the West Indies is to plunge pieces of stem about 30 inches long into the ground, preferably a sandy loam, and let it care for itself, except for an occasional hoeing to kill weeds. At harvest time the rootstocks are dug, washed and rasped or grated to set the starch free. The fibre is removed as in potato-starch making, by maceration in water. The powder is then dried by heating it upon iron plates, a process which results in the familiar form of «pearl tapioca,» seen in Northern markets. Tapioca is highly esteemed for making puddings with or without fruit, etc.

TAPIR, a member of a family (*Tapiridæ*) of hoofed mammals, allied to the horses and rhinoceroses and chiefly distinguished by the fact that the nose is prolonged to form a short proboscis or trunk and the front feet have each four toes, the hind feet possessing three toes only. The little toes of the front feet are unsymmetrical and do not touch the ground, while all the toes are «hoofed.» They are adapted to live in swamps and rarely leave the dense forests covering such wet places. The tapirs possess a very wide distribution and inhabit both the Old and the New World. The best-known species is the South American tapir (*T. americanus*), which inhabits tropical America and is chiefly found living on the banks of rivers, in which it swims and dives with great ease. It is chiefly a nocturnal animal, feeding on roots, fruits and leaves. The adult is colored brown, the young being variegated with lighter spots and stripes on a darker ground. The hair is short and thick, but the neck possesses a short black mane. The average length is from four to six feet. A second species of South American tapir is the *T. villosus,* which is distinguished chiefly by the greater length of its hair, due to the fact that it inhabits elevated foot-hills of the Andes, where the climate is cold.

The only other distinct species is the Malayan tapir (*T. Malayanus* or *Indicus*), found in Malacca and Sumatra and known by the white color of the hinder part of its body, the head and anterior portions being black. The proboscis is larger in the Malayan species than in the South American forms and the former has no mane. It is usually of larger size than the New World forms and appears to be a shy, retiring animal, inhabiting clumps of brushwood.

The existing tapirs seem to approximate more closely than any other perissodactyls to the primitive (Eocene) type of that group. The family, as at present defined, dates back to the Lower Miocene and its remains are found in the White River beds of that age in the Rocky Mountain region. The earliest are separated as the genus *Tapiravus*, but typical tapirs soon appear. «It is thus evident,» remarks Woodward, «that during Miocene and Pliocene times these animals ranged over most of the warm and temperate lands of the Northern hemisphere. Hence is explained the remarkable distribution of the existing tapirs, which are confined to two widely separated areas, namely (1) certain portions of the Indo-Malayan region, and (2) the tropical parts of America. Like the surviving dipnoan fishes they are an illustration of a once dominant race nearly exterminated, but still struggling for existence where competition happens to be least severe in their particular case.»

TAPPAN, tăp'an, **Arthur**, American philanthropist: b. Northampton, Mass., 22 May 1786; d. New Haven, Conn., 23 July 1865. He accumulated a fortune in the dry-goods business in New York and became noted for philanthropy. He was a founder of the American Tract Society; founded Oberlin College, endowed the Lake Seminary in Cincinnati and aided other educational institutions. In 1828 he founded the New York *Journal of Commerce* and in 1833 established *The Emancipator*. He was an ardent abolitionist and a president of the American Anti-Slavery Society, to which at one period he contributed $1,000 a month. He aided fugitive slaves to escape from the country and procured the release of William Lloyd Garrison when the latter was imprisoned in Baltimore, by paying his fine.

TAPPAN, Benjamin, American naval officer: b. New Orleans, La., 10 April 1856. He was graduated from the United States Naval Academy 1876 and in 1886 was commissioned lieutenant. From 1888–91 he served in the office of the Bureau of Naval Intelligence and from 1891–94 on the *Miantonomah*. He was stationed at the Brooklyn navy yard 1895–96 and while on board the *Raleigh* participated in the battle of Manila (1898). During the attack on the city of Manila he captured a Spanish battery and for this act was advanced five numbers by President McKinley.

TAPPAN, Eva March, American educator and author: b. Blackstone, Mass., 26 Dec. 1854. She was graduated from Vassar College in 1875 and was a Fellow of the University of Pennsylvania 1895–96. She has published 'Charles Lamb, the Man and the Author' (1896); 'In the Days of Alfred the Great' (1900); 'Our Country's Story' (1902); 'In the Days of Queen Victoria' (1903); 'Canada's Story' (1903), etc.

TAPPAN, Lewis, American merchant and philanthropist: b. Northampton, Mass., 23 May 1788; d. Brooklyn, N. Y., 21 June 1873. He spent several years in commercial life at Boston, then (1827) settled in New York as partner of his brother, Arthur. Both took a very active part in the anti-slavery cause. Lewis and his brother were among the founders of the *Journal of Commerce* (1827) and (1828–31) Lewis was sole proprietor. The pro-slavery mob, in 1834, sacked his residence. He aided in the organization of the American Missionary Association, acting as treasurer and president for a number of years. His firm failed in the crisis of 1837, but later met all indebtedness. After the failure he established the first mercantile agency in this country and remained its head for a number of years. He published his brother Arthur's 'Life' (1871).

TAPPAN BAY, or **TAPPAN SEA**, the names given to the expansion of the Hudson River near Ossining and Tarrytown, N. Y. See HUDSON RIVER.

TAPPEN, Frederick Dobbs, American financier: b. New York, 29 Jan. 1829; d. Lakewood, N. J., 28 Feb. 1902. He was educated at Columbia Grammar School and New York University, graduating in 1849. Next year he entered the National Bank of New York as clerk, rising, by 1857, to cashier. The bank was reorganized (1865) as the Gallatin National and Tappen became president in 1868. He became member of the conference committee with the New York Clearing House in 1869 and member of the committee in 1872 and was appointed (1873) member of a committee to suggest financial reforms in operations between banks. Then and later he brought about clearing-house reforms in practice to this day. In the 1893 crisis Tappen rendered most important service; by June business was paralyzed and business corporations, banks, railroads, etc., had a $2,000,000,000 liability with gold in the treasury at low ebb, but the Clearing-House Association decided the bank loans could be maintained by extension of credit and disaster was averted. Later he rendered equally useful service in times of panic.

TAPTI, tăp'tē, India, a river rising in Bombay province in the Mahadeo hills and flowing westward into the Gulf of Cambay. It is 430 miles long and navigable for only a short distance.

TAPUL, tā-pool', a group of islands of the Sulu Archipelago, Philippines, lying between the Sulu group on the northeast and the Tawi Tawi group on the southwest, consisting of 38 charted and named islands and some unnamed islets; area, 77 square miles. The more important islands of the group are: (1) Siasi (q.v.), the largest, in the southern part of the group; (2) Bolipongpong, the most northwesterly of the group, heavily wooded; elevation, 955 feet; area, eight square miles; (3) Lapac, west of Siasi, from which it is separated by a narrow channel, with a very rugged surface; highest elevation, 1,344 feet; area, seven square miles; (4) Tapul, the name island, the most northerly of the group, fertile and under cultivation; highest elevation, 1,636 feet; area, six square miles. Though all tropical products and vegetation flourish in the larger islands, the chief industry is mother-of-pearl, pearl and turtle fishing; there are cocoanut plantations of value on one of the islands. Trade is carried on with Sulu, Tawi Tawi and Borneo. Pop. (estimated) 3,000. See SULU.

TAR, a thick, very dark liquid obtained by the dry destructive distillation of various organic substances. That obtained from coal, peat, bituminous shale, etc., is called coal-tar, while that from wood is named wood-tar. They are both very complex mixtures of organic substances. The substance popularly known as tar is wood-tar.

Coal-tar is collected from the hydraulic main and condensers of the gasworks as a black, oily, bad-smelling liquid somewhat heavier than water. It was formerly considered useless and a great nuisance, but, since the discovery of the value of its constituents, it has been made the starting material in many important industries. Coal tar is a very complex mixture of hydrocarbons, acid and basic bodies. Its components are first separated in a rough way by fractional distillation and then each fraction is subjected to an extensive chemical treatment to separate and purify each substance therein. The hydrocarbons occur in largest proportion and they are the most valuable. Some of the important ones are benzene (or benzol), toluene, xylene and anthracene. Of the acid bodies phenol or carbolic acid is the most important. The value of these substances lies not in themselves but in the compounds to which the chemist may pass from them. Nearly all of the varied and beautiful dye-stuffs now used are obtained from the substances mentioned above. The coal-tar colors are of exceeding brilliancy, but many are lacking in permanency (see DYEING).

Wood-tar is a thick, dark colored, viscous material, obtained as a by-product in the destructive distillation of wood in the manufacture of pyroligneous acid (wood vinegar) and methyl alcohol (wood alcohol). It varies somewhat in character with the kind of wood used. Wood-tar has many ingredients in common with coal-tar. The hydrocarbons mentioned above are present in small quantities; small amounts of carbolic acid are found with much larger quantities of homologous substances, the cresols (the whole mixture being called creosote). Products arising from the pyroligneous acid and methyl alcohol are also found, such as acetone, methyl acetate, etc. Wood-tar is prepared in large quantities in northern Europe by a very crude and wasteful process. A hole in the ground or side hill is lined with turf and then filled with wood (usually of coniferous trees), which is afterward nearly covered with turf. The wood is burned slowly with little access to air. The tar collects in the bottom, being usually caught in an iron pan provided with an exit tube. Wood-tar has valuable antiseptic properties because of the creosote it contains. This is often separated, but the wood-tar itself is much used for coating and preserving timber in exposed places.

Tar is a stimulant and antiseptic to the skin and mucous membrane. It is used externally for skin diseases in an ointment, lotion or soap. It is found in many cough mixtures and its vapor is frequently inhaled for pulmonary troubles.

TAR HEEL STATE, a popular nickname applied to North Carolina (q.v.).

TARA, tä'ra, Ireland, a hill in County Meath, six miles east of Trim. According to tradition the *fes of Tara*, the triennial convention here, was established by Ollam Fodlah or Ollav Fola (B.C. 900 or 950). After the decisions of the meeting the princes and others present held a banquet, each guest seated beneath his shield which the heralds had suspended on the walls of the great hall. The palace of Tara, tradition says, was 900 feet square and had 150 apartments and 150 dormitories. The hall had a capacity for entertaining 1,000 guests daily. It was here the early kings of Ireland were crowned. King Cormac Mac Art (3d century A.D.) is said to have founded schools here of military science, law and literature. In the days of Saint Patrick, Tara is said to have been the principal seat of Druidism and idolatry and (about 560 A.D.) fell under the curse of Saint Ruadan and had to be abandoned as a royal residence. A battle here is said to have caused the fall of Danish rule in Meath in 980. In 1798 the Royalist troops, 400 strong, defeated 4,000 Irish insurgents, killing 500. Daniel O'Connell held a monster meeting here 15 Aug. 1843, at which it is said 250,000 persons attended. The so-called remains of the royal palace are represented by six *raths* or circular earthworks, of which the *rath-na-riogh* (king's rath), which is the most extensive, contains the *forradh* (meeting place) which consists of an elevation having a level summit. The "stone of destiny," on which the kings are said to have been crowned, is located here. Certain earthworks enclosing a space about 759 feet by 46 feet and having breaches at intervals supposed to have been the entrances are considered as having been the banqueting hall. Thomas Moore rendered the Tara tradition imperishable with his poem "The Harp That Once Through Tara's Halls."

TARAI, tä-rī, or **TERAI**, India, a moist, jungly and unhealthful tract of land running for several hundred miles along the southern base of the central Himalaya. See HIMALAYA.

TARANTELLA, a swift, whirling Italian dance; so-called because it was popularly thought to be a remedy against the supposed poisonous bite of the tarantula spider, which was said to set people dancing.

TARANTISM, or **TARANTISMUS**, dancing disease (q.v.).

TARANTO, tä-rän'tō (Latin, *Tarentum;* Greek, *Taras*), southern Italy, a city in the province of Lecce, at the northern angle of the Gulf of Taranto, on a rocky tongue of land which separates the ancient inner harbor, a sort of lagoon called the Mare Piccolo (Little Sea), on the east, from the open sea on the west. The side has been made an island by a canal on the southeast, crossed by an iron swing-bridge, which admits the largest war vessels; another bridge at the northwest end also connects it with the mainland. Two islands, Saint Paolo, with a fort and a lighthouse, and Saint Pietro, guard the entrance to the outer harbor. The streets are very narrow, the three principal being the Strada Garibaldi along the Mare Piccolo, inhabited chiefly by fishermen; the Strada Maggiore, in the heart of the town, the main business thoroughfare; and the Strada Vittorio Emanuele, along the sea-front, a fine promenade. The 11th century cathedral, now wholly modernized, and the old castle are the chief objects of interest in the town proper. The Borgo Nuovo, a suburb on the mainland to the southeast, occupying the site of ancient Tarentum, contains a large arsenal and naval hospital and various harbor works have been constructed. The fortifications of the town have been much strengthened since 1895. There is an export trade in oil, wine, licorice, fruit, etc.; and coals, grain, petroleum, etc., are imported. Tarentum was founded by Greeks in 707 B.C., and rapidly became the chief city of Magna Græcia. It was noted for weaving and for the purple dye obtained from a species of mussel. It reached its greatest prosperity under Archytas, the philosopher, in the 4th century B.C., after which luxury and vice caused it to decline. It was compelled to seek the assistance of Greek kings in its wars with the Lucanians and when attacked by the Romans it was assisted by Pyrrhus of Epirus. In 272 B.C., however, it was taken by the Romans and the conquest was repeated in 209, after the city had supported Hannibal in the Second Punic War. It passed later under Byzantine sway, was destroyed by the Saracens in 927 A.D. and later belonged to the Norman kingdom in South Italy. In 1861 it became included in the kingdom of Italy and the Italian government strongly fortified the place, establishing there a torpedo base. It is now one of the four important naval centres of Italy. Pop. about 56,000.

TARANTULA, a large spider (*Lycosa tarantula*) with a body about an inch in length; its bite was formerly supposed to produce a kind of frenzy in human subjects called tarantism. The nervous actions of those victims are supposed to be imitated in the wild musical dance known among the Italians as "tarantella." Doubtless in some cases its bite produces disagreeable symptoms. The species named is a native of Italy, but varieties, or closely allied species, are found throughout the south of Europe. The so-called tarantulas of Texas and adjacent countries are large species of *Mygale*.

TARANTULA-KILLER, a very large burrowing wasp (*Pompilus formosus*) of Texas and southwestward, which stings tarantulas, depositing its eggs in their bodies and carrying the paralyzed spider off to its nest. See WASPS.

TARAPACA, tä-rä-pä-kä', Chile, a province in the northern part of the country, between Bolivia and the Pacific Ocean. Area, 16,689 square miles. The main range of the Andes forms the eastern boundary, while a lower range runs along the coast. The entire intervening country is a rainless desert traversed by a few streams in narrow valleys. The importance of the province lies in its immense deposits of nitrate of soda. These are found in the interior deserts and railroads are built from the coast to reach them. There are also some silver mines in the coast range. The capital and chief port is Iquique. The province was occupied by Chilean troops in 1879 and was ceded to Chile by Peru by the Treaty of Peace in 1883. Pop. 125,961.

TARASCO, an ancient tribe of American Indians which formerly spread over all of the Mexican states of Michoacan, in Guanajuato and Quaretaro. The Tarascos have been absorbed largely in the half-breed population, but Lumholtz states that he came across the pure stock nearly 200,000 strong, in 1896, still living in the mountains of Michoacan. According to their traditions they must have come from the northern regions, as did the Nahuatlans. They do not call themselves Tarascos but name their tribe *Purépecha*. In consequence of their absorption with other races their original customs, in most sections, are fast disappearing, They never mention the sun except as Our Father Sun and they transact no business nor will they shell corn after sun-down. They worshipped the Southern Cross constellation. In each house they place in the best room pictures of a saint or saints, which are said to inhabit that room, while they, out of reverence to the saint, sleep in the kitchen; but they allow strangers to occupy that room. The entire series of their saints is called *Tata Dios,* Father God. Copal incense is burned before the house deity, and the visitor, before mentioning the cause of his arrival, first kisses the saint's picture. The tribe has a great love for music and almost every individual has his guitar. They are hard workers, especially the women, who are badly treated. Like most Indian tribes, the Tarascos are clever potters. Consult Lumholtz, K. S., 'Unknown Mexico' (New York 1902).

TARASCON, tä-räs-kôn, France, a town in the department of Bouches-du-Rhône, on the left bank of the Rhône, opposite Beaucaire, with which it is connected by a suspension-bridge, 55 miles north-northwest of Marseilles. It is surrounded by walls, flanked with towers and entered by three gates. The streets are wide and regular and one of them is lined with arcades. The principal buildings are the old castle, seated on a height overhanging the river; the church, a handsome Gothic structure of the 11th century, with a finely sculptured portal; the town-house, courthouse, theatre, general hospital and public library. Woolen cloth, serge, silk goods, hempen and cotton cloth, vermicelli, soap, starch and cordage are manufactured and there are also brandy distilleries, wax refineries, tanneries, brickworks and building-yards for barges. The trade is in wine, brandy, oil, hemp, wool, wood, coal, medicinal plants, lucerne-seed and madder. Tarascon is the Roman Tarasco and is an interesting type of the mediæval town. It is the locale of Daudet's 'Tartarin de Tarascon.' Pop. 8,631.

TARAXACIN, a crystallizable substance found by Pollex in the milky juice of the root of the ordinary dandelion. It is bitter and acrid in taste. Used somewhat as an alterative and tonic.

TARBELL, Edmund C., American artist: b. West Groton, Mass., 1862. He was a pupil in the Boston Museum of Fine Arts and going to Paris was taught by Boulanger and Lefebvre. In 1900 he took the Clark prize at the National Academy of Design; the Shaw Fund, Society of American Artists (1893); medal at the Columbian Exposition and other awards at Philadelphia, Boston and Paris (bronze medal 1900). In 1906 he was elected to the National Academy. For many years he was instructor at the Boston Museum. His pictures are distinguished by fine atmosphere and color and the bold truthfulness of his outdoor work borders on impressionism.

TARBELL, Frank Bigelow, American archæologist: b. Groton, Mass., 1 Jan. 1853. He was graduated at Yale in 1873 and was assistant professor of Greek and instructor of logic there 1883–87 and was instructor of Greek at Harvard University 1889–92. He has been professor of classical archæology in the University of Chicago from 1894 and has published 'The Philippics of Demosthenes' (1880): 'A History of Greek Art' (1896): 'Catalogue of Bronzes, etc., in Field Museum of National History' (1909).

TARBELL, Ida Minerva, American biographer: b. Erie County, Pa., 5 Nov. 1857. She was graduated from Allegheny College, Meadville, Pa.; was associate editor of *The Chautauquan* 1883–91; studied at the Sorbonne and Collège de France, 1891–94; from 1894 to 1906 was on the editorial staff of *McClure's Magazine;* from 1906 to 1915, associate editor of *The American Magazine*. Her publications include a 'Short Life of Napoleon

Bonaparte' (1895); 'Life of Madame Roland' (1896); 'Early Life of Abraham Lincoln' (with J. M. Davis, 1896); 'Life of Abraham Lincoln' (1900); 'History of the Standard Oil Company' (1904); 'He Knew Lincoln' (1908); 'Father Abraham' (1909); 'The Tariff in our Times' (1911); 'The Business of Being a Woman' (1913); 'The Ways of Women' (1915); 'New Ideals in Business' (1916); 'Making Men at Ford's' (1916).

TARBES, tärb, France, capital of the department of Hautes-Pyrénées, 25 miles east of Pau, on the Adour, here crossed by a handsome bridge. The cathedral is a modern structure, erected on the site of the old castle of the counts of Bigorre, of whose territory Tarbes was the capital; other buildings are the church of Saint John, the church of the Carmelites, with a remarkable spire; the prefecture, occupying the old episcopal palace; the civil hospital, college and barracks. Leather and paper are manufactured and the trade includes, in addition to these articles, wine, iron, cattle and agricultural produce. Tarbes is mentioned by Cæsar under the name of Bigorra. A famous battle was fought here 20 Nov. 1814, the English routing the French. Pop. of the commune, 28,615.

TARDE, tärd, **Gabriel,** French philosopher: b. Sarlat, Dordogne, 1843; d. Paris, 1904. He studied law, became *juge d'instruction* in his native town and held this position for nearly 19 years. He began his contribution to the *Revue Philosophique* in 1880 and between 1882 and 1884 published in it his first studies of the law of universal repetition and imitation. In 1894 he was called to Paris to assume control of the Bureau of Statistics of the Ministry of Justice. He relinquished this post in 1900 and became professor of modern philosophy in the Collège de France; in that year, also, he was elected to the Institute of France. His writings deal largely with the laws that govern mankind in their social relations; how new ideas are brought out, developed and are accepted as custom. He was a thorough believer in the theory that 99 men are imitators to one original. His studies in criminology contain similar views. His publications, several of which have been translated into English, include 'Les Lois de l'Imitation' (1890); 'La Criminalité comparée and La Philosophie pénale' (1891); 'La Logique sociale' (1895); 'L'Opposition universelle' (1897) and 'Les Lois sociales' (1898); 'Essais et Melanges Sociologiques' (1895); 'L'Opinion et la Foule' (1901); 'Psychologie Économique' (1901); 'Underground Man' (1905). Consult 'Gabriel Tardi,' with preface by Bergson (1909).

TARDIEU, tär'dyė, **André Pierre Gabriel Amédée,** French publicist and administrator: b. 22 Sept. 1876. He passed out first in his year from the Ecole Normale and entered the diplomatic service, being attached to the French embassy in Berlin in 1897. He served a while in the Foreign Office and as secretary in the presidency of the Council of Ministers 1899–1902. He was editor of the *Revue des Deux-Mondes* and became foreign editor of the *Temps.* He paid a visit to the United States in 1908 and recorded his impressions of that country in a book, 'Notes sur les Etats-Unis' (Paris 1908). Of President Roosevelt, whom he interviewed, he wrote then, «What particularly characterizes his policy is its essential and emphatic Americanism,» an estimate corroborated by all Americans on the death of that statesman 11 years later. M. Tardieu entered politics in the general election preceding the outbreak of the war. He was made chief censor, a post he soon left for active service in the trenches. Incapacitated by a severe attack of pneumonia, brought on by exposure, he was appointed head of the French commission to the United States in 1917. He labored at Washington and elsewhere for the business efficiency of the Allies and the co-ordination of their economic strength. Returning to France shortly after the formation of the Clemenceau ministry, he later made another important trip to America and subsequently remained in Paris as high commissioner for all matters concerning France and the United States. He was the youngest delegate to the Peace Conference in Paris. He wrote several excellent books on European politics; his 'Questions diplomatiques de l'année 1904' was «crowned» by the French Academy. A remarkable work is his 'Le Mystère d'Agadir,' dealing with Morocco and Germany. He also wrote 'La Conférence d'Algesiras' and 'France et les Alliances' (Paris 1907).

TARDIGRADA, tär'dĭ-grā'dą, a term in zoology applied (1) to the group of sloths and (2) to a group of microscopic animals also known as water-bears, which are usually classed with the *Arachnida.* The water-bears have a cylindrical body bearing four pairs of short clawed feet, while the mouth is furnished with two stylet-like rods. The nervous system is much like that of annelids; circulatory and respiratory organs are lacking. These animals are hermaphrodic, and when the eggs are fertilized the skin of the body is shed, the eggs remaining in it. The development is more like that of the annelids than like that of the arachnids, and the relation of these animals to the spiders is more than doubtful. The species all live in fresh water, being common in moss and fresh-water algæ. Most of the species will stand prolonged drying and will revive upon being placed in water.

TARDIVEL, tär'dē-vĕl, **Jules Paul,** Canadian journalist: b. Covington, Ky., 1851; d. 1905. He went to Canada in his 17th year and was educated at Saint Hyacinth College. He entered the service of *La Minerve* and *Le Canadien* and (1881) established *La Verité* of Quebec, being its editor as well as proprietor for a lengthy period. As a staunch Catholic he propagated the creed in political matters, opposing liberalism and Freemasonry. He was an advocate for entire independence of the province of Quebec and secession from the Canadian Confederation. He wrote 'Vie du Pape Pie IX, ses œuvres et ses douleurs' (1878); 'Notes de voyage' (1890); 'Pour le patrie' (1895), a novel attacking Freemasonry.

TARE, any of several plants. The tare mentioned in the Bible (Matt. xiii, 25) is supposed to be darnel (*Lolium temulentum*), since the Greek word ζιζάνια («wild rice») is used in the oldest Greek manuscript. Darnel is related to the wild rice and eating its seeds was formerly supposed to produce stupefaction. The modern tares are all members of the family *Fabaceæ*. The name is most commonly used for *Vicia sativa*, better known in England and America as the common vetch. This plant is cultivated to some extent in Europe because it will thrive upon poor soils and produce forage where other plants usually fail. Its yield is small, but in such places is deemed worth while. It is also used as a green manure for improving poor land. Its close relative, the wild vetch (*V. hirsuta*), also loosely called tare, is similarly named and used, but it is more often ranked as a weed.

TARE, in commercial technology, is an allowance for the outside packages of goods which cannot be packed without detriment, which is deducted from the weight if he buys by the pound. Obviously the papers, threads, bands, etc., that enclose or bind any goods imported loose cannot be conveniently separated for weighing nor, in many cases, can casks or chests be weighed separately from their contents.

TARENTUM, ta-rĕn'tŭm, Pa., borough in Allegheny County, on the Allegheny River, and on the Pennsylvania and the Allegheny Valley railroads, about 20 miles northeast of Pittsburgh. It is in an agricultural and coal mining region. The chief manufacturing establishments are paper mills, glass factories, foundries, machine shops, flour mills and planing mills. It is a typical manufacturing town and its 65 factories turn out about $3,000,000 in products annually. There are banks and newspapers. The educational institutions are a public high school, public and parish elementary schools and a public library. Pop. 7,414.

TARENTUM. See TARANTO.

TARGUM, the translation of the Old Testament Scriptures into Aramaic. This version originated at a time when Hebrew had given way to Aramaic as the popular language of the Jews. The need of explaining the old Scriptures to the people after their subjugation by the Persians is suggested by Nehemiah viii, 8, where we read that Ezra read the law to the people, while it was interpreted by his assistants, interpreters — Meturgemans as they were called. As the Targum was not committed to writing, little of it has survived. There are indeed three Targums of the Pentateuch and one of the Prophets, as well as of the Psalms, Job, Proverbs, the Song of Songs, Ruth, Lamentations, Esther and Ecclesiastes. The Targum is not of much critical value, but throws considerable light on the life of the Jews at the time it was composed. Consult Berliner, A., 'Targum Ontales' (Berlin 1884); Lagarde, 'Prophetæ Chaldain' (Leipzig 1872).

TARIFF. The taxation of goods by the imposition of customs duties upon passing the national boundary line or some fixed point is an ancient method of raising revenue. The earliest form of this tax was probably the transit duty imposed on goods passing through a district and was justified as a payment for protection or for special facilities. The export duty, levied on goods as they leave the taxing territory, came next in historical order. What in fact could be more just, it was thought, than a tax upon goods of whose use the home community would be deprived and the burden of which would be borne by the foreign consumer. Finally there developed import duties which are made use of in practically every civilized state to-day. Transit duties have disappeared as a form of national finance; export duties are of fiscal importance to-day only in Turkey and India. But import duties contribute a large though variable proportion of the revenues of the United States and of the leading European states. In the United States before the imposition of the income tax they made up nearly one-half of the Federal receipts; before the European War they constituted about one-half of the net receipts of the German Empire; about one-quarter of the total revenues of England; and about 15 per cent of those of France and Italy.

Among the civilized nations of antiquity tariffs for revenue purposes were generally used. The Greeks, and more especially the Athenians, levied customs duties upon both imports and exports, the usual rate being about 2 per cent. The Roman state also resorted regularly to this form of taxation. With the breakdown of centralized government during the Middle Ages the feudal lords claimed the right of imposing transit duties on all goods passing through their domains, nominally as a payment for protection. When feudalism in turn gave way to strong monarchies the rights of the lords in this regard were exercised by the kings and to local tariffs were added national ones. Every European country was covered with a network of customs lines which greatly hindered trade, but were not productive of commensurate revenues. The history of modern tariff legislation has been the simplification of this complicated system.

In England a complex system of import and export duties had slowly developed by the constant addition of new objects of taxation and by the confusing practice of assigning the proceeds of each new duty to a different purpose or fund. In 1787 Pitt consolidated all of the tariff duties into one general fund. At this time about 1,200 articles were subject to import duties and about 50 to export duties. The next step in the direction of simplification of the tariff was effected in 1824 by Huskisson, who abolished most of the export duties, freed raw materials of their burdens and consolidated a mass of tariff acts. The real beginning of modern English free trade was made during the period 1842–60, when some 938 articles were placed on the free list. Practically the only articles upon which import duties were collected after 1860 were sugar, cocoa, coffee, chicory, dried fruit, tea, tobacco, wine, beer and spirits. In spite of the decrease in the number of dutiable articles the revenues from the few remaining ones steadily increased, with a corresponding reduction in cost and simplification of administration. With the increasing competition of German and American manufactures, especially since about 1900, a reaction in favor of protection has arisen in some quarters. Since the outbreak of the European War this movement has taken the form of a demand for preferential treatment of the colonies.

In France the diverse and multifarious provincial tariffs were swept away in 1790 and the following year a common and uniform tariff against foreign countries was established. For the first time France now had economic unity. Duties were at first moderate, but under Napoleon they were made highly protective, a system which was continued under the Restoration and extended to agriculture as well as manufactures. Under the monarchy of Louis Philippe the government was administered in the interest of the middle class and consequently no changes were made in this policy. But with the establishment of the empire a more liberal policy was introduced which culminated in the Commercial Treaty of 1860 with England. By 1881 the pendulum had swung in the other direction again, and the new tariff of that year was much more protective. A decade later protection was extended to agriculture and since that time France has maintained a policy of all-around protection and national self-sufficiency.

Germany's tariff policy has moved along somewhat different lines. At the beginning of the 19th century the present German Empire was a group of mutually antagonistic states so far as their tariff relations were concerned. The great problem was to unite them under a common external tariff and to abolish the local interstate tariffs. This was finally accomplished under the leadership of Prussia by the Zollverein, which continued from 1834 to the establishment of the German Empire in 1871, when complete economic unity was effected. The tariffs under the Zollverein had been moderate and now they moved still further in the direction of free trade, but in 1878 a change was made to protection which has since been carried further, covering agriculture as well as manufactures. The tariff has been made to serve political ends as well as industrial and fiscal purposes in Germany.

In the United States customs duties have been used from the earliest colonial period. Nearly every colonial assembly levied import duties for its own treasury in addition to those imposed by Great Britain in the execution of the Navigation Acts. They seem to have been levied for sumptuary, retaliatory or protective purposes quite as much as for fiscal ends. These colonial tariffs have been classified under the following four heads: (1) tonnage duties or taxes on shipping; (2) export duties on tobacco and other colonial staples; (3) import duties on slaves; (4) regular tariff schedules in which wines and liquors were the most prominent items. These duties were generally low ad valorem duties ranging from 1 to 5 per cent, but even with these rates seem to have been largely evaded.

A national tariff act was made possible by the adoption of the Constitution and the first piece of legislation by Congress was the passage on 4 July 1789 of such an act. The main purpose of this was revenue, but protection was also extended to certain industries which it was desired to encourage, as glass and earthenware. The average rate of duty, however, was low, being about 8½ per cent, but in those days distance was a more effective barrier than it is to-day. No important changes were made until the Act of 1816, but in the meantime the Embargo and Non-intercourse acts and the War of 1812, which had interrupted foreign trade, had called into being manufactures of which it was now felt care should be taken. Accordingly this tariff act gave a substantial measure of protection to those industries most exposed to foreign competition, namely, textiles, hats, cabinet wares, leather and paper. By 1824 other industries were demanding protection such as iron, wool, hemp, glass and lead and a general revision was made in the tariff, resulting in a raising of rates throughout the list but especially in the case of the articles named. For the next few years there was continuous agitation of the tariff question, led by the woolen manufacturers who wished further protection. A convention of the friends of protection was held in Harrisburg in 1827 and systematic propaganda was carried on. The result was the tariff of 1828 which granted the highest protection yet accorded in any act, the chief beneficiaries being the cotton and woolen industries. This "tariff of abominations," as it was called, caused intense opposition both in the North and in the South, and it was replaced in 1832 by a more moderate act which eliminated the worst features of the previous tariff and put the duties back at about the point where they were in 1824.

