Drawing a sprite image with transparent pixels requires two steps. First, the AND mask is drawn to the destination bitmap using a boolean AND raster operation. The white pixels (representing the transparent areas) have a binary value of 11111111 for 256-color images (a decimal value of 255, the last palette slot). Higher color depths will result in a binary value of all ones. When this binary value is ANDed with the colors of the pixels in the destination image, the result is the color of the pixels in the destination image, thereby preserving the destination image data. The black pixels (representing opaque image data), on the other hand, have a binary value of 00000000. When ANDed with the destination image, the result is black. Effectively, this creates a “cutout” area in the destination image where the actual sprite image will appear.

The second step is to draw the OR mask to the destination bitmap using a boolean OR raster operation. The black pixels of the OR mask (representing the transparent areas), when ORed with the destination, will preserve the destination image data, just as the white pixels did in the first step. The actual sprite image data, when ORed with the destination, will be combined with the black “cutout” area produced from the first step. Thus, the sprite image data will be preserved. This results in a perfectly copied sprite with the background image showing through the transparent areas. Figure 3-17 demonstrates the results of each step in the process.

**Figure 3-17:** Using masks with raster operations

The result, while perhaps not blindingly fast, should be more than adequate under most circumstances, if there are not a large amount of sprites on the screen. This technique is easy to implement, but it does require double the storage space for sprite images. The following example demonstrates how this technique is implemented.

## Palettes

As previously discussed, working under palettized video modes provides a number of advantages and disadvantages. Palettized modes can be a real pain at times, requiring careful planning on the part of art production and special considerations on the part of the programmer. However, the advantages of working under a 256-color video mode usually outweigh the disadvantages, primarily because it is a very speedy mode to work under, and palette animation can be used for special effects.

The Windows palette manager is a difficult beast to tame. There are many nuances to working in a palettized mode under Windows, making the creation of games using regular GDI functions difficult indeed. As this book's primary topic is game and graphics programming using DirectX, we will not cover palettes in the depth required for making non-DirectX games. However, it is useful to cover a few of the most basic palette topics in order to prepare the reader for DirectX palettes covered in a later chapter.

### Logical vs. System Palettes

There are two different kinds of palettes used by the Windows operating system: the system palette and logical palettes. The system palette is a Windows-maintained global palette containing all of the colors that can be displayed. The first and last ten palette entries are reserved for the system, and contain the 20 static colors that are used for drawing specific user interface elements, such as window title bars, borders, and 3-D user interface elements. The remaining 236 colors can be set in the application.

Logical palettes are created by the application and contain the colors that the application would like to use.

When the application specifies the palette it wishes to use, the Windows palette manager merges the logical palette with the current system palette. It accomplishes this by examining each entry in the logical palette and mapping it to an existing entry in the system palette, if a particular color exists in both palettes. If no matching entry is found, the color in the logical palette is placed into the first unused entry in the system palette. If an existing entry is not found and there are no more unused palette slots, the Windows palette manager maps the color to the closest approximation in the system palette. This continues until all colors in the logical palette have been merged with the colors in the system palette.

A logical palette must be selected into a device context before it can be used. If the specified device context identifies an active window, the logical palette is treated as a foreground palette and the Windows palette manager will mark all non-static entries in the system palette as unused. This allows the logical palette to potentially replace all non-static colors of the system palette. If the device context does not identify an active window, the logical palette is treated as a background palette, and can set unused palette slots only if any remain after the foreground palette has been merged.

The palette information stored in a DIB bitmap file can be considered a logical palette. Delphi takes care of most palette-specific concerns automatically, as the TBitmap object will load a bitmap's palette and put it into use. In the next chapter, we will learn how to load a palette from a bitmap and use it to initialize the DirectX palette.

**Note:** The TBitmap object has a property called Palette. This property is the handle to the bitmap's logical palette, and can be used in any GDI function that manipulates logical palettes.

---

## Using a Palette

Delphi encapsulates a large portion of the Windows API, making Windows programming easy and fun. Unfortunately, not everything in the Windows API has been conveniently simplified in this manner, and this includes palette functionality. This means that in order to use palettes, one must use low-level Windows API calls throughout most of the process.

In order to begin using a custom palette, a logical palette must first be made. First, variables of type PLogPalette and HPALETTE must be declared. The PLogPalette is a pointer to a logical palette structure, which contains a member for the palette version, a member for the number of palette entries, and then an array of type TPaletteEntry. The TPaletteEntry type is a structure that contains fields for the red, green, and blue components of a color, and a flag indicating how the entry is to be used. The PLogPalette variable is initialized to the appropriate values, including the desired colors, and is then passed to the CreatePalette function. This returns a handle to the newly created palette, which is then assigned to the HPALETTE variable. At this point, the palette can be selected into a device context using the SelectPalette function. If using a bitmap, the palette handle can be directly assigned to the TBitmap.Palette property. To actually merge the logical palette with the system palette so the new colors can be used, call the RealizePalette function. When the application no longer needs the logical palette, it should be deleted by calling the DeleteObject function. The following example demonstrates creating a logical palette to draw a red gradient fill.

**Figure 3-19:** The custom palette

    {we no longer need the logical palette, so delete it}  
    DeleteObject(FormPalette);  
end;
```

---

## Further Adventures in Windows Programming

The rest of this book could be dedicated to Windows GDI programming techniques without ever exhausting the subject. Indeed, several such books have been written that cover Windows graphics programming in much greater detail than that presented here. Our goal with this book is to study DirectX programming techniques under Delphi, so further discussion of GDI programming techniques is beyond our scope. However, if you would like more information concerning graphics programming under Windows, consult the following titles:

*Black Art of Windows Game Programming* (ISBN 1-87873-995-6, Waite Group Press)

*Delphi 2 Multimedia Adventure Set* (ISBN 1-88357-764-0, Coriolis Group)

*The Tomes of Delphi 3: Win32 Core API* (ISBN 1-55622-610-1, Wordware Publishing)

Several more books that cover graphics programming, both Windows-specific and general algorithms, are listed in the bibliography at the end of the book. The remainder of this book will be dedicated to creating high-speed games using DirectX techniques.

**Summary**

In this chapter, we discussed several basic topics in graphics programming. Although all of the examples demonstrated these topics using normal Windows GDI function calls, the concepts and theories presented apply to graphics programming in general. When coding a graphically intensive application under Windows, it is important to keep these points in mind:

- The GDI subsystem is responsible for all of the graphical output displayed to the screen during a Windows session. One of Windows' strongest attributes is its device independence, or its ability to be run on a wide variety of hardware combinations. Due to this requirement, the GDI's primary purpose is to provide a mechanism by which an application can output graphical content without the programmer being concerned about what type of hardware upon which the application will be running. Unfortunately, as a direct consequence of this device independence, the GDI is notorious for its slow performance. Even so, the GDI is very useful when creating tools for games, and some commercial games have been written using little more than generic GDI function calls.
- One must be familiar with a number of terms that describe various common graphical elements. Such graphical elements include pixels, lines, polygons, and bitmaps. A pixel is defined as the smallest, single element in a graphical image or on the display surface. Lines are a collection of pixels, usually arranged in a linear configuration. A collection of lines, arranged in such a way that the ends are connected to form a continuous, closed shape, is known as a polygon. A bitmap is a collection of pixels arranged in a rectangular configuration in such a way that they form a recognizable shape, such as a picture or texture.
- Discussions of graphics programming usually start from a consideration of what resolution the video driver is currently in and how many colors are available in which to draw the graphics. These two concepts are directly related, and are generally referred to in a combined sense as the video mode. Both the resolution and the color depth of the current video mode will affect the perceived quality of the displayed graphical images. The greater the resolution and color depth, the more realistic and detailed the displayed graphics will become. However, on the downside, higher resolution and deeper color depth mean greater memory usage and slower speed.
- The color of every pixel drawn to the screen is determined by three components: a red intensity, a blue intensity, and a green intensity. As these intensities increase or decrease, the color of an individual pixel is affected accordingly. Each intensity can have a minimum value of 0 and a maximum value of 255. If the intensity of each component is 0, the resulting color is black, while if

each component is at 255, the resulting color is white. This gives a maximum of 16,777,216 colors. This is referred to as RGB color, denoting red, green, and blue, respectively.

- Four and eight bits-per-pixel color depths are the only palettized video modes. At 8 bits-per-pixel, each pixel can assume a value between 0 and 255. These values act as an index into what can be considered a 256-entry array known as the color palette. Each entry in this array contains an 8-bit value for the blue, green, and red intensity of a color. Palettized display modes require careful planning of art resources, but are very fast and allow for palette animation special effects. By contrast, 16, 24, and 32 bits-per-pixel video modes directly store the color value for each pixel. This color value is encoded according to the bits-per-pixel used, and can vary from video board to video board. Non-palettized video modes have the advantage of total freedom to display any number of bitmaps simultaneously, without worrying about color problems or palette management. The downside to this is that more memory is required for both display and bitmap storage, and games tend to run slower as it requires longer to move a bitmap from one place in memory to another.
- A device context represents a surface upon which graphical output can be drawn. Specifically, a device context represents the surface of an output device such as a monitor, printer, or plotter, and gives the developer access to modify its appearance. Fortunately, we will not need to be concerned much with device contexts, as the TCanvas object encapsulates the functionality of the device context and makes graphical output much easier.
- Bitmaps come in many varieties, from two color to true color, and in many different formats. The native Windows bitmap format is easy to use, and comes in two subformats: DDB and DIB. The device-dependent bitmap, or DDB, is an older bitmap format and is kept around solely for backward compatibility. The device-independent bitmap, or DIB, stores more information than a DDB and can accurately be reproduced on any output device. The use and display of DIBs is not quite as fast as DDBs, but their flexibility more than makes up for the loss in speed. Fortunately, the TBitmap object encapsulates the functionality of both the DDB and DIB image formats, making bitmap manipulation easy.
- There are many nuances to working in a palettized mode under Windows, making the creation of games using regular GDI functions difficult. There are two different kinds of palettes used by the Windows operating system: the system palette and logical palettes. The system palette is a Windows-maintained global palette containing all of the colors that can be displayed. Logical palettes are created by the application, and contain the colors that the application would like to use.

## CHAPTER 4 An Introduction to DirectX

This chapter covers the following topics:

- The promise of DirectX
- The benefits and drawbacks of DirectX programming
- DirectX architecture
- DirectX components
- DirectX programming under Delphi
- COM fundamentals
- DirectDraw surfaces
- Page flipping
- Initializing DirectDraw
- GDI rendering with DirectDraw
- Displaying bitmaps
- Retrieving DirectDraw capabilities
- DirectX result codes
- Retrieving the DirectX version

Now that we've covered some basic graphics programming techniques, it's time to dive into what really makes game programming under Windows a reality: DirectX. When DirectX was initially introduced, it was not well received among game programmers. People feared that Microsoft was trying to force them into a game development architecture that would potentially render useless any proprietary graphics techniques. Fortunately, this was not Microsoft's aim, and after DirectX was looked over and evaluated by the gaming industry at large, it was embraced, and has now become the standard low-level programming interface around which games are now created. While it is possible to create some cool games using various GDI functions, to make games that will compete in today's market the savvy Delphi programmer must use the DirectX API.

### What is DirectX?

To put it technically, DirectX is really nothing more than a series of DLLs which give the developer access to low-level hardware while still maintaining some level of device independence. More specifically, DirectX is comprised of a number of COM objects which are implemented in the aforementioned DLLs. These COM objects provide the primary interface to system-level hardware in an object-oriented, language-independent fashion. The overall COM architecture allows the DirectX development team to expand and advance DirectX functionality without affecting applications written with earlier versions of DirectX. In essence, developers can now write games with all the power available under DOS while still maintaining the device independence of the Windows operating system.

In practice, DirectX programming is a lot like using Delphi VCL objects without the benefit of a visual environment. Various DirectX objects are instantiated and initialized, and sometimes linked with other DirectX objects through various method calls. Unlike the VCL, however, DirectX uses several very complex data structures as parameters in many methods. The DirectX API itself is huge, spread across numerous subsystems and various objects within those subsystems. We'll examine several of these subsystems closely throughout the remainder of this book.

## **The Promise of DirectX**

Developing games in a DOS environment can be a nightmare. The multitude of new hardware devices pouring out of hardware vendors had dramatically differing interfaces, making it difficult indeed to support more than a handful of devices in any one game. A high-level operating system like Windows, on the other hand, offers many benefits to game developers, such as consistent programming interfaces to new devices, simplified installation and configuration features, and extensive built-in functionality. However, before the advent of DirectX, this level of abstraction in the Windows environment posed a serious performance penalty that was unacceptable in any fast-action, high-performance game.

The DirectX development team's goal was to create a low-level architecture that would provide developers with the hardware control they need at the speed they demanded, while still retaining Windows' device-independent benefits. This was to be accomplished without imposing a restrictive high-level design architecture. First and foremost, DirectX had to be fast in order to allow game developers to create the high-performance, adrenaline-pumping action games demanded by hard-core game players. DirectX applications must also coexist peacefully with other Windows applications, such as spreadsheets and word processors. Therefore, DirectX promises three things to developers: fast execution, minimal style restraints, and a level of abstraction that will provide benefits from future hardware.

## **Speed**

One of the things that makes DirectX so fast is that it takes advantage of hardware acceleration whenever possible. If a hardware device directly supports a certain function within its electronics, such as copying an image from one area in memory to another, the DirectX drivers send the function call directly to the hardware (which is probably where the "Direct" moniker was derived). This results in blindingly fast performance.

Another benefit to hardware acceleration is true multitasking capabilities. Any DirectX function that is supported in hardware will return immediately after the function is called, even before the task of that function is carried out. This allows the CPU to continue processing application instructions while other hardware is carrying out the previous command. For example, if the display hardware supports moving an image from one area to another, the application can instruct the hardware to perform this task while asynchronously performing game logic calculations.

## **Minimal Style Restraints**

By its very nature, DirectX is a very low-level application programming interface. Game developers have spent a lot of time and money in creating innovative techniques for performing graphical output, techniques which can make one game stand apart from the others. If this competitive edge were to be threatened, many game developers would never have taken a second look at DirectX. Therefore, instead of creating a general gaming library that imposed high-level restrictions in how a game is put together, DirectX acts as a general enhancement to the Windows operating system. This results in many low-level function calls that provide

power and speed while not insisting that developers create games “the right way.” While this may not exactly automate certain tasks, it does allow for the greatest level of creativity and ingenuity when designing new games while affording the developer a certain level of device independence.

## Abstraction

The level of abstraction provided by the Windows operating system allows DirectX to take advantage of hardware advances as they become available. The DirectX interfaces were not designed merely to support the currently available hardware; they were designed in such a way that developers can take advantage of new hardware benefits when they are introduced. This shifts the burden of providing support for new hardware from the developers to the hardware manufacturers themselves. In many cases, when users purchase some new hardware device, all that is required for their existing DirectX games to take advantage of new benefits is to download the latest DirectX drivers. For example, when MMX technology was introduced, DirectX drivers were updated to support the new features. If a user downloaded and installed the new DirectX drivers, existing games would immediately and transparently take advantage of the new technology.

**Benefits and Drawbacks of DirectX Programming**

For the most part, DirectX delivers exceptionally on all of its promises. It does indeed give developers a high-performance interface to system-level hardware while maintaining the benefits of the Windows operating system. DirectX offers the game programmer many benefits over using GDI functions, indeed many benefits that weren't even available under DOS. Even so, there are a few drawbacks to using DirectX over GDI, especially in the Delphi environment. While none of the drawbacks are truly serious, Delphi developers should be aware of both the advantages and disadvantages of using DirectX over traditional Windows programming techniques.

**Benefits**

**Speed** As we've already discussed, DirectX allows the game developer to squeeze the maximum performance out of applications. Performing just about any game application task is substantially faster than employing similar GDI functions. In fact, DirectX offers some functionality that would be very difficult and time consuming to emulate using the multimedia API.

**Greater Control** DirectX gives applications incredible control over some things that would be impossible, impractical, or difficult under GDI. Such tasks as direct memory access to bitmapped graphics or audio data (in either hardware or system memory) and full control over the color palette (without the annoying GDI remapping of colors) are now possible through DirectX.

**Feature Emulation** Many features for which hardware acceleration is unavailable are emulated in DirectX. This provides the developer with a certain minimal framework of functionality that is guaranteed to exist with or without hardware support. While this may result in some loss of performance, software emulation of hardware features is implemented using very low-level multimedia API functions and assembly language, and in many cases is almost as fast as the hardware implementation. Most of the standard features have a software emulation, such as copying image data from one memory area to another or mixing sound buffers on the fly.

**Drawbacks**

**Difficult Debugging** DirectX applications are simply harder to debug than traditional Windows applications. Most high-performance games are written in a full-screen video mode, and in a full-screen video mode, you can't set breakpoints and step through your code. There are other debugging techniques you can use to get around this limitation, but once an application initializes a full-screen video mode, most of Delphi's awesome debugging features are completely useless.

**Few Delphi Examples** DirectX has, until recently, been solely the domain of C/C++ programmers. As such, most examples are written in C/C++. All of the DirectX documentation is certainly written for C/C++. Unfortunately, Delphi programmers may be required to learn at least a nominal amount of C/C++ before taking advantage of the DirectX documentation and numerous DirectX books and references that are available. Fortunately, several companies and individuals have written numerous DirectX libraries for Delphi, and there are several Delphi-specific DirectX programming web sites now available. Hopefully, this will result in an increase of DirectX documentation and references for the ambitious Delphi game programmer.

**Steep Learning Curve** Even in its most recent incarnation, DirectX is still a fairly new API. As such, one must usually perform several steps in order to perform certain actions, especially when initializing many of the DirectX subsystems. The programmer is usually required to perform these steps in a very specific order, and unless the programmer is very familiar with how certain DirectX functionality is implemented, it may be very difficult to get things working initially. This, coupled with the fact that the DirectX API is huge and there are few Delphi examples, usually results in a rather steep learning curve for first-time game programmers.

## The DirectX Architecture

The DirectX API itself, in the form of various COM objects and their methods, acts as an interface into the DirectX drivers. On the back side, the DirectX drivers can be thought of as two separate systems: the hardware abstraction layer (HAL) and the hardware emulation layer (HEL).

---

**HAL:** hardware abstraction layer; the DirectX drivers responsible for direct interface to hardware capabilities.

**HEL:** hardware emulation layer; the DirectX drivers responsible for emulating certain functionality if not present in hardware.

---

The HAL represents the hardware itself. When a DirectX object is created, it interrogates the HAL about hardware capabilities. The HEL, on the other hand, represents the software emulation of certain features. If an application asks a DirectX object to perform a certain task, it will be performed in hardware if the HAL indicates that the capability exists. Otherwise, the task will be performed in software if the HEL supports the emulated feature. Some features would be very slow to emulate in software, and thus may not be available in the HEL. These features will simply be unavailable to the application unless the HAL indicates they are present in the hardware. The HAL provides developers with hardware acceleration when available, and the HEL fills in where it can to provide a consistent, base set of features.

It is important to note that, for the most part, this is completely transparent to developers. Unless a developer is using a feature that is specifically implemented in hardware and not emulated by the HEL (such as overlays), an application need not be concerned if hardware support is present or not. However, an application can query DirectX to see if specific features are implemented in hardware or are emulated. An application can then use this knowledge to optimize various game functions, taking advantage of those functions that are specifically supported by the hardware and using a different approach for those functions that are too slow when emulated. This allows game developers to write applications that take advantage of available hardware under various configurations while still functioning adequately under all configurations.

## DirectX Components

DirectX is comprised of many components. Indeed, it seems as if new DirectX components are added every day, and there are sure to be more and more in subsequent versions. While the inventive game developer could potentially make use of all of these DirectComponents, there are only a few that are essential for game development. In this book, we will specifically look at the DirectDraw, DirectSound, and DirectInput components.

### DirectDraw

The DirectDraw component is responsible for all graphical output to the screen. DirectDraw objects provide functionality for such tasks as tear-free animation using page flipping techniques, access to graphical coprocessors, display memory management, and color palette manipulation. It is the core component of DirectX, and serves as the foundation for other DirectX components, such as Direct3D.

### DirectSound

The DirectSound component is responsible for digitized audio playback. It provides stereo and 3-D sound functionality and sound card memory management. It allows the developer to asynchronously play any number of sounds, mixing them on the fly and automatically converting their format to that of the primary sound output stream.

### DirectInput

The DirectInput component is responsible for providing the application with data retrieved from any type of input device. This not only includes the mouse and keyboard, but joysticks, flightsticks, rudder pedals, steering wheels, and other devices that have yet to be invented. DirectInput also supports output devices, such as force feedback peripherals.

### Other DirectX Components

There are several other DirectX components that are of particular interest to game developers, but are not quite as essential as the previous three. Several of these components may be required depending on the type of game being produced, and certainly any game could be enhanced by taking advantage of the functionality represented by these components. This is not an exhaustive list by any means, but game developers may want to further investigate the following components:

**DirectPlay** – Provides transport-independent messaging services between multiple computers. This is an essential component for multiplayer games, and includes functionality for organizing and launching a multiplayer game session.

**DirectSetup** – Provides automated installation of DirectX drivers.

**Direct3D** – Provides three-dimensional graphics rendering functionality. This component is segregated into low-level and high-level interfaces, which provide varying levels of control and expedience.

**DirectMusic** – Provides playback of MIDI music compositions. This component allows developers to directly control the exact sound of each instrument, and includes the ability to mix separate MIDI compositions on the fly to achieve context-sensitive musical transitions.

## DirectX and Delphi

Now that we know what DirectX is, we need to know what is required in order to use DirectX under the Delphi environment. Unfortunately, Delphi programmers do not enjoy the automatic access to DirectX resources that C/C++ developers do. If Microsoft were to include a type library along with the DirectX DLLs, it would be a simple task indeed to import the type library and immediately begin using the DirectX COM objects. Alas, this is not the case, and accessing DirectX functionality is the first obstacle that enthusiastic Delphi game developers must face.

### The DirectX SDK

As a C/C++ developer, you would simply need to purchase the DirectX SDK from Microsoft and install its accompanying files to begin developing DirectX applications. As a Delphi developer, however, there is no need to purchase the DirectX SDK. All that is required is the DirectX redistributable files available for free download from Microsoft's DirectX web site, or from the many commercial games that include them.

However, it may be worth your while to purchase the DirectX SDK, as it includes many benefits. The most important thing you will gain by purchasing the SDK is the DirectX documentation. As this book is not a reference manual, it will not discuss many of the nuances of DirectX programming that are available in the hundreds of pages of DirectX documentation. Dozens of examples are also available in the SDK which, although written in C/C++, are valuable references for investigating some of DirectX's more powerful features. The SDK also includes a DirectX control panel applet that allows you to control numerous global settings that may be helpful during debugging.

Perhaps most importantly, the DirectX SDK includes information on the files that can be distributed with your applications. While you can always suggest that your users visit the Microsoft web site to download the DirectX files if they do not already have them installed, it is a wise practice to always include all required files and DLLs with your applications. Therefore, you will need to be aware of the many legal requirements for bundling the DirectX redistributables with your applications. For more information about the DirectX SDK, check out <http://www.microsoft.com/directx/resources/devdl.htm>. You can order the DirectX SDK for a nominal fee by visiting <http://www.microsoft.com/directx/sdkcdorder.asp>.

### Project JEDI

If you have the DirectX end user redistributable files installed (which you probably do if you've played any recent games), all you will need are the Delphi import files converted from the original DirectX C/C++ header files. All code in this book is based around the Project JEDI DirectX header files written by Erik Unger. Project JEDI (Joint Endeavor of Delphi Innovators) is a nonprofit organization composed of Delphi

programmers all over the world. Their goal is to convert C/C++ header files for various APIs into Delphi import units, thus giving Delphi developers everywhere access to the same programming resources as their C/C++ cousins.

Erik's header files are a raw conversion of the original C/C++ headers, supporting DirectX 6 under Delphi 4. This gives Delphi developers the exact same functionality as would be available under C/C++. This is not a library that automates certain tasks; it is a hard-core unit containing the same low-level objects and methods that the C/C++ programmers use. This book is aimed at teaching the reader how to program DirectX, not how to use some arbitrary DirectX library. Thus, these units were the perfect choice. Indeed, after reviewing several of the DirectX examples used throughout this book, you should be able to comprehend most C/C++ examples, as the DirectX method calls are the same. This book, and the companion CD, contain the latest version of Erik's header files at the time of publication. However, to get more information about the header files, some examples, and the latest version, check out <http://www.delphi-jedi.org/DelphiGraphics/jedi-index.htm>.

**Delphi Graphics and Game Programming Exposed with DirectX 7.0**

by *John Ayres*

Wordware Publishing, Inc.

**ISBN:** 1556226373 **Pub Date:** 12/01/99

**Search this book:**

[Previous](#) [Table of Contents](#) [Next](#)

Erik Unger's headers give Delphi developers access to DirectDraw, DirectSound, DirectInput, DirectPlay, DirectSetup, and Direct3D. This is the full functionality available under all of these DirectX subsystems, including force feedback and 3-D sound. The DXTools unit accompanying the files also includes several utility functions, such as testing the return results of DirectX methods and performing matrix manipulations. Throughout the course of this book, we will develop a utility unit converted from a C/C++ utility unit shipping with the DirectX SDK that simplifies several menial tasks such as loading a bitmap, a WAV file, or a palette. Later in this chapter, we will begin to use our utility unit and Erik's header files to create a baseline DirectX application from which all other examples in this book are based.

**Tip:** While the latest headers at the time of the writing were used for all of the book's examples, it is quite possible that the headers will have gone through several more versions by the time this book goes to print. The examples in this book will compile with the headers included on the CD, but you should get the latest headers from the JEDI page to have access to all the newest features. Bear in mind that the book examples may require a little adjustment when used with the new headers, as method declarations may have changed.

## Other Components and Headers

Fortunately, the Delphi gaming community is starting to see a rise in the number of available DirectX headers and components. Some are freely available, others you must purchase, but all of them give the Delphi developer a little more functionality than the raw headers accompanying this book.

## DelphiX

A freeware component suite written by Hiroyuki Hori, DelphiX comes complete with source code and gives the developer access to DirectDraw, Direct3D, DirectSound, DirectInput (including force feedback support), and DirectPlay. There are several cool components in this suite which allow the developer to bundle graphics and sound into compressed libraries, and includes some awesome alpha blending functionality. The examples clearly demonstrate some of the advanced techniques capable with DelphiX, and there are several freeware tools available that make editing sound and graphics libraries easy. For more information, check out <http://www.ingjapan.or.jp/hori/indexe.html>.

## The Delphi Games Creator (DGC)

Another freeware component suite, the DGC gives developers access to DirectDraw, DirectSound, DirectPlay, and DirectInput. Written by John Pullen, Paul Bearne, and Jeff Kurtz, the DGC comes complete with source code. The DGC also comes with editors for bundling sound and graphics into libraries, and will map all images in a graphics library to a single palette. Palette cycling and cool transition effects are just some of the added functionality available with this component suite. It also includes a scrolling map component and editor for making tile-based map engines. One of the first and oldest freeware DirectX component suites, the DGC has a large following, and is suitable for private or commercial DirectX applications. For more information, check out <http://www.ex.ac.uk/~PMBearne/DGC.html>.

## RingZero GDK

Created by Systems Advisory Group Enterprises, Inc., the RingZero GDK and RingZero 3D are component suites that give the Delphi developer access to DirectDraw, DirectSound, DirectPlay, DirectInput, and Direct3D. Although these component suites must be purchased, you gain the benefit of technical support and continuing updates (which may or may not always be available with freeware components). Source code is also available. These component suites are very easy to use, and can expedite the creation of a DirectX game if you are impatient or have a pressing deadline. Unfortunately, as of this writing, these components only support DirectX 5, and can only be used under Delphi 2 or 3. However, by the time this book reaches store shelves, RingZero may be compatible with Delphi 4 and DirectX 6. For more information, check out <http://www.sage-inc.com>.

## A DirectDraw Tutorial

DirectX has hopefully been installed to your machine by now, and we have the units required to give us access to DirectX components and functionality. At this point, we can begin exploring the world of DirectX programming and all of its nuances, pitfalls, and rewards.

DirectDraw is the core, most fundamental DirectX component, and as such, is a good starting point for a discussion of DirectX programming. We will go over a good number of DirectDraw concepts, many of which are mirrored in other DirectX components. Several of the methods called and tasks performed by the DirectDraw objects are very similar, if not exact, to those of other DirectX components, such as DirectSound and DirectInput. The learning curve discussed earlier starts here, as there are quite a few concepts to explain.

### Features

DirectDraw offers many features above and beyond what is available through the Win32 API. As with all DirectX components, DirectDraw gives the developer more control over graphical output than the Windows API, while providing incredible performance not attainable using GDI functions. DirectDraw provides the following features and many more for powerful Windows game programming:

- Direct access to image memory, whether located in system or display memory
- The ability to specify the location of surface memory (i.e., system or display memory)
- Hardware acceleration for many graphical functions
- Screen resolution and color depth changing on the fly
- Direct control over the system palette (in full-screen mode)
- Powerful page-flipping methods for incredibly fast animation

In the following sections we will see how DirectDraw is used to change the display mode and color depth, how bitmaps are loaded into usable DirectDrawSurfaces, and how page-flipping animation is implemented.

### Functional Overview

DirectX programming primarily consists of creating parent objects, namely objects that represent specific DirectX components, and then using these objects to create child objects that represent a specific

functionality. The following illustration and discussion outline actions that will become familiar when we cover other DirectX components.

DirectDraw programming consists of creating a DirectDraw object and several DirectDrawSurface objects. The DirectDraw object itself acts as a liaison between the application and the display driver. Through the DirectDraw object, we can change the display resolution and color depth as well as create individual DirectDrawSurface and DirectDrawPalette objects.

Individual DirectDrawSurface objects represent display buffer memory. This can be either offscreen storage for image data or the visible display itself. The application uses these surface objects to communicate directly with the video hardware, either through direct memory access of image data or methods that access hardware acceleration. Surfaces provide methods to copy image data to and from each other, performing various operations on the image data such as scaling or ignoring transparent pixels. DirectDrawSurface objects encapsulate much of the power provided by DirectDraw.

DirectDrawPalette objects hold color data for images that are stored in a palettized format. They also represent the application's interface directly to the display hardware's palette. DirectDrawPalette objects will be covered in more detail in the next chapter.

### COM Fundamentals

DirectX objects are COM based, consequently involving all of the associated benefits and drawbacks of using COM objects. Microsoft's Component Object Model (COM) is a huge beast, not unlike that of the VCL. A full-fledged discussion of COM is beyond the scope of this book, and unnecessary for the purposes of DirectX programming. However, there are a few COM theories that we must understand before delving into the heart of DirectX programming.

Working with DirectX objects has some similarities to working with other COM objects, but there are a few differences. The primary difference that most experienced COM programmers will discover is the fact that DirectX objects do not need to be created by using the CoCreateInstance function. Other COM objects frequently used in a traditional COM application, such as IClassFactory, are also unnecessary. All DirectX objects are created through custom function calls that return an instantiated COM object. For example, the DirectDrawCreate function is used to create an instantiated IDirectDraw object (more on this later). If you've never worked with COM objects before, this takes some of the confusion out of the loop, and is similar to creating traditional VCL objects in code.

A COM object can almost be thought of as a VCL object with no properties, only methods. The methods of a COM object are known as an interface. A COM object can have more than one interface, and it can be extended by added new interfaces, similar to deriving a new component from an ancestor. However, the COM standard dictates that an interface can never change. The result of this is that older code is guaranteed

to work with newer COM objects, as the original interfaces will still be implemented and available. For this reason, you will see several different types of interface declarations in the DirectX header files. As each new version of DirectX comes out, offering new functionality, an entirely new interface must be created to support this functionality. However, you can rest assured that your DirectX game will still work when DirectX 7, 8, 9, etc., are introduced in the future.

An interesting feature implemented by COM allows applications to query a COM object to see if it implements a particular interface. This allows your application to be extremely flexible when implementing certain features. For example, force feedback is a newer addition to DirectInput functionality. Your application, upon startup, could query the DirectInput objects to see if they support the interface required to implement force feedback output. If they do not, indicating that the game is running on a machine with an older version of DirectX, you could simply bypass the part of your code that implemented force feedback. However, if the force feedback interface is available, your application can make full use of its features. In this way, game applications can be very robust, taking advantage of special features only on those machines that have them available, while still running acceptably on older machines without those features. We will see an example of this later in this chapter when we discuss how to detect what version of DirectX the user has installed.

## Reference Counting

One fundamental concept in COM is the idea of lifetime management. COM was implemented with the idea that several users, or clients, could potentially use the exact same COM object, thus saving memory and resources. Therefore, the COM objects themselves implement a method of reference counting. Essentially, COM objects keep a count of how many times they are being used. When they are created, this count is initialized to 1. When a new client wishes to use the COM object, this reference count is incremented. When a client no longer needs the COM object and it goes out of scope, such as when an application terminates, the reference count is decremented. When the reference count reaches 0, the object knows it can free itself.

This reference count incrementing and decrementing is accomplished by calling the `AddRef` and `Release` methods implemented in all COM objects. However, fortunately for Delphi developers, Delphi takes care of this automatically and, for the most part, transparently. Reference counting does add some esoteric nuances to using COM objects that are not present when using VCL objects. As a Delphi DirectX developer, don't worry about explicitly freeing DirectX objects after they are created; they will free themselves when they go out of scope or when the application terminates. For more information on general COM programming concepts, look at *Delphi 4 Developer's Guide* by Teixeira and Pacheco (ISBN 0-672-31284-0) or *Delphi Developer's Handbook* by Cantu, Lam, and Gooch (ISBN 0-782-11987-5).

## GUID

COM objects are identified by a unique number known as a GUID, pronounced "goo-id" or "gwid" (like "squid"), which stands for globally unique identifier. Without going into too much detail, Microsoft provides an API call that generates a GUID that is completely unique; it is guaranteed to be unique if the machine on which the GUID was created has a network card installed. The concept of what a GUID is or how it is used is only important to the DirectX developer in that GUIDs are used to identify many individual objects and devices, such as specific DirectX objects (such as memory surfaces or sound buffers) and specific drivers (such as a particular video driver or device). We will be using GUIDs throughout every example in the book.

## Surfaces

Perhaps the single, most important concept in DirectDraw programming is that of the surface. A surface is directly analogous to Delphi's `TBitmap` or `TCanvas` object. It represents a virtual "picture" upon which graphical output can be drawn. In reality, a surface is a linear chunk of memory that is managed as if it were rectangular. Surfaces have width and height, among many other properties. The memory for a surface can be located in a number of places, but primarily it will be found in system memory or in the memory on the display card itself.

**Delphi Graphics and Game Programming Exposed with DirectX  
7.0**

by *John Ayres*

Wordware Publishing, Inc.

**ISBN:** 1556226373 **Pub Date:** 12/01/99

**Search this book:**

[Previous](#) [Table of Contents](#) [Next](#)

There are many, many different types of surfaces, some of which are very specialized for a particular purpose. Surfaces can be used specifically for 3-D rendering, or for storing textures used in 3-D rendering; they can be set up to receive live video feeds, or perhaps to store only transparency information (known as the alpha channel). For the purposes of this book, we will be concerned with only three different types: the primary surface, the backbuffer surface, and off-screen surfaces.

**alpha channel:** A component of color that records levels of transparency/opacity as opposed to actual color data.

## The Primary and Backbuffer Surfaces

Technically speaking, these are really the same type of surface. The primary surface represents the image that the user sees on the display screen. Anything drawn onto the primary surface is immediately displayed. The backbuffer surface has the same capabilities and format of the primary surface, and is used in an animation technique known as page flipping (more on this below).

## Off-screen Surfaces

An off-screen surface, as it will be used in this book, is simply a surface in memory that is never directly displayed on the screen. Typically the same format as the primary and backbuffer surfaces, off-screen surfaces are generally used for storing background graphics and sprite animation frames. They can also be used as work surfaces for composing a graphical image. The image in these surfaces is then copied onto the primary or backbuffer surfaces to be displayed. We'll see an example of this later in the chapter.

## Page Flipping

Page flipping is an incredibly powerful technique for producing flicker-free animation. The term "page flipping" comes from the inspiration for this animation technique—that of traditional cartoon animation. Cartoons (and movies, for that matter) create the illusion of animation by displaying to the viewer a series of

images, one after the other. Someone can create a crude animation by taking a stack of paper, drawing an image on each page, and then flipping through it rapidly. This is the architecture of page flipping animation. The idea is to create two surfaces, the primary surface and the backbuffer surface. The next frame of animation is composed on the backbuffer surface, and then it is “flipped” to the display screen. This updates the entire display screen in one fell swoop, resulting in a flickerless animation.

**Figure 4-1:** Page flipping animation

This page flipping animation architecture is incredibly easy to implement under DirectX. Just about every video card available supports this in hardware, making it incredibly fast. Therefore, we will use this page flipping technique for nearly every animation and game example throughout the book. We will see how to initialize and implement page flipping in the examples to follow.

## Resolution, Color Depth, and Video Memory

We discussed resolution, color depth, and video memory quite a bit in Chapter 3, Basic Graphics Programming. That discussion is just as relevant to DirectDraw programming as it was to GDI graphics programming. However, under DirectDraw, the developer has much more control over the resolution and color depth. This also affects how the memory represented by a surface is directly accessed. To simplify matters, we will be concerned only with 256-color palettized display modes. A number of different display modes may be available under DirectX, and we’ll demonstrate how to retrieve a list of the available display modes shortly.

## Windowed Versus Full-Screen

Perhaps the most powerful aspect of DirectDraw programming is that the application can have control over the entire display screen, known as a full-screen application. However, DirectDraw also allows a developer to take advantage of DirectDraw capabilities for drawing graphics in a regular window while sharing desktop space with other windows. This is known as windowed mode. Generally speaking, it is more difficult to support a windowed DirectDraw application than it is to support a full-screen mode. A windowed DirectDraw application requires a DirectDrawClipper object (not covered in this book), and must handle a number of other requirements typical of a traditional GDI graphical application, such as dealing with a shared palette. We are concerned only with high-performance game programming, so this book will only demonstrate full-screen DirectDraw applications. This will greatly simplify the code, and will provide us with the greatest amount of control and power. The distinction between windowed and full-screen is known as the cooperative level, and will be covered in more detail below.

## Initializing DirectDraw

We’ve covered several COM and DirectDraw programming concepts, so now it’s time to see them in action. There are several tasks the application is required to perform before DirectDraw can be instantiated and the display mode modified. Some of these tasks are optional, some are not. DirectDraw, and DirectDraw surfaces, are instantiated by performing the following:

- Enumerating display devices
- Creating the DirectDraw object
- Enumerating the supported display modes
- Setting the cooperative level
- Setting the display mode
- Creating surfaces

## Enumerating Display Devices

While it is safe to assume that most machines only have one display device attached, the latest version of Windows does allow multiple monitors and other display devices (such as virtual reality headsets) to be installed simultaneously. Although it is not strictly necessary, it may be good practice to allow the user to pick the display device on which to display the DirectDraw application. However, for the examples in the book, we will only be concerned with the primary display device.

The function `DirectDrawEnumerateEx` is used to list all available display devices. It is a callback function that will call the specified function once for each installed display HAL it finds. The first device enumerated will be the primary display device; any others attached to the system will follow. The `DirectDrawEnumerateEx` function is declared as:

```
function DirectDrawEnumerateEx(  
  
    lpCallback: TDDEnumCallbackEx; // the address of the callback function  
  
    lpContext: Pointer;           // an application-specific value  
  
    dwFlags: DWORD                // scope flags  
  
): HRESULT; stdcall;           // returns a DirectX error code
```

The first parameter is the address of the function that is called for each enumerated device. The second parameter is a pointer to an application-defined value, such as a pointer to a TList or perhaps just a variable, and can be set to nil if not needed. The last parameter is a series of flags that control the scope of the enumeration. The callback function itself is defined as:

```
function TDDEnumCallbackEx(  
  
    lpGUID: PGUID; // a pointer to the device GUID  
  
    lpDriverDescription: PAnsiChar; // the device description  
  
    lpDriverName: PAnsiChar; // the device name  
  
    lpContext: Pointer; // the application-specific value  
  
    Monitor: HMonitor // a handle to the monitor  
  
): BOOL; stdcall; // returns TRUE or FALSE
```

The first three parameters of this function are the most interesting. The lpGUID parameter will contain the GUID for the specific device. This GUID must be stored, as it must be used later for creating the DirectDraw object. The lpDriverDescription and lpDriverName parameters contain the textual description and name of the enumerated device. These can be presented to the user in a list of devices, allowing them to choose the desired display object. The lpContext parameter simply contains the pointer passed to the initial DirectDrawEnumerateEx function. The last parameter will be zero in most cases, and can be ignored. The callback function must return a value of TRUE to continue the enumeration; returning FALSE signals the function to stop enumerating devices.

The following example demonstrates enumerating all available display devices.

*Listing 4-1: Enumerating display devices*

implementation

uses

DDraw;

```
function EnumDevices(lpGUID: PGUID; lpDriverDescription: PAnsiChar;
```

```
    lpDriverName: PAnsiChar; lpContext: Pointer;
```

```
    Monitor: HMonitor): BOOL; stdcall;
```

begin

```
    {add the name and description of the enumerated device. here, we would  
    need to store the GUID for the device so it would be available when  
    the user selected the desired display device}
```

```
TStringList(lpContext).Add(lpDriverName+' - '+lpDriverDescription);
```

```
    {continue enumeration}
```

```
    Result := TRUE;
```

end;

```
procedure TForm1.FormCreate(Sender: TObject);
```

begin

```
    {enumerate all attached display devices}
```

```
    DirectDrawEnumerateEx(EnumDevices, lbxDevices.Items, 0);
```

end;

**Figure 4-2:** The list of attached display devices

## Creating the DirectDraw Object

The first truly required step in initializing a DirectDraw application is to create the DirectDraw object itself. To create the DirectDraw object, call the DirectDrawCreate function, which is defined as:

```

function DirectDrawCreate(
lpGUID: PGUID; // the GUID of the DirectDraw device
out lpLpDD: IDirectDraw; // the IDirectDraw object to be instantiated
pUnkOuter: IUnknown // unused, set to nil
): HRESULT; stdcall; // returns a DirectX error code

```

The first parameter takes the GUID of the selected device. It can be set to nil to create a DirectDraw object associated with the primary display device, or it can be set to a GUID as retrieved from device enumeration above. Additionally, it can be set to DDCREATE\_HARDWAREONLY or DDCREATE\_EMULATIONONLY to only use the HAL or HEL, respectively. This allows the developer to perform testing and debugging against emulated or hardware accelerated features. The second parameter takes a pointer to the IDirectDraw object. When this function returns, this object will be instantiated. The last parameter is used for COM aggregation, and must be set to nil as it is currently unsupported.

**Caution:** It is possible to create multiple DirectDraw objects, but this is inadvisable. Each DirectDraw object is independent of the others, and surfaces and other child objects cannot be shared between them.

Now, this function will only return an instantiated IDirectDraw object, but since we are concerned with DirectX 6 functionality, we need to get an instantiated IDirectDraw4 object. Thus, we should create a temporary IDirectDraw object, and once this is instantiated, we can use the QueryInterface method of the object to retrieve an instantiated IDirectDraw4 object. The temporary object can then be released by setting it to nil. We'll illustrate the creation of an IDirectDraw4 object below.

**Note:** Delphi's AS operator can be used to accomplish the same thing. However, use of the QueryInterface method is a little less abstract.

## Enumerating the Supported Display Modes

It is typically much harder to create an application that supports multiple display modes. As discussed in the previous chapter, changing display modes modifies the size of graphics as they are displayed on screen, and changes the amount of screen area that must be filled with graphics. This puts an additional requirement on the programmer to determine how graphics will be displayed in different modes (if they are to be scaled, stretched, etc.), and may put additional requirements on artists if they must develop additional graphics to support different resolutions and color depths. However, allowing the user to choose which display mode works best on their system is a good practice, as the user can then tune the game to achieve acceptable speeds. Even if your game will support only one graphic mode, it is useful to determine if the machine supports this mode. Our examples will be concerned with only one specific display mode in order to simplify the code, but we still need to enumerate the available display modes to ensure that the machine can handle the application.

Enumerating display modes is similar to enumerating display devices. After the IDirectDraw4 object is created, we can call its EnumDisplayModes method to enumerate all display resolutions and color depths supported by the display driver. The EnumDisplayModes method is defined as:

```

function EnumDisplayModes(
dwFlags: DWORD; // scope flags
lpDDSurfaceDesc: PDDSurfaceDesc2; // a surface description structure

```

```
lpContext: Pointer; // an application-defined value
lpEnumModesCallback: TDDEnumModesCallback2 // the callback function
): HRESULT; // returns a DirectX error code
```

The first parameter is a series of flags that determine how the display modes are enumerated, and can be set to zero. The second parameter is a pointer to a TDDSurfaceDesc2 structure that contains information defining the types of display modes to be enumerated. We can use this to enumerate only specific types of display modes, such as all 800 x 600 modes or all palettized display modes. Setting this parameter to nil will enumerate all supported display modes. The third parameter is a pointer to an application-defined value, and the last parameter is a pointer to the callback function itself. The callback function is defined as:

```
function TDDEnumModesCallback2(
const lpDDSurfaceDesc: TDDSurfaceDesc2; // a surface description record
lpContext: Pointer // the application-defined value
): HRESULT; // returns a DirectX error code
```

The first parameter contains a TDDSurfaceDesc2 structure initialized with information about the enumerated display device. This includes information such as the width, height, and color depth. The second parameter contains a pointer to the application-defined value. This function must return DDENUMRET\_OK to continue the enumeration; DDENUMRET\_CANCEL will stop the enumeration.

The TDDSurfaceDesc2 object is complex, and is used in a number of different IDirectDrawSurface4 methods. The TDDSurfaceDesc2 structure is defined as:

TDDSurfaceDesc2 = packed record

```
    dwSize: DWORD; // size of the TDDSurfaceDesc structure

    dwFlags: DWORD; // flags indicating valid members

    dwHeight: DWORD; // surface height

    dwWidth: DWORD; // surface width

    case Integer of

    0: (

        lpitch : LongInt; // distance to start of next row

    );

    1: (

        dwLinearSize : DWORD; // optimized surface size

        dwBackBufferCount: DWORD; // number of backbuffers

    case Integer of

    0: (
```

```

    dwMipMapCount: DWORD;           // number of mip-map levels
    dwAlphaBitDepth: DWORD;         // depth of alpha buffer
    dwReserved: DWORD;             // reserved
    lpSurface: Pointer;            // pointer to surface memory
    ddckCKDestOverlay: TDDColorKey; // color key for destination overlays
    ddckCKDestBlt: TDDColorKey;     // color key for destination blt
    ddckCKSrcOverlay: TDDColorKey;  // color key for source overlays
    ddckCKSrcBlt: TDDColorKey;     // color key for source blt
    ddpfPixelFormat: TDDPixelFormat; // pixel format description
    ddsCaps: TDDSCaps2;            // surface capabilities
    dwTextureStage: DWORD;         // multitexture cascade stage
);

1: (
    dwRefreshRate: DWORD;          // refresh rate
);
);
end;

```

The following listing illustrates creating an `IDirectDraw4` object and enumerating all supported display modes.

***Listing 4-2: Creating `IDirectDraw` and enumerating display modes***

---

```

var
    Form1: TForm1;
    FDirectDraw: IDirectDraw4;

implementation

function EnumModesCallback(const lpDDSurfaceDesc: TDDSurfaceDesc2;
                           lpContext: Pointer): HRESULT; stdcall;
begin
    {list the height, width, and color depth of the enumerated display mode}
    TStringList(lpContext).Add(IntToStr(lpDDSurfaceDesc.dwWidth)+' X '+

```

```

        IntToStr(lpDDSurfaceDesc.dwHeight)+' , '+
        IntToStr(lpDDSurfaceDesc.ddpfPixelFormat.dwRGBBitCount)+
        bits/pixel');

    {continue enumeration}

    Result := DDENUMRET_OK;

end;

procedure TForm1.FormCreate(Sender: TObject);

var

    {we can only get a DirectDraw4 interface from the DirectDraw interface, so we
    need a temporary interface}

    TempDirectDraw: IDirectDraw;

begin

    {create a temporary DirectDraw object. this is used to create the
    desired DirectDraw4 object}

    DirectDrawCreate(nil, TempDirectDraw, nil);

    try

        {we can only get a DirectDraw4 interface through the QueryInterface
        method of the DirectDraw object}

        TempDirectDraw.QueryInterface(IID_IDirectDraw4, FDirectDraw);

    finally

        {now that we have the desired DirectDraw object, the temporary DirectDraw
        object is no longer needed}

        TempDirectDraw := nil;

    end;

    {begin enumerating supported display modes}

    FDirectDraw.EnumDisplayModes(0, nil, lbxDisplayModes.Items, EnumModesCallback);

end;

```

**Figure 4-3:** Supported display modes

## Setting the Cooperative Level

As discussed earlier, the cooperative level determines if the application runs in full-screen mode or if it will share the desktop with other windows. Basically, it determines how the application will work with other applications. The concept of cooperative level is also found in other DirectX components.

Setting the cooperative level requires a simple call to the `IDirectDraw4`'s `SetCooperativeLevel` method, which is defined as:

```
function SetCooperativeLevel  
  
    (hWnd: HWND;                // a handle to the main window  
  
     dwFlags: DWORD             // flags controlling the cooperative level  
  
    ): HRESULT;                // returns a DirectX error code
```

The first parameter is a handle to the application's main window. The second is a series of flags that specify the actual cooperative level. For our discussion, we should pass `DDSCL_EXCLUSIVE` and `DDSCL_FULLSCREEN`, which indicates that our application will be responsible for maintaining the entire display. We'll see an example of its use below.

## Setting the Display Mode

Here's where the real action takes place. We've created the `IDirectDraw4` object, allowed the user to select a display mode or determined that our predefined display mode is supported, and we've set the cooperative level. All that's left is to actually change the display mode itself. This is accomplished through `IDirectDraw4`'s `SetDisplayMode` method. The `SetDisplayMode` method is defined as:

```
function SetDisplayMode(  
  
    dwWidth: DWORD;            // the desired width, in pixels  
  
    dwHeight: DWORD;          // the desired height, in pixels  
  
    dwBPP: DWORD;             // the color depth, in bits  
  
    dwRefreshRate: DWORD;     // the refresh rate  
  
    dwFlags: DWORD            // control flags  
  
    ): HRESULT;               // returns a DirectX error code
```

The first and second parameters specify the desired width and height of the display, in pixels, and it must match a supported display mode as returned by the `EnumDisplayModes` function. The third parameter indicates the number of bits that describe an individual pixel's color, and again this must match a supported display mode. The refresh rate and flags parameters can both be set to zero. When this function is called, the display mode is immediately switched to the mode specified. The screen will likely go blank, you'll hear some clicking, and then the display hardware will reset to

the specified mode.

Now, before we can set the display mode, DirectDraw makes some demands of the main window that must be met before either the SetCooperativeLevel or the SetDisplayMode methods will work. According to the DirectX documentation, the window whose handle is sent to the SetCooperativeLevel method must not have any border, and must be a stay-on-top window. This can be accomplished in Delphi by setting the form's BorderStyle to bsNone and the FormStyle to fsStayOnTop in the form's OnCreate event. Only then will the SetDisplayMode method work correctly.

The following example demonstrates setting the cooperative level and switching the display mode.

*Listing 4-3: Setting the display mode to full screen*

```
var  
  
    Form1: TForm1;  
  
    FDirectDraw: IDirectDraw4;  
  
implementation  
  
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    {initialize form properties.  note that the FormStyle property must be  
    set to fsStayOnTop}  
  
    BorderStyle := bsNone;  
  
    BorderIcons := [];  
  
    FormStyle := fsStayOnTop;  
  
end;
```

```

procedure TForm1.FormActivate(Sender: TObject);
var
    {we can only get a DirectDraw4 interface from the DirectDraw interface, so we
    need a temporary interface}
    TempDirectDraw: IDirectDraw;
begin
    {create a temporary DirectDraw object. this is used to create the
    desired DirectDraw4 object}
    DirectDrawCreate(nil, TempDirectDraw, nil);

    try
        {we can only get a DirectDraw4 interface through the QueryInterface
        method of the DirectDraw object}
        TempDirectDraw.QueryInterface(IID_IDirectDraw4, FDirectDraw);
    finally
        {now that we have the desired DirectDraw object, the temporary DirectDraw
        object is no longer needed}
        TempDirectDraw := nil;
    end;

    {set the cooperative level}
    FDirectDraw.SetCooperativeLevel(Handle, DDSCL_FULLSCREEN or DDSCL_EXCLUSIVE);

    {set the display resolution and color depth}
    FDirectDraw.SetDisplayMode(640, 480, 8, 0, 0);
end;

```

**Note:** You'll notice that the DirectDraw initialization code has been moved to the form's OnActivate event. We've found this is a more appropriate place to put initialization code, and the examples throughout the rest of the book will expound upon the code placed in this method.

---

The result of this example is a bit surprising. The form itself was still visible, albeit in a full-screen mode, and the mouse cursor was still able to manipulate objects on the form. This is possible because the GDI is still outputting graphical images, and by default the memory area to which the GDI is rendering is still visible when the DirectDraw application sets its display mode. This can be useful when a DirectDraw application needs to start up and display an interface to the user that is easily put together using regular Delphi controls.

## Page Flipping

At this point, we can instantiate DirectDraw and adjust the display hardware's display mode, but not much else. We still can't draw anything to the screen, making any sort of animation very difficult. We need to modify our DirectDraw code so it supports the page flipping architecture discussed earlier. In order to accomplish this, we must first create a primary surface and an attached backbuffer surface.

## Creating Surfaces

We will create the primary and backbuffer surfaces simultaneously, creating what is known as a complex surface. A complex surface is one surface with a series of separate surfaces that are implicitly attached to it. These surfaces are arranged in a linear fashion. Typically, page flipping applications create only two surfaces (the primary and one backbuffer). However, some applications may need three or more.

**Note:** The primary surface and all backbuffers must reside in video memory. Thus, the number of backbuffers that can be created is dependent upon the size of the surfaces, the color depth, and the available display memory.

The primary surface is always visible to the user. Animation is accomplished by drawing any graphical output to the backbuffer surface, which is offscreen. When the next frame of animation needs to be displayed, the backbuffer surface memory and the primary surface memory change places (or flip). Only the memory referenced by these two objects change; no other attributes or other attached objects are affected. Your BackBuffer object will always point to the backbuffer surface, and your PrimarySurface object will always point to the primary surface. This is illustrated below.

**Figure 4-4:** Page flipping the primary and backbuffer surfaces

We can create the primary and backbuffer surfaces by calling the IDirectDraw4 method CreateSurface. The CreateSurface method is defined as:

```
function CreateSurface(  
  
var lpDDSurfaceDesc: TDDSurfaceDesc2; // a surface description structure  
  
var lpIddsSurface: IDirectDrawSurface4; // the IDirectDrawSurface4 object  
  
pUnkOuter: IUnknown // unused, set to nil  
  
): HRESULT; // returns a DirectX error code
```

The first parameter is a data structure that defines the type of surface we wish to create. The second parameter is a pointer to the IDirectDrawSurface4 object that is instantiated by the function. The last parameter is used for COM aggregation and should be set to nil.

The TDDSurfaceDesc2 structure is a very complex data structure as we examined above, but for the purposes of this function, we are concerned only with a few members. To begin, we should initialize all members of the surface by calling FillChar(DDSurface, SizeOf(TDDSurfaceDesc2), 0). We need to indicate that we are interested in the

capabilities and buffer count members of this structure, so we need to set its dwFlags member to DDSD\_CAPS or DDSD\_BACKBUFFERCOUNT (by ORing the values, we combine them). We then must set its ddsCaps.dwCaps member to DDSCAPS\_COMPLEX or DDSCAPS\_FLIP or DDSCAPS\_PRIMARYSURFACE. The DDSCAPS\_COMPLEX flag indicates we are creating a complex surface with implicitly attached surfaces, DDSCAPS\_FLIP indicates this will be a flipping structure, and DDSCAPS\_PRIMARYSURFACE indicates that the root surface in the flipping structure will be the primary surface. We must also set the dwBackBufferCount to indicate how many backbuffers we will need. In our case, we can set this to one. Finally, we must set the dwSize member to SizeOf(TDDSurfaceDesc2).

**Caution:** DirectX methods use lots and lots of very complex data structures. These data structures may vary from version to version, and some methods may use only specific members of any particular structure. It is imperative that any data structure with a member denoting its size must have this member initialized by calling SizeOf. Failing to perform these two requirements can lead to failed method calls.

[Previous](#) [Table of Contents](#) [Next](#)

When this method returns, the IDirectDrawSurface4 object will point to the primary surface. However, we really want to perform all of our animation on the backbuffer surface, so we must instantiate an object to point to this surface. This is accomplished through the IDirectDrawSurface4's GetAttachedSurface method. When this method is called on a complex surface with implicitly attached surfaces, it instantiates an IDirectDrawSurface4 object to point to the specified surface. The GetAttachedSurface method is defined as:

```
function GetAttachedSurface(
var lpDDSCaps: TDDSCaps2;           // surface capabilities
var lpIAttachedSurface: IDirectDrawSurface4 // a surface object
): HRESULT;                          // returns an error code
```

The first parameter is a TDDSCaps2 structure whose dwCaps member must be set to DDSCAPS\_BACKBUFFER. The second parameter is an IDirectDrawSurface4 object that will be set to point to the backbuffer surface when the function returns. This function returns the first attached surface whose capabilities match those defined in the function call. In our case, we receive a pointer to our only backbuffer surface. The TDDSCaps2 structure is defined as:

```
TDDSCaps2 = packed record
    dwCaps: DWORD;           // capabilities flags
    dwCaps2 : DWORD;        // more capability flags
    dwCaps3 : DWORD;        // yet more capability flags
    dwCaps4 : DWORD;        // still more capability flags
end;
```

The use of the CreateSurface and GetAttachedSurface functions will be demonstrated below.

## Rendering with GDI

We've created a page flipping surface structure that will demonstrate DirectDraw's animation capabilities, but unless we actually draw something to the screen, we won't be able to tell if anything is happening when we actually flip the surfaces. Let's cover a cool DirectDraw and Delphi trick that will make some tasks incredibly easy.

The IDirectDrawSurface4 object contains a method called GetDC which returns a handle to a GDI device context. This allows us to use any GDI function call to render graphics, or text, directly onto the surface. If we create a TCanvas object and set its handle to the value returned by GetDC, we can take full advantage of all TCanvas methods. This is a very powerful Delphi technique that can make graphics programming incredibly simple. The GetDC method is defined as:

```
function GetDC(  
  
var lphDC: HDC // a variable that receives the DC  
  
): HRESULT; // returns a DirectX error code
```

The only parameter to this method is a variable that will receive the device context handle for the surface.

After we are through using the device context, we must release it before performing any DirectDraw methods that work on the surface, such as flipping or copying surface memory to or from the surface in question. We accomplish this by calling the IDirectDrawSurface4 method ReleaseDC, which is defined as:

```
function ReleaseDC(  
  
hDC: Windows.HDC // a variable containing the DC to release  
  
): HRESULT; // returns a DirectX error code
```

This method's only parameter must be set to the device context handle returned from the previous call to GetDC.

**Caution:** It is absolutely imperative that every call to GetDC be matched with a call to ReleaseDC. When a device context is retrieved, the normal execution of Windows is put on hold. Therefore, any code between GetDC and ReleaseDC must execute as quickly as possible, as messages and other system events could get backed up. Also, any other DirectDraw methods that work directly on the surface must not be called until the device context has been released. Therefore, it is good practice to use a try..finally block, putting the ReleaseDC call in the Finally part to ensure that the device context is released. Otherwise, your system will crash violently.

---

Any GDI function or TCanvas method can be used for rendering graphics to a surface. Bear in mind that you will be suffering from GDI's sluggishness, but you may be able to reuse proprietary GDI graphics rendering methods and leverage your former development investments. Specifically, we'll be using these techniques to perform text output in a number of examples. We will also examine how this makes the process of loading and displaying bitmaps incredibly simple.

## Flipping the Surfaces

OK, we've created our complex flipping structure, we've drawn some text on the front and backbuffer in order to differentiate them, now we're ready for action. To actually flip the contents of the surfaces, call the Flip method of the primary surface object. The Flip method is defined as:

```
function Flip(  
lpDDSurfaceTargetOverride: IDirectDrawSurface4; // surface to flip  
dwFlags: DWORD // wait flags  
): HRESULT; // returns an error code
```

Typically, the first parameter is set to nil as the default behavior is to flip to the next buffer in the chain. However, if there is more than one backbuffer, this parameter can be set to the particular buffer in order to flip it to the screen. The last parameter is set to either zero or DDFLIP\_WAIT. If it is set to zero, the function immediately returns, regardless if the flip operation could be set up. If the DDFLIP\_WAIT flag is specified, the function does not return until the flip operation occurs. Setting this parameter to zero allows the application to perform extra processing while waiting for the display hardware to set up the flip operation. However, the Flip method must continuously be called in order to set up the flip operation. If the flip operation could not be set up, this function will return DDERR\_WASSTILLDRAWING. In most cases, it is easiest to set this parameter to DDFLIP\_WAIT, which is the flag we will use in the examples throughout this book.

## Displaying Bitmaps

The ability to draw text, or even lines and polygons, into a surface is cool, but to really create anything visually exciting, we need to be able to display bitmaps. DirectDraw, unfortunately, does not have any built-in functionality for loading a bitmap, but using GDI techniques and Delphi's TBitmap object, we can easily remedy the situation.

The most common application for loading a bitmap is to store background or sprite images off screen, which will later be copied into the primary or, most likely, the backbuffer surface. Therefore, the first order of business is to create the off-screen surface, which will hold the bitmap image. Again, we will use the CreateSurface method. However, this time we will initialize the dwFlags member of the TDDSurfaceDesc2 structure to DDSD\_CAPS or DDSD\_HEIGHT or DDSD\_WIDTH. We must then set the dwWidth and dwHeight members to the desired width and height of the surface, typically reflecting the width and height of the bitmap image. Finally, we set the ddsCaps.dwCaps member to DDSCAPS\_OFFSCREENPLAIN, indicating that this is a plain, off-screen surface. The color depth of the surface will match that of the primary surface.

**Caution:** You cannot create an off-screen surface wider than the primary surface in video memory unless the hardware specifically supports it. We cover retrieving the hardware capabilities below. However, you can create off-screen surfaces wider than the primary surface in system memory.

---

## Surface Memory Location

When creating a surface, the application can request that the memory for a surface be allocated from a specific area. This allows an application to create surfaces, and thus load bitmaps, into memory on the display hardware, or to system memory. Video memory has the advantage of being incredibly fast when copied into another surface also located on the video memory; display memory has the advantage of being directly accessed by the CPU faster than video memory. When creating a surface, the following four flags can be combined with other flags in the ddsCaps.dwCaps member of the TDDSurfaceDesc2 structure, thereby controlling where the memory for the surface is located.

**Table 4-1:** Memory location flags

Flag	Memory Location
DDSCAPS_LOCALVIDMEM	Conventional video memory. Must be combined with DDSCAPS_VIDEOMEMORY.
DDSCAPS_NONLOCALVIDMEM	Accelerated Graphics Port (AGP) display memory. Must be combined with DDSCAPS_VIDEOMEMORY.
DDSCAPS_VIDEOMEMORY	Video memory.
DDSCAPS_SYSTEMMEMORY	System memory.

**Note:** DDSCAPS\_NONLOCALVIDMEM is applicable only to AGP hardware, and only if the DirectDraw driver for that hardware supports it. You can determine if AGP is supported by DirectDraw by retrieving the hardware capabilities as discussed below.

[Previous](#) [Table of Contents](#) [Next](#)

You do not have to indicate a memory location for surfaces. By default, surfaces will be created in video memory. When video memory is depleted, or a surface is too big to fit into what's left, it is automatically created in system memory. However, if a location is specified in the CreateSurface call and there is not enough memory, it will fail.

### **Loading and Displaying the Bitmap**

Actually loading the bitmap is quite easy. We simply create a TBitmap object and use its LoadFromFile method to pull the bitmap into memory. Of course, we must still somehow copy the bitmap into our off-screen surface. This is where the previous information about GDI comes in. Using GDI, we can retrieve a device context for our off-screen surface and use the GDI BitBlt function to copy the bitmap into the surface itself. Alternatively, we can create another TCanvas object, assign the surface's device context to the TCanvas's handle, and use the TCanvas.Draw method to copy the bitmap into the surface. With that accomplished, we can release the surface's device context and destroy the TBitmap object. This is illustrated in Listing 4-5.

### **Blitting Surfaces**

OK, now that the bitmap has been loaded into our off-screen surface, which should be located in display memory if there was enough room, we need to copy it from the off-screen surface onto our primary surface for display. Usually we would copy it into the backbuffer surface as part of our animation rendering engine, but for this example, we will simply copy it directly to the primary surface.

To copy one portion of a surface into another surface, we use the IDirectDrawSurface4's BltFast method. The BltFast method is defined as:

```
function BltFast(  
  
    dwX: DWORD; // the destination horizontal coordinate  
  
    dwY: DWORD; // the destination vertical coordinate  
  
    lpDDSrcSurface: IDirectDrawSurface4; // the source surface  
  
    var lpSrcRect: TRect; // the rectangular area on the source  
  
    dwTrans: DWORD // transfer flags
```

```
) : HRESULT; // returns a DirectX error code
```

The first two parameters determine the horizontal and vertical coordinates where the source surface area will be copied onto the destination surface. The third parameter is a pointer to the source surface, and the fourth parameter defines the rectangular area in the source surface that is to be copied onto the destination surface. The last parameter contains a series of flags that control certain aspects about the transfer. In particular, the `DDBLTFAST_WAIT` flag can be specified to indicate that the function should not return until the copying has been accomplished. Other flags indicate transparency options, but these will be covered in the chapter on sprite techniques.

If the resulting bitmap looks somewhat corrupted, don't worry. Our current example makes no use of palettes, and thus the resulting appearance of the bitmap will be at the mercy of the current contents of the system palette. We will examine palettes at length in the next chapter.

**Lost Surfaces**

DirectX applications, even under exclusive, full-screen mode, must still coexist gracefully with other Windows applications. This means that users are free to Alt+Tab into and out of a DirectX application into other Windows applications. When a full-screen DirectX application is Alt+Tabbed out of, it is automatically minimized by DirectDraw, and the GDI resumes normal output in the original display mode. This has serious implications for surfaces located in display memory. When the GDI takes over in a situation like this, all display memory is reallocated to the GDI itself, thus wiping out anything stored in a surface located in display memory. When the DirectDraw application is returned to, any methods that manipulate display memory surfaces are likely to return a DDERR\_SURFACELOST error.

When this error is detected, it is a simple matter to restore the surface's memory. Simply call the Restore method of the IDirectDrawSurface4 object in question. The Restore method is defined as:

```
function Restore: HRESULT; // returns a DirectX error code
```

This will restore the memory allocated for that surface, and further methods that manipulate that surface will no longer fail until the surface's memory is lost again. However, the contents of that surface may be undefined, and must be restored. Thus, your application should contain a function that initializes the contents of all surfaces that can be called again and again in the event that surface memory is lost.

**Note:** This only applies to surfaces stored in video memory; system memory surfaces and their content will never be lost. You will need to restore the primary surface memory, which in turn implicitly restores the memory of all attached surfaces (such as the backbuffer).

**Retrieving DirectDraw Capabilities**

DirectX was written so that a developer can take advantage of certain hardware features if they are available, such as overlays or the ability to create off-screen surfaces wider than the primary surface. We can determine what features are available by calling the IDirectDraw4's GetCaps method. The GetCaps method is defined as:

```

function GetCaps(
var lpDDDDriverCaps: TDDCaps;           // hardware capabilities
var lpDDHELCaps: TDDCaps                // emulated capabilities
): HRESULT;                             // returns a DirectX error code

```

The first parameter returns a TDDCaps structure outlining the capabilities supported by the hardware itself, and the second parameter returns a similar structure detailing capabilities that are emulated. The hardware capabilities will vary depending on the available hardware, but the emulated capabilities will remain the same regardless of the hardware (but dependent on the version of DirectDraw installed). These structures are huge, and contain just about anything the developer or application would need to know about available features. The following example illustrates how the members of the individual structures are queried to determine the existence of a particular feature.

***Listing 4-6: Retrieving DirectDraw capabilities***

---

```

procedure TForm1.FormCreate(Sender: TObject);
var
    {we can only get a DirectDraw4 interface from the DirectDraw interface, so we
    need a temporary interface}
    TempDirectDraw: IDirectDraw;

    {hardware and emulated capability structures}
    HALCaps, HELCaps: TDDCaps;
begin
    {create a temporary DirectDraw object. this is used to create the
    desired DirectDraw4 object}
    DirectDrawCreate(nil, TempDirectDraw, nil);
    try
        {we can only get a DirectDraw2 interface through the QueryInterface
        method of the DirectDraw object}
        TempDirectDraw.QueryInterface(IID_IDirectDraw4, FDirectDraw);
    finally
        {now that we have the desired DirectDraw object, the temporary DirectDraw
        object is no longer needed}
        TempDirectDraw := nil;
    end;

## The DirectX Baseline Application

In an effort to expedite the creation of DirectX applications, this book contains a baseline DirectX application that instantiates DirectDraw, sets up a page flipping architecture, and implements a high-speed rendering loop that can attain the highest animation speed possible. This is implemented by providing an event handler for the TApplication's OnIdle event. The OnIdle event is called whenever the application becomes idle; if the Done parameter of this method is set to False, this event will continuously be called by the application, providing a perfect spot for a rendering loop. There are stubbed out methods for drawing surface content and restoring surface content in the event that it is lost. A number of constants are defined at the top of the main unit that control the display resolution and color depth, as well as the cooperative level and the flags for the complex flipping surface. The indicated display resolution and color depth is checked to see if it is supported before setting the display mode. It will also shut off the rendering loop automatically when the application is Alt+Tabbed out of, and restart it when Alt+Tabbed back into. Theoretically, all one must do is load off-screen surfaces in the area indicated in the Activate method, flesh out the RestoreSurfaces method to restore any off-screen surface memory, and complete the DrawSurfaces method to render animation to the backbuffer surface. The act of flipping the surfaces is carried out by the rest of the application. The Escape key will exit the application and return to Windows.

Bear in mind that this is a general architecture meant to assist the reader in quickly getting a DirectX application up and running. It also provides a standardized framework from which every other example throughout the rest of this book will be based, cutting down on the amount of code that must be illustrated in example listings. This is not the best architecture for every game. Indeed, you may need to alter it dramatically depending on the requirements of your application. However, the baseline application tries to be as unimposing as possible, taking care of standard functionality while providing plenty of room for application-specific logic. What follows is a complete listing of the baseline application. Future examples will be based on this application, and thus will not contain any of the code for initializing DirectDraw; code listings will only contain code pertinent to the current discussion. This baseline application will run as is, but the output will be a black screen. However, it is a simple task to implement code in the DrawSurfaces method that will output animation to the screen, and we will see many examples of this in the coming chapters.

Skeleton DirectDraw Application

Author: John Ayres

This is a bare bones DirectDraw application that creates a primary surface with one backbuffer and implements a continuous flip between them. It contains some minimal error checking code as well as an application exception handling routine that flips back to the GDI surface so that exception messages can be seen. The Application.OnIdle event is used to implement the loop that flips the surfaces. This uses a large chunk of CPU time (which is ok in a game), but could potentially be replaced with a While..Do loop or some other looping architecture.

This baseline code is used throughout the book as a starting point for examples. It was designed to be easily extensible, and should provide all of the initialization and startup code that you will need for your own DirectX applications.

## DirectX Result Codes

Just about every DirectX function and method returns an HRESULT, a 32-bit number that maps to a DirectX error code. There are hundreds of error codes, all of which are located in the DDRAW unit. These codes can be translated into a textual form by calling the DXErrorString function located in the DXTools unit. The DXTools unit also contains a procedure called DXCheck that will raise an exception if a DirectX function returns any error code other than DD\_OK.

In theory, every call to any DirectX method should be wrapped with this DXCheck function. In practice, this may be impractical, but you should always check the results of any extremely critical methods, such as blits, flips, and initialization code. Methods such as these can cause an application to waltz off into limbo if they fail and are not gracefully handled, so checking the result code is very important for a robust application.

The DXErrorString function can be incredibly useful when debugging a DirectX application. The result of this function could be written out to a disk-based text file, and later examined if the DirectX application crashes. This tends to happen often when developing DirectX applications, and due to the fact that you cannot step through your code or use any of Delphi's awesome debugging features, this is a useful, if sloppy, debugging technique.

## Retrieving the DirectX Version

Most commercial DirectX applications ship with a version of the DirectX run-time redistributables. The developer knows that the application will be using either the version installed with the application or a more recent version installed by other applications or the operating system. However, sometimes it is necessary to determine which version of DirectX is installed before initializing objects, particularly if the application is to be distributed without the DirectX run-time redistributables, such as on floppy or over the Internet.

Specifically, you should not be checking for an overall DirectX version, but instead you should check for the availability of specific interfaces. As we've seen, the QueryInterface method implemented in every COM object can determine if a specific interface is supported. Using this method, you can determine if certain features are supported on the target machine. For example, if the IDirectDraw4 interface is not available, you know that you're working with a version of DirectDraw older than 6. By querying for other interfaces, you

can determine if 3-D sound or force feedback devices are supported. Using the QueryInterface method is much more reliable than checking the drive for the existence and time stamp of particular files.

Additionally, DirectSetup features a method for retrieving the current version of DirectX that is installed on the machine. See Appendix A for complete information about DirectSetup and how to retrieve the current version of DirectX.