The opposition of the South, however, was too great to be appeased by any half-way measures and in the next year it flamed out in nullification. South Carolina declared the Tariff Acts of 1828 and 1832 null and void and not binding upon the State or its citizens. In order to placate the opponents of protection and at the same time prevent too sudden and radical a revision of duties, Clay introduced the so-called Compromise Tariff of 1833. This provided for a gradual reduction of all duties over 20 per cent to a 20 per cent level by an annual excision of one-tenth per cent until 1842 when they were all to be placed at that point. This agreement was carried out and the reductions took place according to schedule. Hardly had this been effected, however, than the protectionists seized upon the decline in revenues which had followed the panic of 1837 as an excuse for another revision of the tariff, this time in the direction of much higher duties; in general, the Act of 1842 returned to about the level of the Act of 1832. By 1846 good times had returned, there was a surplus in the treasury and a Democratic President and Congress were in office. They decided to make a radical change in the tariff policy which they enacted into law in the Act of 1846. This has often been called a free trade tariff, but it still retained a considerable protectionist flavor although the rates on the great bulk of commercial products were reduced to between 15 and 30 per cent. The next few years were years of unparalleled business prosperity and commercial expansion and the revenues from import duties increased by leaps and bounds. The need of a reduction of revenue was so obvious that in 1857 another tariff measure was enacted lowering many of the duties and enlarging the free list. Before this act was fairly in effect, however, the panic of 1857 cut down importations to such an extent that a deficit resulted and accordingly in 1861 the previous duties were restored.

When the Civil War broke out the necessity for revenue outweighed all other considerations. Heavy excise duties were placed upon domestic manufactures and to compensate these the import duties were raised correspondingly and in some cases a little more. This was done in 1862, the average rate being raised to 37 per cent. The same procedure was followed again in 1864 except that a somewhat greater amount of protection was granted, the average rates being increased by this act to 47 per cent. After the war efforts to reduce the tariff to the ante-bellum basis met with resistance from the protected interests and practically nothing was done until 1870. In that year the duties on articles like tea, coffee, wine, sugar, molasses and spices, which did not affect domestic industries, were reduced. Again in 1872 a general revision was avoided by making a 10 per cent horizontal reduction of all duties and abolishing entirely those on tea and coffee and a few other articles. The loss of revenue resulting from the sacrifice of duties, amounting to about $20,000,000 from tea and coffee, and the shrinkage of other receipts as a result of the panic of 1873, resulted in a deficit of about $50,000,000 and in 1875 the 10 per cent horizontal reduction was repealed. The period of depression came to an end about 1878 and with the return of prosperity a surplus began to heap up in the treasury again. In 1882 a tariff commission was appointed to propose changes, but their recommendations for a reduction of the tariff were rejected by Congress. Internal revenue duties were abolished or reduced, but the import duties were on the whole increased.

This action called forth strong protest from the Democrats, and in 1887 President Cleveland brought the issue to a head by a vehement message urging tariff reform and the necessity of reducing the surplus. Up to this time the surplus revenues had been applied to the payment of the debt, but all available bonds had now been paid. The Democratic House passed the Mills bill providing for a general reduction of the tariff, but the Republican Senate replied by proposing further cuts in internal revenue duties. In the ensuing elections the Republicans were victorious and proceeded to solve the problem of the surplus by the double process of spending it and raising the import duties by the McKinley Act so as to discourage importations. Extravagant pension legislation was inaugurated and a bounty of two cents a pound given to domestic sugar producers; at the same time imported sugar was admitted free, thus sacrificing an annual revenue of $56,000,000. These actions effectually removed the surplus and indeed paved the way for a deficit, which occurred when the panic of 1893 broke upon the country. The Democratic tariff of 1894 reduced the duties on many protected commodities, added to the free list, restored the duty on sugar and provided for an income tax. The failure of the income tax section, however, by being declared unconstitutional, and the continuing depression led to embarrassing deficits, and when the Republicans were returned to power in 1896 they promptly reversed this policy by the passage of the Dingley Tariff in 1897, raising the general average of duties to the highest point since the Civil War, namely, 57 per cent. This was an increase from 37 per cent in 1883 and 49.5 per cent in 1890.

The tariff now remained undisturbed for 12 years, but dissatisfaction with the existing duties grew strong, especially with the burdens on raw materials and the favors to monopolized industries. Efforts were made within the Republican party itself, especially by members representing the Middle West, to secure a revision of those duties favorable to the trusts, though without success, but finally in 1908 a campaign pledge was made by this party to revise the tariff. The Payne-Aldrich Tariff of 1909 was an attempt to redeem this pledge, but the protected interests succeeded in preventing any serious reductions in schedules. This repudiation of party pledges led to an insurgent movement which found expression in the Progressive party and swept the Democrats into power at the next election. The Underwood Tariff of 1913 made important changes, especially in the iron and steel schedules; free wool was provided for, a gradual reduction of the sugar duty with ultimate free sugar, and in general free raw materials for manufactures. The outbreak of the European War the following year necessitated the suspension of the reduction of sugar duties, thus saving a revenue of some $45,000,000 a year. The enormous revenues needed to defray our expenditures since the entry of the United States into the war have been provided, as in the case of the Spanish War in 1898, by increasing the internal revenue taxes and by income, inheritance and excess profits taxes. An expert tariff commission was provided for by the War Revenue Act of 8 Sept. 1916, which it is expected will supply the machinery and the information for the scientific solution of the difficult problems of tariff adjustment after the war.

ERNEST L. BOGART,
Professor of Economics, University of Illinois.

TARIFF ADMINISTRATION IN THE UNITED STATES. The administration of the tariff laws, which comes within the province of the Treasury Department, is directly under the care of the Secretary of the Treasury and one of his assistant secretaries. The machinery furnished by the department and the government for its execution is comprehensive, complicated and far-reaching. All articles imported must follow a certain prescribed and unchangeable routine which begins with the requirement of a certificate of value made before a United States consular office abroad, for every shipment of foreign merchandise destined for entry into the United States. The exact methods of entry of goods, the valuation of the same, their classification and the rate of duties to be paid, in each case, are minutely and exhaustively prescribed; and provision is made for appeal against the interpretation of the Tariff Law, the classification of articles, the tariff charges or duties and, in fact, any other injustice or irregularity that may arise in connection with the administration of the tariff. This system of appeal is very elaborate and is at the service of the importers and the government alike. Naturally the tariff administration takes charge of the collection duties. This it does directly notwithstanding the fact that the extent and importance of the import duties would seem not only to justify but to demand, as in the case of the internal revenue, a separate customs bureau. The division of the country into customs districts facilitates the collection of customs through the various ports of entry. These ports of entry are themselves subject to strict routine regulations and are provided each with an administrative staff adequate to its needs. This staff, in the larger and more important ports of entry, includes a collector, appraiser, surveyor, gaugers, inspectors, a naval officer and officials in accordance with the importance of the port. By law no goods destined for import into the country may be presented at any other place than one of these ports of entry, where the government has provided for the storage and warehousing of goods for the moment or for longer periods of time in case the importer should not wish to make use of the goods imported. The latter may defer the payment of duties, if he so desire, until it is convenient for him to take the goods out of the warehouse. The unloading of all goods destined for importation must be done under the supervision of the customs officials and accomplished within a certain specified time. This is facilitated by the requirement which exacts from every vessel arriving at a port of entry, from a foreign country, a manifest of the nature of the cargo, the names of the consignees, ports of shipment and other information of a like nature, which must be submitted to the revenue officers before reaching the dock, if so desired, and delivered to the collector, upon reaching port, in order to secure his permit to take possession of the cargo, upon the presentation, by the consignee, of a complete and detailed statement of the value and nature of the goods. This statement or invoice forms the basis on which the duty is fixed by the appraisers and the port collector. In case the consignee is dissatisfied with the appraisement, a new one may be ordered, or, in case this is denied at the port, an appeal may be made to the board of general appraisers for a reconsideration of the valuation. The United States Court of Customs Appeals handles appeals as to classification and other similar matters. This permits the remedy of errors, and injustices of all kinds in the administration of the tariff laws and regulations; and this makes the United States tariff administration very efficient and just to all. The collector receives the duties and pays them over to the Treasury Department. (See TARIFF ADMINISTRATION). Consult Bolles, A. S., 'Financial History of the United States' (1886); Dewey, D. R., 'Financial History of the United States' (1903); Goss, J. D., 'History of Tariff Administration in the United States' (1891).

TARIFF LAWS, the various enactments of Congress, extending from 1789 to 1913, to regulate import duties. Those of recent date are: The Morrill Tariff Act (1861); McKinley Tariff Act (1890); Wilson-Gorman Tariff (1894); Dingley Tariff Act (1897); Payne-Aldrich Tariff Act (1909); Underwood Tariff Act (1913). See TARIFF ADMINISTRATION IN THE UNITED STATES.

TARIJA, tä-rē'hä, Bolivia, the capital of the department of the same name, situated among the mountains near the Argentine frontier and having an area of 31,567 square miles. It lies on a fertile mountain plain and has a pleasant climate. The town has a handsome church, and there is considerable transit trade with Argentina. Pop. of town, about 10,000; department, about 165,000.

TARIM, tä-rēm', central Asia, a river of East Turkestan, formed by the confluence of the Aksu, Yarkand and Khotan-Darya at the southern base of the western Tyan-Shan ranges, 60 miles southeast of Aksu. Thence it flows east and finally southeast, losing itself in the group of lakes and salt marshes known as Lob-nor, at the northern base of the Kuen-Lun range. With its main headstream, the Yarkand, the Tarim River encircles the vast desert plain of Turkestan, receiving nearly all its tributaries from the surrounding mountains on its left bank. The Tarim and its basin were first thoroughly explored and mapped by Hedin, during the last years of the 19th century.

TARKINGTON, (Newton) Booth, American novelist: b. Indiana, 29 July 1869. He was graduated from Princeton in 1893 and his first novel, 'The Gentleman from Indiana' (1899), attracted widespread and favorable attention. Thenceforth he followed literature, with the exception of serving one term in the Indiana legislature in 1903. His next works were 'Monsieur Beaucaire' (1900); 'The Two Vanrevels' (1902); 'Cherry' (1903); 'The Beautiful Lady' (1905); 'The Conquest of Canaan' (1905); 'Gust of Quesmay' (1908); 'Beauty and the Jacobin' (1911); 'The Flirt' (1913); 'Penrod' (1914); 'Seventeen' (1916); 'Turmoil' (1917); 'Robert Cortes Holliday' (1918); 'The Magnificent Ambersons' (1918). He has also written several plays, the most successful being 'Monsieur Beaucaire' (after the novel), in which he collaborated with Harry L. Wilson.

TARKIO (tär'kẹ-ō) **COLLEGE,** located at Tarkio, Mo. It was established by private initiative in 1883 under the name of Tarkio Valley College and Normal Institute. A new charter was obtained in 1884 by which the name was changed to Tarkio College and the institution came under the control of the United Presbyterian Church. The college has been from the first coeducational. Its organization includes a collegiate department, a normal department, a preparatory department, a musical department and a commercial department. The collegiate department offers two courses leading to a degree, the classical (degree of A.B.), and the scientific (B.S.), and a third course, the literary, for the completion of which a diploma is granted; this latter omits one year of the work of the scientific course. The normal course occupies four years; students are allowed to pursue the studies they most need. Students in both this and the commercial department can take additional studies in any of the collegiate courses. Bible study is a part of the curriculum in the preparatory and collegiate courses. The college has a campus of 20 acres a little above the town; the chief buildings are the main building, Marshall Hall (women's dormitory) and Gentlemen's Hall. In 1901 David Rankin gave $53,000 toward the increase of the permanent endowment, and the productive funds were in 1917 $163,000. The library in 1917 contained 8,300 volumes; the students numbered 235 and the faculty 23.

TARLAC, tär'läk, Philippines, (1) Pueblo, capital of the province of Tarlac, Luzon, on the Bolso River at the point where its name changes to Tarlac, and on the Manila and Dagupan Railroad, 73 miles northwest of Manila. In addition to the railroad it has excellent highway facilities, and is the centre of trade for the surrounding country. Pop. 12,340. (2) An interior province in the southwestern part of northern Luzon, bounded on the north by Pangasinán, on the east by Nueva Ecija, on the south by Pampanga and on the west by Zambales; area, 1,295 square miles. In shape it is approximately square, measuring 37 miles from north to south and 39 miles from east to west; the eastern part is level, while the western part includes the eastern slopes of the Cordillera de Cabusetan, the highest peak being Mount Iba, 1,604 feet. The province is watered by numerous rivers. Rice is the most important product; sugar is also raised in large quantities, and tobacco and corn on the higher levels. The forests are valuable, and the timber is easily obtained on account of the numerous rivers, and their proximity to the forest lands. There are a few mechanical industries for domestic use only. The province is traversed by the Manila and Dagupan Railroad, the main highways and numerous lesser roads; the rivers also are navigable for native boats, so that the facilities for trade are excellent. Pop. about 135,000.

TARLATAN, a thin and fine species of open, transparent muslin, mostly used for women's wear, originally esteemed as high grade, but later deteriorated. The chief seat of the manufacture is Tarare, in France.

TARLETON, Sir **Banastre,** English soldier in the Revolution: b. Liverpool, 1754; d. Leintwardine, Shropshire, 25 Jan. 1833. In 1775 he entered the English army as cornet in the king's dragoon guards, and obtained leave to accompany Lord Cornwallis to North America, as volunteer. He was present with Clinton's army at the attack on Charleston and other operations, then served with Sir William Erskine's cavalry, attacking and capturing New York (September 1776), Fort Washington and Fort Lee in November. He commanded the advance guard under Harcourt and captured General Lee (13 December) and was present in operations around Brunswick, Princeton and Trenton (1777). In 1780 he fought around Charleston capturing (by surprise) three regiments of American cavalry with their stores, just before the capitulation of Charleston. He aided in the capture of Camden. In the South he had to retreat, after Morgan's victory at Cowpens, to Hamilton Ford. Joining Leslie in January 1780 they returned and successfully attacked Morgan. But in spite of Tarleton's numerous successes the attacks of Lafayette and Wayne rendered the Cornwallis position hopeless and, with the surrender to Washington, Tarleton returned to England (1782) on parole. He was made lieutenant-colonel of light dragoons in December, then entered Parliament (1790) representing Liverpool, retaining his seat till 1807. In 1807 he was again elected to sit till 1812, giving his seat to Canning. He was promoted (1790) to colonel, then to major-general (1794) and lieutenant-general (1801). After several short commissions to Ireland and elsewhere he was made (1808) governor of Berwick and Holy Island. In 1812 he was promoted to general and was created baronet in 1815. He was certainly a clever, daring and successful leader of cavalry, but history would give him the blame for unnecessary cruelty, resorting at times to butchery. He wrote 'History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America' (London 1787).

TARN, tärn (ancient Tarnis), a river of France, which rises on the south slope of Mount Lozère, near Florac, in the department of Lozère. It flows west-southwest, crosses the departments of Averyron and Tarn, passing Alby, turns northwest through Haute-Garonne into Tarn-et-Garonne, where it passes Montauban, turning almost due west, passes Moissac, and joins the Garonne on the right a few miles below. Its whole course is 230 miles, of which about 100 miles, beginning at Alby, are navigable.

TARNOPOL, tär'nō-pōl, Austria, town in Galicia, on the left bank of the Sereth, 80 miles east-southeast of Lemberg, near the Russian border. It has a Roman Catholic and a Greek Catholic church, an old castle, now used as barracks, a new castle, a Jesuit college, a gymnasium, a Polish real-school and several other schools. A thriving trade in refining and brewing, horses, grain, wax, honey, etc., is carried on. Pop. about 35,200.

TARO, a plant (*Colocasia antiquorum esculenta* and related forms) of the arum family, widely grown for food in tropical regions, especially in the islands of the Pacific. The plant has very large heart-shaped leaves, from thick tuberous roots, and small greenish flowers, resembling those of the calla, to which it is related. A form, still grown in Egypt and used as food by the laboring classes, is known to be of great antiquity. In the Pacific region hundreds of forms of taro are recognized by the natives. Taro is used in Hawaii chiefly in the form of poi, a paste made by boiling and grinding the roots and allowing them to ferment for a day of two. The roots are used in many other ways, like the potato. The leaves, also, when cooked to destroy their acridity, are used for food.

TARPAN, a local name for the Asiatic wild ass.

TARPAULIN, originally a broad piece of canvas, thoroughly coated with tar, and used to cover the hatchways of a ship at sea, to prevent the penetration of the rain or seawater which may at times rush over the decks; now any heavy waterproof canvas for protecting goods from water.

TARPEIAN (tär-pē'yan) **ROCK,** Italy, a portion of the Capitol at Rome, so named from the tradition that during a war with the Sabines, Tarpeia, the daughter of the governor of the citadel of Rome, promised to open the gates of the city to the Sabines, provided they gave her what they carried on their left hands, meaning their gold bracelets. The Sabines consented, and as they entered the gates threw not their bracelets but their shields upon Tarpeia, who was crushed to death under the weight. She was buried in the Capitol, which from her was called the Tarpeian Rock; and there Roman malefactors were afterward thrown down a deep precipice. See ROME.

TARPON, or **SILVER KING,** a great and powerful fish (*Tarpon atlanticus*, or *Megalops thrissoides*), known from Virginia to Brazil, and regarded by anglers as the finest of American game fishes. It is related to the herrings and resembles them in general outline, but is sometimes six feet long. Its special marks are the long filamentous appendage of the posterior margin of the dorsal fin and the huge, round, shining scales, which encase the body in an armor of glittering silver, and make the name «silver king» peculiarly appropriate for this noble fish. Among the French and Spanish fishermen about the Gulf of Mexico and West Indies it is called *grande ecaillé*, *sabalo*, *savalle*, etc.; while tarpium, jewfish and big-eyed herring are also heard. Its scales, as large as or larger than a silver dollar, are extensively used in fabricating ornaments, and the flesh is good to eat; but the fish is principally of interest for the sport it affords to the angler with rod and line, who seeks it best by going in a boat, with an experienced man at the oars, among the islands or into the bays of the coast of the Gulf of Mexico, within the Florida reefs or around the shores of Porto Rico, where it spawns. Then may be felt as well as seen the astonishing force and strength which this fish daily puts forth as he chases the swift and agile fishes upon which he subsists. Having seized the angler's baited hook, a struggle begins which taxes tackle and skill to the utmost. The moment the tarpon feels the steel point in his mouth and finds his progress checked, he leaps high into the air, shaking himself violently in hope of casting off the hook — and he often succeeds. Failing, he leaps again and again; «with all the frenzy of the wild horse when he first feels the lasso, he springs through the air and dashes through the water.» An hour or more of the most delicate manipulation, and at the same time of severe labor, is often required to subdue a large tarpon.

TARQUINIUS, tär-kwĭn'ĭ-ŭs, **Lucius** (surnamed PRISCUS), in legendary history the fifth king of Rome. His family was of Greek extraction, his father, Demaratus, being a Corinthian, who crossed to Italy and settled in Tarquinii, a city of Etruria. He introduced among the Etruscans the knowledge of the alphabet. He had married Tanaquil, a Tuscan lady of rank, by whom he had two sons, but on account of foreign extraction he was excluded from public employment. He accordingly removed to Rome, where he was welcomed and admitted to Roman citizenship. He took the name of Lucius Tarquinius. The surname Priscus, the elder, may be considered as a historical distinction. Tarquinius became the confidant of the king of Rome, Ancus Martius, who appointed him the guardian of his children. On the death of Ancus, Tarquinius was elected his successor. He made war on the Latins and Sabines, from whom he took numerous towns, and his reign was distinguished by the erection of great public works. The Roman Cloacæ (q.v.) are the greatest of the works attributed to him. He constructed the Circus Maximus in the valley redeemed by his system of drainage, and instituted the great Roman games. He began the wall around the city. He is also said to have projected or begun the Capitol in honor of Jupiter, Juno and Minerva. For the political changes which he instituted see ROME. After a reign of 36 years, or 38 according to the legends, he was killed by assassins employed by the sons of Ancus Martius in 578 B.C.

TARQUINIUS, Lucius (surnamed SUPERBUS), last of the legendary kings of Rome, was the son of Lucius Tarquinius Priscus. Tarquinius Priscus left two sons, who were too young to succeed him, and his son-in-law, Servius Tullius, excited the patricians against him by extensive constitutional reforms, and Tarquin, on reaching man's estate, murdered his son-in-law and assumed the regal dignity as a hereditary right. As a king he developed all the distinguishing traits of a tyrant. He abolished the privileges conferred by his predecessor on the plebeians; but did not favor the patricians. He banished or put to death the senators whom he suspected. He continued the great works of his father, and compelled the populace to labor in them for inadequate pay. While he thus established his tyranny at home he advanced the power of Rome abroad. By the marriage of his daughter with Octavius Mamilius of Tusculum, he caused himself to be recognized as the head of the Latin confederacy. Through a stratagem of his son Sextus he obtained possession of Gabii, a Latin city, which resisted him. He made war on the Volscians, and took the city of Suessa Pomœtia, the spoils of which he used to build and decorate the Capitol. He formed also a close alliance with the Etrurian cities. To keep down the Volscians, he founded the colonies of Signia and Circeii. It was he who deposited the Sibylline books in the vault of the Capitol. After a reign of nearly 25 years he was engaged in besieging Ardea when the conspiracy broke out by which he was exiled from Rome 510 B.C. The cause and nature of the conspiracy are referred to in the articles BRUTUS (LUCIUS JUNIUS) and LUCRETIA. Tarquin first took refuge at Cære and Etruria. The Etruscan cities of Tarquinii and Veii first espoused his cause, then Lars Porsenna of Clusium, and afterward the Latin states. When all these had been vanquished, according to Roman accounts, Tarquinius, whose sons had perished in the wars, fled to Cumæ, where he died. The chronology of the story of the Tarquins is incompatible with strict historical accuracy, and neither criticism nor comparison of accounts has enabled historians to disentangle the truth from fiction. Some, as Niebuhr and K. O. Müller, hold that the history of the Tarquins points to an Etruscan conquest of Rome. Others accept the main incidents as historical.

TARR, Ralph Stockman, American geologist: b. Gloucester, Mass., 15 Jan. 1864; d. 1912. He was graduated from Harvard in 1891, and was assistant in geology there 1890–91. From 1892–97 he was assistant in geology at Cornell University, and thereafter professor of dynamic geology there until his demise. He has published 'Economic Geology of the United States' (1893); 'Elementary Physical Geography' (1895); 'Elementary Geology' (1897); 'Physical Geography of New York' (1902); 'Geography of Science' (1905); 'Alaskan Glacier Studies' (1914); 'College Physiography' (1914).

TARRAGON, a culinary herb. See ARTEMISIA.

TARRAGONA, tär-rā-gō'nä, Spain, a seaport town on the Mediterranean, capitol of a province of the same name, in Catalonia, 60 miles west-southwest of Barcelona, at the eastern end of the fertile Campo de Tarragona, which is watered by the river Francoli. The old town, situated on a high rocky site, once surmounted by a citadel, has narrow, irregular streets. The chief features are the splendid cathedral, dating from the 12th to 13th century, with a fine west façade and cloisters of great beauty, the archiepiscopal palace, with an ancient tower, and a seminary for priests. The Plaza de la Fuente, on the site of the Roman Circus, separates the old town from the more regular new town to the southwest, which, near where it joins the old town, is crossed by two broad tree-shaded streets. The Paseo de Santa Clara is a fine promenade on the remains of the old Roman walls. The other edifices include the presido or prison, the Torreón de Pilatos, also a prison, the Casa Provincial de Beneficencia, artillery arsenal, infantry barracks, etc. The town and its neighborhood are rich in Roman remains. The spacious harbor is sheltered by a long mole, and has been recently improved. Tarragona was known to the Romans as *Tarraco.* It was captured by the Romans 218 B.C. during the Second Punic War, and made their headquarters in Spain. It is also associated with Julius Cæsar and Augustus, the latter of whom made it the capital of the province of *Hispania Tarraconensis.* It was taken by the Visigoths in 475 A.D., and by the Moors in 713. On 29 June 1811 it was captured and plundered by the French under Suchet. Its archbishop shares with the archbishop of Toledo the title of primate of Spain. Pop., town, 24,548; province, 336,763.

TARRYTOWN (from the Dutch, *Terwen Dorp,* «Wheat Town»), N. Y., village, Westchester County, on the Hudson River, or the expansion of the river called Tappan Sea, and on the New York Central and Hudson River Railroad, about 25 miles north of New York and 130 miles south of Albany. A ferry, which connects the village with Nyack on the west bank of the Hudson, gives Tarrytown the advantages of the West Shore Railroad.

Tarrytown is one of the oldest settlements in New York; its position on the Hudson made it a convenient landing place for boats going from New York to Albany, and gradually it became a trading post. Its first incorporation included Irvington (q.v.). During the Revolutionary War Tarrytown was a centre of importance; every prominent hill in the vicinity was the scene of an encounter or a fortification. In Tarrytown André was captured. On Broadway, one of the prominent streets, about half way to Sleepy Hollow (q.v.) stands a monument commemorating this event so important in the War for Independence. The first monument erected was a small obelisk, raised in 1853 by the inhabitants of the county, and bearing upon its pedestal an inscription which told that it marked the «spot» where, on 25 Sept. 1780, the spy, Maj. John André, was captured by «John Paulding, David Williams, and Isaac Van Wert, All Natives of this County.» In 1880, the centennial anniversary of this capture, there was added a bronze statue of John Paulding; and a bronze panel, upon which was pictured, by Theodore Bauer, the capture of André. The additions of 1880 were the gift of John Anderson. The little stream nearby is called André Brook, and a large whitewood, which formerly stood near the monument, was called André's tree. In 1777 Vaughan's troops landed here; and here, at the tavern kept by Elizabeth Van Tassel, occurred the capture of the British by Major Hunt and a force of volunteers. The village is well known on account of being the birthplace and home of Washington Irving (q.v.). On the north is Sleepy Hollow (q.v.), where he was buried, on the south of the village is Sunnyside (q.v.), where his home still stands. Other points of historic interest are «Lyndehurst,» formerly «Paulding Manor,» the Philipse manor house, erected in 1683; a monument to the Revolutionary soldiers of the manor, unveiled in 1894; and the summer residences of many of the noted men of New York.

Tarrytown is in an agricultural region, but it has about 100 manufacturing establishments with a large annual output. The principal public buildings are the Institution of Mercy, an orphanage for boys; the churches, schools and business blocks. The educational institutions are the Washington Irving High School, Irving Institute, Miss C. E. Mason's School, The Knox School, Hackley School, Mary Mount School, public and parish schools, three public libraries and several private schools. The national bank has a capital of $100,000, the savings bank has deposits amounting to about $2,000,000. Pop. about 5,752; including North Tarrytown, 4,877, which is industrially a part of the village; total, 10,629.

TARSHISH, a place frequently mentioned in the Old Testament. It was formerly believed to be Tarsus in Cicilia, but is now generally identified by Biblical critics with the Tartessus of the Greek and Roman writers. This name was applied to a district in the south of Spain, lying to the west of the Columns of Hercules. Others regard it as some unidentified European coast west of Greece.

TARSIA (Ital. *Intarsia*). Wood inlay; especially that done in Italy at the close of the Middle Ages and during the era of the Renaissance. The word is received into English as being the only one describing inlay of that era and character as distinguished from that of others. Thus nearly all Tarsia work is done with dark wood like walnut, on which straight lines and curves are incised rather deeply and the incisions then filled with light colored wood, producing, when the work is complete, a general effect of yellow on brown. These lines and curves make scrolls of different patterns which terminate in small flowers and clumps of foliage, and in this way help to carry out the great scheme of arabesque decoration which we associate with Renaissance proper in all the schools of Italy. Heavy furniture, such as cupboards and cabinets, ornamental chests for the storing of clothing, and the like, are adorned in this way; but the most effective examples of the art are in the wooden fittings of church choirs and the long rows of cupboards and closets (ambries) which line some of the sacristies of the churches in central and northern Italy.

Wood inlay of later times and of the North is not often called Tarsia, but the process is the same, and the effects produced differ only according to the style of the time. The most interesting wood inlay out of Italy is that of the Dutch — chests of drawers, wardrobe and writing tables in which spirited little bouquets and flowers are relieved on a dark ground. This, and all northern inlaid work, disappear in the 17th century in what we call Marquetry (q.v.), which is a mosaic of veneers rather than an inlay. Consult Jackson, F. Hamilton, 'Intarsia and Marquetry' (1903).

TARSIER, a small lemur of the genus *Tarsius,* having extremely long hind legs, especially in the thin tarsal portion, large, slender toes and enormous eyes. These grotesque little creatures inhabit tropical Africa and the Eastern Archipelago. They are for the most part of nocturnal habits and feed on fruits and insects found in the tree-tops where they spend their lives. The tarsier (*T. spectrum*) is a representative species of this genus, occurring in Borneo, Celebes, the Philippine Islands, etc. It is grayish-brown, with olive tints over the body, and dark tints on the face, forehead and back of the head. The tail is destitute of hairs, but possesses a tuft at its tip.

TARSUS, Asia Minor, an ancient city, the capital of Cilicia, now in the Turkish province of Adana, connected by rail with Adana and the port of Mersina on the Mediterranean. Anciently it was adorned by a number of magnificent buildings. Its inhabitants enjoyed the privileges of Roman citizens, and the city rose to such distinction as to rival Athens, Antioch and Alexandria in wealth and grandeur, as well as in the arts and sciences. It is the birthplace of Saint Paul. It was situated on both banks of the Cydnus, which flowed into a lagoon connected with the sea, which formed its port, but is now silted up. Its origin is ascribed to Sardanapalus. It was early colonized by the Greeks. It is mentioned in the 'Anabasis' of Xenophon as a great and wealthy city. Tarsus was visited by Cyrus in his expedition against his brother Artaxerxes, and partially plundered by his troops. It yielded without resistance to Alexander the Great. Tarsus belonged in general to the empire of the Seleucidæ, but was for a short time connected with Egypt under the second and third Ptolemy. Pompey made Cilicia a Roman province. Out of compliment to Cæsar, who visited the city, the inhabitants changed its name to Juliopolis. It was plundered by Cassius, but Antony and Augustus heaped favors on it. It became a place of importance in the wars of the Romans with the Parthians and the Persians. It was taken by the Saracens in 640, after which its importance declined. The most important remains of the ancient city is the Dunuk Tash or "Tomb of Sardanapalus," presumably part of a Græco-Roman temple. The heterogeneous population of Mohammedans, Armenians, Greeks, Persians, etc., in the modern town is estimated at 25,000.

TARSUS (in anatomy). See ANATOMY; FOOT; OSTEOLOGY.

TARTAGLIA, tär-tal'yä, **Nicola,** Italian mathematician: b. Brescia, about 1500; d. Venice, 13 Dec. 1557. His family name was Fontana and he was given the name of "Tartaglia," the "stutterer," from a defect of utterance contracted during his neglected childhood. From the year 1530 he taught mathematics at Verona and Vicenza, was appointed professor of mathematics at Brescia and in 1534 was called to the same post in Venice. He discovered the method of solving the cubic equation containing the 1st and 3d powers of the unknown quantity, and in repeated contests with the ablest mathematicians of his time defeated them, being able to solve all their problems, while his own remained unsolved. In 1539 and 1540 Cardan, under the promise of strict secrecy, obtained from him his discovery, and afterward, in violation of his promise, published it in his 'Ars Magna.' This led to a violent controversy and a public mathematical contest, in which Cardan being worsted, his townsmen raised a mob and prevented a continuance of it. But the solution is still known as Cardan's rule. His chief work is 'Generale Trattato de' Numeri e Misure' (1560). He also published a treatise on gunnery, 'Nuova Scienza,' which has been translated into English by Lucar; the first Italian translation of Euclid; and seven or eight other mathematical works, the best known of which is 'Quesiti ed invenzioni diversi' (1550).

TARTAN, the typical Scottish plaid; a thin worsted cloth having alternate bands of different colors, forming a checkered pattern, which has been highly specialized by Scotch weavers for the dress of the Scottish Highlanders, each clan having its own peculiar pattern. The well-known Stewart tartan is scarlet in the centres, with dark scarlet crossings and wide-spaced dark independent lines. An endless variety of fancy tartans are now manufactured, some of wool, others of silk or of mixed material. The term is also applied to the checkered patterns themselves.

TARTAR. See ARGOL.

TARTARAGA, a South American turtle of the family *Pelomedusidæ;* specifically the great "arrau" or river-turtle (*Podocnemis expansa*) of the Amazon Basin, the female of which has a shell sometimes measuring three feet in length. This turtle is of great commercial importance throughout northern South America, on account of the eggs, which are periodically collected from the sand banks where they are buried in great quantities, chiefly for the oil to be pressed from them. This is either eaten, like the eggs themselves, or is burned in lamps alone or mixed with tar. The turtles are likewise eaten by man and many animals.

TARTARIC ACID, Dihydroxysuccinic Acid, $\begin{array}{l}CHOHCOOH\\ |\\ CHOHCOOH\end{array}$ exists in four stereoisomeric modifications; these are known as (1) Dextrotartaric acid, or Ordinary tartaric acid, (2) Lævotartaric acid, (3) Racemic acid and (4) Mesotartaric acid.

1. **Dextrotartaric Acid** and some of its salts are widely distributed in the vegetable kingdom, its acid potassium salt being present in large quantities in grape juice. When grape juice is fermented, the acid salt, being only sparingly soluble in the alcohol produced, forms a dirty-white crust or sediment in the fermentation casks; this deposit is known as «argol» or «lees.» Cream of tartar and ordinary tartaric acid are usually obtained from this source. For the preparation of cream of tartar, argol is simply freed from impurities by treatment with animal charcoal and by subsequent crystallization. For the manufacture of ordinary tartaric acid, argol is boiled with dilute hydrochloric acid and then precipitated as calcium tartrate with calcium hydroxide. The yield is increased by adding calcium chloride to the mother-liquor. From the calcium salt thus precipitated tartaric acid is liberated with dilute sulphuric acid.

A number of synthetic methods are also in common use for the manufacture of tartaric acid. According to British Patent 12,467, the compound may be obtained by the electrolytic reduction of glyoxylic acid or its derivatives; the glyoxylic acid used in this process being formed from oxalic acid by the action of amalgams. The method of L. Baekeland (United States Patent 1,190,845) consists in building up the acid from the oxides of carbon by converting them into formates; from these, oxalates are obtained at high temperatures and pressures; the oxalates are reduced to glyoxylates, and the latter electrolyzed into tartrates. Tartaric acid has also been obtained by the oxidation of carbohydrates in the presence of catalyzers (British 108,494).

Dextrotartaric acid crystallizes in transparent prisms, free from water of crystallization. It melts at 170° C.; above this temperature it yields pyrotartaric acid, acetone, acetaldehyde and other decomposition products. It is very soluble in water and alcohol, but is insoluble in ether. In aqueous solution it turns the plane of polarization to the right, reduces ammoniacal silver compounds, is readily decomposed into glyoxal and other products in the presence of uranium salts, and yields large quantities of carbonic acid and acetaldehyde in the presence of manganese dioxide at or above 35° C. Under the influence of ultra-violet rays tartaric acid evolves carbon dioxide. The crystals of the acid show triboluminescence. In the form of its acid potassium salt the compound has been used by the ancients. The pure acid was first described by Scheele in 1769.

2. **Lævotartaric Acid** differs from the dextro compound in that its aqueous solutions turn the plane of polarization to the left. It was first prepared by Pasteur from sodium ammonium racemate. When this salt is allowed to crystallize it deposits two sets of crystals from which dextro- and lævo-tartaric acids may be obtained. Pasteur's observations showed incidentally that the molecule of racemic acid is a complex of dextro- and lævo-tartaric acids. Pasteur also found that when the cinchonine salt of racemic acid is allowed to crystallize, the first crystals consist of the cinchonine derivative of lævotartaric acid. The physical and chemical properties of this compound are practically those of dextrotartaric acid.

3. **Racemic Acid** occurs with ordinary tartaric acid in the grapes of certain districts. It may be prepared (1) by mixing strong equimolecular solutions of dextro- and lævo-tartaric acids, (2) by the saponification of glyoxal cyanhydrin, (3) by heating dextrotartaric acid for a number of hours with caustic alkalis, and by other methods. It separates in triclinic crystals with one molecule of water. It melts at 205–206° C. It is only moderately soluble in cold water or alcohol. Solutions of racemic acid do not show optical activity, the compound being inactive by external compensation.

4. **Mesotartaric Acid** is formed together with racemic acid when a solution of ordinary tartaric acid is heated with caustic alkalis. It has also been prepared synthetically by heating dibromsuccinic acid with water or silver oxide. It crystallizes in long prisms with one molecule of water. The dehydrated acid melts at 140° C. It is optically inactive by internal compensation.

Of the four tartaric acids described in this article, ordinary or dextrotartaric acid is a most important compound. It is extensively employed in dyeing, bleaching, calico-printing, in the preparation of effervescent drinks, in the manufacture of baking powders, seidlitz powders, in photography, and in medicine. Sodium potassium tartrate, or Rochelle salt, forms Fehling's solution with copper sulphate and is used in urine analysis; potassium acid tartrate, or cream of tartar, is a mild cathartic; potassium antimonyl tartrate, or tartar emetic, is occasionally used as a counter-irritant in the form of an ointment, and finds extensive application as a mordant; potassium magnesium tartrate is used as a purgative; iron and potassium tartrate as a mild chalybeate; morphine tartrate has been recommended for hypodermic injection; dimethyl piperazine tartrate as a solvent for uric acid in chronic and acute gout; and paraphenetidin acid tartrate as an antipyretic.

V. S. Babasinian,
Lehigh University.

TARTARIN. 'Tartarin de Tarascon' (1872), 'Tartarin sur les Alpes' (1886) and 'Port-Tarascon' (1890) present Daudet's best remembered characterization, a typical Frenchman of the Midi, such as he has himself described in speaking of his other notable son of the South, Numa Roumestan: «pompous, theatrical, loving parade, costume, the platform, banners, flags, trumpets, clannish, traditional, caressing, feline, with an eloquence brilliant, excited yet colorless, quick to anger and yet giving anger a sham expression even when it is sincere.» Looking back on his creation after many years, Daudet wrote: «It seems to me that 'Tartarin' has qualities of youth, vitality, truth,— a truth from over the Loire, that may swell and exaggerate facts, but never really lies.»

This presentation of «truth from its humorous side,» in the phrase of Daudet's fellow Provençal, Zola, developed out of observation of a traveling companion on a journey to Algeria, Corsica and Sardinia, in 1865. The writing was begun in 1868, but this «cinematograph of the Midi» first showed its subtle caricature of Gascon temperament in 1872. The time, just after the disastrous war with Germany, was unpropitious, and the serial publication in the *Petit Moniteur* met so cold a welcome that it was abandoned. The hero's name was then Chapatin. With its change to Tartarin, but with none in the temper and spirit of the work, the playful satire, under other auspices, was sustained through three volumes and 18 years; and, though the jest was carried further than any other French author has cared to venture in like case, Frenchmen are generally agreed in recognizing in the three volumes together a classic of «admirable fooling.»

'Tartarin,' says Daudet, had two quite distinct characters, the soul of Don Quixote, the body of Sancho Panza. He planned for travels and adventures so vividly that he half believed he had experienced them, his favorite reading supplying the local color for the self-deception that made «of a man who had missed going to Shanghai one who had been there.» «The Southerner's falsehood,» explains Daudet, «is not a lie but a kind of mental mirage.» This Tartarin, who dreamed of daring deeds in exotic lands, till he was 45 had never slept out of his home town. The Quixote in him was always exclaiming: «I go»; the Sancho: «I stay.» «Tartarin cover yourself with glory,» said Quixote. «Cover yourself with flannel, Tartarin,» said Sancho. «Give me a tomahawk,» cries Quixote. «Jeanette, my chocolate,» says Sancho. A lion seen at a circus fires his fancy. At last he feels he must go to Africa to maintain his self-esteem and reputation at home. Elaborate preparations keep his fantasy at fever heat till he sets out for Algeria. Illusion and disillusion follow, in amusing succession, his landing in exotic equipment among the very Europeanized denizens of Algiers. Mistaking a plantation of artichokes for a desert, he shoots a donkey for a lion, where rabbits are the customary game, beguiles himself and is beguiled with Oriental pleasures, is recalled to his Quixotic self by a paragraph in a home journal, turns his face resolutely southward, encounters a tame and blind lion, imagines he has fired at another, is robbed by his companion, an alleged prince, shoots the tame lion and returns with a melancholy camel, whom he sought to abandon in Algiers but who refused to stay lost, much poorer in purse but having earned the privilege of dazzling his fellow-townsmen with tales that he, confirmed by the skin of the tame lion, himself half believes to be true.

So ends this delightful bit of Provençal persiflage. Often, as obvious, it grazes the burlesque, but is always saved with unfailing tact from mere buffoonery. In 'Tartarin on the Alps' the spirit and method are the same, the satiric art a little mellower and more mature. It is also more readily appreciated, as the scene is more generally familiar. The public and the critics join in pronouncing it the masterpiece of French humor in the 19th century. The opening scene where Tartarin, equipped as for the Himalayas with ice-axe, climbing irons, snow-glasses and the rest, makes his entry into the palatial hotel on the Rigi, with its 600 very prosaic tourists, is unforgetable; so, too, is the tale of Tartarin's hunt of the tame chamois, trained to attract strangers and fed in the hotel kitchen. The Swiss Exploitation Trust, creation of the exuberant fancy of Tartarin's fellow Tarasconian Bompard, is itself most genially exploited; and nothing in any of the Tartarin books surpasses the scene of mild mountain climbing where each of these comrades supposes he has sacrificed the life of the other to his own safety by cutting the cord that bound them, while both are safe and sound. In the afterpiece to this episode Tartarin enters the Tarascon Alpine Club as Bompard is narrating how the partner of his daring perished.

Port-Tarascon, many of whose extravagances were suggested and rivalled by the facts of an actual colonizing enterprise some years before at Port-Breton, depends for its full appreciation on fuller knowledge of French political conditions and aspirations than most foreigners possess. Daudet himself probably felt that the once rich vein had been worked a little thin, for here he brings Tartarin to a not unworthy death, after carrying him through strange adventures as head of colonist fellow-townsmen in Polynesia and then, after his enforced return, through a trial whose hilarious humor involves a masterly discrimination between the calculating falsehood of the Nord and the effervescent imagination of the «fecund improvisators» of the Midi, «intoxicated with sap and light, carried away by their own inventions.» For translations of 'Tartarin de Tarascon' and 'Tartarin sur les Alpes' consult 'Everyman's Library.' 'Port Tarascon' has been well rendered by Henry James.

BENJAMIN W. WELLS,
Author of 'Modern French Literature.'

TARTARS. See TATARS.

TARTARUS, tär'ta-rŭs, according to classical antiquity, a deep pit which extends under the surface of the earth as completely as heaven extends over it, holding within closed portals Kronos and the Titans in their prison house. It was the jail established by the mythical gods for those whom they had driven from the supernal world, just as Erebus was a similar prison for men. Later the term came to signify the whole underworld in which the wicked undergo the punishment of their crimes, the exact opposite to the Elysian fields, the afterworld of the good. Tartarus, as a personification, is the son of Æther and Ge (air and land), and father of the giant Typhœus by his own mother, Ge.

TARTARY, tär'ta-rĭ, or **TA'TARY**, a name applied in the Middle Ages to the countries from which the Tartars came or in which they lived, that is, central Asia and what is now southeastern Russia, western and eastern Turkestan, Mongolia and Manchuria. In a narrower sense it includes only southeast Russia and Chinese Turkestan.

TARTE, tärt, **Joseph Israel**, Canadian stateman: b. Lanoraie, Quebec, 11 Jan. 1848; d. 1909. He was educated at L'Assomption College, was a member of the Quebec assembly in 1877-81 and was returned to the Canadian Parliament for Montmorency in 1890. He was unseated by petition in 1891, as a result of his insistive attacks in the administration of Macdonald, whose ministers he charged with corruption, but in 1893-96 was member for L'Islet. He was later, under the Laurier administration, Minister of Public Works, and has also edited, at Montreal, *Le Cultivateur*, and *La Patrie*.

TARTUFFE, a comedy of Molière in five acts in rhymed verse, the first three acts of which were presented for the first time before the king and queen at Versailles, 12 May 1664, when the author was 38 years old. The play made enemies everywhere. There were those among the Jansenists and Jesuits who each thought that the others were aimed at, and a violent attack was written by the curate Pierre Roullé under the title «Le Roy glorieux au monde» (Paris 1664), which upon Molière's protest was censured by the king. The latter nevertheless forbade the play to be presented again until finished. On 5 Aug. 1667, a second version of the play was presented at the Palais-Royal under the title «L'Imposteur.» Molière, apparently upon the suggestion of the papal legate and his entourage, had softened it in several respects; for instance, the original Tartuffe was no longer in ecclesiastical garb. Nevertheless its presentation was stopped, in the king's absence, by the first president of Parliament and interdicted by the archbishop of Paris. The king, despite his prohibition, had shown his favor by taking Molière's players under his patronage in 1665. It was only on 5 Feb. 1669, however, that a third version, the only one known to us now, was acted at the Palais-Royal by the king's permission under the original title, and the poet's long years of waiting for a hearing were rewarded by extraordinary success. The plot of the play, which is masterly in its simplicity and logic, concerns the entrance of one Tartuffe (or Tartufe or Tartufle), a self-seeking adventurer hiding his greed behind the mask of piety, into the house of Orgon, a well-to-do burgher, whose docile daughter, Mariane, has been affianced to Valère. Orgon (played by Molière) and his opinionated old mother, Madame Pernelle, fall completely under the sway of Tartuffe over the protest of the rest of the family, including a rather hot-headed son, Damis, and a sensible and even-tempered brother-in-law, Cléante. Orgon goes even so far as to make a deed of gift to Tartuffe and to promise his daughter to him, despite a previous promise to Valère. It was not on the daughter, however, but on Orgon's second wife, Elmire, young and comely, that Tartuffe had cast longing eyes. To save her step-children, Elmire (played by Molière's wife) consents to lure Tartuffe into an avowal which her husband in hiding may overhear. This scheme being successful, the impostor throws off the mask and impudently claims the house under the deed of gift. Orgon's ruin is narrowly averted by the intervention of Louis XIV, a veritable *deus ex machina*, whose messenger restores the house to Orgon and hales the villain off to prison. It is not only for the singularity and boldness of the subject or the skill in with which it is treated that this play merits approval. The first scene is as happy as it is new, as full of simplicity as of life. Instead of those mutual confidences which are so commonly made use of in this place, an old grandmother, offended at what she has seen amiss in her granddaughter, is introduced giving a severe lecture to those who belong to the house, in which she draws the characters of them all; for we distinguish the truth even through the language of prejudice. From this moment everything is in motion and the action gradually increases to the end. The fine raillery of Dorine (played by Madeleine Béjart), a maid, in the scene with her master, gives us a clear idea of Orgon and prepares us for Tartuffe in the picture of hypocrite, which Cléante opposes to that of the truly devout. Tartuffe, who is only talked of in the first two acts, makes his appearance in the third, when the plot being then more animated receives equal vivacity from the new schemes employed against this villain and from the address with which he turns everything attempted against him to his own advantage. The infatuation of Orgon, which increases in proportion to the measures taken to cure it, gives occasion to that singular and admirable scene of the fourth act, which the necessity of unmasking a vice so abominable as that of hypocrisy renders indispensable. The panegyric of Louis XIV, put in the mouth of the exempt at the end of the play, could not justify the fault of the unraveling in the eyes of the critics. Here indeed is the insuperable difficulty. It is impossible to set on the stage a religious hypocrite and not lend him the language of piety. Consequently an attempt to tear the mask off religious hypocrisy must necessarily take on the occasional aspect of an assault on religion itself. This was the basis of the opposition to the play, and that it was in a measure justified is borne out by the subsequent use of 'Tartuffe' by aggressive enemies of any form of ecclesiasticism as though it were an assault on religion itself. There is an extremely clever translation of 'Tartuffe,' with the French text *en regard*, in the fifth volume of the works of Molière published by John Watts (London 1748).

HERBERT F. WRIGHT.

TASCHEREAU, tăsh'ĕ'rō, SIR **Henri Elzear,** Canadian jurist: b. 7 Oct. 1836; d. 1909. He was called to the Quebec bar in 1857, and was made queen's counsel in 1867. From 1861-67 he sat in the Canadian Legislative Assembly representing Beance County. In 1871 he was appointed judge of the Quebec Superior Court, and (1878) judge of the Supreme Court of Canada. He was created knight in 1902 and from 1902-06 was chief justice of the Supreme Court of Canada.

TASCHEREAU, Jules Antoine, French author and politician: b. Tours, 1801; d. Paris, 11 Nov. 1874. He studied law at Orléans, and entered journalism in Paris. After the overthrow of the Bourbons in 1830, to which he had contributed, he was named general secretary to the prefect of the Seine; and in 1837 he entered the Chamber of Deputies. Meantime he had established and continued to edit the *Revue rétrospective*. He was among the early supporters of Louis Napoleon, and after the *coup d'état* was rewarded with the post of assistant director of the National Library. In 1858 he was given the chief directorship. His permanent literary work consists of critical biographies of Molière, Corneille and Diderot.

TASHKEND, täsh-kĕnd', or **TASHKENT**, Asia, the capital of Russian Turkestan and of the province of Sir-Daria, formerly in the khanate of Khokand, a few miles from the Chirchik and about 40 miles from its confluence with the Sir-Daria or Jaxartes, in a fertile oasis. It is the most important city in Asiatic Russia, and is at the terminus of the Transcaspian Railway, with direct rail route to the Caspian Sea and to Orenburg. It consists of an old town and a new Russian quarter. Its former walls, which were 12 miles in circuit, are now in ruins. The streets in the old town are very narrow. not, however, in consequence of the crowding of the houses, but of the number of gardens and vineyards, whose walls aproach so nearly as to leave only lanes between them. The water led from the river by canals furnishes a copious supply to numerous fountains, and almost every house has its cistern and its bath. The principal buildings include several large mosques, a very extensive bazaar, numerous colleges and a number of old temples surmounted by cupolas. The Russian district of the city has broad streets lined with trees, electrically lighted and traversed by trolley lines, and contains gymnasia, a public library, observatory, museum, a citadel, various civil and military establishments, arsenals, etc. The inhabitants are employed in weaving silk and cotton goods, making articles in leather and felt, etc. The trade in corn, cotton, rice, etc., is very extensive. Tashkend was taken by Russia in 1865; about one-sixth of the present population of 272,000 is Russian.

TASK, The, a descriptive poem written by William Cowper (q.v.) in the summer of 1783, and published two years later in a volume containing also «An Epistle to Joseph Hill, Esq.,» «Tirocinium,» and «John Gilpin» (q.v.). It is in blank verse of excellent quality, though at times echoing Milton a bit too plainly, and it is distributed into six books, the aggregate number of lines being somewhat over 5,000. The metrical form and the theme with which he begins, «the sofa,» are said to have been taken by the poet from Lady Austen, who also told him the story of «John Gilpin,» and the title commemorates the fact that in writing he was obeying her injunction. The scenery, the descriptions of which have perhaps done more than anything else to make the poem a classic standing not far below the great elaborate poems of the language, is that of Olney, in Buckinghamshire, and the neighboring Weston. «The Task» set the seal on Cowper's popularity with his own generation and that succeeding, and without it, despite the extraordinary and too little recognized excellence of his shorter pieces, notable in range and quality, he would perhaps not rank so high as a poet to-day, although it is to be feared that too many readers know his masterpiece only through quotations, such as «God made the country, and man made the town.» «Variety's the very spice of life,» «the cups that cheer but not inebriate,» and the like, or else through selections such as the pathetic description of «Crazy Kate,» or the patriotic «England, with all thy faults I love thee still,» or the picture of the postman outside in the winter evening, while all is domestic comfort within, or the poignant bit of autobiography that begins «I was a stricken deer.» That the desultory and somewhat spun out «Task» with its longueurs, its exhibitions of intellectual narrowness and religious bigotry, its comparative lack of high and sustained imagination, should tempt to skimming and even to tasting by selections does not afford matter for surprise; yet the admirer of Cowper and the student of English poetry must contend that so to treat «The Task» is to stand in one's own light. The ease and skill of the transitions make the very desultoriness of the poem an exhibition of art, Cowper at his narrowest is still perhaps the most urbane of our poets, the descriptions of scenery are scarcely equaled, as etchings in words, whether by Thomson or by Wordsworth, and, although there is little of the latter's philosophic insight into the heart of nature and into that of man, there is in compensation the absolutely sincere expression of the observations, reflections and emotions of a sensitive poetic genius unspoiled by literary or social sophistication. When in addition we think of Cowper's playful humor, his feeling for domesticity, his humanitarianism, his satiric power — witness the passage on the excise in the fourth book — as exhibited in «The Task,» we are led to wonder whether our great-grandfathers in their hearty appreciation of the poem as a whole were not wiser than we are in our reservations and in our glib phrases with regard to Cowper's services as a precursor of the Georgian romantics.

William P. Trent.

TASMAN, täs'män, **Abel Janssen (Janszen, Janzoon)**, Dutch navigator: b. Hoorn, North Holland, about 1602; d. Batavia, Java, October 1659. He was engaged in voyages of discovery in the Pacific and Indian oceans in 1639–42 under the patronage of Van Diemen, governor-general of the Dutch West Indies, and in the latter year was sent to circumnavigate Australia. He sailed from Batavia 14 Aug. 1642, discovered on 24 November the island which he called Van Diemen's Land, but which has since been named Tasmania, and later discovered the southern island of New Zealand, the Friendly Islands, and the Fiji Islands and returned to Batavia 5 June 1643. Details concerning a subsequent voyage along the coasts of New Guinea and north and north-western Australia are exceedingly scanty. He set out on 29 Jan. 1644, discovered the Gulf of Carpentaria, made other important discoveries, and returned to Batavia, but further information is lacking. He ranks as one of the greatest navigators of the 17th century. He published a narrative of his first voyage which was reprinted in 1722 and in 1860. Consult his 'Life' by Walker (Hobart, Tasmania 1896).

TASMAN (tăz'mạn) **SEA,** Oceanica, that part of the Pacific Ocean lying between Tasmania (and southeast Australia) and New Zealand. It is 1,500 miles across, and is crossed by a submarine cable from Sydney to Wellington.

TASMANIA, tăz-mā'nĭ-ạ, Australia, the smallest state of the commonwealth, consisting of the island of Tasmania and its adjacent islets, and situated 140 miles south of the southeastern extremity of the Australian continent, from which it is separated by Bass Strait. The area of the state is 26,385 square miles, and of the main island 24,339 square miles. The main island is heart-shaped, about 180 miles long from north to south, and 175 miles at the widest. The coasts are bold and much indented, forming a number of excellent harbors. The interior is a plateau intersected in various directions by a number of rough and precipitous mountain ranges, rising in Cradle Mountain to a height of 5,069 feet. Some of the intervening basins contain large and beautiful lakes, and rivers are numerous. The geology is characterized by considerable outcrops of palæozoic rocks and extensive flows of tertiary basalt. The mineral wealth is great and mining is the principal industry. The annual value of mineral products is about $4,000,000, mostly gold, silver, copper and tin. The imports in 1916 totaled nearly $5,000,000 and the exports less than $4,000,000. The largest farm crop is oats, 2,000,000 bushels annually, wheat following with 1,000,000 bushels. The climate is temperate, and the rainfall in general sufficient. The flora and fauna are similar to those of southern Australia. There are two remarkable animals peculiar to the island, the Tasmanian wolf and the "Tasmanian devil" (*Thylacinus* and *Dasyurus*), sometimes called the native tiger. The soil is very fertile, especially in the basaltic regions, and well adapted for wheat, which is the principal crop. Grazing has declined, and the manufactures are inconsiderable. The volume of trade amounts to over $20,000,000 annually. The chief exports are copper, fruits, silver, wool, tin, gold, timber, hides and grain. Hobart, the chief port on the southeastern coast, has regular steamship connection with Europe, Australia and New Zealand. There are about 600 miles of railroads. Education is compulsory. There are 16 colleges, and at the head of the educational system is the University of Tasmania. The capital of the state is Hobart with 38,000 population.

Tasmania was discovered in 1642 by the Dutch navigator, Tasman, who named it Van Diemen's Land, after his patron. In 1804 England established a penal colony on the island. This was maintained until 1853, when Tasmania was declared a British colony. In 1900 it became a state of the commonwealth of Australia. The aboriginal inhabitants are almost extinct. There is a remarkable regular shifting of the population between Tasmania and Southern Australia, more than 40,000 emigrants and over 40,000 immigrants being officially recorded every year. Consult 'Statistics of Tasmania' (Hobart, Australia). See AUSTRALIA.

TASMANIAN WOLF, DEVIL, ZEBRA-WOLF, etc. See DASYURE.

TASSAERT, tā-särt, **Nicolas François Octave,** French painter: b. Paris, 1800; d. there by suicide, 1874. He entered the studios of Girard and Lethière and made it his especial artistic aim to portray 'Les Miserables' of Paris — the poor, the suffering, the unfortunate. The exaggerated sentimentality of his pictures was much admired at the time and his realism appealed even to Delacroix and Rousseau. Among his best-known works are 'The Old Musician'; 'A Family of the Unhappy'; 'The Slave Merchant'; and 'Death of Héloïse.'

TASSIE, tăs'ĭ, **James,** English gem engraver: b. Polloshaws, near Glasgow, 15 July 1735; d. London, 1 June 1799. During his early life he worked as a stonemason, then went to Glasgow where he studied art and became associated with Dr. Quin in gem engraving. With him Tassie perfected the discovery of a white "enamel," a hard vitreous paste, especially adapted to the formation of gems and medallions. Going to London in 1766 he became successful through the precision and beauty of his work, copied many of the most artistic gems of ancient and modern times and also made a series of large medallion portraits of many of the famous men of his time. These medallions are of great historic interest and are considered his most valuable work.

TASSO, tăs'sō (Eng. tăs'ō), **Bernardo,** Italian poet: b. Venice, 11 Nov. 1493; d. Ostiglia, 5 Sept. 1569. His education began in Padua, and was continued during his visits to Rome, Ferrara and Venice. He was already known as a poet throughout Italy when Guido Rangone, general of the Pope and a patron of learning, took him into his service and employed him in negotiations with Clement VII at Rome and Francis I in France. He subsequently entered the service of Renata, Duchess of Ferrara, but soon left her court for Padua and Venice. Ferrante Sanseverino, Prince of Salerno, engaged him, in 1531, as secretary, and when that prince followed Charles V to Tunis, Tasso accompanied him, and after his return was sent on public business to Spain. In 1539 he married the rich, beautiful and intellectual Porzia de Rossi, and retired to Sorrento, where he lived till 1547. But the misfortunes of his master, whose estates had been seized by Charles V on account of his opposition to the introduction of the Inquisition into Naples, compelled the poet, at the invitation of the Duke of Urbino, to take up his residence at Pessaro. The leisure which he now enjoyed was employed in finishing his 'Amadigi,' which he published at Venice in 1560. In 1563 the Duke of Mantua appointed him governor of Ostiglia. He was buried at Mantua under a monument erected by the duke, with the inscription "Ossa Bernardi Tassi," but his son Torquato afterward removed his remains to Ferrara. His chief work, 'L'Amadigi di Gaula,' a romantic epic, displays much talent and art. His other works, in five books, are among the best Italian lyric and elegiac poems of the time. Consult Pasolini, 'I Genitori di Torquato Tasso' (1895).

TASSO, Torquato, tōr'kwä'tō, son of the preceding, Italian epic poet: b. Sorrento, 11 March 1544; d. Rome, 25 April 1595. He was

TORQUATO TASSO

early sent to the school of the Jesuits at Naples, and his father being absent from home, his education was at first superintended by his mother, whom he quitted at 10 years of age to rejoin his father at Rome, and never saw her again. At this time he could recite from memory the great Greek and Latin poets. He subsequently pursued his studies under his father's superintendence at Rome, Bergamo, Urbino, Pesaro and Venice. Before the age of 16 he was employed by his father to revise and complete his poem 'L'Amadigi,' and eventually sent to Padua to study law. Tasso, a born poet, found his legal studies a sore burden, but managed to steal time for more congenial pursuits, and at 17, to the surprise of Italy and the indignation of his father, produced the 'Rinaldo,' an epic poem in 12 cantos. The disappointment of the father yielded at length to genuine admiration of this really remarkable production, and he consented to allow his son to abandon law for literature. The reputation of the young poet meanwhile procured for him an invitation to the University of Bologna, where he displayed an aptitude for the study of philosophy, especially that of Plato. He left Bologna on account of a lampoon, which he was unjustly charged with writing. After visiting friends at Castelvetro, Modena and Correggio, he returned to Padua on the invitation of Scipio di Gonzaga. Here he continued the study of Plato, and wrote three 'Discorsi del Poema Eroico.' He determined no longer to imitate Ariosto but take Virgil for his model. He began to construct the plan of his 'Gerusalemme Liberata,' which he at first called 'Godfredo.' The plan of this poem was of a highly prudential character. By celebrating all the great European houses as having taken part in the crusade of Godfrey, he hoped to make himself many powerful friends, and while he was elaborating this project he secured a patron in Cardinal Luigi d'Este, to whom he had dedicated his 'Rinaldo.' The princes of Italy at this time deemed it their chief honor to be esteemed the patrons of art and literature, and the cardinal retained 500 gentlemen in his retinue, one of whom was Tasso, who was also introduced by the cardinal to the court of Ferrara. The Academy of Ferrara supplied learned associates with whom he engaged in philosophical discussions; the courtiers were easily transformed into paladins, and the court ladies into heroines, whose imaginary achievements the poet recorded with daily diligence. Thus the 'Gerusalemme' grew at the court of Ferrara. That nothing might be wanting to his experience, the bard engaged in a course of love-making on his own account. There were at the court of Ferrara two sisters of the reigning duke, Lucrezia, the wife of the Duke of Urbino, and Leonora, the younger, a virgin of 30, and about nine years his senior. Their brother Alfonso served to the poet as model for his 'Godfredo.' In high favor with the ladies, by whom his attentions were received as the gallantries of a courtier and a poet, it would be impossible to imagine a more blissful slave than the poet had now become. In 1571 he accompanied the cardinal on an embassy from the Pope to Charles IX of France. He was received with distinction at the court of France, which he followed to Blois, Tours and Chenonceaux. Ronsard (q.v.) received him in the most friendly spirit. A quarrel with his patron drove him from the French court, and he returned to Ferrara, where Alfonso, at the solicitation of his sisters, received the penniless poet into his own service. In the spring of 1573 his 'Aminta,' a pastoral drama, was represented at the court of Ferrara. It is still considered the most graceful Italian work of the kind, although many prefer the 'Pastor Fido' of Guarini. In April 1575 he announced the completion of the 'Gerusalemme.' Alfonso was eager for its immediate publication, but this judicious counsel was not heeded by the poet, whose sensitive mind dreaded censure, especially the censure of the Church, even more than it coveted applause. He, therefore, sent his poem to his friend Scipio Gonzaga, now a cardinal at Rome, requesting his judgment. Scipio assembled a consulta of churchmen and critics against whose censures, literary and ecclesiastical, the poet was forced to defend himself and to amend and modify his work to meet their views. He was told he ought to be content with monks and nuns as his auditors, and to renounce all mythology, romance and chivalrous adventure, and his mind, divided between art and religion, gave way. To add to his distraction his work at this time was printed piratically without his own revisions. Alfonso wrote a vigorous protest against this disgraceful proceeding to all the Italian courts, but doubts of his favor at court began also to fill the mind of Tasso. He believed that he was persistently calumniated at court, and systematically misrepresented to the Inquisition. On 17 June 1577, he drew his poignard in the apartment of the Duchess of Urbino. He was arrested, but set at liberty after two days and recommended to retire to his country-seat. In spite of strong reassurances he still suspected the office at Rome. He was now received into the convent of Saint Francis at Ferrara, but on the 20th July he started in disguise for his native place where he stayed with his sister Cornelia, till the end of summer. In the autumn he solicited leave to return to Ferrara, and obsequiously accepted a conditional acquiescence to his request. Alfonso is accused of imprisoning him, first, from offense at the addresses paid to his sister; secondly, from jealousy of the Medici, from whom the poet had received an offer; and thirdly, from fear that the poet would strike the glory of the house of Este out of his work. For some years Tasso had lived on intimate terms with Alfonso and his two sisters, especially Lucrezia, who, dismissed by her husband, kept him as her constant companion. He had hesitated about accepting the offer of the Medici, but in 1557 he put away, out of gratitude to the Este family, all thoughts of other service. After many complaints of ill-treatment he again left Ferrara, and wandered, sometimes in want, through Padua, Venice, Urbino and Piedmont, and finally returned to Ferrara (21 Feb. 1579), on the eve of the duke's second marriage. Finding himself treated with complete neglect, he broke out in loud complaint and was imprisoned as a madman in the hospital of Saint Anne of Ferrara. At this time his work was condemned by the Academy della Crusca, to whom he replied with moderation. He remained in the hospital of Saint Anne till July 1586, when he was released at the solicitation of Vincent di Gonzaga, who took him to his estates. Tasso now resided at Mantua, and wrote the tragedy of Torrismondo, which with a genealogical poem he dedicated to Vincent di Gonzaga. Finding that Mantua did not agree with him, he proceeded to Naples, the climate of which he found most congenial, and where he fixed his favorite residence at the monastery of Mount Olivetto. Here he composed the 'Gerusalemme Conquistata,' which he dedicated to Cardinal Aldobrandini. It is a reconstruction of the 'Gerusalemme Liberata,' in which he rejects the chief mystical and chivalrous ornaments of the previous poem, and plumes himself on a precise and slavish imitation of the 'Iliad.' He wished it to supersede the 'Liberata,' but posterity has reversed his decision as to its superiority. Aldobrandini solicited and obtained from the Pope the laurel crown on behalf of Tasso. Urged by his patron, Tasso repaired to Rome, although he declared it was to die. Amid the preparations for the ceremony his health gave way. He retired from the plaudits of the public to the convent of Santo Onofrio, where he expired. (See AMINTA; JERUSALEM DELIVERED). Tasso's chief works include 'Gerusalemme Liberata'; the 'Rime,' and the 'Aminta.' The 'Gerusalemme' was translated into English by Edward Fairfax in 1600. In Italian literature the 'Gerusalemme' shares with the 'Orlando' of Ariosto the place of the greatest epic. Both are full of poetic beauties and admirable for the interest and variety of the narrative. Consult Albertazzi, A., 'Torquato Tasso' (Modena 1911); Boulting, W., 'Tasso and his Times' (New York 1907); Milman, R., 'Life of Tasso' (2 vols., London 1850); Ferrazzi, 'T. Tasso, studi biografici-critici-bibliografici' (1880); Serassi, 'La vita di T. TASTE. See SENSES.