## Summary

In this chapter, we discussed several DirectX and DirectDraw topics. The examples built from initializing DirectDraw all the way to implementing a general page flipping architecture and displaying bitmaps. DirectX programming in general is a very complex topic, filled with many nuances with which the developer must become familiar. We covered DirectDraw programming to a minor degree in order to illustrate this point, and as a foundation upon which the rest of the book's knowledge will be built. When coding a DirectX application, and using DirectDraw in particular, it is important to keep these points in mind:

- The DirectX development team's goal was to create a low-level architecture that would provide developers with the hardware control they need at the speed they demanded, while still retaining Windows' device-independent benefits. This was to be accomplished without imposing a restrictive high-level design architecture. Therefore, DirectX promises three things to developers: fast execution, minimal style restraints, and a level of abstraction that will provide benefits from future hardware.
- DirectX delivers exceptionally on all of its promises, and offers many benefits, such as speed, control, and feature emulation. However, DirectX programming has a number of drawbacks, such as difficult debugging, few Delphi-specific examples, and a steep learning curve. The developer must determine if the benefits and advantages offered by DirectX outweigh the drawbacks and disadvantages for the specific functionality required by the application.
- The DirectX API itself, in the form of various COM objects and their methods, acts as an interface into the DirectX drivers. On the back side, the DirectX drivers can be thought of as two separate systems: the hardware abstraction layer (HAL) and the hardware emulation layer (HEL). The HAL represents the hardware itself. The HEL, on the other hand, represents the software emulation of certain features. It is important to note that, for the most part, this is completely transparent to developers.
- DirectX is comprised of many components. While the inventive game developer could potentially make use of all of these components, there are only a few which are essential for game development: DirectDraw, DirectSound, and DirectInput. Other components that may be useful in a particular game include DirectPlay, DirectSetup, Direct3D, and DirectMusic.
- Under Delphi, you do not necessarily need the DirectX SDK; you only need the DirectX redistributables that are installed with the DirectX SDK or almost any commercially available game. However, the DirectX SDK includes a number of debugging and control panel utilities that can be useful, and is the only source for the DirectX API documentation. In this book, we use the DirectX headers from the JEDI project, translated by Erik Unger. However, there are several other commercial and shareware/freeware DirectX components and headers that can dramatically decrease the production time for a DirectX project under Delphi.

- DirectX objects are COM based, consequently involving all of the associated benefits and drawbacks of using COM objects. Working with DirectX objects has some similarities to working with other COM objects, but there are a few differences. The primary difference is the fact that DirectX objects do not need to be created by using the CoCreateInstance function. All DirectX objects are created through custom function calls that return an instantiated COM object. A COM object can almost be thought of as a VCL object with no properties, only methods. The methods of a COM object are known as an interface. A COM object can have more than one interface, and it can be extended by added new interfaces, similar to deriving a new component from an ancestor. However, the COM standard dictates that an interface can never change. COM objects determine when they can destroy themselves, and thus do not need to be freed by the creating application. A unique identifier called a GUID is used to distinguish individual COM objects.
- Perhaps the single most important concept in DirectDraw programming is that of the surface. A surface is directly analogous to Delphi's TBitmap or TCanvas object. It represents a virtual "picture" upon which graphical output can be drawn. In reality, a surface is a linear chunk of memory that is managed as if it were rectangular. Surfaces have width and height, among many other properties. The memory for a surface can be located in a number of places, but primarily it will be found in system memory or in the memory on the display card itself. There are many different types of surfaces, some of which are very specialized for a particular purpose. For the purposes of this book, we will be concerned with only three different types: the primary surface, the backbuffer surface, and off-screen surfaces.
- Page flipping is an incredibly powerful technique for producing flicker-free animation. The term "page flipping" comes from the inspiration for this animation technique, that of traditional cartoon animation. Cartoons (and movies, for that matter) create the illusion of animation by displaying to the viewer a series of images, one after the other. Someone can create a crude animation by taking a stack of paper, drawing an image on each page, and then flipping through it rapidly. This is the architecture of page flipping animation. The idea is to create two surfaces, the primary surface and the backbuffer surface. The next frame of animation is composed on the backbuffer surface, and then it is "flipped" to the display screen. This updates the entire display screen in one fell swoop, resulting in a flickerless animation.
- There are several tasks an application is required to perform before DirectDraw can be instantiated and the display mode modified. Some of these tasks are optional, some are not. The application may want to enumerate all attached display devices, although this is not specifically required. After the user picks an enumerated display device, or if the application simply decides to go with the primary

display device, the DirectDraw object can be created. Supported display modes can then be enumerated; while not specifically required, the display mode into which the display hardware is switched must be a supported mode, which can be verified by enumerating supported display modes. The cooperative level can then be set, determining if the application will run full screen or windowed. Finally, setting the display mode causes the hardware to switch over to the indicated resolution and color depth. Bear in mind that certain requirements are imposed on the main window before the display mode can be set properly.

- A device context handle can be retrieved from a surface, allowing the application to use GDI rendering functions. When combined with a TCanvas object, the full power of Delphi's built-in graphical rendering functionality can be brought to bear. However, the sluggishness of the GDI will also be present. It is very important that any device contexts retrieved be released before performing any DirectDraw functions that manipulate the surface.
- Bitmaps can be easily loaded and stored into a surface by using the TBitmap object combined with the drawing capabilities of a TCanvas object and a device context retrieved from a surface.
- The memory associated with surfaces located in display memory can be lost if the user Alt+Tabs out of the application. When the DirectDraw application receives focus again, it must call the Restore method of any display memory surfaces, including the primary surface. Their contents will be undefined, so they must be reinitialized by reloading bitmaps or redrawing graphics.
- DirectX was written so that a developer can take advantage of certain hardware features if they are available, such as overlays or the ability to create off-screen surfaces wider than the primary surface. We can determine what features are available by calling the IDirectDraw4's GetCaps method.
- Just about every DirectX function and method returns an HRESULT, a 32-bit number that maps to a DirectX error code. There are hundreds of error codes, all of which are located in the DDraw unit. These codes can be translated into a textual form by calling the DXErrorString function located in the DXTools unit. You should always check the results of any extremely critical methods, such as blits, flips, and initialization code. Methods such as these can cause an application to waltz off into limbo if they fail and are not gracefully handled, so checking the result code is very important for a robust application.
- Sometimes it is necessary to determine which version of DirectX is installed before initializing objects, particularly if the application is to be distributed without the DirectX run-time redistributables, such as on floppy or over the Internet. Specifically, you should not be checking for an overall DirectX version, but instead you should check for the availability of specific interfaces. The QueryInterface method implemented in every COM object can determine if a specific interface is supported.

## CHAPTER 5 Palettes

This chapter covers the following topics:

- The definition of a color palette
- The creation and use of the IDirectDrawPalette object
- Palette animation

Game programmers tend to have mixed feelings about palettized display modes. On one hand, you've got special animation effects and superior performance benefiting you from using a palettized display mode. On the other hand, you've got graphic resource management nightmares, an extra layer of indirection and complexity, and a limited resource in the form of color. With the increasing speed of today's hardware, someday the performance boost available with palettized display modes will not outweigh the benefits of using 16-bit or 32-bit color modes. However, at this point, creating games in a 256-color palettized display mode still has many advantages over the higher color depth modes. Since this book discusses techniques for game and graphics programming under 256 video modes, we should examine how DirectX handles color palettes in a little more depth.

In this chapter, we will examine how palettes are supported under DirectDraw in full-screen exclusive mode. We covered color depth and palettes back in Chapter 3, Basic Graphics Programming, and palettes still work very much the same way under DirectX. For the sake of completeness (in case you skipped Chapter 3), we'll briefly examine what a color palette is and how it works. Then we'll dive right into creating DirectDraw palettes, how they are used, and some special effects you can accomplish with them. If you read the basic graphics programming chapter, skip ahead to the section on the IDirectDrawPalette object.

### What is a Palette?

A color palette is a mechanism by which a potentially large range of colors can be displayed without using enormous amounts of memory. Four and eight bits-per-pixel color depths are the only palettized video modes. As 4 bits-per-pixel color depths are no longer used for games, we will discuss only 8 bits-per-pixel color depths. At 8 bits-per-pixel, each pixel can assume a value between 0 and 255. These values act as an index into what can be considered a 256-entry array known as the color palette. Now, each entry in this array contains an 8-bit value for the blue, green, and red intensity of a color. In effect, this gives 8 bits-per-pixel color depths access to 16,777,216 potential colors, but only 256 of them can be shown at one time. When a bitmap is displayed, the video hardware

looks at the 8-bit pixel value, and using that value as an index into the 256-entry color table, it draws a pixel using the red, green, and blue intensities stored in the indicated color table entry.

**Figure 5-1:** An 8 bits-per-pixel bitmap's pixels act as indices into a color palette

There are many things to consider when working with 8 bits-per-pixel color modes. A major disadvantage to this mode is that all bitmaps to be displayed simultaneously must be drawn using the same palette. This requires a lot of careful planning on the part of art production, and can limit the creativity of artists and the variety of artwork that can be displayed on screen. Bitmaps that are drawn using one palette but displayed on a device in which a different palette is currently being used will have unpredictable results. A bitmap's pixels could be mapped to the closest approximation of the appropriate color in the current palette, but this process is slow, usually produces inadequate results, and is not appropriate for fast action games. Different palettes can be used between scenes, however, which can reduce this effect.

However, 8 bits-per-pixel video modes give the greatest speed advantage, and a tremendous number of colors can potentially be used while taking up the least amount of RAM. Up to four pixels can be moved simultaneously by using 32-bit memory movement instructions, allowing bitmaps to be moved about at blindingly fast speeds. Another major advantage comes from palette animation. If colors within the palette are moved about, or cycled, every pixel drawn using that color is affected simultaneously and automatically. This can be used for various special effects, such as flowing water or lighting. Palette animation is not available under non-paletted video modes. Since this book is concerned with high-performance games and graphics programming, all examples will use only 8 bits-per-pixel video modes in order to squeeze out as much speed as possible.

## The IDirectDrawPalette Object

Using DirectDraw, an application has direct access to the display card's hardware palette registers. In order to set the palette entries of the display hardware, the developer must use the IDirectDrawPalette object. Of all the DirectX objects, the palette object is perhaps the easiest to manipulate and use. It has only a few methods, and using the object is very straightforward.

### Creating the Palette Object

The CreatePalette method of the IDirectDraw object is called to actually create the IDirectDrawPalette object. This simple function takes only a few parameters, and is declared as:

```
function CreatePalette (  
  
    dwFlags: DWORD;                // control flags  
  
    lpColorTable: pointer;         // a pointer to an array of  
                                   // TPaletteEntry structures  
  
    var lplpDDPalette: IDirectDrawPalette; // a pointer to the new  
                                           // IDirectDrawPalette object  
  
    pUnkOuter: IUnknown           // COM aggregation  
  
): HRESULT;                       // returns an error code
```

The first parameter takes a series of constants that can be combined using the OR boolean operator to indicate the type of palette being created and some of its capabilities. In particular, 2-, 4-, 16-, or 256-entry palettes can be created by specifying the appropriate flags. Since we're primarily interested in 256-color display modes, we'll use the DDPCAPS\_8BIT flag to indicate that we want 256 entries in the palette. The third parameter takes a pointer to a variable of type IDirectDrawPalette that will hold the instantiated palette object when this function

returns. The final parameter will be used in the future for COM aggregation. For now, we'll always set this parameter to nil.

The second parameter is really the heart of this function. It is a pointer to an array of palette entry structures that contain the colors used to initialize the palette. In our case, this will be an array of 256 entries. These structures are of type TTrueColor, and are defined as:

```
TTrueColor = record  
  
    case integer of  
  
        1 : (Data : DWORD);           // the color as a 32-bit value  
  
        2 : (R,G,B,A : byte);        // red, green, blue, and alpha intensities  
  
    end;
```

This structure contains members for the red, green, and blue components of a color, defining a 24-bit RGB color value. The final member is useful only under windowed DirectX and with Direct3D, so we will not be concerned with it.

*Note* Incidentally, the TPaletteEntry data structure type could also be used. It is defined somewhat differently, but it is the same size as this structure, and its members map to the same members of the TTrueColor structure.

**Defining Palette Colors**

It would be easy enough for an application to programmatically define all of the colors in the palette. We could simply iterate through all entries in the color table array, setting the red, green, and blue values as necessary to create the desired palette. While this is certainly a workable approach, and is desirable in the case where a custom color gradient effect needs to be achieved, most often an application's palette needs to be initialized with the colors used in a bitmap.

Fortunately for us, we're using Delphi, which makes this whole problem incredibly easy to solve. To start, we'll need to create a TBitmap object, and use it to load in the bitmap whose palette we wish to use. Then, we'll use the GDI function GetPaletteEntries to retrieve all of the bitmap's palette entries. The GetPaletteEntries function is defined as:

```
GetPaletteEntries(  
  
    Palette: HPALETTE;           // a handle to a logical palette  
  
    StartIndex: UINT;           // the starting palette index  
  
    NumEntries: UINT;           // the number of palette entries to retrieve  
  
    PaletteEntries: Pointer      // a pointer to an array of TPaletteEntry structures  
  
): UINT;                       // returns the number of palette entries retrieved
```

The first parameter takes a handle to a logical palette, which we can simply set to the Palette property of the TBitmap object we've just created. The second parameter indicates the index of the first palette slot we would like to retrieve. The third parameter indicates the number of palette slots to retrieve. The final parameter is a pointer to an array of TPaletteEntry structures which will receive the palette data.

The cool thing here is that we can pass this function the same array of TTrueColor structures that we'll use in the call to CreatePalette. The entire procedure only takes a few lines of code, and looks something like this:

```
var
```

```

Palette: array[0..255] of TTrueColor;

DDPalette: IDirectDrawPalette;

TempBitmap: TBitmap;

begin

    the temporary bitmap

    TempBitmap := TBitmap.Create;

    try

        the bitmap, and extract its palette

        TempBitmap.LoadFromFile(c:\somebitmap.bmp');

        GetPaletteEntries(TempBitmap.Palette, 0, 256, Palette);

        the palette object

        DDraw.CreatePalette(DDPCAPS_8BIT, @Palette, DDPalette, nil);

    finally

        TempBitmap.Free;

    end;

end;

```

This creates an `IDirectDrawPalette` object that is initialized with the palette stored in the specified bitmap. We've encapsulated this functionality in the `DDUtil` unit on the companion CD in the function `DDLloadPalette`. You can simply call this function, passing it a pointer to the `DirectDraw` object and the path and filename of the bitmap whose palette you wish to use, and it returns an instantiated `IDirectDrawPalette` object. This makes palette creation and initialization a one-line function call.

---

**Caution:** By default, only 254 palette entries in an 8-bit palette can be used. `DirectDraw` predefines palette slot 0 as black and palette slot 255 as white. You can use all 256 entries by specifying the `DDPCAPS_ALLOW256` flag in the first parameter of the call to `CreatePalette`. However, some video cards use palette slot 0 to define the overscan color, the color of the area around the usable display area. Some versions of Windows NT won't allow this slot to be changed at all. Changing palette slot 0 may cause some unpredictable effects on some video cards, so don't use the `DDPCAPS_ALLOW256` flag unless absolutely necessary.

---

**overscan:** The area on a monitor that borders the usable display area.

## Using the Palette Object

Actually using a palette object is almost as simple as creating one. We use the `SetPalette` method of the `IDirectDrawSurface4` object to associate a palette with a palettized surface. When a palette is associated with a surface, its color table is inserted into the hardware color registers, instantly changing the color of any displayed pixels. The only parameter this function takes is a pointer to the `IDirectDrawPalette` object that was created earlier. The `SetPalette` method is defined as:

```
function SetPalette (  
  
    lpDDPalette: IDirectDrawPalette      // a pointer to an IDirectDrawPalette object  
  
): HRESULT;                             // returns a DirectX error code
```

The only parameter to this method is a pointer to the IDirectDrawPalette object we've created. Only the palette associated with the primary surface will affect the actual hardware palette registers. Thus, you must attach the newly created palette to the primary surface before the new colors take effect. Palettes can actually be attached to any palettized surface, and the same palette can be attached to more than one surface, but only the palette attached to the primary surface will actually affect the display.

---

**Note:** If a surface becomes lost and must be restored, any attached palettes are unaffected, and do not need to be reconnected after a surface is restored. Additionally, palettes do not move when surfaces are flipped, so it is unnecessary to attach palettes to both a primary surface and backbuffer.

---

If an IDirectDrawPalette object is not attached to the primary surface, the current entries in the hardware palette (left over from the last application) will be used. This usually results in bitmaps and graphics that appear garbled or corrupted. Therefore, unless your graphics will only be using the standard 20 Windows colors (left in the palette if the last application ran was a regular Windows application), you should always instantiate and attach a new palette object to the primary surface.

The following examples illustrate what happens when a bitmap is displayed with and without associating a palette with the primary surface. When an IDirectDrawPalette object is created, initialized with the bitmap's palette, and associated with the primary surface, the displayed bitmap appears as it did when it was created. In the second example, the bitmap is shown without associating any sort of palette with the primary surface. The results will be unpredictable, and will depend largely upon whatever application last modified the palette registers.

## Disconnecting Palettes

You can disconnect any palette from a surface by simply calling the `SetPalette` method again with a parameter of `nil`. However, you can directly attach a new palette to a surface without disconnecting any current palette first. When a palette is connected to a surface, its reference count is incremented by one. Attaching the same palette to other surfaces increases the reference count, but attaching the same palette to the same surface again does not increase it.

## Palettes and GDI Functions

When mixing GDI functions with DirectX, GDI functions will use whatever palette is attached to the primary surface at the time the function is called. We must be cautious, since the functions we have examined that load a bitmap into a surface take advantage of the `TBitmap` object, which ultimately uses GDI functions for drawing the bitmap. If there is not currently a palette attached to the primary surface, the current hardware palette will be used. By default, GDI will remap bitmap bits to the closest matching colors available when the bitmap is copied to a surface's DC. Sometimes, the results are acceptable. However, if you subsequently attempt to attach a palette to the primary surface, the bitmap bits will have been translated by GDI and will not match up with the palette entries, resulting in visual garbage. When loading bitmaps using surface DCs and the `TBitmap` object, always load and attach the bitmap's palette to the primary surface first.

---

**Note:** Unlike graphics programming under GDI, there is no color conversion performed when blitting a bitmap from one surface to another. All pixels will be interpreted in terms of the destination surface's palette. Therefore, you need only attach a palette object to the primary surface.

---

## Palette Animation

Apart from the blitting speed benefits realized from having only 8 bits per pixel, palette animation is another great benefit of palettized display modes. Palette animation is a cheap yet powerful method for achieving effects that would be very slow under higher video modes. Animations such as running water and fades are easily implemented using palette animation; the same trick would require constant blitting under non-palettized video modes. We'll examine a cool text effect achievable through palette animation, as well as a generic screen transition where a bitmap fades in and out.

### Animating the Palette

Palette animation works by replacing the color value of a specific color table entry with another value. This instantly changes the color of any pixel drawn using that color table entry to the new color. There are two methods of accomplishing this. The first method requires the creating of multiple palette objects. Each palette object contains different color values in the specific color table entries to be animated. To achieve the animation, you simply call the `SetPalette` method of the primary surface in a continuous loop, changing the palette object used each time. While this will work, it essentially changes all 256 color registers each time, thus making it somewhat slow. It is uncommon to change all 256 color registers during each iteration of a palette animation, so this method is not recommended.

The second method is a more practical solution in that it is generally faster and doesn't waste as many resources as multiple palette objects would. It takes advantage of two methods of the `IDirectDrawPalette` object: the `GetEntries` and the `SetEntries` methods. The `GetEntries` method is defined as:

```
function GetEntries (  
  
    dwFlags: DWORD;           // not currently used, set to 0  
  
    dwBase: DWORD;           // the starting entry  
  
    dwNumEntries: DWORD;     // the number of entries to retrieve  
  
    lpEntries: pointer       // a pointer to an array of TPaletteEntry structures  
  
): HRESULT;
```

This function fills the array of TPaletteEntry structures specified in the fourth parameter with the color values of the palette's entries, starting from the entry specified in the second parameter. We can modify these color values as necessary, and then place them back into the palette using the SetEntries method, which is defined as:

```
function SetEntries (  
  
dwFlags: DWORD;           // not currently used, set to 0  
  
dwStartingEntry: DWORD;   // the starting entry  
  
dwCount: DWORD;          // the number of entries to set  
  
lpEntries: pointer        // a pointer to an array of TPaletteEntry structures  
  
): HRESULT;              // returns an error code
```

**Delphi Graphics and Game Programming Exposed with DirectX 7.0**

by *John Ayres*

Wordware Publishing, Inc.

ISBN: 1556226373 Pub Date: 12/01/99

**Search this book:**

[Previous](#) [Table of Contents](#) [Next](#)

This function simply sets the color values in the palette to those specified in the array of TPaletteEntry structures specified in the fourth parameter, starting from the entry specified in the second parameter. When this action is performed on a palette attached to the primary surface, the colors of pixels drawn using these palette entries are immediately changed, and palette animation has occurred.

---

**Note:** When using this method to change a range of color entries, it is faster to change several entries that are adjacent (i.e., entries 5, 6, 7, 8, 9), as opposed to changing non-contiguous color entries (i.e., 13, 57, 73, 109).

---

It would be easy to demonstrate this technique by filling the screen with a color, say palette slot 5, and then using GetEntries and SetEntries in a loop to continuously change the color in entry 5. Similarly, if displaying a bitmap with a lot of pixels drawn using palette slot 5, this technique could change all of those pixels instantly. This could be useful for creating several variations of a monster using only one bitmap. In level one, the monster could be blue, but in level two, you can change the color table entry to red, and using the same bitmap, display a red version of the monster, perhaps indicating that it is a little tougher.

To demonstrate the technique of palette animation, we're going to do something a little more ambitious. Since the GetEntries and SetEntries methods allow us to change a range of color entries, it would be cool if we could draw a bitmap using a color gradient, and then rotate those color entries so the gradient appears to move. Using this technique is also a good way to implement moving water effects.

We start by loading our bitmap in and displaying it. Then, in our main animation loop, we use GetEntries to retrieve the range of color values to be modified. We then save the value in the last entry, slide all the other entries up one, and place the saved entry in the first spot. This rotates the color entries as illustrated in Figure 5-2.

**Figure 5-2:** Rotating color entries

We then place the modified entries back into the palette by calling `SetEntries`. The bitmap used in this example is simply the words “Delphi Rocks” drawn using a red gradient. Rotating the palette entries using this technique makes the gradient appear to move, and results in a very cool text animation effect. Listing 5-3 shows the heart of the example code that performs the actual palette animation.

*Listing 5-3: Animating a palette*

---

```
procedure TfrmDXAppMain.DrawSurfaces;
var
    {our palette slots to be modified}
    Entries: array[0..29] of TTrueColor;

    {a temporary palette slot holder}
    Temp: TTrueColor;

    {loop variable}
    iCount: Integer;
begin
    {retrieve the range of palette entries to be animated}
    FPalette.GetEntries(0, 9, 30, @Entries);

    {rotate the color entries up one, moving the last palette
    slot into the first slot}
    Temp := Entries[29];
    for iCount := 29 downto 1 do
        Entries[iCount] := Entries[iCount-1];
    Entries[0] := Temp;

    {place the rotated entries into the palette. this will cause
    the colors in the displayed image to change, creating the illusion
    of movement}
```

```
FPalette.SetEntries(0, 9, 30, @Entries);
```

```
end;
```

---

## Screen Transitions

As another use for palette animation, let's examine a very clean, professional screen transition effect known as the fade. A fade is a cinematic effect where an image slowly appears from a solid color, such as black or white.

**fade:** A transition effect where an image slowly appears out of a solid color, such as black or white.

Unlike the previous technique, we'll be performing palette animation on all 256 entries in the palette so that the entire image is affected (however, you could use only a subset of the entries in the palette to fade only portions of the image, but that's beyond the scope of this exercise). We must start by retrieving the entire color table into a permanent array that will hold all of the color's original values. The trick to this technique is in setting the values of a "work" array to a percentage of the values stored in the permanent, or "original colors" array, and then setting the palette's colors to the work array's values. We could simply change the red, green, and blue color components by a constant value, but that would make some colors fade in and out faster than others, causing the image to appear to change as it fades in or out. By setting the individual color elements as a percentage of the original value for that entry, we achieve a smooth transition effect. To fade in from black, the work array values are started at zero, and then gradually increased until they reach the original values. Fading out just reverses the procedure. Listing 5-4 demonstrates the heart of this technique.

**Tip:** Most games require a standardized palette such that all graphics are based on the same palette. If you are creating a game that features many different screens, you could create all backgrounds and artwork with individual palettes for each screen. Then, you could use the fade in/out screen transition and change the palette based on the new screen. This would allow you to use multiple palettes in a game, providing for a richer depth of color.

**Listing 5-4: Performing screen transitions**

```
procedure TfrmDXAppMain.FadeEffect(FadeIn: Boolean);  
  
const  
  
    STEPS = 100;    // we want 100 fade steps  
  
var  
  
    iCount, iCount2: Integer;  
  
begin  
  
    {if we are fading in from black...}  
  
    if FadeIn then  
  
    begin  
  
        for iCount := 0 to STEPS do  
  
        begin  
  
            {modify the work' palette to a percentage of each original palette's
```

```

        color value, based on our current step}

for iCount2 := 0 to 255 do
begin
    AnimPalette[iCount2].R := Trunc(OrgPalette[iCount2].R*(iCount/STEPS));
    AnimPalette[iCount2].G := Trunc(OrgPalette[iCount2].G*(iCount/STEPS));
    AnimPalette[iCount2].B := Trunc(OrgPalette[iCount2].B*(iCount/STEPS));
    AnimPalette[iCount2].A := 0;
end;

{plug the palette into the hardware, causing the colors to take effect}
FPalette.SetEntries(0, 0, 256, @AnimPalette);

        for iCount2 := 0 to 255 do
        begin
            AnimPalette[iCount2].R := OrgPalette[iCount2].R-
                Trunc(OrgPalette[iCount2].R*(iCount/STEPS));
            AnimPalette[iCount2].G := OrgPalette[iCount2].G-
                Trunc(OrgPalette[iCount2].G*(iCount/STEPS));
            AnimPalette[iCount2].B := OrgPalette[iCount2].B-

```

```

Trunc(OrgPalette[iCount2].B*(iCount/STEPS));

AnimPalette[iCount2].A := 0;

end;

{plug the palette into the hardware, causing the colors to take effect}

FPalette.SetEntries(0, 0, 256, @AnimPalette);

{pause for a fraction of a second}

Sleep(10);

end;

end;

end;

```

---

## Summary

In this chapter, we discussed how the `IDirectDrawPalette` object provides an application with hardware palette management functionality within an exclusive, full-screen `DirectDraw` environment. Keep these points in mind when programmatically manipulating the hardware palette:

- The hardware palette is only used under palettized display modes. Thus, you will only be concerned with the palette when creating 256-color games.
- Palettes give us access to a large range of colors while keeping memory requirements to a minimum. This also improves application performance as moving pixels between surfaces is very efficient. Under palettized display modes, we also have access to palette animation, which makes certain special effects easy to implement.
- The colors in the palette could be defined programmatically, but typically they are initialized from the palette of a bitmap containing graphics used in the game.
- By default, only 254 palette entries can be used. `DirectDraw` predefines palette slot 0 as black and palette slot 255 as white. You can use all 256 entries by specifying the `DDPCAPS_ALLOW256` flag in the first parameter of the call to `CreatePalette`. However, bear in mind that some video cards use palette slot 0 to define the overscan color, the color of the area around the usable display area.
- If a surface becomes lost and must be restored, any attached palettes are unaffected, and do not need to be reconnected after a surface is restored.
- Palettes do not move when surfaces are flipped, so it is unnecessary to attach palettes to both a primary surface and backbuffer.
- Only the palette associated with the primary surface will affect the actual hardware palette registers. Thus, you must attach the newly created palette to the primary surface before the new colors take effect. Palettes can actually be attached to any palettized surface, and the same palette can be attached to more than one surface, but only the palette attached to the primary surface will actually affect the display. If a palette is not attached to the primary surface, the current entries in the hardware palette (left over from the last application) will be used.
- When mixing GDI functions with `DirectX`, GDI functions will use whatever palette is attached to the primary surface at the time the function is called.

## CHAPTER 6 Sprite Techniques

This chapter covers the following topics:

- The illusion of animation
- The illusion of motion
- Transparency issues
- Collision detection
- Animation issues

As we discussed in Chapter 2, The Anatomy of a Game, the most important graphical elements of any game are those graphics with which the user interacts, known as sprites. Sprites are such an integral part of any game that knowledge of their implementation and utilization is paramount. Sprites provide the animated elements of a game that make the gaming environment come alive. These can take the form of images that the player directly interacts with, such as a spaceship, or background elements that are non-interactive yet provide animation that makes the environment richer, deeper, and more believable. Without sprites, all you would have is a static bitmap, which would be quite boring.

The natural discussion of sprite implementation also leads to such sprite related issues as collision detection. With the exception of the most simplistic, most games need to detect when one sprite comes into contact with another. This would be important when, say, a missile launched from your ship comes into contact with a space-borne hunk of rock. Most players would expect the game to replace the rock with several smaller rocks and increment their score. Thus, it is important to understand the techniques by which sprite collision can be detected.

In this chapter, we examine several techniques for implementing sprites, discussing animation and movement as well as collision detection and timing issues.

### The Illusion of Animation

The method by which a game displays an animated image on the video screen has actually been around for many decades, even before computers were a household item. Indeed, if you have any knowledge of how movies or cartoons work, you already know the fundamentals of sprite animation.

The basic premise is simple. A series of images is required, where each image shows the character or object to be animated in a slightly different position than the image before it, like a filmstrip. Each image is known as a frame.

**frame:** A single image in a series of images to be animated.

When each image is rapidly displayed one after another, the human brain expects to see smooth motion, and any gaps in movement from one frame to another (provided it is not too large) will be automatically filled in. In essence, it's really nothing more than a complex visual illusion.

**Figure 6-1:** Movie frames

Creating the illusion of animated images using the computer is almost identical to this technique. Instead of a filmstrip, a series of bitmaps is constructed in which each bitmap contains an image of the character or object in a slightly different position. If each bitmap is copied to the video screen in rapid succession, the illusion of animation will be achieved. This is known as frame animation.

**frame animation:** The process of producing animation by rapidly displaying a series of images depicting an object or character in slightly different positions each frame.

Unlike a filmstrip, which contains images of a scene in its entirety, the series of bitmaps to be animated usually contains only an image of the sprite itself. In fact, these images usually only contain images of the sprite in different positions without regard to its actual location in the scene. Location is controlled by other methods, which we'll see shortly. Of course, a series of bitmaps that does depict an entire scene could be used under special circumstances, such as showing an opening animation or perhaps an animation when the user is moving from one level to another. However, for the purposes of this chapter, we will examine only sprite animation techniques.

## Constructing the Animation Frames

The first step that is required is to create the series of bitmaps that will depict the animated object or character. As explained above, each bitmap should display the object or character in a slightly different position. You could store these as individual bitmap files, but the most common practice is to store all of these images in one bitmap, with each frame of the animation in the correct sequence, one after another. Another common practice is to make all frames of the animation equal in size. This simplifies the code when copying the image from the bitmap to the screen, as demonstrated in the example to follow.

**Figure 6-2:** An animated image bitmap

## Producing the Animation

The actual process of producing animation is simple. We start by defining a variable that will hold the current frame number, starting at 0. Through each iteration of the game loop, we increment the frame number by 1. If it goes beyond the actual number of frames, reset it to 0. Then, we copy the appropriate frame out of the bitmap onto the screen, using this frame number as an index.

**Figure 6-3:** Producing animation

Since each frame of the animation is exactly the same size, it is very easy to calculate the appropriate place in the bitmap from which to copy the image. Assuming that we've arranged our frames horizontally in the bitmap, we only need to compute the X offset within the bitmap at which to start and end the copy. These are calculated using the following formulas:

```
XStart := FrameNum * WidthOfOneFrame;
```

```
XEnd := XStart + WidthOfOneFrame;
```

These offsets can easily be used with the Blt or BltFast methods of the IDirectDrawSurface object to copy the correct frame to the backbuffer. Incrementing the frame number each iteration through the game loop causes a new frame of the animation to be displayed each time. If this occurs in rapid succession, and the bitmaps are displayed at the same spot, we achieve the illusion of animation, as the example below illustrates.

***Listing 6-1: Simple frame animation***

---

```
procedure TfrmDXAppMain.DrawSurfaces;
var
    SourceRect: TRect;           // determines the area to copy from in the source bitmap
    SrfcDC: HDC;                // these two are used to make text drawing easier
    TempCanvas: TCanvas;

begin
    {increment the overall frame number}
    Inc(FFrameNum);

    {start the frame number from the beginning if it goes beyond the
    number of frames in the animation}
    if FFrameNum > 5 then
        FFrameNum := 0;

    {blit the entire snake frame bitmap to illustrate the animation frames}
    SourceRect := Rect(0, 0, 540, 50);
    FBackBuffer.BltFast(50, 75, FImages, SourceRect,
                        DDBLTFAST_NOCOLORKEY OR DDBLTFAST_WAIT);

    {blit the current frame of the animation}
    SourceRect := Rect(FFrameNum*90, 0, (FFrameNum*90)+90, 50);
    FBackBuffer.BltFast(275, 215, FImages, SourceRect,
                        DDBLTFAST_NOCOLORKEY OR DDBLTFAST_WAIT);
```

## The Illusion of Motion

Creating the illusion of animation was simple enough. However, even the most complex and beautifully rendered animation would quickly get boring if it stayed in the same spot. So, how do we go about moving the animated sprite across the screen to produce a more interesting and believable animation?

Again, the process is quite simple. On the most primitive level, when the application prepares to draw the next frame of animation, simply change the horizontal or vertical coordinate (or both) at which the image will be drawn into the destination. If these coordinates keep changing, the animated image will be drawn at different positions, creating the illusion of motion.

## Sprite Attributes

Before we begin, a few items of information need to be tracked for each sprite. In particular, its current X (horizontal) and Y (vertical) coordinate must be tracked so the application knows where to draw the sprite. A horizontal and vertical velocity could also be stored. These velocities would indicate the number of pixels to move the sprite, and would be added to the X and Y coordinates on each iteration through the game loop. If we also tracked the current frame of animation, the number of frames in the animation, and a pointer to the bitmap or DirectDraw surface containing the sprite images, we could create a basic sprite object that might look like this:

```
TSprite = class

    FXPos, FYPos,                // tracks the current position

    FXVel, FYVel,                // tracks the velocity

    Height, Width,              // sprite frame height and width

    FCurFrame,                 // tracks the current frame number
```

```

FFrameNum: Integer;           // tracks the number of frames

FImages: IDirectDrawSurface4; // a pointer to the sprite images

end;

```

## The Animation Cycle

The effect we want to produce is the image of an object moving across the screen in a believable manner. To achieve this illusion of motion, we will tackle the process of animation by breaking it into three distinct steps: erasing the sprite image, updating the sprite position, and drawing the sprite image.

If we simply move the sprite and continue to draw it on the screen without ever erasing it, the previous sprite images will still be visible, ruining the animation effect. We want our animation to look like a single object moving about as one would expect to see in a cartoon or movie. Thus, the first thing we must do is erase the previous sprite image. For this example, we will simply clear the entire surface by performing a color fill using the Blt method. The IDirectDrawSurface4's Blt method is defined as:

```

function Blt(

lpDestRect: PRect;           // the destination rectangle

lpDDSrcSurface: IDirectDrawSurface4; // the source surface

lpSrcRect: PRect;           // the source rectangle

dwFlags: DWORD;             // control flags

lpDDBltFx: PDDDBltFX        // a pointer to a TDDDBltFX structure

): HRESULT;                  // returns a DirectX error code

```

The first parameter describes the rectangular area in the destination surface to which the image data is copied. The second parameter identifies the surface whose image data is being copied. The third parameter describes the rectangular area in the source surface from which the image data is copied. Note that if these rectangular areas are not the same size, the resulting image will be scaled as required. The fourth parameter is a series of flags indicating which members of the final parameter are valid and generally control the behavior of the blit. The final parameter is a pointer to a TDDDBltFX structure. This rather large and complex structure contains information for various special graphical effects, such as color fills and raster operations. We'll see an example of this function's use to perform a color fill in Listing 6-2.

**Note:** In the DDUtil unit, we've created a function called ColorFill that uses the Blt method to fill a region with a color. You specify a surface, the color in the form of a TColor, and a rectangular region to be filled (or nil to fill the entire surface). This allows the developer to fill an area with a solid color using only one line of code.

**Figure 6-4:** The animation cycle

Next, we simply add the horizontal and vertical velocities to the horizontal and vertical coordinates of the sprite. At this point, we may do some simple calculations to see if the sprite has moved off screen or out of bounds, and adjust its velocities accordingly. We then increment the frame number and draw the appropriate frame of the sprite image at the new coordinates. Figure 6-4 illustrates this process.

The value of the sprite velocities should take into account the type of animation being performed. If the animation is a top-down view of a ship flying in space, the horizontal and vertical velocities could be adjusted to make the sprite move all around the screen.

However, if the animation is a side view of a walking character, we would probably only want to adjust the horizontal velocity (unless, of course, the character is jumping). The velocity value must also be adjusted to make the animation look more believable (i.e., a character would move faster when running than when walking).

Implementing this animation method is little more than an extension of the previous frame animation example, as the following listing demonstrates.

*Listing 6-2: Simple sprite movement*

---

```
procedure TfrmDXAppMain.DrawSurfaces;
var
    SourceRect: TRect
    SrfcDC: HDC;
    TempCanvas: TCanvas;
    BltFx: TDDBltFx;
begin
    {erase the last frame of animation by using a simple color fill to
    'black out' the entire backbuffer surface}
    FillChar(BltFx, SizeOf(TDDBltFx), 0);
    BltFx.dwSize := SizeOf(TDDBltFx);
    BltFx.dwFillColor := 0;
    FBackBuffer.Blt(nil, nil, nil, DBLT_COLORFILL or DBLT_WAIT, @BltFx);

    {increment the frame number and update the sprite's position}
    with FSprite do
    begin
        Inc(FCurFrame);
```

```
{make sure we roll over the frame number as necessary}
if FCurFrame > FFrameNum then
    FCurFrame := 0;

{add the velocities to the positions. our sprite will only move
 horizontally, so we do not need to bother with the vertical values}
FXPos := FXPos + FXVel;

{see if the sprite is moving offscreen, and adjust
 its position accordingly}
if FXPos < 0 then
    FXPos := DXWIDTH - 90;

{blit the current frame}
SourceRect := Rect(FCurFrame*90, 0, (FCurFrame*90)+90, 49);
FBackBuffer.BltFast(FXPos, FYPos, FImages, SourceRect,
                    DDBLTFAST_SRCCOLORKEY OR DDBLTFAST_WAIT);

end;

.
.
.

end;
```

---

## Transparency Issues

So far, the examples we've seen all demonstrate sprite animation against a solid black background. This may work for some games, but what if we wanted to have some sort of cool background graphic behind our sprites, like a starfield or perhaps a forest, mountains, or other type of setting? This not only makes the overall animation more visually stimulating, but it improves its believability and makes the overall gaming experience more realistic. To do this, we need to draw the frames of the sprite image using some technique for displaying the background through the parts of the sprite image that are supposed to be transparent. Figure 6-5 illustrates the difference between a sprite image being displayed with and without transparent pixels.

**Figure 6-5:** Sprite transparency

Implementing transparency such as this is another broad topic in graphics programming that's been widely studied. There are probably hundreds, if not thousands, of methods to display a graphic with transparent areas. The trick is to do it as quickly as possible so it won't negatively affect the performance of the game. We will examine a few of the most common techniques used to display graphics with transparent pixels. These will include DirectDraw color keying and direct pixel checking.

**Tip:** You can potentially optimize your application by including several different methods for blitting graphics in the game engine. It is perfectly normal to have one blitting function for graphics with no transparency (i.e., tiled graphics such as floors, or textures), a separate general blitting function for sprites with transparent pixels, and then perhaps a highly optimized assembly blitter that's used for displaying graphics when optimum speed is required. The point is that you do not have to use only one blitting technique for all graphics in your game engine; use many blitting techniques for optimization and greater application performance.

## Color Keying

Color keying is the DirectX way of implementing transparency. With color keying, you specify a color that will be transparent. When DirectDraw blits this graphic onto the background, any pixels whose color matches that of the color key will not be drawn to the destination. Thus, the background will “show through” those pixels, as if they were transparent. The effect is similar to a technique that film makers use called blue screen. In a blue screen effect, an actor stands in front of a solid blue background. Later, the film is combined with a background image, which shows through all of the blue areas. Blue, in this case, is considered the color key.

Color keying is very easy to implement in DirectX. It’s supported by the HEL, so you know it will always work, and if supported by the hardware, it’s incredibly fast. The only drawback to color keying is in the fact that every pixel in your image that is the color of the color key will be transparent. Thus, that color cannot be used for anything opaque in the image. However, the loss of one useful color out of 256 is easy to live with.

**Figure 6-6:** Color keying

Under DirectX, there are actually two types of color keys: source and destination. In source color keying, the source image (the image to be copied) is the one containing the transparent pixels. When the source image is copied onto the destination image, the color keyed pixels in the source image are replaced by the pixels in the destination. With destination color keys, the destination image is the one containing the transparent pixels. When the source image is copied onto the destination image, the color keyed pixels in the destination are replaced by the pixels in the source.

In our examples, we will cover only source color keying, as destination color keying is not supported by the HEL and requires hardware support.

### Setting a Color Key

We specify a color key by calling the IDirectDrawSurface4’s SetColorKey method. SetColorKey is defined as:

```
function SetColorKey (  
  
dwFlags: DWORD; // indicates the type of color key  
  
lpDDColorKey: PDDColorKey // the transparent color(s)  
  
) : HRESULT; // returns a DirectX error code
```

The first parameter takes a flag that indicates the behavior of the color key. For our purposes, we’ll set this to DDCKEY\_SRCBLT, indicating a source color key. The second parameter is a pointer to a TDDColorKey structure that defines the color or colors to be interpreted as transparent. The TDDColorKey record is defined as:

```
TDDColorKey = packed record  
  
dwColorSpaceLowValue: DWORD; // low boundary of color space  
  
dwColorSpaceHighValue: DWORD; // high boundary of color space
```

```
end;
```

The values of these fields are specified in the color format of the surface. Since we're using 256-color (or palettized) surfaces, we simply indicate the index of the color that we wish to be transparent. This record structure allows us to define a range of colors that will be transparent. This is primarily useful when working with video data, as shadows and other slight variations in color due to digitizing the video result in a background that will be a range of colors as opposed to one single color. Game artwork should usually be drawn with only one transparent color, and for our purposes, we will define only one color as transparent by setting both record elements to the same value.

In our examples, we'll only set the color key of surfaces that contain source images to be blitted over a background, such as sprite images. For example, to set the color key of an arbitrary surface to palette index 0, we only need a few lines of code:

```
var  
  
    ColorKey: TDDColorKey;  
  
begin  
  
    ColorKey.dwColorSpaceLowValue   := 0  
  
    ColorKey.dwColorSpaceHighValue  := 0  
  
  
    DirectDrawSurface.SetColorKey(DDCKEY_SRCBLT, @ColorKey);  
  
end;
```

*Note:* We have implemented a function in the DDUtil unit called `DDSetColorKey` that allows the developer to set the color key for a surface in one line of code. This function was translated from a similar function in the DirectX SDK. You simply pass in the surface and a color in the form of a `TColor`. The function uses a complex technique for matching the specified color to a format appropriate for the pixel format of the surface, so the function can be used for surfaces of any color depth.

---

## Using Color Keys

Now that we have our color key set up, we can extend the previous sprite example to display the sprite image over a background. After we load the sprite images, we set their color key as described above. Then, when we actually draw the sprite using the `BltFast` method, we specify the `DDBLTFAST_SRCCOLORKEY` in its `dwTrans` parameter to indicate that the source surface has a color key that should be taken into account during the blit.

Additionally, we must also load the image to be used as our sprite background. Now, as discussed previously, during the animation cycle we must erase the last frame of the sprite animation. Instead of simply filling the entire surface with black as we did previously, this time we'll draw the background image into the backbuffer. The background image will fill the entire backbuffer, and thus will erase the last frame of animation.

*Listing 6-3: Sprite transparency through color keying*

---

```

procedure TfrmDXAppMain.FormActivate(Sender: TObject);
var
    .
    .
    .

    {the color key record}
    ColorKey: TDDColorKey;
begin
    .
    .
    .

    {create a palette based on the sprite bitmap}
    FPalette := DDLoadPalette(FDirectDraw,
ExtractFilePath(ParamStr(0))+`SnakeFrames.bmp`);

    {attach the palette to the primary surface so that it takes effect}
    DXCheck( FPrimarySurface.SetPalette(FPalette) );

    {load in the bitmap containing the background and sprite images}
    FImages := DDLoadBitmap(FDirectDraw, ExtractFilePath(ParamStr(0))+
        `SnakeFrames.bmp`);

    {load the background bitmap}
    FBackground := DDLoadBitmap(FDirectDraw, ExtractFilePath(ParamStr(0))+
        `Background.bmp`);

```

```

    {initialize the color key record...}
    ColorKey.dwColorSpaceLowValue := 0;
    ColorKey.dwColorSpaceHighValue := 0;

    {...and set the source color key}
    FImages.SetColorKey(DDCKEY_SRCBLT, @ColorKey);

    {initialize the sprite object}
    FSprite := TSprite.Create;
    FSprite.FXPos := DXWIDTH - 90;
    FSprite.FYPos := 215;
    FSprite.FXVel := -1;
    FSprite.FYVel := 0;
    FSprite.FCurFrame := 0;
    FSprite.FFrameNum := 5;
    FSprite.FImages := FImages;

    .
    .
    .

end;

procedure TfrmDXAppMain.DrawSurfaces;
var
    SourceRect: TRect
begin
    {erase the last frame of animation}

```

```

SourceRect := Rect(0, 0, DXWIDTH, DXHEIGHT);

FBackBuffer.BltFast(0, 0, FBackground, SourceRect,

                    DBBLTFAST_NOCOLORKEY OR DBBLTFAST_WAIT);

{increment the frame number and update the sprite's position}

with FSprite do

begin

    Inc(FCurFrame);

    {rollover the frame number as necessary}

    if FCurFrame > FFrameNum then

        FCurFrame := 0;

    {add the velocities to the positions. our sprite will only move

    horizontally, so we do not need to bother with the vertical values}

    FXPos := FXPos + FXVel;

    {see if the sprite is moving offscreen, and adjust

    its position accordingly}

    if FXPos < 0 then

        FXPos := DXWIDTH - 90;

    {blit the current frame, taking into account a source color key}

    SourceRect := Rect(FCurFrame*90, 0, (FCurFrame*90)+90, 49);

    FBackBuffer.BltFast(FXPos, FYPos, FImages, SourceRect,

                        DBBLTFAST_SRCOLORKEY OR DBBLTFAST_WAIT);

end;

end;

```

**Pixel Checking**

A somewhat more direct way of implementing transparency, this method draws the sprite image one pixel at a time. As it is drawing individual pixels, it checks the pixel it will be drawing to see if its color matches the specified transparent color. If so, it skips drawing that pixel entirely; otherwise it draws the pixel into the destination.

Implementing this method is a bit more involved than color keying. By its very nature, it is pointer intensive and requires some creative pointer manipulation. It also requires more intimate knowledge of the pixel format of both the source and destination surfaces. It is slower than color keying, but through clever optimization can be as fast as non-hardware assisted color keying. However, the biggest benefit that a developer will see from this method is that it allows the creation of incredible special effects, such as lighting and translucency.

**Locking a Surface**

This method requires direct access to the memory that contains both the source bitmap and the destination, which is usually the backbuffer surface. Using normal GDI functions, this would be impossible. This is one of the things that makes DirectDraw so attractive to game developers.

To retrieve a pointer to surface memory, we must use the Lock method of the IDirectDrawSurface4 object. Using this method, we can access the entire surface memory or provide the coordinates for accessing only a specific rectangular area of the memory. The Lock method is defined as:

```
function Lock (  
    lpDestRect: PRect; // the surface region to lock  
    out lpDDSurfaceDesc: TDDSurfaceDesc2; // a TDDSurfaceDesc2 structure  
    dwFlags: DWORD; // indicates locking behavior  
    hEvent: THandle // unused  
): HRESULT; // returns a DirectX error code
```

The first parameter indicates the rectangular area of the surface to lock; specifying nil in this parameter locks the entire surface. The second parameter is a TDDSurfaceDesc2 structure that will be initialized with relevant details about the surface. In particular, the lpSurface member of this structure will contain a pointer to the upper left pixel of the surface memory. Other members of this structure will contain additional information about the surface, such as its height, width, and stride. The third parameter is a series of flags controlling access to the locked memory, such as read-only or write-only. The final parameter is unused and should be set to zero.

As an example, the code for retrieving a pointer to our backbuffer memory would look something like:

```
var
    BackSurfaceDesc: TDDSurfaceDesc2;
begin
    {initialize the size member}
    BackSurfaceDesc.dwSize := SizeOf(TDDSurfaceDesc2);

    {lock the backbuffer memory}
    FBackBuffer.Lock(nil, BackSurfaceDesc, DDLOCK_WAIT or DDLOCK_SURFACEMEMORYPTR, 0)
```

*Note:* It is very important to always set the size member of any record structure that has one before using it in any function call.

---

As with all DirectX functions, it is usually a good practice to check the return code from a call to the Lock method. The DDLOCK\_WAIT flag will cause the Lock method to wait until the surface is available and no longer being accessed by the hardware blitter. However, if the surface is locked by another thread or process, this function will return immediately with a DDERR\_SURFACEBUSY error regardless of the DDLOCK\_WAIT flag.

## Accessing the Memory

When the Lock method returns, the lpSurface member of the TDDSurfaceDesc2 structure will contain a pointer to the surface memory. Exactly how this is used depends entirely on the pixel format of the surface. Since all of our examples deal with 256-color palettized display modes, pixels will be stored as bytes. Therefore, if we typecast the lpSurface member as a pointer to a byte, writing a value at the location reference by this pointer will change one byte on the surface, and thus one pixel in the image the surface contains.

In practice, it is useful to access this pointer as a pointer to an array of bytes. This allows us to access horizontal bytes as if they were stored in a one-dimensional array. Although perhaps not immediately obvious, the process is simple. We'll need to create a new data type that is declared as an array of byte with only one element, and another data type that is a pointer to this previous type, like so:

```
TBytePtr = array[0..0] of Byte;
PBytePtr = ^TBytePtr;
```

Then, if we set a variable of type PBytePtr to the value of the lpSurface member, we can easily reference the surface memory as an array of bytes:

```

var

    BackMem: PBytePtr;

begin

    BackMem := PBytePtr(BackSurfaceDesc.lpSurface);

```

## Drawing the Sprite

We must lock both the backbuffer surface and the surface containing the sprite images. Once this is done, we iterate through each row of the sprite, and each pixel in the row. For each pixel in the current row being drawn, we check to see if it is equal to the specified transparent color. If it is not, we go ahead and set the appropriate pixel in the destination memory to the value of the pixel being checked. If it is indeed equal to the transparent color, we simply move on to the next pixel in the row. The following example demonstrates an implementation of this technique.

### *Listing 6-4: Drawing a sprite with transparent pixels*

---

```

procedure TfrmDXAppMain.DrawSurfaces;

var

    SourceRect: TRect

    BackSurfaceDesc,

    SpriteSurfaceDesc: TDDSurfaceDesc2;

    BackMem, SpriteMem: PBytePtr;

    Row, Col: Integer;

begin

    {erase the last frame of animation}

    SourceRect := Rect(0, 0, DXWIDTH, DXHEIGHT);

    FBackBuffer.BltFast(0, 0, FBackground, SourceRect,

                        DDBLTFAST_NOCOLORKEY OR DDBLTFAST_WAIT);

    {increment the frame number and update the sprite's position}

    with FSprite do

    begin

        Inc(FCurFrame);

        {rollover the frame number as necessary}

        if FCurFrame > FFrameNum then

            FCurFrame := 0;

```

```

{add the velocities to the positions. our sprite will only move
  horizontally, so we do not need to bother with the vertical values}
FXPos := FXPos + FXVel;

{see if the sprite is moving offscreen, and adjust
  its position accordingly}
if FXPos < 0 then
  FXPos := DXWIDTH - 90;

{-begin blitting the current frame-}
{we need to lock both the backbuffer surface and the sprite image
  surface, so begin by locking the backbuffer}
BackSurfaceDesc.dwSize := SizeOf(TDDSurfaceDesc2);

{we 're going to lock the entire surface}
DXCheck(FBackBuffer.Lock(nil, BackSurfaceDesc,
  DDLOCK_WAIT or DDLOCK_SURFACEMEMORYPTR, 0));

{initialize the byte array pointer to point at the locked memory}
BackMem := PBytePtr(BackSurfaceDesc.lpSurface);

{increment this pointer to the position in the buffer at which the
  sprite should be displayed (based on the sprite's position)}
BackMem := Pointer(Longint(BackMem)+FXPos+(FYPos*BackSurfaceDesc.lPitch));

{now, lock the sprite surface}
SpriteSurfaceDesc.dwSize := SizeOf(TDDSurfaceDesc2);

{again, we'll lock the entire surface}
DXCheck(FImages.Lock(nil, SpriteSurfaceDesc,

```

```
DDLOCK_WAIT or DDLOCK_SURFACEMEMORYPTR, 0));
```

```
{initialize the byte array pointer to point at the locked memory}
```

```
SpriteMem := PBytePtr(SpriteSurfaceDesc.lpSurface);
```

```
{increment this pointer to the position of the current sprite frame}
```

```
SpriteMem := Pointer(Longint(SpriteMem)+(FCurFrame*90));
```

```
{iterate through each row of pixels in the sprite image (our sprite image is  
90 X 50)}
```

```
for Row := 0 to 49 do
```

```
begin
```

```
{iterate through each pixel in the current row}
```

```
for Col := 0 to 89 do
```

```
{if the pixel in the sprite image is not 0 (the transparent color),  
copy it into the destination surface}
```

```
if SpriteMem^[Col] <> 0 then
```

```
BackMem^[Col] := SpriteMem^[Col];
```

```
{move to the next row in the sprite and backbuffer surface memory}
```

```
Inc(BackMem, BackSurfaceDesc.lPitch);
```

```
Inc(SpriteMem, SpriteSurfaceDesc.lPitch);
```

```
end;
```

```
*****
```

```
{we have now copied the sprite, so unlock the surface memory}
```

```
FBackBuffer.Unlock(nil);
```

```
FImages.Unlock(nil);
```

```
end;
```

```
end;
```

Of special consideration is the part in the rendering loop (the DrawSurfaces method) where the pointers to the backbuffer and sprite surface memory are incremented to point to the next row:

```
{move to the next row in the sprite and backbuffer surface memory}
```

```
Inc(BackMem, BackSurfaceDesc.lPitch);
```

```
Inc(SpriteMem, SpriteSurfaceDesc.lPitch);
```

Among the values returned by the call to the Lock method is the surface's pitch, or stride. This value is the actual distance between two pixels that are vertically adjacent. It is a result of storing memory that is logically arranged in rectangular fashion, but is actually accessed linearly. Often, the pitch is the same as the width of the surface, as one might expect. However, never assume that the pitch is constant, even for different surfaces in the same video memory. Always use the lPitch value to move vertically between rows.

**Caution:** Some display cards can organize memory differently than others, and the resolution and color depth can have dramatic effects on how memory is accessed directly. Therefore, always increment the row by using the lPitch value.

### Unlocking a Surface

With every call to the Lock method, a call to the Unlock method must be made. This allows the locked surface to be accessed again by other threads and processes, and most importantly by the hardware. A surface cannot be blitted or otherwise manipulated by the hardware unless it has been unlocked. After calling Unlock, any pointers to the surface memory will no longer be valid. Therefore, it is necessary to call Lock again during the next rendering cycle to retrieve a valid pointer to surface memory. The Unlock method of IDirectDrawSurface4 is defined as:

```
function Unlock (
```

```
lpRect: PRect
```

```
// the previously locked rectangular area
```

```
: HRESULT; // returns a DirectX error code
```

The only parameter defines the rectangular area that was passed to the initial Lock method. It is possible to lock multiple rectangular, overlapping areas simultaneously. Thus, DirectDraw needs to know which rectangular area to unlock, and the values for this parameter must match those passed to the original Lock method. Pass nil here if you used nil in the Lock method to lock the entire surface.

**Caution:** When accessing surface memory, it is very important to complete rendering quickly and unlock the surface as soon as possible. This is because Windows is effectively stopped between the calls to Lock and Unlock. This can cause things to get backed up rather quickly, causing all sorts of nasty side effects, like system hangs. This won't occur when locking surfaces explicitly created in surface memory, but always try to use tight, efficient code when locking a surface and always remember to call the Unlock method when you no longer require direct memory access.

## Collision Detection

All games, at some point, must deal with the situation in which one sprite touches another. For some games, this may be when a bullet strikes an alien or when an animated mouth collides with a glowing white pellet to eat it. A game application must determine when these situations happen, and this is where collision detection comes in.

There exist as many different methods to perform collision detection as there do methods to draw a sprite. Many articles have been written on this subject, exploring the nuances of checking large amounts of sprites against each other and the optimizations required to perform such techniques in a timely fashion. In most cases, however, sprite collision can be detected using one of two techniques: bounding boxes and pixel overlap comparisons.

### Bounding Boxes

The bounding box method of collision detection works by defining a rectangular region around the sprite, its "bounding box." To determine if a collision with another sprite has occurred, the application simply determines if their bounding box rectangles intersect. If indeed the rectangles intersect, a collision has occurred and the game application can respond accordingly, as shown in the following illustration.

**Figure 6-7:** Sprite bounding boxes

Notice that in Figure 6-7b, the intersected rectangles would indicate that a collision has occurred, although clearly the sprites are not touching. This is the inherent drawback to using bounding boxes, in that many times during close calls a collision may be flagged when in fact the sprites never touched. Shrinking the size of the bounding boxes to where they do not encapsulate the entire sprite diminishes this error, as shown in Figure 6-7c. However, the reverse effect can occur, where two sprites have collided although no collision was detected. For the most part, it is better to err on the side of the player and allow the infrequent true collisions to go unresolved. However, for some games where precise collision detection is required, it is necessary to actually check the pixels of one image with the pixels of another to see if they overlap, as we examine shortly.

**Tip:** It is possible to use two or more bounding boxes for a sprite, thereby providing a more accurate approximation of the sprite's surface. The GDI also contains many functions to create regions of different shapes and sizes, including circular and polygonal, which can then be used to detect collisions more accurately.

Windows has highly optimized routines that make manipulating rectangles a breeze. In particular, the `IntersectRect` function determines if two rectangles overlap and returns a rectangle that defines the area of intersection. The `IntersectRect` function is defined as:

```
IntersectRect (
```

```

        Sprite.FYPos+Sprite.Height);

{draw the sprite transparently}

Area := Rect (0, 0,  Sprite.Width, Sprite.Heigh);

FBackBuffer.BltFast(Sprite.FXPos, Sprite.FYPos, Sprite.FImages,
                    Area, DBLTFFAST_SRCCOLORKEY or DBLTFFAST_WAIT);

{draw a red border around the sprite to display its bounding box}

    .
    .
    .

end;

begin

    {erase the previous animation frame}

    Area := Rect (0, 0, DXWIDTH, DXHEIGHT);

    FBackBuffer.BltFast(0, 0, FBackground, Area,
                        DBLTFFAST_NOCOLORKEY or DBLTFFAST_WAIT);

    {move and draw the sprites}

    for iCount := 0 to 1 do

        MoveSprite(Sprites[iCount]);

    {if any of the sprite's bounding boxes intersect, signal a collision. real
     world examples would generally require checking many rectangles against
     each other}

    if IntersectRect(Intersection, Sprites[0].Boundary, Sprites[1].Boundary) then

        Messagebeep(0);

end;

```

**Pixel Overlap Comparison**

The bounding box method of collision detection can easily be extended to provide very accurate pixel level collision detection. Basically, a standard bounding box collision detection is performed. It is necessary that the bounding boxes of the sprites be the same dimensions as the sprite images (actually, they could be different, but the resulting offset math makes the pixel offset determinations cumbersome). Once a collision has occurred, it is necessary to determine the exact rectangular intersection area, which is conveniently reported by the IntersectRect function. The coordinates of the upper left corner of the rectangle are subtracted from the coordinates of the upper left corner of each of the sprite image positions. This will give a starting offset of the intersection rectangle relative to the sprites. From this starting offset within the sprite images, a simple embedded loop is used to walk through the pixels in each sprite image, comparing the colors of the pixels in the relative position of each sprite as determined by the intersection rectangle. If any non-transparent pixels match up, then the sprites overlap and a collision has occurred, as illustrated below.

**Figure 6-8:** Pixel level collision detection

This algorithm provides very accurate collision detection. Due to its nature, we must directly access the surface memory as we covered above. This is a slow collision detection technique, but it could possibly be optimized using assembly language. However, for small numbers of sprites, the performance penalty is minimal. The following example demonstrates pixel-accurate collision detection.

*Listing 6-6: Collision detection at the pixel level*

---

```
procedure TfrmDXAppMain.DrawSurfaces;

var

    Intersection, Area: TRect;

    iCount: Integer;
```

```
Sprite1SurfaceDesc,  
Sprite2SurfaceDesc: TDDSurfaceDesc2;  
Sprite1Mem, Sprite2Mem: PBytePtr;  
iRow, iCol: Integer;  
SrfcDC: HDC;  
Hit: Boolean;
```

```
{this function moves and draws a sprite}  
procedure MoveSprite(var Sprite: TSprite);  
var  
    SrfcDC: HDC;  
    TempCanvas: TCanvas;  
begin  
    .  
    .  
    .  
  
end;
```

```
begin  
    {erase the previous animation frame}  
    FBackBuffer.BltFast(0, 0, FBackground, Rect(0, 0, DXWIDTH, DXHEIGHT),  
        DDBLTFAST_NOCOLORKEY or DDBLTFAST_WAIT);  
  
    {move and draw the sprites}  
    for iCount := 0 to 1 do  
        MoveSprite(Sprites[iCount]);  
  
    {retrieve the intersection of the sprite's bounding boxes. if there is
```

indeed an intersection, compare the pixels in intersecting areas of each sprite. if the AND of any two pixels is greater than 0 (our transparent pixel value is 0, so two overlapped image pixels will return a value greater than 0), then there was indeed a pixel level collision.}

if IntersectRect(Intersection, Sprites[0].Boundary, Sprites[1].Boundary) then begin

{at this point, the bounding boxes have collided, so we need to prepare to access the sprite surfaces. we will lock the entire surface of each sprite}

Sprite1SurfaceDesc.dwSize := SizeOf(TDDSurfaceDesc2);

DXCheck(FShip1.Lock(nil, Sprite1SurfaceDesc,  
DDLOCK\_WAIT or DDLOCK\_SURFACEMEMORYPTR, 0));

{initialize the byte array to the intersected rectangular area of the sprite}

Sprite1Mem := PBytePtr(Sprite1SurfaceDesc.lpSurface);

Sprite1Mem := Pointer(Longint(Sprite1Mem)+  
((Intersection.Top-Sprites[0].FYPos)\*  
Sprite1SurfaceDesc.lPitch+  
(Intersection.Left-Sprites[0].FXPos)));

{lock the other sprite's surface}

Sprite2SurfaceDesc.dwSize := SizeOf(TDDSurfaceDesc2);

DXCheck(FShip2.Lock(nil, Sprite2SurfaceDesc,  
DDLOCK\_WAIT or DDLOCK\_SURFACEMEMORYPTR, 0));

{and initialize the other byte array to the intersected rectangular area of the sprite}

Sprite2Mem := PBytePtr(Sprite2SurfaceDesc.lpSurface);

Sprite2Mem := Pointer(Longint(Sprite2Mem)+  
((Intersection.Top-Sprites[1].FYPos)\*  
Sprite2SurfaceDesc.lPitch+

```

        (Intersection.Left-Sprites[1].FXPos)));

{begin determining if a collision has taken place.}
Hit := FALSE;
for iRow := 0 to (Intersection.Bottom-Intersection.Top)-1 do
    for iCol := 0 to (Intersection.Right-Intersection.Left)-1 do
        {if the pixels in the intersected rectangular areas of
        both sprites is something other than a transparent
        pixel, a collision has occurred}
        if Sprite1Mem^[iRow*Sprite1SurfaceDesc.lPitch+iCol] and
            Sprite2Mem^[iRow*Sprite2SurfaceDesc.lPitch+iCol] > 0 then
            Hit := TRUE;

{visually indicate any collisions}
FBackBuffer.GetDC(SrfcDC);
try
    if Hit then
        TextOut(SrfcDC, 10, 460, 'Collision!', Length('Collision!'));
finally
    FBackBuffer.ReleaseDC(SrfcDC);
end;

{we no longer need access to surfaces, so unlock them}
FShip1.Unlock(nil);
FShip2.Unlock(nil);
end;
end;

```

---

## Animation Issues

Apart from getting sprites to move and animate, game developers are confronted with dozens of sprite-based issues, depending on the type of game. Complex sprites may have hundreds of animation frames, segregated into different

actions, all of which must be triggered at the appropriate time by the game state. Collision detection may be a big issue, made even worse by large amounts of sprites that can move around in a virtual world several times the size of the screen. These and other animation issues are sure to appear as you develop your Delphi game masterpiece.

There are a few animation issues that are fairly common among different games, and generally have straightforward resolutions. You've probably noticed that our previous sprite examples demonstrating animation ran incredibly fast, so fast that the animation was unbelievable. This is an issue of timing. Implementing a method to slow down the animation of a sprite is very elementary, and is little more than an extension of our previous sprite movement algorithm.

Another topic to consider is the concept of z-order, or depth. Some games may exhibit many sprites in which collision is infrequent or unimportant. In this instance, it is important to consider which sprites should be drawn first, as the order in which sprites are drawn will connote depth to the viewer. Those sprites that are farthest away should naturally be drawn under those sprites that are closer. Again, implementing such functionality is relatively straightforward.

**z-order:** The position along the z, or third-dimensional, axis. This is an imaginary axis that runs perpendicular to the screen, and gives the illusion of depth.

---

## Timing

In order to slow down sprite animation, the current frame number should not be incremented each time through the game loop. Instead, it should be incremented only at specific intervals. To implement this technique, we need to add two members to our sprite object: one for the current interval measurement and one for a threshold amount. When this current interval measurement exceeds the threshold, we can increment the frame counter.

Technically, we could set the threshold amount to an integer value, and then increment the current interval measurement each time through the game loop. However, this would make the speed of the sprite animation contingent on the speed of the game. A more efficient method would be to base the speed of animation on an elapsed time amount. This would constrain the animation to a specific rate that would be constant on all machines.

We can do this by setting our threshold amount to a specific time interval, measured in milliseconds. Our current interval measurement would then be set to the system time of the last increment of the frame number. In the game loop, we then check to see if the amount of time indicated in the threshold has elapsed since the last increment of the frame number. If so, we increment the frame number and reset the current interval measurement. The following example demonstrates this technique.

*Listing 6-7: Accurate sprite animation timing*

type

## Z-Order

As stated above, the z-order of a sprite is its position along an imaginary third- dimensional axis. Some games may feature foreground sprites and background sprites, while others may have sprites that move closer to and farther from the user, scaling as appropriate in a pseudo three-dimensional viewpoint. In games like these, drawing sprites in the correct order becomes an important issue.

However, actually accomplishing this illusion of depth is quite simple. Essentially, the application needs to draw the sprites starting with the farthest from the user and ending with the closest. As you draw the nearer sprites, their images will obscure those farther away, giving the illusion of depth. This is known as the painter's algorithm; the technique is illustrated below.

**Figure 6-9:** The painter's algorithm

We've already implemented the painter's algorithm in a very simplistic way by drawing the background behind the sprites before drawing them. In a more complex, real-world application, the z-order of the sprites themselves must be taken into account. We can accomplish this by simply adding another member to our sprite object for tracking this z-order.

In practice, we'll need to move the sprites and then sort them by z-order before drawing. The sorting step is necessary in order to draw the sprites in the correct order. Any well-documented, high-performance sorting algorithm will do. In the following example, we don't employ any sort of real sorting algorithm for the sake of code simplicity. However, the example does demonstrate a simple z-ordering mechanism. Sprites that are moving downward have a higher, or closer, z-order than those moving upward. Implementing scaling to draw the sprites larger when they are closer and smaller when they are farther away would improve the illusion.

**Listing 6-8:** *Drawing sprites according to z-order*

## Summary

In this chapter, we discussed several techniques for implementing sprites and sprite animation. We looked at various DirectDraw methods for implementing transparency, and we also took a look at what is required for detecting collisions between two sprites. We also lightly covered some of the more common animation issues facing developers. When writing sprite manipulation code, it is important to keep these points in mind:

- The most important graphical elements of any game are those graphics with which the user interacts. Sprites provide the animated elements of a game that make the gaming environment come alive. These can take the form of images that the player directly interacts with, such as a spaceship, or background elements that are non-interactive yet provide animation that makes the environment richer, deeper, and more believable
- To produce the illusion of animation, a series of images is required, where each image shows the character or object to be animated in a slightly different position than the image before it, like a filmstrip. When each image is rapidly displayed one after another, the human brain expects to see smooth motion, and any gaps in movement from one frame to another will be automatically filled in.
- To produce the illusion of motion, when the application prepares to draw the next frame of animation, simply change the horizontal or vertical coordinate at which the image will be drawn into the destination. If these coordinates keep changing, the animated image will be drawn at different positions.
- A few items of information need to be tracked for each sprite. In particular, its current x and y coordinate must be tracked so the application knows where to draw the sprite. A horizontal and vertical velocity could also be stored. These velocities would indicate the number of pixels to move the sprite, and would be added to the x and y coordinates on each iteration through the game loop. It should also track the current frame of animation, the number of frames in the animation, and a pointer to the bitmap or DirectDraw surface containing the sprite images.
- The process of standard sprite animation is accomplished by following three distinct steps: erasing the sprite image, updating the sprite position, and drawing the sprite image.
- In order to make sprite images more believable, they must contain pixels that are rendered transparently so that the background shows through. This can be accomplished through color keying, or through a more direct approach by drawing each pixel individually and skipping those pixels that are transparent.
- When using the Lock method to access surface memory directly, remember to always call the

Unlock method before using the surface in other method calls.

- All games, at some point, must deal with the situation when one sprite touches another. For some games, this may be when a bullet strikes an alien or when an animated mouth collides with a glowing white pellet to eat it. In most cases, sprite collision can be detected using one of two techniques: bounding boxes and pixel overlap comparisons.
- Bounding box collision detection works by defining a rectangular region around the sprite, its “bounding box.” To determine if a collision with another sprite has occurred, the application simply determines if their bounding box rectangles intersect
- After determining the rectangular intersection area between two sprites, we can access the sprite image surfaces and compare the pixels that are within this intersection rectangle. If any non-transparent pixels overlap, we have a pixel overlap collision. This method is very accurate, but tends to be slow.
- Sprite animation should be regulated to make it look more believable. We can accomplish this by incrementing the current frame number only at specific intervals.
- Games with multiple layers of sprites must take into account the sprites’ z-order. Sprites should be sorted by z-order and drawn starting with the farthest sprites. This will result in closer sprites obscuring sprites that are farther from the viewer, giving an illusion of depth.

## CHAPTER 7 Input Techniques

This chapter covers the following topics:

- Human/computer interaction
- DirectInput fundamentals
- Retrieving keyboard input
- Retrieving mouse input
- Retrieving game controller input

An excellent graphics engine is important to the popularity and enjoyment of a game. The sound effects and music that are synchronized to the action on screen are also imperative. However, think of the most enjoyable game you've ever played, and consider what it would be like if you had no way of interacting with the game elements. It would be like watching a movie, at best. How about if you could interact with the game through only a single button on the keyboard, or perhaps with only the movement of the mouse cursor? Your actions would be limited indeed, as would your enjoyment of the game. As with graphics and sound, user input is a vital piece of overall game development that merits serious consideration.

User input functionality is something most developers, and game players, take for granted. Even so, the method by which a game player interacts with the game can have a profound effect on how skillfully the player navigates the game's environment, and consequently the overall enjoyment of the game. Some game types naturally lean towards certain types of input devices; flight simulators tend to "feel right" when played with a joystick, whereas real-time strategy games are usually best played with the mouse. The supported devices allowing the user to provide game input, and how those devices are implemented in terms of how they manipulate game elements, can make or break a game.

In this chapter, we examine various techniques for retrieving user input through a variety of devices. Regular Windows API functions will be briefly touched upon, as our discussion will focus on how DirectInput provides developers with a responsive and powerful interface to any input device available.

## Human/Computer Interaction

Human/computer interaction is the concept of how humans and machines, typically computers, interact with one another in a method that is meaningful and intelligible to both. Entire volumes have been written on techniques to make human/computer interaction more intuitive, including both input techniques themselves as well as the presentation of the interface. While the majority of this concept is beyond the scope of this book, certain elements are relative to our discussion of user input techniques.

---

**human/computer interaction:** The concept of techniques and methods by which humans and machines, primarily computers, exchange information.

Exactly how user input will be translated into game element manipulation is dependent on the game itself. Flight simulators need input that affects the direction of flight, or perhaps even the selection and use of a weapon. Strategy games, by contrast, need input that determines which token is selected and its direction of movement or combat. These concepts will be accounted for when the game itself is designed. Perhaps the most important consideration for user input is the device by which the user will interact with the machine and, more specifically, the game.

### Input Devices

Technically speaking, today's machines have a wide variety of devices by which they can receive input from users. Some of the more exotic input devices, such as speech recognition, are becoming available to the average computer user, and may one day replace many, or all, of the standard input devices currently in use. While it may be a good marketing hook to provide support for some of these more esoteric input devices, all games should provide support for standard input devices found on almost every machine. These standard input devices consist of the keyboard, the mouse, and game controllers.

### Keyboard

It would be hard to imagine any computer in today's market that doesn't come with a keyboard. The keyboard has been the standard input device since the dawn of the home PC, and it is safe to assume that it will be available for input when your game is executed. Retrieving keyboard input is easy and very straightforward, and can provide a very intuitive interface for almost any game.