TATARS, or **TARTARS,** a nomadic people anciently spoken of as Scythians, known for their incursions and conquests among neighboring nations over a wide extent of territory; their local seat being found both in ancient and modern times in the steppes or uncultivated regions which connect Europe and Asia, as well as on the north of China, in Turkestan and on the shores of the Caspian and Black seas. Tartar, Tatar or Ta-ta appears to have been the name of a tribe of Mongols who occupied about the 9th century a district of Chinese Tartary on the upper Amur. This tribe was dispersed by the attacks of neighboring Mongols, and carrying the terror of its arms in different directions its name came to be applied by the Chinese to various hordes of Mongol robbers. The true Tatars formed part of the horde of Genghis Khan, when that conqueror carried his arms from the country known as Chinese Tartary to Europe, and through some accidental circumstance the name came to be applied to the whole Mongol horde, as well as to the successive hordes of similar origin who followed in their footsteps, and to the districts from which they came, or in which they settled; hence the names of Chinese Tartary, Independent Tartary (see TURKESTAN) and European or Little Tartary, comprising most of the Russian governments of Orenburg, Astrakhan, Ekaterinoslav, the Cossack provinces and the Crimea. For the incursions and conquests of these peoples see GENGHIS KHAN; MONGOLIA; RUSSIA, etc. The name Tatar has, for reasons similar to those already given, been long applied in Europe to the Manchu conquerors of China. The Manchus are Tatars in the generic sense of the term. See MANCHURIA.

TATE, tāt, **Alexander Norman,** English analytical chemist: b. Wells, Somerset, 24 Feb. 1837; d. Orton, Cheshire, 22 July 1892. He studied chemistry in Liverpool, where he established an analytical and consulting laboratory in 1863, and there became known to the world of industrial science in connection with the study of the recently introduced American petroleum. He wrote 'Petroleum and its Products' (1863), and superintended the erection and management of oil-refining works in the Isle of Man and in Flintshire until 1869. He finally settled at Hackins Hey and increased his reputation as an expert in the analyses of oils and fats, and as a teacher of science in the technical schools at Liverpool. He was editor of the scientific magazine *Research* (1888–90) and a contributor to scientific periodicals.

TATE, George, English archæologist and naturalist: b. Alnwick, 1805; d. there, 7 June 1871. He was a linen draper and subsequently postmaster of his native town and became celebrated for his scientific researches and his publications. These include 'The Old Celtic Town of Greaves Ash'; the 'Hut-circles and Forts on Yeverling Bell'; among the long list of valuable papers on the ancient remains of the district, its geology, flora and fauna, and 'Sculptured Rocks of Northumberland and Eastern Borders' (1865) and 'History of Alnwick' (1865–69).

TATE, Henry, English merchant and philanthropist: b. Chorley, Lancashire, 1819; d. Streatham, 5 Dec. 1899. He was a sugar merchant in Liverpool and amassed a fortune through the invention of loaf sugar. He removed to London in 1880 and became famous for his benefactions, giving £42,000 to the Liverpool University College, a still larger sum to Liverpool hospitals and four free libraries to the parish of Lambeth. He established a large private gallery of modern paintings at Streatham and afterward presented it to the public, building for the collection a gallery near Vauxhall Bridge, at a cost of £80,000. The institution, known as the "Tate Gallery," was opened in 1897, and its donor was created a baronet in 1898.

TATE, Nahum, English poet: b. 1652; d. 1715. Son of a Dublin clergyman, he was educated at Trinity College. In 1690 he succeeded Shadwell as poet-laureate. Oldys calls him "a free, good-natured, fuddling companion." His name has survived through his metrical version (1696) of the Psalms, which he wrote in collaboration with Nicholas Brady, certain portions of which appeal to the reader, but most of which has no poetic value. He also wrote dramatic pieces, as 'King Lear' (an adaptation); 'Panacea or a Poem on Tea'; 'Miscellanea Sacra'; 'Innocent Epicure'; etc. The 'Supplement to the New Version' (1703) may have been due solely to his pen, in which the world-renowned "While Shepherds Watched" is ascribed to Tate.

TATIAN, tā'shĭ-an, Christian apologist: b. 2d century in Assyria; d. Edessa, 180. He studied Greek philosophy and became dissatisfied with the pagan systems of his time. At Rome about 150 he was converted to Christianity by the teachings of Justin Martyr (q.v.). His only surviving controversial work, 'Address to the Greeks,' was written 176 and after the death of Justin Martyr he adopted Gnostic Dualism and unchristian conceptions regarding God, the demiurge and the world of æons, and admitted the existence of contradictions in the Scriptures. In practical matters he rejected the use of wine and of animal food, and used only water in celebrating the Eucharist. He was also opposed to marriage, and he gave in his adhesion to the sect of the Encratites. He was answered by Tertullian, Clement of Alexandria, Hippolytus, Origen and others. His 'Diatessaron' was a kind of harmony of the four gospels. In 1876 Dr. Moesinger published at Venice a Latin translation of a commentary on the 'Diatessaron' which had been written by Ephraim Syrus. The translation had been made in 1841 by Aucher, a Mechitarist monk, not from the original Syriac of Ephraim, for that is not extant, but from an Armenian version ascribed to the 5th century. In 1881 Zahn published his 'Tatian's Diatessaron,' in which he sought to restore the work from the available materials. An Arabic version found in Egypt was edited in 1888 by Agostino Ciasca. The original language of the 'Diatessaron' may have been Syriac; Harnack believes that it was Greek. Consult Otto, 'Corpus Apologetarum' (1882); Hamphill, 'The Literature of the 2d Century' (1891); Harris, 'The Diatessaron of Tatian' (1890); Hill, 'The Earliest Life of Christ' (1893).

TATIUS, tā'shĭ-ŭs, **Achilles.** See ACHILLES TATIUS.

TATLER, The, a paper published by Sir Richard Steele in London, from April 1709 to January 1711. The name, Steele asserted, was invented in honor of the fair sex, and he wrote in it under the pseudonym of "Isaac Bickerstaff," used by Swift previously in his joke upon the almanac-maker, Partridge. Its announcement indicated its purpose to present "accounts of gallantry, pleasure and entertainment," and it may be taken as the first venture in magazine literature in English. Steele wrote 188 of the 271 papers issued, Addison 41, and together they produced most of the others. *The Tatler* was succeeded by *The Spectator* (q.v.).

TATTERSALL'S, tăt'ėr-sâlz, located in Knightsbridge Green, London, England, is the great metropolitan mart for horses, of which there is an auction every Monday throughout the year and every Thursday in spring. It has acquired greater celebrity as the headquarters of betting men.

TATTI, tät'tē, **Jacopo.** See SANSOVINO, JACOPO.

TATTNALL, tăt'nąl, **Josiah,** American naval officer: b. Bonaventure, near Savannah, Ga., 9 Nov. 1795; d. Savannah, Ga., 14 June 1871. He was educated in England and in 1811 returned to the United States, where the next year he was appointed midshipman in the navy. He was engaged in the battle of Bladensburg and served in the Algerine war in Decatur's squadron. He was promoted lieutenant in 1818 and was engaged in the suppression of the West Indian piracy under Porter in 1823–24. He was promoted commander in 1838, placed in charge of the Boston navy yard and at the outbreak of the Mexican War was assigned to the command of the *Spitfire* and joined the squadron at Vera Cruz. He took charge of the Mosquito division, with which he covered the landing of General Scott's troops, and after the fall of Vera Cruz led the attack on the forts at Tuspan. He became captain in 1850 and in 1857 was appointed flag-officer of the Asiatic squadron, where he participated in an attack with the French and British on the Chinese. Although a violation of neutrality, he was sustained by public opinion and also by the government. In 1861 he resigned from the United States navy and offered his services to the governor of Georgia. He was appointed captain in the Confederate navy, took command of the *Merrimac* after the engagement with the *Monitor* in 1862 and set out for Hampton Roads. After the surrender of Norfolk and the navy yard he withdrew with the *Merrimac,* and on 11 May 1862 to prevent her capture sunk her off Craney Island. The court-martial, which he requested, after a thorough investigation acquitted him from all blame. He then engaged in the defense of Savannah River, but in 1865 was compelled to destroy his vessels. In 1870 he returned home and was appointed inspector of the port of Savannah, a post which he occupied until his death. Consult Jones, C. C., 'Life of Commodore Tattnall' (1878).

TATTOOING, a word of Polynesian origin, anglicized from the Tahitian *tatu,* denoting the practice of making permanent colored designs or figures in the skin by means of small punctures or incisions, which receive various dyes or pigments. The coloring is mainly dark blue and dull red. A similar custom, known as cicatrization or scar-tattooing, consists in repeatedly cutting the skin at the same place so that in healing a raised scar is left. Both varieties of tattooing may be found among the same people, as in the case of the natives of the South Sea Islands. Among the Admiralty Islanders, the Fijians, the Gonds and the Todas of India, the inhabitants of the Liu-Kiu Islands and other races, color-tattooing is, or was, confined to the women, and the Latuka of the upper Nile Valley are an example of a people among whom scar-tattooing is practised upon women only. Color-tattooing is generally ornamental, but scar-tattooing is more frequently used to produce distinguishing tribal marks. The latter variety is practised by a number of native African peoples, while the Bangala of the Middle Kongo scar the whole body for ornamental purposes. In some races there is a connection between tattooing and marriage. Thus, in the Solomon Islands a girl is not eligible for marriage until she has been subjected to an atrociously cruel process of tattooing on the face and chest, and the native Australians inflict fearful scars on the backs of their young girls before marriage. The Formosans tattoo the faces of girls prior to marriage; and among the Papuans of New Guinea unmarried girls are tattooed all over, except on the face, which is adorned in this way at the time of their marriage. Color-tattooing of an ornamental kind reached its most artistic development among the Maoris of New Zealand and the Japanese, but both these peoples, like several others, have largely abandoned the practice under the influence of civilization. With the Malays tattooing appears to have been a reward of the successful head-hunter. Sailors and some other classes in civilized countries do some tattooing, mainly in one color, making figures, as stars, flags, etc., on their hands, arms, chests, etc. Consult Robley, H. G., 'Moko, or Maori Tattooing' (London 1896).

TAUCHNITZ, towH'nĭts, **Christian Bernhard,** Freiherr von, German publisher: b. Schleinitz, near Naumburg, 25 Aug. 1816; d. 13 Aug. 1895. In 1837 he founded his well-known publishing establishment in Leipzig; in 1860 was created a hereditary noble; in 1866 was appointed consul-general for Great Britain in the kingdom of Saxony; and in 1877 was made a life member of the Saxon first chamber. The firm is best known for its Collection of British and American Authors,' generally called the "Tauchnitz Edition," begun in 1841 and in 1903 extending to about 3,700 volumes.

TAUCHNITZ, Karl Christoph Traugott, German printer and bookseller: b. Grosspardau, near Grimma, 29 Oct. 1761; d. 14 Jan. 1834. In 1797 he set up a printing shop at Leipzig, which he enlarged by the addition of a book-shop in 1798 and a type-foundry in 1800, the style of the firm being Karl Tauchnitz. He first introduced stereotyping into Germany, and won a high reputation by his musical publications, his editions of the Bible and the Koran and his remarkably correct series of Greek and Latin classics.

TAULER, tow'lĕr, **Johann,** German mystic: b. Strasburg, about 1300; d. there, 16 June 1361. At 18 he renounced a fortune to enter the Dominican cloister, where he studied the scholastic theology, and returning to Strasburg came under the influence of Master Eckhart, whose vernacular sermons then attracted thronging audiences. He was the more impelled to mystical and fervent piety by the violence of the war between Pope John XXII and the Emperor Louis the Bavarian, when the bishop of Strasburg forbade the clergy to open their churches. He became one of the so-called "friends of God," an unorganized brotherhood, including priests, nobles and burghers in all the large cities, who represented the height of mysticism, denied the special prerogative of the clergy except in the celebration of the sacraments, and with anti-sacerdotal tendencies dwelt upon worship in the heart and life. He preached with wonderful success in Strasburg and in the neighboring towns, villages and convents. Notwithstanding the papal interdict and amid the ravages of the black death (1348–49) he bestowed the consolations of religion on the forsaken people, preaching in German mingled with Latin. He published in German a treatise on 'Following the Lowly Life of Christ'; addressed a remonstrance to the clergy against leaving the dying untended and unabsolved; and denounced ecclesiastical abuses while maintaining the claims of the electors. His mysticism, though it pronounced silence and suffering the most perfect work, was rather active than passive, taught explicitly the love of others, tended not to asceticism but to the amelioration of society, recommended the discharge of all ecclesiastical duties as a preparation for a higher stage of spiritual perfection and was opposed to the pantheistic tenets of Eckhart and the Beguins. The best of the early editions of his sermons are those of 1498, 1521–22, 1523 and 1543. The hymns and treatise on German theology which have been attributed to him are of doubtful authenticity. Consult Schmidt, 'Johannes Tauler von Strasburg' (1841); Winkworth, 'Life and Times of Tauler, with 25 of his sermons translated from the German' (1857); Junot, 'Les Amis de Dieu au XIVe Siècle' (1870).

TAUNTON, tân'tọn, England, a market town of Somerset, on the Tone, 36 miles by rail south-southwest of Bristol. The principal buildings and institutions are the parish churches of Saint James and Saint Mary Magdalene; an old grammar-school, reconstructed; a Wesleyan Methodist and a Congregational College; a mechanics' institute; and the castle, still in good preservation, and containing the museum of the Somersetshire Archæological and Natural History Society. The industrial establishments include silk-factories, glove and paper-box works, iron and brass foundries, coach-works, breweries, etc. Taunton is of great antiquity, and from the discovery of urns containing Roman coins appears to have been a Roman station. During the Civil War it was defended by the Parliamentarians against the Royalists. The inhabitants suffered much from the rebellion of Monmouth, whose cause they espoused, and who assumed the title of king here on 20 June 1685. Jeffrey (q.v.) held his bloody assize here in the same year. Pop. 22,563.

TAUNTON, Mass., city, county-seat of Bristol County, at the head of navigation on the Taunton River, and on the New York, New Haven and Hartford Railroad, about 36 miles southeast of Boston and 16 miles north of Fall River. Over 100 passenger trains and about 100 freight trains enter the city daily. The Fall River line of steamers, which have daily connection with New York and other places, are so easily reached that practically Taunton has daily communication by water with many of the Atlantic ports. The city gets its coal, iron and lumber at tide water, and freight rates to and from Taunton are less than for inland cities. Electric lines connect the nearby villages and towns with the city, more than 700 cars leaving centre of the city daily.

The city is noted for the extent and variety of its manufacturing industries. The government census of 1910 gives the leading manufacturing establishments of the city as follows: seven cotton mills, with $4,410,390 invested, and employing 3,151 persons, to whom were paid annually $1,125,679. The cost of the material used annually was $2,651,502, and the value of the yearly products was $4,592,466. There were 14 foundries and machine shops, with capital invested, $2,679,203; the value of their yearly products, $2,636,390. The total number of manufactories (1909) was 146; the total capital invested, $16,504,000; the annual average number of employees, 7,835; the annual amount of wages, $4,535,000; the cost of material used, $7,775,000; and the value of the products, $15,380,000. The principal manufactures, besides cotton products, are cutlery, machinists' tools, eyelets, tacks, nails, jewelry, machinery for cotton manufactories, silver and britannia ware, brick, oil-cloth, copper and yellow metal goods, printing presses, stoves, stove linings and kitchen utensils. The city is the distributing centre for a large part of Bristol and adjoining counties; coal is shipped from here to the markets of the interior, and grain, vegetables, poultry and manufactures to outside markets.

The principal public buildings are the State Insane Hospital, a massive group of buildings, situated in a tract of 140 acres, which accommodate over 1,000 patients; the county courthouse (cost over $300,000); Registry building (cost $125,000); the government building ($100,000); city hall; Taunton jail; theatre; Odd Fellows' Hall; Historical Hall; Morton Hospital, the gift of Susan Tillinghast Morton Kimball; Old Ladies' Home, opened January 1871; club buildings, banks, business blocks, schools and churches. There are six each of Congregational and Roman Catholic churches, four Methodist, one each of Unitarian, Baptist, Presbyterian, Christian Scientist, Adventist, Protestant Episcopal and Universalist. The educational institutions are Bristol Academy, opened 18 July 1793; Saint Mary's Academy (Roman Catholic); headquarters of the Old Colony Historical Society, incorporated 4 May 1853; a high school, public and parish schools, graded elementary schools and a public library containing about 55,000 volumes. The city is well supplied with bank institutions; the two national banks had, 1 Sept. 1910, a combined capital of $700,000; the combined surplus of two savings banks was $8,335,000; and five co-operative banks had a combined capital of over $3,000,000. The government of the city is vested in a mayor and nine councilmen chosen by popular vote. Pop. about 36,161.

History.— The first white settlement was made by Elizabeth Pole, an Englishwoman, in 1637. She found here an Indian village called Tecticutt («great river») on the Tecticutt River. Miss Pole bought land from the Indians for a plantation on the east side of the river, within the present limits of Ward Four. The place was first called Cohannet, but when it was incorporated in 1639 it was called by its present name, after Taunton, England. In June 1639 Taunton sent deputies to the General Court assembled at Plymouth. The names which appear on the Taunton records — of men connected with the surveys and the granting of titles — are names of men who were among the history makers of the nation. The early settlers of Taunton recognized the rights of the Indians, and the records show that Miss Pole and others purchased lands from Massasoit and other Indians. William Hooke, the first minister, returned to England as domestic chaplain to Oliver Cromwell. The first mention of a schoolmaster is that of Master Bishop, who was one of the early settlers. Other schoolmasters were William Pole, Mr. Adams, James Green, and in 1683, Samuel Danforth, a minister, was selected to keep a «Gramer scole here in Taunton.» In 1647 an act was passed which made the public schools free and the support of the schools compulsory. In 1682 Taunton received from the court £3 from the funds of the fishing excise of the Cape, for keeping a free colonial, classical and elementary school. In 1701–02 100 acres of land, on both sides of the river, were set apart for school purposes. The history of education in Taunton is an almost complete history of the city. A grist mill was erected in 1639–40; in 1653 the first successful iron works in America were established. Some of the products of the iron works were used as money, as may be seen from the following order:

To the Clerk of the Iron Works,
Ensign Thomas Leonard please pay to Bar' Tipping nine shillings and three pence in iron money.
From yr friend,
Richard Williams.
Taunton 16th 1st — 1685.

In 1659–60 a saw-mill was built, and before 1700 brick making, shipbuilding and many other industries had been begun. The ruins and sites of many of the old manufactories are pointed out as of historic interest; for they mark the beginnings of the mighty industries of the Taunton of the present. On 6 Nov. 1746 the place was made a «shire town,» and on 2 Jan. 1865 was incorporated as a city. The first crucibles in America were made here; the copper blank discs for copper cents were supplied to the government, in large amounts, by the Taunton Manufacturing Company. Taunton has always furnished promptly more than its quota of soldiers when the country called for defenders. In 1774 the people unfurled from the liberty pole on «Taunton Green» a flag, on which was inscribed «Liberty and Union»; and among the «minnit men» at Lexington, 19 April 1775, was a brave band from Taunton. They were among the first to go and the last to return. Robert Treat Paine, one of the signers of the Declaration of Independence, resided here, for whom a statue has been erected in front of the city hall. Consult Waterman, 'History of Taunton Schools'; Emery, 'History of Taunton' (1893); 'Quarter-Millennial Celebration of the City of Taunton.'

TAUNUS, tow'noos, Germany, a mountain range mainly in the Prussian province of Hesse-Nassau, extending eastward from the Rhine, north of the Main, separating the basin of that river from that of the Lahn. The highest summit, Grosser Feldberg, is 2,886 feet in elevation. The district is well wooded, and exhibits much picturesque scenery, as well as ruined castles, etc., and antiquarian remains dating from Roman times. Its scenery and mineral waters attract many visitors; and some of the finest German wines are grown on the south side. The point of most historical interest in the region is the ancient Roman fort uncovered at Saalburg, showing fortifications dating back to the year 200. West of Saalburg the Germans erected a colossal statue of Germania to celebrate their victory over France in 1870–71.

TAURIDA, tow'rē-dā, a government of the Ukrainian Republic, bounded north by Ekaterinoslav; east by the Sea of Azov; southeast, south and west by the Black Sea; and northwest by the government of Kherson, from which it is separated by the Dnieper; area, 23,312 square miles. It is irregular in shape, and being united to the land only on its boundary with Ekaterinoslav for about 90 miles, may be regarded as one large peninsula, subdivided again into two minor peninsulas, of which that in the south, now called the Crimea, and well known in ancient times as the Chersonesus, is the more perfect; the isthmus which connects it with the northern portion being at its narrowest not more than eight miles. The northern peninsula consists almost entirely of an extensive steppe, which stretches across into the southern peninsula. It is generally without a tree, and in many parts composed of parched and saline sands, where vegetation is almost extinct; but in other parts is composed of fertile loams, capable of raising any kind of crop, and often covered with verdant pastures. Simferopol is the capital city. (See also the article CRIMEA). Pop. about 2,133,000.

TAURUS, tâ'rŭs, Asiatic Turkey (or Asia Minor), a mountain chain or series of mountain groups usually considered as beginning in the east on the Euphrates, at the Nushar Cataract, in the pashalic of Marash, whence it stretches west, nearly parallel to the coast of the Mediterranean, for above 500 miles, terminating to the north of the Gulf of Adalia. In the east it takes the name of Jebel-Kurim, or sometimes Anti-Taurus Mountains, in the west that of Ramadan Oglou Balakar. It sends off several branches, of which the most remarkable are Alma-Dagh, which proceeds south into Syria, and becomes linked with the chain of Lebanon; and the Anti-Taurus, which proceeds northeast, sending out ramifications which become linked with Ararat, Elburz and Caucasus. Many of the Eastern peaks are above 10,000 feet.

TAURUS, the Bull, *in astronomy,* a name given the second of the zodiacal constellations. It contains the star of the first magnitude Aldebaran (in the eye), the group of the Pleiades (in the neck), and the Hyades (in the face).

TAUSEN, Hans, Danish reformer: b. Birkende, on Fünen Island, 1494; d. Ribe, 11 Nov. 1561. He studied at Wittenberg and was preacher, from 1525, at Viborg, then, from 1529, at Copenhagen. He edited, with collaborators (1530), «The 43d Copenhagen Article.» In 1535 he published a prayer-book and a book of homilies. He was appointed reading-master of the university (1537) and (1542) bishop of Ribe. Instead of Latin he used his native language in his sermons and books. A selection of his works was brought out by Rördam (Copenhagen 1870). Consult Rön, 'Skiagraphia Lutheri Danici M. Johannis' (1757); Schmitt, L., 'Johannis Tausen, oder der dänische Luther' (Köln 1894).

TAUSIG, Karl, German pianist: b. Warsaw, 4 Nov. 1841; d. Leipzig, 17 July 1871. First he was under his father's tuition, then studied under Bocklet, Thalberg and Liszt in Vienna. He made art tours, then lived in Dresden and later (1861–62) in Vienna. From 1866 he was royal court pianist at Berlin and led, till 1870, an academy of pianoforte playing. As a virtuoso he was equally interpreter of classic as of modern piano-music, but as composer he produced few works. Noteworthy of his productions is his edition of Clementis' 'Gradus ad Parnassum.' His piano score of Wagner's 'Meistersinger' became very popular. His 'Technischen Studien' was published by H. Ehrlich. Consult Weitzmann, 'Der letzte der Virtuosen' (Berlin 1868).

TAUSSIG, tows'ĭg, **Edward David,** American naval officer: b. Saint Louis, Mo., 20 Nov. 1847. On graduating from the United States Naval Academy in 1867, he was appointed successively ensign, master and lieutenant, being made lieutenant-commander 19 June 1892. He has served on the European and Pacific stations and in the coast survey. He took possession of Wake Island for the United States and was placed in charge of Guam 1 Feb. 1899. He was on duty in the Philippines and during the summer of 1900 in North China. He has commanded the *Bennington* and the *Yorktown.*

TAUSSIG, Frank William, American political economist: b. Saint Louis, Mo., 28 Dec. 1859. He was graduated at Harvard in 1879, and has been full professor of political economy there since 1892. He has written 'Tariff History of the United States' (1st ed., 1888; 6th ed., 1914); 'Silver Situation in the United States' (1892); 'Wages and Capital' (1896); 'Principles of Economics' (1911); 'Some Aspects of the Tariff Question' (1915); 'Inventors and Moneymakers' (1915), and has been editor-in-chief of *The Quarterly Journal of Economics.*

TAUTOG, a marine fish (*Tautoga onitis*) of the Atlantic Coast of the United States, related to the cunners and wrasses of the family *Labridæ*, and locally known as blackfish or oysterfish. It is from two to three feet in length, when large, blackish or greenish in color, the young with about three pairs of obscure dark bars; chin white; eye greenish. It abounds about weedy rocks, oyster reefs, etc., near shore, feeding on mollusks, barnacles, etc., and is easily caught. It is one of the best table-fishes of the American coast. The annual catch off the New England coast is about 750 tons.

TAVERN, a name common especially in the rural districts of Great Britain and the United States for a village inn or hotel. Occasionally some city hotel has borne the name.

TAVERNIER, tā-vĕr-nē-ā, **Jean Baptiste,** BARON D'AUBONNE, French traveler: b. Paris, about 1605; d. Copenhagen, 1689. Before his 21st year he had visited a considerable portion of Europe. He subsequently traveled through Turkey, Persia and other Eastern countries, six times by different routes, trading as a diamond merchant, and studying manners and customs. Of his journeys he gave an account, with the assistance of a literary friend. In 1689, having realized a large fortune and obtained a patent of nobility, he retired to the estate of Aubonne, in the Genevese territories, with the view of passing there the remainder of his life. But altering his determination, he was preparing to start once more for the East, when he was suddenly overtaken by death. His travels, 'Voyages en Turquie, en Perse, et aux Indes,' of which there are translations in English (1678 and 1684), Dutch (1682) and German (1684), have gone through several editions in the original French.

TAVOY, tā-voi', Burma, (1) a town in Tenasserim, on the river of the same name, capital of a district, 35 miles from its mouth, 230 miles southeast of Rangoon. It is situated on Tavoy River, about 30 miles from the harbor sheltered by Tavoy Point, a conspicuous peninsula on the Burma coast. It lies in a low situation, which, during the rainy season, becomes almost a swamp. It is laid out in straight streets, and the houses are mostly built of timber and thatched with palm leaves. The trade is inconsiderable. Near the town a mass of native loadstone occurs, and at a short distance from it is a hill entirely composed of specular iron ore. Pop. about 25,063. (2) An executive district which has been under British control since 1824, with an area of 5,308 square miles; pop. about 110,000. (3) An island about 75 miles south of the town of the same name, the largest and most northern of the extensive chain which is called the Mergui or Tenasserim Archipelago. It is about 18 miles long and two broad, and its southern part is surrounded by numerous shoals and small islands, which make navigation dangerous. On the eastern side there is a good and well-sheltered harbor, which has received the name of Port Owen.

TAWAS (tâ'wạs) **CITY**, Mich., village, county-seat of Iosco County, on Tawas Bay (an inlet of Lake Huron), at the mouth of the Tawas River, and on the Detroit and Mackinac Railroad, about 66 miles north of Bay City. It has a good harbor and steamer connection with many of the lake ports. It is in an agricultural and lumbering region, and nearby are large salt deposits. Its industries are connected chiefly with the manufacturing of lumber, and the shipment of salt, lumber and farm products. There is one bank. Pop. about 1,000.

TAWI TAWI, tä'wĕ tä'wĕ, Philippines, (1) A group of islands of the Sulu Archipelago, forming the extreme southwestern part of the Philippines, consisting of 88 islands; area, 462 square miles. Some of the islands, though charted, are unnamed; the others are divided into three sub-groups or clusters; (*a*) the Cinapusan or Kinapusan cluster; (*b*) the Tawi Tawi cluster; and (*c*) the Laparan cluster. The larger islands are mountainous, but of moderate height; the valleys and plains are fertile and covered with tropical vegetation. Rice, corn, hemp and coffee are cultivated, but only for domestic use; the forest wealth is considerable, but is not of commercial value on account of lack of means of transportation. The chief industry is fishing, pearl fishing and gathering of mother-of-pearl, etc. The islands are sparsely populated and, as many are very inaccessible, have been for many years the hiding places of pirates; the few settlements were mostly established by the Spaniards. (2) The largest and name island of the Tawi Tawi group; length from northeast to southwest, 35 miles; greatest width, 15 miles; area, 187 square miles. It is mountainous, and of volcanic formation; they are three groups of two peaks each, one at the southern end, one at the northern end and the third in the east central part; greatest elevation, 1,941 feet. The soil is generally fertile, and the island well wooded; the chief industry, as in the rest of the group, is fishing. The chief settlement is Tatán, on the northwest coast, on a small bay.

TAWNEY, James A., congressman: b. near Gettysburg, Pa., 3 Jan. 1855; d. Excelsior Springs, Mo., 12 June 1919. He was educated at the common schools and learned the blacksmith's and machinist's trade. He went to Winona, Minn., in 1877 and worked there as a machinist for four years. He was admitted to the bar there in 1882 and practised law until 1890, when he was elected to the State senate of Minnesota. In 1893 he was elected to the 53d Congress and served continuously until 1911, when he was defeated by the Progressive party. Mr. Tawney was appointed by ex-President Taft to the International Joint Commission created by treaty with Great Britain for the settlement of disputes between the United States and Canada, and was chairman of the United States section of the commission until his death. Mr. Tawney had great political power in Minnesota, and took an active part in anti-trust legislation. In 1906 he was vice-chairman of the Republican Congressional Campaign Committee. He was known in the Republican party as an insurgent and continually surprised the Republican machine while in Congress by bolting. He was an orator of great power. He was chairman of the House Appropriations Committee until 1910, and long championed a Federal budget system. Tawney was defeated for re-election in 1910, when he opposed reform of the power of the speaker of the House. In 1910 he opposed the efforts of the Republicans to increase appropriations for the army and navy.

TAX ASSESSORS. See TAXATION.

TAX-DEED, an instrument or conveyance whereby the proper officer of the law undertakes to convey the title of the rightful owner to the purchaser at a tax sale or a sale of the land for non-payment of taxes. This deed, according to the principles of the common law, is simply a link in the chain of the purchaser's title. It does not of itself transfer the title of the owner, as in grants from the government of deeds, or as do conveyances between individuals. The deed is not the title itself, or even evidence of it, its recitals not being binding. No presumption arises upon the mere production of the deed that the facts upon which it is based really existed, but when it is shown that the officers of the law have performed every duty imposed upon them the deed becomes conclusive evidence of the title in the purchaser.

TAXALES. See PALEOBOTANY.

TAXATION. What Is a Tax? — A distinction must be made between a tax and the exercise of the power of taxation. Property may be taken from individuals by the government in the exercise of various sovereign powers, such as the power of eminent domain, the penal power, the police power and the taxing power. Where the purpose of the compulsory payment is neither to exercise the right of eminent domain nor to inflict punishment nor primarily for purposes of regulation, we have to deal with the power of taxation. The power of taxation may be exercised, however, in several ways. The government may perform a service for the individual from which a specific benefit is received and where the cost of the service is presumed to be covered by the payment. Such payments are called fees or tolls. Or, again, the government may, with or without the consent of the individual, make an improvement which increases the value of his real estate and may impose what is technically called a special assessment or a betterment charge. Finally, the government may impose a payment on the individual where the special benefit, if any, is merely incidental. Such a payment is called a tax. Taxes in the narrower sense are to be distinguished, therefore, not only from fines and penalties as well as from prices (charges made by the government when it carries on a commercial or industrial undertaking) but also from fees or tolls and from special assessments, both of which are equally manifestations of the taxing power, but which are distinguished from taxes in the narrower sense in that the special benefit accruing to the individual is both positive and measurable.

A tax may, therefore, be defined as a compulsory contribution from the person to the government to defray the expenses incurred in the common interest of all, without reference to special benefits conferred. Each word in this definition is significant. A tax is a contribution, whether in money or in kind; it is compulsory (to distinguish it from a gift); it is paid by a person — either a natural person, like an individual, or an artificial person, like a corporation; it is paid to the government in any of its forms, whether local, State, Federal or international; the expense must be incurred in the common interest of all or, in legal parlance, it must be for a public purpose; otherwise it is confiscation, not taxation. Finally, it must be paid without reference to special benefits conferred. It is levied for the common benefit, not for any special benefit.

The Reason of Taxation.— By the reason of taxation is meant the ground or the philosophical justification of taxation. The older theory may be called the exchange or the contract or the reciprocity theory. It was connected with the 18th-century contract theory of the state. This theory holds that taxes are a mere exchange between the individual and the government, that the government performs certain services like that of protection, for the individual and that the individual gives the government something in return. This theory has been completely superseded by the more modern political philosophy. The modern theory may be called the organic theory of taxation. It does indeed not deny the obligation of the government to do something for the community in return for the payment exacted from the community. In this sense, there is, indeed, reciprocity; but it is an exchange between the community as a whole and the government which represents the community. It is not an exchange of any kind between the state and the individual. Modern political philosophy does not recognize the contract theory. The individual does not contract or bargain with the state. He is born into the state, or, if he transfers his political allegiance, he does so without any reservations. In this sense the state is as much a part of the individual as the family is a part of the individual. Just as the individual involuntarily assumes certain obligations to his family, so he assumes obligations to the state of which he is a member. It is, therefore, as much his duty to support the state as it is to support his family. In fact, we may go further. The state or politically organized community is indispensable to modern civilized man. We cannot conceive of any one living outside of the state. Since no one can throw off the obligations of the state — which can in the last instance demand a man's very life — it is as much the duty of the individual to support the state as it is to support himself. The obligation to pay taxes may, therefore, be declared in modern times to be a natural obligation and the state is everywhere justified in converting this moral obligation into a legal obligation.

The Function of Taxation.— The primary function of taxation, therefore, is to raise revenue. This may be declared to be the fiscal function of taxation. As a matter of fact, however, taxation has always been used for other purposes which may be declared to be secondary or incidental in character. Such a function may be declared the social, rather than the fiscal, function of taxation. Taxation has been at various times employed to check, to prohibit, to destroy or to foster economic activity. At the present time, in the United States, for instance, we have a tax which completely prohibits the issue of State bank notes and certain kinds of future sales on the cotton exchange. We have a tax designed materially to check the import of opium. We have a tax which has utterly destroyed the production of phosphorus matches. We have, or have had, taxes designed to foster or protect certain forms of domestic industry. In this respect there have been two extreme schools of thought, the one represented in the United States by statesmen like Calhoun or publicists like David A. Wells, who have contended that the only function of taxation is fiscal and that protection, for instance, means confiscation. The other extreme represented by certain socialists and by professorial socialists like Adolf Wagner, have maintained that the primary purpose of taxation is to effect changes in distribution. A logical corollary of this position would be that no payment can be considered a tax unless it seeks to effect social changes. The more modern and more moderate position is that while the primary function of taxation must be the fiscal function, there is no reason for refusing to bring about, incidentally, through taxation, desirable social reforms that are recognized as such by the community.

The Nature of Taxation.— Is taxation a good or a bad thing? Is it a benefit or an evil? Here again we have two schools of thought. The older writers, of whom Jean Baptiste Say is a good example, adopted the so-called consumption theory of public finance, and held that governmental functions ought to be reduced to a minimum and that the exercise of governmental power represents the unproductive consumption of the community. The consequence is that all government expenditures should be reduced to a minimum and that, as it has been said, the best tax is the smallest tax. At the other extreme is found the statement which is based upon the productivity theory of public finance. According to this the state is, or ought to be, the chief productive force in the community because, at all events, it is designed to lay the foundations for the exercise of all individual production. Everything extracted from the individual and spent by the government would from this point of view, as it has been put, return in a fertilizing shower to the community. Taxation would, therefore, be the best form of investment.

Here again the modern position is midway between the two extremes. It is undeniable that a tax involves a burden or a sacrifice and in this sense it is something which to that extent represents an evil. But it is equally true that the result of the tax is, or may be, to enable the government to accomplish something which is of undeniable advantage to the community as a whole, even though the particular benefit which accrues to the individual may not always be definitely measureable. The real question, therefore, is: what is the result of the expenditure or what does the government do with the tax? If the expenditure is a foolish or a wasteful one, if no care has been taken in limiting either the end or the means, there can be no doubt that the tax represents an evil. But if the object to be attained is economically or socially desirable, if the money is economically spent and if the balance of the social advantage over the social sacrifice is clear — if, in other words, the government is efficiently carrying out a wise mandate of the people — then the tax represents a good and not an evil. To say that the best tax is the least in amount would bring us back to primitive savagery. On the contrary, the distinguishing mark of modern civilization is the growing proportion between the satisfaction of collective wants on the one hand as over against the satisfaction of individual wants on the other. The more civilized the community the greater, not only absolutely but relatively, will be the amount of taxation as compared with the total social income. While, therefore, it is by no means true that every tax is a good tax or that every expenditure is a wise expenditure, it is nevertheless a fact that in the sense indicated above taxation is a good rather than an evil because it is a necessary means of accomplishing certain desirable political and social aims. The nearer, in other words, every tax comes to being an ideal tax, the more will it represent a balance of benefits over disadvantages.

The Limits of Taxation.— Even though taxation in the above sense may be declared to be good, there is another sense in which there is a definite limit upon the possible advantages of taxation. We have here to consider taxation not, as above, in relation to the returns to be expected, but in relation to the source from which taxes are derived. It is a question not what do you do with the tax, but from what source do you get the tax? In other words, no matter how ideal in other respects a tax is, it may impose too heavy a burden upon the community. The limits of taxation may be legal, political or economic. The legal limitations upon taxation are creatures of positive law. The government, in the United States for instance, is enjoined from levying a tax on exports. The State governments are prohibited from levying any taxes which will interfere with interstate commerce. Both State and local governments are frequently enjoined from levying more than a maximum rate of taxation. The political limits of taxation may be illustrated by the provision of American law, that all taxes must be for a public purpose. The exact formula of what constitutes public purpose is something which has given great trouble to our judges and publicists. The economic limits of taxation are seen when we reflect that the ultimate source of all taxes is the social income and that the demands preferred by government in the form of taxation may trench unduly upon this income. We have had numerous examples both of megalomania and of unwise expenditure in the history of American finance, especially State and local finance. Not a few communities have even become bankrupt through the impossibility of raising sufficient revenue by taxation to defray the present and past expenditures of the community. In the last resort, the community, like the individual, must cut its coat according to its cloth. It may conceivably levy taxes up to the limit of the social income, but if it exceeds that income or trenches upon the capital-replacement fund of the community, it marks the beginning of a backward step in economic progress.

The History of Taxation.— In the history of taxation there is discernible the influence of four sets of causes. First and most significant are the general economic conditions. The fiscal system is always in large part a reflex of the economic system. When economic conditions are simple, the forms of taxation are apt to be simple. Where there is a preponderance of certain economic factors, the tax system will vary accordingly. Thus, in the American colonies, there were three fundamentally different systems of taxation, corresponding to the system of small farms and petty industry in the New England colonies, to the dominance of business interests in the middle colonies and to the plantation system in the Southern colonies. The fiscal system of the feudal ages rested largely upon land. The success of the tax on personal property was and is very different in the towns from what it was in the country. The growth of modern forms of business has brought with it an entirely new system of taxation. Second to be emphasized is the influence of democratic factors. Modern democracy and the changed attitude to the laboring classes has brought with it a considerable alteration in the kinds of taxes and in the proportion between the so-called direct and indirect taxes. The same influence is attributable to the introduction of the modern system of progressive taxation. In the third place, we note the development of the idea of faculty or ability to pay. More and more the system of taxation has been molded by the desire to fit the burden to the capacity of the contributors and the tests that have been progressively employed to measure faculty have, as will be seen below, undergone a continual modification. In the fourth place, side by side with the adoption of individual faculty we note the substitution of the social for the individual treatment in taxation, that is, a system modified by a study of the social consequences and economic effects of the tax system upon the various economic classes in the community as a whole.

Influence and Effects of Taxation.— The effects on production. Here again two theories stand opposed to each other. A former school contended that taxes stimulate production. It had been claimed by some that a new tax evokes a new ability to bear the tax and that in this sense an increase in the seeming burdens may really augment the industry of the people. It has been argued that if industry in general is the result of coping with the natural disadvantages, such as the inclemencies or difficulties of nature, why should not the same result be brought about by artificial disadvantage, like taxation? Attention is directed to the period of the Napoleonic wars where the increase of British taxes seemed to result in greater power to bear the taxes. On the other hand, we find the contention that all taxes are injurious, or, as in the case of the Single Taxers, that all taxes excepting the land value tax exercise a deleterious influence because they are taxes on labor and industry and, therefore, check or repress labor or industry.

The truth again lies in the midway. It is undoubtedly a fact that some taxes seem to increase industry. But if regarded more attentively it will be seen that the tax is the occasion, rather than the cause, of the redoubled activity and in that in almost all cases the lure of profit rather than the fear of loss is the real stimulus to productivity and invention. It is undoubtedly far more frequent that industry is injuriously affected, rather than benefited, by the burden. But it by no means follows that every tax exerts an injurious result. If certain principles of equality are observed, it is possible for a tax to be innocuous so far as the producer is concerned, and, at the same time, to have the consumer benefit more from the results of the government outlay than he suffers from the tax. There is no broad generalization to be framed in this respect. According to the character of the particular impost, taxation may be said to have educational, destructive or regulative effects. There are two points of more general influence. One is connected with the inequality of taxation. If an exclusive or unequal tax is imposed upon some permanent source of revenue, the tax or the excess of the tax over the normal rate will be amortized or capitalized into the diminution of the selling value. If 1 per cent is assessed upon securities, for instance, which bear 5 per cent interest and have been selling at par, the new purchaser will pay only about 80. This is known as the capitalization of taxation. The same tendency of things to seek their level is found in the imposition of a new tax in general. A French writer, Canard, had laid down the principle that every new tax is a bad tax and every old tax is a good tax. What he meant was that the disturbance of industry by the imposition of a new tax often takes some time to allay itself. This of course must not be misinterpreted into the belief that a tax which is inherently bad can ever become good through the lapse of time. The effect of taxation on exchange of wealth is marked. The chief reason, for instance, why there is no large class of real estate dealers in Paris as compared with New York is the existence of a high tax on the transfer of land. It has sometimes been alleged that the downfall of Spain is due to the universal tax on sales, *alcavala,* in the Middle Ages. An important principle connected with the influence of taxation on exchange is the so-called excess-of-price doctrine. In its original form the doctrine held that every time a taxed commodity changed hands the tax grows in arithmetical proportion, for as the profits of each dealer are added to the price, the tax is imposed in each case successively on the new price, including the profits. This alleged principle, however, is open to the objection that according to modern economic theory, profits are not a part of price, but the result of price and that the price is always fixed at the point of minimum cost. The element of truth contained in the principle is due to the fact that interest is a part of cost and that to the extent that interest on the successive prices is of any importance, the tax tends to be cumulative. The influence of taxation on distribution is indisputable. Many taxes are designed to have such an effect, as high inheritance taxes, graduated income taxes, but many taxes also have unexpected effects on distribution. One of the older theories or "leave-them-as-you-find-them" doctrine states that the ideal tax ought to leave every individual in the same relative position as before the imposition of the tax. This is no longer accepted as an ideal.

The influence of taxes on consumption is of less importance than in former times. In the Middle Ages sumptuary taxes were very common. It was, however, not luxurious consumption, but necessary consumption, which was frequently sought to be hit. The ease with which taxes of certain kinds may be made to check consumption are so pronounced that it is primarily in periods of war finance that recourse is taken to this medium.

The political effects of taxation are no less important than the economic. The history of free government itself has been intimately influenced by the effects of taxation.

Incidence of Taxation.— By the incidence of a tax is meant its final resting place. We must distinguish between the impact of a tax or its original assessment, the shifting of a tax or its transfer, and the incidence of a tax or its final resting place. Shifting is the process, incidence is the result. The person who bears the tax is not always the one who pays the tax in the first instance. This has led some writers to lay down the so-called equal-diffusion theory of taxation, the theory, namely, that the body economic is like any organism and that if a liquid is injected into the veins at any point it will at once be diffused throughout the body. The tax, therefore, no matter where imposed, will be shifted to the community at large. This theory suffers from undue generalization. It is true that certain taxes give rise to such changes in economic relations that they may in a sense be said to be ultimately spread over the community. There are, on the other hand, many taxes which do not lead to this phenomena and some taxes which are not shifted at all. A distinction must furthermore be observed between capitalization and shifting. If a tax is shifted, it cannot be capitalized; if it is capitalized, it cannot be shifted. There are certain conditions which predispose to the shifting of taxation. The more general a tax is the less likely is it to be shifted because the smaller the tax the less the field to which the individual can betake himself. Where commodities are produced under varying conditions, much depends upon whether the tax is imposed upon the marginal or the intra-marginal producer. Where a tax is imposed upon land which produced a commodity with a local market, the tendency is for the tax to be shifted to the consumer. If the tax is imposed on the North Dakota farmer whose wheat is sold in Liverpool, the shifting of the tax depends upon the relative cost of producing Argentine or Russian wheat and upon the existence or absence of equal taxes in those countries. Where a tax is imposed not upon commodities or property in particular, but upon profits or income in general, the tendency to shift is much less pronounced. With taxes upon a particular kind of commodity or upon a particular kind of income, the situation is different.

The shifting of the tax is of importance not only as between producer and consumer, but also as between borrower and lender. In taxes imposed upon mortgages or upon funds borrowed the incidence of the tax depends to a large extent on whether the tax is general or exclusive. If the tax is levied as a part of a general income tax, it will not be shifted; if, however, it is an exclusive or unequal tax, either by law or in actual operation, the tax will ordinarily be shifted from the borrower to the lender. A complete study of the shifting of taxation would involve a treatise on the formation and distribution of wealth.

Principles of Taxation.— There are four different sets of principles of taxation, fiscal, administrative, economic and ethical. The *fiscal* principles are those of adequacy and elasticity. Unless a tax is sufficient to bring in the revenue that is needed or expected, it cannot be pronounced successful. Again, unless a tax is so elastic as to respond to the varying changes in economic conditions, it is also to be deprecated. The *administrative* principles of taxation are those of certainty, of convenience and of economy. Unless a tax law is certain in its provisions, it is a bad law. There is a great difference, for instance, between the certainty of a land tax and the uncertainty of a comprehensive or of a complicated income tax. The principle of convenience of taxation includes the question of how the tax is to be paid, when it is to be paid, where it is to be paid, and under what conditions, inquisitorial or otherwise, it is to be paid. The economy of taxation implies that a tax should take out of the pocket of the people as little as possible above what it brings into the government, or, in other words, that the cost of collection should be low. The *economic* principles of taxation may be declared to be innocuity and efficiency. The innocuity or harmlessness of a tax is a most desirable attribute. All taxes, indeed, represent a burden but, as has been pointed out above, certain taxes have a far more destructive effect than others. Other things being equal, the legislator must chose the most innocuous tax. By the efficiency of taxation is meant the capacity of a tax to accomplish the desired result. Many a tax is admirable in other respects, but can be made to work in practice only with difficulty. The present property tax, for instance, in the United States is to-day no longer an efficient tax. The *ethical* principles of taxation are those of uniformity and universality. As these are the most important, they will be discussed separately.

Uniformity or Equality of Taxation.— By equality is of course not meant absolute numerical equality, but relatively proportional equality. Uniformity, in other words, means relative uniformity. The question then arises as to the relation involved. To what should taxes be relative, in order to be equal? In former times the answer was that the real basis of taxation should be either the cost of service to the government or the value of the service to the individual. The more modern theory maintains that taxes should be in some relation to the faculty or the ability of the individual to pay. Much time has been spent upon the problem of what constituted the real elements of faculty. For a long time faculty was stated in terms of sacrifice. By equality of taxation there is meant an equality in the sacrifice imposed upon the individual. In more recent times, however, emphasis has been put upon another aspect of the problem. Sacrifice has to deal with the phenomenon of parting with one's wealth. It involves the question of what is left for immediate consumption after the tax has been paid. But economic life deals not only with consumption, but with production. When we come to consider the production of wealth rather than the consumption of wealth we are confronted by the facts of opportunity or privilege in the amassing of wealth. A man's ability to pay a tax, therefore, must be considered not only from the point of view of consumption but from that of production. In other words, the two elements of faculty are privilege and sacrifice: the easier it is for a man to make his money, the more ability he has to pay taxes; the harder it is for a man to be deprived of his money, the less ability he has to pay taxes.

The Norm of Taxation.— By the norm of taxation is meant the test of faculty. There have been no less than five such tests disclosed in the history of taxation: (1) The first test of faculty was polls. Everyone was supposed to have an equal ability to pay. In a primitive form of society the poll tax was legitimate. It has virtually disappeared to-day except in a few democratic communities like the United States, where it still lingers as a survival of a former and more primitive equality. (2) Expenditure. The advantage of expenditure as a test is that no one can escape because everyone spends something. The disadvantage of expenditure as a sole test of faculty is that some people must spend all they make, while others can save most of what they make. Expenditure thus becomes an increasingly unsatisfactory test of faculty; (3) Property. In a comparatively early form of society wealth in terms of property is an excellent test of faculty. The general property tax is accordingly found everywhere at a certain stage of development. The more complicated and the more differentiated the society, the more apparent, however, are the shortcomings of this test. The chief modern defects of property as a test of equality in taxation are the following: (a) While it is generally true that capital is nothing but capitalized income, there is in modern times frequently a discrepancy between the property and the yield or produce of the property. This may be due to speculation, to chance or to other accidents of economic life; (b) In modern times more and more wealth is derived from personal earnings rather than from property. The property tax would hit the owner of a $10,000 farm but leave untaxed the recipient of a $100,000 professional income; (c) There is a great difference between the legal and economic concept of property. Economically a man's wealth measured in terms of capital is his surplus over debts. Legally, property is independent of the debts. I may own a $10,000 farm even though I have borrowed $8,000 on the farm. The property tax frequently fails to make allowance for debts; (d) The concept of property fails to distinguish between consumption and production property. The property tax makes no distinction between the lawyer's library which contributes to his income and a bibliophile's library which may be a source of expense. 4. Product. The difficulties with the concept of property as a test of faculty led to the substitution of yield or produce as the proper test. Almost everywhere at a certain time the general property tax on the individual was, therefore, replaced by a series of taxes on the things themselves, measured by their product. Instead of a general property tax we now find a land tax, a capital tax, a business tax, a wage tax, etc. Produce is in some respects a more satisfactory test of faculty than property: it gets closer to the realities. But in the course of time a weakness disclosed itself in that not enough attention could be paid to the individual conditions of the recipient of the produce. 5. Income. The modern world has, therefore, come in large measure to an acceptance of the fifth test of faculty, which is that of income rather than of property or of produce. The tendency is accordingly strong for the replacement of the older taxes by modern taxes on individual income and business profits.

Graduated Taxation.—A further refinement, however, of the idea of faculty is seen in the growth of graduated or progressive taxation. Proportional taxation is giving way to graduated or progressive taxation because of the realization of the fact that graduation, although a technical breach of uniformity, really involves a higher uniformity. Progressive taxation is now almost everywhere recognized even in American jurisprudence, as involving no inequality of taxation. A graduated tax is a tax the rate of which increases with every unit of the base. The entering wedge of the theory of progress in taxation is found in the minimum-of-subsistence doctrine, the doctrine, namely, that a certain amount of income should be exempt from taxation because that minimum is indispensable to existence. This wedge was soon pushed further in so that emphasis was placed upon the element of sacrifice. The sacrifice involved in taking by taxation $100 from a man with a $1,000 income was recognized to be far greater than the sacrifice involved in taking $10,000 from the man with a $100,000 income. In one case the tax trenches upon the necessities and in the other it affects only superfluities. After some time, however, the conception of sacrifice was re-enforced by that of privilege. The difficulty of making the first $1,000 of a man's fortune is far greater than that of making subsequent accretions. All modern democracies are accordingly fast developing graduated or progressive taxes.

Differentiated Taxation.— The principle of faculty in taxation results not only in graduated taxation but in what is called differentiated taxation. Graduated taxation implies a change in the rate according to the amount of the income of property; differentiated taxation implies a change in the rate according to the kind of income of the property. The chief example of differentiated taxation is the distinction between what Great Britain calls earned and unearned incomes, i.e., taxation from property at a higher rate than income from labor. Other countries, however, like Italy, pursue the idea somewhat further and distinguish between property incomes, mixed incomes and labor incomes,— mixed incomes being incomes from business where both capital and enterprise are needed. The Federal income tax of the United States embodies the principle of graduated taxation, but has not yet accepted that of differentiated taxation. Where the distinction is made in the property tax rather than in the income tax, we are in the habit of calling it classification of taxation rather than differentiation of taxation. The movement for a classified property tax in lieu of the general property tax is making great headway in the United States. Classification for purposes of taxation has been upheld by the United States Supreme Court as involving no derogation from the constitutional principle of uniformity or equality of taxation.

Principle of Universality.— The other outcome of the doctrine of faculty is universality of taxation. Equality of taxation means among other things that all people should bear their burdens; that everyone should be taxed, and that no one, in contradistinction to his neighbor, should be taxed more than once. The modern world permits exemptions from taxation, but modern exemptions are different from those of former times. The mediæval exemptions were class exemptions and were, therefore, reprehensible. Modern exemptions rest upon presumed lack of ability to pay or upon considerations of public policy. They are permitted, not primarily for the benefit of the individual, but for the benefit of the community. While, with the exception of these justifiable exemptions, everyone should be taxed, it is equally important to avoid double taxation. Double taxation, or duplicate taxation, is of two kinds. It may be imposed by the same jurisdiction or by competing jurisdictions. An example of double taxation by the same jurisdiction is the simultaneous taxation of property and income. Ordinarily, to tax property is virtually to tax the income of the property. To tax the income again will then be double taxation. Where the purpose is to distinguish between earned or unearned incomes or to secure differentiation of taxation, where, in other words, the design is to tax property incomes more than other incomes, this form of double taxation is legitimate. Another example of double taxation is to tax the corporation and also the shareholder or to tax both the property and the mortgage on the property, because under the ordinary conditions of American life a tax on the lender will be shifted to the borrower so that the borrower will pay the tax not only on his own property but on that of the lender. Double taxation by competing jurisdictions is found when the same individual or piece of property is simultaneously taxed by different jurisdictions. An Englishman receiving his income from an American business may be taxed in the United States because the income is earned there; and taxed in Great Britain because he resides there. An American who dies in one State owning railway shares deposited with a trust company in another State, the chief office of the railway being in a third State and the railway line itself running through a fourth State, may conceivably be subject to taxation on the same property in all four States. The avoidance of such double or multiple taxation is possible either, on the one hand, by international agreement or the exercise of interstate comity or, on the other hand, as in some federal governments, by a federal law or ruling which apportions the tax among several states according to equitable principles.

Classification of Taxes.— There are many different ways in which taxes can be classified, according to the criterion employed. If emphasis is put upon property in which taxes are paid, we have taxes in kind and taxes in money. If the criterion is frequency of payment, they may be classified in terms of ordinary and extraordinary taxes. If the criterion is the rate of taxation, we may distinguish between apportioned and percentage taxes. A percentage tax is a tax like the income tax where the rate or percentage is known in advance; an apportioned tax is a tax like the real estate tax in the United States where the rate is arrived at as the result of an apportionment. According to the mode of levy, we may distinguish between taxes on persons and taxes on things. According to the method of measurement we may distinguish between assessed and expenditure taxes or between taxes on acquisition, on possession or on consumption. According to the methods and results of payment we may distinguish between direct and indirect taxes. This distinction is not very exact. It originated in the idea that where the taxpayer and the taxbearer were the same individual, the tax was a direct tax and, if they were different individuals, it was an indirect tax. The difficulty with this, however, is that the individual who would ordinarily transfer a commodity to someone else might consume it himself. The suggestion was, therefore, made to relegate the distinction to the intention of the legislator. Here again, however, we are met with the fact that the legislator frequently has no intention in the matter or that his intention is unknown. Some European writers, therefore, have contended that the criterion should be found in the permanence of the tax. If the tax is a recurring tax or if the phenomenon on which the tax is imposed is recurring, it is indirect, otherwise it is direct. In general, however, it may be said that by direct taxes are meant taxes on pollo, property or income, and by indirect taxes are meant taxes on consumption and on transactions.

The American Tax System.— The American tax system is composed of two elements — the State and local system and the Federal system. The State and local system has gone through several stages. At the end of the 18th century the slight revenue that was needed by the States and localities was derived chiefly from fees, together with poll taxes, taxes on land and taxes on a few articles of personal property. The land taxes were levied first according to quantity, then on gross produce or location and finally according to selling value. The separate property taxes gradually developed into a general property tax, which became the chief source of State and local revenue — the State tax being added to the local tax before the annual rate of taxation was determined. With the progress of society and especially with the growth of intangible personalty, personal property slowly slipped out of the assessment lists, so that the general property tax again became in fact, if not in law, a real property tax in great measure. This led, in the third quarter of the century, to an attempt to tax personal property through special taxes on certain corporations. Toward the close of the century the corporation taxes were supplemented by inheritance taxes. In several States liquor license taxes were added. Only in the Southern States do we also find a system of business or occupation or so-called privilege tax, as a survival of the Slavery system, where the plantation owners attempted to roll off the taxes on urban occupation.

The addition of corporation and inheritance taxes did not entirely solve the problem of the personal property tax. A two-fold movement accordingly developed in the 20th century. On the one hand we find the tendency toward the classified property tax, with lower rates for certain classes of personalty like money, securities, mortgages, etc. On the other hand came the movement for the replacement of the personal property tax by the income tax. Wisconsin took the lead in 1911, Massachusetts followed in part in 1915 and New York imposed a corporate income tax in 1916 and a personal income tax in 1919. Several other States have followed their example. The trend is now strongly toward a system whereby real estate will be taxed for local purposes and the State revenues be derived from an income tax, an inheritance tax and a corporation tax, part of the proceeds of which will be distributed to the local divisions.

The Federal tax system has also gone through several stages. At the beginning the Federal revenues were derived from import duties as well as from a variety of internal excises — including for a short time also a direct tax on land and on slaves. The advent to power of the Anti-Federalists in 1802 caused an abandonment of the so-called internal revenue taxes. From that year until the Civil War the sole reliance of the government was on import duties, except during the period of the war with England when the internal revenue taxes were restored. Shortly after the outbreak of the Civil War a comprehensive system of internal revenue taxes was initiated. These were abandoned one by one after the close of the war until only the taxes on tobacco and liquor remained. This system of import duties together with a few internal excises existed, with a slight interruption during the Spanish War, until 1909. In that year began the fourth period — the supplementing of the tariff by direct as well as by indirect internal taxes. First came the corporation tax in 1909, then the income tax in 1913. With the advent of the World War, finally, there came not only the reintroduction of many indirect internal taxes but also the inheritance tax and the excess profits tax as well as taxes on expenditure. Of these the two former are likely to remain permanently.

Thus while the land tax will continue to be levied primarily by the States, while import duties can be imposed only by the Federal government, and while internal taxes on commodities will probably be reserved more or less exclusively by the Federal government, the income tax, the inheritance tax, the business or excess profits tax and the corporation tax will probably be imposed by both Federal and State governments. The great problem of the future will thus be the fiscal relation of State and Nation.

EDWIN R. A. SELIGMAN,
McVickar Professor of Political Economy and Finance, Columbia University.

TAXIDERMY is the art of stuffing and mounting the skins of animals, or their heads, so as to appear natural and lifelike. It is no longer a question of filling out a skin, but rather of making a statue of a creature long since dead, which will exactly fit the skin of that particular creature, stand erect and pose as the counterpart of life. "Taxidermy, the handmaid of zoology," said Dr. J. A. Allen, "has already become one of the fine arts, requiring the skill and other qualities of both the sculptor and the painter, and capable of yielding results comparable with the masterpieces of either." It is, however, one of the newest of the arts, and there is serious need of a well-established school of taxidermy in connection with some one of our great museums. Prior to 1880 only one American museum (the National) maintained a corps of taxidermists, and the majority of the mounted birds and mammals which found their way into other American museums were mounted at Ward's Natural Science Establishment, by men from France and Germany. Methods were crude and results were far below the standards attained a few years later. Much of the work produced prior to 1880 has since been either dismounted and remounted or else destroyed.