### Mouse

The mouse is another standard input device available on just about every machine. While not quite as old as the keyboard, the mouse is just as necessary and probably more important for user input, thanks to Windows. Since our games will be using DirectX, and will thus be restricted to the Windows platform, we can assume that the mouse will be available for input when the game is executed. Retrieving mouse input is almost as easy and straightforward as retrieving keyboard input, and like the keyboard, it provides a very intuitive interface for certain types of games.

### Game Controllers

About five years ago, this category would probably have been called simply Joysticks. However, in the recent past, a multitude of input devices has been created that are aimed specifically at providing intuitive input for various games. Rudder pedals, steering wheels, gamepads, throttles, and all manner of sundry and arcane input devices are now available, making some games much more enjoyable to play. Even the standard joystick has become incredibly complex, with many sporting impressive arrays of buttons, switches, sliders, and even tactile responses known as force feedback.

---

**force feedback:** A method by which an input device can output tactile feedback to the user through various actuator motors.

Strictly speaking, a game cannot automatically assume that any type of game controller is hooked up to the machine, as game controllers have not yet become a standard input device shipped with new machines. It is good programming practice to provide an alternative form of input in the absence of a more appropriate input device, even if this input interface is somewhat cumbersome or even awkward. Retrieving input from various game controllers is necessarily more difficult than retrieving input from the mouse or keyboard, primarily because of the sheer number and variety of available game controllers. However, if a game lends itself to input from a specific type of game controller, such as a steering wheel for driving games, then the game should provide support for the most appropriately intuitive input device.

## Input Considerations

Even though the developer has determined which input devices will be supported and how they interact with game elements, individual users may find this structure somewhat restrictive based on their particular preferences. To accommodate those who feel your perfect interface could use some improvement, it is important to allow the user to change the configuration of input methods to their desired taste, within the structure of the input interface.

Perhaps the easiest to implement, and the most effective in terms of user configuration preferences, is a method by which users can redefine which keys or buttons perform which actions. This could be accomplished by presenting the user with a dialog box containing all available actions and the keys or buttons to which those actions are mapped. This should include keys on the keyboard and buttons on both the mouse and joystick. For example, the trigger button on a joystick may be used to fire a round of bullets in a flight simulator game, by default. However, the user may be more comfortable performing this action with another button. Allowing for the remapping of input methods in this way lets the individual user customize the game to his or her preferences, thus making it more enjoyable to a wider audience.

**Tip:** For an excellent example of an implementation of this technique, take a look at games like Quake and Halflife.

## DirectInput

DirectInput is the DirectX component responsible for providing user input from all manner of input devices, such as keyboards, mice, and game controllers. As with other DirectX components, the DirectInput API is large, and has its own set of requirements and nuances.

For some devices, DirectInput programming is almost trivial. For others, it is incredibly complex. DirectInput's complexity comes from the fact that it was designed to provide input from future game controllers that have not yet been invented. This forward thinking allows developers to provide support for new game controllers without having to rely on a new version of DirectInput. This support comes at the price of obscurity and complexity, but the marketing hook of supporting the latest input device may well be worth the effort. Fortunately, standard input devices such as the mouse and keyboard are relatively easy to interface with. Even joysticks and similar game controllers, while more complex, are not absolutely arcane in their implementation.

## Features

DirectInput offers many features above and beyond what is available through the Win32 API. As with all DirectX components, DirectInput gives the developer more control over user input than the Windows API, while also providing an improvement in performance. DirectInput provides the following features of specific interest to game developers:

- Responsive input retrieval directly from input device hardware
- Support for almost any input device, including mice, keyboards, joysticks, and other game controllers
- Access to force feedback devices for providing tactile output
- Support for multiple input devices attached to the machine, such as two or more keyboards or mice

Later in this chapter we will see how DirectInput is used to retrieve user input from the keyboard, the mouse, and standard game controllers such as joysticks.

## Functional Overview

Similar to DirectDraw, DirectInput programming consists of creating a DirectInput object and several DirectInputDevice objects. The DirectInput object itself acts as a liaison between the application and input device drivers. Individual DirectInputDevice objects represent the application's interface directly to input hardware or, more specifically, that hardware's device driver. The DirectInput object is used to create individual DirectInputDevice objects, which can then be queried to determine the specific capabilities of the device.

The DirectInputDevice object is used to communicate with all input devices. In other words, there is not a separate object type for communicating with keyboards, mice, or joysticks; they are all interfaced through a DirectInputDevice object. This is one of the reasons why DirectInput programming can be complex. The individual methods of a DirectInputDevice object all work with input devices in similar ways according to the context of the type of device. For example, you set device properties through a single function call, yet the properties themselves are dependent upon the device. You can set the range of motion returned from a joystick as a property, but this wouldn't make any sense if you tried to do the same with a keyboard.

However, at the same time that this type of interface introduces a level of complexity, communicating with different devices is very similar in form from device to device. After you've grasped a particular concept with one device, it is very easy to apply that knowledge to other devices. This may result in what appears to be some redundancy when we discuss individual devices later in the chapter. However, the information reported by these methods is dependent on the device we are communicating with, making these concepts uniquely different depending on the context in which they are used.

## Buttons and Axes

Where DirectInput is concerned, a button is considered to be any switch that has an on and off position. There is no distinction made between buttons on a mouse, keyboard, or joystick. Bear in mind that just because a device is referred to as a button, it does not necessarily have to be physically represented as a button. A device on a game controller that has a specific on and off position may take the form of a physical toggle switch, but will be treated by DirectInput as a button.

Conversely, an axis has a range of positions where its value is affected by the physical movement of a device in some particular direction. Like buttons, axes do not necessarily have a specific physical representation. Joysticks and mice are objects that, generally speaking, represent two axes. However, sliders and dials on joysticks or game controllers and the wheel on a Microsoft IntelliMouse are also axes. Rudder pedals, steering wheels, and flight yokes are other examples of controllers that represent axes.

In similar fashion, an axis does not necessarily have an association with any particular direction in space. Joysticks and mice report movement along the x and y axes, which may translate into the movement of a pointer or a change in the direction of flight. However, in the context of a specific game, this information may be used to indicate the depth at which an object is placed or the circular rotation of a dial. This points out that just because an axis may have a specific name, its value is meaningful only in the context in which it is used and does not have to map to any physical direction or movement.

While many devices report movement along various axes, the measurement of this movement is dependent on the type of device reporting it. Some devices report axis movement as a relative measurement, which others report it as an absolute measurement.

**Relative Measurement** Some axes can move an infinite distance in a particular direction, and lack a default or “rest” position. An example of this type of axis measurement would be that reported by a mouse. Therefore, the values returned by this type of device are meaningful only in relation to the last measurement taken from the device.

**Absolute Measurement** Other axes can physically only move a specific distance. This would include the movement of the joystick or the movement of dials and sliders on a game controller. These values are typically measured from a fixed point and have a specific range.

*Note:* DirectInput does allow the developer to redefine a relative axis to report absolute data and vice versa. The employment and implications of this technique are dependent on the context of the application itself.

## Immediate and Buffered Data

Since DirectInput communicates directly with device hardware, it does not return the state of axis movement or button presses with Windows messages. Instead, there are two flexible methods by which the application can retrieve the state of an input device: immediate and buffered.

Buffered data retrieval simulates the mechanism by which Windows reports input. Individual input events are stored in a buffer, which takes the form of an array of data structures containing the various axis movement values or button clicks. When you create a DirectInputDevice object for a particular input device, there is an additional step required in order to initialize the device to store information in this buffer.

Immediate data retrieval does not report a stream of singular events, but returns the current state of the device at the time of the function call. This will be reported in an initialized data structure dependent upon the specific device type, and can include information on the entire device or only for a specific object on that device, such as a button. There is no additional setup required to retrieve immediate data from a device.

Either of these data retrieval methods are perfectly acceptable depending on the requirements of the individual application. Indeed, both could be used simultaneously. However, it is generally most useful to utilize buffered data retrieval for relative data measurements and immediate data retrieval for absolute data measurements. We will see examples of both later in the chapter.

## Polling and Event Notification

The “when” of retrieving input data may be as important as the “how.” In what seems to be a recurring theme throughout this book, DirectInput provides two choices: polling and event notification.

Polling involves checking the state of the input device at the time that the input is needed. Typically, this is performed in the game loop. The state of the device may be checked only once, or perhaps multiple times, and is usually returned in the form of immediate data. Since the device is only checked at specific intervals, it is possible for the user to manipulate the device between checks, thus resulting in lost input. Polling may seem like a throwback to the days of DOS game programming. Indeed, it is similar, but polling for new input data is incredibly easy to implement, and in most cases is adequate for precise input measurement.

Event notification, on the other hand, is very similar to event-driven programming. This is a mechanism by which DirectInput will notify the application when new input data is available, and is best paired with buffered data retrieval. While this method of retrieving input can be very powerful, it is much more difficult to implement and involves the use of threads, Win32 event objects, and critical sections. We will see examples of both later in the chapter.

## Cooperative Levels

As discussed in the DirectDraw tutorial, a cooperative level determines how the application works with other applications. As with other DirectX components, DirectInput gives the developer a choice as to how the application will share input devices with other applications, in terms of who can gain access to the device and if input can be retrieved based on application focus.

The first measurement of cooperative level determines when your application has access to data from the device, known as foreground or background access. Foreground access means that your application will have access to input data only when its main window has focus. Background access allows your application to retrieve input data whether it has focus or not; input data is available at all times, even if the application is minimized. Foreground mode is the most common for games and other applications. Nevertheless, you may need to use background mode if the application requires access to the device when a dialog box is open.

The second measurement of cooperative level is based on exclusivity, which determines if only a single application has access to a device. Applications that acquire a device in non-exclusive mode can retrieve input from that device unless another application acquires it exclusively. When a device is acquired exclusively, only the acquiring application can receive input from that device. In non-exclusive mode, other applications can acquire the device in non-exclusive or exclusive mode. In exclusive mode, other applications can only retrieve the device in non-exclusive mode. Thus, only one application at a time can have exclusive access to a device. For some devices, such as force feedback, this is a necessity, as two applications sending force feedback effects simultaneously could confuse the user and possibly damage the hardware.

When specifying a cooperative level, the application must indicate either foreground or background in addition to either exclusive or non-exclusive access. The following table summarizes the two cooperative level measurements and their implications for the current application and others in the system.

Measurement	Implications	Validity
Non-Exclusive/Background	Other applications can acquire the device exclusively or non-exclusively; input data is available at all times	All devices except force feedback
Non-Exclusive/Foreground	Other applications can acquire the device exclusively or non-exclusively; input data is available only when application has focus	All devices except force feedback
Exclusive/Background	Other applications can acquire the device non-exclusively; input data is available at all times	All devices except keyboards
Exclusive/Foreground	Other applications can acquire the device non-exclusively; input data is available only when application has	All devices except keyboards

Bear in mind that Windows requires exclusive access to the keyboard at all times, so that functions such as Alt+Tab and Ctrl+Alt+Delete are always available. Thus, an application can only obtain non-exclusive access to the keyboard. Conversely, Windows can only use the mouse in an exclusive mode, and thus loses access to the mouse when another application acquires it exclusively. This means that when an application acquires the mouse in an exclusive mode, the mouse cursor will disappear and Windows will no longer generate mouse messages.

There is a small performance gain when acquiring the mouse in exclusive mode, since mouse messages are not being generated. However, there is no particular performance advantage to exclusive over non-exclusive cooperative levels for other devices.

**Tip:** It is standard practice to inform users to close all other applications before starting your game. It is doubtful that users would try to play two or more games at once, so you should generally set the cooperative level to exclusive/foreground.

## Device Acquisition

Once a device is set up, the application cannot receive input data until it instructs DirectInput that it is ready to do so. This process is known as acquiring the device. Once a device is acquired, input data can be retrieved in whatever manner desired as discussed above. Successfully acquiring the device is dependent on the cooperative level specified by the application and by those of other applications using DirectInput, as we just illustrated.

However, bear in mind that a device can be forcibly unacquired by the application. This may happen when another application receives focus or acquires the device in exclusive mode (again dependent on the cooperative level of both applications and who acquired the device first). In this instance, any method that returns input data will return a value of DIERR\_INPUTLOST or DIERR\_NOTACQUIRED. You will need to check for this error value in your application, possibly attempting to reacquire the device until successful. You may also deliberately unacquire the device, such as when Windows needs the mouse in order to give the user access to menus.

## Initializing DirectInput

As with other DirectX components, several steps are required in order to set up DirectInput and begin interfacing with user input devices. In general, most of these steps are required to read data from keyboards, mice, and game controllers. We will cover these steps in a broad sense here in order to familiarize you with them. They will be covered again more precisely when we look at retrieving data from specific input devices. DirectInput, and DirectInput devices, are instantiated by performing the following:

- Creating the DirectInput object
- Enumerating input devices
- Creating the input device
- Setting the data format
- Setting the cooperative level
- Setting device properties
- Acquiring the device

## Creating the DirectInput Object

The first step in retrieving data from an input device is to create the DirectInput object itself. Creating the DirectInput object involves calling the DirectInputCreate function, which is defined as:

```
function DirectInputCreate(  
  
    hinst: THandle;                // the application instance handle  
  
    dwVersion: DWORD;             // DirectInput version number  
  
    out ppDI: IDirectInput;       // the IDirectInput object to be instantiated  
  
    punkOuter: IUnknown           // unused, set to nil  
  
): HRESULT; stdcall;             // returns a DirectX error code
```

The first parameter is a handle to the calling application's instance. The second parameter indicates the DirectInput version number. Most applications should simply set this parameter to `DIRECTINPUT_VERSION` (a constant defined in the `DInput.pas` file). However, if an earlier version number is indicated, DirectInput will emulate that version. This is useful if you had no need for newer DirectInput functionality, such as force feedback. The third parameter takes a pointer to the IDirectInput object. When this function returns, this object will be instantiated. The last parameter is used for COM aggregation, and must be set to nil as it is currently unsupported.

---

**Caution:** If indicating an earlier version in the call to DirectInputCreate, the application must use the data structures compatible with this earlier version. Note that this will also affect the value to which the `dwSize` member of these structures must be initialized.

---

## Enumerating Input Devices

Technically speaking, this step is not required if your application will only support keyboard and mouse input devices. It may be useful if the target machine has more than one keyboard or mouse attached, but you can still tell DirectInput to create objects that represent the primary keyboard and mouse. However, game controllers are another story. Since there are no primary or default game controllers, applications that wish to support joysticks, steering wheels, etc., must obtain individual GUIDs for these objects through enumeration.

The `EnumDevices` method of the IDirectInput object is used to list all available input devices. It is a callback function that will call the specified function once for each type of device attached to the system as indicated by the scope flags. The `EnumDevices` method is defined as:

```
function EnumDevices(  
  
    dwDevType: DWORD;             // indicates the type to enumerate  
  
    lpCallback: TDIEnumDevicesCallbackA; // the callback function  
  
    pvRef: Pointer;              // an application-defined value  
  
    dwFlags: DWORD               // flags controlling the scope  
  
): HRESULT;                     // returns a DirectX error code
```

The first parameter is a flag indicating the type of devices to enumerate. This can be set to zero to enumerate all devices, `DIDEVTYPE_MOUSE` to enumerate mice, `DIDEVTYPE_KEYBOARD` to enumerate keyboards, or `DIDEVTYPE_JOYSTICK` to enumerate game controllers. The second parameter is a pointer to the callback function

itself. The third parameter is a pointer to an application-defined value. The final parameter is a series of flags that further restrict the enumeration. This can be set to `DIEDFL_ATTACHEDONLY` to restrict enumeration to attached devices and/or `DIEDFL_FORCEFEEDBACK` to enumerate only force feedback devices. The callback function is defined as:

```
function TDIEnumDevicesCallbackA(  
  
var lpddi: TDIDeviceInstance;           // a device description record  
  
pvRef: Pointer                          // the application-defined value  
  
): BOOL; stdcall;                       // returns TRUE or FALSE
```

The first parameter contains a `TDIDeviceInstance` structure initialized with information about the enumerated input device. The second parameter contains a pointer to the application-defined value. This function must return `TRUE` to continue the enumeration; `FALSE` will stop the enumeration.

[Previous](#) [Table of Contents](#) [Next](#)

The TDIDeviceInstance structure passed into this callback function contains everything necessary for presenting the user with a list of choices, as well as creating an input object of the desired type. The TDIDeviceInstance structure is defined as:

TDIDeviceInstance = packed record

```

    dwSize: DWORD; // size of structure

    guidInstance: TGUID; // object instance GUID

    guidProduct: TGUID; // object product GUID

    dwDevType: DWORD; // device type flag

    tszInstanceName: Array [0..MAX_PATH-1] of WideChar; // instance name string

    tszProductName: Array [0..MAX_PATH-1] of WideChar; // product name string

    guidFFDriver: TGUID; // force feedback driver

    wUsagePage: WORD; // HID usage page code

    wUsage: WORD; // HID usage page

```

end;

An application could display a list of available input devices based on the instance name and product name available from the TDIDeviceInstance structure. If the instance GUID was stored along with this information, the application could create an input device using the GUID of the associated device that the user selected. The following example demonstrates creating an IDirectInput object and enumerating all attached game controllers.

*Listing 7-1: Creating an IDirectInput object and enumerating game controllers*

```

var

    Form1: TForm1;

    FDirectInput: IDirectInput;

implementation

function EnumInputDevs(var lpddi: TDIDeviceInstance; pvRef: Pointer): Integer;
    stdcall;

begin
    {display the instance name and product name of the enumerated game device}
    TStringList(pvRef).Add(lpddi.tszInstanceName+' - '+lpddi.tszProductName);

    {continue enumeration}

    Result := 1;

end;

procedure TForm1.FormActivate(Sender: TObject);

begin
    {create the DirectInput object}

    DirectInputCreate(hInstance, DIRECTINPUT_VERSION, FDirectInput, nil);

    {enumerate all attached game devices}

    FDirectInput.EnumDevices(DIDEVTYPE_JOYSTICK, EnumInputDevs,
                               lbxJoysticks.Items, DIEDFL_ATTACHEDONLY);

end;

```

---

At this point, the method calls for creating and initializing input device objects are the same, but the arguments passed into these methods are different depending on the input device itself. We will cover them briefly here, but we will wait to demonstrate any examples until we get to the sections where we demonstrate reading input data from various devices.

**Figure 7-1:** Attached game devices

## Creating the Input Device

The `DirectInput` object has been created, and we've presented the user with a list of input devices from which one device has been selected. Given this device's instance GUID, we can now create an `IDirectInputDevice` object representing the device. We create this object by calling `IDirectInput`'s `CreateDevice` method. The `CreateDevice` method is defined as:

```
function CreateDevice(  
    rguid: PGUID; // the device instance GUID  
    var lpDirectInputDevice: IDirectInputDevice; // the IDirectInputDevice object  
    pUnkOuter: IUnknown // unused, set to nil  
): HRESULT; // returns a DirectX error code
```

The first parameter is the instance GUID for the desired input device. For game controllers, this should be a GUID retrieved from device enumeration. For the primary keyboard, you can use `GUID_SysKeyboard`, and for the primary mouse, you can use `GUID_SysMouse`. The second parameter is a pointer to the `IDirectInputDevice` object. When this function returns, this object will be instantiated. The final parameter is used for COM aggregation and should be set to `nil`.

This function will only return an instantiated `IDirectInputDevice` object, but if we wish to use force feedback devices, we need to get an instantiated `IDirectInputDevice2` object. We should probably retrieve an `IDirectInputDevice2` object anyway, as some game controllers have a special requirement for retrieving data, as explained below. Thus, we should create a temporary `IDirectInputDevice` object, and once this is instantiated, we can use the `QueryInterface` method of the object to retrieve an instantiated `IDirectInputDevice2` object. The temporary object can then be released by setting it to `nil`.

## Setting the Data Format

Once the device has been created, you must instruct `DirectInput` as to the format in which input data should be reported. This step is required, as input data from a mouse, for example, would be completely different than that retrieved from the keyboard or a joystick. You may be asking, why should we do this if `DirectInput` knows what kind of device we just created? Again, this is part of `DirectInput`'s open architecture. Setting the data format in this manner allows the developer to declare a custom data format for new devices not yet created. We'll see an example of this later when we cover game controllers. Actually, setting the data format is quite easy, and requires calling the `IDirectInputDevice`'s `SetDataFormat` method. The `SetDataFormat` method is defined as:

```
function SetDataFormat(  
    var lpdf: TDIDataFormat // a data format structure  
): HRESULT; // returns a DirectX error code
```

The only parameter to this method is a variable of type `TDIDataFormat`. The `TDIDataFormat` structure is a complicated beast due to this open architecture. Fortunately, there are several standard, predefined data formats that we can use for communicating with just about any input device. For the keyboard, we can set this parameter to `c_dfDIKeyboard`; the mouse uses `c_dfDIMouse`. Joysticks supposedly could use either `c_dfDIJoystick` or `c_dfDIJoystick2` (for advanced game controllers and force feedback). However, in practice, we have found that neither

of these data structures seem to work correctly. Game controllers come in all shapes and sizes and can have a wide variety of buttons, axes, sliders, POV hats, etc. Therefore, creating a custom data structure on the fly based on the type of objects available on the device usually provides better results. We'll see an example of this later in the chapter when we discuss game controllers.

**POV hat:** The point-of-view (POV) hat is a device that typically rests on the top of a joystick, and can be used to indicate a viewing direction separate from movement direction.

The value passed to this function ultimately determines the data structure used when retrieving immediate data from any particular device. The parameters of the `GetDeviceState` method (covered below in the individual sections for each different device) are directly affected by the value passed to `SetDataFormat`. Each of the predefined values for `SetDataFormat` correspond to the following data structures that must be subsequently used in the call to `GetDeviceState` when retrieving immediate data.

*Table 7-2: Data formats and their data structures*

Format	Structure
c_dfDIKeyboard	TDIKeyboardState
c_dfDIMouse	TDIMouseState
c_dfDIJoystick *	TDIJoyState
c_dfDIJoystick2 *	TDIJoyState2

\* Don't use these; use the technique for building a custom data format later in the chapter.

**Setting the Cooperative Level**

We are almost ready to begin using the device, so now it is time to set the cooperative level. The cooperative levels and their ramifications were explained above. Setting the cooperative level requires a call to the IDirectInputDevice's SetCooperativeLevel method. The SetCooperativeLevel method is defined as:

```
function SetCooperativeLevel(
    hwnd: HWND; // a handle to the application window
    dwFlags: DWORD // cooperative level flags
): HRESULT; // returns a DirectX error code
```

The first parameter is the handle to the application's main window. This lets Windows and DirectInput know the application to which the input data should be sent. The second parameter is a combination of flags indicating the desired cooperative level. This must be set to one of each from DISCL\_BACKGROUND/ DISCL\_FOREGROUND and DISCL\_EXCLUSIVE/DISCL\_NONEXCLUSIVE.

**Setting Device Properties**

This step may be optional depending on the type of input device and the method by which input data is retrieved (i.e., immediate or buffered). However, some devices have certain properties that must be initialized before data can be retrieved from them. For example, joysticks must have their axes ranges set before they can return meaningful input data. Also, if you intend on using buffered data retrieval, you must set the size of the buffer. Setting device properties is accomplished by calling the IDirectInputDevice's SetProperty method. The SetProperty method is defined as:

```
function SetProperty(
    rguidProp: TRefGUID; // property identifier
    var pdiph: TDIPropHeader // the property data structure
```

```
): HRESULT; // returns a DirectX error code
```

This is another method where DirectInput's open architecture results in complexity. The first parameter identifies which property of the device to set. The value of this parameter is very dependent on the type of the device. For instance, it would be meaningless to set the range of an axis for a keyboard device. This parameter could be a GUID provided by the manufacturer of the device that identifies some specific property. Fortunately, however, there are several predefined values that we can use for setting specific properties. Perhaps the most common value passed to this parameter is `DIPROP_BUFFERSIZE`, which indicates we wish to set the size of the buffer for buffered data retrieval.

The second parameter is a pointer to a `TDIPropHeader` data structure. Here's where the complexity comes in. This parameter is a little misleading, because the method actually takes a pointer to whatever data structure is defined for the particular property being set. This could be some huge, custom data structure as defined by the product manufacturer. The only requirement is that the data structure must begin with a `TDIPropHeader` structure, which lets DirectInput know just how big the main structure is and the object on the device (such as an axis) whose properties are being set. Fortunately, most properties require only a single `DWORD` of information (such as buffer size) or perhaps two `LongWords` (in the case of ranges). The `TDIPropHeader` structure itself is defined as:

```
TDIPropHeader = packed record

    dwSize: DWORD; // the size of the main structure

    dwHeaderSize: DWORD; // the size of the TDIPropHeader structure

    dwObj: DWORD; // the device object identifier

    dwHow: DWORD; // indicates how to identify the device object

end;
```

The first member of this structure identifies the size of the overall structure. The second member should be set to the size of the `TDIPropHeader` structure. The third member identifies the device object (such as an axis) whose property is being set. There are a number of predefined identifiers that we will use to set various properties, and we'll see examples of this later in the sections on mouse and joystick programming. This member could be set to zero if a property that affects the entire device is being set, such as the buffer size. The last member tells DirectInput how the `dwObj` member is interpreted. This should be set to `DIPH_DEVICE` in the case of properties that affect the entire device. For individual device objects, there are two methods by which these objects can be identified. In this book, we will be concerned only with the offset method, so we should set this last member to `DIPH_BYOFFSET`.

DirectInput defines two standard structures that are most commonly used with `SetProperty`. The `TDIPropDWord` structure is used for setting properties that take only a single `DWORD` of information (such as buffer size), and the `TDIPropRange` structure is used for setting properties requiring two `LongWords` (such as ranges). The `TDIPropDWord` structure is defined as:

```
TDIPropDWord = packed record

    diph: TDIPropHeader; // the TDIPropHeader structure

    dwData: DWORD; // the value for the DWORD property

end;
```

The `TDIPropRange` structure is defined as:

```
TDIPropRange = packed record

    diph: TDIPropHeader; // the TDIPropHeader structure
```

```
lMin: Longint;           // the minimum range value

lMax: Longint;          // the maximum range value

end;
```

We'll see examples using the SetProperty method with these two data structures later in the chapter.

---

*Note:* Device properties can be retrieved by using the GetProperty method, which takes the exact same parameters.

---

## Acquiring the Device

The input device has been set up, and we are now ready to begin retrieving data. As explained above, we must acquire the device, which is accomplished by calling IDirectInputDevice's Acquire method. This simple method is defined as:

```
function Acquire: HRESULT;           // returns a DirectX error code
```

Subsequent calls to Acquire, once the device has been acquired, have no effect. A device can similarly be unacquired by calling the Unacquire method, which also takes no parameters.

## Retrieving Input Data

While the steps required for initializing and setting up DirectInput and DirectInputDevices are similar for every device, exactly how the input data is retrieved and extracted varies from device to device. This will also depend on whether you will be using immediate data retrieval or buffered data retrieval. This leads to subtle nuances in which initialization steps are required, and how the data returned from certain methods is interpreted.

In this section, we will take a look at examples for reading input data from three standard devices: the keyboard, the mouse, and the joystick. Each is similar in implementation, but there are differences that warrant a closer inspection. At the same time, we will also demonstrate both immediate data retrieval and buffered data retrieval. While we will only implement one or the other method of data retrieval in each example to simplify the code, immediate or buffered data retrieval can be used for any input device.

One thing to consider when developing your game application is if the complexity of DirectInput is even warranted. The Windows API contains numerous powerful functions that allow the user to read input from the keyboard, the mouse, or even game controllers. There is no support for force feedback, but if your application only requires a very simple interface to input devices, you may want to stick with standard Windows messages, or perhaps the Win32 API. In the following examples, we will demonstrate simplistic methods for reading input from devices using Win32 API functions before delving into the more complex DirectInput methods. Which you choose will be totally dependent on the type of game and the performance it will require, but either or both techniques are perfectly acceptable.

[Previous](#) [Table of Contents](#) [Next](#)

**Keyboard Input**

Of all input devices, the keyboard is perhaps the least complex. Having been the standard for input since almost the dawn of computers themselves, reading keyboard input is very straightforward and easy.

DirectInput approaches the keyboard not as a text input device, but as a gamepad with many buttons (according to the DirectInput documentation). As such, you gain the benefit of being able to differentiate between the left and right versions of identical keyboard buttons, such as Shift, Alt, and Ctrl. However, DirectInput completely ignores such control panel settings as repeat rate and other keyboard properties. Thus, pressing a key registers as a single key press, regardless of how long it has been held down. Similarly, releasing a key also registers as a singular event. Therefore, you must specifically write your code to respond to a key being held down, starting when a key press is noted and ending when the key has been detected as released (if necessary).

**Windows Functions**

Windows provides developers with the `GetAsyncKeyState` function, which is very similar to retrieving immediate keyboard data using DirectInput. `GetAsyncKeyState` simply indicates if a specific key is pressed or released at the time of the function call. `GetAsyncKeyState` is defined as:

```
function GetAsyncKeyState(  
    vKey: Integer           // a virtual key code  
): SHORT;                 // returns a key press state code
```

This function's only parameter takes a virtual key code, such as `VK_LEFT` for the left cursor key. It returns a 16-bit value that indicates, if the most significant bit is set, the specified key is currently pressed. For applications that only require a modicum of keyboard input, this function may be more than adequate. The following example demonstrates the use of this function.

*Listing 7-2: Retrieving keyboard input through `GetAsyncKeyState`*

```

procedure TForm1.Timer1Timer(Sender: TObject);
begin
    {poll the keyboard to check the state of various keys. the program can
    respond to multiple keys changing states simultaneously}
    if (GetAsyncKeyState(VK_LEFT) and $8000) = $8000 then
        shpLeft.Brush.Color := clRed
    else
        shpLeft.Brush.Color := clMaroon;

    if (GetAsyncKeyState(VK_RIGHT) and $8000) = $8000 then
        shpRight.Brush.Color := clRed
    else
        shpRight.Brush.Color := clMaroon;

    if (GetAsyncKeyState(VK_UP) and $8000) = $8000 then
        shpUp.Brush.Color := clRed
    else
        shpUp.Brush.Color := clMaroon;

    if (GetAsyncKeyState(VK_DOWN) and $8000) = $8000 then
        shpDown.Brush.Color := clRed
    else
        shpDown.Brush.Color := clMaroon;
end;

```

---

Unfortunately, this method cannot distinguish between left and right versions of certain keyboard keys, such as Shift, Alt, etc. Although easy to implement, it must still go through the Windows operating system to retrieve input data, which for many games may be too slow. For the best response times and total keyboard input control, we must use DirectInput.

### **DirectInput Initialization**

We must follow most of the steps outlined above to initialize DirectInput to receive keyboard data. In most cases, we only need to determine if a particular button is being pressed at a specific time, so immediate data retrieval is the perfect solution. This being the case, initialization of DirectInput is very straightforward.

The first order of business is creating the `DirectInput` object. We can then immediately create an `IDirectInputDevice` object for the primary keyboard using the `GUID_SysKeyboard` value. Since it's not likely that the keyboard will have force feedback capabilities, we'll skip querying for an `IDirectInputDevice2` object. We must then set the data format to `c_dfDIKeyboard`, the standard keyboard data format. We'll set the cooperative level for foreground, non-exclusive, and finally acquire the device so we can retrieve data. That's all there is to initializing `DirectInput` for immediate keyboard data retrieval. These steps are illustrated in the example below.

*Note:* Remember, the keyboard cannot be acquired in an exclusive cooperative level.

---

**Listing 7-3:** *Initializing DirectInput for keyboard data retrieval*

---

```
{create the DirectInput object}

DirectInputCreate(hInstance, DIRECTINPUT_VERSION, FDirectInput, nil);

{create the DirectInputDevice object for the primary keyboard}

FDirectInput.CreateDevice(@GUID_SysKeyboard, FDirectInputDevice, nil);

{set the data format for keyboard data}

FDirectInputDevice.SetDataFormat(c_dfDIKeyboard);

{set the appropriate cooperative level}

FDirectInputDevice.SetCooperativeLevel(Handle, DISCL_FOREGROUND or
                                        DISCL_NONEXCLUSIVE) );

{acquire the keyboard}

FDirectInputDevice.Acquire;
```

---

## Reading Input Data

Retrieving immediate data from any device involves a single call to the `IDirectInputDevice`'s `GetDeviceState` method. This method returns a snapshot of the state of the device at the time the function was called, including all pressed keys, axis movements, etc. The `GetDeviceState` function is defined as:

```
function GetDeviceState(
    cbData: DWORD; // the size of the data structure
```

```

lpvData: Pointer // a pointer to the appropriate data structure
): HRESULT; // returns a DirectX error code

```

Remember the call to the `SetDataFormat` method? This indicated to `DirectInput` the structure in which to report device data. The value passed to `SetDataFormat` indicates the data structure to be passed into `GetDeviceState` in the `lpvData` parameter. For keyboards, we use the `TDIKeyboardState` structure. The first parameter must be set to the size of this data structure.

The `TDIKeyboardState` structure itself is simply a 256-entry array of bytes. Each entry corresponds to a specific key on the keyboard. The array can be indexed using the `DIK_*` constants defined in the `DInput.pas` file for each specific key. If the hit bit of this byte is set, the key is currently down; otherwise it is up.

Therefore, to retrieve the current state of all keyboard keys, we simply call the `GetDeviceState` method of the `IDirectInputDevice` object we just created and check the high bit of the keys with which we are concerned. We must check for input data each time we need it, a technique known as polling as we discussed when we looked at polling versus event notification. The following example demonstrates this technique.

***Listing 7-4: Retrieving immediate keyboard input data***

---

```

procedure TfrmDXAppMain.DrawSurfaces;

var
    KeyboardState: TDIKeyboardState;
    SourceRect: TRect;

begin
    .
    .
    .

    {retrieve the current state of the keyboard as immediate data}
    FDirectInputDevice.GetDeviceState(SizeOf(KeyboardState), @KeyboardState);

    {if any of the cursor keys are held down, display an appropriate graphic}
    if (KeyboardState[DIK_UP] and $80) = $80 then
    begin
        SourceRect := Rect(0, 110, 110, 110+110);

        FBackBuffer.BltFast(265, 75, FImage, SourceRect, DDBLTFAST_NOCOLORKEY or
            DDBLTFAST_WAIT);
    end;
end;

```

```
if (KeyboardState[DIK_DOWN] and $80) = $80 then
begin
    SourceRect := Rect(2*110, 110, (2*110)+110, 110+110);
    FBackBuffer.BltFast(265, 295, FImage, SourceRect, DDBLTFAST_NOCOLORKEY or
        DDBLTFAST_WAIT);
end;

if (KeyboardState[DIK_LEFT] and $80) = $80 then
begin
    SourceRect := Rect(3*110, 110, (3*110)+110, 110+110);
    FBackBuffer.BltFast(155, 185, FImage, SourceRect, DDBLTFAST_NOCOLORKEY or
        DDBLTFAST_WAIT);
end;

if (KeyboardState[DIK_RIGHT] and $80) = $80 then
begin
    SourceRect := Rect(110, 110, 110+110, 110+110);
    FBackBuffer.BltFast(375, 185, FImage, SourceRect, DDBLTFAST_NOCOLORKEY or
        DDBLTFAST_WAIT);
end;

end;
```

---

**Mouse Input**

The other standard input device, the mouse, is probably used in just about every type of game for allowing the user to choose options and to set up game parameters. While it is almost as easy to read mouse data as it is the keyboard, there are certain nuances that must be considered.

The mouse returns data for up to three buttons and up to three axes. Since DirectInput works directly with the mouse driver, any control panel settings for the mouse are ignored, such as button swapping. However, the application could check on the status of button swapping by calling `GetSystemMetrics(SW_SWAPBUTTON)`. The axis data returned by the mouse is relative by nature, as the mouse can move infinitely in any direction. These values are arbitrary and not based on screen coordinates, control panel settings, etc. The x-axis and y-axis values returned by the mouse correspond to the horizontal and vertical movements of the physical device; mouse wheel values will be reported as a z-axis. As in the windowed world, mouse travel to the left or away from the user is negative, and right or toward the user is positive.

DirectInput allows you to retrieve axis movement, but it does not provide a mouse cursor (under exclusive mode). This must be implemented in the application itself. This is certainly not a difficult task, as you know where to draw the mouse cursor by the x-axis and y-axis values you've retrieved (as they pertain to your application). This allows you to implement elaborate animated mouse cursors using techniques as discussed in the chapter on sprites. The animation could even be context sensitive based on the position of the cursor or the current game state. The only thing to keep in mind is that you will want to draw the mouse cursor as the last step of your rendering process so it is not obscured by other graphics.

*Note:* Setting a non-exclusive cooperative level will display a mouse cursor, but it will flicker horribly in a page flipping architecture such as that used throughout this book. It is usually best to acquire the mouse exclusively and implement your own mouse cursor drawing functionality.

One drawback to drawing the mouse cursor in this manner is that its responsiveness will be very dependent on the frame rate of the application itself. For example, say the user starts the game on a very slow machine, and it has a frame rate of about five frames per second. If you draw your mouse cursor at the end of the rendering loop, it will be very jerky and unresponsive, and could make leaving the game very difficult indeed. In order to combat this dependence on the game's overall frame rate, we will be implementing a multithreaded solution for drawing the

mouse cursor.

This multithreaded architecture will also be useful for detecting available mouse input through event notification. This technique involves the use of Windows event objects as well as a critical section for thread synchronization. This complex architecture will be covered in more detail below.

## Windows Functions

Windows provides developers with the `GetCursorPos` function, which is very similar to retrieving immediate mouse data for the cursor position using `DirectInput`. The `GetAsyncKeyState` function can be used to retrieve the current state of mouse buttons. The `GetCursorPos` function is defined as:

```
function GetCursorPos(  
    var lpPoint: TPoint // receives coordinates of cursor  
): BOOL; // returns TRUE or FALSE
```

This function's only parameter is a `TPoint` variable that receives the horizontal and vertical coordinate of the mouse cursor's current position. For applications that only require a modicum of mouse input, this function may be more than adequate. The following example demonstrates the use of this function.

### *Listing 7-5: Retrieving mouse input through `GetCursorPos`*

---

```
procedure TForm1.Timer1Timer(Sender: TObject);  
var  
    CursorPos: TPoint;  
begin  
    {retrieve the position of the mouse cursor}  
    GetCursorPos(CursorPos);  
  
    {the retrieved position is in screen coordinates, so we must convert them  
    to client coordinates}  
    CursorPos := ScreenToClient(CursorPos);  
  
    {draw the background into the offscreen buffer, erasing the last frame'  
    Offscreen.Canvas.Draw(0, 0, Background);  
  
    {now, transparently draw our custom mouse cursor into the offscreen buffer.  
    note that we've moved the hotspot' so that it will be in the center of the
```

```
    cursor}

    BitBlt(Offscreen.Canvas.Handle, CursorPos.X-16, CursorPos.Y-16,
          CursorAND.Width, CursorAND.Height, CursorAND.Canvas.Handle, 0, 0,
          SRCAND);

    BitBlt(Offscreen.Canvas.Handle, CursorPos.X-16, CursorPos.Y-16,
          CursorOR.Width, CursorOR.Height, CursorOR.Canvas.Handle, 0, 0,
          SRCPAINT);

    {finally, draw the new frame of animation onto the screen}

    Canvas.Draw(0, 0, Offscreen);

end;
```

---

One drawback with `GetCursorPos` is that it reports the position of the mouse in relation to the screen, and thus is an absolute measurement as it reports values in the range of 0, 0 to screen width, screen height. This may be fine for some games, but others may require the infinite resolution and quicker response offered by `DirectInput`.

## DirectInput Initialization

We must follow most of the steps outlined above to initialize `DirectInput` to receive mouse data. Since we are dealing with a stream of relative axis values, we will use the buffered method of input data retrieval. Therefore, unlike the keyboard, we must set certain properties of the device to initialize this buffer. Due to our multithreaded architecture, we have a few more tasks to complete, some of which are not directly related to `DirectInput`.

*Note:* Retrieving immediate mouse data is similar to retrieving immediate keyboard data, and will return the cumulative sum of all axes movements since the last call to `GetDeviceState`.

---

The first order of business is creating the `DirectInput` object. We can then immediately create an `IDirectInputDevice` object for the primary mouse using the `GUID_SysMouse` value. Since it's not likely that the mouse will have force feedback capabilities, we'll skip querying for an `IDirectInputDevice2` object. We must then set the data format to `c_dfDIMouse`, the standard mouse data format. We'll then set the cooperative level for foreground, exclusive. These steps are illustrated below.

*Listing 7-6: Initializing DirectInput for mouse data retrieval*

```
{create the DirectInput object}

DirectInputCreate(hInstance, DIRECTINPUT_VERSION, FDirectInput, nil);

{create the DirectInputDevice object for the primary mouse}

FDirectInput.CreateDevice(@GUID_SysMouse, FMouseDevice, nil);

{set the data format for mouse data}

FMouseDevice.SetDataFormat(c_dfDIMouse);

{set the appropriate cooperative level}

FMouseDevice.SetCooperativeLevel(Handle, DISCL_FOREGROUND or DISCL_EXCLUSIVE);
```

With this accomplished, we should now set the size of the buffer that will hold our mouse input data. This property takes only a simple DWORD of information, so we can use a TDIPropDWord structure in our call to SetProperty. After initializing the appropriate size members, we should set the diph.dwObj member to zero and the diph.dwHow member to DIPH\_DEVICE, indicating that this property affects the entire device. Setting the dwData member to 64 indicates we want to set the buffer size to hold 64 “data packets” (this number is arbitrary, and can be higher or lower as dictated by the application requirements). Thus, our buffer will be capable of holding 64 individual instances of mouse input, be that axis movement, button presses, etc. If we do not retrieve and flush this buffer before this limit is

reached, any subsequent input data will be lost. This process is illustrated below.

**Listing 7-7: Setting the size of the buffer**

---

```
procedure TfrmDXAppMain.FormActivate(Sender: TObject);
var
    .
    .
    .

    {the mouse property structure}
    MouseProp: TDIPropDWord;
begin
    .
    .
    .

    {initialize our property structure}
    MouseProp.diph.dwSize := SizeOf(TDIPropDWord);
    MouseProp.diph.dwHeaderSize := SizeOf(TDIPropHeader);
    MouseProp.diph.dwObj := 0;
    MouseProp.diph.dwHow := DIPH_DEVICE;
    MouseProp.dwData := 64;           // we want 64 data packets'

    {set the size of the buffer property}
    DXCheck( FMouseDevice.SetProperty(DIPROP_BUFFERSIZE, MouseProp.diph) );
```

---

**Event Notification** As we've previously discussed, DirectInput has a method known as event notification where it can signal the application that an input event has occurred on some device. This releases the application from the requirement of polling the device through every iteration of the game loop, but it introduces some serious implications.

This technique works by using a Windows event object. Basically, an event is little more than a flag that exists in a

“signaled” or “non-signaled” state, and is used for thread synchronization. Using the `IDirectInputDevice`’s `SetEventNotification` method you can pass the device an event, which will be set to a signaled state when new input is available.

The only way this is useful is in a call to one of the Win32 API wait functions. These functions halt execution of a thread until the event object passed into the function becomes signaled. This is useless in a single-threaded application, as it would halt the execution of the primary thread unless the mouse is moving, making for a boring game indeed. This is why we must use this technique in a multithreaded application. We’ll see one of these wait functions in action below.

We will actually want to create two events, one which is passed to `DirectInput` to signal the availability of new mouse input and one to signal the thread to terminate. We can create these events using the Win32 API function `CreateEvent`, which is defined as:

```
function CreateEvent(  
  
    lpEventAttributes: PSecurityAttributes; // pointer to security attributes  
  
    bManualReset: BOOL; // flag for manual reset event  
  
    bInitialState: BOOL; // flag for initial state  
  
    lpName: PChar // name of the event object  
  
): THandle; // returns a handle of the event object
```

For our purposes, we can set the first parameter to `nil`, and the second and third parameters to `FALSE`. We can set the final parameter to an appropriate name for the event, but it is unimportant to our application. These events will be stored in an array for easy management. We will also create a `TCriticalSection` object, which we will use to synchronize the main thread and our secondary input thread. Using the critical section object will be covered below when we read the mouse data from the buffer.

Now that we’ve created our events, we need to tell `DirectInput` which event to signal when mouse input becomes available. This is accomplished by calling the `IDirectInputDevice`’s `SetEventNotification` method, defined as:

```
function SetEventNotification(  
  
    hEvent: THandle // a handle to the event to be signaled  
  
): HRESULT; // returns a DirectX error code
```

The only parameter to this method is the handle of the event to be signaled, which we just created above. The following example demonstrates the setup required for initializing event notification.

#### ***Listing 7-8: Initializing event notification***

---

```
{create our events, one for indicating new mouse input data, one for  
    indicating that the application is terminating}  
  
FMouseEvents[MOUSEEVENT] := CreateEvent(nil, FALSE, FALSE, MouseEvent');  
  
FMouseEvents[QUITEVENT] := CreateEvent(nil, FALSE, FALSE, QuitEvent');
```

```
{create our critical section synchronization object}

FCritSec := TCriticalSection.Create;

{set the event notification}

DXCheck( FMouseDevice.SetEventNotification(FMouseEvents[MOUSEEVENT]) );
```

---

**Secondary Thread Creation** Now that the critical section and events have been set up, we need to create our secondary thread. This second thread is where we will perform all input data retrieval. We used the File | New menu to create a new TThread object, using the Execute method as the location for our code that retrieves mouse input. We'll examine the details of this code below when we cover reading input data. To actually create the thread, we call our TThread object's Create method, passing its only parameter a value of TRUE to indicate we want the thread to be suspended upon creation. The thread should be suspended as we have not yet acquired the mouse. We then set its Priority property to tpTimeCritical, indicating we want it to be immediately responsive, and its FreeOnTerminate property to TRUE, indicating it should free itself when it is terminated. These steps are illustrated in the following listing.

**Listing 7-9: Creating the secondary input thread**

---

```
{create our secondary input thread}

FMouseThread := TMouseThread.Create(TRUE);

{we want it to be supremely responsive}

FMouseThread.Priority := tpTimeCritical;

{indicate it should free itself when it terminates}

FMouseThread.FreeOnTerminate := TRUE;
```

---

**Device Acquisition** Now that the events have been created and set up and the secondary input thread has been initialized, we can acquire the device by calling the Acquire method. As a final step, we must begin executing the input thread by calling the thread's Resume method. We are now finally ready to start retrieving buffered, event-driven mouse input data.

**Reading Input Data**

As we previously mentioned, our secondary thread will handle the task of retrieving the input data from the buffer. Thus, all of the code we are about to review is located in the Execute method of our secondary TThread object.

The first item of note in the Execute method concerns the notification events we created. After checking for termination, the very first task we perform in the thread is to call the WaitForMultipleObjects Win32 API function. This function halts execution of the thread until one or more event objects become signaled (known as blocking the thread). The WaitForMultipleObjects function is defined as:

```
function WaitForMultipleObjects(  
  
    nCount: DWORD; // the number of objects in the array  
  
    lpHandles: PWOHandleArray; // a pointer to an array of object handles  
  
    bWaitAll: BOOL; // wait flag  
  
  
    dwMilliseconds: DWORD // timeout interval  
  
): DWORD; // returns an array index
```

We pass in our array of object handles and the number of objects in the array in the first two parameters. We only want the thread to be blocked until either of the events becomes signaled, so we set the third parameter to FALSE. We want the thread to wait indefinitely until one of the events is signaled, so we set the final parameter to INFINITE. This function call will not return until either of the events becomes signaled.

When the function does return, we need to check its return value. We subtract the constant WAIT\_OBJECT\_0 from this return value to get the index in the array of the object that became signaled. If the Quit event was signaled (indicating we are terminating the application), we should immediately terminate the thread and exit the Execute method. Otherwise, we know it was the mouse event that became signaled, and we are ready to start retrieving mouse input data.

---

**Note:** We set the Quit event to signaled using the SetEvent Win32 API function in the main form's OnDestroy event. We must also use the CloseHandle Win32 API function to dispose of the event handles we created. See the full example on the CD for details.

---

Once past this, we make use of our critical section object. A critical section is a device that is used to synchronize access to variables and objects from multiple threads. This is accomplished by calling the TCriticalSection's Enter method. If one thread calls the Enter method of a critical section after another thread has already called it, this second thread is blocked until the first thread calls the TCriticalSection's Leave method. At this point, the other thread becomes unblocked, and any other thread will be blocked in a similar fashion until the current thread calls the Leave method. By using critical sections, we can allow only one thread at a time access to specific variables and objects. This is important, as this secondary input thread will be drawing to the primary DirectDraw surface, and surfaces can only be accessed by one thread at a time. It will also be updating global variables that track the mouse cursor, as well as a list of mouse click events that are used by the primary thread to determine if the user clicked on something interactive.

Now we are ready to being retrieving input data from our buffer. This is accomplished by calling the IDirectInputDevice's GetDeviceData method. The GetDeviceData method is defined as:

```
function GetDeviceData(  
  
    cbObjectData: DWORD;           // the size of the device data structure  
  
    rgdod: PDIDeviceObjectData;   // a pointer to the device data structure  
  
    var pdwInOut: DWORD;          // a variable indicating the number of elements  
  
    dwFlags: DWORD                // data removal flags  
  
): HRESULT;                       // returns a DirectX error code
```

The first parameter is set to the size of a TDIDeviceObjectData structure. The second parameter is a pointer to an array of TDIDeviceObjectData structures which, upon return, will contain the buffered device data. The third parameter indicates how many elements to retrieve, and should be equal to or less than the number of elements in the array. When this method returns, it will contain the actual number of elements retrieved. The last parameter indicates if the data should be removed from the buffer. Setting this to zero removes the data from the buffer; a value of DIGDD\_PEEK leaves the buffer intact.

---

**Note:** You do not have to remove the entire contents of the buffer at once. You may remove them one at a time or in similar small increments, if desired.

---

This method will return one TDIDeviceObjectData structure for each individual input event that has occurred on the device since the last time data was retrieved. This means there is one event for a button press, one for a button release (even if it was the same button), one for every individual movement along *each* axis, etc. This is why it is important to set the buffer size to an appropriate number, as it is easy to overflow the buffer if a lot of activity is occurring.

The TDIDeviceObjectData structure contains all the information necessary to report any input event on the specific device. The TDIDeviceObjectData structure is defined as:

```
TDIDeviceObjectData = packed record  
  
    dwOfs: DWORD;                 // the device object identifier  
  
    dwData: DWORD;                // the data
```

```
dwTimeStamp: DWORD; // when the event occurred

dwSequence: DWORD; // the event sequence number

end;
```

The first member, dwOfs, indicates what actually caused the input. This value is very specific to the type of device being used. In the case of buffered keyboard data, this value will be one of the DIK\_\* key values. For mice, this could be DIMOFS\_X, DIMOFS\_Y, or DIMOFS\_Z to indicate movement along one of the axes, or DIMOFS\_BUTTON0, DIMOFS\_BUTTON1, or DIMOFS\_BUTTON0 to indicate a change of state in one of the mouse buttons. There are similar DIJOFS\_\* values defined for various buttons and axes on joysticks. The dwData member contains the data for the input event, and again is very specific to both the device and the object on that device that signaled the input event. In the case of one of the axes, dwData will contain either relative or absolute axis movement, in arbitrary units. In the case of buttons, if the high bit is set, the button was pressed; if it is clear, the button was released.

If we enter a loop to retrieve one input event at a time, we can examine all of these members and update various global variables accordingly. In our example on the CD, we add any axis movement to global mouse cursor variables, and then ultimately clip them to the boundaries of our DirectDraw screen resolution. While our example is concerned only with button presses, we do store each mouse button press in a list of button press objects, storing the location of the press and the button that was pressed. We can use this later in our application logic to determine if the user clicked on an interactive game element.

**Tip:** The dwTimeStamp member of this structure indicates when the input event actually occurred. The time stamps from subsequent events could potentially be used to determine if the user double-clicked on some item. The dwSequence number, on the other hand, indicates the chronological sequence in which input events were obtained. This is useful for determining the order of input from two separate devices, as DirectInput never assigns the same sequence number for events from different devices, even if they have the same time stamp. This might come in handy if developing a multiplayer game where two people can play from the same machine.

All of this new functionality has been added to our baseline application so we can easily create DirectX applications with mouse support. While we are not going to cover it here, this new baseline application contains some additional code for drawing the mouse cursor on the primary surface from the secondary input thread. This solves the problem we noted earlier about the mouse cursor dependency on the animation frame rate. The following listing illustrates using the event notification and buffered data retrieval methods for obtaining mouse input data.

**Listing 7-10: Retrieving buffered mouse input data**

**Game Controller Input**

Game controller input programming can be both fun and complex. The fun comes from the fact that game controllers can be of almost any shape and size, and tend to resemble non-computer input devices such as steering wheels, rudder pedals, flight yokes, etc. This incredible variety is also the cause of the complexity. Since game controllers can have almost any number of axes, buttons, sliders, etc., the developer never knows the exact configuration of an attached controller without deducing what is available programmatically. This leads to a level of complexity not found in similar code for interfacing with keyboards and mice.

Game controllers can return a wide range of information. Data for up to three axes can be returned, including their rotation, velocity, acceleration, and force (with the existence of force feedback). Additionally, the state of two sliders, four POV hats, and 128 buttons can also be retrieved. By default, all of the axis information returned from game controllers is absolute, as most axes can move only so far in either direction. However, these values are arbitrary and not based on screen coordinates, etc. Like the mouse, axis data corresponds to the physical movement of the device. However, since game controllers can be almost any shape, the sign of these values and their relation to the direction of physical movement on the device is dependent upon the device itself (such as rotation of an axis). Also unlike the mouse, game controllers do take into account control panel settings, such as calibration. Therefore, you do not have to worry about writing specific code for calibrating a game controller before retrieving its state.

**Tip:** To run the control panel application for game controllers to begin calibration (or any control panel associated with any IDirectInputDevice, for that matter), simply call IDirectInputDevice's RunControlPanel method, passing zero in its two parameters. This allows users to easily calibrate game controllers from within your game.

Game controller input programming has a number of additional nuances that one must be aware of. As stated earlier, the predefined data format structure for joysticks and game controllers does not seem to work appropriately. Thus, in the examples below, we will enumerate all objects on an input device (such as axes, buttons, etc.) and create a custom data format. This will provide support for a wider range of game controllers (theoretically, all game controllers) and will result in more robust and stable code.

## Additional Game Controller Considerations

Above and beyond what is required to set up buffered data retrieval, game controllers require that the developer set up additional properties for each axis before input data can be retrieved. Specifically, the range of values for each axis must be set, as well as their deadzone and saturation levels.

**Range** A minimum and maximum range must be set for each axis. These values are completely arbitrary; DirectInput will scale the data returned from the driver to fit within this range, but these values are meaningful only within the context in which they are used. The center position of the axis will be the center of this specified range.

**Deadzone** The deadzone indicates an area around the center of an axis in which the axis can move, yet the position will be reported as the lowest value within the range. This allows a joystick to wander around a little in the center without reporting movement. This can be useful for setting sensitivity levels. This deadzone range is not subtracted from the overall range; DirectInput compresses the range values into a smaller part of the physical range of the axis. The deadzone value is always between 0 and 10,000, indicating a percentage of the overall range of axis travel in hundredths of degrees. For example, a value of 2,000 indicates we wish the first 20 percent of the physical range of axis travel to fall within the deadzone. This range is based on the center position of the axis, with one-half of the range on either side.

**Saturation** Saturation is similar to the deadzone in that it defines an area at the extent of axis travel in which the axis can move but the position will be reported as the highest value within the range. Again, this can be useful for setting sensitivity levels. However, some joysticks may only report the highest range values when the stick is moved to a diagonal position. Like the deadzone, saturation values are always between 0 and 10,000 (hundredths of degrees), and indicate the percentage of physical axis travel at which the highest range values will be reported. For example, a value of 9,000 indicates that the saturation zone begins at 90 percent of the physical range of axis travel (the last 10 percent of axis travel will fall within the saturation zone). Again, this range is based on the center position of the axis, and the range values themselves are compressed into the remaining part of the physical axis range.

**Caution:** It is possible to set a saturation and a deadzone that completely obscure discrete axis measurements (i.e., saturation and deadzone can be set such that axis values will only be reported as the minimum or maximum value in the specified range).

---

**Note:** Axes on a game pad do not report discrete values; they only report values at the central and extreme ends of the specified range.

---

## Game Controller Objects

Game controllers come with a variety of objects with which the user can provide input data. These objects include axes, POVs, and buttons. Although most game controllers exhibit input objects that are not available on the keyboard and mouse, data retrieved from these objects is not unlike that retrieved from more conventional input devices.

**Lateral and Rotational Axes** Game controller axes come in two flavors: lateral and rotational. A lateral axis moves in a straight line, such as left and right or forward and backward. Conversely, a rotational axis moves in a circular fashion, rotating about the x-, y-, or z-axis. The twisting motion on some joysticks is an example of a rotational axis. The values returned from each axis type is similar, however, and will be within the range specified by the developer.

**POV Hats** A point-of-view hat is neither a button nor an axis (it has more than two positions but reports values in a fixed range). The data reported by a POV is in polar coordinates, with 0 to the north (or top) and subsequent values increasing in a clockwise direction. These values are reported in hundredths of degrees (i.

e., 9000 = 90 degrees). When the POV is centered, the low word of the reported value will be \$FFFF. Most POVs have a granularity of 45 or 90 degrees.

**Caution:** While the GetProperty method of IDirectInputDevice can be used to retrieve the granularity, some game controller devices report this information incorrectly.

**Buttons** Game controller button state is reported exactly as keyboard or mouse buttons: If the high bit of the low word is set, the button is down; otherwise it is up.

### Windows Functions

Windows provides several functions to developers for determining game controller capabilities and retrieving input data. For the most part, these functions are incredibly powerful and can report almost as much data as their DirectInput counterparts. For most applications, these functions may supply all the required power.

**Note:** MMSystem must be added to the Uses clause of any unit employing these functions.

Game controller capabilities can be retrieved by using the joyGetDevCaps function. joyGetDevCaps is defined as:

```
joyGetDevCaps(  
  
  uJoyID: UINT;           // the game controller identifier  
  
  lpCaps: PJoyCaps;      // a TJoyCaps structure  
  
  uSize: UINT            // the size of the TJoyCaps structure  
  
): MMRESULT;           // returns an error condition
```

```

CrossHairY := JoyToRelative(0, pbCrossHairSurface.Width, JoyCaps.wYmin,
                            JoyCaps.wYmax, JoyPos.wYpos);

{draw the X, Y axis crosshair}
DrawCrossHair(CrossHairX, CrossHairY);

{draw the Point Of View direction}
if (JoyCaps.wCaps and JOYCAPS_HASPOV) = JOYCAPS_HASPOV then
    DrawPOV(JoyPos.dwPOV);

{draw the position of additional axes}
if (JoyCaps.wCaps and JOYCAPS_HASZ) = JOYCAPS_HASZ then
    shpZBarPos.Width := JoyToRelative(0, pnlZBar.Width, JoyCaps.wZmin,
                                       JoyCaps.wZmax, JoyPos.wZpos);

if (JoyCaps.wCaps and JOYCAPS_HASR) = JOYCAPS_HASR then
    shpRBarPos.Width := JoyToRelative(0, pnlRBar.Width, JoyCaps.wRmin,
                                       JoyCaps.wRmax, JoyPos.dwRpos);

if (JoyCaps.wCaps and JOYCAPS_HASU) = JOYCAPS_HASU then
    shpUBarPos.Width := JoyToRelative(0, pnlUBar.Width, JoyCaps.wUmin,
                                       JoyCaps.wUmax, JoyPos.dwUpos);

if (JoyCaps.wCaps and JOYCAPS_HASV) = JOYCAPS_HASV then
    shpVBarPos.Width := JoyToRelative(0, pnlVBar.Width, JoyCaps.wVmin,
                                       JoyCaps.wVmax, JoyPos.dwVpos);

{test the joystick buttons}
for iCount := 0 to 31 do
    if (ButtonLights[iCount] <> nil) then
        if Longbool(JoyPos.wButtons and Trunc(Power(2, iCount))) then

```

```

        ButtonLights[iCount].Brush.Color := clRed

    else

        ButtonLights[iCount].Brush.Color := clMaroon;

end;

```

---

Unfortunately, some game controllers have objects that provide input that joyGetPosEx simply cannot detect. Additionally, there is no Win32 API support for force feedback capabilities. These functions can allow a developer to rapidly implement game controller support, and may be useful for prototyping.

However, for the best response times, support for any game controller, and force feedback functionality, developers must use DirectInput.

**Figure 7-2:** Win32 joystick input

## DirectInput Initialization

We must follow most of the steps outlined above to initialize DirectInput to receive game controller data. However, since there is no system game controller and we are required to set up our own data format, there are several additional steps that must be taken.

As always, we start by creating the DirectInput object. We must know the exact instance GUID of the game controller device before a DirectInputDevice object can be created, so we must enumerate the attached game controllers. Therefore, we call the EnumDevices method, passing it a type of DIDEVTYPE\_JOYSTICK to indicate that we wish to enumerate game controllers. Usually there is only one game controller connected to the system. However, you may wish to create a list of all attached devices and present it to the user, as we explained earlier in the chapter. Once the instance GUID of the game controller is known, we can create the input device by calling the CreateDevice method. We need to use the Poll method, which is only available in the IDirectInputDevice2 interface, so we'll need to use QueryInterface to retrieve the appropriate object.

Now that we've created the device, we can retrieve its capabilities. We need to know how many buttons, axes, etc., this controller has; this and other information can be retrieved by calling the GetCapabilities method of the IDirectInputDevice object. GetCapabilities is defined as:

```

function GetCapabilities(

var lpDIDevCaps: TDIDevCaps           // a TDIDevCaps structure

): HRESULT;                           // returns a DirectX error code

```

The only parameter to this method is a pointer to a TDIDevCaps structure. This structure describes the capabilities of the queried device, and is defined as:

```

TDIDevCaps = packed record

    dwSize: DWORD;                     // the size of the structure

    dwFlags: DWORD;                    // device flags

```

```
dwDevType: DWORD; // device type identifier
dwAxes: DWORD; // number of axes
dwButtons: DWORD; // number of buttons
dwPOVs: DWORD; // number of POVs
dwFFSamplePeriod: DWORD; // force feedback sample period
dwFFMinTimeResolution: DWORD; // force feedback time resolution
dwFirmwareRevision: DWORD; // firmware version
dwHardwareRevision: DWORD; // hardware version
dwFFDriverVersion: DWORD; // device driver version
end;
```

Apart from the various members that denote the number of available objects, the dwFlags member may be of particular interest. This member contains a combination of flags that denote various attributes of the overall device. You can check to see if this member contains DIDC\_ATTACHED, indicating that a game controller is physically attached to the machine. Checking it for DIDC\_FORCEFEEDBACK indicates that the device supports force feedback.

In addition to retrieving the capabilities of the overall input device, we may also want to retrieve information on a specific object on that device. This is accomplished by calling the IDirectInputDevice's GetObjectInfo method. GetObjectInfo is defined as:

```
function GetObjectInfo(
var pdidoi: TDIDeviceObjectInstance; // a TDIDeviceObjectInstance structure
dwObj: DWORD; // object identifier
dwHow: DWORD // object identification method
): HRESULT; // returns a DirectX error code
```

The first parameter takes a pointer to a TDIDeviceObjectInstance structure that will contain information about the desired object when the function returns. The second parameter is the device object identifier whose information we wish to retrieve. The final parameter should be set to DIPH\_BYOFFSET. The TDIDeviceObjectInstance structure is another large structure that we will use again later when we construct our custom data format. The TDIDeviceObjectInstance structure is defined as:

```
TDIDeviceObjectInstance = packed record
    dwSize: DWORD; // size of the structure
    guidType: TGUID; // object type GUID
    dwOfs: DWORD; // offset (also object identifier)
    dwType: DWORD; // object type
```

```

dwFlags: DWORD; // attribute flags
tsizName: Array [0..MAX_PATH-1] of CHAR; // object name
dwFFMaxForce: DWORD; // maximum force magnitude
dwFFFForceResolution: DWORD; // force resolution
wCollectionNumber: WORD; // link collection number
wDesignatorIndex: WORD; // designator index
wUsagePage: WORD; // usage page
wUsage: WORD; // usage
dwDimension: DWORD; // dimensional units
wExponent: WORD; // dimension exponent
wReserved: WORD; // reserved

end;

```

Incidentally, this method can be used to simply detect the existence of a specific object. If the return value is not `DI_OK` for a specific object, then we know it doesn't exist on the input device. The following example demonstrates creating the object, retrieving device capabilities, and using the aforementioned technique to determine if any rotational axes are available on the device.

***Listing 7-12: Creating the input device and querying capabilities***

---

```

procedure TestForRotationalAxis(Offset: Integer; AxisName: string;
                                Panel: TPanel; Shape: TShape);

var
    ObjectInst: TDIDeviceObjectInstance;

begin
    {we will be retrieving information on a device object, so prepare a
    data structure}

    FillChar(ObjectInst, SizeOf(TDIDeviceObjectInstance), 0);

    ObjectInst.dwSize := SizeOf(TDIDeviceObjectInstance);

    {this simply determines if the specified object exists. we are using this
    here to specifically test for rotational axes (see where this function
    is called), but we could also use it to determine the existence of
    other axes or even buttons}

```

```
if FDirectInputDevice.GetObjectInfo(
    ObjectInst, Offset, DIPH_BYOFFSET) = DI_OK then
with frmJoyTestBed.memControllerInfo.Lines do
begin
    Add(    +AxisName+' rotational axis');
    Panel.Color := clMaroon;
end
else
begin
    Panel.Color := clBtnFace;
    Shape.Width := 0;
end;
end;

procedure TfrmJoyTestBed.FormActivate(Sender: TObject);
var
    FJoyList: TStringList;
    iCount: Integer;

    DevCaps: TDIDevCaps;

    TempDevice: IDirectInputDevice;

    .
    .
    .

begin
    {create the DirectInput object}
    DirectInputCreate(hInstance, DIRECTINPUT_VERSION, FDirectInput, nil);
```

```

{create a list to hold information on each available game controller}

FJoyList := TStringList.Create;

{enumerate attached game controllers}

FDirectInput.EnumDevices(DIDEVTYPE_JOYSTICK, EnumInputDevs, FJoyList,
                        DIEDFL_ATTACHEDONLY);

{we'll add this information to a list box in a dialog box, and display this
to the user so they can choose their desired input controller}

frmDevices := TfrmDevices.Create(Self);

for iCount := 0 to FJoyList.Count-1 do
    frmDevices.lbxJoyDevices.Items.Add(FJoyList[iCount]);

frmDevices.ShowModal;

{create the input device based on the input controller specified by the user}
DXCheck( FDirectInput.CreateDevice(PGUID(FJoyList.Objects[0])^, TempDevice,
                                    nil) );

{close this dialog box, and delete the list of GUIDs}

frmDevices.Release;

for iCount := 0 to FJoyList.Count-1 do
    Dispose(PGUID(FJoyList.Objects[0]));

FJoyList.Free;

{we need the new version of the input device interface, so retrieve it}
try
    DXCheck(TempDevice.QueryInterface(IDirectInputDevice2, FDirectInputDevice));
finally
    TempDevice := nil
end;

{retrieve the capabilities of this device}

```

```

DevCaps.dwSize := SizeOf(DevCaps);

FDirectInputDevice.GetCapabilities(DevCaps);

.
.
.

{determine if the controller is unplugged}
if (DevCaps.dwFlags and DIDC_ATTACHED) <> DIDC_ATTACHED then
    ShowMessage(Controller is unplugged');

{create button indicators}
for iCount := 0 to DevCaps.dwButtons-1 do
begin
    ButtonLights[iCount]           := TShape.Create(GroupBox2);
    ButtonLights[iCount].Left       := 96+((iCount mod 5)*(49+5));
    ButtonLights[iCount].Top        := 48+((iCount div 5)*(17+5));
    ButtonLights[iCount].Width      := 49;
    ButtonLights[iCount].Height     := 17;
    ButtonLights[iCount].Brush.Color := clMaroon;
    ButtonLights[iCount].Parent     := GroupBox2;
end;

{indicate if a POV is available}
if DevCaps.dwPOVs > 0 then
begin
    Label9.Enabled := TRUE;
    Panel2.Color := clWhite;
end
else
begin
    Label9.Enabled := FALSE;

```

```

    Panel2.Color := clBtnFace;

end;

{display controller capabilities}

with DevCaps, memControllerInfo.Lines do

begin

    Add(Number of buttons: +IntToStr(dwButtons));

    Add(Number of axes: +IntToStr(dwAxes));

    Add(Number of POVs: +IntToStr(dwPOVs));

    Add(' ');

    Add(Rotational Axes:');

    TestForRotationalAxis(DIJOFS_RX, RX', pnlRXBar, shpRXBarPos);

    TestForRotationalAxis(DIJOFS_RY, RY', pnlRYBar, shpRYBarPos);

    TestForRotationalAxis(DIJOFS_RZ, RZ', pnlRZBar, shpRZBarPos);

end;

.

.

.

end;

```

---

**Setting the Data Format** Now that the device has been created and its capabilities have been determined, we need to set the data format. As mentioned earlier, we must generate our own data format programmatically to ensure that the greatest number of input devices are supported. We begin by declaring a variable of type `TDIDataFormat`. `TDIDataFormat` is defined as:

```

TDIDataFormat = packed record

    dwSize: DWORD;           // size of this structure

    dwObjSize: DWORD;       // size of a TDIOBJECTDATAFORMAT structure

    dwFlags: DWORD;        // attribute flags

    dwDataSize: DWORD;     // size of data packet

```

```
dwNumObjs: DWORD; // number of objects in the array  
rgodf: PDIOBJECTDATAFORMAT; // array of TDIOBJECTDATAFORMAT structures  
end;
```

This structure carries information that describes a device's data format. The first member should be set to the size of the TDIDataFormat structure. The second member is set to the size of a TDIOBJECTDataFormat structure. The third member is a series of flags that describe certain attributes of the data format. For our purposes, we can set this member to DIDF\_ABSAXIS to indicate that axes measurements are absolute. The fourth member indicates the size of the data packet returned from the driver. This value must be a multiple of 4, and must exceed the largest offset value for an object's data in the packet. For our purposes, we'll set this to the size of the TDIJoyState2 structure. The fifth member indicates the number of objects that are in the sixth member, which is a pointer to an array of TDIOBJECTDataFormat structures. The TDIOBJECTDataFormat structure is defined as:

```
TDIOBJECTDataFormat = packed record

    pguid: ^TGUID;           // object GUID

    dwOfs: DWORD;           // object offset

    dwType: DWORD;          // object type

    dwFlags: DWORD;         // attribute flags

end;
```

The TDIOBJECTDataFormat structure contains information about a specific object on the input device, such as an individual axis or button. The first member is the object's unique identifying GUID. The second member is the object's offset within the data packet. This is also the object identifier that we have used in other methods. The third member indicates the object type (such as a button or axis), and the final member contains attribute flags for the object.

After we initialize the first four members of the TDIDataFormat structure, we must begin building the array of TDIOBJECTDataFormat structures for each object on the device. To do this, we must employ the EnumObjects method. EnumObjects works the same as all other enumeration functions in that it calls a callback function once for each object on the input device. The EnumObjects method is defined as:

```
function EnumObjects(

lpCallback: TDIEnumDeviceObjectsCallbackA;    // the callback function
```

```

pvRef: Pointer; // application-defined value
dwFlags: DWORD // enumeration flags
): HRESULT; // returns a DirectX error code

```

The first parameter is a pointer to the callback function, the second parameter is a pointer to an application-defined value, and the final parameter is a series of flags that control the scope of enumeration. For our purposes, we'll set this final parameter to DIDFT\_ALL to indicate we wish to enumerate all devices. The callback function itself must be defined as:

```

function TDIEnumDeviceObjectsCallbackA(
var lpddoi: TDIDeviceObjectInstance; // a TDIDeviceObjectInstance structure
pvRef: Pointer // the application-defined data
): BOOL; stdcall; // returns TRUE or FALSE

```

The first parameter is an initialized TDIDeviceObjectInstance structure containing all the information we need about this specific object. The only other parameter is a pointer to the application-defined value. This callback function should return TRUE to continue enumeration or FALSE otherwise.

As we are enumerating, for each object, we can save the GUID, offset, and type as reported from the TDIDeviceObjectInstance structure into our array of TDIOBJECTDATAFORMAT structures. We also must keep a count of the number of objects found.

When enumeration completes, we will have a correctly initialized TDIDataFormat structure, complete with an array of correctly initialized TDIOBJECTDATAFORMAT structures. This entire data structure is then sent to the SetDataFormat method to finally set the correct data format for the game controller. This is illustrated in the following example.

***Listing 7-13: Setting the data format***

---

```

procedure SetDataFormat;

function DIEnumDeviceObjectsProc(const peff: TDIDeviceObjectInstance;
                                pvRef: Pointer): HRESULT; stdcall;

begin
    {if the offset is not beyond the indicated data size... (useful if
     we were to use the TDIJoyState data structure instead) }
    if peff.dwOfs < FDataFormat.dwDataSize then
    begin
        {save the type GUID for this object}
        FDataFormatGUIDs[FDataFormat.dwNumObjs] := peff.guidType;
    end
end

```

```

    {add the object information to our custom made data format}
    with FDataFormatObjects[FDataFormat.dwNumObjs] do
    begin
        pguid := @FDataFormatGUIDs[FDataFormat.dwNumObjs];
        dwOfs := peff.dwOfs;
        dwType := peff.dwType;
        dwFlags := 0;
    end;

    {if this object is an axis, store it in our axis list}
    if (peff.dwType and DIDFT_AXIS) > 0 then
    begin
        FAxisList[NumAxes] := peff.dwOfs;
        Inc(NumAxes);
    end;

    {increment the number of objects found}
    Inc(FDataFormat.dwNumObjs);
end;

{continue enumeration}
Result := DIENUM_CONTINUE;
end;

begin
    {enumerate all objects on this input device. this will build our custom data
    structure programmatically with the correct information for each object}
    FDirectInputDevice.EnumObjects(@DIEnumDeviceObjectsProc, nil, DIDFT_ALL);

    {set the data format for the input device}
    DXCheck( FDirectInputDevice.SetDataFormat(FDataFormat) );

```

```

end;

procedure TfrmJoyTestBed.FormActivate(Sender: TObject);
var
    .
    .
    .

begin
    .
    .
    .

    {initialize our axis tracking variable}
    NumAxes := 0;

    {now we need to begin creating the data format structure and setting the
    data format, so we must initialize the overall data format structure}
    with FDataFormat do
    begin
        dwFlags := DIDF_ABSAXIS;
        dwDataSize := SizeOf(TDIJoyState2);
        dwSize := SizeOf(FDataFormat);
        dwObjSize := SizeOf(TDIObjectDataFormat);
        dwNumObjs := 0;
        rgodf := @FDataFormatObjects;
    end;

    {create and set a data format specifically made for this device}

```

```
SetDataFormat ;
```

```
.  
. .  
. . .
```

```
end ;
```

---

***Setting Axis Properties*** With the data format set, we are now ready to start setting various properties for all of the axes.

As discussed above, we must set the range, deadzone, and saturation for each axis. To accomplish this task, we'll need variables of type TDIPropRange for the range and TDIPropDWord for the deadzone and saturation. As we illustrated in the mouse example, we must initialize the various size members of this structure. Unlike the mouse example, however, we will set the dwObj members of both structures to the object identifier for each individual axis. We could set this to DIPH\_DEVICE, setting the properties for all axes on the device, but we may want to set different ranges, deadzones, and saturations for each device. For the TDIPropRange structure, we'll set the lMin and lMax members to 1,000 and 1,000, respectively. For the TDIPropDWord structure, we'll set the dwData member to 1,000 for deadzone properties (indicating 10 percent deadzone), and 9,000 for saturation properties (indicating that the last 10 percent is saturation). We can then call the SetProperty method once for each axis and each property. Once this is complete, we can finally set our cooperative level and acquire the device so we can start retrieving input. This is illustrated in the following listing.

## Reading Input Data

Compared to setting up DirectInput for game controllers, actually reading their input data is rather simple.

Game controllers usually do not generate hardware interrupts. As such, Windows (and the device driver) is not informed that an input event has occurred on the device. Thus, for almost all game controllers, the Poll method must be called to instruct the driver to retrieve device information before the application can retrieve the device's state. The Poll method takes no parameters. If a game controller does not require polling, this method has no effect. Therefore, it's usually a good practice to always call the Poll method regardless of the game controller or its driver.

Once this is done, the application can call the GetDeviceState method, passing in a pointer to a TDIJoyState2 structure. Although you can use buffered data techniques, most applications can get by with retrieving immediate game controller data. The TDIJoyState2 structure is defined as:

```

TDIJoyState2 = packed record

    lX: Longint;           // x-axis position
    lY: Longint;           // y-axis position
    lZ: Longint;           // z-axis position
    lRx: Longint;          // x-axis rotation
    lRy: Longint;          // y-axis rotation
    lRz: Longint;          // z-axis rotation
    rglSlider: Array [0..1] of Longint; // extra axes positions
    rgdwPOV: Array [0..3] of DWORD;    // POV directions

```

```

rgbButtons: Array [0..127] of BYTE;      // 128 buttons

lVX: Longint;                            // x-axis velocity
lVY: Longint;                            // y-axis velocity
lVZ: Longint;                            // z-axis velocity
lVRx: Longint;                           // x-axis angular velocity
lVRy: Longint;                           // y-axis angular velocity
lVRz: Longint;                           // z-axis angular velocity
rglVSlider: Array [0..1] of Longint;     // extra axes velocities
lAX: Longint;                            // x-axis acceleration
lAY: Longint;                            // y-axis acceleration
lAZ: Longint;                            // z-axis acceleration
lARx: Longint;                           // x-axis angular acceleration
lARy: Longint;                           // y-axis angular acceleration
lARz: Longint;                           // z-axis angular acceleration
rglASlider: Array [0..1] of Longint;     // extra axes accelerations
lFX: Longint;                            // x-axis force
lFY: Longint;                            // y-axis force
lFZ: Longint;                            // z-axis force
lFRx: Longint;                           // x-axis torque
lFRy: Longint;                           // y-axis torque
lFRz: Longint;                           // z-axis torque
rglFSlider: Array [0..1] of Longint;     // extra axes forces

end;
```

This rather large structure defines the state of every object on the game controller. The position and rotation of various axes is easily retrievable, as is the state of buttons, POVs, etc. The following listing illustrates how to retrieve the current state of a game controller.

*Listing 7-15: Retrieving immediate game controller input data*

```
procedure TfrmJoyTestBed.tmrJoyPollTimer(Sender: TObject);
var
    DevState: TDIJoystate2;
    iCount: Integer;
begin
    {more often than not, game controllers do not generate hardware
    interrupts. thus, we have to poll the device driver in order to
    get the current state of the device.}
    FDirectInputDevice.Poll;

    {retrieve the state of all objects on the device}
    DXCheck( FDirectInputDevice.GetDeviceState(SizeOf(DevState), @DevState) );

    {we're assuming here that the game controller has an X and Y axis
    (as joysticks and gamepads do), so draw a crosshair}
```

```

DrawCrossHair((DevState.lX + 1000) div 20, (DevState.lY + 1000) div 20);

{draw slider bars for any other axes}
for iCount := 2 to NumAxes-1 do
    case FAxisList[iCount] of
        DIJOFS_Z   : shpZBarPos.Width := (DevState.lZ + 1000) div 20;
        DIJOFS_RX  : shpRXBarPos.Width := (DevState.lRx + 1000) div 20;
        DIJOFS_RY  : shpRYBarPos.Width := (DevState.lRy + 1000) div 20;
        DIJOFS_RZ  : shpRZBarPos.Width := (DevState.lRz + 1000) div 20;
    end;

{if a POV is available (availability of which should probably be placed
in a global variable as opposed to checking the enabled state of a
label), then draw a crosshair}
if Label9.Enabled then
    DrawPov(DevState.rgdwPOV[0]);

{test the joystick buttons}
for iCount := 0 to 127 do
    if ButtonLights[iCount] <> nil then
        if (DevState.rgbButtons[iCount] and $80) = $80 then
            ButtonLights[iCount].Brush.Color := clRed
        else
            ButtonLights[iCount].Brush.Color := clMaroon;
        end;
    end;
end;

```

---

## Summary

In this chapter, we discussed several techniques for retrieving user input data from various input devices. We examined both common Win32 API functions and their DirectInput counterparts for reading the state of keyboard, mice, and game controller devices. We also covered various techniques for retrieving this data, including immediate and buffered data as well as polling and event notification. When coding user input data

routines using DirectInput or Win32 API functions, it is important to keep these points in mind:

- Input is one of the three fundamental parts of a game, and as such is important to overall game enjoyment. Exactly how user input will be translated into game element manipulation is dependent on the game itself. Flight simulators need input that affects the direction of flight, or perhaps even the selection and use of a weapon. Strategy games, by contrast, need input that determines which token is selected and its direction of movement or combat.
- Input devices go beyond the standard mouse and keyboard. There are now a wide variety of peripheral game controllers in all shapes and sizes. Rudder pedals, steering wheels, gamepads, throttles, and all manner of sundry and arcane input devices are now available, making some games much more enjoyable to play. Even the standard joystick has become incredibly complex, with many sporting impressive arrays of buttons, switches, sliders, and even tactile responses known as force feedback.
- An important user input consideration is support for user configurable controls. Even though the developer has determined which input devices will be supported and how they interact with game elements, individual users may find this structure somewhat restrictive based on their particular preferences.
- DirectInput is the DirectX component responsible for providing user input from all manner of input devices, such as keyboards, mice, and game controllers. DirectInput offers many features above and beyond what is available through the Win32 API. As with all DirectX components, DirectInput gives the developer more control over user input than the Windows API, while also providing an improvement in performance.
- Similar to DirectDraw, DirectInput programming consists of creating a DirectInput object and several DirectInputDevice objects. The DirectInput object itself acts as a liaison between the application and input device drivers. Individual DirectInputDevice objects represent the application's interface directly to input hardware, or more specifically, that hardware's device driver.
- Where DirectInput is concerned, a button is considered to be any switch that has an on and off position. There is no distinction made between buttons on a mouse, keyboard, or joystick. An axis has a range of positions where its value is affected by the physical movement of a device in some particular direction. Some axes can move an infinite distance in a particular direction, and are measured in relative values. Other axes can physically move only a specific distance, and are measured in absolute values.
- Buffered data retrieval simulates the mechanism by which Windows reports input. Individual input events are stored in a buffer, which takes the form of an array of data structures containing the various axis movement values or button clicks. Immediate data retrieval does not report a stream of singular events, but returns the current state of the device at the time of the function call.
- Polling involves checking the state of the input device at the time that the input is needed. Typically, this is performed in the game loop. Event notification, on the other hand, is very similar to event-driven programming. This is a mechanism by which DirectInput will notify the application when new input data is available, and is best paired with buffered data retrieval.
- As discussed in the DirectDraw tutorial, a cooperative level determines how the application works with other applications. As with other DirectX components, DirectInput gives the developer a choice as to how the application will share input devices with other applications, in terms of who can gain access to the device and if input can be retrieved based on application focus. Bear in mind that Windows requires exclusive access to the keyboard at all times, so that functions such as Alt+Tab and Ctrl+Alt+Delete are always available. Thus, an application can only obtain non-exclusive access to the keyboard.
- Once a device is set up, the application cannot receive input data until it instructs DirectInput that it is ready to do so. This process is known as acquiring the device. Bear in mind that a device can be forcibly unacquired by the application. This may happen when another application receives focus or acquires the device in exclusive mode.
- Several steps are required in order to set up DirectInput and begin interfacing with user input devices. In general you must create the DirectInput object, enumerate input devices, create the input device, set the data format, set the cooperative level, set device properties, and then acquire the device.
- While the steps required for initializing and setting up DirectInput and DirectInputDevices are similar for every device, exactly how the input data is retrieved and extracted varies from device to device. This will also depend on whether you will be using immediate data retrieval or buffered data retrieval. This leads to subtle nuances in which initialization steps are required, and how the data returned from certain methods is interpreted.
- Retrieving keyboard data is the easiest. The GetAsyncKeyState Win32 API function could potentially be used if the full power of DirectInput was not needed. However, you would not be able to differentiate between left and right versions of certain keys, such as Shift or Ctrl.
- Mouse data is best retrieved using a buffer coupled with event notification. This requires setting up a secondary thread and using critical sections to synchronize variable access. The Win32 API function

GetCursorPos function could potentially be used instead, but this function reports absolute values relative to the screen.

- Game controller data input retrieval is very complex. We must set up a custom data format, but this complexity results in support for a wider range of devices. We must also set up the range, deadzone, and saturation properties for each axis. We could use the joyGetPosEx function, but this function only supports up to six axes and 32 buttons, and has no support for force feedback.

## CHAPTER 8 Force Feedback

This chapter covers the following topics:

- Creating and using standard force feedback effects
- Creating and using custom force feedback effects
- Modifying a force feedback effect on the fly
- Shaping force feedback effects with envelopes

Cutting-edge computer games offer an entertainment experience very similar to Hollywood movies. Such games feature almost photo-realistic environments, complete with appropriate lighting, 3-D sound effects, and music to enhance the emotional impact. However, consider how much more realistic and immersive a gaming experience would be if you could feel the blow of your axe against an enemy's armor, or the resistance of gravity and air as you wheel your jet fighter through a tight turn. This is what force feedback technology is all about.

Force feedback allows the game developer to add the illusion of mass and momentum to game elements previously only represented as dots of colored light. Like sound and music, it adds an intangible realistic element to a game that could not be accomplished otherwise. Force feedback support appeared in DirectX 5, and since then, game manufacturers have slowly implemented force feedback support into their products. Like sound and music, no game absolutely requires force feedback in order to make it entertaining. On the other hand, unless you're making a game like Solitaire, it would be crazy to ignore the exciting functionality this new technology offers; it is certainly a requirement for action games to actively compete in the retail market.

The force feedback API is part of DirectInput. At the time of this writing, force feedback functionality is available primarily on joysticks and a few wheels, but the technology is designed to work with devices of any shape and size. The result is a very flexible yet complex system. For our purposes, we will focus our discussion of force feedback as it applies to joysticks, but keep in mind that the concepts to follow can be applied to any type of force feedback device.

---

**Tip:** These examples were written and tested specifically on the Microsoft SideWinder® Force Feedback Pro joystick, but they should work on any force feedback device with an x- and y-axis.

---

## Features

Force feedback has no equivalent in the Win32 API world, and as such cannot be compared to any existing functionality. As we've discussed, the purpose of force feedback is to provide the user with tactile output based on conditions within the game world. This is accomplished through either an active push on one or more of the axes supported by the device, or through some form of resistance along those axes when the user manipulates the device. Considering this, DirectInput's force feedback functionality provides the following features of interest to game developers:

- Several different standard effects representing a wide range of tactile responses
- Device-specific effects implemented by the device driver (when available)
- Modification of effects on the fly (when available)
- Creation of customized effects
- Triggered effects controlled by the device

In the following sections we will discuss how the Delphi game developer can take advantage of each of these features to create tactile feedback that provides a new level of realism to game environments.

## Functional Overview

In order to begin using force feedback, the application must already have an initialized `IDirectInputDevice2` object. An elaborate data structure is then initialized depending on the type of effect desired. `IDirectInputDevice2` uses this initialized data structure to create an `IDirectInputEffect` object.

The `IDirectInputEffect` object represents the developer's direct interface to the force feedback hardware. This is not to be confused with the functionality provided by the `IDirectInputDevice2` object; `IDirectInputDevice2` is responsible for communicating user input from the device, whereas `IDirectInputEffect` is responsible for outputting tactile feedback responses to the device. Through the `IDirectInputEffect` interface, the application can query the force feedback hardware's capabilities, start and stop the effect, modify the effect on the fly, and control other aspects of the force feedback hardware itself.

Once an effect is created, it must be downloaded to the device. This typically happens automatically, as we'll discuss below. The act of downloading an effect tells the driver to prepare the effect for playback. How this is accomplished is determined by the driver, but typically the effect's parameters are placed into hardware memory so that the device will not need to communicate with the system in response to axis movement and button presses. However, a device can only handle a finite number of effects, and may return a `DIERR_DEVICEFULL` error. The workaround is to simply unload another, hopefully unused, effect and then try again.

Once an effect is created, it must be explicitly started. Effects can play infinitely or for a specified amount of time, and can be stopped if necessary. Alternatively, when the effect is being created, it can be associated with a button on the device. The device driver will then start the effect when the button is pressed. Triggered effects such as this will stop when the effect duration has been reached or when the button is released, whichever comes first. This functionality is totally independent of the application. Some devices even support repeating an effect while the button is held down, perfect for re-creating the kickback of a machine gun or other automatic weapon.

## Basic Concepts

When discussing force feedback effects, it is necessary to understand several general concepts as they apply to the effect itself. These concepts define the action of the effect, such as its strength and direction. Such

concepts include kinetic forces, conditions, magnitude, coefficient, gain, duration, sample period, axes, direction, and envelope.

## Kinetic Force

A kinetic force is an effect that actively pushes on one or more axes. This push can be in a single direction or in alternating directions such as occurs with periodic effects. This active push is applied regardless of the position or movement of the axis (or axes). An example of this is a push on the joystick in the direction of the user to simulate recoil from firing a rocket.

**kinetic force:** An active push on one or more axes on a force feedback device.

**Note:** Force feedback devices are required to have a safety feature installed that prevents the playback of effects unless the user is actively gripping the device. This helps avoid potential injury that might occur if the user is trying to pick up the device while a kinetic force effect is playing.

### Condition

Unlike a kinetic force, a condition is a resistance or force that is applied to one or more axes in response to their movement or position. For example, the self-centering effect that a force feedback joystick automatically exhibits is a condition that tries to move the stick back to its center position. Another example would be to apply a dampening effect to the stick in order to re-create the resistance of moving around in an underwater environment. There are currently four different types of conditions, which we'll cover in more detail shortly.

**condition:** A resistant force applied to one or more axes on a force feedback device in response to the movement or position of those axes.

### Magnitude

Magnitude is a measurement of the strength of a kinetic force, relative to the total maximum force that can be output by the device. The magnitude of a force can be expressed as an integer value between -10,000 and 10,000, where positive values represent a force in one direction and negative values represent the same force in the opposite direction. The DI\_FF NOMINALMAX constant defined by the DInput unit, initialized to 10,000, represents the total maximum force that can be exerted by the device on any given axis. This constant

allows the developer to define the magnitude of a force as a percentage of the total maximum force available on the device (i.e., `DI_FFNO`

**magnitude:** A measurement of the strength of a kinetic force output by a force feedback device, relative to the total maximum force available on the device itself.

## Coefficient

Coefficient is conceptually similar to magnitude, except that it is a measurement of the strength of resistance to movement along an axis. Like magnitude, this value is expressed as an integer between 10,000 and -10,000, where positive values represent resistance and negative values represent acceleration (i.e., it has the effect of pulling along the direction of motion). Again, it is best to use the `DI_FFNO` constant to define a coefficient as a percentage of the total maximum force.

**coefficient:** A measurement of the strength of resistance output by a force feedback device in response to the movement of an axis, relative to the total maximum force available on the device itself.

**Note:** In the case of a spring condition (discussed later in this chapter), a negative coefficient has the effect of pushing the axis away from the defined neutral point.

## Duration

Duration defines how long the effect will play, measured in microseconds. The constant `DI_SECONDS`, found in the `DInput` unit, can be used to define the duration in terms of one-second intervals (or fractions thereof). The constant `INFINITE` can also be used to indicate an effect with no duration. This type of effect will play until explicitly stopped or the `IDirectInputEffect` object is freed. In the case of triggered effects, playback is stopped when the duration expires or the button is released.

**Tip:** An infinite duration is typically used for condition effects or periodic forces; it typically doesn't make sense to specify an infinite duration for a constant or ramp force.

## Sample Period

Sample period defines the interval between actual changes in the strength of a force, measured in microseconds. Setting this to a large value will cause the strength of the effect to be adjusted fewer times over the course of its duration, which may cause a ratcheting sensation. Setting this value to zero allows for the smoothest change in relative force strength.

## Gain

Gain acts as a scaling factor for magnitudes and coefficients. It is expressed as a value between 0 and 10,000, indicating the percentage by which to scale the magnitude or coefficient. For example, 10,000 indicates no scaling, whereas 5,000 indicates 50 percent of the specified magnitude or coefficient. Gain can be applied to the entire device or only to individual effects. The `DI_FFNO` constant can again be used here to easily define a scaling factor as a percentage of the nominal value.

**gain:** A scaling factor for magnitudes and coefficients, measured in hundredths of a percent.

**Note:** Use the SetProperty method of the IDirectInputDevice interface in order to set the gain for the entire device.

## Axes

Axes determine what axis (or axes) of movement on the force feedback device will be affected by the force feedback effect. This also indirectly determines the available directions for an effect, depending on how many axes will be affected by the force feedback output. Of course, the axes available are totally dependent on the type of device. For example, most force feedback joysticks allow output along the x and y axes, as shown below. Other devices, such as steering wheels, may define these axes differently. Axes can be identified by using the DIJOFS\_\* constants.

**Figure 8-1:** Axes of force feedback output

**Direction**

Direction can be a complicated concept when it comes to force feedback. Bear in mind that the force feedback API was designed to work not only with such devices as joysticks, but with other devices like steering wheels, throttle controls, and devices that can move in three dimensions. In a nutshell, direction determines the bearing of an effect along an axis (or axes) when its magnitude or coefficient values are positive. Negative values act in the opposite of the defined direction.

Single axis directions are easily handled, as you can simply control the sign of the magnitude or coefficient in order to define the direction. In the case of multiple axes, however, there are three available coordinate systems: spherical, polar, and Cartesian. The Cartesian coordinate system may be useful if force feedback is being used in conjunction with Direct3D. The spherical coordinate system is necessary for defining the direction of an effect on three or more axes of movement. Since our discussion is focused on joystick programming, however, we'll use the polar coordinate system. The polar coordinate system is perhaps the easiest to use, as it requires only the compass direction of the force, measured in hundredths of a degree. The DI\_DEGREES constant is defined in the DInput unit, and can be used to easily specify a direction in terms of degrees.

Bear in mind that the direction of a force is in terms of the direction from which the force originates. For example, a force from the north would push the stick toward the user, and would thus have a direction of zero. A force from the west, pushing the stick to the right, would have a direction of  $90 * DI\_DEGREES$ . The following illustration graphically explains the concept of direction as it applies to a joystick.

**Figure 8-2:** Forcefeedback direction

**Envelope**

An envelope is a set of values that modify the magnitude of a force at the beginning and end of playback, and can be applied to all forces except conditions. This allows a developer to define the attack and fade of a force, like a musical note. We'll examine envelopes in greater detail later in the chapter.

**envelope:** A series of values that shape a force at the beginning and end of playback.

## Force Feedback Effects

Force feedback effects are divided into six different categories: conditions, constant forces, periodic forces, ramp forces, device-specific effects, and custom forces. Each one of these is defined by an overall basic effect structure, which describes certain global attributes for the effect such as duration and direction, and a more type-specific structure, which describes very specific effect attributes depending on its category. Some of these categories even have subtypes. This makes for a rather complex system, but it should be more than adequate for just about any tactile feedback desired.

### Base Effect Structure

All force feedback effects are defined by a primary structure called `TDIEffect`. This structure is used when creating the effect as well as modifying the effect after it has been created. This complex structure defines the overall parameters of the effect and includes members that hold other structures that further define the effect, and are dependent on the type of effect desired. The `TDIEffect` structure is defined as:

```
TDIEffect = packed record

    dwSize : DWORD;                // the size of the structure, in bytes

    dwFlags : DWORD;               // indicates the directional coordinate
                                   system and axes/button identification

    dwDuration : DWORD;            // duration of the effect in microseconds

    dwSamplePeriod : DWORD;        // the sample period, in microseconds

    dwGain : DWORD;                // the gain for the specific effect

    dwTriggerButton : DWORD;       // trigger button identifier

    dwTriggerRepeatInterval : DWORD; // repetition interval, in microseconds

    cAxes : DWORD;                 // number of axes involved in the effect

    rgdwAxes : ^DWORD;             // array of axis identifiers

    rglDirection : ^longint;       // array of direction bearings

    lpEnvelope : PDIEnvelope;      // pointer to a TDIEnvelope structure

    cbTypeSpecificParams : DWORD;  // the size of the structure in the
                                   lpvTypeSpecificParams member

    lpvTypeSpecificParams : pointer; // pointer to type-specific data structure

end;
```

As usual with all DirectX data structures, the `dwSize` member should be set to `SizeOf(TDIEffect)`. The `dwFlags` member indicates both the directional coordinate system as well as the method by which axes and buttons are to be identified. For our purposes, we'll use the values `DIEFF_POLAR` to indicate a polar coordinate system and `DIEFF_OBJECTOFFSETS` to indicate button and axis data format offsets (using the OR operator to combine them). Most of the other members, such as duration, sample period, and gain, correspond directly to the concepts

covered earlier, and should be set accordingly. The `dwTriggerButton` member indicates the button that will start the effect. This member can be set to a button offset (i.e., `DIJOFS_BUTTON1`) or `DIEB_NOTRIGGER`, indicating that the effect is not triggered. Assigning a value to `dwTriggerRepeatInterval` will cause the effect to be repeated as long as the button is held down (if supported). The `cAxes` member should be set to the number of axes involved in the effect, and the `rgdwAxes` member should point to an array of `DWORDs`, with each member holding a `DIJOFS_*` constant for each individual axis. The `rglDirection` member is a pointer to an array of `longints` that define the direction of the effect. There must be `cAxes` members in this array, but for the polar coordinate system, the bearing is stored in the first member, and the last member (remember, we're only using two axes) is set to zero. The `lpEnvelope` member points to a `TDIEnvelope` structure, which we'll discuss in more detail shortly. Finally, the `cbTypeSpecificParams` should be set to the size, in bytes, of the data structure pointed to by the `lpvTypeSpecificParams` member. This data structure is dependent on the type of desired effect; we'll take a closer look at each effect type below, and examine their individual type-specific parameter data structures.

*Note:* If two or more effects are assigned to a button, the last one downloaded to the device will be the one triggered.

**Supported Effect Parameters** Unfortunately, some members of the TDIEffect structure may be unsupported by some drivers. For example, a specific driver may not allow an effect to be associated with a trigger, or it may not support repeated playback of triggered effects. However, the application can use the GetEffectInfo method of the IDirectInputDevice2 interface to determine which TDIEffect parameters are supported. The GetEffectInfo method is defined as:

```
function GetEffectInfo(  
  
var pdei: TDIEffectInfoA; // effect information structure  
  
const rguid: TGUID // effect GUID  
  
) : HRESULT; // returns a DirectX error code
```

The rguid parameter should be set to the GUID of the effect for which information is requested (these GUIDs are listed below when we get to creating the effect). The pdei parameter should be set to a variable of type TDIEffectInfoA. When this method returns, the TDIEffectInfoA structure will be initialized with all of the relevant information concerning the specified effect. The TDIEffectInfoA structure is defined as:

```
TDIEffectInfoA = packed record  
  
    dwSize : DWORD; // size of the structure in bytes  
  
    guid : TGUID; // the effect GUID  
  
    dwEffType : DWORD; // effect type flags  
  
    dwStaticParams : DWORD; // supported parameter flags  
  
    dwDynamicParams : DWORD; // dynamically modifiable parameters  
  
    tszName : array [0..MAX_PATH-1] of CHAR; // effect name
```

end ;

The dwStaticParams member contains a series of flags that indicate which members of the TDIEffect structure are supported. These flags are listed in Table 8-1. If you combine each flag with the dwStaticParams member using a Boolean AND operation, you can easily determine which TDIEffect members are supported by the driver. However, it is not always necessary to determine if a specific member is supported or not. If a member of this structure is not supported, it will simply be ignored by the driver. Therefore, you could go ahead and assign values to specific members and never worry about getting an error when you create the effect. On the other hand, you'll probably need to know if an effect can be assigned to a trigger button and if this effect can be repeated if that is integral to game play, and find an appropriate alternative if this functionality is not supported.

**Table 8-1: Supported TDIEffect member flags**

Flag	Supported TDIEffect Member
DIEP_DURATION	dwDuration
DIEP_SAMPLEPERIOD	dwSamplePeriod
DIEP_GAIN	dwGain
DIEP_TRIGGERBUTTON	dwTriggerButton
DIEP_TRIGGERREPEATINTERVAL	dwTriggerRepeatInterval
DIEP_AXES	cAxes, rgdwAxes
DIEP_DIRECTION	rglDirection
DIEP_ENVELOPE	lpEnvelope

The dwSize member, of course, must be set to `SizeOf(TDIEffectInfoA)` before calling the `GetEffectInfo` method. The `guid` member contains the GUID of the effect, and the `tszName` member contains the name of the effect type. The `dwEffType` member will contain a series of `DIEFT_*` flags indicating the effect type. You may want to check this member, as if it contains the `DIEFT_DEADBAND`, `DIEFT_FFATTACH`, `DIEFT_FFFADE`, `DIEFT_POSNEGCOEFFICIENTS`, `DIEFT_POSNEGSATURATION`, or `DIEFT_SATURATION` flags, the effect supports the `lDeadBand` parameter (covered below under condition effects), the attack and fade envelope parameters, positive and negative coefficient values (covered below under condition effects), positive and negative saturation values (also covered below under conditions), and saturation of condition effects, respectively.

Incidentally, `dwDynamicParams` also contains a series of `DIEP_*` flags that indicate which members of the TDIEffect structure can be changed dynamically while the effect is playing. This allows an application to modify an effect on the fly to reflect changes in the game world or to create more complex effects. We'll look at an example of modifying an effect on the fly later in this chapter. The following listing demonstrates how the `GetEffectInfo` method can be used to determine which members of the TDIEffect structure are supported.

## Conditions

As we've discussed, conditions are force feedback effects that respond to the position or motion of an axis. Condition effects are divided into four subtypes: spring, friction, damper, and inertia, all of which produce similar but subtly different tactile feedback sensations.

All condition effects use a TDICCondition structure for their type-specific parameters. The TDICCondition structure is defined as:

```
TDICCondition = packed record
```

```
    lOffset : longint;           // effect offset

    lPositiveCoefficient : longint; // positive offset coefficient

    lNegativeCoefficient : longint; // negative offset coefficient

    dwPositiveSaturation : DWORD; // positive offset max force output

    dwNegativeSaturation : DWORD; // negative offset max force output

    lDeadBand : longint;       // inactive region
```

```
end;
```

Each condition subtype makes use of specific members of this structure, as we'll examine below. Unlike other effects, conditions can accept an array of TDICCondition structures in the lpvTypeSpecificParams member of the TDIEffect structure. Each TDICCondition structure defines condition parameters for each axis, with each TDICCondition structure in the array matching up to the axis specified in the rgdwAxes member at the same index. When using an array of TDICCondition structures in this manner, the cbTypeSpecificParams member of the TDIEffect structure must be set to `SizeOf(TDICCondition)` multiplied by the number of members in the

array. We'll see an example of this later in the chapter.

**Spring** A spring condition causes the device to exert a force on an axis when it is moved away from a central location. This central location is defined by the `IOffset` member. A value of 0 puts this point at the center of the axis. The `IOffset` member can be set to values ranging from 10,000 to 10,000 (or you can use the `DI_FFMINOMINALMAX` constant again), with negative values to the left and positive values to the right, relative to the axis.

The `IPositiveCoefficient` indicates the strength of the force exerted on the axis when it is moved to the farthest position from the defined central location. This force is increased from 0 to `IPositiveCoefficient` as the axis is moved, giving a sensation of increased resistance as the axis is moved farther and farther away from the neutral point. Again, the `IPositiveCoefficient` can be set to values in the range 10,000 to 10,000, with positive values pushing the axis toward the central location and negative values pulling the axis away from the central location. If the driver supports negative coefficients, the `INegativeCoefficient` member can be set to values within this range, which can be used to indicate a different amount of force to be applied when the axis is moved to the negative side of the central location. If negative coefficients are not supported, the positive coefficient is used.

The `IDeadBand` member defines an area around the central location in which the axis can move before any amount of force is applied. The saturation values define a similar area at the farthest distance of the axis, with the negative saturation value indicating an area on the negative side of the central location. As with coefficients, if negative saturation values are not supported, the positive saturation value is used. `dwPositiveSaturation`, `dwNegativeSaturation`, and `IDeadBand` members can be set in the range of 0 to 10,000, indicating a percentage of the range of travel in hundredths of a percent.

**Note:** The `IDeadBand` member may not be supported by some drivers.

---

**Friction** The friction condition causes the device to exert a constant force on an axis as the axis is moved, regardless of its position. The `IPositiveCoefficient` member indicates the strength of this force, with values ranging from 10,000 to 10,000. Positive values indicate a push on the axis in the opposite direction of its movement, giving a resistant sensation, and negative values indicate a pull on the axis in the direction of its movement, giving an accelerating sensation. The `IOffset`, `INegativeCoefficient`, `dwPositiveSaturation`, `dwNegativeSaturation`, and `IDeadBand` members are ignored.

**Damper** The damper condition causes the device to exert a force on an axis in proportion to its velocity of movement. In other words, the faster the axis is moving, the more force is exerted. The `IPositiveCoefficient` member indicates the maximum force applied, with values in the range of 10,000 to 10,000. Like friction, positive values indicate a push on the axis in the opposite direction of its movement, and negative values indicate a pull on the axis in the direction of its movement.

The `IOffset` member is used to define a central point very similar to the spring condition. However, this central point is in relation to the axis' velocity, with a value of 0 indicating no velocity. A value other than 0 will cause a force to be applied to the axis even when it is not moving. The saturation and deadband parameters act in a similar manner in relation to velocity, and can be used to indicate a minimum and maximum velocity range in which force would be exerted on the axis.

**Inertia** The inertia condition is very similar to the damper condition, except that force is exerted in proportion to the acceleration of an axis. In other words, no force will be applied if the axis is moving at a steady velocity. Like the damper condition, the `IPositiveCoefficient` member is used to indicate the maximum force, with positive values causing resistance and negative values causing acceleration. Also like the damper condition, the `IOffset` can be used to define a central point relative to the acceleration of the axis, with non-zero values generating acceleration. Saturation and deadband work in a similar manner.

## Constant Forces

A constant force is simply a push on an axis at a given magnitude. It is the simplest of all force feedback effects, and as such, it has a very simple type-specific data structure. Constant forces use a TDIConstantForce structure for their type-specific parameters, which is defined as:

```
TDIConstantForce = packed record  
  
    lMagnitude : longint;           // the strength of the force  
  
end;
```

The only member of this structure, lMagnitude, indicates the strength of the force in the range 10,000 to 10,000. Positive values push the axis in the direction indicated by the rglDirection member of the TDIEffect structure; negative values push the axis in the opposite direction.

**Ramp Forces**

A ramp force creates a steadily increasing or decreasing push on an axis over the duration specified by the `dwDuration` member of the `TDIEffect` structure. Ramp forces use a `TDIRampForce` structure for their type-specific parameters, which is defined as:

`TDIRampForce = packed record`

```
    lStart : longint;           // the starting force magnitude
    lEnd   : longint;          // the ending force magnitude
end;
```

As with constant forces, the `lStart` and `lEnd` members indicate the strength of the force in the range 10,000 to 10,000, with positive values pushing the axis in the indicated direction and negative values pushing in the opposite direction.

---

*Note:* The `dwDuration` member of the `TDIEffect` structure cannot be set to `INFINITE` for ramp forces.

---

**Periodic Forces**

A periodic effect causes a force to be applied to an axis in an oscillating manner. This is also known as a wave effect, as the magnitude and direction of a force changes over time. Similar to conditions, periodic forces are divided into subtypes: sine, triangle, sawtooth up, sawtooth down, and square. These produce alternating forces on an axis in a manner suggested by their name, as indicated by the following illustration.

**Figure 8-4:** Periodic forces

All periodic effects use a TDIPeriodic structure for their type-specific parameters. The TDIPeriodic structure is defined as:

```
TDIPeriodic = packed record
```

```
    dwMagnitude : DWORD;           //the absolute force magnitude
    lOffset : longint;             //neutral wave position
    dwPhase : DWORD;               //force start position
    dwPeriod : DWORD;              // wave frequency
```

```
end;
```

The dwMagnitude member indicates the absolute magnitude of the force to be exerted on the axis, in a range of 0 to 10,000. While the force is playing, this magnitude will steadily cycle between this value through the negative of this value and back again, creating a push on the axis in alternating directions. The manner in which this cycling takes effect is determined by the force type, as indicated in Figure 8-4. For example, a sine force would cycle the magnitude, and thus direction, of the force in a steady, smooth manner, where a square force would push the axis in alternating directions at the greatest magnitude in a very jarring, immediate manner.

The lOffset member indicates the center of the waveform in relation to the amount of force exerted, and will raise or lower the absolute magnitude of the force appropriately. For example, a value of zero indicates that the waveform will oscillate around zero magnitude. A value of 1,000, however, indicates that the waveform will oscillate around 1,000 magnitude, modifying the positive and negative magnitudes of the waveform accordingly. This is visually illustrated in the figure below.

**Figure 8-5:** Modifying the waveform offset

**Note:** The sum of dwMagnitude and the absolute value of lOffset cannot exceed 10,000 or DI\_FFNO MINALMAX.

The dwPhase member indicates the point at which the waveform should start, and is measured in hundredths of degrees. For example, setting this member to 9,000 for a sine periodic effect shifts the starting point by 90 degrees, and creates a cosine effect. This member is not always supported by all drivers. Finally, the dwPeriod member indicates the frequency of the waveform, measured in microseconds. For most drivers, this value cannot be set above one second, and it will have a minimum practical value based on how fast the motors in the device can reverse their direction.

## Device-Specific Effects

Many force feedback manufacturers provide several effects built in to the device driver. Many of these may be standard effect types, such as ramp forces, constant forces, or conditions, but some may be custom forces. Additionally, some of these forces may have adjustable type-specific parameters. If they have adjustable parameters

and are not a custom force, you can use the type-specific parameters structure appropriate for the force type to modify the force during playback. Otherwise, you'll need to get the type-specific parameters structure from the driver documentation if you wish to change an adjustable device-specific custom force on the fly.

Of course, device-specific forces are going to change from device to device, but non-adjustable device-specific forces are perhaps the easiest to use as the application needs to know nothing about them. In order to use a device-specific effect, we must first retrieve a list of available effects; this is accomplished by using the EnumEffects method of the IDirectInputDevice2 interface. The EnumEffects method is defined as:

```
function EnumEffects(  
  
    lpCallback: TDIEnumEffectsCallbackA;        // a pointer to the callback function  
  
    pvRef: pointer;                             // application-specific data  
  
    dwEffType: DWORD                            // flag affecting enumeration  
  
    ) : HRESULT;                               // returns a DirectX error code
```

The pvRef parameter is simply a pointer to application-specific data, which will be passed to the callback function. The dwEffType parameter contains a DIEFT\_\* flag which determines what type of effects are to be enumerated. In our case, we'll use the DIEFT\_HARDWARE flag to indicate that we want only hardware-specific effects. The lpCallback parameter is a pointer to the callback function. The callback function itself must be defined as:

```
function TDIEnumEffectsCallbackA(  
  
    pdei: TDIEffectInfoA;                       // a TDIEffectInfoA structure  
  
    pvRef: pointer                             // a pointer to application-specific data  
  
    ) : BOOL; stdcall;                         // returns TRUE or FALSE
```

The pdei parameter contains an initialized TDIEffectInfoA structure that has all of the pertinent information about the enumerated effect. In particular, the GUID member of this structure contains the GUID for the enumerated effect, which will need to be recorded for subsequent use when the effect is created. The pvRef parameter simply contains a pointer to the application-defined data specified when the EnumEffects method was called. This callback function should return TRUE to continue enumeration or FALSE to cancel it. Listing 8-2 demonstrates how to use the EnumEffects method to enumerate all device-specific effects that do not have any adjustable type-specific parameters.

**Figure 8-6:** Microsoft SideWinder Force Feedback Pro device effects

Like all effects, you'll use a TDIEffect structure when creating device-specific effects. However, some effects may have default values that will be used by the driver whenever certain specific members of the TDIEffect structure are set to a particular value. For example, the Microsoft SideWinder Force Feedback Pro joystick will use default values for the sample period and duration if the dwSamplePeriod and dwDuration members of the TDIEffect structure are set to 1000. Other devices will probably use different values, and may require delving into the driver documentation.

## Custom Forces

If none of the standard effect types provide the tactile feedback sensation desired, you can attempt to create it using a custom force. A custom force is little more than an array of magnitudes. It replays this array of magnitudes as constant forces; each element is played in sequence at a constant interval and in the same direction (which can be reversed by negative magnitudes). Custom forces use the TDICustomForce structure for their type-specific parameters, which is defined as:

```
TDICustomForce = packed record

    cChannels : DWORD;           // number of channels

    dwSamplePeriod : DWORD;      // sample period

    cSamples : DWORD;           // number of elements in sample array

    rgfForceData : ^longint;     // pointer to the array of samples

end;
```

The cChannels member indicates how many axes are involved in the force, and results in each sample in the samples array being rotated amongst the axes (i.e., in the case of two axes and a cChannels setting of 2, element 1 applies to the first axis, element 2 to the second, element 3 to the first, etc.). This functionality may not be supported by all drivers.

The dwSamplePeriod member is very similar to the dwSamplePeriod member of the TDIEffect structure. The dwSamplePeriod member of the TDICustomForce structure indicates how long each element in the samples array will play, whereas the dwSamplePeriod in the TDIEffect structure indicates how long DirectInput waits before recalculating the force output by the device. Most devices do not support the dwSamplePeriod member of the TDICustomForce structure, and instead use the dwSamplePeriod member of the TDIEffect structure to determine how long to play each sample. In most cases, both members should be set to the same value to avoid any confusing behavior.

The cSamples member should be set to the number of elements in the array, which is pointed to by the rgfForceData member. This array contains a series of longints that define the magnitudes in the range 10,000 to 10,000.

---

**Note:** Applying an envelope to a custom force may not be supported by all drivers.

---

## Creating Effects

As usual, a specific series of steps must be taken by the application in order to create a force feedback effect and prepare it for playback. Some of these steps may be optional depending on certain properties of the effect. In general, a force feedback effect is initialized and used by performing the following steps:

- Create and acquire the DirectInput device
- Query for force feedback support
- Initialize a TDIEffect structure and the appropriate type-specific parameters structure
- Create the effect object
- Download the effect (sometimes optional)
- Start the effect (sometimes optional)
- Stop the effect (sometimes optional)

## Create and Acquire the DirectInput Device

Force feedback is a subsystem of DirectInput. As such, an initialized IDirectInputDevice2 interface must be created before any force feedback functionality can be utilized. Please refer to Chapter 7, Input Techniques, for a detailed explanation of creating an IDirectInputDevice2 object. Specifically, we'll be using the code from that chapter for communicating with the joystick. Other game controllers will function similarly.

## Query for Force Feedback Support

While you could certainly require the user to have a force feedback joystick installed before using your application, it would be much wiser to allow input from any game controller attached to the system, and use force feedback only when it was available on the device. In order to determine if a device supports force feedback, we must call the GetCapabilities method of the IDirectInputDevice2 interface. This method is described in the Input Techniques chapter, but for the sake of completeness, its definition is reprinted here:

```
function GetCapabilities(
    var lpDIDevCaps: TDIDevCaps           // a TDIDevCaps structure
): HRESULT;                             // returns a DirectX error code
```

The only parameter to this method is a pointer to a TDIDevCaps structure. Again, for the sake of completeness, it is defined as:

```
TDIDevCaps = packed record

    dwSize: DWORD;                       // the size of the structure

    dwFlags: DWORD;                      // device flags

    dwDevType: DWORD;                   // device type identifier

    dwAxes: DWORD;                      // number of axes

    dwButtons: DWORD;                   // number of buttons

    dwPOVs: DWORD;                      // number of POVs

    dwFFSamplePeriod: DWORD;            // force feedback sample period

    dwFFMinTimeResolution: DWORD;      // force feedback time resolution

    dwFirmwareRevision: DWORD;         // firmware version

    dwHardwareRevision: DWORD;         // hardware version

    dwFFDriverVersion: DWORD;          // device driver version

end;
```

The only member we're concerned with at this point is the dwFlags member. If this member contains the flag

DIDC\_FORCEFEEDBACK, then we know that this device supports force feedback functionality. Incidentally, we can check for other DIDC\_\* flags to determine if the device supports such force feedback parameters as attack and fade (which refer to envelopes), deadband, negative coefficients and saturations, etc.

**Initialize a TDIEffect Structure and the Type-Specific Parameters Structure**

Now that we have a device and we know it supports force feedback, it is time to define the type of effect we wish to create. This is accomplished by initializing a TDIEffect structure and a type-specific parameters structure appropriate for the desired effect.

The first thing we should do is initialize the type-specific parameters structure. For example, if we were creating a periodic effect, we would need a TDIPeriodic structure, initialized in the following manner:

```
PeriodicInfo.dwMagnitude := DI_FFNOMINALMAX;
```

```
PeriodicInfo.lOffset := 0;
```

```
PeriodicInfo.dwPhase := 0;
```

```
PeriodicInfo.dwPeriod := DI_SECONDS div 20;
```

This indicates that we want a periodic effect that uses the maximum magnitude available on the device with no offset or phase shift and a relatively quick frequency. This will result in a vibrating effect, which we could potentially use to portray the feel of a powerful weapon such as a chainsaw or machine gun.

**Tip:** Remember that the overall strength of any effect will be scaled by the gain set for the device.

Next, we need to define the axes on which this effect will be played. We're using the joystick, so we'll indicate that the effect should use both the x- and y-axis. We'll use a small array of DWORDs, indicating the axes themselves using DIJOFS\_\* flags. We'll also indicate the direction of the effect. In this case, we'll be using the polar coordinate system, so we need a small array of longints (with as many elements as there are in the axis array). We simply need to indicate only the compass bearing of the desired direction in the first element, and set the last

element to zero. This is accomplished like so:

```
AxisArray[0] := DIJOFS_X;  
AxisArray[1] := DIJOFS_Y;  
  
DirArray[0] := 180*DI_DEGREES;  
DirArray[1] := 0;
```

With this completed, we need to initialize the TDIEffect structure. For example:

```
EffectInfo.dwSize := SizeOf(TDIEffect);  
EffectInfo.dwFlags := DIEFF_OBJECTOFFSETS or DIEFF_POLAR;  
EffectInfo.dwDuration := INFINITE;  
EffectInfo.dwSamplePeriod := 0;  
EffectInfo.dwGain := DI_FFNOINALMAX;  
EffectInfo.dwTriggerButton := DIJOFS_BUTTON0;  
EffectInfo.dwTriggerRepeatInterval := INFINITE;  
EffectInfo.cAxes := 2;  
EffectInfo.rgdwAxes := @AxisArray;  
EffectInfo.rglDirection := @DirArray;  
EffectInfo.lpEnvelope := nil;  
EffectInfo.cbTypeSpecificParams := SizeOf(TDIPeriodic);  
EffectInfo.lpvTypeSpecificParams := @PeriodicInfo;
```

Here, we've indicated that we have an effect of infinite duration, and that we'll be using a polar coordinate system with device objects indicated by offsets. We've set the gain to maximum, so our effect will play with the strongest possible force available on the device (scaled by any gain set for the device itself). We've hooked the effect up to button 0 on the device, so it will automatically play when the user presses the button. A trigger repeat interval of infinite will really have no effect, as the effect will automatically continue to play until the button is released because of the infinite duration. We've also indicated the axes and direction, and we set up the cbTypeSpecificParams and lpvTypeSpecificParams members to indicate the size of and point to our type-specific parameters structure, respectively.

### Create the Effect Object

Now that the effect is completely defined, it needs to be created. The CreateEffect method of the IDirectInputDevice2 interface is used to generate an initialized IDirectInputEffect object. The CreateEffect method is defined as:

```

function CreateEffect(

const rguid: TGUID;           // the effect type guid

lpeff: PDIEffect;           // pointer to a TDIEffect structure

var ppdeff: IDirectInputEffect; // returns an IDirectInputEffect object

punkOuter: IUnknown         // COM aggregation

) : HRESULT;                // returns a DirectX error code

```

The first parameter takes a GUID for the type of effect to be created. This can be either a predefined GUID for standard effects (listed below) or a GUID obtained from calling the EnumEffects method. The second parameter takes a pointer to the TDIEffect structure we initialized above. The third parameter takes a pointer to the IDirectInputEffect object, which will be instantiated when the method returns. The final parameter is used for COM aggregation and should be set to nil.

**Table 8-2: Predefined effect GUIDs**

GUID	Description
GUID_ConstantForce	Constant forces
GUID_RampForce	Ramp forces
GUID_Square	Square wave periodic forces
GUID_Sine	Sine wave periodic forces
GUID_Triangle	Triangle wave periodic forces
GUID_SawtoothUp	Sawtooth up wave periodic forces
GUID_SawtoothDown	Sawtooth down wave periodic forces
GUID_Spring	Spring conditions
GUID_Damper	Damper conditions
GUID_Inertia	Inertia conditions
GUID_Friction	Friction conditions
GUID_CustomForce	Custom forces

## Download the Effect

Once an effect is created, it must be downloaded into the device before it can be played. Downloading an effect is accomplished by calling the Download method of the IDirectInputEffect interface, which is defined as:

```

function Download : HRESULT;           // returns a DirectX error code

```

Now, it is not always necessary to download an effect. If the input device is in an acquired state when the effect is created, it is downloaded automatically. It is also downloaded automatically whenever the Start method is called (see below). For some effects, such as a triggered effect that was created before the device was acquired, the Download method must be used (as the Start method will not be called for triggered effects). Also, there is a little bit of a lag when an effect is initially downloaded, so explicitly downloading an effect before gameplay starts may reduce any detectable pause the first time an effect is to be played.

As discussed earlier, a DIERR\_DEVICEFULL error may be returned when using a force feedback effect. This indicates that the device has reached its maximum number of downloadable force feedback effects, and room must be created before a new effect can be used. An existing effect can be unloaded from a device by calling the Unload method of the IDirectInputEffect interface, which is defined as:

```

function Unload : HRESULT; // returns a DirectX error code

```

It is possible to use the DIPROP\_FFLOAD flag with the GetProperty method of the IDirectInputDevice2 interface to retrieve the memory load for the device. You'll need to use a TDIPropDWORD structure, and upon returning, the dwData member of this structure will contain a value in the range of 0 to 100, indicating the percentage of device memory in use. Checking this value before downloading a new effect may give you some indication as to whether or not the device will be able to hold the new effect without unloading an existing one.

*Note:* If a device is unacquired (as would happen when another application gained focus), all effects are automatically unloaded. Effects should be downloaded again when the device is reacquired, especially triggered effects for which the Start method will never be called.

**Start the Effect**

Once the effect is downloaded, it can be played. Triggered effects are started whenever the specified button is pressed, but non-triggered effects must be explicitly told to begin playing. This is accomplished by calling the Start method of the IDirectInputEffect interface. Note that the input device must be acquired at the exclusive cooperative level before the Start method will succeed. The Start method is defined as:

```
function Start(  
  
    dwIterations: DWORD;           // number of times to repeat the effect  
  
    dwFlags: DWORD                 // playback flags  
  
    ) : HRESULT;
```

The dwIterations parameter indicates how many times to play the effect. This parameter can be set to a positive integer value or to INFINITE, indicating it will continue playing until explicitly stopped. Of course, for effects that have a defined duration of INFINITE, the dwIterations parameter is effectively useless, and some devices do not even support multiple iterations.

The dwFlags parameter indicates how the effect should be played on the device. By default, an effect will be mixed with other effects currently playing on the device when it is started. Setting this flag to DIES\_SOLO will stop all other currently playing effects before playing the new effect. The DIES\_NODOWNLOAD flag can also be used to indicate that the effect should not automatically be downloaded. This parameter can be set to zero or any combination of these two flags.

---

*Note:* If the effect is already playing when Start is called, it will stop and be restarted from the beginning.

---

## Stop the Effect

Effects with a finite duration or those associated with a button will automatically stop when the duration has been reached or the button is released. However, some effects, such as those explicitly started with an infinite duration, will continue to play until the device is unacquired. Sometimes, it may be necessary to stop an effect, and this is where the Stop method of the IDirectInputEffect interface comes in. It is defined as:

```
function Stop : HRESULT; // returns a DirectX error code
```

## Case Study

Creating force feedback effects, while somewhat confusing, isn't quite as complicated as other DirectX subsystems. The following listing is a case study example which demonstrates how to create each type of effect. While not particularly robust, this example should serve to demonstrate how the above steps are followed for each effect type.

## Additional Effect Considerations

While this is not meant to be a complete reference to DirectX, there are several more force feedback specific methods that have not been discussed, but may be very useful to applications that incorporate force feedback functionality. In particular, applications may need to determine the status of an effect or the state of the overall force feedback system, send a command to the force feedback system, or modify effect parameters on the fly.

## Retrieving Effect Status

There may be times when the application needs to determine if an effect is currently playing or not. This is easily accomplished by calling the `GetEffectStatus` method of the `IDirectInputEffect` interface. The `GetEffectStatus` method is defined as:

```

function GetEffectStatus(

var pdwFlags : DWORD                // flags indicating the effect status

) : HRESULT;                        // returns a DirectX error code

```

The only parameter to this method is a variable that will be initialized to one or more flags. The effect is currently playing if the DIEGES\_PLAYING flag is present in the pdwFlags variable.

### Retrieving the Force Feedback System State

Another useful method of the IDirectInputDevice2 interface is the GetForceFeedbackState method. This method returns a series of flags which indicate the overall state of the force feedback device. The GetForceFeedbackState method is defined as:

```

function GetForceFeedbackState(

var pdwOut: DWORD                // flags indicating overall device state

) : HRESULT;                    // returns a DirectX error code

```

The pdwOut parameter is simply a variable that, upon return, will be initialized with the flags that indicate the overall force feedback system status. This can be a combination of one or more flags from the following table.

**Table 8-3: Force feedback state flags**

Flag	Description

DIGFFS_EMPTY	The device has no downloaded effects.
DIGFFS_STOPPED	No effects are playing.
DIGFFS_PAUSED	All active effects are paused.
DIGFFS_ACTUATORSON	Force feedback actuators are enabled.
DIGFFS_ACTUATORSOFF	Force feedback actuators are disabled.
DIGFFS_POWERON	Power to the force feedback device is available.
DIGFFS_POWEROFF	Power to the force feedback device is not available.
DIGFFS_SAFETYSWITCHON	The safety switch is on.
DIGFFS_SAFETYSWITCHOFF	The safety switch is off, and the device cannot operate.
DIGFFS_USERFFSWITCHON	The force feedback switch is on.
DIGFFS_USERFFSWITCHOFF	The force feedback switch is off, and force feedback effects cannot be played.
DIGFFS_DEVICELOST	The device has been unacquired and must be reacquired.

## Sending Commands to the Force Feedback System

There are times when it is necessary to send global commands to the force feedback system. For example, if the user pauses the game, it would be nice to pause all playing effects without having to enumerate them all and call Stop for each one, and then restart them when the user resumes play. This can be accomplished through the SendForceFeedbackCommand method of the IDirectInputDevice2 interface. The SendForceFeedbackCommand method is defined as:

```
function SendForceFeedbackCommand(
    dwFlags: DWORD // the command value
) : HRESULT; // returns a DirectX error code
```

The single parameter of this function takes one value from the following table.

<i>Table 8-4: Force feedback system commands</i>	
Command	Description

DISFFC_RESET	Resets the entire device. All effects are destroyed and must be re-created.
DISFFC_STOPALL	All actively playing effects are stopped.
DISFFC_PAUSE	All actively playing effects are paused. When restarted, they continue playing to the remainder of their duration. New effects cannot be started.
DISFFC_CONTINUE	Continues playing from a paused state.
DISFFC_SETACTUATORSON	Turns force feedback actuators on.
DISFFC_SETACTUATORSOFF	Turns force feedback actuators off. Effects can still be played but will be ignored by the device.

## Modifying an Effect at Run Time

In order to further customize an effect to reflect changes in the game world, an effect can be modified while it is playing, provided that this is supported by the driver. As we examined earlier, we can use the `GetEffectInfo` method to determine which parameters can be dynamically changed during effect playback. In practice, we can change any of the parameters at any time; the parameters listed in `dwDynamicParams` indicate those parameters that can be changed without restarting the effect. Changing a parameter that is not included in `dwDynamicParams` will cause the force feedback system to stop and then restart the effect.

To change an effect's parameters during playback, call the `SetParameters` method of the `IDirectInputEffect` interface. The `SetParameters` method is defined as:

```
function SetParameters(
    var peff: TDIEffect;           // a TDIEffect structure with new parameters
    dwFlags: DWORD                // control flags
) : HRESULT;                    // returns a DirectX error code
```

The first parameter contains a `TDIEffect` structure that contains the new values for the effect parameters to be changed. It is not necessary to initialize the entire structure, only those members containing the new effect parameters. The second parameter contains a series of flags that indicate which members of the `TDIEffect` structure contain the new information. These are the same flags as returned by the `GetEffectInfo` method, and are listed in Table 8-1. Some additional flags available with this method control the behavior of the force feedback system when the effect is modified. For example, calling the `SetParameters` method automatically downloads the effect. This can be disabled by including the `DIEP_NODOWNLOAD` flag in the second parameter. These additional flags are listed below.

**Table 8-5: Parameter flags**

Flag	Description
DIEP_NODOWNLOAD	Effect parameters are updated but not downloaded to the device.
DIEP_NORESTART	Suppresses restart of an effect. If the effect must be restarted, an error code of DIERR_EFFECTPLAYING is returned, and the effect continues to play with the original parameters.
DIEP_START	Starts playing the effect if it is not playing already.
DIEP_TYPESPECIFICPARAMS	Indicates that the lpvTypeSpecificParams and cbTypeSpecificParams members of the TDIEffect structure contain new data.

The following listing demonstrates changing an effect's direction at run time.

PeriodicEffect.Start(1, DIES_SOLO);

{enable the timer that changes the effect direction}

tmrDirChanger.Enabled := TRUE;

end;

procedure TfrmJoyTestBed.tmrDirChangerTimer(Sender: TObject);

var

    DirArray: array[0..1] of longint;

    EffectInfo: TDIEffect;

begin

    {increase the effect direction angle}

    Inc(EffectDir, 2);

```

```

{roll the angle over nicely}
if EffectDir > 360 then

    EffectDir := 1;

{display the new angle}
lblAngle.Caption := Effect Angle: +IntToStr(EffectDir);

{indicate the new direction}
DirArray[0] := EffectDir*DI_DEGREES;
DirArray[1] := 0;

{set up the effect parameters}
FillChar(EffectInfo, SizeOf(TDIEffect), 0);
EffectInfo.dwFlags := DIEFF_POLAR;
EffectInfo.dwSize := SizeOf(TDIEffect);
EffectInfo.rglDirection := @DirArray;
EffectInfo.cAxes := 2;

{dynamically change the parameters, indicating that the effect
should not restart. if the device doesn't support this, the change
will fail, but the effect will continue to play}
PeriodicEffect.SetParameters(EffectInfo, DIEP_DIRECTION or DIEP_NORESTART);
end;

```

---

## Envelopes

The basic effect types give the developer a wide range of possibilities for creating tactile feedback. Indeed, using custom forces or modifying a force at run time gives us even greater control over the “feel” of the feedback. We can further customize an effect by using an envelope.

An envelope is a method by which a force can be shaped, and is very similar in concept to envelopes in musical terms. Specifically, an envelope describes the starting magnitude for an effect and the amount of time it takes for the magnitude to go from this initial starting point to the magnitude defined by the type-specific parameters of the specific effect. This is known as the attack. Similarly, the envelope also describes the final magnitude of the effect

and the amount of time it takes for the magnitude to go from the effect-defined magnitude to this final level. This is known as the fade. These times take place during the entire duration of the effect, so the sum of both times should not exceed this duration. Any remaining time indicates the sustain, and determines how much time the effect is played at the defined magnitude. A visual illustration of an envelope is shown in Figure 8-7.

**envelope:** A series of values that shape a force at the beginning and end of playback.

**Figure 8-7:** An envelope shaping an effect

**Note:** Envelopes do not apply to condition effects.

---

Envelopes are defined by a `TDIEnvelope` structure. A pointer to this structure is placed in the `lpEnvelope` member of the `TDIEffect` structure when an effect is defined. The `TDIEnvelope` structure is defined as:

```
TDIEnvelope = packed record

    dwSize : DWORD;           // the size of the structure in bytes

    dwAttackLevel : DWORD;    // the initial magnitude

    dwAttackTime : DWORD;     // the attack duration

    dwFadeLevel : DWORD;     // the ending magnitude

    dwFadeTime : DWORD;      // the fade duration

end;
```

As usual with so many DirectX structures, the `dwSize` member must be set to `SizeOf(TDIEnvelope)`. The `dwAttackLevel` member defines the starting magnitude for the effect. Actually, this defines a percentage, in hundredths of a percent, of the maximum available force in the direction of the effect, and thus can be a value between 0 and 10,000. The `dwFadeLevel` member is very similar, except that it defines the percentage of maximum available force at the end of effect playback. Both `dwAttackTime` and `dwFadeTime` define the duration of the attack and fade in microseconds.

**Note:** Neither the attack nor fade levels need to be less than the sustain level. If they are defined greater than the sustain level, the effect will start at a greater level than the sustain and will fall down to it (or vice versa in the case of fade level).

---

The following example demonstrates applying an envelope to a sine wave periodic force.

## Summary

In this chapter, we discussed techniques for utilizing force feedback technology. We examined how to use both standard and custom effects, as well as how to modify effects on the fly. We also looked at shaping effects using envelopes. When using force feedback technology in your games, it is important to keep these points in mind:

- Force feedback is part of the DirectInput subsystem, and was designed to work not only with joysticks but with any type of input device.
- When discussing force feedback effects, it is necessary to understand several general concepts as they apply to the effect itself. Such concepts include kinetic forces, conditions, magnitude, coefficient, gain, duration, sample period, axes, direction, and envelope.
- A kinetic force is an effect that actively pushes on one or more axes. This push can be in a single direction or in alternating directions such as occurs with periodic effects.
- A condition is a resistance or force that is applied to one or more axes in response to their movement or position.
- Magnitude is a measurement of the strength of a kinetic force, relative to the total maximum force that can be output by the device. The magnitude of a force can be expressed as an integer value between 10,000 and 10,000, where positive values represent a force in one direction and negative values represent the same force in the opposite direction.
- The `DI_FFNOINALMAX` constant is set to 10,000 and represents the total maximum force that can be exerted by the device on any given axis. This constant allows the developer to define the magnitude of a force as a percentage of the total maximum force available on the device.
- Coefficient is a measurement of the strength of resistance to movement along an axis. Like magnitude, this value is expressed as an integer between 10,000 and 10,000.
- Duration defines how long the effect will play, measured in microseconds.
- The constant `DI_SECONDS` can be used to define the duration in terms of one-second intervals (or fractions thereof).
- Sample period defines the interval between actual changes in the strength of a force, measured in microseconds.
- Gain acts as a scaling factor for magnitudes and coefficients. It is expressed as a value between 0 and 10,000, indicating the percentage by which to scale the magnitude or coefficient.
- Axes determine what axis (or axes) of movement on the force feedback device will be affected by the force feedback effect.

- Direction determines the bearing of an effect along an axis (or axes) when its magnitude or coefficient values are positive. Negative values act in the opposite of the defined direction.
- An envelope is a set of values that modify the magnitude of a force at the beginning and end of playback, and can be applied to all forces except conditions.
- Force feedback effects are divided into six different categories: conditions, constant forces, periodic forces, ramp forces, device-specific effects, and custom forces.
- All force feedback effects are defined by a primary structure called TDIEffect. This structure is used when creating the effect as well as modifying the effect after it has been created.
- Each type of effect is defined by different parameters. These parameters are stored in a type-specific parameter data structure which differs from effect to effect.
- Some members of the TDIEffect structure may be unsupported by some drivers. However, the application can use the GetEffectInfo method of the IDirectInputDevice2 interface to determine which TDIEffect parameters are supported.
- Some effects must be downloaded to the device after they are created before they can be played. However, if the input device is in an acquired state when the effect is created, it is downloaded automatically. It is also downloaded automatically whenever the Start method is called. For some effects, such as a triggered effect that was created before the device was acquired, the Download method must be used.
- A DIERR\_DEVICEFULL error may be returned when using a force feedback effect. This indicates that the device has reached its maximum number of downloadable force feedback effects, and an existing effect must be unloaded from a device by calling the Unload method.
- Triggered effects are automatically started when the trigger is pushed, and stopped when the trigger is released. Otherwise, effects must be explicitly started using the Start method. For effects with infinite duration, the Stop method must be called to halt playback.
- Use the GetEffectStatus method to determine if an effect is currently playing.
- Use the GetForceFeedbackState method to determine the overall state of the force feedback device.
- Use the SendForceFeedbackCommand method to send global commands to the force feedback system.
- The SetParameters method allows a force feedback effect to be modified on the fly.

## CHAPTER 9 Sound and Music

This chapter covers the following topics:

- Playing sound effects using multimedia functions and DirectSound
- Playing MIDI music using MCI commands
- Playing Red Book (CD) audio using MCI commands

Most people discuss games in terms of the technology used for the graphics engine. Hot first-person shooters are discussed in terms of colored lighting, interactive environments, the polygon count of characters, etc. Real-time strategy game discussions feature such terms as computer AI, realism of surface features (such as hills), tactical advantages of weapons, etc. Although rarely the topic of discussion, the importance of the third major piece of a game, sound and music, is not lost on game developers.

Regardless of the technological accomplishment represented by the game's graphics engine, no game is truly complete without some sort of sound effects to bring the environment to life, or a driving soundtrack to set the mood. Would Quake have been as good if you couldn't hear a heavy-breathing mutant around the corner? Would X-Wing have given you the same thrill without the musical fanfare following a completed mission? Indeed, music and sound effects round out a game and add the polish that can make a good game great.

In this chapter, we examine various techniques for incorporating sound effects and music into Delphi games. We will examine using DirectSound for manipulation and playback of sound effects, and we will take a look at regular Windows MCI commands for playing music in both MIDI and Red Book Audio formats.

DirectX 6.1 and above features a DirectX component known as DirectMusic. DirectMusic could potentially revitalize the use of MIDI through its incredible features. It provides an interface for supporting downloadable instrument sounds as well as methods to change the playback of MIDI files on the fly. This can result in context-sensitive musical playback that, supposedly, may never be the same twice. Unfortunately, we were unable to cover DirectMusic in this volume, but look for several articles about its use appearing in trade magazines in the very near future.

## Sound Effects

Sound effects are very important in a game, as they help to immerse the player in the environment depicted by the game's playing area. Viewing an animation of a ship exploding is much more exciting when accompanied by a loud roar. Walking down a dark passageway is much more realistic when the hollow sounds of boot heels on damp stone is heard. Using sound effects in this manner can draw the user into the environment in ways that even the most advanced 3-D engine could never hope to accomplish.

In addition to immersion and suspension of belief, sound effects can give audible clues to the user that indicate a change in the environment. For example, the hum of an engine could be changed to reflect the amount of damage it has taken, providing a correlation to the engine's maximum speed. A low growl or heavy breathing sound could signal the presence of an unknown assailant, heightening the user's tension level and excitement. Even the subtle sounds of clicks and whirs emitted when the game's buttons and sliders are manipulated help make the environment all the more real to the user.

The Windows Multimedia API contains a number of sound output functions. Some are very easy to implement but lack the control that might be required for some games. Most games will need to play several sound effects at once, such as the whine of an engine, laser bursts, and explosions. Playing several sound effects simultaneously is known as mixing, and unfortunately such functionality is not built in to the Windows Multimedia API.

**mixing:** Combining several sounds in real time in such a way that they can be played simultaneously.

---

Low-level multimedia sound output functions could be used to implement mixing or even manipulate the sounds in real time to create special effects such as echo or reverb. However, such code is difficult to write at best, and just as difficult to debug. Let's examine the easiest method to implement sound output under Windows, and then we'll take a look at how DirectSound provides all the sound output power that a game will ever need.

### Simplistic Sound Effects

Not every game requires the power of full-blown DirectSound implementation. Indeed, if your game uses few sound effects, or does not require the ability to play several sounds simultaneously, it is much easier to implement the sound output functionality built into the Windows API. By far, the easiest yet most flexible function available for playing sound effects is the PlaySound function. The PlaySound function can play audio files in the WAV format, from either a file on disk, a resource, or even an image of the sound in memory. It can play the sound asynchronously, allowing the application to continue processing, and it can play sounds in a continuous loop. This function would be perfect for almost any gaming need except for one major drawback: It cannot play more than one sound at a time. As stated above, low-level audio functions could be used to implement mixing, but this is difficult, and now obsolete thanks to DirectSound. The PlaySound function is defined as:

```
function PlaySound(  
  
    pszSound: PChar;           // the sound to be played  
  
    hmod: HMODULE;            // a module handle  
  
    fdwSound: DWORD           // flags controlling sound playback  
  
): BOOL;                     // returns TRUE or FALSE
```

The first parameter indicates the sound to be played, and can be a filename, an alias, or a resource identifier as specified by the flags in the third parameter. If the first parameter is set to nil, any currently playing WAV is stopped. The second parameter contains the handle of the executable or DLL if the sound to be played is a resource; otherwise it should be set to zero. The final parameter is a series of flags that indicate how to interpret the first parameter as well as how the sound file should be played, such as in a loop.

*Note:* You must include MMSystem in the Uses clause of any unit that will use the PlaySound function.

---

The following example demonstrates how to use the PlaySound function to play sound effects from various locations.

end;

procedure TForm1.btnPlayFileClick(Sender: TObject);

begin

    {play a sound from a WAV file}

    PlaySound('File.wav', 0, SND_FILENAME or SND_ASYNC);

end;

procedure TForm1.btnPlayResClick(Sender: TObject);

begin

    {play a sound from a resource (see the WaveRes.rc file for the
    resource script)}

    PlaySound('WaveResource', hInstance, SND_RESOURCE or SND_ASYNC);

end;

procedure TForm1.btnPlayMemClick(Sender: TObject);

begin

    {play a sound from a WAV file image in memory}

    PlaySound(WaveFile.Memory, 0, SND_MEMORY or SND_ASYNC);

end;

procedure TForm1.btnPlayLoopClick(Sender: TObject);
```

```

begin
    {play a continuously looping sound from a file}
    PlaySound('Loop.wav', 0, SND_FILENAME or SND_ASYNC or SND_LOOP);

    btnPlayStop.Enabled := TRUE;
end;

procedure TForm1.btnPlayStopClick(Sender: TObject);
begin
    {stop all sound output}
    PlaySound(nil, 0, SND_PURGE);

    btnPlayStop.Enabled := FALSE;
end;

```

---

As illustrated, it is relatively simple to play a sound file by simply passing the PlaySound function the name of the WAV file. Playing a sound from a resource is almost as simple. The WAV files must be compiled into a resource by using the BRCC32.exe resource compiler included with Delphi (see the WaveRes.rc file in the directory containing the above example on the companion CD). Once this is complete, the resource file is linked into the executable using the \$R compiler directive. Then, it's a simple matter of passing the PlaySound function the name of the WAV resource (as opposed to the name of a WAV file), the handle of the module containing the resources (useful for putting WAV resources into DLLs), and the SND\_RESOURCE flag.

**Note:** WAV files must be compiled using a resource type of "WAVE" in the resource script file before PlaySound can find them.

---

Playing sounds from memory is easy enough, and improves the performance of your application as PlaySound does not have to reload the WAV file or resource each time it is called. By using the TMemoryStream object, a WAV file can easily be loaded into memory and passed to the PlaySound function via its Memory property.

Together with the ability to continuously play a sound (by using the SND\_LOOP flag) or stop all sound output (by using the SND\_PURGE flag), the PlaySound function is relatively powerful. If your game or application will not require the ability to play multiple sounds simultaneously, the PlaySound function will probably provide all the functionality required. However, to optimize sound output performance, play a virtually unlimited number of sounds simultaneously, or produce special effects, DirectSound is the way to go.

## DirectSound

DirectSound is that portion of DirectX that is responsible for the manipulation and playback of digitized sound (music is handled via other API functions described later in the chapter). While not nearly as simplistic as the PlaySound function, the methods in the DirectSound API provide the developer with plenty of audio playback control while not being nearly as difficult as writing your own mixing and manipulation code with low-level audio API calls.

### Features

DirectSound offers many features above and beyond what is available through the Win32 API. As with all DirectX components, DirectSound gives the developer more control over sound output than the Windows API, while also providing an improvement in performance. DirectSound provides the following features of specific interest to game developers:

- Automatic use of hardware acceleration (when available)
- Automatic conversion of WAV formats
- Simultaneous output of a virtually unlimited number of sounds
- Special effects such as panning, volume control, frequency adjustment, and 3-D placement

In the following sections we will discuss how the Delphi game developer can take advantage of each of these features to create rich sound output for applications or games.

### Functional Overview

Similar to DirectDraw, DirectSound programming consists of creating a DirectSound object and several sound buffers. The DirectSound object itself represents the developer's direct interface to the audio hardware. Through the IDirectSound interface, the application can query the audio hardware's capabilities, create sound buffers, and control other aspects of the hardware itself.

Of primary interest to DirectSound programmers is the secondary sound buffer object (or specifically the IDirectSoundBuffer object). A secondary sound buffer object represents a sound, or WAV file, in memory. It is a similar relationship as surfaces are to bitmaps in DirectDraw programming. This memory is typically located in system RAM. However, some sound cards contain hardware RAM for the purpose of accelerating sound output. DirectSound will automatically take advantage of this hardware memory by placing secondary sound buffers in the sound card RAM. All of this is transparent to the developer. The majority of time spent in programming DirectSound will be in creation and manipulation of these secondary sound buffers.

When a secondary sound buffer is played, its sound information is mixed with other secondary sound buffers and placed in the primary buffer. The primary buffer represents the conglomeration of all the sounds that will be played simultaneously, and is constantly streamed out to the sound output hardware. As secondary buffers are mixed into the primary buffer, DirectSound automatically converts their format into that of the primary buffer. This makes it easy for the developer to use sounds in varying formats, such as 8- and 16-bit sound, or sounds recorded at different sampling rates. As this mixing occurs, any special effects are applied to the sound, such as panning, volume, or 3-D positioning. The number of buffers that DirectSound can mix is limited only by processing time.

DirectSound provides a software mixer for combining system memory buffers and hardware buffers into the primary buffer. System memory buffers are always mixed in software, but if a hardware mixer is available, the mixed system buffers are streamed to the hardware mixer, along with the hardware buffers. This elaborate process is illustrated in Figure 9-1.

**Figure 9-1:** DirectSound functional overview

**Sound Buffers** As stated above, the majority of time spent when programming DirectSound is in creation and manipulation of secondary sound buffers. The primary sound buffer can also be accessed, allowing the developer to change the primary sound buffer format or even implement custom mixing algorithms. There are a number of attributes and concepts associated with sound buffers that must be explained and understood before they can be put to good use.

**Audio Format** As of this writing, all sound buffers must contain sound data in the pulse code modulation (PCM) format.

**pulse code modulation (PCM):** An uncompressed audio format; the most common format for Windows WAV files.

Fortunately, this is the most common format for Windows WAV files. Unfortunately, you cannot assume that any file with the .wav extension is in the PCM format. WAV files are also stored in the Resource Interchange File Format (RIFF), which is a complex, variable length file format consisting of header "chunks" followed by data "chunks" of variable length.