In March 1880, at Ward's establishment in Rochester, N. Y., Messrs. Hornaday, Webster, Lucas, Martens, Bailly, Critchley and Fraine organized the National Society of American Taxidermists and seriously began the task of developing taxidermy up to the level of the fine arts. All jealousy and exclusiveness were swept aside and the three competitive exhibitions that were held in Rochester, Boston and New York finally opened the eyes of scientific men and of the general public also to the possibilities of scholarly taxidermy, when properly encouraged and paid for. The upward impetus then gained has already carried American taxidermy beyond the original hopes of the founders of the society and the museums of America are now being filled with mounted vertebrates that in large measure are not only of real educational value but are also agreeable to the eye. No modern American museum is now complete without a well-equipped department of taxidermy, in charge of a chief taxidermist on a salary, which in 1880 would have been considered unattainable.

In a modern, high-class taxidermist, the first requisite is not a knowledge of methods in mounting, but the thorough education of the eye in animal forms and expressions. This must be secured by courses in drawing, modeling, carving and painting. The skeletons and external muscles of animals must be well studied, the latter from life. Besides the making of numberless sketches from life, hundreds of live-animal photographs should be collected and arranged for reference. Casts of heads and special parts of dead animals are of great importance and should be diligently collected. At all times must the natural history of the vertebrates be studied and kept in mind. When this preparatory work has been accomplished the aspirant for taxidermic honors must secure admission to the laboratory of some master-taxidermist and work with him to acquire a knowledge of methods.

A comparison of American with European taxidermy is of but passing interest, chiefly for the reason that without an international exhibition it is impossible to draw parallels of positive value. From three inspections of European zoological museums, made in 1876, 1896 and 1902, it is the opinion of the writer that the best of our museum taxidermy is now decidedly in advance of the best to be found in Europe. The groups of mammals, great and small, that now are so intensely interesting to visitors in the museums of Washington, New York, Pittsburgh, Chicago, Milwaukee and at the University of Kansas, have no counterparts in Europe. The British Museum of Natural History at South Kensington contains a fine series of groups of birds, mounted with natural accessories. In the museum of the Amsterdam "Natura Artis Magistra," there are a number of excellent groups of birds. In the museums of the American cities mentioned above the huge family groups representing the bison, moose, elk, caribou, musk-ox, deer, antelope, eland, zebra and other animals, all provided with carefully-studied natural accessories, constitute enduring monuments to the skill of American taxidermists.

Of all museum officers who have actively promoted the development of American taxidermy, Prof. Spencer F. Baird and Dr. G. Brown Goode stand first. As early as 1880 they advocated the attainment of perfection in results, regardless of time or cost. It was by their consent and co-operation that the National Museum set the pace in the development of large groups of mammals, which really began in 1887 with the group of American bison. In this connection honorable mention is due Prof. Henry A. Ward, founder of Ward's Natural Science Establishment, for the far-reaching influence exerted by him for the improvement of taxidermic methods generally and the co-operation which he extended to the Society of American Taxidermists.

With the improvements noted in museum taxidermy, equal advances have been made in the class of what is known as custom taxidermy. The number of trophy heads of large mammals that are now mounted annually in the United States cannot be less than about 1,800. About two-thirds are heads of deer and the remainder consist of moose, mountain-sheep, caribou, elk, antelope, mountain-goat, buffalo, musk-ox and bear, about in the order named. Twenty-five years ago a finely-mounted head was a rarity, but to-day, outside of the workshops of amateurs, a badly-mounted head is seldom seen. The standards of excellence have risen very greatly. The demands of patrons are more intelligent and good work is better compensated than heretofore.

As the world's mammals, birds and other vertebrates decrease, museums multiply, and the desire to provide fine collections becomes more earnest and insistent. Taxidermy now offers a good field for a limited number of young men of real artistic instincts who can bring to it adequate education and training and unlimited capacity for hard work.

Some important American works on taxidermy should be enumerated: Hornaday, 'Taxidermy and Zoological Collecting' (1892); Davie, 'Methods in the Art of Taxidermy' (1894); Rowley, 'Art of Taxidermy' (1900); Reed, C. K., 'Guide to Taxidermy' (Worcester 1908).

W. T. Hornaday,
Director New York Zoological Park.

TAXING DISTRICT. See District.

TAXONOMY IN PLANTS, derived from the Greek words ταξὶς *taxis*, meaning arrangement, and νομος, *nomos*, law. Called sometimes taxology. It is the study of classification, especially from a biological aspect, and treating of the morphology of plant life. Ray (1703) divided the vegetable kingdom into two general classes: the Flowering and the Flowerless, basing everything on one single characteristic. Endlicher, a little over a century later, formed the plant world into two groups: *Cormophyta* and *Thallophyta*, but the division was very imperfect and overlapping. Later we find two groupings by Linnæus under the titles: *Phanerogamia* and *Cryptogamia*, the former having flowers with stamens and pistils, the latter flowerless, seedless and propagated by spores. But the designation *Cryptogamia*, still retained by a few, their generative method being no longer *cryptic* (occult) or hidden from our present advanced knowledge. *Thallophyta*, still remaining in general use, no longer describes the class formerly considered by the expression. Thus with ever-increasing knowledge of the life-workings of the plant realm bringing new facts we have had to change repeatedly the system in taxonomy to bring the additional facts into close relation. And so the system of Ray gave way to the Endlicher, the latter to the greatly improved system of Linnæus (1735) with its 24 classes divided according to the number and disposition of the stamens, with variant orders according to the number of styles or stigmas, etc. This method of systematization, proving its deficiencies ever more with a deeper investigation of plant nature, had to give way (1813) to the Candolle system, soon to be displaced by the Sachs method of classification with its seven divisions, *Protophyta, Zygophyta, Oophyta, Carpophyta, Bryophyta, Pteridophyta, Phanerogamia.* The Sachs system is much in use to this day, but the most recent classification of botanists, based on the great advances brought about by microscopic and other researches into the plant structure, which keep disclosing weaknesses of the former system, are the following four main classifying divisions: (1) *Thallophyta;* (2) *Bryophyta;* (3) *Pteridophyta;* (4) *Spermaphyta.* The first three belong to the *Cryptograms*, the latter to the *Phanerogams.* It is an improvement generally considered better suited to the enlarged range of the botanist's vision; but already criticism is creeping in and taxonomy in plants may be subjected soon authoritatively to a further revision.

(1) *Thallophyta.* This division includes all of the four primary classes, the uni-cellular organic growth, having root, stem and leaf undefined. Under this head come the algæ, fungi, bacteria and lichens. (See Botany). (2) *Bryophyta.* These include the mosses and liverworts (*hepatica*), with distinct sexual organs in some, but in this division (as above stated) is the liverwort and other plants of the thallus type. (See Bryophyllum). (3) *Pteridophyta.* These are often termed *vascular cryptogams* and include, chiefly, the ferns with their propagation by spores. Their stem, leaf and root are clearly defined. (See Pteridophyta). (4) *Spermophyta* or *Phanerogams.* These are lately being divided into *angiosperms* and *gymnosperms* and the *angiosperms* are subdivided into *dicotyledons* and *monocotyledons.* The *Spermophyta* are the highest division of plants including those having true flowers and seeds. They are for the most part land plants, while many of the former divisions are aquatic. Their female cell (*oospore*) is fertilized in propagation and, protected by the *ovule*, becomes a seed, the seed formation being the characteristic of this group (termed also seed-

plants). *Gymnosperms* of this division have unisexual flowers, naked ovules with direct pollen fertilization, etc. (See GYMNOSPERM). *Angiosperms* have a closed seed vessel (*carpel*) and other distinguishing characteristics. See PLANTS, CLASSIFICATION OF.

TAY, tā, (1) a river in Scotland, in the county of Perth, formed by two head-streams, the one issuing from the northeast end of Loch Tay and the other from Loch Lyon, a small lake on the borders of Argyllshire. The two streams unite about two miles northeast of Loch Tay, whence the river flows past Aberfeldy, Dunkeld and Perth, at which last town it widens out into an estuary from one to three miles in breadth, becoming the northern boundary of the county of Fife. The whole length is 120 miles and the area of basin 2,250 square miles. Vessels of 500 tons ascend to Newburgh and those drawing nine feet to Perth. Its principal tributaries are the Tummel and Isla on the left and the Bran, Almond and Earn on the right. During the upper part of its course the Tay flows with a rapid current through a wild and highly romantic country and subsequently, after entering Strathmore, through the richest and finest valley in Scotland. In the summer of 1878 a railway bridge spanning the estuary of the Tay at Dundee was opened for traffic, but on 28 Dec. 1879 13 spans, crossing the navigable part of the river, were blown down in a violent storm, a passenger train, which then happened to be crossing, being precipitated at the same time into the river. A second bridge, over two miles long, with 85 spans and carrying two lines of rail, was opened in 1887. (2) A loch in the county of Perth, a picturesque sheet of water 15 miles long and about one mile broad; receiving at its southwest end (near Killin) the Lochay and the Dochart and discharging at its northeast end at Kenmore by the Tay. It is 100 to 600 feet deep and is well supplied with fish. On its northwest shore rises Ben Lawers.

TAYABAS, tä-yä'bäs, Philippines, (1) Pueblo province of Tayabas; on Tayabas River, five miles inland, 65 miles southeast of Manila. Under Spanish jurisdiction it was the capital of the province, and is the largest town. It is an important road centre and carries on a large trade. Pop. 15,000. (2) Province, forming the western part of southern Luzon; bounded on the north by the Pacific Ocean, and Lamón Bay and Ambos Camarines, on the east by Ambos Camarines and the Visayan Sea, on the south by the Mindoro Sea, and on the west by Batangas and Laguna; area, about 5,000 square miles. The outline is very irregular; its extreme length from Point Piapi in the northwest to Point Pagsanján in the southeast is 102 miles; and the distance from the northeastern boundary to Sandoval Point on the southwest is 47 miles. Its coasts are indented by three of the largest bays of the Philippines, Lamón on the north, Ragay on the east and Tayabas on the south. The province is generally mountainous, the main central chain extends from northwest to southeast, and this range sends out spurs on each side. There are numerous small rivers and streams. The soil of the valleys is fertile; on the lower levels rice, sugar and coffee are raised and grain on the higher levels; a special product is a seed called lumbang from which an oil is made; the cocoanut is grown in large quantities. The forests contain a variety of woods for building purposes, besides gum and resin trees; and large quantities of timber and forest products are exported. The mechanical industries of this province are of considerable importance; the manufactures include hats, cigar cases and boxes and native fabrics; there are also mills for extracting cocoanut oil and a number of boat-building yards for the construction of native boats. Stock-raising is also of some importance. The province has good communication by water with all parts of the Philippines, and is traversed by the main highway from Sorsogón to Manila; there are also several other roads and trails. The inhabitants of the western part of the province are Tagalogs, those of the eastern part are Bícols. Civil government was established in March 1901, in accordance with the law of the Philippine Commission. Pop. about 150,000.

TAYGETUS, tā-ĭj'ĕ-tŭs, Greece, a mountain range running down the central peninsula of southern Morea. It is a steep and unbroken ridge rising in Hagios Elias to a height of 7,904 feet. It separated ancient Sparta from Messenia and was known in the Middle Ages as Pentedaktylon.

TAYLOR, tā'lôr, (James) Bayard, American writer: b. Kennett Square, Pa., 11 Jan. 1825; d. Berlin, Germany, 19 Dec. 1878. He had a secondary education at West Chester and Unionville, and in 1842 was apprenticed to a printer in the former town, but did not serve out his apprenticeship. In 1844 he set sail for Liverpool, and during the next two years he traveled, chiefly on foot, in Great Britain, Belgium, Germany, Austria, Italy and France. He described his journeys for several American newspapers, his letters being collected and published on his return under the title 'Views Afoot or Europe Seen with Knapsack and Staff' (1846). In 1847 he received an appointment on the staff of the New York *Tribune*, and two years later went to California as special correspondent of that newspaper at the gold-fields, his letters being republished in 1850 as 'Eldorado, or Adventures in the Path of Empire.' In 1851 he was again in Europe, and before returning to the United States in 1854 he visited Egypt, Asia Minor, India, Hongkong, China and Japan. Among the literary results of this tour were 'A Journey to Central Africa' (1854); 'The Land of the Saracen' (1854), and 'A Visit to India, China and Japan' (1855). On these traveling experiences he lectured with much success. He had by this time gained some reputation as a poet by 'Ximena and Other Poems' (1844); 'Rhymes of Travel, Ballads, and Other Poems' (1848); 'A Book of Romances, Lyrics and Songs' (1851), and 'Poems of the Orient' (1855); and in 1855 he published a collective edition of these under the title 'Poems of Home and Travel.' 'Northern Travel' (1857) contains an account of a visit to Sweden, Denmark and Lapland. In 1862–63 he was secretary of legation and for a time chargé-d'affaires at Saint Petersburg, and in 1870 he lectured at Cornell University on German literature. He became United States Ambassador at Berlin in May

1878. In addition to works already mentioned the following may be enumerated: 'At Home and Abroad' (1859–62); 'Byways and Europe' (1869); a translation of Goethe's 'Faust' in the original metres (1870); the novels; 'Hannah Thurston' (1863); 'John Godfrey's Fortunes' (1864); 'The Story of Kennett' (1886); 'Joseph and His Friend' (1870); 'The Poet's Journal' (1863), and other volumes of verse. Two collections of miscellaneous writings appeared posthumously, 'Studies in German Literature' (1879), and 'Essays and Notes' (1880). It is by his translation of 'Faust,' one of the finest attempts of the kind in any literature, that Taylor is generally known; yet as an original poet he stands well up in the second rank of Americans. His 'Poems of the Orient' and his Pennsylvania ballads comprise his best work. His verse is finished and sonorous, but at times over-rhetorical. Consult the 'Life and Letters' by his wife and H. E. Scudder (1884).

TAYLOR, Bert Leston, American author: b. Goshen, Mass., 13 Nov. 1866. His column headed 'A Line o'Type or Two' in the *Chicago Daily Tribune,* conducted humorously, attracts much popularity. He has written 'The Well in the Wood' (1904); 'The Charlatans' (1906); 'A Line-o'-Verse or Two' (1911); 'The Pipesmoke Carry' (1912); 'Motley Measures' (1913); also two booklets, 'The Bilioustine' and 'The Book Booster' (1901).

TAYLOR, Brook, English mathematician: b. Edmonton, 18 Aug. 1685; d. 29 Dec. 1731. He was educated at Saint John's College, Cambridge; in 1712 chosen a Fellow of the Royal Society, and in January 1714 appointed its secretary. The most important of Taylor's works, published in 1715, is entitled 'Methodus Incrementorum Directa et Inversa.' It contains, among other theorems of less consequence, a celebrated one, which is hence called 'Taylor's Theorem,' the importance of which was first recognized by Lagrange, who proposed to make it the foundation of the differential calculus. His other works include two treatises on linear perspective, besides contributions to the 'Philosophical Transactions.'

TAYLOR, Charles Fayette, American surgeon: b. Williston, Vt., 25 April 1827; d. Los Angeles, Cal., 25 Jan. 1899. He was educated in the public schools and was graduated (1856) at the University of Vermont. He next settled in New York studying the new 'Swedish movement' system which he learned from Dr. Roth in London. His specialization became treatment of the deformed and crippled in which he achieved a great reputation and founded the New York Orthopedic Dispensary. He invented the Taylor splint for spinal diseases, also the long extension hip splint. Among his works are 'The Theory and Practice of the Movement Cure,' 'Mechanical Treatment of Hip Joint Disease,' etc.

TAYLOR, Charles Henry, American journalist: b. Boston, 14 July 1846. He made his start in life as a printer and reporter and was private secretary to the governor of Massachusetts for three years. He served during the Civil War with the 38th Massachusetts Regiment and was lieutenant-colonel on the staff of Governor Claflin. He was member of the legislature in 1872, and in 1873 became manager and editor of the Boston *Daily Globe.* He built up the property and made it one of the most influential journals of New England.

TAYLOR, Charles Jay, American artist: b. New York, 11 Aug. 1855. Attended College City of New York, afterward graduated at Law School, Columbia University (1874), LL.B., subsequently studied art, National Academy Design, Art Students League and in London and Paris. Has illustrated many books, contributed drawings to prominent periodicals and exhibited at the National Academy of Design, Pennsylvania Academy Fine Arts, World's Fair, Chicago; Exposition Universelle, Paris; Pan-American, Buffalo, where awarded medal; Carnegie Institute, Pittsburgh, and at Panama-Pacific Exposition, San Francisco. He served on advisory committee on Fine Arts for the Panama-Pacific, representing Pennsylvania; also was one of the International Jury of Awards, Section of Fine Arts, for the same exposition. From 1911, professor of fine arts, Carnegie Institute of Technology, Pittsburgh.

TAYLOR, David Watson, American naval constructor: b. Louisa County, Va., 4 March, 1864. He was graduated at the United States Naval Academy in 1885, with the highest record ever made there. At Greenwich, England, in 1885, he received the highest honors of the Royal College, repeating the record in 1888. He was made captain, United States navy, in 1901 and, by 1917, was promoted to rear-admiral. In 1914 he became chief constructor of the United States navy and chief of the Bureau of Construction and Repair.

TAYLOR, Edward Thompson, American Methodist missionary: b. Richmond, Va., December 1793; d. Boston, Mass., 6 April 1871. At the age of seven he ran away to sea, and followed the sea until the age of 17. During the War of 1812 he was captured on a privateer of war, the *Black Hawk,* and was taken to England, being confined in Dartmoor prison. Being converted, he acted as chaplain in the prison and after his release, for a time was a tin and iron peddler, then a buyer of rags and a farmer. In 1819 he became a Methodist minister, and in 1828 was appointed missionary to the Seamen's Bethel in Boston, where he served for many years, attaining a wide reputation. Here he was called "Father Taylor" and was greatly loved by the sailors. In his sermons, which he delivered in the common language of his day, he made free use of nautical terms, and possessed a genial wit. In 1832 he visited Europe, and delivered many addresses. In 1842 he visited Palestine, and was chosen chaplain of the United States frigate *Macedonia,* when it sailed with relief in 1846, for famine stricken Ireland. Consult 'Father Taylor the Sailor Preacher' (1872).

TAYLOR, Sir Frederick Williams, Canadian financier: b. Moncton, New Brunswick, 1863. He entered the Bank of Montreal in 1878, becoming successively assistant inspector at head office (1897), joint manager at Chicago (1903), manager of London branch (1906), and general manager at Montreal (1913). He carried through huge banking loans to Canada during his London services.

He is a director of the Allen Line Steamship Company, Ltd., vice-president of the Canadian Bankers' Association, etc. For valuable services he was knighted in 1913.

TAYLOR, Frederick Winslow, American efficiency engineer: b. Germantown, Phila., 20 March 1856; d. 21 March 1915. Educated at Phillips Exeter Academy, but left on account of eyesight trouble, and was graduated (1883) at Stevens Institute of Technology. In 1878 he entered service at the Midvale Steel Company, Philadelphia, becoming, successively gang-boss, assistant foreman, foreman of machine shop, master mechanic, chief draughtsman and (1889) chief engineer. In the latter year he commenced his notable career of efficiency expert reorganizing manufacturing plants (shop accounting and sales departments) of which the Bethlehem Steel Company, Cramps' Shipbuilding Company, etc., were examples. He was the inventor of the Taylor-White process of treating modern high-speed tools, receiving a personal gold medal at Paris Exposition, 1900. Patents granted to him number over 100. He was president of the American Society of Mechanical Engineers, 1905–06. He wrote 'Concrete, Plain and Reinforced' (1905), in collaboration with S. E. Thompson; 'Art of Cutting Metals' (1905); 'Principles of Scientific Management' (1911); 'Shop Management' (1911), and contributed numerous articles on his special topic to *Proceedings of American Society of Mechanical Engineers.*

TAYLOR, George, American statesman, one of the signers of the Declaration of Independence: b. Ireland, 1716; d. Easton, Pa., 23 Feb. 1781. Disliking the medical profession, for which he was destined, he came to America as a «redemptioner,» and on arriving bound himself for a term of years to an iron manufacturer at Durham, Pa. His education and intelligence being discovered, his employer made him his clerk, and after his death Taylor married his widow and became master of the establishment. He was a member of the provincial assembly in 1764–70, when he was a judge of the County Court and colonel of militia. In October 1775 he was again elected to the provincial assembly and was active in the promotion of revolutionary measures. The action of some of the members of the Continental Congress the next year in refusing assent to the Declaration of Independence, led to the election of new members, 20 July 1776, of whom Taylor was one. He signed the Declaration on 2 August; subsequently negotiated a treaty with several of the Indian tribes on behalf of the United States, and in March 1777 retired from Congress to private life.

TAYLOR, Graham, American sociologist: b. Schenectady, N. Y., 2 May 1851. He was graduated (1870) at Rutgers College and at the Reformed Theological Seminary, New Brunswick, N. J., in 1873. He was ordained for the Dutch Reformed ministry in 1873, becoming pastor at Hopewell, N. Y. From 1880–92 he filled the pulpit of the Fourth Congregational Church, Hartford, Conn. He acted as professor of practical theology at Hartford Theological Seminary from 1888–92, and, since 1892, has served as professor of social economics at the Chicago Theological Seminary. He was founder of the Chicago Commons Social Settlement and has been resident warden since 1894. He is president of the Chicago School of Civics and Philanthropy and associate editor of *The Survey.* He has written 'Religion in Social Action' (1913), besides numerous editorial contributions to the *Chicago Daily News,* etc.

TAYLOR, Hannis, American diplomat: b. Newberne, N. C., 12 Sept. 1851. He was educated at the University of North Carolina and was Minister to Spain, 1893–97. From 1892 he was professor of constitutional and international law at Columbia; special counsel for the United States government before the Spanish Treaty Claims Commission in 1902, and counsel for the United States before the Alaskan Boundary Commission in 1903. He published 'The Origin and Growth of the English Constitution'; 'International Public Law' (1902); 'Jurisdiction and Procedure of the Supreme Court of the United States: The Science of Jurisprudence' (1908); 'The Origin and Growth of the American Constitution' (1916); 'Cicero — A Sketch of His Life and Works' (1916); 'Due Process of Law' (1916).

TAYLOR, Sir **Henry,** English poet and essayist: b. Bishop-Middleham, Durham, 18 Oct. 1800; d. Bournemouth, 27 March 1886. At 14 he entered the navy as midshipman, but returned after a few months. In 1817–20 he held a small appointment in London. Returning to his father's country home, he gave himself to serious study, and in 1822 wrote an article on Moore that was published in the *Quarterly Review.* He went to London, and in 1824 received a clerkship in the Colonial Office, with which he retained his connection for 48 years. He mingled with the intellectual life of the city, contributed to the *Quarterly Review* and wrote his first tragedy, 'Isaac Comnenus,' in 1827. He was favorably reviewed by Southey, but failed to attract popular notice. From 1828 to 1834 he was engaged upon another poetic drama, 'Philip van Artevelde,' his principal achievement in literature. It was formed upon Elizabethan models, and its style is marked by dignity and refinement. His other works include 'The Statesman' (1836), containing prose commentaries on official life and the conduct of business; 'Edwin the Fair' (1842), a historical drama; 'The Eve of the Conquest and other Poems' (1847); 'Notes from Life' (1847); 'The Virgin Widow,' a comedy afterward called 'A Sicilian Summer' (1850), and 'Saint Clement's Eve' (1862), a romantic drama. His autobiography was published in 1885. Consult his 'Works' (1878), and 'Correspondence,' edited by Dowden (1888).

TAYLOR, Henry Ling, American surgeon: b. New York, 17 March 1857. He was graduated (1877) at Sheffield Scientific School and obtained his diploma at the College of Physicians and Surgeons (Columbia) in 1881. Like his father, Charles Fayette Taylor (q.v.), he specializes on orthopedic branches and was professor of orthopedic surgery (1902–17) at Post-Graduate Medical School and Hospital, New York. He is consulting orthopedic surgeon at Mountainside Hospital, Montclair, N. J., and associate surgeon at the Hospital for Ruptured and Crippled. He was president American Orthopedic Association in 1908. He has written 'Orthopedic Surgery for Practitioners' (1900).

TAYLOR, Henry Osborn, American author: b. New York, 5 Dec. 1856. He was graduated from Harvard in 1878, received the degree of LL.B. at Columbia in 1881 and that of Litt.D. at Harvard in 1912. He has published 'Treatise on the Law of Private Corporations' (5th ed., 1902); 'Ancient Ideals: A Study of Intellectual and Spiritual Growth from Early Times to the Establishment of Christianity' (2 vols., 2d ed., 1913); 'The Classical Heritage of the Middle Ages' (3d ed., 1912); 'The Mediæval Mind' (2 vols., 2d ed., 1914); 'Deliverance — The Freeing of the Spirit in the Ancient World' (1915). Mr. Taylor is a member of the National Institute of Arts and Letters.

TAYLOR, Isaac (known as TAYLOR OF ONGAR), English Congregational clergyman and author: b. London, 1759; d. Ongar, Essex, 11 Dec. 1829. He was originally an engraver, but entered the ministry and was pastor at Colchester, 1796–1810 and at Ongar, Essex, 1811–29. He published many works, chiefly books for the young, among which are 'Advice to the Teens'; 'Beginnings of British Biography'; 'Beginnings of European Biography'; 'Biography of a Brown Loaf'; 'Book of Martyrs for the Young'; 'Bunyan Explained to a Child'; 'Child's Life of Christ'; 'Mirabilia; or, The Wonders of Nature and Art'; 'Scenes in America, in Asia, in Europe, in Foreign Lands.'

TAYLOR, Isaac, English writer, son of the preceding: b. Levenham, Suffolk, 17 Aug. 1787; d. Stanford Rivers, 28 June 1865. His life was almost entirely passed in retirement at the place where he died, and is only remarkable for the literary work which he produced. His first book is entitled 'Elements of Thought' (1823). It was succeeded by numerous others, most of which are of a partly philosophical, partly religious cast. The principal are 'The Natural History of Enthusiasm' (1829); 'The Natural History of Fanaticism' (1833); 'Spiritual Despotism' (1835); 'Physical Theory of Another Life' (1836); 'Ancient Christianity' (1839–43); 'Loyola and Jesuitism' (1849); 'Wesley and Methodism' (1851); 'Restoration of Belief' (1855); 'World of Mind' (1857); 'Ultimate Civilization' (1860), and 'Spirit of Hebrew Poetry' (1861). The first of these works is that by which his name is chiefly known, although originally published anonymously. The work on ancient Christianity was composed with the view of correcting the errors which the author believed many were likely to fall into in consequence of the appeals of the writers of the Oxford tracts to the authority and practice of the early Church.

TAYLOR, Isaac, English scholar, son of the author of 'The Natural History of Enthusiasm': b. Stanford Rivers, Essex, 2 May 1829; d. Settrington, Yorkshire, 18 Oct. 1901. He was graduated from Trinity College, Cambridge, and in the following year issued a translation of Bekker's 'Charicles.' He was ordained in 1857, and in 1860 published 'The Liturgy and the Dissenters.' In the latter year he became a curate in London, and in 1864 published the first of the works by which he is chiefly remembered, 'Words and Places, or Etymological Illustrations of History, Ethnology and Geography.' In 1865–69 he held a curacy in a Bethnal Green parish, and his arduous labors there are described in 'The Burden of the Poor.' He became vicar of Holy Trinity, Twickenham, in 1869, and in 1875 was presented to the rectory of Settrington, near Malton, in Yorkshire, which he retained until his death. In 1879 he first propounded the theory of the Greek origin of runes in a work entitled 'Greeks and Goths: A Study on the Runes'; and he published in German a treatise 'Ueber den ursprung des glagolitischen Alphabets,' but his *magnum opus*, 'The Alphabet: an Account of the Origin and Development of Letters,' did not appear until 1883. In 1885 he was appointed canon of York. His other works include 'The Family Pen: Memorials, Biographical and Literary, of the Taylors of Ongar' (1867); 'Etruscan Researches' (1874); 'Leaves from an Egyptian Note-Book' (1888); 'The Origin of the Aryans' (1889); and 'Names and their Histories: A Handbook of Historical Geography and Topographical Nomenclature' (1896).

TAYLOR, Isaac Ebenezer, American physician: b. Philadelphia, 25 April 1812; d. New York, 30 Oct. 1889. He was graduated from Rutgers College in 1830, and in medicine from the University of Pennsylvania in 1834. He subsequently studied in Europe, settled in New York, and had charge of the department of women's diseases at the City, Eastern, Northern and Demitt dispensaries for seven years each. In 1851 he was elected physician to Bellevue Hospital, where he initiated important reforms, secured the foundation of the hospital college, and became its head, 1861. He was subsequently president of the medical board of the hospital; attending physician and head of the medical board of the Charity Hospital, and obstetrical physician to the Maternity Hospital. He was the first American to introduce uterine auscultation, helped introduce the hypodermic method of treatment by morphia and strychnia, and was the earliest in this country to use the speculum in diseases of women and children. He published a monograph on this subject in 1841.

TAYLOR, James Knox, American architect: b. Knoxville, Ill., 11 Oct. 1857. He took a special course (1877–79) in architecture at the Massachusetts Institute of Technology, then served in New York architects' office three and a half years. From 1882–92 he practised at Saint Paul and at Philadelphia from 1892–1905. In 1895 he was appointed senior draughtsman at the United States architect's office and then, till 1897, principal draughtsman. From 1897–1912 he was supervising architect and since 1912 has been director of architecture at the Massachusetts Institute of Technology, Boston.

TAYLOR, James Munroe, American educator: b. Brooklyn, N. Y., 5 Aug. 1848. He was graduated from the University of Rochester in 1868 and was pastor of a Baptist church in South Norwalk, Conn., 1873–82, and at Providence, R. I., 1882–86. From 1886 to February 1914 he was professor of ethics and president of Vassar College. He has published 'Psychology' (1893); 'New World and Old Gospel' (1900); 'Practical or Ideal' (1901); 'Before

Vassar Opened' (1914); 'Vassar: A History' (1915).

TAYLOR, Jane, English poet and author, daughter of Isaac Taylor, 1759–1829 (q.v.): b. London, 23 Sept. 1783; d. Ongar, Essex, 12 April 1823. She was educated under the supervision of her father and early displayed literary ability. Her work, which was very successful, bears some similarity in thought to that of Cowper. Her first work was 'The Beggar Boy' (1804) and in conjunction with her sister Ann (Mrs. Gilbert, of Nottingham, 1783–1824), she published 'Original Poems' and 'Hymns for Infant Minds.' Her other work includes 'Display,' a didactic tale (1815); 'Essays in Rhymes' (1816), and (published posthumously) 'Contributions of Q. Q. to a Periodical' (1826); 'Correspondence' (1825), etc. Consult Taylor, Isaac, 'Memorials of the Taylor Family' (1867).

TAYLOR, Jeremy, English prelate and author: b. Cambridge, 1613; d. Lisburn, County Antrim, Ireland, 13 Aug. 1667. After graduation in 1630 from Caius College, Cambridge, he was ordained in 1634, attracted some attention by his divinity lectures at Saint Paul's and was sent by Laud to Oxford, where he was admitted perpetual Fellow in 1636. He was presented to the rectory of Uppingham, Rutland, in 1638, to that of Overstone, Northamptonshire, in 1643. By this time he had made much of a reputation by his casuistical discourses. In the civil war he was committed to the Royalist party. As chaplain in ordinary to the king, he accompanied the army and was taken prisoner by the Parlimentarians in the battle before Cardigan Castle (1645). Soon released, he remained in Wales, having found, as he later said, that the «great storm» had «dashed the vessel of the church all in pieces.» While chaplain to Richard Vaughan, Earl of Carbery, at Golden Grove, Carmarthenshire, he did some of his best literary work, including 'The Liberty of Prophesying' (1646); 'Holy Living' (1650), and 'Holy Dying' (1651). He was twice imprisoned at Chepstow, occasionally preached to small Episcopalian congregations in London and in 1658 was appointed to a weekly lectureship at Lisburn, County Antrim. In April 1660 he signed the «declaration» of the Loyalists and in August following the Restoration was made bishop of Down and Connor. He found the diocese a troublesome one, owing to difficulties with the Presbyterian leaders, who refused to recognize Episcopal jurisdiction. At his first visitation he declared 36 churches vacant, their incumbents not having been episcopally ordained. Contrary to his purpose, he contributed greatly toward the establishment of Loyalist Presbyterians in northern Ireland as an independent ecclesiastical organization. Of his works, the best known is probably the 'Liberty of Prophesying' — by which he meant expounding — a defense of toleration. He rests this plea for private judgment on the uncertainty and inadequacy of tradition, the fallibility of any arbiter that may be selected on points of controversy, and the difficulty of expounding the Scriptures. Coleridge thought the result of the argument was that «so much can be said for every opinion and sect» that appeal must be made to «some positive jurisdiction on earth.» Perhaps Taylor's was merely a «legal settlement.» At any rate, it is otherwise inconsistent with his procedure in Ireland. But he was at his best not as an accurate theologian or polemic but as a preacher of righteousness. His literary genius is generally thought to be seen to best advantage in his sermons. They do not lack rhetorical faults — redundancy, diffuseness, a burdensome extent of quotation and illustration; but they are always eloquent, with a certain vividness, dignity and solidity for which many critics have been unable to find an equal in English prose. His devotional works, inspiring for their deep piety, are also highly valued for their usefulness. Next to the 'Liberty of Prophesying' they are most famous among Taylor's writings and now the most widely read. There are collected editions by Bishop Heber (1820–22) and by Eden (1847–54). (See HOLY LIVING; HOLY DYING). Consult Coleridge's 'Literary Remains'; Hunt, 'Religious Thought in England' (1870); Tulloch, 'Rational Theology' (1872); Barry, 'Classic Preachers' (1878); Dowden, 'Puritan and Anglican' (1901); 'Life' by Heber (1822), revised by Eden (1854); Gosse, 'Jeremy Taylor' (1904).