**Resource Interchange File Format (RIFF):** A complex, variable length file consisting of variable length "chunks." Each chunk can describe data or a header (which contains a description of the data following it). Commonly used for multimedia file formats, such as WAV files.

The data chunks in WAV files can contain audio data in any number of different formats (you can examine this by opening the Sound Recorder under Accessories and choosing Save As). WAV RIFF files contain a header "chunk" in the form of a TWaveFormatEx structure, which allows the developer to check the format of the WAV file before copying its data into a secondary sound buffer. The TWaveFormatEx structure contains a number of useful pieces of information describing the WAV file, such as the number of channels, the sampling rate, and the number of bits per sample. The TWaveFormatEx structure is defined as:

TWaveFormatEx = packed record

```

wFormatTag: Word;          // format type, must be WAVE_FORMAT_PCM for
                             DirectSound compatibility

nChannels: Word;          // number of channels (1 = mono, 2 = stereo)}

nSamplesPerSec: DWORD;    // the sample rate, in hertz (samples per second),
                             typically 11025 (telephone quality), 22050 (radio
                             quality), or 44100 (CD quality)

nAvgBytesPerSec: DWORD;   // average transfer rate (nSamplesPerSec*nBlockAlign)

nBlockAlign: Word;        // bytes per sample (nChannels*nBitsPerSample/8)

wBitsPerSample: Word;     // number of bits per sample (8 or 16)

cbSize: Word;             // number of bytes of extra information, can be
                             ignored

end;

```

**hertz (Hz):** A measurement of samples per second.

---

The audio format of secondary buffers will be dictated by the format of the WAV file they contain. However, the primary buffer has a default audio format of 22,050 Hz, 2 channels, 8 bits per sample. DirectSound gives the developer the abilities to change this format, as we'll see shortly.

**Buffer Memory Locations** When DirectSound creates a secondary sound buffer, it automatically tries to locate the buffer in RAM on the sound card, if available. If there are no hardware buffers available, the sound is stored in system memory. Sound buffers located in hardware have the shortest path to the primary sound buffer, and thus are appropriately suited for sounds that are needed quickly and will be repeated often (such as gunshots), or looped continually (such as an engine hum). Although sound buffers are created in hardware memory by default, the developer can specify the desired memory location of a sound buffer by using specific flags, as described later in this chapter. The number of sound buffers that DirectSound can make are restricted only by available free memory (system memory and sound card hardware memory)

The existence of hardware buffers usually indicates the existence of a hardware mixer. Each hardware buffer takes up one hardware mixing channel (even if the buffer isn't playing), and the number of available hardware buffers is limited by the number of hardware mixing channels. This affects the number of sounds that can be mixed by the hardware mixer. DirectSound will take up the slack by performing any necessary mixing in the software mixer. This will all be transparent to the developer but is useful knowledge when optimizing performance.

**Buffer Types** Secondary sound buffers come in two flavors: static and streaming. Static buffers are used for short sounds that can be placed into memory in their entirety. These are typically short, often repeated or looping sounds. Streaming buffers are used for large sounds that cannot fit into a reasonably sized block of memory, or for sounds that change often and must be copied into the buffer in pieces as it is playing.

By default, DirectSound tries to create a streaming buffer. However, like the buffer memory location, the developer can indicate a desired buffer type through the use of various flags in the buffer creation function.

**Optimum Buffer Configuration** Since DirectSound tries to locate secondary sound buffers in hardware memory first, sound buffers should be created in order of importance. This will ensure that the sounds used most often will enjoy the greatest performance. However, to optimize performance, the developer should dictate the type of buffer when one is created, and where it will be placed. In general, static buffers should be used for short, often repeated or

looping sounds, and should be placed in hardware memory. Streaming buffers, on the other hand, should be placed in system memory (on ISA cards you have no choice, as hardware streaming buffers are not supported). Locating a streaming buffer in hardware does not eliminate any processing overhead as new audio data is continually moving between hardware and software. Thus, hardware buffers should be reserved only for buffers that are not continually updated.

The exception to this rule is when a sound buffer will be duplicated. DirectSound allows copies of a sound buffer to be created that contain their own play and write pointers but do not copy the actual buffer memory. This is useful when a certain sound will be played multiple times, but you want the user to hear the end of the previous sound while the beginning of the next sound is being played (i.e., the dissipation at the end of a laser burst while the next laser burst is charging). Duplicating a hardware buffer requires using hardware resources that may be needed elsewhere. Indeed, the call to duplicate a hardware buffer will fail if there are an insufficient number of hardware resources available. For this reason, it is better to place static buffers that will be duplicated in system memory. An example of duplicating a sound buffer for this purpose will be demonstrated later in the chapter.

**Buffer Memory Format** The memory in a DirectSound sound buffer is conceptually circular. Basically, this means that when DirectSound comes to the end of a buffer, it automatically goes back to the beginning. Think of sound buffer memory like the surface of a cylinder, as illustrated by Figure 9-2.

Each buffer contains a play and write pointer into the memory containing the audio data. The current play position indicates the offset of the next byte that will be sent to the mixer. The current write position is located beyond the current play position and indicates the first byte in the buffer at which it is safe to write new data. The data located between the play and write positions is queued for playback and should never be altered. The write position maintains a distance of approximately 15 milliseconds of play time ahead of the play position. Nevertheless, applications should be writing data to the buffer well ahead of the current write position to allow for any delays in moving the data into the buffer. This information is typically useful only when dealing with streaming buffers, as the application must track the point at which it is safe to stream more audio data into the buffer.

**Figure 9-2** Sound buffer memory is conceptually circular

**Audible Focus** The final important concept when dealing with sound buffers is that of audible focus. When a sound buffer is created, the developer can determine if the sound will continue to be heard when another application receives focus. By default, sounds will not be heard when the application loses focus (although they continue to play silently). A sound buffer can be given Global focus upon creation, indicating that the sound will always be audible unless another application receives focus and obtains exclusive access to the audio hardware (it will continue to play when the application is in the background). Alternatively, a sound buffer can have Sticky focus, indicating that it will be audible unless another application using DirectSound receives focus.

### Initialization

As with DirectDraw, there are several steps the developer must follow to set up DirectSound before loading and playing sound buffers. Some of these steps are somewhat optional, but in general, DirectSound is instantiated by performing the following:

- Enumerating audio devices
- Creating the DirectSound object
- Setting the cooperative level
- Retrieving audio device capabilities
- Setting the format of the primary buffer

**Enumerating Audio Devices** DirectSound provides a function that returns information for every audio output device with an installed hardware driver detected in the system. As a general rule, it is unnecessary for most applications to enumerate all audio output devices. The user can select a preferred audio output device through the Multimedia control panel applet, and DirectSound should be created using this selection unless there is good reason to do otherwise. However, if the developer wants the application to check all available audio drivers for certain capabilities, or just wishes to provide the user with a list of available audio drivers to choose from, the DirectSoundEnumerate function is used. The DirectSoundEnumerate function is defined as:

```
function DirectSoundEnumerate(
    lpDSEnumCallback: TDSEnumCallback;           // a pointer to the callback function
    lpContext: Pointer                             // an application-defined value
): HRESULT;                                       // returns a DirectX error code
```

The first parameter is a pointer to a user-defined callback function. DirectSoundEnumerate prepares a list of every installed audio driver and sends information about each one, one at a time, to this user-defined callback function. This information includes the GUID for the device, the description of the device, and the module name of the DirectSound driver for the device. The other parameter is a 32-bit user-defined value (this is defined as a pointer but is intended for application-specific use and is ignored by the function). The TDSEnumCallback callback function itself is defined as:

```
function TDSEnumCallback(
    lpGuid: PGUID;                                // the audio device GUID
    lpstrDescription: PAnsiChar;                  // a description of the device
    lpstrModule: PAnsiChar;                       // the module name
    lpContext: Pointer                             // the user-defined value
): BOOL;                                         // returns TRUE or FALSE
```

The first parameter is the GUID for the enumerated audio device. The second and third parameters contain textual information describing the audio device. The final parameter contains the user-defined value passed to the original DirectSoundEnumerate function. Every time the callback function is called, it should return a value of TRUE to continue the enumeration or FALSE if no other driver information is required.

The first device enumerated by this function is always the preferred audio output device selected by the user, as described above. This device is known as the primary sound driver.

**primary sound driver:** The audio output device selected by the user on the Audio tab of the Multimedia control panel applet.

---

Actually, this is not a true device enumeration, as no GUID will be returned for this device and the callback function will only receive a description string of “Primary Sound Driver” for the purpose of displaying it in a list. Once the primary sound driver has been enumerated, the callback function is called once for every available sound card.

---

**Note:** On any system with a sound card, the callback function will be called at least twice: once for the primary sound driver and once for the actual sound card hardware. A GUID will be received on the second and subsequent calls.

---

The following example demonstrates the use of the DirectSoundEnumerate function to retrieve the names of all available audio drivers installed on the system.

*Listing 9-2: Enumerating audio output devices*

---

{the user-defined enumeration function. note that the stdcall keyword must be used before Windows can call this function correctly}

```
function EnumSoundDevices(lpGuid: PGUID; // the device GUID
                           lpstrDescription: PAnsiChar; // the description
                           lpstrModule: PAnsiChar; // the module name
                           lpContext: Pointer // the user-defined info
                           ): BOOL; stdcall; // stdcall must be used
```

begin

```
{add the description and the module name of the enumerated driver to the
list box. the first one will be the primary sound driver, and will not
contain a module name}
```

```
Form1.lbxSoundDevices.Items.Add('lpstrDescription' - +lpstrModule);
```

```
{indicate that we wish to continue enumeration}
```

```
Result := TRUE;
```

```

end;

procedure TForm1.FormCreate(Sender: TObject);
begin
    {begin enumerating all available audio drivers}

    DirectSoundEnumerate(EnumSoundDevices, nil);
end;

```

---

**Figure 9-3:** The list of drivers retrieved from DirectSoundEnumerate

**Creating the DirectSound Object** To begin actually using DirectSound functionality, a DirectSound object must be created. This is accomplished by calling the DirectSoundCreate function. The DirectSoundCreate function is defined as:

```

function DirectSoundCreate(

lpGuid: PGUID;           // the sound device GUID

out ppDS: IDirectSound; // the IDirectSound object to be instantiated

pUnkOuter: IUnknown     // unused

): HRESULT;             // returns a DirectX error code

```

The first parameter is a pointer to the GUID of the desired audio device (retrieved through enumeration as explained above, or set to nil to indicate the primary sound driver). The second parameter is an IDirectSound interface which will be instantiated when the function returns. The final parameter is used for COM aggregation and should be set to nil.

**Caution:** It is possible to create multiple DirectSound objects, but this is inadvisable. When an additional DirectSound object is created, its cooperative level (explained below) overrides that of any previously created objects. A single DirectSound object should be created for the duration of the application.

---

**Setting the Cooperative Level** Once the DirectSound object is created, the application should immediately set its cooperative level. The cooperative level determines how the audio device will be shared between the current application and others, as well as access to certain functionality. The cooperative level is set by calling the SetCooperativeLevel method of the IDirectSound interface. The SetCooperativeLevel method is defined as:

```

function SetCooperativeLevel(

hwnd: HWND;           // a window handle

dwLevel: DWORD       // the cooperative level flags

```

```

): HRESULT; // returns a DirectX error code

```

The first parameter is a handle to the application's main window. The second parameter contains a series of flags indicating the desired cooperative level. The flags indicating each cooperative level are described in the table below. Most applications will use the Normal cooperative level, as this allows the most compatible operation with other applications that use the sound card. However, games will normally use the Priority or Exclusive levels, as these allow for the most efficient and optimized use of audio hardware. The cooperative levels below are listed in ascending order, and each level has the abilities of all levels below it.

**Table 9-1: DirectSound cooperative levels**

Level	Flag	Abilities	Restrictions
Normal	DSSCL_NORMAL	Can play secondary sound buffers.	Cannot set the format of the primary sound buffer, cannot write to the primary sound buffer, and cannot call the Compact method.
Priority	DSSCL_PRIORITY	Can change the format of the primary buffer, has first rights to hardware resources, and can call the Compact method.	
Exclusive	DSSCL_EXCLUSIVE	Mutes all sound output from background applications.	
Write Primary	DSSCL_WRITEPRIMARY	Can write directly to the primary sound buffer.	Cannot play secondary sound buffers.

**Note:** When using DirectDraw in conjunction with DirectSound, the window handle passed to the SetCooperativeLevel method of the IDirectSound object must also be sent to the SetCooperativeLevel of the IDirectDraw4 object.

**Retrieving Audio Device Capabilities** Most applications will be concerned with simply creating a DirectSound object and several secondary buffers, and outputting sound, letting DirectSound take care of the details. However, when creating high-performance, CPU-intensive games, it may be necessary to take a more active role in defining how the system will use available hardware resources. This is where the GetCaps method of the IDirectSound object comes in handy. The GetCaps method is defined as:

```

function GetCaps(
var lpDSCaps: TDSCaps // a TDSCaps structure
): HRESULT; // returns a DirectX error code

```

The only parameter for this function is a TDSCaps structure that is initialized with the capabilities of the audio device when the function returns. Several members of this structure, such as the dwMaxHwMixingAllBuffers, dwMaxHwMixingStaticBuffers, and dwTotalHwMemBytes members, can be used to optimize performance by determining what sounds can be placed in hardware buffers in the most efficient manner. Unfortunately, some members of this structure may not be universally supported by all drivers, and the values returned by some members may just be estimates. The best way to use the GetCaps method is to call it after creating each hardware sound buffer.

**Note:** The dwSize member of the TDSCaps structure must be initialized to SizeOf(TDSCaps) before calling the GetCaps method.

Of particular interest to the game programmer is the value of the dwFlags member. This member contains a combination of one or more flags that indicate device capabilities. Specifically, if the DSCAPS\_EMULDRIVER flag is included in this value, a DirectSound driver is not actually present in the system, and all DirectSound functionality is being emulated. This means that no hardware acceleration is available, secondary sound buffers can only be created in system memory, and playback latency will be higher. See the example program in Listing 9-3 for a list of available flags.

The TDSCaps structure is defined as:

TDSCaps = packed record

```
dwSize: DWORD; // the size of the structure, in bytes
dwFlags: DWORD; // capability flags
dwMinSecondarySampleRate: DWORD; // minimum sample rate for secondary
// buffers in hardware
dwMaxSecondarySampleRate: DWORD; // maximum sample rate for secondary
// buffers in hardware
dwPrimaryBuffers: DWORD; // number of primary buffers (always 1)
dwMaxHwMixingAllBuffers: DWORD; // maximum number of hardware buffers
dwMaxHwMixingStaticBuffers: DWORD; // maximum number of static hardware
// buffers
dwMaxHwMixingStreamingBuffers: DWORD; // maximum number of streaming hardware
// buffers
dwFreeHwMixingAllBuffers: DWORD; // number of free hardware buffers
dwFreeHwMixingStaticBuffers: DWORD; // number of free static hardware
```

```

        buffers
dwFreeHwMixingStreamingBuffers: DWORD; // number of free streaming hardware
        buffers
dwMaxHw3DAllBuffers: DWORD; // maximum number of 3-D hardware
        buffers
dwMaxHw3DStaticBuffers: DWORD; // maximum number of 3-D static hardware
        buffers
dwMaxHw3DStreamingBuffers: DWORD; // maximum number of 3-D streaming
        hardware buffers
dwFreeHw3DAllBuffers: DWORD; // number of free 3-D hardware buffers
dwFreeHw3DStaticBuffers: DWORD; // number of free 3-D static hardware
        buffers
dwFreeHw3DStreamingBuffers: DWORD; // number of free 3-D streaming hardware
        buffers
dwTotalHwMemBytes: DWORD; // total hardware memory, in bytes
dwFreeHwMemBytes: DWORD; // free hardware memory, in bytes
dwMaxContigFreeHwMemBytes: DWORD; // largest contiguous block of free
        hardware memory, in bytes
dwUnlockTransferRateHwBuffers: DWORD; // rate of data transfer to hardware
        buffers, in kilobytes per second
dwPlayCpuOverheadSwBuffers: DWORD; // percentage of CPU cycles used to mix
        software buffers
dwReserved1: DWORD; // reserved, not used
dwReserved2: DWORD; // reserved, not used
end;

```

The following example demonstrates how to create the DirectSound object, set its cooperative level, and retrieve audio hardware capabilities.

***Listing 9-3: Creating DirectSound and retrieving hardware capabilities***

---

```

procedure TForm1.FormCreate(Sender: TObject);
var

```

```

At this point, the pointer to the primary sound buffer object can be released, as the new format settings are persistent until the format of the primary sound buffer is again modified.

*Note:* The cooperative level of the DirectSound object must be set to a minimum of DSSCL\_PRIORITY before the format of the primary sound buffer can be changed.

---

In the following example, the sample sound is known to have a format of 44,100 Hz, 2 channels, 16 bits per sample. The format of the primary sound buffer is changed to that of the sample sound to facilitate the most optimum audio playback environment. Several functions not yet discussed are used in the example, but will be explained later in the chapter.

**Listing 9-4:** *Setting the format of the primary sound buffer*

---

```
var
    DXSound: IDirectSound;
    Sound: IDirectSoundBuffer;

procedure TForm1.FormCreate(Sender: TObject);
var
    BufDesc: TDSBufferDesc;
    Format: TWaveFormatEx;
    PrimeBuf: IDirectSoundBuffer;
begin
    {create the DirectSound object}
    DirectSoundCreate(nil, DXSound, nil);

    {set its cooperative level high enough to allow the application to
    change the format of the primary buffer}
    DXSound.SetCooperativeLevel(Handle, DSSCL_PRIORITY);

    {initialize the buffer description structure to indicate we wish to
    retrieve the primary buffer}
```

```

FillChar(BufDesc, SizeOf(TDSBufferDesc), 0);

BufDesc.dwSize      := SizeOf(TDSBufferDesc);
BufDesc.dwFlags     := DSBCAPS_PRIMARYBUFFER;
BufDesc.dwBufferBytes := 0;
BufDesc.lpwfxFormat := nil;

{retrieve the primary buffer}
DXSound.CreateSoundBuffer(BufDesc, PrimeBuf, nil);

{initialize the wave format structure to the desired primary buffer
format settings. this will be the same format used by the example
sound, which should have lower playback latency since it no longer
needs to be converted}
FillChar(Format, SizeOf(TWaveFormatEx), 0);
Format.wFormatTag      := WAVE_FORMAT_PCM;
Format.nChannels       := 2;
Format.nSamplesPerSec  := 44100;
Format.wBitsPerSample  := 16;
Format.nBlockAlign     := (Format.nChannels*Format.wBitsPerSample) div 8;
Format.nAvgBytesPerSec := Format.nSamplesPerSec*Format.nBlockAlign;

{set the format of the primary buffer}
PrimeBuf.SetFormat(Format);

{release the primary buffer (it retains the settings just defined)}
PrimeBuf := nil;

{load in the example sound}
Sound := DSLoadSound(DXSound, ExtractFilePath(ParamStr(0))+`Sample.wav`,
FALSE);

```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    {play the example sound (the primary buffer is now in the same format  
    as this sound buffer)}
```

```
    Sound.SetCurrentPosition(0);
```

```
    Sound.Play(0, 0, 0);
```

```
end;
```

---

## Creating Buffers

Now that DirectSound has been properly instantiated, the application has checked that the sound card provides the desired capabilities, and the format of the primary sound buffer has been changed to match that of the sounds to be played, it is time to start loading and playing sounds.

As with initialization, there are several steps the developer must follow in order to properly create a secondary sound buffer and load it with sound data. Unlike initialization, however, none of these steps are optional, and some are repeated regularly when creating a streaming buffer. In order to load and play a WAV file, the application must perform the following:

- Describe the format of the WAV file to be played
- Describe various secondary sound buffer attributes, such as the size of the buffer and any buffer capabilities
- Create the sound buffer (an IDirectSoundBuffer object) using the above information
- Copy the sound data from the WAV file into the buffer
- Play the sound buffer
- Repeat the last two steps for streaming buffers

By far, the most complex step in initializing a secondary sound buffer is copying the data from a WAV file into the sound buffer itself. Unfortunately, DirectSound does not come with any built-in methods for retrieving audio data from a file or a resource. However, the DirectX SDK comes with several units that contain functions for performing this necessary step, specifically the Wave.C and DSUtil.C units. These units have been converted to Pascal, and live in the form of the DSUtil.pas, DSWaveFiles.pas, and DSWaveResources.pas units. The DSUtil unit contains a function (DSLoadSound, used in the previous example) that will load a sound from a WAV file or a resource, passing back an instantiated IDirectSoundBuffer interface (static sounds only). The DSUtil unit uses functions located in the DSWaveFiles and DSWaveResources units to provide this functionality, and the examples that follow will discuss how to use these functions to initialize sound buffers with sound data.

For the most part, the steps required to load and play a sound are identical for both static and streaming buffers. The primary difference is in how a streaming buffer is continually loaded with new information as it is played. The most common situation, and easiest to follow, is loading and playing static buffers, which is discussed first, followed by streaming buffers.

**Static Buffers** The first step in creating any secondary sound buffer is to initialize a `TWaveFormatEx` structure with information concerning the format of the sound buffer. Of course, this information comes from the desired sound itself. As described earlier in the chapter, WAV files are stored in the RIFF file format, which includes the information we are seeking conveniently configured in the `TWaveFormatEx` format. Parsing WAV file information out of a RIFF file is not too terribly complicated, but is involved enough that it would take several pages just to describe the process. Instead of wasting space describing such an esoteric task, we will use several functions from the `DSWaveFiles.pas` unit (converted from the original `Wave.C` unit found in the DirectX SDK) that perform this function. These functions use several of the low-level multimedia input/output functions, and perusing their code may provide useful insight for providing your own wave parsing routines.

To retrieve the desired information, we call the `WaveOpenFile` function. This function opens the WAV file and initializes a `TWaveFormatEx` structure (passed in as a variable parameter) with the WAV file's format information. Then we must call the `WaveStartDataRead` function, which positions a file pointer at the start of the actual sound data within the WAV file, and retrieves the total size of the sound data.

At this point, we are just about ready to create the actual sound buffer object, so we must initialize a `TDSBufferDesc` structure with information describing what type of sound buffer to create. The `TDSBufferDesc` structure is defined as:

```
TDSBufferDesc = packed record

dwSize: DWORD;           // the size of the structure, in bytes

dwFlags: DWORD;         // buffer description flags

dwBufferBytes: DWORD;   // the size of the sound buffer, in bytes

dwReserved: DWORD;     // reserved, must be 0
```

```
lpwfxFormat: PWaveFormatEx; // a pointer to the TWaveFormatEx structure  
end;
```

**Note:** The dwSize member of the TDSBufferDesc structure must be set to SizeOf(TDSBufferDesc) before calling the CreateSoundBuffer method.

For static buffers, the dwBufferBytes member should be set to the total size of the sound data as retrieved by the WaveStartDataRead function. The lpwfxFormat member should point to the TWaveFormatEx structure initialized by the WaveOpenFile function. The most important member of this structure, dwFlags, can be set to a combination of values that determine several things about the sound buffer, including its location in memory and its type. By default, DirectSound tries to create a streaming buffer, so this member must be set to DSBCAPS\_STATIC in order to create a static buffer. Also by default, the sound buffer will be located in hardware memory if any is available. The DSBCAPS\_LOCHARDWARE flag can be used to force the sound buffer into hardware memory (failing if there is not enough free hardware memory for the buffer), or the DSBCAPS\_LOCSOFTWARE flag can be used to force the sound buffer into system memory. Several other flags are available which provide other controls over the buffer, such as panning and volume, which will be explained below.

Now that the buffer description has been initialized, the CreateSoundBuffer method of the IDirectSound object is called. The CreateSoundBuffer method is defined as:

```
function CreateSoundBuffer(  
  
    const lpDSBufferDesc: TDSBufferDesc; // the buffer description  
  
    var lpIDirectSoundBuffer: IDirectSoundBuffer; // the sound buffer object  
  
    pUnkOuter: IUnknown // unused  
  
): HRESULT; // returns a DirectX error code
```

The first parameter is the TDSBufferDesc structure that has been initialized as discussed above. The second parameter is an IDirectSoundBuffer object that will be instantiated when the function returns. The final parameter is used for COM aggregation and should be set to nil. This creates a secondary sound buffer that is now ready to receive actual sound data.

In order to start copying audio data from the sound file into the buffer, we must retrieve a pointer directly to the sound buffer memory itself. This is accomplished by calling the Lock method of the IDirectSoundBuffer object (this is similar to calling the Lock method of a DirectDraw surface). The Lock method is defined as:

```
function Lock(  
  
    dwWriteCursor, // offset of start of lock  
  
    dwWriteBytes: DWORD; // number of bytes to lock  
  
    var lpLpvAudioPtr1: Pointer; // first memory pointer  
  
    var lpdwAudioBytes1: DWORD; // number of bytes locked  
  
    var lpLpvAudioPtr2: Pointer; // second memory pointer  
  
    var lpdwAudioBytes2: DWORD; // number of bytes locked
```

```
dwFlags: DWORD // lock control flags
): HRESULT; // returns a DirectX error code
```

The first parameter is the offset, in bytes, of the beginning of the locked memory from the start of the sound buffer. The second parameter indicates how many bytes should be locked. The next four parameters indicate where the buffer is actually locked and how many bytes were locked. These parameters are explained in detail below under streaming buffers. The final parameter can indicate that the entire buffer should be locked, or locking should begin from the position of the Write cursor.

The information returned by this function is, in turn, used in a call to the WaveReadFile function, which actually copies the audio data from the WAV file into the sound buffer. Once the data is copied, the Unlock method of the IDirectSoundBuffer is called to unlock the sound buffer memory, and the WaveCloseReadFile function is called to close the actual WAV file. The Unlock method is defined as:

```
function Unlock(
lpvAudioPtr1: Pointer; // offset of first lock
dwAudioBytes1: DWORD; // number of bytes to be unlocked
lpvAudioPtr2: Pointer; // offset of second lock
dwAudioBytes2: DWORD // number of bytes to be unlocked
): HRESULT; // returns a DirectX error code
```

The four parameters passed to this function correspond to the pointers and byte lock counts retrieved from the initial Lock method.

The sound buffer has been created and loaded with audio data, and is now ready to be output through the audio hardware. The SetCurrentPosition method of the IDirectSoundBuffer object can be called to set the actual position within the sound data to start the audio playback. The SetCurrentPosition method is defined as:

```
function SetCurrentPosition(
dwPosition: DWORD // the current position offset
): HRESULT; // returns a DirectX error code
```

The only parameter in this function is the offset, in bytes, from the beginning of the buffer to which the current playing position should be set.

Finally, the Play method is called to actually begin audio playback. The Play method is defined as:

```
function Play(  
dwReserved1, // reserved  
dwReserved2, // reserved  
dwFlags: DWORD // play control flags  
): HRESULT; // returns a DirectX error code
```

The first two parameters are unused and should be set to zero. The third parameter can be set to zero to simply play the sound once, or it can be set to DSBPLAY\_LOOPING to continuously play the sound. The Stop method can be called to discontinue any sound playback from the buffer (the Stop method has no parameters).

**Note:** Like DirectDraw surfaces, the memory allocated to secondary sound buffers can be lost when another application takes over the sound hardware. In this case, any calls to the Lock or Play methods will return DSERR\_BUFFERLOST. The Restore method can be called to reallocate the buffer memory. However, the contents of this memory will be invalid, and the audio data must be recopied into the sound buffer.

The following example demonstrates how to create a static sound buffer, load it with audio data from an external WAV file, and play it.

*Listing 9-5: Creating and playing static wave files*

var

```

DXSound: IDirectSound;

Sounds: array[0..5] of IDirectSoundBuffer; // holds all of our sound objects

const
  {the names of the WAV files to be used}
  FileNames: array[0..5] of string = ('bigz05.wav', 'bigzap.wav', 'bloop.wav',
                                       'boingg.wav', 'bwik.wav', 'elslide.wav');

procedure TForm1.FormCreate(Sender: TObject);

var
  iCount: Integer;

begin
  {create the DirectSound object}
  DirectSoundCreate(nil, DXSound, nil);

  {set its cooperative level (we won't change the primary buffer format, so
   a cooperative level of Normal is all that is needed)}
  DXSound.SetCooperativeLevel(Handle, DSSCL_NORMAL);

  {load in the six example sounds}
  for iCount := 0 to 5 do
    LoadSound(FileNames[iCount], Sounds[iCount]);
end;

.
.
.

{this function is used to load a WAV file and initialize an
 IDirectSoundBuffer object with the audio data}
procedure TForm1.LoadSound(FileName: string; var Buffer: IDirectSoundBuffer);

var
  Audio: PByte;

```

```

Junk: Pointer;

NumBytesLocked: DWORD;

JunkBytes: DWORD;

WaveFormat: PWaveFormatEx;

mmioHndle: HMMIO;

ChunkInfo,

ChunkInfoParent: TMMCKInfo;

BufDesc: TDSBufferDesc;

begin

    {open the specified WAV file and read its format information}

    WaveOpenFile(PChar(ExtractFilePath(ParamStr(0))+FileName), mmioHndle,

                WaveFormat, @ChunkInfoParent);

    {advance the file pointer to the beginning of audio data, and retrieve the

     size of the buffer required to hold all of the audio data}

    WaveStartDataRead(mmioHndle, @ChunkInfo, @ChunkInfoParent);

    {initialize a buffer description record, including the size of the audio

     data and its format retrieved from the previous two function calls}

    FillMemory(@BufDesc, SizeOf(TDSBufferDesc), 0);

    BufDesc.dwSize := SizeOf(TDSBufferDesc);

    BufDesc.dwFlags := DSBCAPS_STATIC; // could also use DSBCAPS_LOCHARDWARE to

                                     // force the buffer into hardware memory

    BufDesc.dwBufferBytes := ChunkInfo.cksize;

    BufDesc.lpwfxFormat := WaveFormat;

    {create the sound buffer object}

    DXSound.CreateSoundBuffer(BufDesc, Buffer, nil);

    {lock the entire buffer}

    Buffer.Lock(0, 0, Pointer(Audio), NumBytesLocked, Junk, JunkBytes,

```

```
DSBLOCK_ENTIREBUFFER);
```

```
{copy the audio data into the sound buffer object}
```

```
WaveReadFile(mmioHndle, NumBytesLocked, Audio, @ChunkInfo, JunkBytes);
```

```
{unlock the buffer}
```

```
Buffer.Unlock(Audio, NumBytesLocked, nil, 0);
```

```
{close the WAV file. at this point, the IDirectSound buffer has been  
initialized and is ready to be played}
```

```
WaveCloseReadFile(mmioHndle, WaveFormat);
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
{the Tag property of each button is set to the appropriate index into  
the array of IDirectSoundBuffer objects. when a button is pressed, reset  
the current position of the appropriate buffer, and start playing it}
```

```
Sounds[TButton(Sender).Tag].SetCurrentPosition(0);
```

```
Sounds[TButton(Sender).Tag].Play(0, 0, 0);
```

```
end;
```

---

The DSWaveResources.pas unit contains functions similar to those found in the DSWaveFiles.pas unit for loading WAV file information from resources. Internally, dramatically different API functions are called, mainly those used for manipulating resources on a binary level as opposed to multimedia file input/output functions. Specifically, the DSGetWaveResource function is called to initialize both the TDSBufferDesc and the TWaveFormatEx structures. The CreateSoundBuffer method is then called as usual, and the DSFillSoundBuffer function is called to actually copy the audio data into the buffer. The following example demonstrates how to use these functions to create and play static sound buffers from audio data in a resource. This example also demonstrates how to check for a lost sound buffer and restore its contents.

**Listing 9-6:** *Creating and playing static wave files from resource information*

---

```
var
```

```
DXSound: IDirectSound;
```

```

Sounds: array[0..5] of IDirectSoundBuffer; // holds all of our sound objects

const
    {the resource names of the waves to be used}
    ResNames: array[0..5] of PChar = ('bigz05', 'bigzap', 'bloop',
                                       'boingg', 'bwik', 'elslide');

    {this function is used to load a wave resource and initialize an
    IDirectSoundBuffer object with the audio data}
procedure LoadSound(ResName: PChar; var Buffer: IDirectSoundBuffer);
var
    BufDesc: TDSBufferDesc;
    pbWaveData: PByte;
begin
    {empty the buffer description record}
    FillMemory(@BufDesc, SizeOf(TDSBufferDesc), 0);

    {load the wave resource, initializing the format and required buffer size}
    if DSGetWaveResource(0, ResName, BufDesc.lpwfxFormat, pbWaveData,
                        BufDesc.dwBufferBytes) then
    begin
        {initialize the remaining buffer description members}
        BufDesc.dwSize := SizeOf(TDSBufferDesc);
        BufDesc.dwFlags := DSBCAPS_STATIC; // could also use DSBCAPS_LOCHARDWARE to
                                           // force the buffer into hardware memory

        {create the sound buffer object}
        DXSound.CreateSoundBuffer(BufDesc, Buffer, nil);

        {fill the sound buffer with the audio data from the resource}
        DSFillSoundBuffer(Buffer, pbWaveData, BufDesc.dwBufferBytes);
    end;
end;

```

```

end;

{this function is used to restore the contents of an IDirectSoundBuffer object
 when its memory has been lost. it is very similar to the LoadSound function}
procedure ReloadSound(ResName: PChar; var Buffer: IDirectSoundBuffer);
var
    BufDesc: TDSBufferDesc;
    pbWaveData: PByte;
begin
    {empty the buffer description record}
    FillMemory(@BufDesc, SizeOf(TDSBufferDesc), 0);

    {load the wave resource, initializing a pointer to the wave data
     and the size of the data}
    if DSGetWaveResource(0, ResName, BufDesc.lpwfxFormat, pbWaveData,
        BufDesc.dwBufferBytes) then
    begin
        {restore the buffer's memory}
        Buffer.Restore;

        {fill the sound buffer with the audio data from the resource}
        DSFillSoundBuffer(Buffer, pbWaveData, BufDesc.dwBufferBytes);
    end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    {the Tag property of each button is set to the appropriate index into
     the array of IDirectSoundBuffer objects. when a button is pressed, reset
     the current position of the appropriate buffer, and start playing it}
    Sounds[TButton(Sender).Tag].SetCurrentPosition(0);

```

```

{attempt to play the sound. if the buffer memory has been lost...}
if Sounds[TButton(Sender).Tag].Play(0, 0, 0) = DSERR_BUFFERLOST then
begin
    {...restore the sound buffer}

    ReloadSound(ResNames[TButton(Sender).Tag], Sounds[TButton(Sender).Tag]);

    {play the restored sound buffer}

    Sounds[TButton(Sender).Tag].SetCurrentPosition(0);

    Sounds[TButton(Sender).Tag].Play(0, 0, 0);

end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
    iCount: Integer;
begin
    {create the DirectSound object}

    DirectSoundCreate(nil, DXSound, nil);

    {set its cooperative level (we won't change the primary buffer format, so
    a cooperative level of Normal is all that is needed)}

    DXSound.SetCooperativeLevel(Handle, DSSCL_NORMAL);

    {load in the six example sounds}

    for iCount := 0 to 5 do

        LoadSound(ResNames[iCount], Sounds[iCount]);

end;

```

**Streaming Buffers** As mentioned previously, streaming buffers are used for large sounds that will not fit into a reasonably sized chunk of memory. A good use for streaming buffers would be for playback of digitized dialog, or perhaps a digitized music track. Creating streaming buffers is very similar to creating static buffers. The application must first read in a WAV file (or resource) and retrieve its format. Then, it must set up a TDSBufferDesc structure with the appropriate attributes.

There are two major differences between creating streaming buffers and creating static buffers: the flags used in the buffer description structure and the size of the buffer itself. As you would expect, the dwFlags member of the TDSBufferDesc structure will not contain the DSBCAPS\_STATIC flag. However, this member should contain the DSBCAPS\_GETCURRENTPOSITION2 flag to ensure the most accurate play position tracking. As for the size of the buffer, instead of setting it to the total size required to hold all of the audio data as in static buffer creation, it is set to a size large enough to hold approximately two seconds worth of audio data. Two seconds is an arbitrary number and depends on the application's specific needs. The actual size of the buffer is dependent on the wave's sample rate and bits per sample (the nAvgBytesPerSec member of the wave's TWaveFormatEx structure should be used).

To actually begin loading data into the buffer, we must first know where the current play and write positions are within the buffer (described earlier under Buffer Memory Format). The GetCurrentPosition method of the IDirectSoundBuffer object retrieves the offset from the beginning of the buffer for both the play and write positions. The GetCurrentPosition method is defined as:

```
function GetCurrentPosition(  
  
    lpdwCapturePosition,           // the current play position  
  
    lpdwReadPosition: PDWORD      // the current write position  
  
): HRESULT;                       // returns a DirectX error code
```

The first parameter is set to the current position of the play cursor, as an offset from the beginning of the buffer in bytes. The second parameter is set to the current position of the write cursor, again as an offset in

bytes from the beginning of the buffer.

How the data is loaded into the buffer is up to the application. For example, data could be written into the buffer right at the start of the write position (not recommended), or it could be written into the buffer at some point ahead of the current play position. In our examples below, we'll write data into the buffer based on the current play position.

You may have noticed how the Lock method returns two lock start offsets and two bytes locked counts. This is again due to the circular nature of buffer memory. For example, say the buffer is 5,000 bytes long, and the Lock method is called with a starting offset of 3,000 and a request to lock 3,000 bytes. The last 2,000 bytes in the buffer can be locked, but the final 1,000 requested bytes must be locked from the beginning of the buffer. This is why two offsets and two byte counts are returned. Again, depending on how your application copies data into the buffer, these values can be used to continuously copy data into the buffer in a circular format.

All that remains is to play the buffer and determine exactly when to write data into the buffer. We've already seen how a buffer can be played. In the case of streaming buffers, it might be useful to fill the buffer with silence and start playing it immediately, especially if the sound will be looped. Filling the buffer with silence involves simply zeroing out the buffer's memory using the techniques described above for writing data into a buffer.

*Note:* We have a function in the DSUtil unit called FillBufferWithSilence that performs this task.

---

As for when to write data into the buffer, there are two methods available to the application: polling and notification. Polling involves using the GetCurrentPosition method as described above. GetCurrentPosition is called at regular intervals (like every pass through the game's main loop), writing data into the buffer based on the Play or Write position returned at that moment. The advantages to this method are that it's simple and easy to implement. The disadvantages are that unless polling is performed at regular intervals, the Play position can easily race past the point where new data should have been copied into the buffer, resulting in old data being played back and a generally messed up audio output. The other method, notification, involves using the IDirectSoundNotify interface together with a number of low-level API functions such as CreateEvent and WaitForMultipleObjects to create event objects that are signaled when the Play position reaches certain points within the buffer. The advantage to this method is that it is more efficient than continually calling the GetCurrentPosition method. The disadvantages are that it is much more difficult to set up, requires multiple threads (in some cases), and is consequently more difficult to debug. For our purposes, the polling method will be more than adequate.

The following example demonstrates creating a streaming buffer and writing data into the buffer by polling the current play position.

        begin
            WaveStartDataRead(mmioHndle, @ChunkInfo, @ChunkInfoParent);

            WaveReadFile(mmioHndle, NumBytesLocked-BytesRead,
                Pointer(Longint(Audio)+BytesRead), @ChunkInfo, BytesRead);

```

```

end;

{unlock the buffer}

Sound.Unlock(Audio, NumBytesLocked, nil, 0);

{store the last known playing position}

LastPlayPos := CurPlayPos;

end;

end;

end;

```

---

## Duplicating Buffers

It is quite common in action games to have a short sound that is repeated often, such as gunshots, laser bursts, or even explosions. To play a regular static buffer in its entirety, the `SetCurrentPosition` method is called to “rewind” the sound, and then the `Play` method is called to begin audio output. If this sound is to be repeated rapidly, such as when the user is frantically pressing the fire button, the sound may seem to stutter, as each time the sound is replayed the previously playing sound is started from the beginning. The solution would be some method by which this sound buffer can be copied, sharing the sound data with the original buffer but with its own playing position. Fortunately, `DirectSound` provides a method by which a static buffer can be duplicated.

By calling the `DuplicateSoundBuffer` method, another `IDirectSoundBuffer` object is created. This new object has its own play and write pointers, but it shares the audio data with the original sound (as opposed to creating its own sound buffer). It can be played or stopped regardless of the state of the original sound, but since it shares the original buffer, a duplicated buffer should not be locked nor should its data be modified. The `DuplicateSoundBuffer` method is defined as:

```

function DuplicateSoundBuffer(

lpDsbOriginal: IDirectSoundBuffer;           // the original sound buffer

var lpDsbDuplicate: IDirectSoundBuffer      // the duplicated sound buffer

): HRESULT;                                 // returns a DirectX error code

```

The first parameter is a pointer to the sound buffer that is to be duplicated. The second parameter is an `IDirectSoundBuffer` object that is instantiated as a copy of the original when the function returns.

Bear in mind that although the sound buffer is not reproduced, duplicating a sound buffer does require some resources. Thus, it is better to locate static buffers to be duplicated in system memory, as duplicating a hardware buffer may require additional hardware resources that are not available or should be used for more efficient purposes.

**Note:** Calling `DuplicateSoundBuffer` on a hardware buffer will fail when no more (or insufficient) hardware resources are available.

---

The DirectX SDK comes with an object that encapsulates this buffer duplication, making it easy to manage sounds that must be played multiple times concurrently. While the following example makes no use of any such object, it is easy to see how one could potentially be created to encapsulate the functionality as illustrated. The example demonstrates how to play a single sound multiple times by using the DuplicateSoundBuffer method to create several copies of the sound. For comparison purposes, the original sound can be played as well, illustrating how using the DuplicateSoundBuffer method can help eliminate stutter from sounds played in rapid succession.

```

    {play a duplicated buffer from the beginning}

    SoundArray[CurSound].SetCurrentPosition(0);

    SoundArray[CurSound].Play(0, 0, 0);

end;

```

## Buffer Controls

The `IDirectSoundBuffer` interface contains several methods by which the application can control certain aspects of the sound. Specifically, an application can control pan, frequency, and volume. This allows a developer to implement several special sound effects that can greatly enhance a game. For example, the pan control can be used to move the sound of an engine whine from side to side as a spaceship crosses the screen. Volume could be used to reduce and finally eliminate an engine whine as a ship moves farther away. The frequency could even be adjusted up or down to indicate the speed of an engine, or perhaps even damage.

Specifically, pan is controlled through the `GetPan` and `SetPan` methods, frequency is controlled through the `GetFrequency` and `SetFrequency` methods, and volume is controlled through the `GetVolume` and `SetVolume` methods. All methods take but a single parameter. Pan and volume are expressed in relative terms, but frequency is expressed in hertz. All attributes have an acceptable range, and pan and volume have a neutral value, which is illustrated in Table 9-2.

The desired sound buffer controls are specified when the `IDirectSoundBuffer` object is created. As mentioned previously, the `dwFlags` member of the `TDSBufferDesc` structure can be set to a combination of values that indicate the memory location of the sound buffer and other attributes. The three flags used to give control of a buffer's pan, frequency, and volume are illustrated in Table 9-2. Additionally, the `DBSCAPS_CTRLALL` or the `DBSCAPS_CTRLDEFAULT` flags can be used to indicate that the buffer has access to all controls or the pan, frequency, and volume controls, respectively.

**Caution:** As an issue of performance, buffers with additional controls require additional processing time for real-time modification of the sound data. Therefore, it is suggested that only the specific control flags truly needed for a buffer be used, and the `DBSCAPS_CTRLALL` or `DBSCAPS_CTRLDEFAULT` flags should only be used for buffers that actually need all controls.

**Table 9-2:** Pan, frequency, and volume ranges and neutral values

Control	Flag	Neutral Value	Range
Frequency	<code>DBSCAPS_CTRLFREQUENCY</code>	None	Software buffers: <code>DSBFREQUENCY_MIN</code> to <code>DSBFREQUENCY_MAX</code> .  Hardware buffers: dwMinSecondarySample rate to dwMaxSecondarySampleRate (see the <code>GetCaps</code> method)
Pan	<code>DBSCAPS_CTRLPAN</code>	<code>DSBPAN_CENTER</code>	<code>DSBPAN_LEFT</code> to <code>DSBPAN_RIGHT</code>
Volume	<code>DBSCAPS_CTRLVOLUME</code>	<code>DSBVOLUME_MAX</code>	<code>DSBVOLUME_MIN</code> to <code>DSBVOLUME_MAX</code>

The following example demonstrates how to create a sound buffer using the pan, volume, and frequency

controls, retrieve their settings, and modify their values in real time.

**Listing 9-9:** *Using buffer controls for special effects*

## Music

Music, like sound effects, adds depth to a game, giving it a feeling of completeness. Even more than sound effects, music adds mood to a game, and when used effectively can adjust the user's frame of mind as effectively as a movie sound track.

Most games feature music that changes in response to changing conditions within the game. An effective use of music would be to play something eerie and mysterious when exploring catacombs, change to a heart-pounding rock-and-roll piece during the heat of combat, and end with a euphoric anthem to signal victory or a melancholic hymn to signal defeat. The difficulty comes in writing such musical ballads; programmatically outputting the result is easy by comparison.

The topic of musical output, while poorly documented, has been explored by a number of adventurous programmers, and as such there are several techniques for its implementation. One simple technique may be to simply digitize a musical piece and use the methods described above for its playback. Several other techniques involve digitized music compressed in various formats and then uncompressed on the fly as it is output to the audio device. However, for our purposes, we will examine only two common musical output techniques: MIDI and CD audio. Both of these techniques use Win32 MCI API commands, and as such do not make use of DirectX or DirectSound functionality.

**Tip:** As stated at the beginning of the chapter, the DirectX 6.1 and above SDK contains the new DirectMusic component that brings the power of DirectX to MIDI output. The header files were not available during the production of this book, and thus we were unable to cover them in this chapter. However, the DirectMusic header files are available on the CD accompanying this book.

## MCISendCommand

All of the examples to follow make use of a very powerful Win32 API function called MCISendCommand. This is a high-level command in the Media Control Interface (MCI) subsystem of Windows. The MCISendCommand function is simple in its declaration but very complex in terms of what it can do. You

**Desktop Library**  
[Click to access!](#)

can use the `MCISendCommand` function to take advantage of any native Windows multimedia functionality, including playback of WAV files, video files, and MIDI and CD music (as we'll see below), and interaction with video recording and playback equipment. Our uses of this function will be limited solely to MIDI and CD audio output, but you should be aware that this is a very powerful and complex function that unfortunately is poorly documented. The `MCISendCommand` function is defined as:

```
function mciSendCommand(  
  
mciId: MCIDEVICEID;           // the MCI device identifier  
  
uMessage: UINT;               // the command message  
  
dwParam1,                     // command message flags  
  
dwParam2: DWORD               // address of parameter structure  
  
) : MCIERROR;                 // returns an MCI error code
```

The first parameter to this function is the identifier of the MCI device to which the command should be sent. This is retrieved when the device is first opened. The second parameter is the actual command to be sent to the device. Each command instructs the device to perform a different task, and we'll see several commands in the following examples. The third parameter is a series of flags that are dependent on the type of command sent, and indicate which members of the structure identified by the last parameter contain valid data. In particular, the `MCI_WAIT` flag is used often to indicate that the function should not return until the command has been carried out. The final parameter takes a pointer to a data structure, again dependent upon the type of command being sent. Some data structures must be initialized, while others are initialized by the function and contain pertinent data when it returns. For some reason, due to the way this function was declared, you must pass the structure's address by typecasting it as a longint. This will be illustrated in the examples to follow.

## Notification

`MCISendCommand` is asynchronous by nature, and will return immediately unless the `MCI_WAIT` flag was specified. In this event, you can usually specify the `MCI_NOTIFY` flag to indicate that the function should notify the application when it has completed. This is accomplished by sending the application an `MM_MCINOTIFY` message. It is a simple matter to define a handler for this message, and this technique is used in Listing 9-10.

## MIDI

MIDI, or Musical Instrument Digital Interface, is a format for describing musical sound, much the same as the WAV format describes digitized sound. It is an effective means of providing music within a small footprint. Both software for creating MIDI files and freeware or shareware MIDI songs are readily available.

**MIDI (Musical Instrument Digital Interface):** A digital format for describing music.

---

In order to implement MIDI music playback, several steps must be followed. With the exception of detecting available hardware, none of these steps are optional. Outputting MIDI music is implemented by performing these tasks:

- Check for MIDI output hardware existence
- Open the MIDI output device

- Set the time format
- Commence playback
- Retrieve playback status
- Close the device

## Check for MIDI Output Hardware Existence

The target machine must have a device capable of outputting MIDI music. It would be very difficult these days to find a sound card that did not also include the ability to output MIDI music. Thus, it is safe to assume that any machine with a sound card is capable of outputting MIDI. However, the developer can use the function `midiOutGetNumDevs` to determine if there are indeed any devices that can output MIDI music. The `midiOutGetNumDevs` function takes no parameters and returns a simple integer. If this integer value is greater than zero, at least one hardware device has been found that is capable of MIDI music output.

## Open the MIDI Output Device

The first real step in playing MIDI music is to open the “sequencer” device (the hardware device capable of outputting MIDI music) and the MIDI file that will be played. This requires a variable of the type `TMCI_Open_Parms`. This data structure describes the device being opened and the file that will be played on the device. The `TMCI_Open_Parms` data structure is defined as:

```
TMCI_Open_Parms = record

    dwCallback: DWORD;           // a window handle

    wDeviceID: MCIDEVICEID;     // the device identifier

    lpstrDeviceType: PAnsiChar; // the name of the device

    lpstrElementName: PAnsiChar; // the name of the element

    lpstrAlias: PAnsiChar;      // a device alias

end;
```

**Delphi Graphics and Game Programming Exposed with DirectX**

**7.0**

by *John Ayres*

Wordware Publishing, Inc.

ISBN: 1556226373 Pub Date: 12/01/99

**Search this book:**

[Previous](#) [Table of Contents](#) [Next](#)

The first member of this structure can be set to the handle of a window which will receive the MM\_MCINOTIFY message (if so desired) when the function completes. The second member will be set to the MCI device identifier when the function returns, and should be stored for later use. The third parameter is set to the name of the device; for MIDI file playback, this should be set to 'sequencer.' The fourth parameter is set to the name of the MIDI file, which is opened and prepared for playback when this function returns. The final member contains a device alias and for our purposes can be ignored.

For our purposes, we can also ignore the dwCallback member. Thus, to open the MIDI device and a MIDI file, we must initialize lpstrDeviceType to 'sequencer,' set lpstrElementName to the filename of our MIDI file, and pass the structure to the MCISendCommand function, specifying MCI\_OPEN as our command message. For example:

```
{open the MIDI output device, loading the Canyon MIDI song}

OpenParms.lpstrDeviceType := 'sequencer';

OpenParms.lpstrElementName := 'C:\Windows\Media\Canyon.mid';

MCISendCommand(0, MCI_OPEN, MCI_OPEN_TYPE or MCI_OPEN_ELEMENT or MCI_WAIT,

               LongInt(@OpenParms));

{save a handle to the device}

MCIDeviceID := OpenParms.wDeviceID;
```

When this command returns, the wDeviceID member of TMCI\_Open\_Parms will contain a device identifier for the opened MIDI sequencer. The application should store this value, as it will be used in all subsequent MCISendCommand function calls.

**Set the Time Format**

The MCI subsystem needs to know the time format for playback of various media so it will not come out garbled or trashed. MIDI music is timed by the millisecond, so we must inform MCI to set the time format for playback to milliseconds. This is accomplished by initializing a variable of type `TMCI_Set_Parms`. The `TMCI_Set_Parms` structure is defined as:

```
TMCI_Set_Parms = record

    dwCallback: DWORD;           // a window handle

    dwTimeFormat: DWORD;        // the time format

    dwAudio: DWORD;             // audio output channel

end;
```

The first member of this structure can be set to the handle of a window which will receive the `MM_MCINOTIFY` message (if so desired) when the function completes. The second parameter is a flag that indicates the time format. The final member indicates the audio output channel.

For our purposes, we are only interested in the `dwTimeFormat` member, which should be set to `MCI_FORMAT_MILLISECONDS` to indicate a millisecond time format. This initialized structure is then sent to the `MCISendCommand` function with a command message of `MCI_SET`. We must also pass in the device ID that we recorded from the previous call to indicate the device whose time format is being set. For example:

```
{set the time format to milliseconds}

SetParms.dwTimeFormat := MCI_FORMAT_MILLISECONDS;

MCISendCommand(MCIDeviceID, MCI_SET, MCI_WAIT or MCI_SET_TIME_FORMAT,

               LongInt(@SetParms));
```

## Commence Playback

The final step simply informs the multimedia system that we wish to play the file. This requires a variable of the type `TMCI_Play_Parms`. The `TMCI_Play_Parms` data structure is defined as:

```
TMCI_Play_Parms = record

    dwCallback: DWORD;           // a window handle

    dwFrom: DWORD;              // play start position

    dwTo: DWORD;                // play end position

end;
```

The first member of this structure can be set to the handle of a window which will receive the `MM_MCINOTIFY` message (if so desired) when the function completes. The second member indicates the position at which to start playback, and the final member indicates the position at which to end playback.

This data structure allows the application to specify the exact position from which to begin playback and an exact position at which to end the playback. Even though the `MCISendCommand` function requires a variable of this type, there is no need to initialize any of the members to simply play the MIDI file; it will play it from start to

finish by default. The MCI\_PLAY command message instructs Windows to begin playback. For example:

```
{commence song playback, indicating that we wish to receive an MM_MCINOTIFY
message when the playback has completed}

PlayParms.dwCallback := Handle;

MCISendCommand(MCIDeviceID, MCI_PLAY, MCI_NOTIFY, LongInt(@PlayParms));
```

Notice that we set the dwCallback member to the handle of our main window, and indicated that we wished to be notified when the function finishes. If we had used the MCI\_WAIT flag, our application would hang until the MIDI file had finished playing. Obviously, this is not acceptable, so we indicated that we would instead like to receive the MM\_MCINOTIFY message when the music stops. In our example below, we use this to implement a looping feature.

## Retrieve Playback Status

While certainly not a required step, most applications at some point may need to know the current position of playback. This could be used to change the music according to the context, waiting for playback to reach a specific point so the music can be changed at an appropriate time. We can retrieve the current playback status by using a variable of type TMCI\_Status\_Parms. TMCI\_Status\_Parms is defined as:

```
TMCI_Status_Parms = record

    dwCallback: DWORD;           // a window handle

    dwReturn: DWORD;            // the status value

    dwItem: DWORD;              // the status item

    dwTrack: DWORD;             // length

end;
```

The first member of this structure can be set to the handle of a window which will receive the MM\_MCINOTIFY message (if so desired) when the function completes. The second member contains the status value when the function returns. The third member contains a flag indicating the item whose status is to be retrieved. For our purposes, this can be set to MCI\_STATUS\_POSITION to indicate we wish to retrieve the status of the playback position. The final member indicates the length or number of tracks. The MCI\_STATUS command message indicates we wish to retrieve the device's status. For example:

```
{retrieve the current position of the song playback}

StatusParms.dwItem := MCI_STATUS_POSITION;

MCISendCommand(MCIDeviceID, MCI_STATUS, MCI_WAIT or MCI_STATUS_ITEM,

                LongInt(@StatusParms));
```

## Close the Device

When the application terminates or MIDI music playback is no longer required, the MCI device must be closed and released by calling the MCISendCommand with a command message of MCI\_CLOSE. The MCI device ID

must be passed in to the first parameter, but the last two parameters are unused and should be set to zero.

The following example implements the discussed steps in order to play back a MIDI music file.

end;

```

---

## CD Audio

MIDI offers the advantage of providing large musical scores with minimal space requirements. However, unless the user has a dedicated MIDI sound card (unlikely unless they are a musician), musical sound quality will always be less than perfect. Many games are circumventing this limitation by playing their musical scores directly off of the CD on which the game is distributed. This offers the highest possible sound quality, although the amount of music

available to the game will be limited by the number of scores and their length, as CD audio requires much more storage space than MIDI files.

The method by which data and music is stored on the CD varies. In a mixed-mode CD, all executable data must be placed in what a regular CD player would recognize as the first track. Multisession CDs do not have this requirement.

**Caution:** While the application is accessing data from the CD, it cannot play a musical track, and vice versa.

---

The music data itself is stored on the CD in a format known as Red Book Audio. This format provides for stereo music at the highest quality, and is the format used by the professional music industry to record music onto conventional audio CDs. An interesting side effect to this arrangement is that a CD game taking advantage of Red Book Audio music can be placed into a conventional CD player and played as if it were any regular music CD. The data track will be nothing but white noise, but the musical tracks can be replayed as desired.

**Red Book Audio:** The digital format used to store professional music on conventional audio CDs.

---

It is important to note that the end user's machine must be set up correctly before it can play CD audio music. This involves installing a small wire that runs directly from the CD to the audio output hardware. While most new machines have this installed automatically, it may not always be available. Also, as an added benefit, this direct connection between the hardware results in true multitasking when playing CD audio. The audio signals are sent directly to the sound output hardware, bypassing the CPU completely. Thus, playing CD audio involves almost no CPU utilization, resulting in almost no performance penalties.

Like MIDI music playback, several steps must be followed in order to initialize and commence the playback of a CD audio track. CD audio playback is implemented by performing these tasks:

- Open the CD device
- Check for the existence of the CD
- Set the time format
- Retrieve the number of tracks and their length
- Commence playback
- Stop playback
- Close the device

## Open the CD Device

If the music for a game is stored on a CD along with the executable code, the target machine must contain a CD-ROM drive in order to use the application. Thus, we do not need to check for the existence of a CD-ROM drive. However, it is good practice to test for the existence of a CD in the drive before attempting to play a track from it. This will be discussed in a moment.

Like MIDI, we must first open the CD device. However, unlike MIDI, we do not need to specify a file. Again, we will need a variable of the type `TMCI_Open_Parms`, but this time its `lpstrDeviceType` member must be set to the string `'cdaudio'`. For example:

```
{open the cd audio playback device}

OpenParms.lpstrDeviceType := 'cdaudio';

MCISendCommand(0, MCI_OPEN, MCI_OPEN_TYPE or MCI_WAIT, Longint(@OpenParms));
```

```
{save a handle to the cd audio device}
```

```
MCIDeviceID := OpenParms.wDeviceID;
```

## Check for the Existence of the CD

Once the CD audio device is opened, we can poll it to determine if a CD is actually inserted. To accomplish this, we need a variable of the type `TMCI_Status_Parms`. The `dwItem` member of this data structure must be set to `MCI_STATUS_MEDIA_PRESENT` to indicate that we wish to test for the presence of a CD in the drive. We then call the `MCI SendCommand` function, passing `MCI_STATUS` in its second parameter. For example:

```
{determine if a CD is present in the drive}
```

```
StatusParms.dwItem := MCI_STATUS_MEDIA_PRESENT ;
```

```
MCI SendCommand(MCIDeviceID, MCI_STATUS, MCI_WAIT or MCI_STATUS_ITEM,
```

```
LongInt(@StatusParms));
```

When this function returns, if the dwReturn member is set to zero, there is no CD present in the drive, and the application should display an error message asking the user to insert the CD, repeating the check as necessary. If the dwReturn member is greater than zero, there is a CD in the drive, although it may not be the game's CD. Each CD contains a unique identifying number that we can use to determine if it is the required CD. The example in Listing 9-11 demonstrates how to extract this identifying number.

### Set the Time Format

Like MIDI, we must inform the MCI subsystem as to the timing format used for playback. Red Book Audio is timed by tracks, minutes, seconds, and frames, where there are 75 frames per second. We will use a variable of type TMCI\_Set\_Parms, setting its dwTimeFormat member to MCI\_FORMAT\_TMSF to indicate this unusual timing format. For example:

```
{set the time format for the CD audio device}

SetParms.dwTimeFormat := MCI_FORMAT_TMSF;

MCISendCommand(MCIDeviceID, MCI_SET, MCI_WAIT or MCI_SET_TIME_FORMAT,

                Longint(@SetParms));
```

### Retrieve the Number of Tracks and Their Length

While it's not absolutely necessary to retrieve the number of tracks on a CD, you do need to record the length of each track. More specifically, you must record the length of the very last track for reasons that are explained below. For the purposes of our example, however, we will record the number of tracks on the CD and the length of each so they may be displayed by our CD player example.

We make use of another TMCI\_Status\_Parms variable, setting its dwItem member to MCI\_STATUS\_NUMBER\_OF\_TRACKS to indicate we wish to retrieve the number of tracks. Once this is accomplished, we can then set dwTrack to a specific track number (we'll iterate through each track) and the dwItem member to MCI\_STATUS\_LENGTH, indicating we wish to retrieve its length. For example:

```

{retrieve the number of tracks on the CD}

StatusParms.dwItem := MCI_STATUS_NUMBER_OF_TRACKS ;

MCISendCommand(MCIDeviceID, MCI_STATUS, MCI_WAIT or MCI_STATUS_ITEM,

               LongInt(@StatusParms));

NumTracks := StatusParms.dwReturn;

{for each track, indicate its length}

for iCount := 1 to NumTracks do

begin

    StatusParms.dwTrack := iCount;

    StatusParms.dwItem := MCI_STATUS_LENGTH;

    MCISendCommand(MCIDeviceID, MCI_STATUS, MCI_WAIT or MCI_STATUS_ITEM or

                  MCI_TRACK, LongInt(@StatusParms));

    .

    .

    .

end;

```

## Commence Playback

Once the CD device is opened, and we have determined that a CD does in fact exist, we can play a track. For this, we will need a variable of the type `TMCI_Play_Parms`. However, we must make use of the `dwFrom` and `dwTo` members of this structure in order to indicate the exact desired track to play.

Because of the unusual timing format, we must use the `MCI_MAKE_TMSF` function to encode an appropriate starting and ending play position. Playing a single track is relatively simple, as we can specify a starting track with an ending track one greater than the starting track. For example:

```

PlayParms.dwFrom := MCI_MAKE_TMSF(1, 0, 0, 0);

PlayParms.dwTo   := MCI_MAKE_TMSF(2, 0, 0, 0);

MCISendCommand(MCIDeviceID, MCI_PLAY, MCI_FROM or MCI_TO, Longint(@PlayParms));

```

This indicates that we wish to play track one in its entirety. However, this technique will not work on the last track, since there is not another track beyond it (and setting the from member to a value one greater than the number of tracks on a CD results in an error). Therefore, you must specify the exact length of the track when playing the very last one. This is why we recorded all of the track lengths earlier. We'll see an implementation of this in Listing 9-11.

## Stop Playback

Before another CD track can be played, the currently playing track must be stopped. This is accomplished by simply calling the MCICommand function with a command message of MCI\_STOP. For example:

```
MCICommand(MCIDeviceID, MCI_STOP, MCI_WAIT, 0);
```

## Close the Device

As with MIDI, the MCI device must be closed and released by calling the MCICommand with a command message of MCI\_CLOSE when the application terminates. The MCI device ID must be passed in to the first parameter, but the last two parameters are unused and should be set to zero.

The following example implements the discussed steps in order to play back Red Book Audio data from a CD.

**Summary**

In this chapter, we discussed several techniques for playing both sound effects and music. We examined various DirectSound methods for performing digitized audio playback, including changing the format of the primary buffer as well as duplicating sound buffers. We also covered the steps required to output MIDI music as well as more superior techniques for playing audio tracks from a CD. When coding for sound or music output using DirectSound or Win32 multimedia API functions, it is important to keep these points in mind:

- Sound effects are very important for game enjoyment, as they not only enhance the believability of the gaming environment but also provide the player with audible clues that indicate changes in the game state.
- The PlaySound function is incredibly powerful for what it does. It can be used to play sounds from a file, from a resource, or from memory. While it may be adequate under some circumstances, it cannot play multiple sounds simultaneously.
- DirectSound offers many features above and beyond what is available with Win32 API functions. Hardware acceleration is automatically utilized when available. A virtually unlimited number of sounds can be mixed and played simultaneously, and several special effects can be applied to the output, such as panning, volume control, and frequency adjustment.
- Similar to DirectDraw, DirectSound programming consists of creating a DirectSound object and several sound buffers. The DirectSound object itself represents the developer's direct interface to the audio hardware. Through the IDirectSound interface, the application can query the audio hardware's capabilities, create sound buffers, and control other aspects of the hardware itself.
- DirectSound buffers are circular in nature. This is important when dealing with streaming buffers, as accessing buffer memory may require extra steps when starting near the end of the buffer.
- When DirectSound creates a secondary sound buffer, it automatically tries to locate the buffer in RAM on the sound card, if available. If there are no hardware buffers available, the sound is stored in system memory. Sound buffers located in hardware have the shortest path to the primary sound buffer, and thus are appropriately suited for short sounds that are needed quickly and will be repeated often.
- Secondary sound buffers come in two flavors: static and streaming. Static buffers are used for short sounds that can be placed into memory in their entirety. These are typically short, often repeated or looping sounds. Streaming buffers are used for large sounds that cannot fit into a reasonably sized

block of memory or for sounds that change often, and must be copied into the buffer in pieces as it is playing. By default, DirectSound tries to create a streaming buffer.

- Sound buffers should be created in order of importance. This will ensure that the sounds used most often will enjoy the greatest performance. However, to optimize performance, the developer should dictate the type of buffer when one is created, and where it will be placed. In general, static buffers should be used for short, often repeated or looping sounds, and should be placed in hardware memory. Streaming buffers should be placed in system memory. The exception to this rule is when a sound buffer will be duplicated. Duplicating a hardware buffer requires using hardware resources that may be needed elsewhere. Thus, it is better to place static buffers that will be duplicated in system memory.
- When a sound buffer is created, the developer can determine if the sound will continue to be heard when another application receives focus. By default, sounds will not be heard when the application loses focus (although they continue to play silently).
- DirectSound is optimized for 16-bits-per-sample sounds. Therefore, changing the primary sound buffer format for 16-bit sounds can further reduce playback latency and reduce the load on the CPU when processing sound data.
- The most complex step in initializing a secondary sound buffer is copying the data from a WAV file into the sound buffer itself. Unfortunately, DirectSound does not come with any built-in methods for retrieving audio data from a file or a resource. However, the DSUtil.pas, DSWaveFiles.pas, and DSWaveResources.pas units contain translations from DirectX SDK sound utility functions to copy audio data from a WAV file or a resource into a DirectSound buffer.
- Music, like sound effects, adds depth to a game, giving it a feeling of completeness. Even more than sound effects, music adds mood to a game, and when used effectively can adjust the user's frame of mind as effectively as a movie sound track.
- The Windows Media Control Interface features the MCISendCommand function that allows us to easily play both MIDI music and Red Book Audio from CDs. However, DirectX 6.1 and above feature a new DirectX component called DirectMusic that may revolutionize the use of MIDI.
- The MCISendCommand function is asynchronous by nature, and will return immediately unless the MCI\_WAIT flag was specified. In this event, you can usually specify the MCI\_NOTIFY flag to indicate that the function should notify the application when it has completed. This is accomplished by sending the application an MM\_MCINOTIFY message. It is a simple matter to define a handler for this message.
- MIDI, or Musical Instrument Digital Interface, is a format for describing musical sound, much the same as the WAV format describes digitized sound. It is an effective means of providing music within a small footprint, and both software for creating MIDI files as well as freeware or shareware MIDI songs are readily available.
- MIDI musical sound quality is less than perfect. Many games are circumventing this limitation by playing their musical scores directly off of the CD on which the game is distributed. This offers the highest possible sound quality, although the amount of music available to the game will be limited by the number of scores and their length, as CD audio requires much more storage space than MIDI files.
- Music data is stored on the CD in a format known as Red Book Audio. This format provides for stereo music at the highest quality, and is the format used by the professional music industry to record music onto conventional audio CDs. The end user's machine must be set up correctly before it can play CD audio music. This involves installing a small wire that runs directly from the CD to the audio output hardware, and while most new machines have this installed automatically, it may not always be available.

## CHAPTER 10 Optimization Techniques

This chapter covers the following topics:

- Optimization theory
- Delphi-specific optimization techniques
- General optimization techniques
- Additional optimization considerations

The technique of optimizing code has been elevated to an art form. With today's more advanced hardware, operating systems, and compilers, typically only the more experienced programmers will be relegated the duty of optimization. One must be intimately familiar with the workings of these three elements to truly be a master optimizer. However, there are several general techniques that are well publicized that can dramatically increase the speed at which an application runs, and you don't have to eat, sleep, and breath assembly code to use them. Fortunately, Delphi helps a lot in the optimization department. There are also a number of Delphi-specific code traps that can dramatically slow down your applications. Optimization is a very broad topic, and there are several books that examine it exhaustively. In this chapter, we will examine a number of both Delphi-related optimization techniques and some general techniques that can be applied in almost any programming language.

**Note:** You should run the examples in this chapter with optimization turned off (under Project | Options | Compiler). The example code is somewhat simplistic, and Delphi's internal optimizations are usually so good that they can further optimize the code. Running the examples with optimization turned off gives you a better idea as to how the illustrated optimization will benefit application performance in a real-world situation. Also note that because the examples are simplistic, the loops within them are generally repeated more times than what would normally be encountered.

### Optimization Theory

While optimization can be considered more an art than a science, there are a few general optimization rules that everyone should follow. The most important step in optimization is knowing where to optimize. After you've determined where the bottlenecks are in application execution, the next step is to evaluate the problem and determine how to optimize the code.

You could take a guess at which part of your code is the slowest, but this method will most likely result in wasted time and increased frustration. The best course of action would be to employ a profiler to time program execution. Profilers generally report the number of times a particular function was called and the average length of execution. Using a profiler can quickly highlight the bottlenecks in an application, indicating a general location where optimization would be most effective.

The freeware Delphi profiler GpProfile is an excellent profiling tool for all 32-bit versions of Delphi, and it comes with source code. At the time of this writing, it is available at <http://members.xoom.com/primozg/gpprofile/gpprofile.htm>. Additionally, several Delphi tool vendors are working on retail versions of Delphi profilers, which should be available by the time this book reaches store shelves.

**profiler:** A profiler is an application that typically measures application execution time. The level at which an application is timed usually varies, from timing the execution of individual lines to the execution time of functions, procedures, or the overall application.

---

In general, it is best to ignore optimization until the application is almost complete. Trying to write optimized code from the outset can be very distracting. Concentrate on actually getting the application to run first. Chances are that a developer could spend several hours optimizing a piece of code that is ultimately replaced midway through development. Optimizing code as a last step in the development process ensures that the time will be well spent.

### Timing Code

In the absence of a profiler, there are several techniques a Delphi programmer can employ to time the execution of functions and methods. The one employed by the examples in this book involves the use of the `timeGetTime` function. The `timeGetTime` function retrieves the time that has elapsed since Windows was started, in milliseconds. Under Windows 95, this has a precision of 1 millisecond. Under Windows NT, the default precision is 5 or more milliseconds, but this can be adjusted by calling the `timeBeginPeriod` and `timeEndPeriod` functions.

**Note:** You must include `MMSYSTEM` in the `Uses` clause of any unit using the `timeGetTime` function.

---

Timing a function involves only three steps: recording the current value of `timeGetTime` in a variable, running the function code, and then again recording the current value of `timeGetTime`. The difference of these two values equals the total function execution time, as the following example illustrates.

#### *Listing 10-1: Using `timeGetTime` to time function execution*

---

```
procedure TForm1.Button1Click(Sender: TObject);  
  
var
```

```

StartTime,

EndTime: LongInt;

begin

    {start tracking the time}

    StartTime := timeGetTime;

    {code to be timed goes here}

    {record the ending time}

    EndTime := timeGetTime;

    {the difference between the starting and ending times gives

    us the overall time required to execute the timed code}

    Label1.Caption := 'Elapse Time: '+IntToStr(EndTime - StartTime);

end;

```

---

The `timeGetTime` function should be as accurate as required for just about any profiling needs. However, if more accuracy is required, the `QueryPerformanceCounter` and `QueryPerformanceFrequency` functions can be used. These functions give the developer access to the high-resolution performance counter that is present in just about every computer manufactured since the 486 was cutting-edge technology. `QueryPerformanceFrequency` returns the number of counts per second that the high-resolution timer records, and `QueryPerformanceCounter` returns the current count. Bear in mind, however, that these functions are useful only for timing very short periods, and cannot be used to time anything that executes for more than one second.

### Examining the Algorithm

Once the bottleneck has been found, the first step in optimizing the code should be to reevaluate the algorithm. Examining the algorithm embodied by the code and finding a better algorithm will typically result in improved performance over that gained by any one particular optimization technique described below.

The classic example is the bubble sort versus the binary sort. Both algorithms achieve the same result—a sorted list. However, the binary sort method is much faster than the bubble sort. Had a developer spent time employing various specific optimization techniques such as using assembly language or lookup tables, the performance of the original code may have been improved, but most likely would have resulted in a lot of wasted time and effort.

**Effective Optimization**

Knowing where to begin is probably the hardest part about optimizing code. In general, don't worry about optimizing short pieces of code that are not called very often in the application. For example, if a few lines of code (or even one line) takes two seconds to process but is only called a few times during the entire life of the application, it is not worth examining. If possible, this type of code should be placed where a user will not mind the wait. In the typical game application, this usually involves the loading of game resources such as graphics and sound. This type of code should be executed when an application is starting and a splash screen is being displayed. Code of this nature can also be executed when changing levels or starting a level.

Typically, the best place to begin optimization is within the innermost part of loops. Take, for example, the following pseudo-code:

```
for iCount := 0 to 10 do  
  
begin  
  
    {outer loop code}  
  
    for iCount2 := 0 to 100 do  
  
begin  
  
    {inner loop code}  
  
end;  
  
end;
```

If the outer loop code took a total of 100 milliseconds to execute for one iteration, excluding the inner loop, it would take a total of 1000 milliseconds, or one full second, for the entire loop to process (iterating 10 times).

If the inner loop code took a total of 10 milliseconds to execute one iteration, it would take a total of 1000 milliseconds to process (iterating 100 times). Since the outer loop code takes longer to execute than the inner loop code (excluding the fact that the inner loop is executed with the outer loop code), one might be tempted to try optimizing the outer loop. The grand total execution time required to process this example is approximately 11 seconds (1 full second for the inner loop, executed 10 times (1 \* 10), plus 1 more second for the outer loop). Even though the outer loop takes longer to process than the inner loop, if the total execution time of the outer loop was reduced to even 1 millisecond, the entire process will still take more than 10 seconds to execute. Now, if the inner loop execution time was cut in half (from 10 milliseconds to 5), the total execution time would be reduced from 11 seconds to approximately 6 seconds. That's a big savings. As this example illustrates, the biggest performance enhancements will usually come from optimizing code performed in the innermost loops.

**Tip:** Typical culprits, and places to begin looking for optimization opportunities, usually include loops that redraw the entire screen a pixel at a time as well as manager loops that perform specific actions on each item in a list.

Finally, knowing when to quit is almost as important as knowing where to start. Optimization gurus state that any code, however optimized, could always be optimized further. However, there is a diminishing margin of returns encountered at a certain level of optimization. For example, say a developer spends 10 hours optimizing code, decreasing its execution time by 100 milliseconds. The time spent was probably worth it. Now, if it takes another 5 or 10 hours to reduce the execution time by another 10 milliseconds, the developer's time could probably be better spent elsewhere. At some point, execution time will only be dropping by a few milliseconds, and a decision will need to be made about whether or not the time spent performing the optimization is worth the performance increases.

## Delphi-Specific Optimization Techniques

Delphi itself offers a number of very useful optimization options. The compiler performs quite a few automatic optimizations. There are several other options available that also affect how Delphi generates machine code. All of these options are available on the Compiler tab of the Project Options dialog, accessed using Project|Options.

**Figure 10-1:** Project options

**Caution:** If you are not familiar with these settings or have never used them before, Delphi may act in a manner that might be quite unfamiliar. Get to know these settings and how they affect Delphi's overall performance and behavior.

## Automatic Compiler Optimizations

The very first check box under Code Generation is the Optimization option. Clicking this box on activates a number of automatic compiler optimization techniques. Unfortunately, with this setting, it's an all-or-nothing affair. Turning this option off for debugging purposes is useful, but always turn this option on before performing a final build. When this option is on, it allows the compiler to perform a number of heavy-duty optimizations that can dramatically affect the performance of code. Some of these optimizations include register optimizations, call stack elimination, common subexpression removal, loop induction variables, and dead code elimination.

## Register Optimization

If Delphi determines that a particular variable is used heavily, it will store that variable in a hardware register. This eliminates the need to access the value of the variable by loading it from memory, resulting in much faster code. Delphi takes this one step further by determining if certain variables are used extensively in different parts of code. If so, a single register can be used for each variable.

## Call Stack Elimination

Delphi offers a number of different calling conventions that affect how parameters are passed to a function. Different calling conventions are required based on the task being accomplished, such as calling functions stored in C or C++ DLLs, or using Windows API functions. However, by default, Delphi uses a calling convention known as register. The register calling convention will pass up to three parameters to a function by using hardware registers. This makes it unnecessary to create a stack frame, eliminating quite a bit of initialization and cleanup code and improving application performance. However, if more than three parameters are passed, registers cannot be used and a stack frame will be created. Bear in mind that while a normal function can pass up to three parameters and still use this optimization, object methods can only pass two parameters, as Self is automatically passed as the third parameter. If a function requires more than three parameters, one way to still benefit from this optimization is to create a record structure defining all of the parameters. A single pointer to this record can then be passed to the function, allowing the function to access all of the required information while passing only one parameter in a register.

**Tip:** A stack is also generated when a function returns more than a 32-bit number, such as returning a string. Try to write functions that don't return anything more than a single 32-bit number.

## Common Subexpression Removal

When compiling complex mathematical equations, Delphi will examine the equation to determine if any computations are performed more than once. If so, these common subexpressions are removed. Instead, Delphi will perform this calculation only once, and the resulting value will be used wherever the original calculation was located in the equation. The result is a mathematical computation that is reduced to a very compact, efficient form. This allows the developer to write computationally intensive code in a clear, concise manner without obscuring it by hand-optimizing the equation.

## Loop Induction Variables

If a variable is used only as an index into an array or a string, Delphi will instead replace the variable with a pointer that is incremented to directly access the string or array values. This eliminates multiplication operations and increases the speed at which array or string values are accessed. Additionally, using an index that is of a data type native to the hardware (such as a 32-bit integer type) will improve performance.

## Dead Code Elimination

While processing code, if Delphi detects that there is a block of code that is never called from the application, or code that ultimately has no effect, it will not be compiled into the final application. This is useful for reducing the size of the final build. However, during debugging, the compiler may remove code that would be useful to examine after a breakpoint.

## Additional Compiler Optimizations

While these automatic compiler optimizations are quite handy, there are several other options available under the Project Options dialog box that can affect the behavior of an application.

## Aligned Record Fields

When this option is turned on, all elements of record structures are adjusted so that they align on DWORD (32-bit) boundaries. The Intel architecture natively uses a 32-bit information format, and aligning the elements of a record so that each element begins at an address evenly divisible by 32 bits improves performance when accessing each element. The packed keyword can be used when declaring a record structure that will force alignment of the

elements in that record structure to 32-bit boundaries.

**Caution:** Bear in mind that this can change the size of a record structure, which is a problem when reading in information that was previously saved as non-aligned records. This may also have an effect on function calls to Windows or other third-party DLLs that take a record structure as a parameter.

---

## Stack Frames

When this option is checked on, the compiler will always pass parameters to functions on the stack, creating stack frames for every function and defeating the stack frame elimination optimization. This can be turned on for debugging purposes, but should always be turned off for the final build.

## Range Checking

When this option is turned on, all array and string indexing expressions are verified as being within their defined bounds, and all assignments to scalar and subrange variables are checked to be within range. This generates additional code when accessing array and string elements, ultimately degrading application performance. Turn this option on only while debugging, and make sure it is off for the final build.

## Overflow Checking

Similar to range checking, overflow checking controls the generation of overflow checking code for certain integer arithmetic operations. The code for each of these integer arithmetic operations is followed by additional code that verifies that the result is within the supported range. Thus, when this option is turned on, additional code is generated for every arithmetic operation performed, degrading performance. Again, turn this option on for debugging purposes, but turn it off for the final build.

**Tip:** You can force any of these options on or off in your source code by including compiler directives. These directives, however, will override any settings made in this dialog box, which may cause confusion.

---

## Other Delphi-Specific Optimization Techniques

While these compiler optimizations help to improve overall application performance, there are several other tricks specific to Delphi that can dramatically increase application speed. Armed with a little knowledge about specific details about Delphi and the Object Pascal language, a developer can avoid common pitfalls that can completely negate the performance benefits realized by the compiler optimizations. Let's examine some very specific techniques that can improve performance in a number of ways.

## Exceptions

Exceptions are intended to inform both the user and the developer when something has gone wrong. Although they are very useful when employed correctly, they are incredibly slow. The developer should avoid trapping for exceptions at all costs, especially within a loop. The classic example is trapping for the `EZeroDivide` exception when performing division. If a number is divided by zero, it will raise an `EZeroDivide` exception. This could be put into a `Try..Except` block, simply swallowing the exception if it occurs. However, this is incredibly slow, and a simple example of this iterated as few as 10,000 times will take several seconds to execute on a Pentium 333 (on which the example was tested). If this `Try..Except` block is replaced by a simple `If..Then` to check if the divisor is zero before performing the math, 10,000 iterations take place in less than a millisecond (again, tested on a Pentium 333). Therefore, do not rely on exceptions for trapping errors when writing high-performance code. The following example demonstrates this technique.

---

*Note:* You will need to turn off Stop on Delphi Exception for this example, located in Tools | Debugger Options | Language Exceptions.

---

**Listing 10-2:** *Exception handling in a loop*

---

```
procedure TForm1.Button1Click(Sender: TObject);
var
    iCount: Integer;
    Junk: Real;
    Divisor: Integer;

    StartTime,
    EndTime: LongInt;
begin
    {make sure that optimization is off}
    {$O-}

    {begin recording the time}
    StartTime := timeGetTime;

    {perform a task that may or may not generate an exception (in this example
    it will always generate an exception). we don't want the user to see this
    exception, so we programmatically handle it}
    Divisor := 0;
    for iCount := 0 to 10000 do
    begin
        try
            Junk := 10 / Divisor;
        except
            on EZeroDivide do;
        end;
    end;
end;
```

```

{recording the ending time...}
EndTime := timeGetTime;

{...and display the elapsed time}
Label1.Caption := 'Elapse Time (exception): '+IntToStr(EndTime - StartTime);

{begin recording the time}
StartTime := timeGetTime;

{perform the same task as before, but this time specifically check for
instances that may create an exception}
Divisor := 0;
for iCount := 0 to 10000 do
begin
    if Divisor <> 0 then
        Junk := 10 / Divisor;
end;

{record the ending time...}
EndTime := timeGetTime;

{...and display the elapsed time}
Label2.Caption := 'Elapse Time (if..then): '+IntToStr(EndTime - StartTime);
end;

```

**Tip:** Try..Finally blocks incur little to no overhead, so it is safe to wrap high-performance code within a Try..Finally block.

## Object Method Types

When declaring an object method, it can be defined as one of three types: static, virtual, or dynamic. Each one has its strengths and weaknesses. Static methods do not gain the benefits of inheritance or polymorphism, one of the cornerstones of object-oriented programming. Virtual and dynamic methods both allow for inheritance and polymorphism, but the way in which applications access these methods is implemented differently. Without expounding on the inner workings of Delphi too greatly, virtual methods create an entry in a Virtual Method Table that is stored with each object. Dynamic methods, on the other hand, use a different method call-dispatching algorithm. Where dynamic methods are optimized for code size, virtual methods are optimized for speed. However, static methods are the fastest of all, since they are called directly with no need for method dispatching or VMT lookups. In general, try to use static methods as often as possible, but definitely use virtual instead of dynamic when using object-oriented programming techniques.

## Variants

The variant data type is another new Delphi addition that makes certain programming practices incredibly easy. Using the variant type is almost essential when performing OLE or COM programming. However, because of its abilities to store just about any type of data, inexperienced programmers may be tempted to use only variables of type variant so as to avoid any data type incompatibilities. Unfortunately, because of its flexibility, the variant data type is very slow and should be avoided in high-performance code. With the variant being a 16-byte structure, it also wastes space. Unless you are doing some sort of OLE programming, avoid variants and use native data types.

*Listing 10-3: Variants versus native types*

---

```
procedure TForm1.Button1Click(Sender: TObject);  
  
var  
  
    iCount: Integer;
```

```
Junk: Variant;

Junk2: Integer;

StartTime,

EndTime: LongInt;

begin

    {turn optimization off}

    {$O-}

    {begin recording the time}

    StartTime := timeGetTime;

    {perform some standard task using a variant data type}

    Junk := 0;

    for iCount := 0 to 100000 do

        begin

            Junk := Junk + 1;

        end;

    {record the ending time...}

    EndTime := timeGetTime;

    {...and display the elapsed time}

    Label1.Caption := 'Elapse Time (variant): '+IntToStr(EndTime - StartTime);

    {begin recording the time}

    StartTime := timeGetTime;

    {perform the same function using a native data type}

    Junk2 := 0;

    for iCount := 0 to 100000 do
```

```
begin
    Junk2 := Junk2 + 1;
end;

{record the ending time...}

EndTime := timeGetTime;

{...and display the elapsed time}

Label2.Caption := 'Elapse Time (integer): '+IntToStr(EndTime - StartTime);
end;
```

---

## String Parameters

An entire chapter could be written on the internal operations performed when Delphi works with strings. Both string and variant local variables within a function or method require prologue and epilogue code to be generated around the function to initialize and deinitialize the variable. Temporary storage variables may be generated when passing string results from one function as the parameter to another (such as passing the result of an `IntToStr` directly as a parameter), further increasing the generated code. Variant and string local variables automatically generate a stack frame within a function, defeating register optimizations. In general, avoid creating small utility routines that work on or use strings. If necessary, string or variant data should be processed in fewer, large routines that do as much as possible. Never use string variables or parameters to process information where an integer variable or parameter could accomplish the same task.

## Data Types

The data types used by your application will impact its overall performance. Certain mathematical functions perform faster using certain data types; indeed, some data types are incredibly slow by comparison. In general, you'll achieve the greatest performance when using native data types, such as integer. The `MathTest` example on the CD in the directory for this chapter can be used as a benchmark for testing execution speed of different operations on different data types. All of the floating-point and integer data types are tested, and though the exact execution times will vary from machine to machine, it is easy to see which data types perform better under certain circumstances than others.

## General Optimization Techniques

We gain a lot of benefit from the automatic optimization that Delphi provides. We can also improve performance by being aware of the inner workings of certain Delphi code constructs. However, we should also be aware of general coding practices that can be used to improve performance in any language.

### Loop Unrolling

It is very common for the point of execution within an application to jump from one point to another during the course of execution. For example, an `If..Then` statement causes the point of execution to skip some instructions based on the expression value. The time required for the execution point to change a single time is minimal. However, when the execution point jumps around repeatedly, these minimal time increments can accumulate.

The biggest offenders in this category are loops, such as For..Next, While..Do, and Repeat..Until. Applications typically revolve around looping constructs such as these, performing the same functions on large amounts of data. This results in the execution point changing repeatedly. The amount of code and the task it performs within loops are prime targets for optimization. However, one technique you can use to improve loop performance is to unroll it.

The concept of unrolling a loop is simple. Instead of performing one block of operations several times, perform several blocks of the same operations a fewer number of times. For example, if you have a loop that performs one operation 10,000 times, try performing 10 of those operations within the loop, and reduce the loop to run only 1,000 times. This will reduce the number of execution point jumps by an order of magnitude, and can dramatically improve overall performance. The following example illustrates this technique.

***Listing 10-4: Unrolling a loop***

---

```
procedure TForm1.Button1Click(Sender: TObject);
var
    StartTime,
    EndTime,
    iCount: Integer;
    Accum: Real;
begin
    {turn optimization off}
    {$O-}

    {initialize our variable and start tracking the time}
    Accum := 0;
    StartTime := timeGetTime;

    {perform some task many, many times}
    for iCount := 0 to 999999 do
        Accum := Accum + 0.5;

    {record the ending time...}
    EndTime := timeGetTime-StartTime;

    {...and display the elapsed time}
```

```
Label1.Caption := 'Regular loop time: '+IntToStr(EndTime);

{rest the variable and start tracking time}

Accum := 0;

StartTime := timeGetTime;

{perform the same task as before, but this time repeat the task several
times within the loop, and adjust the number of loops accordingly. note
that the task is performed the same number of times as before, but now
we've got an order of magnitude less jumps}

for iCount := 0 to 99999 do

begin

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

    Accum := Accum + 0.5;

end;

{record the ending time...}

EndTime := timeGetTime-StartTime;

{...and display the elapsed time}

Label2.Caption := 'Unrolled loop time: '+IntToStr(EndTime);

end;
```

**Lookup Tables**

Most game applications require the use of complicated or sophisticated mathematical functions. Functions such as Sin and Cos are common, and some games may require even more arcane trigonometry or calculus equations. Unfortunately, even with math coprocessors, these functions are quite slow, and if they are required in a loop, the application can slow to a crawl. However, if the total range of all inputs to a mathematical function or equation is known, you may be able to use a lookup table.

Simply put, a lookup table is an array that contains the results of a mathematical function or equation for all known input values, where the input value acts as an index into the table. For example, the Sin and Cos functions both take an argument in the form of a degree (actually they take radians, but the argument can be converted to radians and it's easier to think of it as a degree). The total range of inputs that return unique outputs is 0 to 359 degrees. Thus, you can create a 360-entry array and put the Sin or Cos value for each input in the range in its appropriate entry. Then, instead of calling the Sin or Cos function, you simply use the argument as an index into this array. Retrieving predetermined values in this manner is incredibly fast, usually much more so than actually running the equation or function. The table is generally initialized when the application starts. This technique can be applied to any area where a limited range of input values is known. The following listing illustrates this technique.

*Listing 10-5: Using lookup tables*

---

```
procedure TForm1.Button1Click(Sender: TObject);  
  
var  
  
    StartTime, EndTime, iCount: Integer;  
  
    Lookup: array[0..359] of Real;  
  
    SinValue: Real;  
  
begin
```

```
{turn optimization off}

{$O-}

{generate the lookup table}
for iCount := 0 to 359 do
    Lookup[iCount] := Sin((iCount)*(PI / 180));

{begin tracking the time}
StartTime := timeGetTime;

{perform a slow mathematical calculation}
for iCount := 0 to 99999 do
    SinValue := Sin(50*(PI / 180));

{record the ending time...}
EndTime := timeGetTime-StartTime;

{...and display the elapsed time}
Label1.Caption := 'Sine Calculation: '+IntToStr(EndTime);

{start tracking the time}
StartTime := timeGetTime;

{perform the calculation by finding the answer in the lookup table}
for iCount := 0 to 99999 do
    SinValue := Lookup[50];

{record the ending time...}
EndTime := timeGetTime-StartTime;
```

```
{...and display the elapsed time}

Label2.Caption := 'Sine Lookup: '+IntToStr(EndTime);

end;
```

---

## Binary Bit Shifting

Every PC processor has built-in hardware to shift the bits in a register left or right. This has the result of effectively multiplying or dividing the number in this register by a power of 2. Applications can take advantage of this hardware through the use of the shl and shr functions. Shl shifts bits to the left, multiplying the number by two; shr shifts them to the right, dividing by two. This can be used for incredibly fast integer multiplication and division, as it bypasses the math coprocessor. The only drawback to this is that the multiplication or division has to be a multiple of two. However, if an equation can be broken down into components that use simple addition or subtraction with multiplication or division by a power of 2, performance can be dramatically improved. For example, the equation  $Y * 320 + X$  would require one multiplication and one addition by the math coprocessor. However, the equivalent function  $((Y \text{ shl } 8) + (Y \text{ shl } 6)) + X$  requires two shifts and two additions. Although the number of functions performed on this equation has increased, additions take less time than multiplication, and the shifts are almost instantaneous, resulting in faster performance. The following example demonstrates how to use bit shifting for multiplication.

### *Listing 10-6: Bit Shifting*

---

```
procedure TForm1.Button1Click(Sender: TObject);

var

    iCount: Integer;

    Result: Longword;

    StartTime,

    EndTime: LongInt;

begin

    {we must run this example with optimization turned on to see the

    performance gains}

    {$O+}

    {set up a dummy variable and begin tracking the time}

    Result := 1;

    StartTime := timeGetTime;
```

```
{perform some function or task}

for iCount := 0 to 10000000 do
    Result := Result * 2;

{record the ending time...}
EndTime := timeGetTime;

{..and display the elapsed time}
Label1.Caption := 'Elapse Time (multiply): '+IntToStr(EndTime - StartTime);

{set up a dummy variable and begin tracking the time}
Result := 1;
StartTime := timeGetTime;

{perform some function or task using a faster method}
for iCount := 0 to 10000000 do
    Result := Result shl 1;

{record the ending time...}
EndTime := timeGetTime;

{...and display the elapsed time}
Label2.Caption := 'Elapse Time (shl): '+IntToStr(EndTime - StartTime);

end;
```

## Additional Optimization Considerations

Developers are always discovering new tricks and techniques to squeeze a little more performance out of an application. The topics we've covered have only scratched the surface of the myriad of arcane programming constructs that programmers use to improve performance. Beyond the specific optimization techniques we've discussed in this chapter, developers should be aware of general coding practices that should help improve overall performance.

Memory allocation is one of those key areas that can dramatically affect the performance of an application. The task of dynamically allocating memory is an expensive one in terms of time. If possible, you should always dynamically allocate all memory up front, when the application starts. Of course, this is only possible if the total amount of required memory can be determined when it is allocated. If it is impossible to determine the total amount of required memory, try allocating the memory in larger blocks, using up the allocated memory until more is needed. For example, if you're using dynamic arrays, instead of allocating one entry at a time, try allocating 10 entries at a time and using those 10 until more are required. This results in fewer dynamic memory allocations, which in turn results in better performance.

As an alternative to dynamic memory allocation, you may want to try using only global variables. Global variables cause the system to allocate their memory when the application starts; by using only these global variables, you never have to dynamically allocate memory, and thus never incur the cost of such a task. Of course, this may only be applicable if the number of variables required is not too great. Otherwise, the hassle of managing such constructions in terms of coding and code maintenance may outweigh the speed benefits.

Another advantage to using global variables is that they can be used within local functions without creating a stack. In this manner, you could potentially pass hundreds of parameters to a procedure or function without creating and initializing a data structure as discussed above. You have all of the disadvantages associated with using global variables in such a manner, but you may be able to utilize this method in a limited fashion where you need both speed and a large parameter list.

Constant arrays are another area that one should look at. Constant arrays are easy to maintain, but their use incurs an array dereference. If possible, simply use several constants instead. This may be harder to maintain in the long run, but you avoid the array dereference, and ultimately it will improve performance where the

constants are used.

However, where optimization is paramount and speed is critical, one may have to drop down to assembly language. It's hard to beat the speed of hand-optimized assembly. Unfortunately, assembly language, even verbosely documented, is both hard to maintain and hard to modify. It also takes a developer experienced in assembly language to do a decent job. Assembly language can be written right in the Delphi IDE; you simply have to enclose it within an `asm..end` block. An assembly language tutorial is beyond the scope of this book. However, several general Delphi books contain discussions of using assembly language within Delphi, and many good 32-bit assembly language references are available. Fortunately, with the speed of today's machines and Delphi's optimizing compiler, the use of hand-optimized assembly is not quite as necessary as it was just a few years ago.

## Summary

In this chapter, we discussed several techniques for improving the performance of games and applications. We looked at the optimizations that Delphi performs, as well as some Delphi-specific optimization techniques. We also examined some general optimization techniques that are language independent and discussed further optimization considerations. When optimizing your Delphi applications and games, it is important to keep these points in mind:

- The most important step in optimization is knowing where to optimize. After you've determined where the bottlenecks are in application execution, the next step is to evaluate the problem and determine how to optimize the code. Never guess at where your bottlenecks might occur; either use a profiler or some technique for timing code execution.
- Reevaluating an algorithm can have a greater impact on performance than any collection of singular optimization tricks or techniques.
- The task of optimization has a diminishing margin of returns. Spending 10 hours to improve performance by 10% may be worthwhile; spending another 10 hours to improve performance by only 1% is probably a waste of time.
- Optimization should be the last task in application development. Trying to optimize code halfway through the development cycle can be a waste of time, especially if the optimized code gets cut out in favor of another method.
- Never spend time optimizing code that is only called once or twice throughout the entire execution of an application. The most common place to begin optimization is within loops, specifically inner loops that may be performed thousands of times.
- Delphi itself offers a number of very useful optimization options. The compiler itself performs quite a few automatic optimizations, such as register optimizations, call stack elimination, common subexpression removal, the use of loop induction variables, and dead code elimination. Other optional compiler optimizations include aligned record fields, elimination of stack frames, range checking, and overflow checking.
- Exceptions should only be used when an error occurs that must be responded to. Never use exceptions to account for errors (such as dividing by zero), as they are incredibly slow.
- Virtual methods are optimized for speed, and dynamic methods are optimized for size. However, static methods are the fastest as they do not incur a dereference.
- Never use a variant when a standard data type will do. Bear in mind that some standard data types are faster than others for certain operations.
- Avoid using strings as parameters or as return values from functions, as this implicitly creates extra code that slows down the application.
- Loops should be unrolled so as to reduce the number of jumps the application performs.
- Lookup tables should be used for mathematical functions and equations when a finite range of input values is known.
- When multiplying or dividing by a power of 2, using binary bit shifting, as this takes advantage of hardware available in every PC.

## CHAPTER 11 Special Effects

This chapter covers the following topics:

- Bitmap transformations
- Bitmap scaling
- Bitmap rotation
- Lighting tricks
- Transition effects
- Simple texture mapping
- Star fields
- Fire plasma effects

Although interactive computer games are slowly gaining ground, it is probably safe to say that movies and television are the most popular forms of entertainment among the masses. A good film or movie with Oscar-winning actors and exotic, beautiful sets and locations can be very enjoyable. Indeed, classic films such as *Ben Hur* and *Gone with the Wind* are timeless in their ability to enthrall and entertain.

Everyone enjoys a realistic, stirring performance by a good actor, and of course a good plot can make or break a movie (the same rule applies to games). Even so, when people watch movies, they want to be transported to another place and time, and it would be very difficult to achieve an effective illusion without the use of special effects. What would the *Star Wars* movies have been like without the massive space battles? Or *Star Trek* without the transporter? Special effects provide visualization of events or actions that could not take place in reality, and, in an ironic way, can add an air of “realism” to fantastic settings.

The same holds true for computer games. It is easy to portray exotic locations and creatures using computer graphics. Even so, you can accomplish only so much by just relying on the blitting functions to copy graphics from one surface to another. As we’ve already examined, the Lock method gives us the ability to directly manipulate the contents of a surface. This gives us incredible power, limiting game world visualization only to our imaginations.

This chapter examines how the Lock method can be used to produce effects that would be difficult to reproduce by using Blt or BltFast alone. While a comprehensive discussion of computer graphic special effects could probably fill several volumes, we'll examine a few selected case studies to demonstrate the power of directly manipulating surface contents and to spark our imagination for further applications of this technique.

**Caution:** Always remember to call the Unlock method on a surface before it is used with other DirectDraw methods, such as Flip, or your application will crash.

---

## Bitmap Manipulation

Simply manipulating bitmaps in one way or another can produce many cool effects. The texture mapping that is performed in 3-D games could be considered a bitmap manipulation. Basically, by taking a plain, flat bitmap and drawing it in some way other than just blitting it to the screen in a plain, flat manner can give the bitmap an appearance of depth or texture. This can also stretch the art budget dollar, since producing visual effects programmatically will reduce the amount of artwork required.

There are thousands of ways that bitmaps can be manipulated to produce all kinds of interesting effects. In the interest of space, we'll examine only a small handful. Indeed, even the implementation of these examples can vary widely from programmer to programmer, but we'll examine some simplistic ways to produce some interesting effects by manipulating bitmaps. Specifically, we'll look at bitmap transformations, scaling, rotation, a cheap lighting effect, transition effects, and a very simple texture mapping routine to produce the illusion of a bitmap wrapped around a sphere.

### Bitmap Transformations

This rather broad title addresses techniques for transforming bitmaps and drawing them in a non-linear or non-rectangular manner. You could classify every effect in this section as a bitmap transformation. However, our discussion deals with techniques for using mathematical equations to modify the location of pixels as they are drawn to a destination. Specifically, we're going to look at using the Sin function to apply a sine wave to a bitmap of the Texas state flag in order to produce an animation of a flag blowing in the wind.

### Basic Theory

At the heart of this technique is the Sin function. If you've ever taken a trigonometry class, you should be very familiar with this function. Without going into a lot of detail, the Sin function takes a number, more specifically a degree on a circle (i.e.,  $0^\circ$  to  $360^\circ$ ), and returns a value between -1 and 1. If you graphed out the result of the Sin function, it would look something like Figure 11-1.

This produces what is known as a sine wave. It is a cyclic function that will return a result in the range of -1 to 1 for any value. If we scaled the resulting values from this function and used these as vertical offsets, we could easily produce a simple but effective wave animation with our bitmap.

**Figure 11-1:** A graph of the Sin function results

**Tip:** Remember that the trigonometry functions are notoriously slow, so you should probably use an optimization like a lookup table for trig function results in real-world applications.

---

We'll need to draw our bitmap as vertical strips of pixels in order to make this work. Beginning with a starting value of 0, we use the Sin function with this value to determine the vertical offset for the first strip of pixels. We then draw the first vertical strip of pixels within the bitmap at some starting point within our destination, with the top of this strip offset vertically by the return value of the Sin function. Iterating horizontally through our bitmap, we'll add 1 to the value passed to the Sin function as we draw each vertical strip of pixels, using this offset to modify the starting point of the top of the strip. This will produce an oscillating offset for the starting point of the top of each vertical line of pixels, as demonstrated in Figure 11-2.

**Figure 11-2:** Using Sin to modify vertical starting points

If we increment the starting point each time we draw the bitmap, it will make the wave appear to move, and we'll produce an effective animation. Of course, we'll need to scale the values returned from the Sin function by some constant in order to produce a more pronounced wave effect. We'll also need to scale the values given to the Sin function in order to increase the frequency of the waves. The following listing demonstrates this concept.

        DestSrfcInfo.dwSize := SizeOf(TDDSurfaceDesc2);
        DXCheck( FBackBuffer.Lock(nil, DestSrfcInfo, DDLOCK_SURFACEMEMORYPTR or
                    DDLOCK_WAIT, 0) );

        {this positions the initial starting point of destination drawing
         so that the flag will be centered horizontally and vertically}
        DestPtr := PByteArray(integer(DestSrfcInfo.lpSurface)+
                                (DestSrfcInfo.lPitch*((DXHEIGHT div 2)-
                                (FlagSrfcInfo.dwHeight div 2)))+
                                ((DXWIDTH div 2)-(FlagSrfcInfo.dwWidth div 2)));

        {increment our starting angle. this produces the motion of the wave,
         and a larger value will make the wave move faster. a negative value
         makes the wave move from left to right; positive values reverse
         this direction. incidentally, we never have to 'roll over' this
         value as Sin will return a value in the range -1 to 1 for any

```

```

argument}

Inc(AngleStart, -5);

{begin iterating through each vertical strip}
for DestX := 0 to FlagSrfcInfo.dwWidth do
begin
    {we want to add 1 to the starting angle for each column in the bitmap}
    AngleBegin := DestX+AngleStart;

    {the FREQUENCY value increases the frequency of the wave across
    the bitmap. with a value of 360, the waves will peak and valley only
    once across the entire length of the bitmap. our frequency value is
    720, which causes 2 peaks and valleys, and makes a nice effect.
    increasing or decreasing this value accordingly may simulate wind
    strength. this value is divided by the width of the bitmap to produce
    an 'angles-per-pixel' ratio so that the effect will spread evenly
    across the horizontal length of the bitmap. this value must be in
    terms of radians instead of degrees, so we must multiply it by
    (PI/180). finally, the MAGNITUDE value scales the results and produces
    offsets, in our example, between -10 and 10. this makes the peaks appear
    higher and the valleys appear lower.}
    StartY:=Trunc((Sin(((FREQUENCY/FlagSrfcInfo.dwWidth)*AngleBegin)*
        (PI/180))*MAGNITUDE));

    {begin drawing the vertical strip of pixels}
    for DestY := 0 to FlagSrfcInfo.dwHeight do
        {the vertical offset is added to the vertical destination value, which
        may move this column of pixels up or down}
        DestPtr[DestSrfcInfo.lPitch*(DestY+StartY)+DestX] :=
            FlagPtr[FlagSrfcInfo.lPitch*DestY+DestX];
    end;
end;

```

```
finally
    {release all locks}
    FFlag.Unlock(nil);
    FBackBuffer.Unlock(nil);
end;
end;
end.
```

---

## Alternatives/Enhancements

The resulting animation from our bitmap transformation, while effective, is a little cheesy. We could produce a more realistic effect by applying another sine wave along the x-axis, perhaps at a 45-degree angle from horizontal. If we scaled the horizontal sine wave offset so that pixels moved left or right very little at the left side of the image, but they moved a large distance at the right side of the image, we could produce a more realistic wind effect. The result would make the flag look like it folded back on itself, and that it was attached to a flagpole.

## Scaling

Sometimes it may be necessary to draw a bitmap image at a size other than its original dimensions. For example, we could create the illusion of a creature getting closer to the user by drawing its image larger and larger as it draws nearer. By scaling an image in this manner, we can produce the illusion of depth, or even provide zooming functionality for things like sniper scopes.

## Basic Theory

Scaling a bitmap involves drawing the pixels of the source bitmap into the destination according to a specific ratio. This ratio determines the final size of the bitmap as it appears in the destination. The ratio is expressed as a fraction, or a floating-point number; the larger the number, the larger the bitmap, and vice versa. For example, a ratio of 2 indicates that the final bitmap will be twice as large as its original size, whereas a ratio of 0.5 indicates that the final bitmap will be half of its original size.

Specifically, the ratio indicates how each pixel is mapped into the destination. If we iterate through the pixels in the destination and divide their coordinates by the scaling factor, we can determine which pixel to select from the source. This is accomplished by the following equations:

```
Source_X := Trunc(Destination_X / Scale);
Source_Y := Trunc(Destination_Y / Scale);
```

A scaling factor less than 1 causes pixels in the source image to be skipped, thus resulting in a smaller final image. Similarly, a scaling factor greater than 1 causes pixels in the source image to be replicated, resulting in a larger final image. The following listing demonstrates this technique.

---

## Alternatives/Enhancements

Scaling is implemented by DirectDraw; it is emulated by the HEL, and some video cards provide hardware support for scaling. Thus, you do not really need this algorithm to scale a bitmap. However, when you use DirectDraw to perform scaling, you are relying on the implementation present in the current driver or hardware of the end user's machine. This could potentially lead to differing results from system to system. Using our own techniques, we can control the scaling, ensuring a consistent result on every machine. We could also employ interpolation techniques to determine the color of a scaled pixel from those around it. The resulting image could be of a much higher quality than that capable from DirectDraw, as it will not have the jagged edges produced by the DirectDraw scaling algorithms.

**Tip:** To let DirectDraw perform scaling, use the Blt function and specify the desired size for the destination rectangle.

---

As with most of these bitmap manipulation effects, scaling a bitmap can be very computationally intensive. We could pre-compute the scaled pixel positions relative to an arbitrary starting point for the entire range of scaling values when the application starts. The resulting lookup table would be very fast, but it would probably take up loads and loads of memory, depending on the range of scaling values. It might be possible to provide several bitmaps at specific sizes and scale between them as needed. This might allow us to optimize the scaling routine, but it would require more storage space for bitmaps. However, this would allow us to improve the quality of the images as they get larger.

## Rotation

Most top-down, 2-D, sprite-based games feature sprite images that seem to be able to rotate in any direction. This could be accomplished by drawing the sprite image in all possible rotations, but this would be required for all frames of animation and would result in a large number of images for even one sprite. While this is a perfectly acceptable way of implementing rotation, we could use bitmap rotation equations to allow us to rotate images to any arbitrary angle while saving on memory space.

## Basic Theory

You may remember from trigonometry that it is mathematically possible to rotate a point about the origin by an arbitrary angle. Given an original x and y coordinate and an arbitrary angle, a point can be rotated using the following equations:

```
New_X := Original_X * Cos(Angle) - Original_Y * Sin(Angle);
```

```
New_Y := Original_X * Sin(Angle) + Original_Y * Cos(Angle);
```

This new point is rotated about the origin by the specified angle, as illustrated below.

**Figure 11-3:** Rotating a point

**Caution:** A common mistake made when implementing these equations is to rotate the x coordinate, and then use this newly rotated value in the rotation equations for the y coordinate. The result will be a highly skewed image which will eventually shrink into nothing if rotations continue. This is why you must store the rotated values into separate variables.

If we treat each pixel in a bitmap as a point, we can use these equations to rotate the pixels in the bitmap. Now, most bitmap rotation algorithms map the pixels from the source bitmap to the destination bitmap, but most of the time, this results in a rotated image that contains holes. Therefore, we should iterate through the pixels in our destination image, determining the pixels we should draw from the source image. If we determine the center of the source image, like so:

```
CenterX := (SourceImageWidth / 2);
```

```
CenterY := (SourceImageHeight / 2);
```

then we can determine which pixels to pull from the source image based on the pixel being drawn in the destination image using these equations:

```
SrcX := Trunc(CenterX+(DestX-CenterX)*Cos(Angle)-(DestY-CenterY)*Sin(Angle));
```

```
SrcY := Trunc(CenterY+(DestX-CenterX)*Sin(Angle)+(DestY-CenterY)*Cos(Angle));
```

This will result in a perfectly rotated image with no holes.

Incidentally, we should load our source image into system memory as opposed to video memory. This will speed up the rotation, as it is much faster to access a surface in system memory than video memory. Also, we'll further optimize this by creating a sine and cosine lookup table instead of calling the Sin and Cos functions, using the angle as the index within these tables. The following listing demonstrates this technique.

## Alternatives/Enhancements

Unlike bitmap scaling, rotation is not something that is emulated by DirectDraw. Some cards provide hardware support for bitmap rotation, but even these could be restricted to rotations by only 90-degree angles. Therefore, you cannot rely on DirectDraw for bitmap rotation on every machine; you must implement this functionality yourself.

Bitmap rotation can be very slow due to its mathematically intense nature. However, rotation could be optimized by the use of assembly language. A less dramatic approach may be to use lookup tables that contained the rotated pixel coordinates for all angles. The angle could then be used as an index into this lookup table. This would result in incredibly fast bitmap rotation, but it would be a memory hog.

## Lighting Tricks

In nature, the color of an object can vary according to the intensity of light to which it is subjected. When the lights go down, things appear darker; when an object moves into the shadow of another object, its color darkens. Modeling this in our graphics engines can make our game worlds appear much more realistic and dynamic. There are many ways to model realistic lighting, but one method in particular is easy to implement and produces acceptable results.

## Basic Theory

This technique works by imposing restrictions on the palette of an image. For example, say we want to display an image that will have four different levels of light intensity. We need to segregate our palette into four different segments, so  $256 / 4 = 64$  palette slots per segment.

Now, our artists need to draw the image using only the first 64 palette slots. These slots should contain the colors of the image at their brightest intensity. The other three segments of 64 palette slots contain exactly the same colors as those in the first 64 slots, but at darker and darker intensities. In other words, the second segment of 64 slots contains the colors of the first 64 slots at 75% of their original intensity, the third segment of 64 slots contains these colors at 50% intensity, and the final segment contains the colors at 25% of their original intensity.

When the application draws the image, it needs to draw it one pixel at a time. Then, depending on the light level, we simply add 0, 64, 128, or 192 to the color of the original pixel. This will draw the pixel using the colors lower and lower in the palette, resulting in an image with darker and darker pixels. Using this technique, we can create a spotlight effect as demonstrated in Listing 11-4.

**Figure 11-4:** A segregated palette

    FBackBuffer.Unlock(nil);

end;

end;

```

---

## Alternatives/Enhancements

This is a really cheap trick that is easy to implement and does not put too great a strain on your artists. However, another method for implementing lighting involves creating a lookup table for each level of light intensity desired. Specifically, the application creates a 256-entry array of integers, and begins iterating through each entry in the original palette. For each color, the application determines the color components at a darker intensity, and then searches the original palette for an entry that is the closest match for this darker color. The number of this matching palette entry is then placed into the array at the index of the original color. The pixels in the bitmap now act as an index into the new array, which in turn then act as an index into the original palette. It is possible to create many more light intensity levels using this technique as opposed to the one described above. It also allows your artists to use more colors, but they must be mindful to use a palette containing several shades of each individual color so that the color-matching step finds an appropriate match.

Alternatively, you could use a non-palettized video mode. Using a non- palettized color mode frees your artists to use whatever colors they wish, and the results of this trick can be much more spectacular than that shown here. The effect will take a little longer, depending on the chosen video mode, as the application must move double to quadruple the information. However, using this technique, the banding side effect of the technique shown above can be eliminated, and the lighting effect can be much more realistic.

**Tip:** It is possible to lessen the banding effect using the above illustrated technique by using a mask for the lighted area instead of programmatically calculating the distance from the mouse cursor. The pixels in each band could be dithered somewhat around the edges of each band to help lessen the banding effect.

---

## Transition Effects

While it is perfectly acceptable to simply move from one scene to another with no fanfare, providing some sort of animation during scene transitions makes the software appear to have a smoother flow. We can take another lesson from the motion picture industry here. Typically, movies use a number of different wipes, fades, and other effects to smoothly transition from one scene to another. The next time you watch any of the *Star Wars* films, pay attention to how these transition effects create a smooth flow throughout the movie.

**Basic Theory**

Each transition effect may be implemented in wildly differing ways or with only subtle, minor differences, depending on the desired effect. In this example, let's use three simple effects that are relatively easy to implement yet provide cool animation effects. Specifically, these transition effects will be melt, crawl, and dissolve.

**Melt** This is the classic melting screen effect made popular by id software's Doom. It works by first drawing the next scene image to the back buffer, and then drawing the closing scene one column at a time into the back buffer. An array of integers, one entry per column of pixels, is used to track the vertical offset of the start of the pixel column. By starting some columns before others, we can create the illusion of the foreground screen melting away to reveal the next scene.

**Figure 11-5:** The melt effect

**Crawl** This is a variation of the dissolve effect below. Starting from one side of the screen, we use two variables to track a beginning and ending column (or row), spaced some arbitrary distance apart. At each frame of the animation, we increment both the beginning and ending columns (or rows). These define an area into which several pixels from the next scene are drawn. Their coordinates are chosen at random and copied into the back buffer at the same position. Past the ending column (or row), the "exposed" portion of the next scene is drawn. The effect appears to eat away at the foreground image, revealing the image of the next scene underneath.

**Figure 11-6:** The crawl effect

**Dissolve** This is a common effect that makes one image appear to dissolve, revealing the image beneath it. It works by randomly choosing a pixel from the next image and copying it to the back buffer (over the previous image) at the same position. However, it is rather slow to use the entire screen area for the range of random pixel selection. Thus,

we constrain the random pixel selection to an  $8 \times 8$  pixel area, and then replicate that throughout the entire image. In other words, the screen is divided into  $8 \times 8$  blocks. The next pixel is chosen from the first  $8 \times 8$  area, and we use this coordinate as an offset for each  $8 \times 8$  block throughout the screen. This creates a fast, effective dissolve effect.

**Figure 11-7:** The dissolve effect

The following listing demonstrates a simple implementation of these three effects. Press the spacebar to move from one image to the next.

**Alternatives/Enhancements**

The only thing limiting transition effects from one scene to another is the imagination of the programmer. While the three covered here are easy to implement, you can probably think of several dozen more that could be implemented just as easily. Many transition effects available from third-party products are little more than extensions of the effects implemented in the above example.

The effects demonstrated above rely on the fact that the images involved in the transition have the same palette. Using some palette manipulation, it may be possible to use images with two different palettes. This would require a new palette to be created for each frame of the transition animation, but this would result in a more flexible scene transitioning system.

**Tip:** Using a non-palettized display mode would, of course, eliminate this drawback.

**Simple Texture Mapping**

We've seen how easy it is to blit rectangular sections of bitmaps onto the screen or into offscreen buffers. If you've done any basic Windows graphics programming, you also know how easy it is to draw geometric shapes. It would be cool if we could somehow draw geometric shapes but use a bitmap as the contents of that shape, as opposed to simply filling it with color. The technique of mapping a bitmap image onto a geometric shape is known as texture mapping.

**texture mapping:** A general term for algorithms that map a bitmap image onto a geometric shape.

Texture mapping techniques can be applied in many exciting ways. Texture mapping techniques allow us to produce very convincing graphical images of real-world objects, which would be very difficult or impossible to

achieve otherwise. Algorithms that implement texture mapping range from the childishly simple to the absurdly complex. Let's look at a relatively simple texture mapping method that will allow us to wrap a bitmap around a circular shape to produce the illusion of a sphere.

## Basic Theory

Perhaps the first thing we will need is the texture to be mapped onto the shape. In this example, we'll create an animation of a planet spinning in space. Thus, our texture map should look like a planet, and will be rectangular in shape.

**Figure 11-8:** The texture map

Next, we need to define the circular shape itself. Specifically, we'll be using some of the scaling techniques described previously, so we need a series of points that define the perimeter of the circle. We can generate these points by using the equation for a circle:

```
MinorAxis := Sqrt((Radius * Radius)-(MajorAxis * MajorAxis))
```

The circle is generated at application startup and therefore does not have to be particularly fast. However, we'll make use of the symmetrical property of circles to generate points only for the first quadrant. These points can then be mirrored around the horizontal, vertical, and diagonal axes to form an entire circle, as illustrated in Figure 11-9.

**Figure 11-9:** Using symmetry to mirror points around a circle

Since our circular shape will be drawn one line of pixels at a time, the generated points serve as endpoints for each line of the circle. The actual texture mapping occurs by using the scaling techniques described above in conjunction with these endpoints to stretch each line of the texture bitmap between the endpoints of each line in the circle.

**Figure 11-10:** Defining a circle using endpoints

By defining a rectangular area smaller than the texture map, and then using scaling techniques to stretch the defined rectangular area not only vertically across the circular shape but also horizontally between each pair of endpoints, the resulting image seems to warp and magnify at the center of the circle. This produces a convincing illusion of an image wrapped around a sphere. The following listing demonstrates this technique.

**Listing 11-6:** *Wrapping a texture around a sphere*

### Alternatives/Enhancements

There are hundreds, and probably thousands, of ways to map a texture onto a geometric shape. Texture mapping is an integral part of 3-D programming, unless you want your models to look like flat colors. Full 3-D texture mapping is beyond the scope of this book, but the idea behind it remains the same.

Using the lighting techniques described earlier, the spinning planet could be made more realistic by modifying the palette and drawing part of the texture using darker colors, creating a “night” effect. Additionally, you could use a second texture for the clouds, and use transparency techniques to make the clouds appear to move around while the planet stays still, or at least moves at a different rate. Alternatively, a bitmap with text could be used to create an interesting marquee.

### Dynamic Images

The ability to mold and shape a bitmap allows us to produce some pretty spectacular special effects. Creating an image on the fly can produce even more dramatic effects. Blitting sprite images on top of a background certainly creates a new image on the fly, but what we’re concerned with here is creating an image based on some sort of algorithm or mathematical function as opposed to just creating a composited layer of bitmaps.

You could create dynamic images such as this in any manner imaginable. Fractal imaging comes to mind, which uses various mathematical equations to produce stunning graphics of everything from abstract forms to images that model natural objects, such as leaves or mountains, in an incredibly lifelike way. Full 3-D games use collections of points and polygons to produce realistic gaming environments. While this list could go on and on, we’ll look at two methods for creating some pretty cool special effects: 3-D star fields and fire.

### Star Fields

Everyone has seen the Windows star field screen saver. At a fast enough velocity, it resembles something that you would see on the bridge of the *Enterprise* going at warp speed. Science fiction-based games are quite popular, and may benefit from the ability to produce a cool warp-speed star field animation that could be used when traveling from system to system.

## Basic Theory

This technique makes use of some very basic 3-D concepts. Specifically, each star is tracked as a point in 3-D space. Before we discuss how the stars are moved and how they are subsequently drawn to the screen, we must first understand some very basic 3-D graphics principles.

In a 2-D world, for which most of the examples in this book have been written, coordinates are typically based off of a flat grid. In mathematical terms, this can be considered a Cartesian grid, where the y-axis represents vertical placement and the x-axis represents horizontal placement. The origin, or where these two axes meet, is where the x-axis and y-axis are both at 0. The y-axis increases as you move upward and decreases as you move downward. Similarly, the x-axis increases to the right and decreases to the left. (For the moment, we'll ignore the fact that on a computer screen, the origin is in the upper left-hand corner and y increases as you move downward.) The figure at the top of the following page demonstrates a typical Cartesian coordinate system.

Using this system, simple 2-D sprites can be tracked by a simple x and y coordinate (as we've been doing throughout this book). They can move left and right or up and down, but this system has no method for tracking depth, or which sprites are on top of each other.

**Figure 11-11:** A Cartesian coordinate system

To track depth, we need to add another axis. This is known as the z-axis, and in concept, it is perpendicular to the x and y axes. You can think of it as another axis that runs straight into the computer screen. The z-axis increases as you go “into” the computer screen, and decreases as you come “out of” the computer screen. The following figure demonstrates this concept.

**Figure 11-12:** A 3-D coordinate system

A star can be effectively tracked as a single point, so one x, y, z coordinate will represent a single star. If we now initialize a star at a specific coordinate, and then modify its z coordinate, it will appear to move toward or away from the user as desired.

The values for each axis in a system such as this are somewhat arbitrary. In our example, each axis can range from -1000 to 1000. Stars can be positioned anywhere within this square area. Now, even though we've got an acceptable method of tracking star positions, we still can't draw them to the screen. How do we convert these arbitrary axis positions into actual screen coordinates that we can draw?

This is where perspective projection comes in. The equations are very simple, and will produce a correct 2-D coordinate for a 3-D point that will accurately reflect the perspective in relation to its depth on the z-axis. Skipping the lengthy derivation and proofs for producing these equations, they are:

```
Screen_X := XPos / ZPos * VIEWDISTANCE;
```

```
Screen_Y := YPos / ZPos * VIEWDISTANCE;
```

Dividing the horizontal and vertical positions by the depth is what gives us the correct perspective. The

viewing distance constant is required because without it, the origin of the z-axis is effectively the glass of the computer screen. By multiplying by a constant viewing distance, we effectively push the origin of the z-axis into the computer screen. By modifying this, we can make things appear closer or farther away, depending on the size of this value.

To further enhance this illusion, we've dynamically created a grayscale palette and based the color of the pixel drawn to the screen on its z-axis position. This causes the stars to fade from black to white as they move toward the user, which further enhances the 3-D effect. The following listing demonstrates this effect.

{start the star as far back as necessary}  
  
Stars[Index].Z:=1000;  
  
end;  
  
end.
```

---

## Alternatives/Enhancements

Allowing the user to specify the velocity of the stars through some sort of throttle control would create the perception of speed. By modifying the starting position of the stars, it would even be possible to create the sensation of turning. Coupled with a fast bitmap scaling algorithm, this effect could be used to create a pretty cool arcade-type space shooter.

*Tip:* While this animation is pretty fast in its current implementation, there's really no need to use a three-dimensional coordinate system with perspective projection unless we're going to be creating a full 3-D game. This same effect can be reproduced using only x and y velocities and integer math, which could dramatically speed up the effect and leave more CPU time for more critical tasks. Remember, graphical effects do not have to be totally accurate; as long as it looks right, it is right.

---

Alternatively, if this was going to be used simply as a static animation or a transition from scene to scene, it may be faster just to create an actual animation using bitmaps drawn by an artist. However, the method by which stars are implemented could be considered a primitive particle system. By starting several "stars" at the exact same coordinate but giving each one a different heading and velocity and implementing a lifespan counter for each one so it disappears after a certain amount of time, a very realistic particle explosion system could be created. Adding gravity effects to the particles could produce an even more remarkable effect.

**Fire**

The fire effect is a really cool trick that, when performed properly, can create a very convincing illusion of fire. This effect is well documented both on the Web and in various books on graphics programming, and has been around for quite some time. It is a very computationally intensive effect, but it can be highly optimized and runs quite fast when implemented in assembly code. There are numerous ways of implementing this effect, but we'll examine one that produces a nice effect at decent speeds.

**Basic Theory**

The first thing we need to accomplish is creating an appropriate palette. For an effective fire, we'll create a palette that ranges from white in the upper slots (255-192), through yellow and orange, to red, and finally to black in the lowest slots (63-0). We could adjust the palette range somewhat and put some blues in, to simulate a cooler flame, or perhaps add some grays at the end, which would effectively simulate smoke.

This effect involves moving pixels that already exist in a surface. Therefore, we need to create a new surface that will contain the image of the fire. Since we'll be reading values from this surface, we'll place it in system memory. This algorithm is a CPU hog, so even though we'll create a surface that's the same size as the screen, we'll only use a small part of it for the effect. In our example, we've defined a starting and ending vertical position as well as a starting and ending horizontal position, which will confine the effect to the rectangle defined by these coordinates.

Now for the real work. Starting at the first row of pixels (defined by our starting vertical position) in the fire effect surface, we begin iterating through each column (as defined by our starting and ending horizontal position). We retrieve the current value of this pixel, subtract a random amount from this number, and then place the new value in the row of pixels above our current row. In effect, this produces an animation of pixels moving upwards on the screen. Additionally, we add a random number between -1 and 1 to move the pixels left or right in a chaotic manner.

**Figure 11-13:** Flaming pixels

Relative to the colors we defined in our palette, the pixel colors will slowly move from white, through yellow and red, and finally to black as they move upward due to the subtraction of a random value from their current color. This produces a very effective illusion of flames. At each frame of the animation, we'll need to place some random pixel values on the bottom row of the effect to give the algorithm some starting values. Implementing this effect is very simple, as illustrated by the following example.

*Listing 11-8: The flame effect*

### Alternatives/Enhancements

The strength of the blaze could easily be controlled by writing smaller starting pixel values on the bottom line, or perhaps writing values on only a few pixels and initializing the rest to 0. Because of the way this algorithm works, any pixels drawn into the fire canvas will become part of the blaze. By drawing text into the surface, the letters would appear to burn, creating a very cool effect.

Perhaps the easiest modification to this effect is changing the colors used in the palette. By defining a different range, we could make green fire, purple fire, etc. Indeed, by coupling this with some palette cycling, we could make the fire change colors on the fly. Employing a different method for moving the pixels could also dramatically change the effect. Various other plasma effects demonstrated in examples found throughout the Web use both of these techniques.

### Summary

In this chapter, we discussed several techniques for providing visual special effects that can enhance and complement a game application. We examined various bitmap manipulation methods, including lighting and simple texture mapping, as well as methods for dynamically creating images. When creating visual effects for your games, it is important to keep these points in mind:

- Computer graphic special effect techniques can be used to produce visual images that would be difficult or impossible to reproduce using blitting techniques alone.
- By drawing bitmaps using mathematical equations to modify the location of pixels as they are drawn to a destination, you can produce some very cool effects. Manipulating and transforming bitmaps in this way can give images a sense of texture or depth, and can stretch the art budget dollar.
- Bitmaps can be easily scaled to a larger or smaller size. DirectDraw supports this natively, but by using our own methods, we can control certain aspects and produce images with much better resolutions.
- Rotating an image is only supported by DirectDraw if it is available in the hardware. We can use our own techniques for rotating images, but most simple implementations are slow due to the mathematical intensity of the algorithm.
- Lighting techniques can be used to create game worlds that are more realistic. A cheap, simple

method is to segregate the palette into four segments of 64 slots, with the first segment containing the full intensity colors, and the other segments containing the same colors at darker and darker intensities. This results in banding, but the effect is quick and produces adequate results.

- Transition effects give a game a better sense of flow. Pay attention to how modern movies transition between scenes for inspiration. Many transition effects are relatively easy to implement.
- Texture mapping is a complex subject with intense math requirements. However, we can use scaling techniques in order to produce some simple texture mapping effects.
- Using some basic 3-D mathematical algorithms, it is fairly easy to produce a realistic star field. The equations used in this effect are at the core of real-time 3-D graphics programming techniques.
- By moving the pixels in an image, we can create a very realistic fire effect. It is possible to modify how these pixels move as well as perform a little palette rotation to produce some very interesting plasma effects.

## CHAPTER 12 Artificial Intelligence Techniques

This chapter covers the following topics:

- Antagonist movement techniques
- Finite state machines
- Probability machines
- Path finding techniques

There is no more dangerous opponent than a living, breathing human being. Humans can be incredibly unpredictable, and good game players can change tactics in a fraction of a nanosecond to take advantage of some new predicament within the game world. This is what makes multiplayer games so attractive; when facing real opponents, the replayability factor of just about any game is dramatically extended.

However, you can't always hook up with another human player. Some people may not even have the necessary hardware, and some may just want to play a game by themselves without worrying about the competition level introduced by battling other humans. In order for a single-player game to grab and hold the player's interest, it needs to be challenging, as good graphics and sound will entertain a user for only so long. This is where artificial intelligence techniques come in. In essence, artificial intelligence is the process of simulating intelligent thought and behavior through algorithmic methods.

As one would surmise from such a broad topic, a discussion of artificial intelligence could cover volumes upon volumes. Indeed, artificial intelligence is an area of specialty in the realm of computer science. Several large colleges and corporations spend millions of dollars (or more) yearly on furthering the research of artificial intelligence. Everything from simulating the thought process of an ant to accurately modeling the interaction of neurons in the human brain is being researched, with varying degrees of success.

Of course, most of these scholarly experiments employ technology that is either beyond the reach of game programmers or is simply "too much" for a game application. What we're interested in accomplishing is not an accurate model of living, thinking organisms, but a close facsimile thereof. We need game entities that appear to behave in an intelligent manner, but they do not have to truly be intelligent. As long as they challenge the player and provide a few surprises every now and then, we've done our job.

In this chapter, we examine various techniques for implementing simplistic artificial intelligence that will give our

game's enemy units a sense of personality and behavior. Since we are concentrating on artificial intelligence programming, the examples in this chapter will use very simple graphics so we don't unnecessarily complicate the code.

## Movement

The most noticeable display of artificial intelligence is in the movement of enemy units. Indeed, in most action games, the user is going to be primarily concerned with the movement of enemy units, such as whether they are aggressively chasing the user's ship or running like cowards. Let's look at several techniques that can be used to breathe life into the movement of game world antagonists.

### Random Movement

Perhaps the simplest simulation of artificial intelligence is to introduce an element of randomness. When an enemy unit moves in a fashion that is unpredictable to the player, that unit can appear to exhibit a rudimentary intelligence. Consider the apparently random flight path of a common housefly. It darts about here and there, yet it always appears to have a mind of its own and to know where it's going.

Random movement is simple to implement. For example, say we have a very basic sprite structure defined as:

```
TSprite = record  
  
    XPos, YPos: Integer;           // horizontal and vertical sprite position  
  
end;
```

To implement random movement, we can simply use the Object Pascal function `Random` to return a number indicating the number of units to move in a particular direction. The `Random` function takes a single integer argument as the extent of the range of numbers to be returned, and returns an integer in the range  $0 \leq X < \text{Argument}$ . If we specify a range of 3, which would randomly return the numbers 0, 1, or 2, and then subtract 1, our modified range of returned numbers would be -1, 0, or 1. By adding this translated number to the horizontal and vertical positions of our sprite, it would appear to move about randomly. The following listing demonstrates this technique.

#### *Listing 12-1: Random movement*

ColorFill(FBackBuffer, clBlack, nil);
```

```
{move the enemy randomly. this could be either no movement  
or movement by one pixel in a positive or negative direction}
```

```
Enemy.XPos := Enemy.XPos + Random(3)-1;
```

```
Enemy.YPos := Enemy.YPos + Random(3)-1;
```

```
{check for collisions with the side of the screen}
```

```
if Enemy.XPos < 0 then
```

```
    Enemy.XPos := 0;
```

```
if Enemy.XPos > DXWIDTH - 1 then
```

```
    Enemy.XPos := DXWIDTH - 1;
```

```
if Enemy.YPos < 0 then
```

```
    Enemy.YPos := 0;
```

```
if Enemy.YPos > DXHEIGHT - 1 then
```

```
    Enemy.YPos := DXHEIGHT - 1;
```

```
{retrieve a device context for use with GDI output techniques}
```

```
FBackBuffer.GetDC(SrvcDc);
```

```
TempCanvas := TCanvas.Create;
```

```
try
```

```
    {initialize the canvas properties}
```

```
    TempCanvas.Handle := SrvcDc;
```

```
    TempCanvas.Font.Color := clWhite;
```

```
    TempCanvas.Pen.Style := psClear;
```

```
    TempCanvas.Brush.Style := bsSolid;
```

```
    TempCanvas.Brush.Color := clRed;
```

```
{draw a small red circle at the current sprite position}
```

```
TempCanvas.Ellipse(Enemy.XPos, Enemy.YPos, Enemy.XPos + 3, Enemy.YPos + 3);
```

```
{draw some text}
```

```
TempCanvas.Brush.Style := bsClear;

TempCanvas.TextOut(0, 0, 'Random Movement')

finally
    {clean up the temporary canvas and device context}

TempCanvas.Handle := 0;

FBackBuffer.ReleaseDC(Srfdc);

TempCanvas.Free;

end;

end;
```

This does indeed move our sprite around the screen randomly, but it merely jitters around the middle of the screen and doesn't really project an air of intelligence at all. We could improve this by waiting a random amount of time before changing directions, which would give us a more housefly-like behavior, but there is no real intelligence underneath, and this enemy would pose no true threat to the player.

### Aggression/Evasion

In order to portray a sense of intelligence, enemy units should react in a manner dictated somewhat by the actions of the player. This could be anything from the player's movements (or lack thereof) to the number of rockets or bullets the player launched to the status of a player's shields or hit points. When an enemy reacts to the player's actions or current status, its intelligence can be convincingly real.

This can also give an enemy a sense of personality. An enemy that actively hunts down the player can be perceived as confident, powerful, and aggressive. By contrast, an enemy that constantly eludes the player or turns tail can be perceived as cowardly, injured, or perhaps even cunning, like an assassin stalking its target.

**Tip:** Varying the velocity, perhaps according to the proximity of the player, will enhance this technique and improve the perceived intelligence.

Modeling aggression is simple enough. The application simply examines the horizontal and vertical position of the enemy unit and the player unit, and adjusts the enemy unit's horizontal and vertical positions to bring it close to the player. For example, if the player unit's horizontal position is less than the enemy's, subtracting 1 from the enemy's horizontal position brings it closer to the player. If the player's horizontal position is greater than the enemy's, adding 1 to the enemy's horizontal position brings it closer to the player. The same holds true for the vertical position. This is illustrated below.

**Figure 12-1:** Chasing the player

Modeling evasion is just as simple. Indeed, if we simply reverse the signs of the values being added to the horizontal and vertical position of the enemy, it will run from the player instead of chasing after it. This is illustrated below.

**Figure 12-2:** Evading the player

Of course, most games would need to take into account obstacles and line of sight, but the basic principle holds true. The following example illustrates how to implement chase and evasion algorithms. The player's dot is controlled by the cursor keys, and the enemy dot will either chase or flee from the user based on its current status, which is toggled by the Enter key.

    YPos := YPos + YOffset;

    {clip to the screen boundaries}

    if XPos < 0 then
        XPos := 0;

    if XPos > DXWIDTH - 1 then
        XPos := DXWIDTH - 1;

    if YPos < 0 then
        YPos := 0;

    if YPos > DXHEIGHT - 1 then
        YPos := DXHEIGHT - 1;

end;

```

---

We could have just as easily made the chase/evade decision based upon whether or not the player was actively moving. If the player's sprite position has changed, we could have switched to evade mode; if the player hadn't moved, we could go right to chase mode. This would certainly keep players on their toes, and in the event our enemy units could kill a player, this would certainly discourage anyone from waiting around somewhere for very long!

### **Patterned Movement**

Chasing the player, running from the player, and moving around randomly can get pretty boring after a while. Typically, enemy units need to exhibit more complex movement, and one way to simulate this is through movement patterns.

For example, take the old arcade game Galaxian. When the enemies appeared in each round, they flew onto the screen in a complex flight path. Although their movements were a bit predictable, it made their appearance more menacing and deliberate. We can use patterned movement in our games to model similar complex, deliberate movements and make our enemies appear to move about more intentionally. Indeed, we could create several patterns and choose one randomly (or in a more context-sensitive manner), as illustrated in Figure 12-3.

**Figure 12-3:** Movement patterns

There are several methods by which patterned movement can be implemented based on the type of game and the sprite engine. If we had a simple, 2-D shooter, our patterns could simply be based off of a series of horizontal and vertical offsets that move the unit in the desired manner. These offsets would be relative to the current position of the sprite, so the patterns could be used anywhere within the game world.

**Tip:** It is relatively easy to flip the movement pattern horizontally or vertically, thus increasing the flexibility of this technique.

To implement this method of patterned movement, we could make an array of TPoints, filling each entry with the horizontal or vertical offset for that position within the pattern. As we move the sprite, we keep track of an index into this array of offsets, incrementing the offset at a preset time to advance to the next movement within the pattern. Once the pattern is complete, we can choose another array (or another row within a multidimensional array) and reset the index to 0, thus starting a new pattern. This technique is illustrated below.

**Listing 12-3:** *Implementing patterned movement*

```
TSprite = record
    XPos, YPos: Integer;
    CurPattern,
    CurPatternIdx: Integer;
    PatternIdxChange,
    CurTimer: Longint;
end;

TPatterns = array[0..5, 0..31] of TPoint;

const
    {in this example, the patterns are stored as direct X and Y offsets, but
    any method of specifying a direction and/or offset will do}
```

```
Patterns: TPatterns = (  
  ((x: 1; y: 0), (x: 1; y: 0), (x: 1; y: 0), (x: 0; y: 1), (x: 0; y: 1), ...  
  ((x: -1; y: -1), (x: -1; y: -1), (x: -1; y: -1), (x: -1; y: -1), ...  
  ((x: 1; y: 0), (x: 1; y: 0), (x: 1; y: 1), (x: 1; y: 1), (x: 0; y: 1), ...  
  ((x: 1; y: 0), (x: 1; y: 0), (x: 1; y: 0), (x: 1; y: 0), (x: 0; y: -1), ...  
  ((x: 1; y: 0), (x: 1; y: 0), (x: 1; y: 0), (x: 1; y: -1), (x: 0; y: -1), ...

This makes our enemy sprite appear to move in a more deliberate manner. We can adjust the offsets accordingly to make some patterns move the sprite faster or slower, and with some minor modifications we could make some patterns longer than others. By selecting different patterns, the movement appears more deliberate while at the same time reducing its predictability.

*Note:* In real-world situations, we should make sure that the sprite is not positioned such that a movement pattern will run it into a movement boundary immediately. In our example, we simply clip to the edges of the screen, but this can make a movement pattern almost useless. In a real-world situation, we should reverse the pattern when it detects a movement boundary, or even exit the pattern immediately and choose another form of movement.

## Finite State Machines

We've been examining methods by which intelligent movement can be modeled, and so far we've come up with some acceptable algorithms that can provide convincing, if somewhat limited, intelligent movement. However, we haven't discussed methods by which enemy units determine which movement technique to use.

We could just randomly pick something, but this would not model any sort of intelligent thought process. We need an algorithm by which an enemy unit can make a series of rational decisions based on various inputs from the game world, such as the current environment as well as the actions of the player. This can be accomplished through a method known as a finite state machine. A finite state machine is a logical construction that consists of several "states," each of which defines a specific behavior, and "state transitions," which define specific rules for moving from state to state.

**finite state machine:** A logical construction that contains a series of states defining specific behaviors and a series of state transitions defining rules for moving from state to state.

Using finite state machines, enemy units can have very complex behavioral models. These can include not only movements but also different tactics or other actions based on the actions of the player, the state of other game objects, and the overall situation. State machines also allow for the easy extension of behaviors, as all that would be required is the logic for the behavior under the new state and logic for moving into and out of this state. An arbitrary state machine could be visualized as illustrated below.

**Figure 12-4:** An abstracted finite state machine

Each circle in the illustration represents a specific state, or behavior, and the lines connecting them represent the logic determining how one state leads to another.

One way to model this in software would be to define each state as an integer value or perhaps an enumerated type. A case statement could then be utilized to execute the appropriate code for the current state. The transitions from state to state could be controlled in a number of ways, from randomly choosing a different state at a specific interval to complex logic that considers the player's attributes versus the computer controlled adversary's. In the following example, we've used a case statement to control the logic for each state, and we simply choose a random state after a specific amount of time has elapsed. While viewing the animation, you can definitely tell a difference in the sprite's movement behavior among the various states.

**Listing 12-4:** Movement behavior through a finite state machine

---

Implementing artificial intelligence as a finite state machine makes it easy to specify some very complex behavior and add new behavior if necessary. When coupled with some logic to control state changes based on the current game state, such as hit points, power, player hit points, etc., enemy sprites can appear to be very intelligent indeed.

However, the current implementation lacks personality. Enemy sprites may exhibit some fairly complex thought patterns, but they all think alike, and that can soon become boring to players. What is needed is a way to imbue enemy sprites with a little more character and individualism.

**Probability Machines**

That's where probability machines come in. A probability machine is really just an extension of a finite state machine, allowing the application to simulate personalities based on a certain distribution factor. Using this technique, we can make some sprites appear more passive, some more aggressive, some a little bit sneakier, etc.

It works by choosing the next state based on a weighted distribution as identified by the type of personality we're modeling. For example, let's say we have five states, and we want to model an aggressive behavior. Whenever it comes time to change states, we want to choose the next state based on a percentage chance as illustrated below.

*Table 12-1: Aggressive personality percentage chance for state selection*

State	Percentage
Chase	50%
Evade	10%
Wait	10%
Random Movement	10%
Patterned Movement	20%

So, in this example, an aggressive personality would choose the chase state 50% of the time. A more timid personality would likely choose the evade state more often. Other personality types would result in varying distributions.

One way to implement such a system would be to create an array of 10 elements, where each element holds a state (either as an integer index or an enumerated type). This array would then be populated by each state a number of times equal to its probability of selection divided by 10. Over time, each state would be selected according to its probability. For example, if the chase state had a 50% chance of selection, it would be in the array five times, and over time, it would indeed have a 50% chance of being selected when the state changed. This is the method by which personalities are implemented in the following example.

As you can see from this simplistic example, the change in behavior of the enemy sprite is subtle, but you should be able to tell a definite personality, especially between the Aggressive and Defensive postures. Indeed, if we changed a sprite's personality based on game state (i.e., going from Aggressive to Defensive when hit points went below 30%), the sprite would seem a little more dynamic.

We could even change the distribution based on the success of a particular state within a personality during the game. For example, if the game timed how long it took to kill the player during each state and found that a particular state was more effective, it could modify the distribution so that that state was chosen more often. This would make the game grow with the player; the sprites would appear to "learn," and the game would become more challenging.

## Path Finding

Most games feature some form of entity or sprite that must move from one position in the game world to another. Usually, this is pretty simple, as we can determine an appropriate x and y velocity that will move the sprite in the direction of its goal and sit back until it gets there. This will work fine for game worlds that are flat and don't feature any obstacles that would hinder movement. Unfortunately, most game worlds tend to be a bit more complex, with several immobile or impassible objects. The presence of these objects negates the possibility of game entities always moving in straight lines to get from their origin to their destination, posing a problem that has been researched heavily over the years by both the academic world and the gaming industry alike.

When a game entity encounters an object that hinders its movement, it must find another direction of movement leading around the obstacle and toward the final destination. This is known as path finding. Technically, path finding describes algorithms for determining the shortest, most direct path from a starting position to an ending position, avoiding all impassible obstacles.

**path finding:** Algorithmic techniques for determining the shortest, most direct path from a starting position to an ending position based on terrain and obstacles in the game world.

There are numerous applications for such techniques. Real-time strategy games such as Age of Empires and WarCraft make heavy use of path finding algorithms. Indeed, any game that features entities moving through a world filled with impassible obstacles needs to implement some form of path finding. Path finding algorithms can be applied to real-world problems as well. We'll focus our discussion on path finding as it applies to 2-D game worlds, and we'll examine one well-known algorithm that produces acceptable results.

## Algorithms

The subject of finding a particular path over a specific terrain and algorithms for accomplishing this task have been researched almost as extensively as methods for producing graphical output. Several books have been published that cover this subject to varying degrees of depth. Many of these algorithms, while accurate, tend to be too slow for implementation in a game. However, three algorithms are well documented and well known in the game industry, and tend to serve as the basis from which most game implementations of path finding algorithms are drawn. These are known as breadth first search, depth first search, and A\* (pronounced "A-Star").

### Breadth First Search

The breadth first search algorithm is very exhaustive, and while it can eventually find a very accurate, short path, it typically takes way too long for most games. It searches for the shortest path by choosing the next node in a particular direction and determining its distance from the destination. It performs this for all available directions, then it moves to the node closest to the destination and performs these calculations again. However, if two or more nodes are the same distance from the destination, it recursively performs these calculations for each of these nodes. Essentially, this algorithm explores all possible paths from the starting point to the destination, as long as those paths lead toward the destination. This can result in an exponentially increasing number of calculations depending on the size of the map and the position of obstacles. Calculation times for this algorithm are typically measured in seconds. While this may be completely appropriate for real-world problems, it is way too slow for a game application, which needs to calculate paths in milliseconds, if not faster.

### Depth First Search

By contrast, the depth first search simply chooses a direction toward the destination and begins moving along nodes in that direction until it reaches the destination. If it encounters an obstacle, it backs up one node and tries again in a different direction. While this algorithm can eventually find some path to the destination, it typically will not be the shortest or the most direct route. However, also unlike breadth first search techniques, path calculation times are much, much shorter. While this will find some type of path in a short amount of time, it will usually result in a path that makes game entities wander about almost aimlessly, and certainly in no logical or intelligent manner.

### A\*

Perhaps the most widely documented solution for path finding problems is the A\* algorithm. A\* combines the best of both breadth first search and depth first search to determine the shortest path in a relatively minimal amount of time. Like the depth first search, it chooses a direction toward the destination, and begins moving along nodes in that direction. Like the breadth first search algorithm, it checks the distance of the next nodes in several directions to determine which is closest to the destination. It then moves to this next node and starts the calculations again. The result is a single path for which several directions were considered at each node. This typically produces a fairly intelligent looking path within an acceptable amount of time.

### Basic Implementation

In our example, we'll take a fairly typical approach and define a two-dimensional game world composed of square tiles. We'll need to define a starting point and an ending point, and populate this map with several impassible obstacles, like so:

**Figure 12-5:** The game world

Additionally, we'll need to set up a list that will hold information for the nodes we have selected on our path. We'll also need an array the size of the game world to mark nodes that have already been explored. We'll examine how these two requirements are utilized below.

We begin by determining the direction of the goal relative to our starting point. We'll use this to determine which nodes we should look at next. Based on this direction, we'll examine three nodes—the next node in the direction of the goal and the two nodes to either side of it. In this example, our goal is directly east of the starting point, so we'll examine the northeast, east, and southeast nodes relative to our starting point:

**Figure 12-6:** Examining nodes

Now, for each of these nodes being examined, we need to determine their distance from the destination. If you remember your algebra, the distance formula is:

```
Distance := Sqrt(Sqr(X2 - X1) + Sqr(Y2 - Y1));
```

**Tip:** The Sqrt and Sqr functions are very slow. We could simply use multiplication in the case of the Sqr function, and perhaps utilize a lookup table for the Sqrt function in order to optimize this equation.