TAYLOR, John, English poet: b. Gloucestershire, 24 Aug. 1580; d. London, 25 July 1653. When young he was taken to London and apprenticed to a waterman, hence the title of «water-poet,» by which he is commonly known. He was at the taking of Cadiz, under the Earl of Essex, in 1596, and afterward visited Germany and Scotland. At home he was many years collector for the lieutenant of the Tower of London and his fees of the wines from all the ships which brought them up the Thames. When the civil war broke out he retired to Oxford, where he kept a common victualing house, and wrote pasquinades upon the Roundheads. He afterward kept a public house at Westminster. Certain of his works are published under the title 'All the Works of John Taylor, the Water-Poet, being Sixty and Three in Number, collected into one volume by the author, with sundry new Additions, corrected, revised, and newly imprinted' (1630). His pieces were subsequently increased to more than double that number. They are not destitute of natural humor and of the jingling wit which prevailed so much during the reign of James I. As a mirror of the coarse manners of his times they are invaluable to the historian and antiquary.

TAYLOR, John, Mormon president: b. Milnthorp, Westmoreland County, England, 1 Nov. 1808; d. Salt Lake City, Utah, 25 July 1887. He was born of parents professing the faith of the Church of England, but while a youth became a Methodist local preacher. In 1832 he emigrated to Canada and in 1835 was converted to the Mormon faith during the missionary tour of Porley P. Pratt. He was ordained a high priest by Joseph Smith in 1837 and in 1840 went as a Mormon missionary to various parts of the British Isles. The following year he returned and settled at Nauvoo, Ill., where in 1844, in company with several other Mormon leaders, charges of sedition and disloyalty were brought against him. The Carthage jail where the prisoners were confined was attacked by a mob, two of his companions were killed and he was severely wounded. Returning from a second mission to England in 1846 he went to the new Mormon settlement in Salt Lake City and in 1849 was elected an associate judge of the Mormon State of Deseret. He subsequently translated and published the 'Book of Mormon' in French and German. In 1854 he was elected a member of the legislative council and the next year began a mission in New York, published *The Mormon* and took charge of Mormon followers in the East. From 1877 to 1880 he was president of the Twelve Apostles and in the latter year organized the first presidency of the Church anew and took the chief place himself. In March 1885 he was among those indicted by a Federal grand jury under the Edmunds Law; but remained in concealment until his death.

TAYLOR, John Louis, American jurist: b. London, England, 1 March 1769; d. Raleigh, N. C., 29 Jan. 1829. Arriving in this country in his 12th year he gained an education at William and Mary College, Virginia, and was admitted to the bar after reading law without tuition. He settled at Fayetteville and became member of the legislature (1792–95). Moving to Newbern (1796) he was appointed (1798) judge of the Superior Court, a position he held for 20 years, being chief justice 10 years of the time. In 1818 he was elected as the first chief justice of the Supreme Court of North Carolina. He was appointed (1817), jointly with Judge Henry Potter, to revise the statute laws of the State, which caused publication of the work 'Potter's Revisal' (1821), which work he continued and published (1825), known as 'Taylor's Revisal.' He also wrote 'Treatise on Executors and Administrators' (1825).

TAYLOR, Mary Imlay, American novelist: b. Washington, D. C. She has published 'An Imperial Lover'; 'A Yankee Volunteer' (1898); 'The Cardinal's Musketeer' (1900); 'The Cobbler of Nîmes' (1900); 'Anne Scarlett' (1901); 'Little Mistress Good Hope' (1902); 'The Rebellion of the Princes' (1903); 'On the Red Staircase' (1906); 'The Impersonator' (1906); 'My Lady Clancarty' (1907); 'The Reaping' (1908); 'Caleb French' (1910); 'The Long Way' (1913). She is also the author of the photoplays, 'The Ploughshare'; 'Friend Wilson'; 'Daughter,' etc.

TAYLOR, Nathaniel William, American Congregational clergyman: b. New Milford, Conn., 23 June 1786; d. New Haven, Conn., 10 March 1858. He was graduated at Yale in 1807 and five years later became the pastor of the First Congregational Church at New Haven, in which position he continued until 1822, when he resigned to become professor of theology at Yale. This chair he held during the remainder of his life. He maintained the "New Haven theology," and especially on the doctrine of total depravity, which was regarded as heretical, led him into a controversy with the less liberal branch of the Congregational church in 1828–30. His works were edited and published by Noah Porter (1858–59).

TAYLOR, Philip Meadows, English military officer and author: b. Liverpool, 25 Sept. 1808; d. Mentone, France, 13 May 1876. He entered the Nizam's army in India in 1824 and in 1841 was made administrator of the state of Shorapore, subduing its rebellious ruler. He rendered valuable service in keeping order during the berar mutiny in 1857, for which he was promoted to the rank of colonel. He published 'Confessions of a Thug' (1839); 'Tara' (1863); 'Ralph Darnell' (1865); 'Manual of the History of India' (1870); 'A Noble Queen' (1878), and other works. His autobiography was published in 1877.

TAYLOR, Richard, American soldier, son of Zachary Taylor (q.v.): b. New Orleans, La., 27 Jan. 1826; d. New York, 12 April 1879. He was graduated from Yale in 1845, after which he went to his father's camp on the Rio Grande and was present at Palo Alto and Resaca de la Palma. He sat in the Louisiana senate in 1856–60 and was a member of the Louisiana Secession Convention. He aided in the organization of the Confederate troops, commanded a brigade under "Stonewall" Jackson and fought at Front Royal, Middletown, Winchester, Strasburg, Cross Keys, Port Republic and also in the seven days' battle before Richmond. He was then promoted major-general and assigned to the command of Louisiana, where he succeeded in strengthening the Confederate position, an advantage which was lost by the fall of Vicksburg in 1863. On 8 April 1864 he met and defeated General Banks at Sabine Cross-Roads, but on the following day lost his advantage and was in his turn defeated. He was promoted lieutenant-general in 1864 and placed in command of the Department of Alabama and Mississippi. After the surrender of Lee and Johnston he capitulated to General Canby at Citronelle, 8 May 1865. He published 'Destruction and Reconstruction' (1879).

TAYLOR, Robert William, American physician: b. London, England, 11 Aug. 1842; d. 1908. He was graduated at the College of Physicians and Surgeons, New York (1868) and started practice in that city. He was professor of diseases of the skin at Woman's Medical College, New York, and in the medical department of the University of Vermont; also surgeon in the venereal department of Charity Hospital, Bellevue Hospital Dispensary, New York Dispensary, etc. He wrote 'A Practical Treatise on Sexual Disorders of the Male and Female' (New York, 3d ed., 1905).

TAYLOR, Rowland, English martyr: b. Rothbury, Northumberland; d. Hadleigh, Suffolk, 9 Feb. 1555. He was graduated at Cambridge University and appointed by Cranmer, to whom he was domestic chaplain, rector of Hadleigh and he became archdeacon of Exeter and a canon of Rochester. Under Mary he was imprisoned, as a heretic, for more than a 12-month and on being condemned to the stake suffered at Hadleigh. Consult Cooper, 'Athenæ Cantabrigienses' (1858).

TAYLOR, Thomas, English scholar: b. London, 15 May 1758; d. Walworth, 1 Nov. 1835. He was educated (with the idea of becoming a Dissenting minister) at Saint Paul's School, London, but entered a banking house as clerk, and subsequently served for several years as assistant secretary to the Society for the Encouragement of Arts, Manufactures and Commerce. On the condition of his devoting himself to literary work for the last 40 years of his life he received during that period a pension of $500 a year from his friend, W. Meredith, who also defrayed the expenses of publishing his translation of 'Aristotle' in 10 volumes (1806-12). His edition of 'Plato' in English (1804) was published at the expense of the Duke of Norfolk, who locked up nearly the whole edition in his own house, where it remained until 1848 when it was sold by auction. Taylor's works comprise about 60 volumes and include treatises on arithmetic and geometry and translations of Proclus and Plotinus. Opinions differ as to the exactness of his scholarship, but he well deserved his title of «Platonist» and did good service to British philosophy and literature by introducing to the public as completely as possible the masters of Greek thought in an English garb.

TAYLOR, Sir Thomas Wardlaw, Canadian jurist: b. Auchtermuchty, Fifeshire, Scotland, 25 March 1833. He was educated at Edinburgh University, removed to Canada and in 1858 was admitted to the bar of Upper Canada. He was master in chancery, 1872-83 and puisne judge of Queen's Bench of Manitoba, 1883-87. From 1887 to 1899 he was chief justice of Manitoba and administrator of the government of that province in 1890 and 1893. His specialty is equity jurisprudence and he has published 'Commentaries on Equity Jurisprudence' (1875); 'Chancery Statutes and Orders'; 'Public Statutes Relating to the Presbyterian Church.'

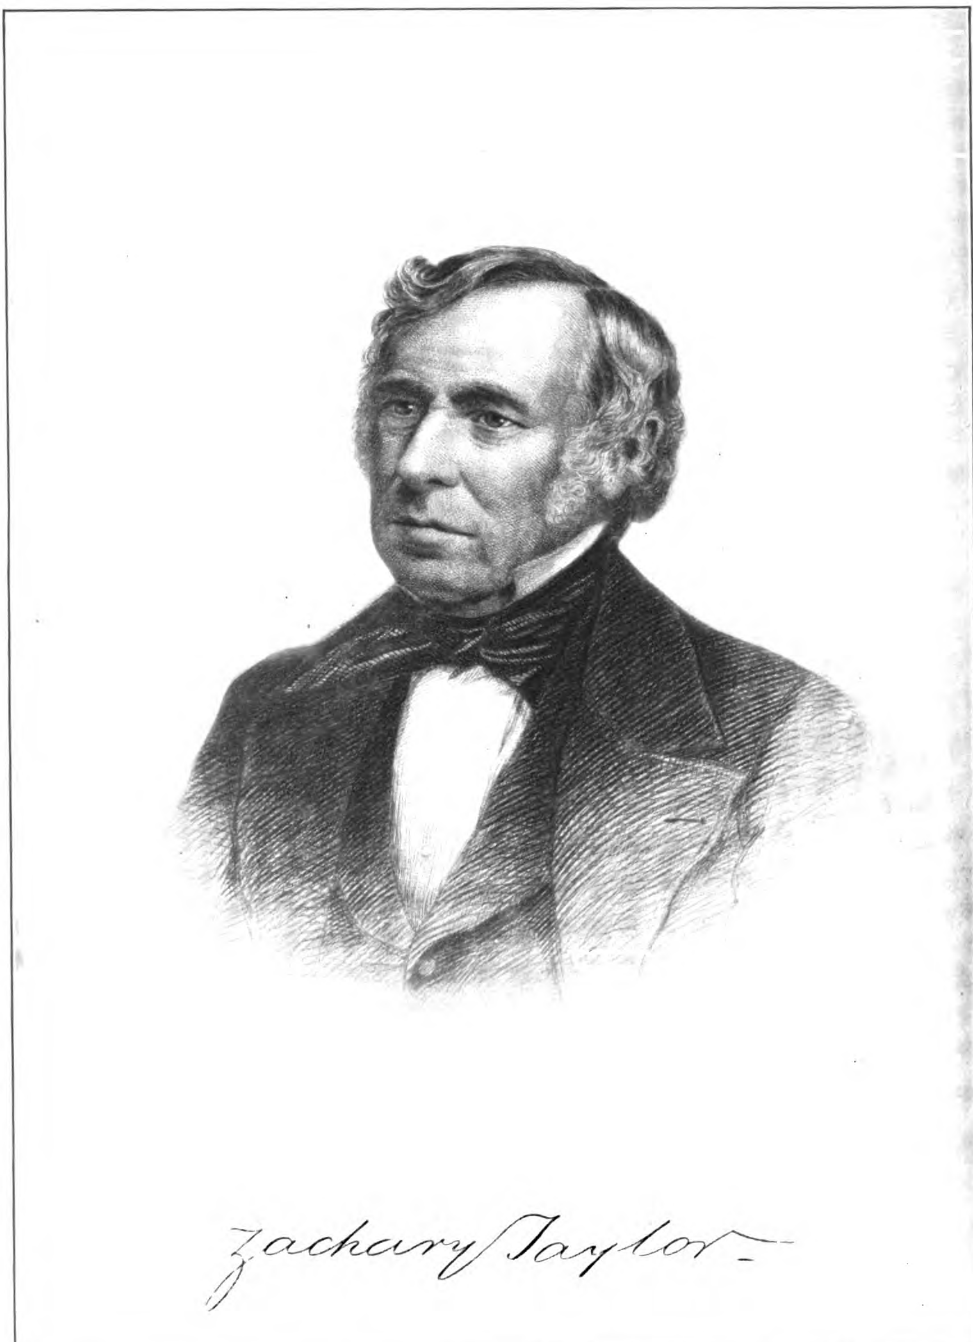
TAYLOR, Tom, English dramatist and journalist: b. Bishop-Wearmouth (Sunderland), 19 Oct. 1817; d. Wandsworth, 12 July 1880. He was educated at the University of Glasgow and at Trinity College, Cambridge, graduating from the latter in 1840. He was elected a Fellow of his college in 1842 and in 1845-47 he was professor of the English language and literature in University College, London. Called to the bar in 1846, he was on the northern circuit for a time, but in 1850 was appointed assistant secretary, in 1854 secretary to the board of health. On the formation of the local government board he was made secretary of the sanitary department and when his post was abolished in 1871 he retired with a pension. He engaged in journalistic work at an early stage in his career and in 1844 began his connection with *Punch,* which continued until his death; in 1874 he succeeded Shirley Brooks as editor. He was the author of a large number of successful plays, including 'To Parents and Guardians' (1845); 'Masks and Faces' (1852), in collaboration with Charles Reade, 'To Oblige Benson' (1854), an adaptation from the French; 'Our American Cousin' (1858), first produced at Laura Keane's theatre, New York, when Sothern created the character of Lord Dundreary; 'New Men and Old Acres' (1859), partly by A. W. Dubourg; 'The Overland Route' (1860); 'The Ticket-of-Leave Man' (1863), based upon a French work; 'The Fool's Revenge' (1869), based upon Hugo's 'Le Roi S'Amuse'; 'Twixt Axe and Crown' (1870), adapted from the German; 'Joan of Arc' (1871); 'Lady Clancarty' (1874), and 'Settling Day' (1877). He wrote a striking poem on the death of Lincoln eulogizing the martyr and atoning for the past critical offenses of *Punch.*

TAYLOR, William, American Methodist bishop: b. Rockbridge County, Va., 2 May 1821; d. Palo Alto, Cal., 18 May 1902. He became a Methodist preacher in 1842, served as an itinerant until 1849 and was then sent as missionary to California. He was engaged in that field until 1856 after which he spent five years in Canada and in the eastern States. In 1862 he went out as an evangelist and continued his work for many years in Australia, Asia, Africa and South America. He was particularly successful in his work among the Kaffirs in South Africa, where he established numerous independent mission churches and in 1884 was elected missionary bishop for Africa. He is said to have visited in the course of his missionary work every English-speaking country in the world. After his elevation to the office of bishop he went to Central Africa where he established a chain of 36 mission stations along the Kongo. He published 'Seven Years Preaching in San Francisco' (1856); 'Infancy and Manhood of Christian Life' (1867); 'The Story of My Life' (1882); 'Pauline Methods of Missionary Work' (1889), etc.

TAYLOR, William Ladd, American artist and illustrator: b. Grafton, Mass., 10 Dec. 1854. He was educated at Worcester, Mass., and studied art at Boston and New York schools and under the tuition of Boulanger and Lefebvre, Paris, from 1884-85. Since that time he has been painter and illustrator. Some of his best works are Selections from Longfellow's poems; a series of illustrations depicting 19th century New England, his 'Pioneer West' series, 'Psalms' series, pictures from the Old Testament, etc.

TAYLOR, William Mackergo, American Congregational clergyman: b. Kilmarnock, Scotland, 23 Oct. 1829; d. 8 Feb. 1895. He was graduated at the University of Glasgow and studied theology at Divinity Hall of the United Presbyterian Church, Edinburgh, till 1852. He then was ordained and became pastor at Kilmaurs till his fame called him (1855) to a new congregation at Bootle, Liverpool, where he preached till 1871, obtaining a great and growing congregation. In the latter year he accepted the invitation to fill the pulpit of the Rev. Dr. Storrs, Brooklyn, for a vacation season, which caused his call to the Broadway Tabernacle Church, New York, where he gained great popularity. He wrote much for the *Scottish Review* and over 30 of his works were published. He was for four years editor-in-chief of *Christian at Work.* Yale and Amherst (1872) conferred the degree of D.D. and (1883) the College of New Jersey gave him its LL.D. diploma.

TAYLOR, Zachary, 12th President of the United States: b. Orange County, Va., 24 Sept. 1784; d. 9 July 1850. His father, Col. Richard Taylor, served under Washington and he held a number of important offices in Kentucky where he migrated soon after the birth of Zachary. Young Taylor grew up in the vicinity of Louisville in the midst of its exciting frontier life. In 1808 aroused by the Chesapeake outrage, Taylor asked for a commission in the army and in May was commissioned first



Zachary Taylor

lieutenant in the Seventh United States infantry. In 1812 he was made a captain and in the War of 1812 gained distinction in defeating an Indian attack on Fort Harrison, for which success he was breveted a major. In May 1814 he received a regular commission as major but left the service at the close of the war on being reduced to the rank of captain. He re-entered the army in 1816 and in 1819 was promoted to a lieutenant-colonelcy. For the next few years he was stationed at different frontier posts but in 1832 during the Black Hawk War, as colonel, received the surrender of the Indian chieftain. In 1832 he was ordered to Florida in the Seminole campaign and at the battle of Okeechobee (25 Dec. 1837) won a decisive victory over the Indians, for which he was breveted a brigadier-general. Taylor spent the next four years in Florida and was then given command of the First Department of the army with headquarters at Fort Jessup, La. On 28 May 1845 Taylor, in command of the army of the Southwest, was ordered to hold himself in readiness to defend Texas from a possible invasion should the latter State accept the terms of annexation. On 30 July 1845 he was ordered to «occupy, protect and defend Texas,» and to approach the Rio Grande which was «claimed to be the boundary between the two countries» (Texas and Mexico). At the same time he was cautioned to keep away from the Mexican settlements and posts. In August, Taylor selected a position at Corpus Christi on the Nueces. Then followed a series of ambiguous orders from the War Department commanding him to check any Mexican army endeavoring to cross the Rio Grande or any *attempt* to do so. Taylor reported there was no concentration of Mexicans on the Rio Grande nor any signs of war; but, beginning to understand what the administration desired of him, asked for definite orders to advance. This the War Department refused to give and for a few months a delay ensued while the administration renewed its negotiations with the Mexican government. At last, in obedience to instructions from Washington, on 11 March 1846 Taylor began his advance from Corpus Christi to the Rio Grande. On the 28th he arrived opposite the Mexican town of Matamoras and began the construction of Fort Texas, afterward called Fort Brown, upon the present site of Brownsville. Taylor blocked the mouth of the Rio Grande with a view of cutting off all supplies from Matamoras and thus forcing the Mexican troops stationed there either to withdraw or to assume the offensive. On 12 April General Ampudia summoned him to retire beyond the Nueces, and with Taylor's refusal to do so the first conflict occurred on 24 April when a party of dragoons were ambushed by the Mexicans. President Polk at once sent a message to Congress recommending a declaration of war, asserting that «Mexico has passed the boundary of the United States, has invaded our territory and shed American blood upon the American soil.»

The war on Mexico began with the advance of Taylor's forces. On 8 and 9 May, Taylor defeated the Mexicans at the battle of Palo Alto and Resaca de la Palma and forced them to cross the Rio Grande. Following in quick pursuit, Taylor occupied Matamoras (18 May). With the refusal of Mexico to negotiate, Polk determined to conquer the northern provinces and in August, Taylor resumed his advance and after a three days' battle captured the city of Monterey (21–23 September). By this time Polk began to distrust Taylor on account of his supposed Whig affiliations. It was embarrassing for a Democratic administration to have a Whig general reaping all the glory, and with a view toward checking his operations Polk detached most of Taylor's experienced troops for the intended advance upon Vera Cruz under Gen. Winfield Scott. Santa Anna, the Mexican commander-in-chief, learning of Taylor's weakened condition rapidly concentrated 20,000 men and marched northward to crush him. To retire to the Rio Grande meant a loss of all the prestige so far gained and, therefore, Taylor decided to fight. He took a position at the hacienda Buena Vista, five miles south of Saltillo. Here after three unsuccessful attempts by Santa Anna, Taylor gained the most decisive victory of the whole war and remained in undisputed possession of the region. Taylor's brilliant victory, handicapped as he had been by the authorities in Washington, suggested him as a possible Presidential candidate to the Whig politicians. Thurlow Weed learned from the «general's brother that Taylor had always been an admirer of Clay and preferred home-made goods to foreign importations.» Taylor meetings became the fashion throughout the country; he was nominated at public assemblies in Ohio, Kentucky, Virginia, Pennsylvania and elsewhere, and although he had never even voted and had no views on political topics, supported by Weed, Crittenden and Stephens, he gained the nomination at the Whig Convention (May 1848) over the claims of Webster and Clay. In the succeeding campaign Taylor carried eight slave States while his opponent secured seven. The one all-absorbing question after the inauguration of Taylor was the question of what should be done with slavery in the Territories. Both parties in the campaign had side-stepped the issue, the Whigs having adopted no platform and the Democrats having trusted to the well-known views of their candidate, Lewis Cass. President Taylor, although master of a plantation in Louisiana, admitted anti-slavery leaders in the Whig party to his counsel and William H. Seward became his confidential adviser. The Wilmot proviso, the question of the organization of the Territory of Oregon and the admission of California already had demanded immediate attention. Accordingly the first message of the President was awaited with interest. Taylor already had made up his mind to recommend the admission of California as a free State and his fatherly message breathed with devotion to the Union. But Clay and Webster determined to take matters into their own hands and in January Clay offered his plan of compromising the sectional issue. Taylor characterized the Territorial portion of Clay's measures as the «Omnibus Bill» and was preparing to oppose them when he died on 9 July 1850.

Bibliography.— Stoddard, W. O., 'Zachary Taylor'; Howard, O. O., 'Zachary Taylor' (in 'Great Commanders Series,' 1892).

R. C. McGrane.

TAYLOR, Pa., town in Lackawanna County, on the Central Railroad of New Jersey and the Delaware and Lackawanna Railroad. It is situated three miles southwest of Scranton, its chief industries being coal-mining and silk-mills. Pop. in 1900 was 4,215 and in 1915, 11,591.

TAYLOR, Tex., town in Williamson County, on the Missouri, Kanasas and Texas and the International and Great Northern railroads, about 30 miles northeast of Austin, the capital of the State. It is in an agricultural and stockraising section. The chief manufacturing establishments are cottonseed-oil mills, cotton-compresses, railroad shops, flour and planing mills. There are about 75 manufactories, with an annual output of over $500,000. There are good banking facilities and newspapers. There are large shipments of grain, vegetables, cotton products, fruit and livestock. Pop. 5,314.

TAYLOR INSTITUTION, Oxford England, connected with the university, is designed mainly for the promotion of the study of modern European languages. It owes its foundation to a bequest of Sir Robert Taylor. The building belonging to it was erected in 1848. The institution comprises four teacherships of modern European languages and a library, and there are in connection with it a scholarship and an exhibition. It is under the management of nine curators, all of whom must be members of convocation. The library is open free to all members of the university, and other literary persons may be admitted by special permission. The curators of the institution have also the administration of a fund bequeathed by William Thomas Horner for the encouragement of the study of the Polish and other Slavonic languages.

TAYLOR UNIVERSITY, located at Upland, Ind. The forerunner of the university was the Fort Wayne Female College, organized in 1846 at Fort Wayne, Ind. In 1852 this college united with the Collegiate Institution at the same place, and became a coeducational school. The name was changed to Taylor University in 1890. In 1893 a new charter was obtained, and the university moved to its present site, the citizens of Upland donating 10 acres of ground and $10,000. It is under the control of the National Association of Local Preachers of the Methodist Episcopal Church. It was named for Bishop Taylor, the first Methodist missionary bishop to Africa, who had a part in its organization. The departments of the university are the college of liberal arts, the academy, commissioned by the State as a high school, the Reade theological seminary, the school of music, the school of expression, the normal department and the commercial department. The college offers two courses, classical and scientific, leading respectively to the degrees of A.B. and B.S. A part of the work of each course is elective. The theological school offers two courses; the English Bible and the seminary course, leading to the degree of B.D. A very strong school of music accredited by the State Teachers' Training Board has a separate building. The course in expression requires four years. The commercial department offers two courses: bookkeeping and stenography. The spirit of the college is markedly religious, a number of graduates every year become missionaries; and the students' religious organizations are strong. The library contains 7,000 volumes. The students average annually 340 and the faculty 19.

TAYLORVILLE, Ill., city, county-seat of Christian County, on the South Fork of the Sangamon River, and on the Wabash and the Baltimore and Ohio Southwestern railroads, about 24 miles southeast of Springfield and 27 miles southwest of Decatur. It is in an agricultural and coal-mining region, and has considerable manufacturing interests. There is an iron foundry, paper mill and manufactories of wagons, agricultural implements, chemicals, brick and tile. The chief shipments are coal, hay, livestock and manufactures. There are eight churches, a high school, graded schools and a public library. There are three banks, one national with a capital of $80,000, and two private banks. Pop. about 5,446.

TAYRA, tī-rą, a brown, elongated, weasel-like fur-bearer (*Galictis barbera*) of Mexico and South America, which sometimes gathers in large bands. It has a long bushy tail.

TAYTAY, tī-tī', Philippines, (1) pueblo, province of Paragua, island of Palawan, on the northeast coast on Taytay Bay. It is the chief town of the province and is protected by a fort mounting several guns and capable of accommodating a garrison of 700. Agriculture and fishing are the chief industries. Pop. (estimated) 7,420. (2) Pueblo, province of Rizal, Luzon, 10 miles east of Manila. Pop. 6,800.

TAYUG, tä-yoog', Philippines, pueblo, province of Pangasinan, Luzon, in the extreme northeast of the province, near the Agno River, 34 miles east of Lingayen. It is on the highway from San Quintin to Aseñgan. Pop. 19,612.

TCHAD, chăd, or **CHAD,** Africa, a large lake in the Sudan, situated at the common junction of Kamerun, British Nigeria and French Sahara, lat. 13° N., long. 14° E. It lies about 750 feet above sea-level. Its area during the rainy season is about 30,000 square miles, but in the dry season it shrinks to less than 7,000 square miles, and is then surrounded by vast marshes, while the remaining water is very shallow. The water is drinkable, although the lake has no apparent outlet; it appears to be gradually drying up and liable eventually to be a desert. Rarely is more than 20 feet of water to be encountered, and the marshy areas increase in size.

TCHAIKOVSKY, chī-kŏf'skē, **Peter, Ilich,** the greatest of Russian composers: b. Votinsk, government of Viatka, 7 May (not 25 Dec.) 1840; d. Saint Petersburgh, 6 Nov. 1893, of cholera. His father, a mining engineer, had no intention of making a musician of him, but had him educated at the Technological Institute in Saint Petersburg, after leaving which he obtained a post in the Ministry of Justice. But Peter was a gifted amateur, whose playing in social circles was much appreciated. In 1861 he wrote to his sister: "I told you I was studying the theory of music with considerable success. It is generally agreed that with my uncommon talents (I hope you will not take this for mere boasting) it would be a pity not to try my luck in this career." Shortly thereafter he entered the Conservatory, where he soon attracted the attention of Anton Rubinstein, who relates that once he gave the young man a theme and asked him to write a set of variations on it. He expected about a dozen, but Tchaikovsky brought him over 200! From Rubinstein he also took lessons in orchestration; the instruments on which he practised were the piano and the organ; also the flute, of which he afterward made such admirable use in his 'Nutcracker Suite' and other works. His talent was ere long generally appreciated; in 1865 Laroche, afterward an eminent critic, referred to him as "the future star of Russian music"; this led to his being sent to Moscow in 1866 to teach the theory of music at the newly opened Conservatory. Although he disliked giving lessons, he proved a conscientious and useful teacher. Thenceforth he devoted most of his spare time to composing; but although he had "an almost feminine craving for approval and encouragement," his experiences were little more than a series of disappointments. His wordly prospects nevertheless steadily improved and in 1877 he married, to the surprise of his friends. The hasty marriage had a tragic sequel. The union was not a happy one, and the pair soon separated. The composer was so despondent that he attempted to commit suicide in such a way as to avoid scandal by standing up to his chest in the icy river one night, in the hope of catching a deadly cold. In the following year another woman influenced his life, in a happier way. He did not know her, and she preferred to keep her identity concealed, but she put aside for his benefit a sum of money which made it possible for him to give up his Conservatory classes and save his energy for his creative work. Many master-works now came from his pen. He had never cared for society and detested city life, so his friends were not surprised when, in 1885, he took a house near the village of Klin, where he was isolated as completely from the world as was Wagner when he wrote his 'Meistersinger' score in his villa near Lucerne. He became known as "the Hermit of Klin," and refused to see any one but friends and such musicians as he chose now and then to invite for a party. By constitution he was strong, wiry and not easily fatigued; he was fond of outdoor exercise and many of his musical ideas came to him on his walks. He aged much as he neared his 50's; his scant hair grew white and his face lined. In May 1891 he visited America and gave concerts in New York and other cities. Two years later he conducted some of his works at Oxford and received the degree of doctor of music from the university. In the autumn of 1893 the world was startled by the news of his death. He succumbed to an attack of cholera, after a short illness. There were rumors of his having committed suicide, but his friend and biographer Kashkin discountenances them.

The suicide rumors were strengthened by the character of his last symphony, which is now known throughout the world as the 'Pathetic,' the most lugubrious of all symphonic works. A more heart-rending wail of grief than its adagio lamentoso has never been heard; and as this slow movement, contrary to all precedent, closes the symphony, it seemed like an intentional farewell to the world. "This music," says Huneker, "is a page torn from Ecclesiastes; it is the cosmos in crape." Schubert once said that the world liked best those of his songs which were born of sorrow. It was the doleful sixth symphony that made Tchaikovsky famous. Seldom has a work so great and deep won so instantaneous a success — a success so remarkable as to unduly overshadow his other five symphonies except, to some extent, the fifth, which resembles the sixth in mood and music. Like Beethoven, Tchaikovsky is greatest in his orchestral works, which include, beside the six symphonies, seven symphonic poems: 'The Tempest'; 'Francesca da Rimini'; 'Manfred'; 'Romeo and Juliet'; 'Hamlet'; 'Fatum'; 'Le Voyevode.' In these, which contain some of his best and most mature music, he manifests his sympathy with Liszt and modern program music. Among his other orchestral works the three that have become most famous are the '1812' overture, the 'Marche Slave' and the 'Nutcracker Suite,' which contains the best musical numbers of one of his three ballets. His 11 operas are much less modern in spirit and structure than his symphonic works and the only one of them that has attracted much attention outside of Russia is the fourth, 'Eugene Onegin.' It has been said of his operas that "just as the gracious beauty of Italian melody seemed doomed to pass away under a new dispensation, it was reincarnated in the works of this northern composer." There is much beautiful melody also in some of his 100 lyric songs; the best-known of them are the 'Spanish Serenade,' 'None but a Lonely Heart,' 'Why so Pale are the Roses.' Not a few of the songs are pot-boilers and the same is true of many of his pianoforte pieces, the best of which, however, deserve to be better known. Pianists neglect them because of their awkward technique. Three pianoforte concertos, a violin concerto, a string sextet and other pieces of chamber music must be added to the list of his compositions. His work as a whole is characterized by a remarkable variety; now it is classical, even old-fashioned, now ultra-modern; now Russian, now cosmopolitan. German critics have described his symphonies as rough, patchy, barbarous, nihilistic; but music lovers the world over are showing a keener insight and are learning to love this Russian music as they learned to love the Polish music of Chopin, the Hungarian of Liszt, the Norwegian of Greig. The authoritative life of Tchaikovsky has been written by his brother Modest. A shorter volume (in English) by Rosa Newmarch, includes extracts from his critical writings and diaries. Consult also Kashkin, 'Reminiscences'; Huneker, 'Mezzotints in Modern Music'; Riemann, 'Geschichte der Musik seit Beethoven.' A 'Catalogue Thematique' of the compositions is issued by Jurgenson, Moscow.

Musical Editor New York 'Evening Post.'

TCHEKHOV, Anton P. See Chekhoff; Cherry Orchard, The; and Sea Gull, The.

TCHIKUN, an American Indian tribe of the Apache (q.v.) family, formerly residing at Hot Springs, N. Mex.

TE DEUM LAUDAMUS, tē dē'ūm lâ-dā'-mŭs, or more abbreviated, **TE DEUM**, is the beginning of the hymn of praise usually ascribed to Saint Ambrose and Saint Augustine, although it cannot be traced farther back than the end of the 5th century, while Saint Augustine died in 430. The opening words, meaning, «We praise thee as God,» show that it was originally a hymn to Christ, but it is now always regarded as a hymn to the Father, the English version beginning, «We praise thee, O God.» In addition to its place in church services it is often sung on particular occasions, as on the news of victories and on high festival days. Among the great composers of music for this hymn are Hasse, Naumann, Haydn and Handel.

TEA, an evergreen shrub or small tree (*Camellia thea*) of the order (*Ternstrœmiaceæ*). The plant naturally attains a height of 30 feet, but under cultivation is pruned so that it rarely exceeds five feet. It bears lanceolate leaves about four inches long and rather large fragrant white flowers singly or in twos or threes, mostly in the axils of the leaves. It is a native of India and China, and has been cultivated in the latter country more than 2,000 years. Of several recognized species, only two have become commercially valuable: *C. thea*, var. *Bohea*, and *C. thea*, var. *viridis*. The latter is indigenous to India, the former recognized as a hybrid of Chinese species, probably with the original India variety.

Cultivation.— The ground on which a plantation of tea is to be set out is dug over in trenches to the depth of at least 18 inches, and 24 inches is preferred if the expense — about double — is not deterrent. As the plantation is of a permanent character, intended for a productive period of probably 30 years, every effort is made to have the soil in the best of condition, and well manured. The plants are taken from a nursery where they have been grown from seed for from six to 12 months, and set four feet apart both ways for «hill» culture. Where the ground is especially favorable they are set five feet apart. On poor soil the «hedge» system is practised, the plants being three feet apart in the hedge, and the hedges five feet apart. The plant has a tap-root descending eight to 10 feet into the earth. From this the feeding roots ramify in all directions. The cultivation consists in keeping the ground loose and free from weeds by surface hoeing, and once a year trenching the soil — from 18 inches in depth between the rows to nine inches next the «collar» of the plants. This is done in the late autumn, just after pruning, and the prunings along with green manure, preferably from leguminous plants, are spaded under. These prunings are estimated to restore to the soil 95 pounds of combined nitrogen, 56 pounds of potash and 19.6 pounds of phosphoric acid per acre. The pruning is done while the plant is passive, usually in December. On the hill plantations pruning is done annually: on level gardens, every other year or every third year — the practice being to prune alternately one-half or one-third of the plantation. The unpruned trees furnish the smaller leaves and, therefore, the higher grade tea, and their flushes come earlier, thus extending the picking season. On new plantations pruning begins when the trees are 12 to 18 months old, at which time the centre stem is cut down to within nine inches or even six inches above the ground — the object being to produce a growth of many branches and twigs, and thus a larger bulk of leafage which may be plucked without injury to the plant. The second pruning takes off everything to a level of 18 inches above the ground. As much of the tea is picked by children, the height of the plants in such localities is restricted to 30 inches. A very small plucking is made the second year, and the third year the yield is about 150 pounds per acre. The full yield of about 400 pounds per acre begins with the fifth year. The plant continues to yield well until its 10th year, when it is cut down and new sprouts developed from the trunk. This process is repeated until the plantation is 30 years old, when it is removed and new plants set out.

Plucking.— Plucking is an operation necessarily done by hand, and requires judgment as to the amount of leafage that may be removed at one picking without halting the normal growth of the plant. The plucking follows the «flush,» that is, the springing into leafage of the terminal buds after the winter rest. The second flush in the season is the leafing out of the top axillary buds on the stumps of the terminal bud-stems removed at the first picking. The succeeding flushes are not well marked, but there are generally 10 and sometimes 15 in the course of the growing season. In a well-ordered plantation the trees are plucked over about 30 times during the season, with the intent of getting the leaves while in their very best condition. The bud produces the finest quality of finished tea; the partly opened leaf next below it, being slightly less valuable, and the next leaves below distinctly coarser. The usual practice is to pluck the bud with the two adjacent open leaves. Plantations which produce only the highest grade of tea pluck the bud and one leaf. Many growers, however, pluck the bud and the first three leaves. The first few crops are thus very large, but the endurance of the plantation is seriously affected, and the net profits very decidedly reduced. The quality, however, does not depend wholly upon the plucking: much depends upon the soil and the climate. The average yield is about two and one-half ounces of finished tea per plant per season.

Processing.— The handling of the tea leaves after plucking is determined by the kind of finished tea to be produced. In the case of black tea the leaves are wilted or withered on trays in a draught of dry cool air often produced by fans. This is continued until the leaf is soft and flaccid. The average time required for withering is 18 hours: less than that does not allow sufficient development of the peculiar enzyme required for the subsequent fermentation upon which the flavor of the finished tea so largely depends. Withering is followed by rolling on tables of granite, the motion of the rollers being to crush the cells of the leaf without breaking its structure. In this process of rolling the leaves incidentally receive the characteristic twist noticeable in finished tea. The time occupied in rolling is from 20 to 40 minutes. The leaves are then run through a sifter which grades them into sizes, and then are spread upon glass or glazed-tile tables to ferment. During this process they are covered with cloths freshly wrung out of cold water. The time required for proper fermentation depends upon the previous development of the ferment during withering, and may take from two to six hours. The temperature is kept scrupulously to 85° F., or slightly below, and the time of completion is determined by the odor, which at first resembles chopped cabbage, but becomes fruity, resembling that of fine ripe apples. Lightly fermented tea yields when finished a pale, pungent infusion, the pungence due to an excess of unfermented tannin. Fully fermented tea yields a deep-colored, soft-flavored liquor of good body. The best tea is that which receives a medium fermentation and has in consequence a brisk taste, with high flavor and aroma. The final step in the process is drying the leaves rapidly to check further fermentation. The trays go first to a position near the furnace where the temperature is 260° and thence travel away from the source of heat, finishing where the heat is at 100°. In many factories a second firing is given after a few days, and this is considered to enhance the ultimate quality of the tea as it comes into the market after overseas transportation.

Before packing the finished tea is sorted over by hand, and vagrant bits of stalks and red leaves are removed. It is then sifted into grades. In the ordinary factory these are five: Broken Orange Pekoe, Orange Pekoe, Pekoe, Pekoe Souchong and Pekoe Fannings. The first is composed almost wholly of terminal buds and broken portions of the youngest and tenderest first leaves; the second is of the smallest leaves and a few buds; the third and fourth grades are of the coarser leaves, and the Souchong is usually chopped up to show a smaller range of size in the market. The Fannings are the finer fragments and dust, used chiefly in the manufacture of caffeine, or of «brick tea.»

Green Tea.— In the manufacture of green tea the freshly plucked leaves are thrown directly into a roasting pan at a temperature of 250° and are kept tossing about until flaccid, when they are emptied upon a mat of bamboo and rolled by hand. They are then dried quickly over a charcoal fire. The older leaves are deficient in proper color and are treated with small quantities of Prussian blue, indigo or soapstone. The former teas are called «natural green,» or «unfinished green,» in contrast with the doctored leaves, which go under the title of «true green» or «finished green.»

Oolong tea is prepared by a combination of the two methods, being slightly withered and lightly fermented and then treated as for green tea.

Brick Tea is a condensed preparation of the coarser leaves and even the prunings of the plantation. These are panned and steamed, and then placed in piles under cloth covers. A peculiar ferment resembling a black fungus spreads through the mass, which is then sorted, mixed with a glutinous rice paste, lightly steamed and then pressed into molds four feet long, nine and one-fourth inches wide and four and one-fourth inches deep. Three «bricks» are made in this depth, containing when dry four and one-half pounds each. Another form of brick tea is made into tablet form, four and one-half inches square and one and one-fourth inches thick and weighing half a pound each.

Tea Culture in the United States.— In the United States the first tea shrub was planted at Middleton Barony, S. C., in 1800 by the French botanist Micheaux. It was still living at the close of the 19th century, when it was about 15 feet high. In 1848 experiments were made upon an extensive scale by Junius Smith of Greenville, S. C., and in 1858 the government engaged Robert Fortune to collect tea seed for distribution in the South. These experiments were cut short, the former by the death of the experimenter, the latter by the Civil War. About 1880, the United States Department of Agriculture commenced experiments which were abandoned owing to various changes in the staff and the distance from the managing headquarters. About 10 years later Dr. Charles U. Shepard of Summerville, S. C., devoted his private means to tea experimentation. His opinion was that the previous experiments had not been conclusive and that the production of high grade teas at a profit to the grower could be accomplished in many Southern States and that a demonstration would attract capital to the industry. Once demonstrated as profitable he believed that the industry would furnish employment to many thousands of people, especially women and children, and would make valuable large areas of land which yielded little or nothing. In 1900 he had about 60 acres planted to this crop, a factory fully equipped, a trained band of pickers and facilities for meeting every requisite from planting to final sale. In 1900 the yield was about 5,000 pounds and when the present area reaches full bearing the annual output should be more than 12,000 pounds.

The tea plant, though a native of a subtropical climate, will succeed at high elevations in tropical countries and some of the numerous varieties will even withstand frost. In South Carolina the plants have resisted a temperature of zero, but the yield was lessened for the next two years. This is the lowest recorded temperature in that locality during 150 years. Ample water, especially during the leaf-forming season, is essential. This is supplied in the East by copious rains, but in the United States, where the rainfall is less than one-half the Eastern annual average, the deficiency is made up by improved methods of tillage or by artificial irrigation or both. In the East the tea gardens are generally planted on high ground or slopes so as to permit the excess water to seep away; in America they are planted on rather low ground such as well-drained pond-beds and swamps. Such lands are also naturally rich as a rule and, therefore, demand less initial application of fertilizers.

History.— The history of the tea-growing industry is said to have commenced in Korea before the 4th century before Christ, and to have reached Japan more than 1,000 years later. Tea was unknown to Europeans until the 16th century when Maffel, a Portuguese, mentions it in his 'Historiæ Indicæ' as a product of Japan and China. Not until 1615, however, was it mentioned by an Englishman, when Wickman wrote about it in a letter now owned by the East India Company. During that century small quantities found their way as presents to wealthy Londoners or later into the markets where they commanded £10 or £5 a pound. In 1657 a considerable quantity was purchased by Thomas Garraway, who opened a sort of restaurant where the beverage was served. As the importations increased, the customs and the excise each affixed duties. At one time (1660–89) a duty of 8d a gallon was levied upon the beverage. And somewhat later 5s. plus an ad valorem duty of 5 per cent was also operative. The American tea trade began in 1784 and within three years had developed to more than 1,000,000 pounds. The first direct importation from Japan came from Yokohama to San Francisco in 1868. Since 1870 the annual average importation is somewhat in excess of $15,000,000.

From the beginning of the commerce in tea, China has held first place as a producing and exporting country. The choicest grades, however, are probably unknown in America, but are consumed mostly at home or in Russia, where they command enormous prices. The reasons assigned for the non-exportation to distant countries are that the quality usually deteriorates during long transportation, and that some kinds do not keep well unless highly "fired," a process which impairs their flavor. The industry attracted the attention of the English in India and in 1836 Royle and Falooner, British botanists, commenced in Ceylon to experiment upon an extensive scale. The result was several brands of tea which were superior to many of the Chinese teas. Ceylon began to market tea in 1873 and the industry there has continued to thrive. Tea has been grown more or less in other sub-tropical and tropical climates, notably in South Africa, where somewhat more than a domestic supply is raised.

The large number of plants whose leaves have been used as substitutes for tea may be grouped as resembling or not resembling the real plant in composition. The best known of the former are as follows: Maté, Paraguay tea, Jesuits' or Saint Bartholomew's tea, which is obtained from the leaves of a South American species of holly (*Ilex paraguayensis*). This is extensively used in various South American countries, especially in the Argentine Republic, where the annual consumption is estimated at 13 pounds per capita, or about 27,000,000 pounds. Kola nut, coffee leaves and guarana are also used, but to a smaller extent. The principal substitutes unlike tea are probably Siberian tea (*Saxifraga crassifolia*), Chilean tea (*Eugenia ugni*), Appalachian tea (*Prinos glabra*), Trinidad tea (*Eugenia pimenta*), Labrador tea (*Ledum buxifolium*), and New Jersey tea (*Ceanothus americanus*). The last was used during the War of Independence and also during the War of the Rebellion. It is described as "a good substitute for indifferent black tea." The leaves of the partridge berry (*Mitchella repens*) are sometimes used in America.

In conservatories and greenhouses tea is often grown as ornamental plants and as objects of interest. The plants are managed like their close relatives, the camellias, but are less popular because more limited in their uses, especially because their flowers are axillary and hence less useful for cutting than those of the camellias.

Production.— The world's annual production of finished tea amounts to something over 800,000,000 pounds. The World War so affected production and shipment of the crop that it is necessary to take the figures of production for 1912, as being the latest complete record under normal conditions, to form an accurate idea of the tea-growing industry. In that year the areas devoted to tea were as follows: China, 5,120,000 acres (approximately); India, 575,000 acres, of which 354,276 acres were in Assam; Ceylon, about 395,000 acres; Java, nearly 100,000 acres; Japan, about 100,000 acres; South Africa (Natal and Nyassaland) about 4,600 acres. The crops sold in the world's markets from these producing countries amounted to a grand total of 731,000,000 pounds, contributed thus: India, 295,000,000 pounds; Ceylon, 193,000,000 pounds; China, 112,000,000 pounds; Java, 63,000,000 pounds; Japan, 43,000,000 pounds; Formosa, 25,000,000 pounds.

Consumption.— The chief purchasing countries of the 1912 crop were: United Kingdom, 295,000,000 pounds; Russia, 147,000,000 pounds; United States, 83,000,000 pounds; Canada, 34,000,000 pounds; Australia, 29,000,000 pounds; Holland, 12,000,000 pounds; Germany, 9,000,000 pounds; New Zealand, 7,000,000 pounds; South Africa, 7,000,000 pounds. In per capita consumption the British Empire as a whole was in remarkable degree the largest consumer, the average being 6.2 pounds, about 10 times the per capita consumption of all the rest of the world put together (excluding the United States). For the individual countries the per capita consumption figures were: New Zealand, 7.4 pounds; Australia, 6.8 pounds; United Kingdom, 6.4 pounds; Canada, 4.3 pounds; Holland, 2.1 pounds; South Africa, 1.2 pounds; United States, 0.9 pound; Russia, 0.9 pound; Germany, 0.1 pound; France, 0.07 pound.

Infusion.—As found in the market tea yields from 31 to 49 per cent of its substance to an infusion with boiling water, the Indian teas giving slightly more than the Ceylon teas, and the China teas slightly less. In this water extract the tannin constituent ranges from 14.33 per cent in India teas and 12.29 per cent in Ceylon teas to 9.50 per cent in China teas. (With thorough fermentation the proportion of tanning would fall below 5 per cent). Caffeine varies from 2.78 to 3.84 per cent in India teas, and ranges up to 4.14 per cent in Ceylon tea and 4.91 per cent in tea dust. In making the infusion for beverage purposes the finest flavored tea is produced by pouring fresh and actively boiling water upon the dry leaves and allowing it to stand not longer than one and one-half minutes, when the infusion should be immediately poured off the grounds. This brief infusion is sufficiently long to absorb practically all of the delicate essential oil which gives the tea its particular flavor. It is also long enough to dissolve out sufficient of the tannic acid to make the taste sprightly, without being astringent. The infusion will also contain about four-fifths of the contained caffeine. The strong, biting quality preferred by some tea drinkers is gained by a five-minute infusion, which dissolves a large proportion of tannin, but at the expense of the volatile oil of the tea which is dissipated by the continued heat. In moderate quantities tea as a beverage is not considered harmful, the average dose of caffeine being mildly stimulating, and the tannin, owing to its transformation to gallic acid in the intestinal tract, being innocuous. There is also a valuable proportion of albuminoid extractives in the infusion, and the water imbibed is a necessity to the continued health of the system.

Imports.— The imports of tea into the United States for the fiscal year ended 30 June 1918 reached the record figure of 151,314,932 pounds, despite the great difficulties of a scarce and expensive ocean tonnage. The value of the importation was $30,889,030. Of the whole, 52,996,474 pounds came from Japan; 44,540,467 pounds from India and Ceylon, and 21,082,866 pounds from China.

M. G. KAINS,
Crop Expert.

TEA, Varieties of. Teas were named mostly after the place of origin, as Japanese tea, including all from that country, but more specifically a brownish-green leaf tea, well-twisted. The qualities are indicated as long-leaf, wiry or well-curled, light-colored, etc. Ceylon tea is named mostly after the large plantations there; the varieties are termed pekoes, pekoe souchongs, souchong, congou, broken leaf, etc.; the congou is black, the souchong a black inclining to red, the pekoe black with yellowish tips, while the red leaf is known as kaisow. The hyson is a large-leaved green tea; the hyson skin is the remnants discovered in putting up hyson. Oolong is a greenish yellow tea, and Twankay a green tea lightly or imperfectly rolled. Bohea is a standard black tea gathered three times a year from old plants. The variety largely advertised as "English breakfast" is souchong, while imperial is any good bluish-green tea, long leaf, tight-rolled. Imperfect teas are named in the trade as broken leaf, dust, ends, fannings, etc.

TEA IN AMERICA. About 1880 the United States Department of Agriculture established a small tea-growing plantation near Summerville, S. C., and various varieties were raised in an experimental way. Later the plan was extended and the Pinehurst Tea Gardens opened in the suburbs, being supplied with native tea grown on a tract of about 100 acres and manufactured and cured by competent people. Further experiments were made at a place christened Tea, in Colleton County, S. C., and at Pierce, Texas. While it was found possible to grow good teas and to cure them satisfactorily, it was apparently impossible to produce them in competition with the teas of China and Japan, cured by cheap Oriental labor. Hence the experiments were wholly negative commercially.

TEA-TREE, a name applied not only to the *Thea* bushes (see TEA), but to various species of *Leptospermum* and *Melaleuca* — myrtaceous shrubs found from China to Australia, New Zealand and Tasmania. The tea-tree forms a common and almost impenetrable scrub of Victoria, in moist situations. It is a shrub of varying height and dark-green color, the branches bushy and growing perpendicularly, the leaves resembling the needles of a fir. The stems are straight, the wood hard and valuable for many bush purposes. Several of the tea-trees belonging to the genus *Melaleuca* furnish the aromatic, pungent cajeput oil (see CAJEPUT) of commerce. It is especially obtained from *M. leucadendron,* a tree reaching 30 feet in height, with terminal spikes of white flowers, and elliptical to lanceolate leaves, from which the oil is distilled. It has a crooked trunk, papery bark, employed in packing, and yields a wood which is white, close-grained, hard and durable, even under the ground. *M. squarrosa* or swamp tea-tree has a thin bark, and the thin, spongy cortex of *M. axillaris* can be used as a filter or blotting paper. The New Zealand tea-tree or tea-scrub is *Leptospermum scoparium,* a heather or juniper-like shrub with leathery foliage, like needles, and many small white blossoms. The common name is said to have been derived from the use of the foliage of this shrub and that of *L. lanigerum* by Captain Cook for tea, but the native name of the former is "ti." The white tea-tree is *L. ericoides,* of New Zealand. Other tea-trees are the bottle-green *Kunzea corifolia,* and the broad-leaved *Callistemon salignus,* both of Australia and Tasmania; the Ceylon, *Elæodendron glaucum,* and the red scrub tea, *Rhodamnia trinervia,* several of which are myrtaceous and have hard, heavy close-grained wood.

TEACH, or THATCH, Edward ("BLACKBEARD THE PIRATE"), American pirate: b. Bristol (?), England; d. on the James River, Va., 22 Nov. 1718. He is supposed to have gone out to the West Indies during the war of the Spanish succession, engaged as a privateer, and to have turned pirate in 1713 when the privateers refused to recognize the peace. He is first heard of in 1716 and from that time he cruised among the West Indies, along the Spanish Main, and the coasts of Virginia and Carolina, in his sloop, *Queen Anne's Revenge,* capturing numerous prizes and making his name a terror wherever known. In June 1718, his sloop was wrecked off North Carolina, and Thatch, with some 30 of his men surrendered to the king's proclamation. He made an ally of the governor, Eden, who afterward countenanced his piracy in view of a certain share in the spoils, and for a time led a rollicking life, forcing the planters to supply his wants and exacting toll from all vessels which came up or down the river. The planters at length appealed to Col. Alexander Spottiswood, lieutenant-governor of Virginia, who fitted out an expedition against the pirate, and on 22 Nov. 1718 the sloops moved up the river. Every man in the commander's boat was killed, and the captain, Robert Maynard, slew Thatch in a hand-to-hand struggle. His career is one of the most romantic in the history of American piracy, «Blackbeard the Pirate» being considered the ideal type of the pirate of fiction. Consult his 'Life' in Charles Johnson's 'Lives of the Pyrates' (1724).

TEACHERS, Professional Training of. Richard Mulcaster of London advocated the professional training of teachers as early as 1561 and suggested that a teachers' college be organized as a department in a university. Nothing definite or permanent appears to have come from this suggestion. The first genuine effort for the professional training of teachers undertaken in the world was undoubtedly by Jean-Baptiste de La Salle at Rheims in 1681. Three years later the institution which he founded at Rheims became known as the «Institute of the Brothers of the Christian Schools.» He later established a similar school at Paris. In this school he organized a regular, systematic course of instruction for the preparation of teachers for their professional work. Augustus Hermann Francke conducted an orphans' school at Halle and in 1697 he selected certain poor students in attendance upon this school and organized them into a «teachers' class.» The members of this class gave instruction to the other pupils in the orphans' school, and for this service Francke allowed them free tuition and board. Twelve years later Francke selected 12 students from the pupils in his orphan asylum to be trained as teachers. These students were selected upon «their piety, knowledge, and aptness to teach.» Francke called this institution a «Teachers' Seminary.» Hecker — a pupil of Francke — has the honor of establishing the first regularly organized institution devoted to the special work of training teachers. This school was established at Pomerania, Prussia, in 1735 and Hecker gave to it the name used by Francke and called it a teachers' seminary. Hecker established a second school of this type at Berlin in 1748. Frederick the Great gave official endorsement to the effort to provide special training for those who were to be employed as teachers in the schools, by raising Hecker's school at Berlin to the rank of a royal primary school for the purpose of training parish clerks and teachers. He gave this school further royal favor by directing that all parish clerks and all teachers appointed by the Crown should be selected from its students. Little progress was made in the establishment of institutions of this kind or in the training of teachers in Europe until after the French Revolution. At the beginning of the 19th century, the development of institutions to train teachers took on new life and the Prussian system of normal schools was firmly established. Six normal schools had been organized in that country.

It was about this time that the subject of preparing teachers for public schools began to receive attention in America. Men interested in public education began to discuss the subject. The manner in which these men first treated the subject does not indicate that they were familiar with what had been done in Europe in the training of teachers or with the system of normal schools which Prussia had established. The papers prepared by these men reveal a consciousness of the necessity of establishing adequate educational facilities in America and of preparing teachers to take charge of such schools as should be established. The papers written by these men indicate that these writers were speaking from the experiences and needs of the nation and not from historical knowledge of what had taken place in other countries. Among the numerous articles which appeared at this time and which exerted great influence in developing the idea that teachers should be professionally trained were the address of Denison Olmstead in 1816 on the «State of Education in Connecticut,» the pamphlet issued in 1823 by William Russell, principal of the New Haven Academy, on the subject of «Suggestions on Education,» the publication entitled «Lectures on School-keeping» issued in 1829 by Samuel R. Hall who founded a school for training teachers at Concord, Vt., in 1823, the articles published by James G. Carter in the Boston *Patriot* in the winter of 1824–25, the paper of Rev. Thomas H. Gallaudet in 1825 on a «Plan of a Seminary for the Education of the Instructors of Youth,» the pamphlet of Walter R. Johnson of Germantown, Pa., issued in 1825, on «Observations of the Improvement of Seminaries of Learning in the United States, with suggestions for its Accomplishment,» and many others. These articles gave to the public much valuable literature on the subject of education in general as well as upon the importance of special training for those who were to teach. The democracy of the nation was developing and with this development came a demand for schools. In the beginning of the 19th century 15 States either established systems of schools or reorganized existing systems. New York provided for State supervision of her schools in 1812 and 11 other States soon followed in making similar provision. The expansion, enlargement and improvement of educational facilities has always been coupled with a demand for better teachers.

The type of teachers employed in the schools in many cases was a potent argument in behalf of a system of training teachers. The men employed as teachers in the academies and colleges were generally men of education and character. This was not true of the men employed in the elementary schools. Often these teachers possessed little education, had received, of course, no training and had no intention of remaining permanently in the teaching service. Men often sent their sons to Europe to be educated and sometimes imported teachers from Europe to instruct their sons. Men who were unable to get other employment because of their lack of education or of proper character often enlisted in the teaching ranks. But even in this demoralized situation, able young men who were either working their way through college or had completed their college courses and intended to enter either the professions of the law, medicine, or ministry, or business careers, taught a few terms or years. Among the many men of this type, the following may be mentioned: John Adams, Eli Whitney, Daniel Webster, William Ellery Channing, William H. Seward, Salmon P. Chase, and in later times James G. Blaine and Elihu Root. As late as 1837 Horace Mann stated that, of the teachers employed in the State of Massachusetts outside of the city of Boston, about 200 expected to devote themselves to teaching and that the others were not generally qualified and that some of them thought more of what they were to get at the end of the term than they did of what they were to give during the term. Leading men in public affairs in all parts of the country recognized this condition in educational matters and gave it consideration.

In 1794 the teachers of New York City formed an organization known as the "Society of Associated Teachers." The purpose of this society was to promote the interests of its members and of education generally. Members were elected to the society by ballot, and a three-fourths vote was necessary to an election. This society did much of the work now performed by the professional supervisory staff of a school system. It passed upon the qualifications of teachers, upon textbooks, upon the proper professional decorum of teachers and discussed the pedagogical questions of that early date. It had been a voluntary organization without legal status. Several of its members petitioned the legislature of the State for a charter incorporating the "Society of Teachers in New York City." The petition was honored and the original society of 1794 discontinued. The charter granted the organization stated, in the following language, the object of the society:

> "For the relief and benefit of decayed teachers and their families, widows and children of deceased teachers, and for the discussion of literary subjects and for the promotion of science among the members of the society."

The society immediately entered upon a program for the intellectual improvement of its members, and its official reports show that prior to 1815 and for several years subsequent thereto the society gave special work to train and equip young men for the teaching service in New York City. This society was undoubtedly the first agency in America which gave definite work to the training of teachers for public schools.

In 1805 through the initiative and influence of DeWitt Clinton, the legislature of New York incorporated "A Society for establishing a free school in the city of New York for the education of such poor children as do not belong to or are not provided for by any religious society." This society became known as the Free School Society of New York City. Its annual report for 1814 contains the following statement:

> "From the commencement of the society it has been an object of great interest to train up young men for the office of teachers in similar institutions. The realization of their wishes in this respect is in part accomplished."

Mr. Fitzpatrick in his work on DeWitt Clinton states that a youth educated in this school was superintending a similar school in New Brunswick, N. J., and that the society had received an application from Newburgh, N. Y., for a teacher. The Free School Society adopted the Lancasterian system of schools. The report of the Free School Society for 1819 gives an account of what the society was doing to train teachers and specifically states that those who desire to become teachers are invited to attend its school where they may be properly instructed in six or eight weeks to become competent teachers of the Lancasterian system. Here is a second organization endeavoring to train teachers for public schools. See article LANCASTERIAN SCHOOLS, Vol. 16, p. 687.

The official records do not indicate the precise year in which the academies in New York State first began to train teachers for the common schools. The academies did this work before legislation had been enacted authorizing the establishment of teachers' training classes. The report of the Regents to the legislature in 1821 contains the announcement that the academies were training teachers for the common schools and the Regents expressed the opinion that the schools of the State must look to the academies for their supply of teachers. In the annual report of the Regents for 1823 the statement is made that because of the distribution of public funds under its direction to the academies subject to its supervision, such action "insures a supply of competent teachers for the common schools." New York was undoubtedly the first State which took specific action to solve the problem of providing trained teachers for the common schools. One of the vital questions in the establishing of agencies for the training of teachers was bitterly contested in New York. This question was, Shall the established educational institutions be utilized for this purpose or shall separate institutions devoted solely to such work be organized? The academies in New York were numerous, influential and under the control of the Regents. The friends of these institutions were zealous in their efforts to have the academies designated to train teachers. The State was giving these institutions financial support from the literature fund. The academies began to give special training to those who were going out to teach as early at least as 1821 and such instruction has been given continuously since that date. The friends of the academies endeavored to increase the amount of State aid to these institutions and based their argument upon the service which the academies were rendering the State in training teachers. They were successful in 1827 and not only succeeded in obtaining larger financial support but also obtained statutory recognition to train teachers without specifying how such service should be performed. The Regents, however, at once designated certain academies for this purpose and other academies continued to do such work voluntarily. The academies still pressed their interests at the legislature and in 1834 obtained the enactment of a law specifically authorizing the Regents to designate academies in which training classes should be organized. These training classes have been continued since that time and 80 were maintained in the year 1918–19. Through this agency about 25,000 teachers have been supplied the rural schools of the State.

In 1823 Rev. Samuel Hall opened a school at Concord, Vt., for the training of teachers. He was sent to this town as a preacher by the Domestic Missionary Society of Vermont. He consented to remain upon the distinct understanding that he should be allowed to organize a school for the training of teachers. He admitted to his school a class of young pupils for the purpose of having the opportunity of showing those whom he was training the best methods of teaching and of disciplining and governing a school. The literature relative to this school shows that Mr. Hall had no textbooks, periodical or other helps or equipment, and that he conducted the school on his own knowledge and judgment of educational methods of procedure and his experience in teaching. Growing out of his experience in this school he gave a series of lectures on "school keeping." There was a great demand for this work and the supply was soon exhausted. The State of New York purchased 10,000 copies of this volume and put one in each of the school districts of the State.