Using this equation, we find that the node directly to the east is the closest to the destination. We'll add this new node to our list of nodes along the path, as well as mark this new node as visited in our array of visited nodes (we also need to add the starting node to the list as well as mark it as visited before we start searching for a path). We then move to this new node, and begin the process again.

**Note:** The phrase “moving to the new node” indicates that we are simply tracking the current node we are processing in our algorithm. The actual movement of the game entity does not take place until the entire path is determined; it does not move in real time.

We'll continue this process until we encounter an obstacle. Even though the next eastward node would be closest to the destination, it is an impassible obstacle and cannot be selected. Therefore, we need to select one of the other two nodes that are closest to the destination and are not blocked. In this example, either of these nodes will work just fine, so we'll pick one at random.

**Figure 12-7:** Moving past an obstacle

Notice that we have now changed directions from east to northeast, which affects which nodes we'll examine on the next pass. Specifically, the next nodes we will examine will now be north, northeast, and east of the current node.

**Figure 12-8:** Examining nodes in a new direction

Once again, we'll see that the eastward node is the closest to the goal. This entire process continues until the goal is finally reached.

**Figure 12-9:** A path from start to finish

### Back Stepping

This basic algorithm will get us there in simple game worlds, but what about situations where we run into larger obstacles, such as the one below.

**Figure 12-10:** A large wall

As we can see here, all three examined nodes are blocked, and thus the path cannot proceed any further. This is where the array that tracks which nodes have been visited comes in. We need to delete the current node we are on from our list of path nodes, and back up to the previous node. When we reexamine the next closest nodes, we'll treat the node we just visited as an impassible obstacle. This keeps us from choosing a node that we know will not work.

**Note:** When we back up to a previous node, we also need to reset our direction to the direction we were facing in this previous node.

**Figure 12-11:** Backing up and reexamining nodes

Continuing with this process, we see that our algorithm finds a relatively direct path to the destination.

**Figure 12-12:** Pathing around a large wall

Backing up and reexamining nodes in the previous direction really boosts this algorithm's intelligence. Indeed, while our implementation of this algorithm isn't totally infallible, it is pretty smart, and can get us around some fairly complex obstacles as illustrated below.

**Figure 12-13:** Navigating a complex game world

## Case Study

Unlike most examples throughout this book, the path finding example is implemented using standard Delphi controls for the visual feedback. This was done to highlight the path finding algorithm and to make it easier to examine the algorithm at run time. You can't really set breakpoints and step through code once DirectDraw has exclusive access and has set the video mode to full screen. Implementing an A\* path finding algorithm using standard Delphi controls allows you to step through it line by line to examine what's happening as it runs. This will also make it easier to improve the algorithm's performance and accuracy if you wish to play with it. In the output from this test application, the blue square is the origin, the red square is the destination, black squares indicate impassible obstacles, and purple squares indicate the final path. Green squares indicate nodes that were visited but did not belong on the final path.

The following listing demonstrates a simple, straightforward implementation of the A\* algorithm.

**Listing 12-6:** *The A\* test bed*

                {this is a clear node that we could move to. calculate
                the distance from this node to the destination.

                NOTE: since we're interested in just relative distances as
                opposed to exact distances, we don't need to perform a square
                root. this will dramatically speed up this calculation}
                EvalDist := ((EndPt.X - EvalPt.X)*(EndPt.X - EvalPt.X)) +
                    ((EndPt.Y - EvalPt.Y)*(EndPt.Y - EvalPt.Y));

                {if we have found a node closer to the destination, make this
                the current node}
                if EvalDist < Dist then
                    begin
                        {record the new distance and node}
                        Dist := EvalDist;
                        NewPt := EvalPt;

                        {record the direction of this new node}
                        NewDir := SearchDirs[iCount];
                    end
            end
        end
    end
end

```

```

        end;

end;

{at this point, if NewPt is still (-1, -1), we've run into a wall and
cannot move any further. thus, we have to back up one and try again.
otherwise, we can add this new node to our list of nodes}

{we've got a valid node}
if NewPt.X <> -1 then
begin
    {make this new node our current node}
    CurPt := NewPt;

    {point us in the direction of this new node}
    Dir := NewDir;

    {mark this node as visited}
    VisitedNodes[CurPt.X, CurPt.Y] := TRUE;

    {create a node object}
    GetMem(TempNode, SizeOf(TNode));

    {initialize this node object with the new node information}
    TempNode^.Direction := Dir;
    TempNode^.GridPt.X := CurPt.X;
    TempNode^.GridPt.Y := CurPt.Y;

    {put this new node in the path list}
    PathQueue.Add(TempNode);

    {if we've recorded 50 nodes, break out of this loop}

```

```

    if PathQueue.Count > 50 then
        Break;
    end
else
begin
    {we've backed up to the point where we can no longer back up. thus, a
    path could not be found. we could improve this algorithm by
    recalculating the starting direction and trying again until we've
    searched in all possible directions}

    if PathQueue.Count = 1 then
        Break;

        {point us in the direction of the previous node}
        Dir := TNode(PathQueue[PathQueue.Count-2]^).Direction;

        {retrieve the coordinates of the previous node and make that
        our current node}
        CurPt := Point(TNode(PathQueue[PathQueue.Count-2]^).GridPt.X,
            TNode(PathQueue[PathQueue.Count-2]^).GridPt.Y);

        {free the last node in the list and delete it}
        FreeMem(PathQueue[PathQueue.Count-1], SizeOf(TNode));
        PathQueue.Delete(PathQueue.Count-1);
    end;
end;

{at this point, we've found a path from the starting node to the destination
node, so we should populate the grid and allow it to display the final path}

{specify visited nodes}
for iCount := 0 to 14 do
    for iCount2 := 0 to 14 do

```

```

    if VisitedNodes[iCount, iCount2] then

        grdPath.Cells[iCount, iCount2] := NODEVISITED;

{specify nodes on the path}

for iCount := 0 to PathQueue.Count-1 do

begin

    grdPath.Cells[TNode(PathQueue[iCount]^).GridPt.X,

                    TNode(PathQueue[iCount]^).GridPt.Y] := NODEPATH;

end;

{specify the starting and ending nodes}

grdPath.Cells[StartPt.X, StartPt.Y] := NODESTART;

grdPath.Cells[EndPt.X, EndPt.Y] := NODEEND;

end;

```

---

### Enhancements

Although this algorithm is relatively powerful, it is easy to bog it down and send it on a wild goose chase. In particular, large U-shaped sections of obstacles can make the algorithm calculate dozens or even hundreds of nodes that will not be part of the final path. This could potentially overflow the list of path nodes, or at a minimum cause a noticeable pause when a unit calculates a path over long distances. Therefore, your game world should avoid such constructions.

**Caution:** This implementation could potentially get the sprite caught in an infinite loop on some maps, resulting in an overflow situation which would most likely crash the machine.

One way to avoid an overflow on the path list would be to restrict the number of nodes in this list to some arbitrary number. Our example constrains the path to a total number of 50 nodes. This may need to be adjusted for large maps, but it will ensure that the path node list never overflows, and it will restrict pathing time to a maximum amount. If a unit tries to path to a destination, but the path node list reaches the limit before the destination is reached, you could just set a flag for that entity, and repath when the unit reaches the last node in its list. Allowing the user to set waypoints for a unit will further improve pathing, as the paths between each waypoint tend to be shorter and encounter fewer obstacles.

This algorithm is somewhat intelligent, but it can be easily fooled by certain obstacle constructions. Looking at nodes in the three directions relative to the direction of the destination is somewhat of an optimization, and cuts down on the number of calculations required at each node. However, this sometimes leads to paths that look less than intelligent, even downright stupid. The algorithm could be changed so that it checks all eight directions at each node. While this will dramatically increase the number of calculations, the overall path will tend to be much shorter and look more natural.

Additionally, this algorithm does not take into account nodes with different movement costs. For example, say that the game world was populated by terrain consisting of hard rock, grasslands, mud, swamp, and water. While water terrain might be impassible, the others can be moved through but at different degrees of

difficulty. Hard rock or roads would certainly be the easiest to move over, but grasslands, mud, and swamp would all impose penalties to movement while not being totally impassible. Elevation could also be a factor. This algorithm would need to be modified somewhat if your game world features terrain with varying movement costs.

## Summary

In this chapter, we discussed techniques for implementing simplistic artificial intelligence routines that give our sprites the ability to display cunning and strategy when moving around the game world. We looked at different movement techniques, including chasing or evading the player and patterned movement. We also looked at controlling the movement decisions based on a finite state machine, as well as techniques for weighting the selected states as a method for implementing rudimentary personalities. When using artificial intelligence techniques in your games, it is important to keep these points in mind:

- No matter how good your artificial intelligence algorithms may be, there is no greater challenge than playing another human being. However, some people may be unable to hook up with someone else to play a multiplayer game, or they may just enjoy playing by themselves. Therefore, it is important to include artificial intelligence algorithms in your games that make the antagonists at least moderately challenging.
- The most noticeable display of artificial intelligence is in the movement of enemy units. In most action games, the user is going to be primarily concerned with the movement of enemy units, such as whether they are aggressively chasing the user's ship or running like cowards.
- Perhaps the simplest simulation of artificial intelligence is to introduce an element of randomness. When an enemy unit moves in a fashion that is unpredictable to the player, that unit can appear to exhibit a rudimentary intelligence. Consider the apparently random flight path of a common housefly. It darts about here and there, yet it always appears to have a mind of its own and to know where it's going.
- An enemy that actively hunts down the player can be perceived as confident, powerful, and aggressive. By contrast, an enemy that constantly eludes the player or turns tail can be perceived as cowardly, injured, or perhaps even cunning, like an assassin stalking its target.
- We can use algorithms that make enemy units move about in a specific pattern. This can make antagonists appear to move in a very deliberate manner. Very complex movements can be modeled this way, where some patterns could be useful for evading the player, such as a zigzag pattern, and some patterns could be useful for chasing the player, such as a circular pattern to move around the player's flank.
- A finite state machine is a logical construction that consists of several "states," each of which defines a specific behavior, and "state transitions," which define specific rules for moving from state to state. Finite state machines are a method by which an enemy unit can make a series of rational decisions based on various inputs from the game world, such as the current environment as well as the actions of the player.
- A probability machine is an extension of a finite state machine, allowing the application to simulate personalities based on a certain distribution factor. Using this technique, we can make some sprites appear more passive, some more aggressive, some a little bit sneakier, etc. It works by choosing the next state based on a weighted distribution as identified by the type of personality we're modeling.
- Most games feature a game world filled with moving sprites which must navigate around immovable or impassible obstacles. Path finding artificial intelligence routines must be utilized in order to make the sprite appear to move in an intelligent manner, selecting the most direct, shortest path available.
- Breadth first search and depth first search techniques could be used, but these are typically too slow or too inaccurate for game applications. The A\* (pronounced "A-star") algorithm combines the best of breadth first search and depth first search to find a fairly direct, short path in a short amount of time.

## CHAPTER 13 Putting It All Together

This chapter covers the following topics:

- The Delphi Blocks game architecture
- User input implementation
- Sound and music implementation
- Graphics implementation
- Potential enhancements

Each individual piece of a game is interesting to study and can be downright fun to program. Sound and music programming is always interesting, as it's cool to programmatically control a sound's properties such as volume or panning, and perhaps even more interesting to output music from various sources. Input programming is also a lot of fun, especially when reading from devices other than the standard mouse or keyboard. Force feedback is especially cool, as it's unusual to control an external peripheral using code instead of the other way around. And, of course, graphics programming is never boring, and is limited to only what your imagination can stir up. However, while each piece is interesting individually, orchestrating them together into a digital masterpiece is incredibly rewarding and entertaining.

We've covered many useful game programming techniques throughout this book, and now it's time to put them together and make something useful. In this chapter, we will examine a full-fledged game written using the techniques and examples that we've developed throughout the course of the text. We'll break down several important aspects of the game, and see how all of these parts come together to make a working, playable game application.

### Delphi Blocks

Our case study game is called Delphi Blocks. If you remember the old Breakout game, this one will be very familiar. While we're not breaking any new technological ground with this application, it does serve as a working example of bringing graphics, sound, and input programming together to make a working, playable,

and even fun game.

The basic idea is to destroy all of the blocks on the screen using a ball. This ball bounces around the screen, off of blocks and the screen sides. The user can control a small paddle at the bottom of the screen to deflect the ball toward the blocks. If the ball goes off of the bottom of the screen, it is lost and another ball is put into play. The user has three balls; when all of them are lost, the game is over. The game play is simple, but it is easy to learn without ever consulting a manual and can be addictive.

## General Game Architecture

This is a simplistic game with an equally simplistic architecture. The code is encapsulated into one unit, although we could have easily segregated several portions of the code into individual units in order to increase its readability and adaptability. In general, we decided to make the overall game level based to facilitate a more intuitive player advancement system, using a state-driven architecture to ease implementation and simplify game control.

## Player Advancement

As stated above, the player's goal is to destroy every block on the screen. We'll use a level based system of advancement, so that when all of the blocks have been destroyed, the level is increased and a new grid of blocks is generated. The score for each block is based on the level, so the higher the level, the more each block is worth. However, the speed of the ball is also based on the level, so at higher levels the ball will be moving at more and more rapid velocities, making the game harder and justifying the score increase for each block. This type of advancement is important, as it challenges the players and forces them to get better in order to play the game for longer periods of time.

## Game States

The game is state driven, using the basic state-driven architecture we covered back in Chapter 2. There are four specific states: Idle, Playing, Intermission, and Game Over. Game execution flows through the states in the following manner:

**Figure 13-1:** Delphi Blocks state flow

**Idle** This state is basically a demo state. All it does is sit and display a static image with a full grid of blocks and the game title while waiting for the user to start a new game. Unlike the other states, though, in this state we display two buttons, one for starting the game and one for quitting. We'll discuss how the buttons work when we cover user input.

**Playing** This is the main game state, and includes the logic for moving the sprites and performing the graphics rendering. Additionally, it also checks to see if the current level has been cleared, and if so, it initializes a new level and puts the game in intermission.

**Intermission** This state simply provides the player with a short pause between levels. This is important, as a twitch game like Delphi Blocks can get rather hectic at higher levels, and you really need to provide players with an opportunity to catch their breath every now and then. All this state does is display a full grid of blocks with an indicator of the next level.

**Game Over** The game goes into this state when the player has lost all of the available balls. It serves to indicate to the user that the game has been completed, and a new one must be started. Like the intermission state, it simply displays a full grid of blocks with the words "Game Over" superimposed over them.

## User Input

During the idle state, the user has the choice of selecting two buttons, one for starting a game and one for quitting the application. While actually playing the game, the user has control over a paddle that can move left and right. At higher levels, the user needs to be able to move the paddle rapidly and intuitively. Thus, the most obvious form of control for this type of game would be the mouse. We've used a modification of the baseline application with mouse support in order to accomplish this task. Using this baseline, it was very easy to get mouse support up and running with little effort.

## Buttons

The buttons were actually very easy to implement. They are displayed only during the idle state, and it is in this idle state that we check for click events. If a click is detected, we simply check to see if the mouse cursor was located over one of the buttons, and take the appropriate action:

```
{determine if the mouse was clicked in one of the buttons}

if MouseClickList.Count>0 then

begin

    {while there are any events in the mouse click list, retrieve
    them all and empty the list}

    while MouseClickList.Count > 0 do

    begin

        {free the current mouse data}

        if MouseData <> nil then

        begin

            MouseData.Free;

            MouseData := nil;

        end;

        {retrieve and delete the click event}

        MouseData := TMouseData(MouseClickList[0]);

        MouseClickList.Delete(0);

    end;

    {if the quit button was pushed...}

    if PtInRect(Rect(416, 350, 544, 414),

                Point(MouseData.XPos, MouseData.YPos)) then

        Close;
```

```
{if the start button was pushed...}  
  
if PtInRect(Rect(96, 350, 224, 414),  
  
    Point(MouseData.XPos, MouseData.YPos)) then  
  
    StartGame;
```

## Baseline Differences

While the baseline application with mouse support was functional, we needed to make some minor modifications. Specifically, we want to show a mouse cursor during the idle state, but we want to suppress the display of the mouse cursor during any other state. Therefore, we ripped all of the mouse cursor display code out of the mouse input thread and added a variable to control mouse cursor display. If the mouse cursor is to be hidden, only the horizontal position of the mouse cursor is updated, and it is clipped according to the dimensions of the paddle graphic.

## Sound and Music

Any game can be improved by using sound effects, and this game is certainly no different. We decided to use a few simple sounds to indicate when a ball hits a block, hits the side of the screen, hits the paddle, or falls off of the bottom and dies. There's not much opportunity for sounds to overlap, so we could have used regular Windows multimedia function calls to output the sound. However, we went with DirectSound in case we wanted to expand the sound functionality at a later date. DirectSound programming is relatively easy anyway, and this architecture certainly would support advanced sound functionality if we needed it.

We also wanted to have some music playing in the background, so the application uses MCI commands to continuously play a MIDI file while the application is active. We could have easily used DirectSound to stream a large WAV file to the sound card, which would have given us better sound quality, but this example shows how Windows multimedia functions and DirectSound can be used simultaneously.

## Graphics

The graphical requirements for this application are not very stringent, and were thus very easy to implement. This is a 2-D sprite game that doesn't feature very much animation, so all of the graphics easily fit into one file. We load this bitmap into an offscreen surface, letting DirectDraw determine its location; if there is enough video memory available, the surface will be located on the video card itself. Since we use nothing but simple blits, available hardware acceleration will dramatically improve the performance of the game. The game images are arranged in the single bitmap like so:

**Figure 13-2:** Delphi Blocks game graphics

The largest part of the graphic file is the background screen. The images for the block sprites are located below the background, including the image of the ball and paddle. We also see the button images as well as the cursor sprite image.

## Sprites

This game features a large amount of sprites in the form of the blocks and the ball. We could easily extend the block grid to be larger or smaller, and the game is already set up to support more than one active ball. In order to encapsulate this functionality, we will use an object to manage all of the block sprites, and another object to manage all of the ball sprites.

The block manager itself is pretty simplistic. It contains an array property that holds a 10×15 grid of TBlock objects, with each TBlock object representing one block sprite on the screen. The manager contains functions for initializing the entire block grid as well as drawing all of the blocks or deleting one specific block from the grid. This encapsulation allows us to deal with the large quantity of block sprites using one simple class. It is defined as:

```
{defines the manager that will track all of the blocks}

TBlockMgr = class
    {this static grid can be modified to increase or decrease the overall
    block area and size}

    BlockGrid: array[0..14, 0..9] of TBlock;

    NumBlocks: Integer;

    destructor Destroy; override;

    procedure Draw;

    procedure InitializeBlocks;

    procedure KillBlock(Row, Col: Integer);

end;
```

The ball manager object is very similar in functionality and design. It contains a list object that tracks several TBall objects. This allows us to add any number of active balls to the screen and track them all simultaneously. Additional methods move and draw all of the active balls, clear the entire list of balls, or delete a specific ball sprite. It is defined as:

```
{defines the manager that will track all of the ball sprites. note that
```

```

this gives us the ability to add and track several active balls at once}
TBallMgr = class
    BallList: TList;

    VelCoefficient: Integer;

    FTotalBalls: Integer;

    function GetActiveBalls: Integer;

    constructor Create;

## Collision Detection

Collision detection really is the heart of this game. The entire idea is to make a ball collide with a block, and the balls must bounce off the walls and the paddle in a predictable manner.

Bouncing off the walls is a relatively simple behavior to implement. We simply check the horizontal and vertical coordinates of a ball after it has been moved, and if it has collided with the sides or top of the screen, its horizontal or vertical velocity is reversed as appropriate. A collision with the bottom of the screen results in a lost ball.

Collision with the paddle is a little more involved. To simplify matters, we use the bounding box collision detection technique covered in Chapter 6. To review, each ball has a bounding rectangle, as does the paddle. When these two rectangles intersect, a collision has occurred. The paddle is rectangular, and the ball is almost rectangular, so this collision detection technique is accurate enough for our purposes.

However, we would like to give the user some control over the ball so he or she can influence its direction.

Therefore, the angle of deflection that the ball takes is dependent on the position at which the ball collides with the paddle. Towards the center of the paddle, the ball tends to deflect at a 90-degree angle to the paddle itself, or straight upward. As the ball collides nearer and nearer to the edge of the paddle, the deflection angle becomes more and more acute, as the following illustration shows:

**Figure 13-3:** Ball deflection angle

Collisions with the blocks are where things get kind of hairy. We first perform a bounding box collision test to see if they collided. However, we need to know if the ball hit the top, sides, or bottom of the block in order to determine which velocity to reverse. Unfortunately, it is impossible to determine this from a simple bounding box collision, as illustrated below:

**Figure 13-4:** Which side was hit—the top or the left?

Therefore, we need a more accurate method of collision detection that can determine which side of the box was hit. This can be accomplished by using a general line segment intersection algorithm. The specific algorithm used in the example is covered on page 199 of *Graphics Gems III* by David Kirk. The algorithm was deduced by Franklin Antonio. The math behind this algorithm is complex, and although it is documented thoroughly in the example code, please consult *Graphics Gems III* for a detailed explanation of this algorithm.

**Enhancements**

We've created a complete game application that utilizes the vast majority of the techniques covered throughout the book. However, while it serves as a good case study, it certainly is not ready to be shrink-wrapped and put on store shelves. This is by design, as it leaves many opportunities for you, the reader, to exercise some creativity and take this basic game to the next level.

The first thing that should be enhanced is the collision detection code. While it is very accurate, it is incredibly math intensive, and a better, more optimized method could probably be implemented. We are also redrawing the entire screen each frame, which could be optimized by only drawing the paddle and any active balls in their new positions using dirty rectangle animation techniques.

Some general game enhancements might include the ability to track high scores, or perhaps show some skill statistics during the game over state. Additional balls can easily be activated in response to certain events, as the game already supports such functionality. It would be easy to tie such events to special blocks, where some blocks add another ball or perhaps increase/decrease the size of the paddle. You could even take this one step further and perhaps give the paddle a laser or other such weapon, or even make blocks that are indestructible or take multiple hits to destroy.

Perhaps the easiest modification would be to provide better graphics, or even different graphic sets depending on the level. These could even be themed; you could have an ice level, or a lava level, or even a water level. Techniques from the special effects chapter or the palettes chapter could be used to make some blocks glow, rotate, fade in and out, etc.

From a usability standpoint, it might be good to provide users with a configuration screen when the application starts so they can specify things like sound volume or skill level. This could include such things as a sound theme, utilizing better sound effects or different sound effects based on the user's preference or level. Context-sensitive music would also improve the feel of the game. You might also want to support input devices other than the mouse, such as the keyboard or joystick. Providing force feedback support would really add a new dimension to this game. If you want to provide this type of configuration while in full screen video mode, a more general architecture should probably be created to support user interface objects like buttons and menus.

A very fun enhancement for this game would be to include multiplayer support. One player could be at the bottom, and the other player could be at the top. This would also allow you to use some artificial intelligence techniques if you allowed the user to play against the computer. Using some of the incredible Internet technology now available in Delphi, it wouldn't be too hard to make this game playable over the Internet.

**The Case Study Code**

The case study itself is presented here in its entirety so that you can see an entire game application laid out in all its glory. The code is heavily commented so as to make it easy to understand. This demonstrates how sound, user input, and graphics come together to form a complete, workable, usable game application.

```
Delphi Blocks
```

```
Author: John Ayres
```

```
Based on the baseline architecture with mouse support, this project is a 'Breakout' style of game. The object is to hit the moving ball with the paddle and destroy all of the blocks on the screen. If the ball goes off of the bottom of the screen, it is lost and a new one is created. You have three balls before the game is over. This is a simple implementation of a game that shows how to use the mouse input functionality of DirectInput in a real-world situation.

## Summary

In this chapter, we discussed how graphics, user input, and sound and music programming techniques come together to create a complete game application. We examined how each part of a game is implemented, including techniques for tracking several sprites as well as using DirectSound and Windows multimedia functions simultaneously. We also looked at various ways to enhance and improve the Delphi Blocks game. When using these techniques to create your own games, it is important to keep these points in mind:

- The state-driven architecture is useful for many styles of games and is easy to implement. More complex games may require an equally more complex architecture, but the concepts are similar.
- Always implement the most natural form of user input for the type of game being developed. For Delphi Blocks, this was the mouse, but for other games, it might be the joystick or keyboard. While not absolutely necessary, it is good programming practice to give the user a choice of input devices.
- Sound and music always enhance a game. Sound for Delphi Blocks was implemented using DirectSound in order to allow for easier modification. However, music was implemented using Windows multimedia functions in order to show how the two can coexist gracefully. This should demonstrate how you can use whatever method is appropriate for your gaming application.
- The simple 2-D graphics in this game use straightforward techniques for implementing the game animation. These techniques are acceptably fast, but could be optimized. However, bear in mind that optimization has a diminishing margin of returns, so only optimize those parts that truly need it.
- While not a commercial quality game, this case study could easily be extended and molded into one within a few weeks. Remember, Delphi can do anything that C can do; you just have to have the knowledge and patience.

## APPENDIX

### Installing DirectX

This appendix covers the following topics:

- Retrieving the version number of the currently installed DirectX
- Installing DirectX components, either in full or in part
- Overriding the default behavior of installation to provide custom status messages and feedback

Before a game written using the DirectX API can be run on a user's system, that system must have DirectX installed. Fortunately, Microsoft allows game developers to redistribute the DirectX run-time components and drivers at no charge. Additionally, they've included methods that make the installation of DirectX largely automated. In keeping with their naming convention for this technology, setup of DirectX components and drivers is accomplished through the DirectSetup API.

In this appendix, we'll examine how the DirectSetup API allows us to install DirectX with a minimum of hassle. We'll also examine ways to determine the current version of DirectX already installed, as well as how to override the default behavior of the installation in order to provide our own interface.

### DirectX Redistributables

DirectX is available from a number of sources. Many computer manufacturers are shipping machines with DirectX already installed. Indeed, future versions of Windows will include DirectX automatically. The DirectX run-time components are also available both online (at Microsoft's web site) as well as part of the installation for hundreds of commercial games and applications.

**Tip:** You may want to suggest that users download the latest DirectX drivers straight from the Microsoft web site as part of your standard technical support. Users can retrieve the end user DirectX files from <http://www.microsoft.com/directx/homeuser/downloads/default.asp> at the time of this writing. Microsoft technical support should also be able to help users if they are having trouble installing DirectX drivers.

If DirectX is already installed on a user's system, it is not necessary to install it again when the user installs your application (unless, of course, the application uses a more current version of DirectX than that currently installed).

Thus, if you are certain that your end users already have DirectX installed, there is no need to worry about the techniques described here. Unfortunately, although Microsoft is taking steps to make it simple for users to upgrade their Windows installation, we cannot always assume that users have DirectX installed on their machines.

Microsoft allows developers to redistribute the run-time portion of DirectX royalty free with our applications. This distribution is subject to the terms of their end user license agreement, also known as an EULA, which accompanies the DirectX SDK. Therefore, you'll need to obtain the DirectX SDK in order to get all of the information and rights necessary for redistributing DirectX. For more information on obtaining the latest DirectX SDK and other DirectX run-time components, please visit <http://www.microsoft.com/directx/developer/downloads/default.asp>.

**EULA:** End user license agreement; a legal document that details specific licensing issues concerning software.

The redistributable files themselves are located in the Redist directory of the DirectX SDK. The license agreement for redistributing DirectX run-time components instructs us that we must not modify DirectX in any way, nor change the files that must be redistributed, with one exception. The DirectX redistributable files come in several localized flavors, and we can leave out any specific language for which we will not support. Thus, if we only want to ship the English language version of DirectX, we need only include the 'eng' directory under the DirectX\Drivers directory of the redistributable files. This may be desirable, as the size of the entire redistributable file set is over 50 MB. Please see the DirectX SDK EULA.txt file that ships with the DirectX SDK for more details concerning redistribution of DirectX with applications.

**Note:** At the time of this writing, the DirectX redistributables cannot be installed under Windows NT. DirectX can only be installed on NT through NT service packs.

---

## DirectSetup

As mentioned previously, DirectSetup is responsible for installing DirectX components on an end user's machine. Unlike the other DirectX subsystems, the DirectSetup API is rather small. There are only a few functions included in this API, and full installation of all DirectX run-time components and drivers can be accomplished by calling one simple function. Alternatively, the default behavior of the entire installation process can be overridden and monitored. The DirectSetup API can make installation of DirectX as simple or as complicated as necessary, giving developers plenty of flexibility in their installation programs.

### Features

DirectSetup provides several techniques by which an application can have a varying degree of control over the installation of DirectX. The following features are of interest to any developer implementing DirectX installation functionality:

- Quick, painless installation of the entire DirectX system, run-time components only, or drivers only through one simple function call
- Ability to override the default behavior of DirectX installation to provide custom status reports and installation query messages
- Testing of the DirectX installation without copying any files into system directories
- Determination of the version of the currently installed DirectX system

In the following sections we will see how DirectSetup is used to install DirectX components in an automated, default manner as well as techniques to override this default behavior to provide additional feedback.

### Functional Overview

The purpose of DirectSetup is to install DirectX in a manner such that it does not inadvertently affect the system. Therefore, it takes a very conservative approach, and by default, it will not replace any driver that is questionable or may impact the system in any negative way. In addition, it also backs up any driver that is replaced, so that the user may reverse the installation and restore the original drivers if necessary.

In contrast to other DirectX subsystems, the DirectSetup API is not a collection of COM components, but rather a small handful of functions. Indeed, our discussion of DirectSetup will encompass only three of these functions: DirectXSetupGetVersion, DirectXSetup, and DirectXSetupSetCallback.

The first function, DirectXSetupGetVersion, is rather simple. It merely retrieves the version and revision numbers of the DirectX components currently installed. This function can be used to determine if the current DirectX version is older than the one included with the application, or if DirectX is installed at all.

---

*Tip:* You can also determine the version of DirectX currently installed on the user's machine using techniques from Chapter 4, An Introduction to DirectX.

---

The second function, DirectXSetup, is perhaps the most important. This function performs the actual installation of all of the DirectX components. Using this function, we can indicate if the entire DirectX system should be installed or only certain parts. Specifically, we can instruct the function to install only run-time components, audio drivers, or display drivers.

The final function, DirectXSetupSetCallback, is used to provide a callback function used by the installation procedure that notifies the application when an installation event occurs. This allows the application to customize the behavior of the installation process and display status messages and message boxes different from the default. This function must be used to install a callback function before the DirectXSetup function is called.

## Using DirectSetup

In what should be a very familiar theme by now, using DirectSetup involves some very specific steps performed in a specific order. Not surprisingly, some of these steps are optional, some are not. In order to use DirectSetup to install DirectX, the application must perform the following:

- Locate the DirectX redistributables in the same directory as the setup application
- Retrieve available drive space
- Retrieve the current version of DirectX (optional)
- Set a callback function (optional)
- Call the DirectXSetup function

### Locate the DirectX Redistributables

More a requirement than a step, this is a task the developer must perform when packaging the application files for distribution. In order to use DirectSetup functions, the DirectX redistributable files must be placed somewhere on the distribution media (presumably a CD). Specifically, the dsetup.dll, dsetup16.dll, and dsetup32.dll must be in the same directory as the setup application so they'll be loaded when the application starts. The other DirectX redistributable files must be located in a directory named DirectX (not case sensitive) which may be located elsewhere, but typically it is more convenient to simply place them in the same directory as the setup application (see below for more details). In the example for this chapter, we placed the redistributables in the same directory as the example code, so refer to the accompanying CD for an example of directory structure.

### Retrieve Available Drive Space

Technically speaking, this step is not an absolute requirement, as the DirectX installation procedure will fail gracefully if it runs out of disk space. DirectX requires a minimum of 15 MB of free space (if you only use one language) on the drive in which Windows is installed. Out of courtesy to your customers, who may be computer novices that could get confused by insufficient disk space error messages during an install, you should always check and inform users if they do not have enough space to install DirectX.

### Retrieve the Current Version of DirectX

Since many machines now have DirectX already installed, either by another application or by the manufacturer, you may want to check to see if the currently installed DirectX version is older than that shipped with your application. If the installed version is more current than the one you are shipping, you can skip DirectX installation altogether.

In order to retrieve the version number, the application must call the `DirectXSetupGetVersion` function. The `DirectXSetupGetVersion` function is defined as:

```
function DirectXSetupGetVersion(  
  
var lpdwVersion: DWORD;           // the version number  
  
var lpdwRevision: DWORD           // the revision number  
  
    : Integer;                     // returns non-zero if successful
```

The first parameter is a `DWORD` variable that will contain the major version number in the high-order word and the minor version number in the low-order word when the function returns. The second parameter is also a `DWORD` variable that will contain the release number in the high-order word and the build number in the low-order word. The minor version number reflects the “commercial” version of DirectX, and will be 6 for DirectX 6 or higher, 5 for DirectX 5, etc.

*Note:* There was no version 4 of DirectX.

---

## Set a Callback Function

If the developer wishes the DirectX installation to proceed using its standard, default behavior, this step can be skipped. However, in order to customize the behavior of the installation process, the application needs to inform `DirectSetup` that it should call a callback function during the installation process. This is accomplished by calling the `DirectXSetupSetCallback` function, which is defined as:

```
function DirectXSetupSetCallback(  
  
Callback: TDSetup_Callback         // pointer to the callback function  
  
    ) : Integer;                   // returns zero
```

Currently, this function only returns zero, whether it succeeded or failed. The only parameter for this function is a pointer to the callback function. This function will be called by the installation process at various times when certain events happen or the user needs to supply additional information. The callback function itself must be defined as:

```
function TDSetup_Callback(  
  
Reason: DWORD;                     // reason flags  
  
MsgType: DWORD;                    // message type flags  
  
szMessage: PChar;                  // message string  
  
szName: PChar;                      // driver name string  
  
pInfo: Pointer                      // additional driver information  
  
    : DWORD; stdcall;              // returns MessageBox return values
```

We’ll examine this callback function in more detail below when we cover techniques for customizing the installation

process.

## Call the DirectXSetup Function

To begin the process of actually copying DirectX system files onto the hard drive and configuring Windows with the new components, we must call the DirectXSetup function. The DirectXSetup function is defined as:

```
function DirectXSetup(  
  
    hWnd: HWND; // parent window handle  
  
    lpzRootPath: PAnsiChar; // DirectX redistributables path  
  
    dwFlags: DWORD // installation control flags  
  
    : Integer; // returns a DirectX error code
```

The first parameter is a handle to a window that will be used as the parent window for any dialog boxes that need to be displayed during the installation. The second parameter is the path for the location of the DirectX redistributable files. Setting this to nil causes DirectSetup to look for the files in the current directory, as described above.

The third parameter is set to a series of flags that indicate how DirectX is to be installed. This controls whether the entire DirectX system will be installed, or only certain parts. The available flags for this parameter are shown in Table A-1. The DirectSetup documentation recommends that applications perform a full install using the DSETUP\_DIRECTX flag. However, an application could provide the user with a method to install only the run-time components or perhaps just audio and/or video drivers in the case of a malfunction or for troubleshooting purposes. Another very useful flag is DSETUP\_TESTINSTALL, which runs through a test installation of DirectX but doesn't actually replace any drivers or copy any run-time components to the system. Using this in conjunction with a callback function allows the developer to make a detailed list of drivers that will be replaced during the installation, which could then be presented to the user in a summary format before the actual installation process began.

**Table A-1:** DirectXSetup control flags

Flag	Description
DSETUP_DDRAWDREV	Installs display drivers only
DSETUP_DIRECTX	Performs a full installation of DirectX
DSETUP_DSOUNDREV	Installs audio drivers only
DSETUP_DXCORE	Installs run-time components only
DSETUP_TESTINSTALL	Performs a test installation without installing files

This function can return a number of error codes that indicate various problems such as insufficient disk space or missing source files. However, the application should specifically watch out for the DSETUPERR\_SUCCESS\_RESTART return value. This indicates that the machine must be rebooted before DirectX functionality will be available. DirectSetup does not automatically inform the user of this, so your installation application will need to do the job. A return value of DSETUPERR\_SUCCESS indicates that installation was successful and no reboot is necessary. See the DSetup.pas file (part of the JEDI DirectX headers) for a complete listing of error codes returnable by DirectXSetup.

## Overriding Default Behavior

If the application did not specify a callback function, calling the DirectXSetup function will launch the installation of DirectX, and it will proceed to install DirectX drivers and components without any intervention from the user or the application. DirectSetup will provide a simple status window to the user, but this is the only feedback it outputs. The following illustration shows the default DirectSetup installation status box.

### **Figure A-1:** Default DirectSetup status message

If any sort of error occurs, such as insufficient drive space, it will not display any message to the user, relying on the application to interpret the return value and display the appropriate message. It also will not ask the user for any sort of confirmation. If it encounters an unrecognized driver or other potential driver incompatibility problem, it simply skips the driver and returns success, without ever bothering the user. As mentioned before, this approach is taken so that the system is not left in an unusable state due to driver conflicts. However, this can lead to an unusable DirectX installation.

Therefore, it might be wise to provide a little more customized feedback to the user, especially if your application is to be widely distributed. As mentioned previously, we should set up a callback function using the `DirectXSetupSetCallback` function. For the sake of completeness (and so you don't have to flip back and forth in this section), the callback function itself is defined as:

```
function TDSetup_Callback(  
  
Reason: DWORD; // reason flags  
  
MsgType: DWORD; // message type flags  
  
szMessage: PChar; // message string  
  
szName: PChar; // driver name string  
  
pInfo: Pointer // additional driver information  
  
: DWORD; stdcall; // returns MessageBox return values
```

The first parameter contains one of several flags that indicate why the callback function was called. These flags are listed in Table A-2 below. As you can see, this callback function is called on several occasions, notably when an error has occurred or when DirectSetup is about to install DirectX drivers or components. Of particular interest is the `DSETUP_CB_MSG_NOMESSAGE` flag. This flag is sent to the callback function merely to provide a method for updating a status bar. When this flag is received, none of the other parameters contain any useful information, and the callback function should return immediately.

<b>Flag</b>	<b>Description</b>
<code>DSETUP_CB_MSG_NOMESSAGE</code>	Update pulse
<code>DSETUP_CB_MSG_CANTINSTALL_UNKNOWNOS</code>	The operating system cannot be determined, and DirectX can't be installed
<code>DSETUP_CB_MSG_CANTINSTALL_NT</code>	Cannot install under Windows NT
<code>DSETUP_CB_MSG_CANTINSTALL_BETA</code>	Pre-release beta version of Windows 95 detected; cannot install DirectX
<code>DSETUP_CB_MSG_CANTINSTALL_NOTWIN32</code>	16-bit version of Windows detected; cannot install DirectX
<code>DSETUP_CB_MSG_CANTINSTALL_WRONGLANGUAGE</code>	The DirectX driver or component is not localized to the installed Windows language
<code>DSETUP_CB_MSG_CANTINSTALL_WRONGPLATFORM</code>	The DirectX driver or component is for another type of computer
<code>DSETUP_CB_MSG_PREINSTALL_NT</code>	DirectX is already installed on this version of NT
<code>DSETUP_CB_MSG_NOTPREINSTALLEDONNT</code>	DirectX cannot be installed on this version of NT
<code>DSETUP_CB_MSG_SETUP_INIT_FAILED</code>	General setup failure
<code>DSETUP_CB_MSG_INTERNAL_ERROR</code>	An internal error has occurred
<code>DSETUP_CB_MSG_CHECK_DRIVER_UPGRADE</code>	A driver is being considered for upgrade

DSETUP_CB_MSG_OUTOFDISKSPACE	Insufficient disk space to install all DirectX components
DSETUP_CB_MSG_BEGIN_INSTALL	Installation has begun
DSETUP_CB_MSG_BEGIN_INSTALL_RUNTIME	Installation of DirectX run-time components has begun
DSETUP_CB_MSG_BEGIN_INSTALL_DRIVERS	Installation of device drivers has begun
DSETUP_CB_MSG_FILECOPYERROR	An error occurred copying a file

The second and third parameters are used when a message should be presented to the user. These values are intended to be used with the MessageBox function, with the MessageType parameter indicating the flags to be used with MessageBox, and the szMessage parameter containing the text of the message to be presented. In any case when MessageType is not zero, the callback function should return a value commensurate with the values returned by the MessageBox function for the flags indicated in the MessageType parameter. Ideally, the callback function will just pass all of this to the MessageBox function, in turn passing its return value back as the return value for the callback. However, the application can display any form of dialog box desired with any type of feedback desired, as long as the callback return value matches that which would be returned by the MessageBox function for the given flags in the MessageType parameter. The sole exception to this rule is that the function can always return zero, in which case DirectSetup will act in a default manner as if no callback function had been specified.

In the case where MessageType is zero, the DirectSetup documentation states that we should always return IDOK. The IDOK return value, in this case, will suppress the default status window displayed by DirectSetup. However, if we return zero when MessageType is zero, the default status dialog box will be displayed. This allows us to display our own status indicator or use DirectSetup's default status indicator as desired.

**Caution:** It is possible through the use of the callback function to provide default responses and install DirectX without any intervention from the user, or even without the user being aware of the installation. This is very bad programming practice, and can potentially lead to an incorrect installation. Always inform the user that DirectX is being installed, and especially give the user the appropriate feedback and options when drivers are being upgraded.

## Verification of Driver Upgrade

The most interesting of all of the reason flags is DSETUP\_CB\_MSG\_CHECK\_DRIVER\_UPGRADE. This indicates that DirectX is considering upgrading a driver, and verification from the user is recommended. The MessageType and szMessage parameters will most certainly contain values indicating the type of message box to display as well as a text description of the problem and recommended user action. The fourth parameter, szName, will contain the name of the driver being considered for upgrade.

The final parameter, pInfo, is a pointer to a TDSetup\_CB\_UpgradeInfo structure that contains additional information about the driver in question. This simple structure is defined as:

```
TDSetup_CB_UpgradeInfo = record
    UpgradeFlags: DWORD;           // driver upgrade information flags
end;
```

The only member of this structure, UpgradeFlags, can contain one or more flags from Table A-3 which indicate the status of the upgrade. Of particular interest are the DSETUP\_CB\_UPGRADE\_FORCE and DSETUP\_CB\_UPGRADE\_KEEP flags. DSETUP\_CB\_UPGRADE\_FORCE indicates that Windows may not function correctly unless the driver is upgraded. In this case, DirectSetup will upgrade the driver regardless of the value returned by the callback function. The DSETUP\_CB\_UPGRADE\_KEEP flag, on the other hand, indicates that Windows may not function correctly if the driver is upgraded. In this case, Direct Setup will not upgrade the driver, again regardless of the return value. Other flags indicate the type of driver being upgraded or other warnings that the user should take into account when deciding to allow or disallow the upgrade.

**Table A-3:** Driver upgrade information flags

Flag	Description
DSETUP_CB_UPGRADE_KEEP	The system may fail if the driver is upgraded
DSETUP_CB_UPGRADE_SAFE	This driver is safe to upgrade; upgrading recommended
DSETUP_CB_UPGRADE_FORCE	The system may fail if the driver is not upgraded
DSETUP_CB_UPGRADE_UNKNOWN	Existing device driver unrecognized; upgrading is not recommended
DSETUP_CB_UPGRADE_HASWARNINGS	Upgrading the driver may affect one or more programs; upgrading is not recommended
DSETUP_CB_UPGRADE_CANTBACKUP	Existing system components cannot be backed up, and therefore cannot subsequently be restored
DSETUP_CB_UPGRADE_DEVICE_ACTIVE	The device driver is currently in use
DSETUP_CB_UPGRADE_DEVICE_DISPLAY	This is a display device driver
DSETUP_CB_UPGRADE_DEVICE_MEDIA	This is a media device driver (typically an audio device)

The following example demonstrates how to use the `DirectXSetup` function in conjunction with a callback function to suppress the default status dialog box as well as provide custom feedback information to the user. It also illustrates how to perform both a test installation as well as a full installation of all DirectX components.

***Listing A-1: Installing DirectX***

```

{this time, we'll perform a full installation of DirectX. we're still
using the ErrorString function as described above}

lbxStatus.Items.Add(ErrorString(DirectXSetup(Handle, nil, DSETUP_DIRECTX)));

{indicate that installation has finished}

lbxStatus.Items.Add('DirectSetup finished');

end;

end.

```

**Figure A-2:** The customized DirectXSetup feedback

## Summary

In this appendix, we discussed how DirectXSetup can automate the task of installing DirectX onto an end user's machine. We examined various installation methods, including the standard, no-frills installation as well as a highly customized installation that overrides the default behaviors of DirectXSetup. We also discussed retrieving the version of the currently installed DirectX, as well as some issues with redistribution of DirectX files. When writing an installation program that uses DirectXSetup to install DirectX components, it is important to keep these points in mind:

- If the version of DirectX installed on the target machine is equal to or more current than the version shipping with your application, there is no need to install DirectX.
- Only those files located in the Redist directory of the DirectX SDK are redistributable with applications. Refer to the DirectX SDK EULA.txt file for more information, or visit <http://www.microsoft.com/directx/developer/downloads/default.asp>.
- The only change to the redistributable files that can be made is that languages unsupported by your application can be left out. This can dramatically reduce the storage requirements for the DirectX redistributable file set.
- Redistributables, and in particular the dsetup.dll, dsetup16.dll, and dsetup32.dll, must be located in the same directory as the installation program.
- The minimum required disk space for DirectX is 15 MB, if you are installing only one language version.
- The minor version number returned by DirectXSetupGetVersion reflects the commercial version of DirectX.
- The DirectXSetup function can perform a full installation of all DirectX components, an installation of specific components (such as run-time components or drivers), or a test installation. The test installation acts like a real installation, except it makes no changes to the system.
- By default, DirectXSetup does not provide any feedback to the user other than a status dialog box, nor does it retrieve confirmation from the user concerning driver replacement. If any driver upgrade would cause any type of problem, it will simply be skipped and the DirectXSetup function will return success, with no indication to the user of any problems encountered.
- A callback function can be specified, which will be called by DirectXSetup at various times throughout the installation process. This allows the application to override default behavior and provide customized feedback to the user.
- If the MsgType parameter of the callback function is anything other than zero, it should return a value commensurate with that returned by the MessageBox function.

- If the MsgType parameter contains zero, the callback function should return a value of IDOK. However, returning a value of zero causes DirectSetup to perform the default action.

## Glossary

### A

**artificial intelligence (AI):**

The concept of cognitive software that thinks and reacts to situations in a sentient manner. In relation to game programming, this is the section of code responsible for determining the actions and reactions of game antagonists in relation to the actions and reactions of the player.

**alpha channel:**

A component of color that records levels of transparency/opacity as opposed to actual color data.

### B

**bitmap:**

A collection of pixels arranged in a rectangular configuration in such a way that they form a recognizable shape, such as a picture or texture.

**BLT:**

bit block transfer. Pronounced "blit," this is the act of copying the pixels of a bitmap image onto the screen or other graphical output surface for display.

### C

**coefficient:**

A measurement of the strength of resistance output by a force feedback device in response to the movement of an axis, relative to the total maximum force available on the device itself.

**color depth:**

A measurement of the number of bits per pixel required to describe the color of an individual pixel.

**condition:**

A resistant force applied to one or more axes on a force feedback device in response to the movement or position of those axes.

## *D*

### **device context (DC):**

Represents the surface of an output device such as a monitor, printer, or plotter, allowing the application to perform graphical output.

### **device-dependent bitmap (DDB):**

An older bitmap image format that stores only height, width, color depth, and image pixels.

### **device-independent bitmap (DIB):**

A flexible bitmap image format that includes all necessary information to accurately reproduce the image on any device.

## *E*

### **end user license agreement (EULA):**

A legal document that details specific licensing issues concerning software.

### **envelope:**

A series of values that shape a force at the beginning and end of playback.

## *F*

### **fade:**

A transition effect where an image slowly appears out of a solid color, such as black or white.

### **finite state machine:**

A logical construction that contains a series of states defining specific behaviors and a series of state transitions defining rules for moving from state to state.

### **frame:**

A single image in a series of images to be animated.

### **Frame animation:**

The process of producing animation by rapidly displaying a series of images depicting an object or character in slightly different positions each frame.

### **force feedback:**

A method by which an input device can output tactile feedback to the user through various actuator motors.

## *G*

### **gain:**

A scaling factor for magnitudes and coefficients, measured in hundredths of a percent.

### **Graphical Device Interface (GDI):**

The Windows subsystem responsible for all graphical output during a Windows session.

## *H*

### **HAL:**

Hardware abstraction layer; the DirectX drivers responsible for direct interface to hardware capabilities.

### **HEL:**

Hardware emulation layer; the DirectX drivers responsible for emulating certain functionality if not present in hardware.

### **hertz (Hz):**

A measurement of samples per second.

### **human/computer interaction:**

The concept of techniques and methods by which humans and machines, primarily computers, exchange information.

## *K*

**kinetic force:**

An active push on one or more axes on a force feedback device.

**L****line:**

A collection of pixels, usually arranged in a linear or connecting configuration.

**M****magnitude:**

A measurement of the strength of a kinetic force output by a force feedback device, relative to the total maximum force available on the device itself.

**masking:**

The act of using two bitmaps, an AND bitmap and an OR bitmap, along with raster operations to draw one bitmap over another while simulating transparent pixels in the source bitmap.

**Microsoft Foundation Classes (MFC):**

Microsoft's object-oriented component hierarchy, similar to Delphi's VCL.

**mixing:**

Combining several sounds in real time in such a way that they can be played simultaneously.

**MIDI (Musical Instrument Digital Interface):**

A digital format for describing music.

**O****overscan:**

The area on a monitor that borders the usable display area.

**P****path finding:**

Algorithmic techniques for determining the shortest, most direct path from a starting position to an ending position based on terrain and obstacles in the game world.

**pixel:**

The smallest, single element in a graphical image or on the display surface.

**polling:**

A method for retrieving input or checking some data value manually (as opposed to letting a separate thread check it automatically), usually repeated often at regular intervals.

**polygon:**

A collection of lines, arranged in such a way that the ends are connected to form a continuous, closed shape.

**POV hat:**

The point-of-view (POV) hat is a device that typically rests on the top of a joystick, and can be used to indicate a viewing direction separate from movement direction.

**primary sound driver:**

The audio output device selected by the user on the Audio tab of the Multimedia control panel applet.

**profiler:**

A profiler is an application that typically measures application execution time. The level at which an application is timed usually varies, from timing the execution of individual lines to the execution time of functions, procedures, or the overall application.

**pulse code modulation (PCM):**

An uncompressed audio format; the most common format for Windows WAV files.

**R****raster graphics:**

Graphics that are composed of a collection of pixels that together form a picture or image. Generally

refers to bitmaps, icons, and other such graphical types.

**raster operation (ROP):**

A Boolean function performed on pixels when they are copied from bitmap to bitmap that determines how the pixels from the source, the destination, and the destination device context's selected brush are combined.

**Red Book Audio:**

The digital format used to store professional music on conventional audio CDs.

**resolution:**

A measurement of the number of pixels displayed on the screen.

**Resource Interchange File Format (RIFF):**

A complex, variable length file consisting of variable length "chunks." Each chunk can describe data or a header (which contains a description of the data following it). Commonly used for multimedia file formats, such as WAV files.

**RGB color:**

Refers to the method by which colors are represented, usually in the form of a red, green, and blue component, respectively.

**S**

**sprite:**

An image that animates and moves around the screen in some fashion. Typically associated with images that the user can interact with, either directly or through interaction with other sprites.

**T**

**texture mapping:**

A general term for algorithms that map a bitmap image onto a geometric shape.

**V**

**vector graphics:**

Graphics that are represented by a series of connected points in a virtual 2-D or 3-D Cartesian (or similar) coordinate system. Generally refers to lines, polygons, curves, and other such graphical types.

**video mode:**

The video hardware state that dictates the display resolution and number of available colors for graphical output.

**Z**

**z-order:**

The position along the z, or third-dimensional, axis. This is an imaginary axis that runs perpendicular to the screen, and gives the illusion of depth.

## Bibliography

There are a lot of great books out there on Windows graphics programming, game programming, and DirectX programming. The information contained in this publication is based in part on research and knowledge gleaned from the following books:

Abrash, Michael. *Michael Abrash's Zen of Graphics Programming*. Coriolis Group, 1996.

Ayres, et. al. *The Tomes of Delphi 3: Win32 Graphical API*. Wordware Publishing, 1998.

Bargen and Donnelly. *Inside DirectX*. Microsoft Press, 1998.

Kawick, Mickey. *Real-Time Strategy Game Programming*. Wordware Publishing, 1999.

Kirk, David. *Graphics Gems III*. Academic Press, 1992.

LaMothe, Andre. *Black Art of 3D Game Programming*. Waite Group Press, 1995.

LaMothe, Andre. *Teach Yourself Game Programming in 21 Days*. SAMS Publishing, 1994.

LaMothe, Ratcliff, et. al. *Tricks of the Game Programming Gurus*. SAMS Publishing, 1994.

Lyons, Eric R. *Black Art of Windows Game Programming*. Waite Group Press, 1995.

Swokowski, Earl W. *Fundamentals of Trigonometry*. PWS-KENT Publishing Company, 1989.

Trujillo, Stan. *High Performance Windows Graphics Programming*. Coriolis Group, 1998.

## Index

### A

- A\*, 457
- absolute measurement, 208
- accessing memory, 184-185
- Acquire, 219
- action games, 13
- adventure games, 13
- AI, *see* artificial intelligence
- algorithms
  - fire, 418
  - painter's, 197
  - path finding, 456-457
  - rotation, 387-388
  - scaling, 383
  - star fields, 412
  - texture mapping, 405
- aligned record fields, 363-364
- alpha channel, 116
- animation, 172-174, *see also* frame animation
  - cycle, 175-177
  - issues, 194-195, 197
  - palette, 164-167
- architecture, 17, 24
  - DirectX, 107-108
- artificial intelligence, 32
- artificial intelligence techniques
  - aggression/evasion, 429-430
  - finite state machines, 437-438
  - movement, 426
  - path finding, 455-456

- patterned movement, 433-434
- probability machines, 446
- random movement, 426
- audible focus, 311-312
- audio buffers, 309, 322-323
  - audible focus, 311-312
  - controls, 336-337
  - creating, 322-326
  - duplicating, 334-335
  - format, 309
  - frequency, 336
  - locking, 324-325
  - memory format, 311
  - memory locations, 310
  - optimum configuration, 310-311
  - pan, 336
  - playing, 325-326
  - static, 323-326
  - streaming, 330-331
  - types, 310
  - unlocking, 325
  - volume, 336
- audio format, 309-310
- automatic compiler optimizations, 362-363
- axes, 207-208, 238, 262

## **B**

- back stepping, 460-461
- background graphics, 19
- baseline application, 142-150
- BGR, 78
- binary bit shifting, 372
- BitBlt, 87
- bitmap manipulation, 378
  - bitmap transformations, 378
  - dynamic images, 412
  - lighting tricks, 392
  - rotation, 387
  - scaling, 383
  - texture mapping, 405
  - transition effects, 396-397
- bitmaps, 74, 86-87
  - device-dependent, 86
  - device-independent, 87
  - direct pixel access, 89
  - displaying images, 87
  - displaying under DirectDraw, 133-135
  - loading, 87, 135
  - masking, 92
  - raster operations, 91
- blitting surfaces, 135
- Blt, 176
- BltFast, 135
- board games, 14
- bounding boxes, 188-189
- breadth first search, 456
- brushes, 82
- buffered data, 208-209
- buffers, *see* audio buffers

buttons, 207-208, 238

## C

C/C++, 5-7, 8-9

calibration, 236

call stack elimination, 362-363

canvas, 81

    drawing on, 82-85

card games, 14

casual gamers, 12

CD audio, 346

    implementing, 347-350

    Red Book Audio, 347

children, 11

coefficient, 260

collision detection, 33, 188

    bounding boxes, 188-189

    pixel overlap comparison, 191-192

color

    components, 78

    depth, 77

    keying, 179-181

    palette, *see* palettes

common subexpression removal, 363

compiler optimizations, 363-364

    automatic, 362-263

Component Object Model (COM), 114-115

    GUID, 115

    reference counting, 115

components,

    color, 78

    DirectX, 108-109

conditions, 260, 271-272

    damper, 273

    friction, 272

    inertia, 273

    spring, 272

constant arrays, 374

constant forces, 273

cooperative levels, 209-210, 217

    DirectDraw, 124

    DirectInput, 209-211, 217

    DirectSound, 314-315

coordinate systems,

    3-D, 413

    Cartesian, 412

coordinates, 81

CopyMode property, 91

crawl, 397

CreateDevice, 215

CreateEffect, 282

CreateEvent, 228

CreatePalette, 157

CreateSoundBuffer, 324

CreateSurface, 128

creating

    DirectDraw objects, 120-121

    DirectInput objects, 212

    DirectSound objects, 314

- effect objects, 282-283
- force feedback effects, 279-285
- input devices, 215
- surfaces, 127-129
- custom forces, 278-279

## D

- damper, 273
- data types, 368-369
- DC, *see* device context
- DDB, *see* device-dependent bitmaps
- dead code elimination, 363
- deadzone, 237
- Delphi and DirectX, 109-112
- Delphi Blocks, 473-474
  - code, 481-514
  - enhancements, 480-481
  - game states, 474-475
  - general game architecture, 474
  - graphics, 477-480
  - music, 476
  - player advancement, 474
  - sound, 476
  - user input, 475-476
- Delphi Games Creator (DGC), 112
- Delphi games development, 7
- Delphi games programming, 5-10
- DelphiX, 111-112
- demo state, 39-40
- depth, 194, *see also* z-order
- depth first search, 457
- device context, 80-81
- device-dependent bitmaps, 86
- device-independent bitmaps, 87
- device-specific effects, 276
- devices, *see also* game controller input, keyboard input, mouse input
  - acquiring, 211, 219
  - audio, 312-313
  - CD audio, 346-347
  - enumerating, 212-214
  - game controllers, 205, 236
  - keyboard, 204, 220
  - MIDI, 341
  - mouse, 205, 224
  - peripheral input, 22
  - polling, 31, 209
  - standard input, 22
- DIB, *see* device-independent bitmaps
- direct pixel access, 89
- Direct3D, 109
- DirectDraw, 108
  - displaying bitmaps, 133
  - features, 113
  - functional overview, 113-114
  - initializing, 118-129
  - rendering with GDI, 129-130
  - retrieving capabilities, 139
  - surfaces, 116
- DirectDrawCreate, 120

- DirectDrawEnumerateEx, 118
- DirectInput, 109, 206
  - buffered data, 208-209
  - buttons and axes, 207-208
  - cooperative levels, 209-211
  - device acquisition, 211
  - features, 206-207
  - functional overview, 207
  - game controller input, 236-237
  - immediate data, 208-209
  - initializing, 211-219, 221, 226
  - keyboard input, 220-223
  - mouse input, 224-225
  - polling and event notification, 209
- DirectInputCreate, 212
- direction, 262-263
- DirectMusic, 109
- DirectPlay, 109
- DirectSetup, 109, 519
  - callback function, 521-523
  - features, 519
  - functional overview, 519-520
  - overriding default behavior, 523-525
  - using, 520-523
  - verification of driver upgrade, 526-527
- DirectSound, 108-109, 307
  - audible focus, 311-312
  - audio format, 309-310
  - buffer memory format, 311
  - buffer memory locations, 310
  - buffer types, 310
  - creating buffers, 322-326
  - features, 307
  - functional overview, 308
  - initialization, 312-316, 320
  - optimum buffer configuration, 310-311
  - sound buffers, 309
- DirectSoundCreate, 314
- DirectSoundEnumerate, 312
- DirectX, 104-106
  - and Delphi, 109-112
  - architecture, 107-108
  - baseline application, 142-150
  - benefits, 106
  - components, 108-109
  - components and headers, 111-112
  - drawbacks, 107
  - HAL, 107
  - HEL, 107
  - redistributables, 517-518, 520
  - result codes, 150
  - SDK, 110
- DirectXSetup, 522
- DirectXSetupGetVersion, 521
- DirectXSetupSetCallback, 522
- display mode, setting, 124-125
- dissolve, 397
- Download, 283
- drawing

- lines, 83
- pixels, 82
- polygons, 83-84
- sprites, 185
- text, 85
- DuplicateSoundBuffer, 334
- duration, 261
- DXErrorString, 150
- dynamic images, 412
  - fire, 418
  - star fields, 412

## **E**

- effects, *see* bitmap manipulation, force feedback, sound effects
- EnumDevices, 213
- EnumDisplayModes, 121
- EnumEffects, 276
- enumerating
  - audio devices, 312-313
  - display devices, 118-119
  - input devices, 212-214
  - supported display modes, 121-123
- EnumObjects, 247
- envelope, 263, 296-297
- EULA, 518
- event notification, 209, 227-228
- exceptions, 365

## **F**

- fade, 166
- females, 11-12
- finite state machines, 437-438
- fire, 418
- first-person shooters, 13
- Flip, 130
- flipping, *see* page flipping
- force feedback, 205, 257
  - axes, 262
  - coefficient, 260
  - condition, 260
  - creating effects, 279-285
  - direction, 262-263
  - duration, 261
  - envelope, 263, 296
  - features, 258
  - functional overview, 258-259
  - gain, 261
  - kinetic force, 259
  - magnitude, 260
  - modifying at run time, 293-294
  - sample period, 261
- force feedback effects, 263-266
  - conditions, 271-273
  - constant forces, 273
  - custom, 278-279
  - device-specific effects, 276
  - periodic forces, 274-275
  - ramp forces, 273-274
- forces,

- constant, 273
- custom, 278-279
- kinetic, 259
- periodic, 274-275
- ramp, 273-274
- frame, 172
- frame animation, 172-173
- frames, rendering, 34
- frequency, 336
- friction, 272
- full-screen mode, 117-118

## G

- gain, 261
- game
  - architecture, 24-27
  - logic, 32
  - markets, 11-12
  - modules, 24-27
  - states, 35-41
  - types, 12-14

- Graphical Device Interface, 70
  - rendering with, 129-130
- graphical elements, 72-76
  - bitmaps, 74
  - classification of, 75
  - lines, 73
  - pixels, 72
  - polygons, 73-74
- graphics, 18-19
- GUID, 115

## H

- HAL, 107
- hardware palette, 160
- hat, *see* POV hat
- HEL, 107
- hertz (Hz), 310
- HPALETTE, 97
- human/computer interaction, 204

## I

- IDirectDraw, 120
- IDirectDrawPalette, 157
- IDirectDrawSurface, 128
- IDirectInput, 212
- IDirectSound, 314
- images,
  - displaying, 87-88
  - loading, 87
- immediate data, 208-209
- inertia, 273
- initialization, 25
- input considerations, 205-206
- input data,
  - reading, 251
  - retrieving, 219-220
- input devices, 204-205, *see also* devices
  - enumerating, 212-214
  - peripheral, 22
  - standard, 22
- interactive images, 19
- intermission state, 40
- internal loop, 38
- IntersectRect, 189
- introduction, 25

## J

- joyGetDevCaps, 239
- joyGetPosEx, 239

## K

- keyboard, 204
  - input, 220-223
- kinetic force, 259

## L

- lighting tricks, 392

- lines, 73
- Lock, 184, 324-325
- locking surfaces, 183-184
- lookup tables, 370-371
- loop induction variables, 363
- loop unrolling, 369
- loops, *see also* game loop
  - internal, 38
- lost surfaces, 138-139

## M

- magnitude, 260
- masking, 92
- MCISendCommand, 340-341
- measurements, 208
- melt, 396
- memory,
  - accessing, 184-185
  - allocation, 373
  - buffer format, 311
  - video board, 78
- Microsoft Foundation Classes (MFC), 2
- MIDI, 341
  - implementing, 341-345
- mixing, 304
- modes,
  - non-palettized, 80
  - palettized, 79-80
- motion, 175-177
- mouse, 205
- mouse input, 224
  - device acquisition, 229
  - DirectInput initialization, 226-227
  - event notification, 227-228
  - mouse cursor responsiveness, 224
  - reading input data, 229-232
  - secondary thread creation, 229
  - Windows functions, 225
- movement, 426
  - aggression/evasion, 429-430
  - patterned, 433-434
  - random, 426
- music, 21, 339-340
  - CD audio, 346-350
  - MIDI, 341-345
  - Red Book Audio, 347

## N

- non-palettized modes, 80

## O

- object method types, 366-367
- Object Pascal, 8
- objects
  - IDirectDraw, 120
  - IDirectDrawPalette, 157
  - IDirectDrawSurface, 128
  - IDirectInput, 212
  - IDirectSound, 314

- TBitmap, *see* TBitmap
- TCanvas, *see* TCanvas
- TDIEffect, 264
- TDIEnvelope, 297
- optimization, 357, *see also* profilers
  - automatic compiler optimizations, 362-363
  - compiler optimizations, 363-364
  - considerations, 373-374
  - Delphi-specific, 361-369
  - general, 369-372
  - theory, 358
- optimum buffer configuration, 310
- overflow checking, 364
- overscan, 159

## P

- page flipping, 116-117, 126-127
- painter's algorithm, 197
- palettes, 79, 95, 156-157
  - and GDI functions, 163
  - animation, 164-167
  - DirectDraw, 157-160
  - disconnecting, 163
  - hardware, 160
  - HPALETTE, 97
  - logical vs. system, 96
  - primary surface, 160
  - TPaletteEntry, 97
  - using, 97
- palettized modes, 79-80
- pan, 336
- Pascal, *see* Object Pascal
- path finding, 455-456
  - algorithms, 456-457
  - back stepping, 460-461
  - basic implementation, 457-460
  - enhancements, 470-471
  - example, 462-470
- paused state, 40
- pens, 82
- periodic forces, 274-275
- peripheral input devices, 22
- pixel checking, 183
- pixel overlap comparison, 191-192
- pixels, 72
- Play, 325
- playing state, 40
- PlaySound, 305
- polling, 30-31, 209
- polygons, 73-74
- POV hat, 216, 238
- primary buffer format, 320-321
- primary sound driver, 313
- probability machines, 446
- profilers, 358
  - effective optimization, 360
  - examining the algorithm, 359
  - timing code, 358
- Project JEDI, 110-111

pulse code modulation (PCM), 309  
puzzle games, 14

## R

ramp forces, 273-274  
range checking, 364  
range, 237  
raster graphics, 75  
raster operations, 91  
real-time event-driven programming, 23  
real-time strategy games, 12-13  
rectangles, manipulating, 189  
Red Book Audio, 347  
reference counting, 115  
register optimization, 362  
relative measurement, 208  
ReleaseDC, 129  
rendering with GDI, 129-130

**Article #10291: Problems with printing, preview and paper size in Quick Reports.**

QUESTION:

I'm having problems with PrintPreview and Paper Size in QuickReports, Is there a fix for this?

ANSWER:

Yes. For Delphi 4 users a QuickReports upgrade to version 3.0.5 for Delphi 4 users is now available from the QuSoft web page at: <http://www.qusoft.com/scripts/download.dll> .

The file is called QR305SD4.EXE. This is the version which shipped with Delphi 5. This version includes some significant bug fixes, including issues with custom page sizes, qr2demo, DIV function, title length, expression wizard and pop-up menu items (right mouse click).

For Delphi 5 users there is now an update to version 5.0.7 available from the same site. This file is called QR307SD5.EXE.

Fixes here include several printer issues, particularly with HP printers which we've heard several reports about. For more detailed information see <http://www.qusoft.com/scripts/download.dll>

Last Modified: 16-DEC-00

## Article #10306: Unidirectional property not supported for all Databases

Question:

What databases support the unidirectional property of a TQuery?

Answer:

Databases that are supported:

Interbase

Oracle

Sybase

MSSQL

Informix

Database that are not supported:

ODBC

DB2

Paradox

Access

dBASE

FoxPro

In databases where the unidirectional property is not supported setting the unidirectional to true does nothing. No error message is generated.

Last Modified: 19-OCT-99

## Article #10307: BDE Error 000F

**Question:** I'm getting BDE Error 000F. What does this mean?

**Answer:** BDE Error 000F usually indicates that the buffer manager ran out of memory, though there may be other causes for this error. Increasing the BDE SHAREDMEMSIZE parameter in BDE Admin may solve the problem, or just delay the error from occurring.

Last Modified: 26-OCT-00

**Article #10308: Help | About for BDE Admin version 5.1 says version 5.1**

Q. How come Help | About for BDE Admin with BDE 5.10 says version 5.01? Is it a bug?

A. For version BDE 5.10 BDE Admin was not recompiled only the version resource was changed. Therefore, Help | About remains unchanged by design.

Last Modified: 27-OCT-99

## **Article #10309: Blobs are not supported as params for a Stored Proc**

Q. Are blobs supported as params (either input or output) to a Stored Proc?

A. No. Trying to do so results in the error "Capability not supported".

Last Modified: 13-FEB-01

## **Article #10310: How do I make a TQuery not use memory as scrolls forward**

Q. I notice that as I scroll my TQuery forward more and more memory is used. How do I prevent this?

A. If your TQuery is forward only cursor, then setting unidirectional to true will resolve the problem.

Note that any memory used by the TQuery is freed when the TQuery is closed.

Last Modified: 01-OCT-99

## **Article #10312: Opening TQuery results in Operation Not Applicable Error**

### Question:

When I open my TQuery, why am I getting an "Operation Not Applicable Error" when my TQuery returns no records?

### Answer:

If you have Unidirectional set to True for your TQuery this error will occur. If you think you may be in this condition, run a select count(\*) query to determine the number of records returned from your Query before running the TQuery.

Note: in Delphi 2 and 3 this condition does not occur.

Last Modified: 19-OCT-99

## **Article #10314: Oracle 8.0.5 client is not supported**

Q. Is Oracle client 8.0.5 supported by the BDE Native driver?

A. No. Due to blob inconsistencies that QA and R&D encountered with this client it is not certified. Version 8.0.4 and 8.1.5 are supported.

"Data Truncated" is a common error that occurs when using the 8.0.5 Client.

Last Modified: 01-OCT-99

## Article #10315: Procedures and Functions in Oracle Packages not listed

**Question:** I have a procedure (or a function) in my Oracle package, but when I get a list of stored procedure names for my TStoredProc it is not listed. Why is this?

**Answer:** Only procedure names listed in *sys.all\_objects* are listed, because returning these results is a fast query. To get a list of procedures in packages, each package would require parsing which would be a slow operation.

Last Modified: 26-OCT-00

## **Article #10317: Different types of dBASE Unique style indexes**

Unique Indexes in dBASE tables have historically operated differently than unique indexes in other databases. Most or all other databases use unique indexes to prevent duplicate entries from being placed in a table. The way dBASE tables have worked is not to prevent duplicate entries from being entered in a table, but to only display unique values in the index when the index is selected.

One side effect of this technique is dealing with deleted records. If you delete the record which displays when the unique index is chosen, no values for the record deleted will be displayed even though they exist in the database until the database is packed.

When Visual dBASE 7 was released it offered a new way to create unique indexes. It added the new option of creating unique indexes which are distinct. Such indexes operate in the manner that most other database operate in that duplicate values are prohibited.

Visual dBASE can create and use either style of index. Delphi and C++ Builder can use either style index, but can only create distinct unique indexes. So, if you need to create unique indexes which are not distinct you must use Visual dBASE to create them.

Visual dBASE is owned by dBASE2000. For additional information on Visual dBASE see [www.dbase200.com](http://www.dbase200.com)

## Article #10318: Table is Full with Paradox Tables

### Question:

I am attempting to add data to my Paradox table but I'm getting the Error "Table is Full". What is the cause of this and how can I add more records?

### Answer:

Paradox tables have a block size which determines the maximum record size for a table and the table's maximum size. By default tables have a block size of 4K. Regardless of the block size, tables can have a maximum of 64K blocks. This means by default a table can grow to 256 MB.

You can increase the block size of a table in 1 of two ways.

1. Run BDE Admin and change the block size for the Paradox driver to a revised number. Legal block sizes are 1024, 2048, 4096, 16384 and 32768. If your block size is larger than 4096 then you must also change level to be at least 5. Finally, create a new table and batchmove your data from your old table to your new table
2. It is possible to change the block size of an existing table by calling dbiDoRestucture. For an example see [www.borland.com/devsupport/bde/files/pxrest.zip](http://www.borland.com/devsupport/bde/files/pxrest.zip)

## Article #10319: TIBQuery.RecordCount doesn't return count of all records

### Question:

When I execute TIBQuery.RecordCount why doesn't it give me a count of all my records in my Query?

### Answer:

TIBQuery.RecordCount does the same thing as TIBSQL.RecordCount. Here is what Help says for TIBSQL.RecordCount:

Use the RecordCount property to see how many records are returned by a query. If the result set is to return 100 rows, RecordCount will only be 100 after all the records have been visited. That is, after looking at the first record, RecordCount is 1, and so forth.

The reason RecordCount operates in this fashion is calculating all the records in a dataset is potentially time consuming operation as it would require scanning through the entire dataset. The most efficient way to calculate the number of records in a dataset is to execute a `SELECT COUNT(*)` statement.

## Article #10320: Use GetResults to get output params from MSSQL and Sybase

### Question:

I'm calling a StoredProc on MSSQL or Sybase that returns a result set and other other output parameters. Why do I never get any values in my output parameters?

### Answer:

For MSSQL and Sybase, parameters are not returned until you go to the end of the result set. You must execute code similar to the following:

```
with StoredProc1 do
begin
  Open;
  Last;
  GetResults;
  //Retrieve output parameters here
end;
```

For more information on GetResults see TStoredProc.GetResults in Delphi or C++ Builder Help.

Last Modified: 19-OCT-99

## Article #10350: Executing Oracle functions

### QUESTION:

Can I execute an Oracle User Function via a Stored Proc?

### ANSWER:

Yes. There are a number of things to remember about this process:

1. Functions cannot be dragged and dropped from SQL Explorer like procedures can.
2. The first parameter in the parameter list (parameter 0) is the return value of the function. The DataType should match the return data type of your function. The name must be Result. The ParamType must be ptResult.
3. If you are creating a TStoredProc dynamically Prepare does not automatically load function parameters with BDE 5.10 like it did with previously with older versions of the BDE. You'll have to use TStoredProc.Params.CreateParam to add all parameters to your TStoredProc.

Last Modified: 18-OCT-99

## **Article #10357: How to query dates using Day-Month-Year using local SQL**

### Question:

How do I query a Paradox or dBASE table using Day-Month-Year instead of Month-Day-Year?

### Answer:

The local SQL engine uses the separator to decide the format of a date. A / is interpreted as M/D/Y. A . is interpreted as D.M.Y.

### Examples:

11/1/99 is November 1, 1999.

11.1.99 is January 11, 1999.

Last Modified: 19-OCT-99

**Article #10359: MS SQL Server 7: "Could not find object" or blank fields.**

**QUESTION:**

What causes BDE Error 8712 "Could not find object" when accessing MS SQL Server 7 table? Other Symptoms could be columns not appearing or blank.

**ANSWER:**

MS SQL Server 7 introduces new field types called NVARCHAR, NCHAR and NTEXT. These types represent Unicode data and are not supported by the BDE.

The workaround is to change these field types to VARCHAR or TEXT.

Please note there are no ODBC drivers which have been certified by Borland which support MSSQL Server 7, only up to MSSQL Server 6.5 (see the Readme.txt file).

We recommend using the ADO components available with Delphi 5 to connect to MS SQL Server 7.

## Article #10385: Non-blob column in table required to perform operation with Oracle

### Question:

Why am I getting the error "Non-blob column in table required to perform operation" when trying to access a BLOB or CLOB with Oracle 8?

### Answer:

TTables and Live TQueries may not allow access to Oracle 8 CLOB or BLOB fields when the user has a role of DBA, EXP\_FULL\_DATABASE, IMP\_FULL\_DATABASE or SELECT\_CATALOG\_ROLE especially if the table was created by a user without one of these roles. Users with these roles return LOB indexes in the list of index definitions because the BDE queries a different set of system views compared to users without these roles.

These LOB indexes do not have corresponding column definitions. The error will occur when the primary key has a name that causes it to be sorted after the LOB indexes in the result set.

The error does not occur for users with roles other than DBA, EXP\_FULL\_DATABASE, IMP\_FULL\_DATABASE or SELECT\_CATALOG\_ROLE.

To determine what roles a the current user has query SYS.USER\_ROLE\_PRIVS.

To determine what roles all users have been granted query SYS.DBA\_ROLE\_PRIVS when logged in as a user with a GRANTED role of DBA, EXP\_FULL\_DATABASE, IMP\_FULL\_DATABASE or SELECT\_CATALOG\_ROLE.

## Article #10432: How do I add a system menu item for the "right click" of the application's task bar icon?

**Question:** How do I add a system menu item for the "right click" of the application's task bar icon?

**Answer:** [FAQ 2054D](#) describes how to add a custom menu item to the system menu of a form, but what if you want to add one to the task bar's right click?

The reason that FAQ 2054D doesn't add anything to the task bar's right click menu is because Delphi creates a hidden window. You have to set the system menu for this hidden window to make it work.

Here is an example of how to do that, and then respond to the proper message:

```
type
  TForm1 = class(TForm)
    procedure FormCreate(Sender: TObject);
  private
    procedure OnAppMessage(var Msg: TMsg; var Handled: Boolean);
  end;

var
  Form1: TForm1;

implementation

const
  SC_MyMenuItem = WM_USER + 1;

{$R *.DFM}

procedure TForm1.FormCreate(Sender: TObject);
begin
  // Assign the application's OnMessage event to my own
  // procedure so I can check for the hidden window's WM_SYSCOMMAND
  // message.
  Application.OnMessage := OnAppMessage;
  AppendMenu(GetSystemMenu(Application.Handle, FALSE), MF_SEPARATOR, 0, '');
  AppendMenu(GetSystemMenu(Application.Handle, FALSE),
    MF_STRING,
    SC_MyMenuItem,
    'My Menu Item');
end;

procedure TForm1.OnAppMessage(var Msg: TMsg; var Handled: Boolean);
begin
  // Check to see if the message is a system command
```

```
// and the message's wParam is SC_MenuItem
if (Msg.message = WM_SYSCOMMAND) and (Msg.wParam = SC_MenuItem) then
begin
    ShowMessage('Got the message');
    Handled := True;
end;
end;
```

## Article #10452: How to handle exceptions in TThread objects

### Question:

I have a TThread object which may raise an exception in the Execute procedure. When an exception is raised, I want to be able to show that exception to the end user. How do I go about doing this in the most efficient way?

### Answer:

With a TThread object, if you don't catch an exception in the Execute procedure of a TThread, you may get access violations. The Delphi IDE may break fine on the exception, but often when the application is run outside of the IDE you get an "Application error has occurred" exception and your application stops running.

If you don't care about showing the end user that an exception occurred, you can simply wrap your Execute procedure with a try..finally block such as:

```
procedure TMyThread.Execute;  
begin  
  try  
    // Do your thread stuff here  
  except // Eat all exceptions  
  end;  
end;
```

Quite often, this isn't the best solution and you will want to show the message to the end user, or allow your application to further process the message.

The easiest way to do this, is to add an Exception object to your TThread class, and call the appropriate handler based on the type of exception. Here is an example of how to do this. The project consists of one form with a Button placed on it:

```
unit Unit1;  
  
interface  
  
uses  
  Windows, Messages, SysUtils, Classes,  
  Graphics, Controls, Forms, Dialogs, StdCtrls;  
  
type  
  TForm1 = class(TForm)  
    Button1: TButton;
```

```

    procedure Button1Click(Sender: TObject);
private
    { Private declarations }
public
    { Public declarations }
end;

TMyThread = class(TThread)
private
    FException: Exception;
    procedure DoHandleException;
protected
    procedure Execute; override;
    procedure HandleException; virtual;
public
end;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TMyThread.DoHandleException;
begin
    // Cancel the mouse capture
    if GetCapture <> 0 then SendMessage(GetCapture, WM_CANCELMODE, 0, 0);
    // Now actually show the exception
    if FException is Exception then
        Application.ShowException(FException)
    else
        SysUtils.ShowException(FException, nil);
end;

procedure TMyThread.Execute;
begin
    FException := nil;
    try
        // raise an Exception
        raise Exception.Create('I raised an exception');
    except
        HandleException;
    end;
end;
end;

```

```
procedure TMyThread.HandleException;
begin
  // This function is virtual so you can override it
  // and add your own functionality.
  FException := Exception(ExceptObject);
try
  // Don't show EAbort messages
  if not (FException is EAbort) then
    Synchronize(DoHandleException);
finally
  FException := nil;
end;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  // Create an instance of the TMyThread
  with TMyThread.Create(True) do
  begin
    FreeOnTerminate := True;
    Resume;
  end;
end;

end.
```

## **Article #10476: Delphi doesn't run after installing using a Read-Write CD drive**

### **Question:**

I just installed Delphi using a Read/Write CD drive. It took an unusually long time to install, and now it doesn't run - it just gives an error message. How can I fix this problem?

### **Answer:**

It appears that some Read-Write CD Drives don't work quite right when trying to install Delphi. They may take an unusually long time to install, with the CD-ROM 'clicking' as it does a reading-stopping-reading process. There is a known problem with HyVal IDE drive causing this problem.

The solution is to install a new driver for the RW-CD that hopefully doesn't have the problem. Or, you can try installing from a traditional CD-ROM drive instead of the RW-Drive. If you are on a network, another alternative is to 'Map' someone else's CD-ROM drive and install Delphi from this mapped drive.

## Article #15002: 'General SQL Error -2147221164 Table: Alias:<Alias Name>'

Question and Answer Database

FAQ2B.txt      'General SQL Error -2147221164 Table: Alias:<Alias Name>'  
Category      :Database (MSACCESS)  
Platform      :Win95/NT  
Product       :

Question:

"General SQL Error -2147221164 Table: Alias: "  
error: I get this error when I try and open a MSACCESS  
database. What is the problem?

Answer:

This problem seems to be closely related to a DAO DLL versioning  
problem. The easiest way to resolve this is to un-install Office  
97 from Control Panel | Add/Remove Programs. There is information  
related to this problem in Microsoft's knowledge base  
<http://www.microsoft.com/kb/articles/q141/2/94.htm>

## Article #15004: Application Server Forms

Question and Answer Database

FAQ4D.txt      Application Server Forms  
Category      :DCOM/MultiTier/ActiveForm  
Platform       :All  
Product        :Delphi 3.x

Question:

Do I need a form in the application server?

Answer:

Yes. It doesn't need to be visible, but you do need one.  
To make the form not visible, set  
Application.ShowMainForm := False in the project file.

Example project source:

```
begin
  ?Application.ShowMainForm := False;?
  Application.Initialize;
  Application.CreateForm(TForm1, Form1);
  Application.Run;
end.
```

## Article #15012: 'Syntax error in query. Incomplete query clause'

Question and Answer Database

FAQ12B.txt 'Syntax error in query. Incomplete query clause'  
Category :Database (MSACCESS)  
Platform :Win95/NT  
Product :

Question:

"Syntax error in query. Incomplete query clause" error:  
I get this error when I run a query against a table with a space in the table name. I have double quotes around the name but it still does not work. What am I doing wrong?

Answer:

You need to change the double quotes " " to brackets [ ]

Example:

```
SELECT * FROM "MY TABLE NAME" needs to change to  
SELECT * FROM [MY TABLE NAME]
```

## Article #15014: Re-executing export From Table

Question and Answer Database

FAQ14D.txt Re-executing export From Table

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

After using the right-click to create the provider function, how can I re-execute the context menu option to "Export from Table"?

Answer:

Once you have exported a provider interface, the context menu option is no longer visible. To re-display the context menu option you must delete the associated property in the Type Library Editor and press the Type Library Editors Refresh button. You should also delete the "Get\_XXX" entry in the RemoteDataModule source.

## Article #15021: 'Can't delete or change record. Since related record exists in table ='xxx'

Question and Answer Database

FAQ21B.txt 'Can't delete or change record. Since related record exists in table ='xxx'

Category :Database (MSACCESS)

Platform :Win95/NT

Product :

Question:

"Can't delete or change record. Since related record exists in table ='xxx', referential integrity rules would be violate" error: What causes this error and how do I get around the problem?

Answer:

The problem is that referential integrity is currently not supported with the MSACCESS driver. Borland recognizes this as a problem and is working on a solution. Currently, the only workaround is to remove referential integrity from the MSACCESS tables. You can see this behavior with Access 95 by changing the RI value in the master table to the same value and trying to post. Access 97 has fixed this problem.

## Article #15032: Single and multiple application server instances

Question and Answer Database

FAQ32D.txt      Single and multiple application server instances  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

Question:

What is the difference between single and multiple instance application servers in a multi-tier application?

Answer:

This can best be thought of from the point of view of the application server and how many clients can it support. One multi-instance server can support multiple clients. A single instance server can only support one client. Multi-instance servers create multiple data modules in one instance of the server. Single instance servers are launched for each client.

## Article #15039: Other non-BDE file needed to access Microsoft Access databases

Question and Answer Database

FAQ39B.txt      Other non-BDE file needed to access Microsoft Access databases

Category        :Database (MSACCESS)

Platform        :Win95/NT

Product         :

Question:

What other software do I need to access Microsoft Access databases and tables?

Answer:

You must have Microsoft's DAO version 3.0 drivers installed. BDE 4.00 and 4.01 does not support DAO 3.5 (Access 97). If you upgrade Access 95 to Access 97, DAO 3.0 still resides on your machine, so the driver will function correctly. If you install Access 97 with no prior version of Access 95, the driver will not function.

## Article #15041: Locating the servers available in the registry

Question and Answer Database

FAQ41D.txt    Locating the servers available in the registry  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

Question:

How do I locate the application servers available in the registry of the machine?

Answer:

Read the registry key under HKEY\_CLASSES\_ROOT\CLSID\\* looking for keys that have a subkey "Borland DataBroker". These entries are application servers. Here's an example that loads application server names to a Listbox.

```
procedure TForm1.FormCreate(Sender: TObject);
var

uses Registry;
    I: integer;
    TempList: TStringList;
begin
    TempList := TStringList.Create;
    try
        with TRegistry.Create do
            try
                RootKey := HKEY_CLASSES_ROOT;
                if OpenKey('CLSID', False) then
                    GetKeyNames(TempList);
                CloseKey;
                for I := 1 to TempList.Count - 1 do
                    if KeyExists('CLSID\' + TempList[I]
                        + '\Borland DataBroker') then
                        begin
                            if OpenKey('CLSID\' + TempList[I] + '\ProgID', False)
                                then begin
                                    Listbox1.Items.Add(ReadString(''));
                                    CloseKey;
                                end;
                        end;
            end;
        end;
    end;
end;
```

```
        end;  
    end;  
finally  
    Free;  
end;  
finally  
    TempList.Free;  
end;  
end;
```

## Article #15050: Logging in to the remote datamodule

Question and Answer Database

FAQ50D.txt    Logging in to the remote datamodule  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

Question:

How is the UserName and Password passed to the remote datamodule?

Answer:

On the RemoteDataModule, drop a TDatabase and add an automation procedure (use Edit | Add To Interface) for login. Make sure that the HandleShared property is True on the TDatabase.

```
procedure Login(UserName, Password: WideString);  
begin  
  { DB = TDatabase }  
  
  { Something unique between clients }  
  DB.DatabaseName := UserName + 'DB';  
  DB.Params.Values['USER NAME'] := UserName;  
  DB.Params.Values['PASSWORD'] := Password;  
  DB.Open;  
end;
```

After you have created the automation method on the RemoteDataModule (using Edit | Add To Interface), you can call that method using;

```
RemoteServer1.AppServer.Login('USERNAME', 'PASSWORD');
```

## Article #15057: Current MSACCESS driver limitations

Question and Answer Database

FAQ57B.txt Current MSACCESS driver limitations

Category :Database (MSACCESS)

Platform :Win95/NT

Product :

Question:

What restrictions are there on the MSACCESS driver?

Answer:

BCD (binary coded decimal) support is not available.

Key violation tables cannot be created with DbAddIndex.

(All other DbAddIndex functionality is supported.)

QBE, heterogeneous queries, and queries using the local SQL engine are not supported.

In the SDK, DbDoRestructure and DbRegenIndex are not available.

Opening a table when TTable.Exclusive is set to True prevents the user from opening that table again, even in same session.

## Article #15059: Database login for multiple clients

Question and Answer Database

FAQ59D.txt Database login for multiple clients

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

### Question:

Since the middle tier is doing the database access on behalf of multiple thin clients, do we lose the ability to associate a particular database user ID with a particular human user? This would seem to be a problem if you want to grant different access rights to different groups of users at the database level.

### Answer:

Yes, if you want to use one connection to the database for all clients. If you want, you can have the clients login to the database. To do this, create an automation method on the RemoteDataModule that takes the user name and password and use that to login to the database. Also, drop a TSession on your RemoteDataModule and set it's AutoSessionName property to True.

FAQ77D.txt     Minimizing Connections  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

Question:

How can I demonstrate the use of fewer database connections than clients using our three-tier application? For example, I would like to show 10 clients using no more than 5 database connections.

Answer:

Actually, you can have all 10 clients use 1 database connection. Put a TDatabase on the RemoteDataModule and set HandleShared to True. The database will login once no matter how many clients are connected to your application.

**?Note: Be sure to check your licensing agreement with the database server vendor. The fact that it's possible doesn't unburden you of any licensing obligations you may have.?**

## Article #15084: 'Cannot Load IDAPI Service Library' error

Question and Answer Database

FAQ84B.txt 'Cannot Load IDAPI Service Library' error  
Category :Database (MSACCESS)  
Platform :Win95/NT  
Product :

Question:

"Cannot Load IDAPI Service Library" error: What does this error mean and how can I resolve it?

Answer:

If Access 95 or Office 95 was not used to load the DAO 3.0 engine on the machine, the cause is a missing registry entry. To fix this, place the following entry in the registry:

key name: HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Shared Tools\DAO  
string: Path  
value: (path to your DAO3032.DLL)

Another cause of this error is if the registry is set to read only. The only workaround for this cause is to either make the registry read / write, or make that particular entry read / write.

## Article #15085: Accessing InterBase thru an AT service

Question and Answer Database

FAQ85C.txt      Accessing InterBase thru an AT service

Category      :Database Issues

Platform       :All

Product        :C++Builder 1.x

Question:

I have an app that, thru BDE, updates an InterBase table. From the command-line it runs fine. But if I try to run it thru an AT service I get:

```
Error connecting to db: Unknown user name or password.
unavailable database. Alias: myalias
```

How can I make this work?

Answer:

First, as you are probably already doing, you need to set the following properties on your Database object:

```
MyDatabase->AliasName = "myalias";
MyDatabase->LoginPrompt = false;
MyDatabase->Params->Add("USERNAME=SYSDBA");
MyDatabase->Params->Add("PASSWORD=masterkey");
```

Then, you will need to install BDE 4.0, the one that ships with Delphi 3.0.

And finally, you will need to set the AT service to be interactive, like:

```
AT 11:30 /INTERACTIVE c:\myexe
```

```
7/2/98 10:32:32 AM
```

## Article #15093: 'Translate error, value out of bounds' error

Question and Answer Database

FAQ93B.txt 'Translate error, value out of bounds' error  
Category :Database (FoxPro)  
Platform :Win95/NT  
Product :

Question:

"Translate error, value out of bounds" error with blank date fields: What causes this error and how do I get around the problem?

Answer:

Fox Pro stores one of three things in a date field:

An actual date (ex 19970727 is 7/27/1997)  
8 Spaces (ASCII 20)  
8 Zeros (ASCII 30)

All of these are acceptable to Fox Pro. The Fox Pro driver for the BDE only accepts 1 & 2 as valid dates and returns a translate error for the 3rd (8 ASCII zeros) as it doesn't consider this as a valid date. To fix the problem, restructure the date field to a char field and then restructure the table again changing the char field back to a date field. This translation writes back only valid values to the date field and fixes the problem.

## Article #15095: Moving the application server to another machine

Question and Answer Database

FAQ95D.txt     Moving the application server to another machine  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

### Question:

When server is moved to a different machine the client machine is not able to communicate or rather find the server. I know it needs to be registered as well with the server machine but how?

### Answer:

When you move the server to another machine you need to do 2 things.

- 1) Register the server.     SERVER.EXE /REGSERVER
- 2) Change the ComputerName property of the TRemoteServer to point to the name of the server.

## Article #15104: Using Multiple Servers

Question and Answer Database

FAQ104D.txt Using Multiple Servers  
Category :DCOM/MultiTier/ActiveForm  
Platform :All  
Product :Delphi 3.x

### Question:

It appears that only one remote data module will work reliably in a project. Is this case?

### Answer:

No. You can have multiple Remote Data Modules in a project. The caveat is that multiple Remote Data Modules should not access one another because you can't count on the other Remote Data Modules being created or know what state they're in. Remote Data Modules are created on demand when a client requests one. You can use regular data modules to partition the application and access those from the RDM.

7/16/98 4:31:28 PM

## Article #15111: Paradox table version level

Question and Answer Database

FAQ111B.txt Paradox table version level

Category :Database (Miscellaneous)

Platform :All Windows

Product :

Question:

When I create a Paradox Table in the Database Desktop and request a Paradox Version 7 table, the request is not honored. How can I work around this?

Answer:

The Database Desktop will create a table with the lowest version that will handle the tables needs and is declared in the BDE Administrator (IDAPI Configuration utility) under the Configuration>Drivers>Paradox>Level setting. To get a Version 7 table in the Database Desktop, simply use a version 7 feature. To permanently change the Paradox Table level for all tables made by the Database Desktop, go to the BDE Administrator and go to the Configuration>Drivers>Paradox>Level setting and change it to 7.

Example for changing the level of a Paradox Table in the Database Desktop:

Use the restructure option in Database Desktop to create or modify an index to use unique or descending attributes.

## Article #15138: BDE network installation

Question and Answer Database

FAQ138B.txt - BDE network installation

Category :Install Issues

Platform :Win95/NT

Product :

Question:

I want to put the entire BDE DLLs and configuration files on our LAN. Is this possible and is there an easy way to setup the client machines? I don't know what the registry settings are for the BDE.

Answer:

[www.borland.com/devsupport/bde/files/bdenet.zip](http://www.borland.com/devsupport/bde/files/bdenet.zip) has a BDE network installation example that allows a user to setup the BDE and SQL Links on a client machine without having to install the BDE and SQL Links to the client. Registry entries are placed into the client machines so that the client can access a network version of the BDE. Two programs are included: one which helps configure the .INI file that is necessary to create the registry entries, and another program that shows how the methods work to create the registry entries.

This is not officially supported by Borland. It was developed by Developer Support to help in BDE network installations.

## Article #15158: DBCLIENT.DLL

Question and Answer Database

FAQ158D.txt      DBCLIENT.DLL  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

Question:  
What is the role of DBClient.DLL?

Answer:

DBCLIENT.DLL contains the low-level implementation of TClientDataSet. It manages all of the data and implements functionality like filters, sorting, etc. The relationship between TClientDataSet and DBCLIENT.DLL is very similar to the one between TTable and the BDE. The functionality is surfaced through two COM interfaces (DSBase & DSCursor) and requires OLE registration. If DBCLIENT.DLL is placed in any directory on the path or in the EXE directory on the client machine, it will automatically be registered by the VCL code in TClientDataSet. Otherwise it must be registered using REGSVR32.EXE or TREGSVR.EXE.

## Article #15167: Modifying application server SQL from the client.

Question and Answer Database

FAQ167D.txt - Modifying application server SQL from the client.

Category :DCOM/MultiTier/ActiveForm  
Platform :All-32Bit  
Product :

Question:

Is it possible to modify the TQuery.SQL property when it resides in a remote data module?

Answer:

Yes. There are three different avenues to accomplish this:

1. If it is a parameterized query, you can use the IProvider.SetParams call. Assuming you have 2 parameters (Param1 and Param2). The following code fragment demonstrates matching by index, Value1 goes to the first parameter, etc...

```
ClientDataSet1.Provider.SetParams(VarArrayOf(Value1, Value2));
```

Or matching by param name:

```
var  
  V: Variant;  
  ParamCount: Integer; //used for ease of reading  
begin  
  ClientDataSet1.Close;  
  ParamCount := 2;  
  V := VarArrayCreate([0, ParamCount - 1], varVariant);  
  V[0] := VarArrayOf(['Param1',Value1]);  
  V[1] := VarArrayOf(['Param2',Value2]);  
  ClientDataSet1.Provider.SetParams(V);  
  ClientDataSet1.Open;  
end;
```

For more example code see \demos\midas\setparam.

2. If you want to change the SQL, then you can use the `IProvider.DataRequest` method.

On the Client;

```
CDS.Data := CDS.Provider.DataRequest('select * from customer');
```

On the server, you must use a `TProvider` object, and assign the `OnDataRequest` event;

```
function TForm1.Provider1DataRequest(Sender: TObject;  
  Input: OleVariant): OleVariant;  
begin  
  //assumes DataSet is a TQuery.  
  Provider1.DataSet.Close;  
  TQuery(Provider1.DataSet).SQL.Text := Input;  
  Provider1.DataSet.Open;  
  Result := Provider1.Data;  
end;
```

For more example code see `\demos\midas\adhoc`.

3. Create you own interface function that executes the SQL statement.

In the `RemoteDataModule`:

a. Edit | Add To Interface "procedure `ExecSQL(SQL: WideString);`" This will add a procedure to your interface.

b. On the server, code the new procedure:

```
procedure RemoteData.ExecSQL(SQL: WideString);  
begin  
{ Query1 is kept in the RemoteDatamodule for this purpose}  
  Query1.SQL.Text := SQL;  
  Query1.ExecSQL;
```

end;

c. On the client, call the new procedure:

```
RemoteServer1.AppServer.ExecSQL('Delete from deal details  
  where dealnumber=1');
```

## Article #15176: Displaying a bitmap on the client area of an MDI parent form.

Question and Answer Database

FAQ176D.txt - Displaying a bitmap on the client area of an MDI parent form.

Category :Windows API  
Platform :All-32Bit  
Product :

Question:

How do I display a bitmap to the client area of an MDI parent form?

Answer:

Here are the necessary steps to add wallpaper to a MDI parent form:

Create a new project  
Set the form's FormStyle to fsMDIForm  
Drop an image on the form and select a bitmap into it.  
Find the { Private Declarations } comment in the form's definition and add these lines right after it:

```
FClientInstance : TFarProc;  
FPrevClientProc : TFarProc;  
procedure ClientWndProc(var Message: TMessage);
```

Find the "implementation" line and the {\$R \*.DFM} line that follows it. After that line, enter this code:

```
procedure TMainForm.ClientWndProc(var Message: TMessage);  
var  
    Dc : hDC;  
    Row : Integer;  
    Col : Integer;  
begin  
    with Message do  
        case Msg of
```

```

WM_ERASEBKGDND:
begin
  Dc := TWMEraseBkGnd(Message).Dc;
  for Row := 0 to ClientHeight div Image1.Picture.Height do
    for Col := 0 to ClientWidth div Image1.Picture.Width do
      BitBlt(Dc,
        Col * Image1.Picture.Width,
        Row * Image1.Picture.Height,
        Image1.Picture.Width,
        Image1.Picture.Height,
        Image1.Picture.Bitmap.Canvas.Handle,
        0,
        0,
        SRCCOPY);
      Result := 1;
    end;
  else
    Result := CallWindowProc(FPrevClientProc,
      ClientHandle,
      Msg,
      wParam,
      lParam);
  end;
end;

```

In the OnCreate method for the form, type the following lines of code:

```

FClientInstance := MakeObjectInstance(ClientWndProc);
FPrevClientProc := Pointer(GetWindowLong(ClientHandle,
  GWL_WNDPROC));
SetWindowLong(ClientHandle,
  GWL_WNDPROC, LongInt(FClientInstance));

```

Add a new form to your project and set its FormStyle property to fsMDIChild.

Now you have a working MDI project with "wallpaper" where the image bitmap is tiled to cover the MDI form's client area.

## Article #15185: ServerName property (TMidasConnection or TRemoteServer)

Question and Answer Database

FAQ185D.txt ServerName property (TMidasConnection or TRemoteServer)

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

I get the impression that in order to register the server interfaces with the client I have to execute the server at each client. Is this true?

Answer:

No. On the client, fill in the ComputerName and ServerGUID properties of the TRemoteServer. This allows the GUID to be located in the remote computer's registry in the CLSID section. The GUID will have a ProgID section containing the server name that is used to populate the ServerName property of TRemoteServer drop down list.

## Article #15218: MS SQL error '17824 Unable to write to ListenOn connection ...

Question and Answer Database

FAQ218B.txt MS SQL error '17824 Unable to write to ListenOn connection ...

Category :Database (MSSQL)

Platform :Win95/NT

Product :

Question:

What would cause error:

MS SQL Server error "17824 Unable to write to ListenOn connection 'xxx', loginname 'xxx', hostname 'xxx'."

Answer:

PROBLEM:

After establishing a number of concurrent application connections to the MS SQL Server the following error is encountered:

MS SQL Server error "17824 Unable to write to ListenOn connection 'xxx', loginname 'xxx', hostname 'xxx'."

POSSIBLE CAUSE:

It is possible that the PROCEDURE CACHE percentage is set too low. Please see your MS SQL Server documentation and NT Event Viewer for more information on debugging network errors and tuning your MS SQL Server's PROCEDURE CACHE.

Relevant SQL Server options:

MAX PROCEDURE CACHE ...

MAX WORKER THREADS

PROCEDURE CACHE

The procedure cache holds entries for each procedure and other maintenance overhead.

Settings for the PROCEDURE CACHE include:

MAX PROCEDURE CACHE ACTIVE %

MAX PROCEDURE CACHE USED%

PROCEDURE CACHE USED%

MAX WORKER THREADS

The max worker threads option allows control over the number of threads allocated to the user pool.

## Article #15227: Performance with two or more queries

Question and Answer Database

FAQ227B.txt Performance with two or more queries

Category :Database (MSSQL)

Platform :All

Product :Applies to all

Question:

Using MSSQL, or Sybase for that matter, why does a second simple select query run more slowly than a preceding query.

Answer:

MS SQL has a "pending result sets" behavior where the 1st query will only retrieve a small set of records (usually enough to fill a grid or any other data aware controls), and there will be a pending result set. The second query causes that pending result set to be retrieved. This can be tested by closing the first query before running the second or connecting each query to a TDatabase. The BDE uses a "special" connection type that is restricted to one per database connection. When a second query is run within the same database connection, the BDE must fetch and cache the previous query's records before starting the next query.

Suggestions:

Close the first query before opening the second

Use multiple databases, one per query

Use a more restrictive where clause to limit the number of records

Use a more restrictive domain result to retrieve only the fields you need

## Article #15236: 'Memo too large' error with MSSQL

Question and Answer Database

FAQ236B.txt 'Memo too large' error  
Category :Database (MSSQL)  
Platform :Win95/NT  
Product :

### Question:

Using BLOB I/O an error, 'Memo Too Large' is returned. The error is: General SQL Error: 7134, unmapped [text: text table and table reference by the text pointer disagree.]. This is not a problem if the table does not contain a unique index. In this case all BLOB information is retrieved through the execution of the query. What does this error mean and how can I resolve it?

### Answer:

A fix to MSSQL server is available from Microsoft:

<ftp://ftp.microsoft.com/bussys/sql/transfer/sql265i.exe> - Intel Patch  
or

<ftp://ftp.microsoft.com/bussys/sql/transfer/sql265a.exe> - Alpha Patch

The password to use when extracting the files is "6.50.265" (without the quotation marks). To extract with the password, the syntax is:  
`sql265i.exe -s6.50.265`

## Article #15238: TCP/IP: TMidasConnection, Socket Server

Question and Answer Database

FAQ238D.txt TCP/IP: TMidasConnection, Socket Server

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

How does the socket server (\bin\Scktsrvr.exe) interact with TMidasConnection?

Answer:

The socket server is something like a service that replaces DCOM, but without the security. When a client application sets Connected = True on a TMidasConnection, the socket server on the server machine creates the remote data module. Then it takes the IDispatch invoke and GetIDsOfNames methods and marshals them through the socket connection, using TCP/IP.

**Article #15253: 'Vendor initialization failure: ORANT71.DLL' error.**

Question and Answer Database

FAQ253B.txt 'Vendor initialization failure: ORANT71.DLL' error

Category :Database (Oracle)

Platform :Windows NT

Product : BDE versions prior to 5.0

Question:

When attempting a connection to Oracle using the BDE Oracle SQL Links driver, why am I getting the error, Vendor initialization failure: ORANT71.DLL, when the driver's Vendor Init parameter is set to ORA73.DLL [or ORA72.DLL]?

Answer:

The BDE always searches the path first for the DLL specified in the Vendor Init parameter and if that fails, the BDE searches, by default, for ORANT71.DLL. Thus the Vendor Init error means that the BDE failed to find and load the DLL you specified and ORANT71.DLL.

## Article #15255: TCP/IP: Load balancing, OLE Enterprise

Question and Answer Database

FAQ255D.txt TCP/IP: Load balancing, OLE Enterprise

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

If I use TMidasConnection with the sockets (TCP/IP) transport, can I still take advantage of OLE Enterprise load balancing and fail over? Would I then have to install OLE Enterprise on the client machines?

Answer:

You can take advantage of OLE Enterprise without installing it on the clients machines. Just set up the server (the machine running SCKTSRVR.EXE) as a OLE Enterprise client. That way, when a request comes in from a real client, SCKTSRVR will attempt to create the object, and OLE Enterprise will intercept and provide the service.

## Article #15262: 'External Exception C0000008' or 'Access Violation'

Question and Answer Database

FAQ262B.txt 'External Exception C0000008' or 'Access Violation'  
Category :Database (Oracle)  
Platform :All  
Product :Applies to all

Question:

"External Exception C0000008" or "Access Violation" error with 2.3.3 SQL NET client: I get an Access Violation with Delphi 3 and an External Exception error with Delphi 2 when connecting to an Oracle server when in Delphi's IDE or Turbo Debugger with NT4. If I run the application alone, it executes correctly. How do I get around the problem?

Answer:

Borland has determined that this is a problem with SQL NET 2.3.3. Oracle also recognizes this as a SQL NET problem. There are a couple of workarounds:

Rename or remove the registry entry

HKEY\_LOCAL\_MACHINE\SOFTWARE\ORACLE\OTRACE73

This is the solution that Oracle support recommends!  
Start Oracle's Installer and remove the "Oracle Trace collection Servces 7.3.3.x.x"

Turn off Integrated Debugging in Delphi's IDE

Use an Oracle SQL NET that is older than 2.3.3

## Article #15264: TCP/IP: Retrieving Client IP and Host Name

Question and Answer Database

FAQ264D.txt - TCP/IP: Retrieving Client IP and Host Name

Category :DCOM/MultiTier/ActiveForm  
Platform :All-32Bit  
Product :

Question:

At client, how can I get the IP address or host name of itself.

Answer:

The following example requires using the Winsock API encapsulated in WinSock.pas.

```
uses
  WinSock;

procedure GetHostInfo(var Name, Address: string);
var
  WSADATA: TWSADATA;
  HostEnt: PHostEnt;
begin
  { no error checking... }
  WSASStartup(2, WSADATA);
  SetLength(Name, 255);
  Gethostname(PChar(Name), 255);
  SetLength(Name, StrLen(PChar(Name)));
  HostEnt := gethostbyname(PChar(Name));
  with HostEnt^ do
    Address := Format('%d.%d.%d.%d', [
      Byte(h_addr^[0]),
      Byte(h_addr^[1]),
      Byte(h_addr^[2]),
      Byte(h_addr^[3])]);
  WSACleanup;
end;
```

## Article #15273: Error: "Application is not licensed to run this feature"

Question and Answer Database

FAQ273D.txt Error: "Application is not licensed to run this feature"

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

"Application is not licensed to run this feature" error when running demo application from \demos\db\clientds.

Answer:

This error occurs when attempting to use Delphi 3 Client/Server features from Delphi 3 Professional or Standard editions. This could happen if you compiled the demos using a compiler other than the one that comes with Delphi 3 C/S. Check that the Delphi 3 Professional was not installed previously without first being un-installed. To correct this situation, uninstall Delphi, double check for leftover Delphi files, and finally re-install Delphi 3.0 C/S.

## Article #15280: 'ct\_cursor(CLOSE); user api layer: external error

Question and Answer Database

FAQ280B.txt     'ct\_cursor(CLOSE); user api layer: external error  
Category       :Database (Sybase)  
Platform       :Win95/NT  
Product        :

Question:

SELECT INTO statment returning error "ct\_cursor(CLOSE); user api layer: external error: A cursor must be opened before this command type can be intialized." What is wrong and how do I get around the problem?

Answer:

The Sybase CTLIB client will always parse a passthrough sql statement weather or not we (Delphi, BDE, SQL Links, etc.) issue an 'open' or 'exec'. If a SELECT is found to be the **FIRST** word, it (Sybase CTLIB) will try to create a cursor hence the error message. There is a workaround. Place a comment in front of the SQL text like so:

CHANGE

```
select * into #temptable from oldtable
```

TO

```
/**/select * into #temptable from oldtable
```

## Article #15289: 'External Exception C0000008' error on application exit

FAQ289B.txt 'External Exception C0000008' error on application exit

Category :Database (Sybase)

Platform :Windows NT

Product :Delphi

### Question:

I get an External Exception error in Delphi when connecting to Sybase server when in Delphi's IDE or Turbo Debugger with NT4 running the 10.0.4 Sybase client. If I run the application alone, it executes correctly. How do I get around the problem?

### Answer:

In NT4.0 anything that is being debugged with any debugger will cause the OS to report exceptions that would otherwise be ignored. "External Exception C0000008" one of those types of errors. Changing the Sybase client version will solve the problem. You can move back to the 10.0.3 client.

## Article #15305: Hetergenious joins

Question and Answer Database

FAQ305B.txt Hetergenious joins  
Category :Database (Miscellaneous)  
Platform :All  
Product :Applies to all

Question:

Hetergenious joins: How do I join files from differing alias (heterogeneous joins) using a SQL statment?

Answer:

For each server table, a connection must exist before the query is executed. A TDatabase can be used to establish the connection.

The SQL statement must use real alias names, as set up in the BDE configuration utility, not DatabaseName properties from a TDatabase.

The SQL syntax should be formatted as follows: a double quote, a colon, a real alias name, a colon, the table name, and a double quote. See example below.

Leave the DatabaseName property of the TQuery blank, unless the alias is local. For example, specifying DBDEMOS in the Query's DatabaseName property will work, but using IBLOCAL will cause a general SQL error.

Example:

```
SELECT A.ITEMNO, B.VENDORNO  
FROM ":DBDEMOS:ITEMS" A, ":IBLOCAL:VENDORS" B  
WHERE A.VENDORNO = B.VENDORNO
```

## Article #15313: File Extensions for dBASE and Paradox tables

Question and Answer Database

FAQ313B.txt    File Extensions  
Category     :Database (Miscellaneous)  
Platform     :All  
Product      :Applies to all

Question:

What are the file extensions for dBASE and Paradox tables?

Answer:

File Extensions for Paradox Tables.?

.DB        Paradox table?  
.FAM      listing of related files (like a table's .TV file)?  
.LCK      Lock file?  
.MB       Blob file?  
.PX       Primary index?  
.TV       Table view settings (not used by BDE)?  
.VAL      Validity checks and referential integrity?  
.Xnn      Secondary single-field index, numbered?  
.Ynn      Secondary single-field index, numbered?  
.XGn      Composite secondary index ?  
.YGn      Composite secondary index ?

File Extensions for dBASE Tables?

.DBF      dBASE table  
.DBT      Memos for a dBASE table  
.MDX      Maintained index of a dBASE table  
.NDX      Non-maintained index of a dBASE table  
.TVF      Table view settings for a dBASE table

## Article #15321: Unsupported Expression Indexes

Question and Answer Database

FAQ321B.txt      Unsupported Expression Indexes

Category        :Database (FoxPro)

Platform        :Win95/NT

Product         :

### Question:

What types of FoxPro indexes are not supported by the BDE?  
When trying to open some tables, I get an "Invalid Index Descriptor" error.

### Answer:

This error occurs when the production index (.CDX) associated the table has an index tag which has an expression which the BDE cannot evaluate. The solution is to delete the tag using FoxPro create an equivalent index that the BDE can understand.

The following conditions are not supported by the BDE and will cause "Invalid Index Descriptor" error.

DTOC(, 1) format not supported; Use DTOC().

ALLTRIM function not supported; Use LTRIM(RTRIM(Field)).

## Article #15329: 'Insufficient memory for this operation' error

Question and Answer Database

FAQ329B.txt 'Insufficient memory for this operation' error

Category :Database (Miscellaneous)

Platform :All

Product :Applies to all

### Question:

Whenever I attempt to open many query or table cursors, I finally reach a point when I get an error, "Insufficient memory for this operation". What do I do?

### Answer:

First, you should read the technical document at

[www.borland.com/devsupport/bde/ti\\_list/TI2751.html](http://www.borland.com/devsupport/bde/ti_list/TI2751.html)

Some current internal limits of BDE. This document will tell you what most of absolute BDE limits are.

IMPORTANT: If your application is not reaching one of the limits covered there and you are also getting the above error message, most likely the SHAREDMEMSIZE setting in the BDE will solve your problem. This setting will allow you to increase the BDE's internal object memory pool. A setting between 4096 and 8192 should be more than plenty.

## Article #15331: Error: 'Missing Data Provider or Data Packet'

Question and Answer Database

FAQ331D.txt     Error: 'Missing Data Provider or Data Packet'  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

Question:

Why does the error "Missing Data Provider or Data Packet" occur?

Answer:

The error occurs when the ClientDataSet can't resolve to a Provider reference on the application server or if the Provider doesn't return records. Check that the TClientDataSet ProviderName is filled in.

Background info: The error message originates in DBConsts.pas as a constant SNoDataProvider which in turn shows up in DBClient.pas (the unit that supports TClientDataSet). The error is triggered in two situations:

- 1) When the TClientDataSet.Provider can't obtain a reference to a provider through the RemoteServer component.
- 2) When the Provider doesn't return records to the TClientDataSet (during TClientDataSet.OpenCursor).

## Article #15337: Sybase SQL Anywhere update mode

Question and Answer Database

FAQ: FAQ337B - Sybase SQL Anywhere update mode

Category: Database (ODBC)

Platform: All-32Bit

Product:

Question:

I am using Sybase SQL Anywhere version 5.5 and I want to be able to set the UpdateMode for my dataset (Query or Table) to be upWhereKeyOnly. When I watch SQL Monitor to see the update logic used, it appears to act like UpdateMode is set to upWhereAll. Why can't I update by key only?

Answer:

This problem has to do with the fact that primary key indexes are not surfaced by SQL Anywhere in the BDE. If you run the stored procedure sp\_statistics with your table name as a parameter(ex. sp\_statistics customer), it should return all indexes on the table specified. Doing this you will see that the index on the primary key doesn't surface a index name.

The way to correct this is by configuring your DSN for SQL Anywhere to allow keys to be seen. This is done by checking the check box titled Microsoft Applications(Keys in SQL statistics) in the Additional Connection Options Section of the ODBC Configuration dialog for SQL Anywhere. After setting this, when you connect to your SQL anywhere database you will be able to see primary keys and UpdateMode will work as expected.

## Article #15344: Error connecting to an Oracle 7.x server using the Oracle 8 client and BDE 5.

Question and Answer Database

FAQ344B.txt Error connecting to an Oracle 7.x server using the Oracle 8 client and BDE 5.

Category :Database (Oracle)

Platform :All

Product :BDE 4.0

### Question:

I am trying to use BDE 5.0 and the Oracle 8 client software to connect to my Oracle 7.x server. I created a new alias and when I attempt to retrieve data using it, I am getting the error ORA-12663 "Services requested by client not available on server." All of the Oracle supplied tools connect and let me see data. What is wrong?

### Answer:

First, be sure you are using at least v8.0.4 of the Oracle client. Next be sure that in your Oracle alias for your 7.x server, you set the 'Object Mode' setting to false. When you create new Oracle aliases in BDE administrator with BDE v5.0, the Object mode parameter is set to true regardless of what DLL32 (SQLORA8.dll or SQLORA32.dll) you have selected. For aliases that will reference Oracle 7.x servers, Object Mode must be set to false for correct operation.

## Article #15346: Error: 'RPC Server is unavailable'

Question and Answer Database

FAQ346D.txt     Error: 'RPC Server is unavailable'

Category     :DCOM/MultiTier/ActiveForm

Platform     :All

Product      :Delphi 3.x

Question:

The client machine displays error "RPC Server is unavailable".

Answer:

The error is usually caused because the server can't be located. Make sure you can ping the server machine using the string you typed into the ComputerName property of the TRemoteServer. You might also want to try using an IP address instead in case there is some problem with your DNS configuration or the hosts file. Try setting the "Default Authentication Level" to (Run DCOMCNFG on the server to do this.) Lastly, check the Microsoft Developer's Network on the Web for the latest information on this Microsoft transport. The MSDN can be located at the time of the writing at [www.microsoft.com/msdn](http://www.microsoft.com/msdn).

## Article #15372: 'Insufficient memory to complete operation' error

Question and Answer Database

FAQ372B.txt 'Insufficient memory to complete operation' error  
Category :Database (Miscellaneous)  
Platform :All  
Product :BDE

### Question:

"Insufficient memory to complete operation" error when attempting various BDE / Database operations: What is wrong?

### Answer:

More than likely, you have hit one of the BDE fixed, but configurable, memory limitations. Use the BDE Administrator (BDEADMIN.EXE) to increase MEMSIZE and SHAREDMEMSIZE settings. You might also want to re-evaluate the application hitting this limitation because it is likely that the application is a serious resource hit on the machine. Not using auto-create forms and only opening tables and queries when needed can free up resources.

## Article #15374: Error: 'Windows Socket Error: (10060), on API 'connect?'

Question and Answer Database

FAQ374D.txt     Error: 'Windows Socket Error: (10060), on API 'connect?'  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

### Question:

I have a 3 tier app. using the TMidasConnection. I can connect to the server app when I use a client machine within the local net. I can also connect to it if I dial in directly into the local net. But, if I try to connect via the Internet (through an ISP) I get the error "Windows Socket Error: (10060), on API 'connect'". While connected to the ISP, I can ping my server machine, but the component does not see it.

### Answer:

You are probably running into the firewall. If the server is not outside the firewall sometimes you can use a Port # > 1024 to access it, but you should check with your IS department.

Product      :Applies to all

### Question:

Accessing the PDOXUSRS.NET file on Novell drive takes 7-10 seconds with Windows 95 Client to Novell. Occurs with any BDE client.

### Answer:

Problem only occurs with Novell client. Microsoft is OK. So, the simplest solution is to switch to Netware client. Also, according to Novell the problem only occurs with Windows 95. Windows NT is fine.

Novell has a discussion of this problem on their web site. It may be found by going to [support.novell.com/search/kb\\_index.htm](http://support.novell.com/search/kb_index.htm), search on [pdoxusrs.net](http://pdoxusrs.net), then select the document called "slowness when launching Paradox on Windows 95"

Here is the solution this document states:

```
Cache writes = off
Close Behind Ticks=0
File Caching=0
Lock Delay=1
Lock Retries=1
Read Only Compatibility= on
True Commit=On
Opportunistic Locking=off (with the older client)
```

## Article #15381: Connection Checklist

Question and Answer Database

FAQ381D.txt      Connection Checklist  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

Question:

What kinds of things can I check for every time I deploy a multi-tier application?

Answer:

Note: This list is not intended to be inclusive, but covers some of the most often missed items.

### ?On the Server?

- Export all dataset interfaces by right clicking the dataset components and selecting the "Export from .." context menu option.
- Rebuild the application.
- If you're running TCP/IP as the transport layer, run `\bin\Scktsrvr.exe` on the server.

### ?On the Client?

1. If possible, verify your connectivity setup. If you're using TCP/IP, you can ping the server from the client.
2. On the TRemoteServer or TMidasConnection:
  - Verify the ComputerName.
  - If the application is on another computer, verify the GUID.
  - If local, verify the ServerName.
  - Verify that you can set `Connected = true`.
  - If using TMidasConnection, check that your `ConnectType` matches the connectivity you have set up (i.e. `ctSockets` for TCP/IP, etc).
3. Verify that each TClientDataSet `ProviderName` and `RemoteServer` properties are set.

Also, check that you have needed files on both client and server and that they are registered.

See: "Files and components for Borland MIDAS"

[www.borland.com/midas/papers/components.html](http://www.borland.com/midas/papers/components.html).

## Article #15387: 'Invalid BLOB handle' error

Question and Answer Database

FAQ387B.txt 'Invalid BLOB handle' error

Category :Database (Miscellaneous)

Platform :All

Product :BDE 4.0

Question:

"Invalid BLOB handle" error: What is the cause and how do I fix this error?

Answer:

If the error occurs on a non-live (dead, canned) query or a table with no indexes, then increasing the new BDE 4.x configuration parameter 'BLOBS TO CACHE' will fix the problem. This setting determines how many BLOBs will be cached on the client. Applications that deal with fetching dead BLOBs using dead table opens or queries can set a limit on the number of BLOBs to cache depending on the resource available on the client. Setting a value 100 means the application can work with a maximum of 100 BLOB records cached. Fetching more than 100, then scrolling back 100 records results in an "Invalid BLOB handle in record buffer" error message.

NOTE:This parameter does not apply to live table opens.

Default Value: 64

Range: 64 to 65536

## Article #15389: Displaying a list of constraint error messages

Question and Answer Database

FAQ389D.txt     Displaying a list of constraint error messages

Category        :DCOM/MultiTier/ActiveForm

Platform        :All

Product         :Delphi 3.x

Question:

How can I show a list of constraint error messages to the user on the client, correct the errors and re-post at one time?

Answer:

You can only ever have one failed constraint at a time. For example, if you have 3 record level constraints and they are all going to fail when you post, then you will get an exception when you post that corresponds to the first constraint that failed. From there, you can't get the second constraint that failed until you fix the problem with the first one and attempt to re-post.

## Article #15394: Checking for NULL in OnUpdateData handler

Question and Answer Database

FAQ394D.txt      Checking for NULL in OnUpdateData handler

Category        :DCOM/MultiTier/ActiveForm

Platform        :All

Product         :Delphi 3.x

Question:

How can I tell if a user has changed a string field to null in the OnUpdateData event handler? How can I differentiate between a field that was changed to a null string and a field that was not changed at all.

Answer:

Use the NewValue property on the TField when reading the second record (the one which contains the edits). If the returned variant is empty (or Unassigned) then that field was not modified. Here is some code that demonstrates this:

```
var
  NewVal: Variant;
begin
  NewVal := DataSet.FieldByName('MyStrField').NewValue;
  if VarIsEmpty(NewVal) then
    ShowMessage('Field was not edited')
  else if VarIsNull(NewVal) then
    ShowMessage('Field was blanked out')
  else
    ShowMessage('New Field Value: ' + String(NewVal));
end;
```

If you look at the source for the RecError form (in the repository), you will see how it uses this information to display the '' string when showing the reconcile errors. On the server you add record level constraints using the constraints property of your TQuery/TTable or field level constraints using persistent TField objects (either CustomConstraint or ImportedConstraint). If you use field level constraints, they are enforced when data is posted to the field (i.e. when you tab out of a data aware

control associated with the field).

## Article #15401: Benefits of the ConstraintBroker

Question and Answer Database

FAQ401D.txt Benefits of the ConstraintBroker

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

What are the main benefits of the ConstraintBroker?

Answer:

The ConstraintBroker allows you to include check constraints with the data. That means that when you request the data, you get the rules. Those rules are automatically and codelessly enforced. Since they are codelessly enforced, you don't have to re-write or update your application if the rule changes. In fact, this is a simple way of updating the client application without shutting it down. Every application that uses the ConstraintBroker automatically has this feature.

## Article #15408: Getting the Win95 Desktop ListView Handle

Question and Answer Database

FAQ408D.txt Getting the Win95 Desktop ListView Handle

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get a handle to the Windows 95 Desktop to access the Desktop icons?

Answer:

The Windows 95 Desktop is overlaid with a ListView component. You simply need to get a handle to the ListView. Example:

```
function GetDesktopListViewHandle: THandle;
var
  S: String;
begin
  Result := FindWindow('ProgMan', nil);
  Result := GetWindow(Result, GW_CHILD);
  Result := GetWindow(Result, GW_CHILD);
  SetLength(S, 40);
  GetClassName(Result, PChar(S), 39);
  if PChar(S) <> 'SysListView32' then Result := 0;
end;
```

Once you have the handle, you can use the list view-related API functions in the CommCtrl unit to manipulate the desktop. See the LVM\_xxxx messages in the Win32 online help.

For example the following line of code:

```
SendMessage(GetDesktopListViewHandle, LVM_ALIGN, LVA_ALIGNLEFT, 0);
```

will align the desktop icons to the left side of the Windows 95 desktop.

## Article #15414: Deploying Midas

Question and Answer Database

FAQ414D.txt    Deploying Midas  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

Question:

Once I'm done developing an application server, how do I deploy to a dedicated PC?

Answer:

You need to purchase a MIDAS license for the application server. When you purchase a MIDAS license you receive a CD with the MIDAS suite for install. You need to install the EXE's and DLL's that you created for your app, the rest (which also includes the runtime packages, BDE, SQL Links, etc.) are installed by the MIDAS software.

## Article #15420: Table data subset through IProvider

Question and Answer Database

FAQ420D.txt Table data subset through IProvider

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

How can I position a TTable and get data from that starting position from the Provider?

Answer:

Using TQuery and Provider.SetParams is preferred. However, it is possible to do this with TTable. First have the client retrieve only the meta-data from the table by setting PacketRecords = 0, then calling Open. Next call an automation method on the server (you must define this method), which will cause the table to be positioned on the desired record. Finally, set PacketRecords to some value greater than zero, and call GetNextPacket.

## Article #15426: TProvider Component vs. Provider Property

Question and Answer Database

FAQ426D.txt TProvider Component vs. Provider Property

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

What is the purpose of the TProvider component vs. the Provider property of the dataset? When would the TProvider component be necessary?

Answer:

The Provider property of the dataset is an interface of type IProvider. A TProvider is not required, you can just use DataSet.Provider. Look at TDBDataSet.GetProvider for how it gets the IProvider. TProvider is useful, if you need any of the events.

This example will open a client dataset looking at a TTable on the same form.

?

```
uses BDEProv;  
...  
procedure Button1Click(Sender: TObject);  
begin  
    ClientDataSet1.Provider := Table1.Provider;  
    ClientDataSet1.Open;  
end;  
?
```

## Article #15432: How do I make changes to the VCL code?

Question and Answer Database

FAQ432D.txt    How do I make changes to the VCL code?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I make changes to the VCL code?

Answer:

Note: Custom changes to the vcl are not supported by Borland or Borland Developer Support.

-But if you choose to do so...

VCL source code changes should never be made to the interface section of a unit. VCL source code changes should only be made to the implementation section.

The safest way to make changes to the VCL is to create a new directory called "patched". Copy the VCL file you want to change to the new directory. Make your changes (with comments) to the copied file. Next, add the path to your patched directory to the beginning of your library path. Restart Delphi/C++ Builder, and rebuild your project.

The library path setting can be found off the main menu of:

Delphi 1 : Options | Environment | Library

Delphi 2 : Tools | Options | Library

Delphi 3 : Tools | Environment Options | Library

C++ Builder : Options | Environment | Library

## Article #15438: Providing lookup capability

Question and Answer Database

FAQ438D.txt Providing lookup capability

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

How do I provide lookup capability using ClientDataSets?

Answer:

Add an automation method to the server which can perform the lookup for you and return the result. You could do this in the OnGetText method of a TField object. Then you would just use a regular TDBEdit instead of a data aware component like the TDBLookupComboBox. Some master tables that change infrequently you may want to store locally. With the data stored locally you could use an automation method to check for changes and refresh the client if necessary.

## Article #15443: Reading the autoincrement value of Paradox table

Question and Answer Database

FAQ443B.txt Reading the autoincrement value of Paradox table

Category :Database (Miscellaneous)

Platform :All

Product :Applies to all

Question:

How is the next autoincrement value determined for a Paradox table?

Answer:

The current highest value is stored beginning at byte 73 decimal. The next value is determined by adding 1 to it.

Here is a simple Delphi function that returns the current autoincrement value.

```
function getAutoInc(filename : string) : LongInt;
var
    mystream : tfilestream;
    buffer : longint;
begin
    mystream := tfilestream.create(filename,
                                   fmOpenread + fmShareDenyNone);
    mystream.Seek(73, soFromBeginning);
    mystream.readbuffer(buffer, 4);
    mystream.Free;
    getAutoInc := buffer;
end;
```

## Article #15445: MasterSource/MasterFields behavior

Question and Answer Database

FAQ445D.txt MasterSource/MasterFields behavior

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

Are MasterSource/MasterFields like a filter in the sense that the ClientDataSet retrieves all records and filters for those records that match the linked fields?

Answer:

It really depends on how you have it set up. If you set PacketRecords to -1 then yes, that is the way it works. If you have PacketRecords to 0 and FetchOnDemand as True, then it will use Provider.SetParams and fetch just the records that match the master.

## Article #15450: The ordinal 237 could not be located ..

Question and Answer Database

FAQ450B.txt     The ordinal 237 could not be located ..

Category     :Database (Oracle)

Platform     :Win95/NT

Product      :

### Question:

I'm attempting to connect to Oracle and I'm getting the error "The ordinal value 237 could not be located in the dynamic link library ORA73.DLL"

### Answer:

This error occurs when you have a working install of Oracle other than version 7.3.2 and then install MTS and switch VENDOR INIT in BDE Admin to MTXOCI.DLL.

The error occurs because MTS installs version 7.3.2 of ORA73.DLL to WindowsSystem32.

To solve the problem rename ORA73.DLL in Windows/System32 and make sure ORA73.DLL is in your path.

## Article #15457: Problem using Oracle 8 driver(sqlora8.dll) with Oracle 7.x servers

Question and Answer Database

FAQ457B.txt      Problem using Oracle 8 driver(sqlora8.dll) with Oracle 7.x servers

Category        :Database(Oracle8)

Platform        :Win95/NT

Product         :

### Question:

I am trying to use BDE 5.0 and the Oracle 8 client software to connect to my Oracle 7.x server. I created a new alias and when I attempt to retrieve data using it, I am getting the error ORA-12663 "Services requested by client not available on server." All of the Oracle supplied tools connect and let me see data. What is wrong?

### Answer:

First, be sure you are using at least v8.0.4 of the Oracle client. Next be sure that in your Oracle alias for your 7.x server, you set the 'Object Mode' setting to false. When you create new Oracle aliases in BDE administrator with BDE v5.0, the Object mode parameter is set to true regardless of what DLL32(SQLORA8.dll or SQLORA32.dll) you have selected. For aliases that will reference Oracle 7.x servers Object Mode must be set to false for correct operation.

## Article #15459: Resource Usage

Question and Answer Database

FAQ459D.txt     Resource Usage  
Category     :DCOM/MultiTier/ActiveForm  
Platform     :All  
Product      :Delphi 3.x

### Question:

How is memory used differently when a remote datamodule is created as a single vs. multiple instance?

### Answer:

A single instance server is going to require more memory for each additional client because the OS must create a whole new process and duplicate all of the data storage space. A multi-instance server will only require as much memory as used by the remote data module and DBCLIENT.DLL for data. The best way to figure out how much this is to use the task manager in NT4.0 and examine the memory used before and after client #2 connects.

## Article #15464: How much does MTS improve connect times?

Question and Answer Database

FAQ464B.txt      How much does MTS improve connect times?

Category        :Database(MTS)

Platform        :Win95/NT

Product         :

Question:

I've heard MTS Pooling can improve second and subsequent connect times to Oracle and MSSQL. Can you tell me more about the speed improvements?

Answer:

In small tests done in Developer Support, we have seen the following for second a subsequent connects:

Oracle 8, MTS ON, Average Connect Time: .13 seconds

MSSQL, MTS ON, Average Connect Time: .13 seconds

Oracle 8, MTS OFF, Average Connect Time: .45 seconds

MSSQL, MTS OFF, Average Connect Time: .65 seconds

## Article #15471: Phantom records appear on post

Question and Answer Database

FAQ471B.txt Phantom records appear on post

Category :Database (Oracle)

Platform :Win95/NT

Product :

Question:

I'm using an Oracle 8 database and I'm getting a duplicate copy of my record whenever it is posted. What is the cause?

Answer:

This occurs when using the Oracle 7 client to connect an Oracle 8 database. This is an unsupported configuration.

The Oracle 8 SQL Links 5.0 driver was tested using the Oracle 8.0.4 client (OCI).

We recommend using the Oracle 8 SQL Links driver and Oracle 8.0.4 client when connecting to an Oracle 8 server.

## Article #15497: General SQL Error, Can't load MSJTER32.DLL

Question and Answer Database

FAQ497B.txt    General SQL Error, Can't load MSJTER32.DLL  
Category     :Database (MSACCESS)  
Platform     :Win95/NT  
Product      :

### Question:

How come I'm getting a General SQL Error about not being able to load MSJTER32.DLL when trying to connect to Access?

### Answer:

MSJTER32.DLL comes with Access 95. The most common cause of this error is when DLL32 in BDEADMIN is configured to connect to Access 95 DAO and the Access 97 DAO is installed. To configure BDEADMIN to use the Access 97 DAO, Select the Configuration Tab, Configuration: Drivers: Native: MSACCESS and set DLL32 to IDDA3532.DLL.

Another way to get this error is if BDEADMIN is configured to connect to the Access 95 DAO and the Access 95 DAO is not installed. Obtain the Access 95 DAO from Microsoft.

## Article #15504: Single Tier Applications

Question and Answer Database

FAQ504D.txt Single Tier Applications

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

How do I set up a single tier application using Client Datasets?

Answer:

Currently, the only way to activate a client dataset at design time is to associate it with a provider, to load data from a file, or to assign data from another dataset. Typically, for a single tier application you would create the dataset at runtime using the CreateDataSet method.

Here is how you might code the FormCreate and FormDestroy methods:

?

### ?OnFormCreate:?

```
if FileExists('MYDATA.CDS') then
  ClientDataSet.LoadFromFile('MYDATA.CDS')
else
begin
  ClientDataSet.FieldDefs.Add('Field1', etc.);
  ClientDataSet.FieldDefs.Add('Field2', etc.);
  ClientDataSet.CreateDataset;
end;
```

### ?OnFormDestroy:?

```
if ClientDataSet.Active then
begin
  // Next line is optional,
  // if you don't want undo support you could
  // set LogChanges = False instead.
```

```
ClientDataSet.MergeChangeLog;  
ClientDataSet.SaveToFile('MYDATA.CDS');  
end;  
?
```

Once you've run the app once and created the data file, you can easily load it at design time (from the right-click component menu) if you need to have the dataset active at design time for some reason.

## Article #15509: Preventing windows task switching

Question and Answer Database

FAQ509D.txt Preventing windows task switching

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I prevent task switching (Alt-Tab, Ctrl-Esc, Ctrl-Alt-Del) in my application?

Answer:

Preventing a user from switching to another application is possible under Windows 95 and earlier versions of Windows by tricking Windows into thinking the screen saver is running. This method does not work under Windows NT, and is not guaranteed to be available in future versions of Windows. Many versions of Windows may also respond to a task switching trap installed by a CBT (Computer Based Training) application hook. To prevent task switching under Windows NT, you will need access to a third party keyboard device driver.

The following code will trick Windows into believing that the screen saver is running:

```
var
  OldValue : LongBool;
begin
  {turns the trap on}
  SystemParametersInfo(97, Word(True), @OldValue, 0);

  {turns the trap off}
  SystemParametersInfo(97, Word(False), @OldValue, 0);
end;
```

7/16/98 4:31:28 PM

## Article #15514: Using Stored Procedures

Question and Answer Database

FAQ514D.txt Using Stored Procedures  
Category :DCOM/MultiTier/ActiveForm  
Platform :All  
Product :Delphi 3.x

Question:

How do I use stored procedures in a multi-tier environment?

Answer:

You'll need to get the provider interface and set the parameters before trying to open the client dataset. Unfortunately there is no way to do this at design time, but it should work OK at run time. Here is some code that shows basically what you need to do:

?

```
procedure TDBClientTest.Button3Click(Sender: TObject);
var
  Params: Variant;
begin
  ClientData.Provider := RemoteServer1.GetProvider
('ProviderName');
  Params := VarArrayCreate([0, 1], varVariant);
  Params[0] := VarArrayOf(['@InParam1', 101]);
  Params[1] := VarArrayOf(['@InParam2', 'test_param']);
  ClientData.Provider.SetParams(Params);
  ClientData.Open;
end;
?
```

This example assumes the stored procedure takes 2 parameters, and binds them by name. If you need to update the data returned from a stored procedure, you will need to use a TUpdateSQLProvider.

## Article #15519: Testing IDispatch Descendants

Question and Answer Database

FAQ519D.txt    Testing IDispatch Descendants

Category     :DCOM/MultiTier/ActiveForm

Platform     :All

Product      :Delphi 3.x

Question:

Is there a minimal test I can perform to test the validity of the GUID, and that the interface descends from IDispatch (and therefore supports automation methods)?

Answer:

Call `CreateRemoteComObject` and use the name of the computer and the GUID you are trying to connect to. If it returns an error, this indicates a server problem, otherwise a client problem.

?

```
const
  MyGUID = '{444...111}'; //Whatever the guid is...
var
  Unk: IUnknown;
  Disp: IDispatch;
begin
  { Make sure this line works correctly }
  Unk := CreateRemoteComObject('server1',
    StringToGUID(MyGUID));
  { If it does, then cast it to a IDispatch }
  Disp := Unk as IDispatch;
end;
?
```

If this works and problems remain, then you'll need to step through your client code and see where it is failing. If not, then run the server in the debugger and connect with the client, then you should be able to debug near to where it fails.

## Article #15529: Drag and Drop with Files

Question and Answer Database

FAQ529D.txt Drag and Drop with Files

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I accept files that are dropped on my application?

Answer:

You must interface with the Windows Shell API module to let Windows know that your application accepts dropped files (this can be done in your main form's create event), and then you must respond to the drag events as they happen by creating an event handler.

The following is an example of a Delphi form that accepts dropped files and adds the names of the files to a memo component:

```
unit Unit1;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, StdCtrls;

type
  TForm1 = class(TForm)
    Mem1: TMemo;
    procedure FormCreate(Sender: TObject);
  private
    procedure WMDROPPFILES(var Message: TWMDROPPFILES);
      message WM_DROPFILES;
    { Private declarations }
  public
    { Public declarations }
  end;
```

```

var
  Form1: TForm1;

implementation

{$R *.DFM}

uses ShellApi;

procedure TForm1.FormCreate(Sender: TObject);
begin
  {Let Windows know we accept dropped files}
  DragAcceptFiles(Form1.Handle, True);
end;

procedure TForm1.WMDROPPFILES(var Message: TWMDROPPFILES);
var
  NumFiles : longint;
  i : longint;
  buffer : array[0..255] of char;
begin
  {How many files are being dropped}
  NumFiles := DragQueryFile(Message.Drop,
                           -1,
                           nil,
                           0);

  {Accept the dropped files}
  for i := 0 to (NumFiles - 1) do begin
    DragQueryFile(Message.Drop,
                  i,
                  @buffer,
                  sizeof(buffer));
    Form1.Memo1.Lines.Add(buffer);
  end;
end;

end.

```

## Article #15534: Getting a handle on your files

Question and Answer Database

FAQ534D.txt Getting a handle on your files

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How do I get a file handle when using Delphi file variables?

Answer:

If you are using a TextFile, typecast your your textfile variable like this to expose the handle property:

```
TheHandle := TTextRec(MyFile).handle;
```

For binary files, typecast your file variable like this:

```
TheHandle := TFileRec(MyFile).handle;
```

## Article #15539: TSocketDispatcher

Question and Answer Database

FAQ539D.txt     TSocketDispatcher  
Category        :DCOM/MultiTier/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

### Question:

In the Help File is the following: Add a TSocketDispatcher object to a form or data module to create an application server that implements an IDispatch interface using TCP/IP. There is no TSocketDispatcher Component on the pallet. So how do you create it?.

### Answer:

You don't really need to do this. ScktSrvr.EXE is in the \delphi30\bin directory. Running it on your AppServer will allow sockets to connect to your application. If you want to use it anyway, look at the ScktSrvr.EXE file found in \delphi30\source\vcl directory. It has the code that instantiates a TSocketDispatcher.

The help file currently contains this note:

?

Application servers do not need to explicitly add a TSocketDispatcher so that they can connect to TMIDASConnection components in client applications. Delphi ships with an executable called ScktSrvr.exe. Run ScktSrvr on the server machine. If the application server does not want to use the default port number (211), pass the port number the application server should use for listening for client connections as a command line argument. If ScktSrvr.exe is running on the server machine, it will automatically launch the application server after it accepts client requests.

## Article #15544: How to use the TUpdateSQLProvider.OnUpdateRecord method

Question and Answer Database

FAQ544D.txt    How to use the TUpdateSQLProvider.OnUpdateRecord method

Category     :DCOM/MultiTier/ActiveForm

Platform     :All

Product      :Delphi 3.x

Question:

How do I use TUpdateSQLProvider.OnUpdateRecord?

Answer:

In the UpdateRecord event, if UpdateKind is ukModify then there are 2 records that designate the important values. The first record contains old values, the second contains new values. In the event, the cursor will start on the second record.

The following example forces a field called Test to UpperCase.

```
procedure TForm1.UpdateSQLProvider1UpdateRecord(DataSet:
  TClientDataSet; UpdateKind: TUpdateKind;
  UpdateQuery: TQuery; var Applied: Boolean);
begin
  with DataSet do
  begin
    if (UpdateKind in [ukModify, ukInsert]) and
      (not VarIsEmpty(FieldByName('TEST').NewValue) then
      UpdateQuery.ParamByName('TEST').Value :=
      UpperCase(FieldByName('TEST').NewValue);
    end;
  end;
end;
```

I use VarIsEmpty on the NewValue to see if the value has changed, then I set the correct param for the query to the value I actually want it to be.

## Article #15549: About Deploying DBClient in a Web Application

Question and Answer Database

FAQ549D.txt About Deploying DBClient in a Web Application

Category :DCOM/MultiTier/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

I include dbclient.dll in the "additional files" section of the web deployment options but it never downloads to the client. How do I get the file down to the client, and once there, how does one register the Dll?

Answer:

Your INF file should have something like this;

```
[Add.Code]
```

```
dbclient.dll=dbclient.dll
```

```
[dbclient.dll]
```

```
file=http://yoursite.com/dbclient.cab
```

```
clsid={9E8D2F81-591C-11D0-BF52-0020AF32BD64}
```

```
RegisterServer=yes
```

```
FileVersion=4,0,0,36
```

Replace "yoursite" with your HTTP address where the cab file resides. FileVersion is the version of the file in your CAB file (check the version information of DBCLIENT to make sure the above matches).

Make sure FileVersion is the version of your DBCLIENT.DLL. You can put dbclient.dll in a cab file using CABARC found in the delphi\bin directory. A sample CABARC command line might look like the following example.

```
CABARC N DBCLIENT.CAB DBCLIENT.DLL
```

## Article #15554: Retrieving a long file name from the command line.

Question and Answer Database

FAQ554D.txt Retrieving a long file name from the command line.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I retrieve a long file name that contains spaces from the command line passed to my application?

Answer:

The Windows API function `GetCommandLine()` will provide you with the complete command line to your application. Note: you will need to make a copy of the returned string, and parse out the executable path and name from the beginning of the returned string.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  s:= GetCommandLine;
  Delete(s, 1, pos('exe"', s) + 4);
  Mem1.Lines.Add(s);
end;
```

## Article #15559: Getting the local internet machine name and IP address.

Question and Answer Database

FAQ559D.txt - Getting the local internet machine name and IP address.

Category :Internet/WEB

Platform :All-32Bit

Product :

Question:

How do I get the local internet machine name and IP address?

Answer:

Getting the local machine name and IP address is a straight forward process that is most easily accomplished using the TCP component. Simply drop a TCP component from the internet page of the component palette on to a form, and access the following members of the TCP component:

```
Memo1.Lines.Add(TCP1.LocalHostName);  
Memo1.Lines.Add(TCP1.LocalIp);
```

If you prefer not to use the TCP component, here is an example that interfaces directly with your winsock layer:

```
uses Winsock;
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
var  
    wVersionRequested : WORD;  
    wsaData : TWSaData;  
begin  
    {Start up WinSock}  
    wVersionRequested := MAKEWORD(1, 1);  
    WSASStartup(wVersionRequested, wsaData);  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var  
    p : PHostEnt;
```

```
s : array[0..128] of char;
p2 : pchar;
begin
  {Get the computer name}
  GetHostName(@s, 128);
  p := GetHostByName(@s);
  Mem1.Lines.Add(p^.h_Name);
  {Get the IpAddress}
  p2 := iNet_ntoa(PInAddr(p^.h_addr_list^^));
  Mem1.Lines.Add(p2);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  {Shut down WinSock}
  WSACleanup;
end;
```

## Article #15569: What is Delphi/400 Client Server Suite?

### Question:

What is the Delphi/400 Server Suite?

### Answer:

The Delphi/400 Client Server Suite is combination of Borland's Delphi Client Server Suite and two other software products acquired under license from TCIS of France. Those two products are ClientObjects/400 and ScreenDesigner/400.

Delphi/400 is now distributed by [System Objects](#)

Last Modified: 30-JAN-02

## Article #15574: Hiding your application from the Windows Taskbar.

### Question:

How do I hide my application from the Windows Taskbar?

### Answer:

It is possible to have your application running without an icon appearing in the task bar. Here's how to do this:

- In Delphi go to the menu option Project -> View Source.
- Add the Windows unit to the uses clause.
- Add `Application.ShowMainForm := False;` to the line after "Application.Initialize;"
- Add: `ShowWindow(Application.Handle, SW_HIDE);` to the line before "Application.Run;"
- If you still want your form to show then Add: `ShowWindow(Form1.Handle, SW_SHOWNORMAL);` to the line just before "Application.Run;"

Your main project source file should now look something like this:

```
program Project1;

uses
  Windows,
  Forms,
  Unit1 in 'Unit1.pas' {Form1},
  Unit2 in 'Unit2.pas' {Form2};

{$R *.RES}

begin
  Application.Initialize;
  Application.ShowMainForm := False;
  Application.CreateForm(TForm1, Form1);
  Application.CreateForm(TForm2, Form2);
  ShowWindow(Application.Handle, SW_HIDE);
  ShowWindow(Form1.Handle, SW_SHOWNORMAL); //Only add this if you
want your form to show.
  Application.Run;
end.
```

- In the "initialization" section (at the very bottom) of each unit that uses a form, add:

```
begin
  ShowWindow(Application.Handle, SW_HIDE);
end.
```

Last Modified: 10-MAY-01

## Article #15580: Using an animated cursor.

Question and Answer Database

FAQ580D.txt Using an animated cursor.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How do use an animated cursor?

Answer:

You will first need to get a handle to a Windows cursor and assign it to the TScreen component's Cursors array.

Predefined cursors start at a negative index, and user defined custom cursors are assigned positive indexes.

The following is an example of a Delphi form that uses an animated cursor:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  h : THandle;
begin
  h := LoadImage(0,
                'C:\TheWall\Magic.ani',
                IMAGE_CURSOR,
                0,
                0,
                LR_DEFAULTSIZE or
                LR_LOADFROMFILE);
  if h = 0 then ShowMessage('Cursor not loaded') else begin
    Screen.Cursors[1] := h;
    Form1.Cursor := 1;
  end;
end;
```

## Article #15585: More Info on Delphi/400 Client Server Suite

Question and Answer Database

FAQ585D.txt - More Info on Delphi/400 Client Server Suite

Category :AS400

Platform :All

## Article #15597: Retrieving a users login name.

Question and Answer Database

FAQ597D.txt Retrieving a users login name.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get the user's login name under 32-bit versions of Windows?

Answer:

The following function demonstrates how to use the GetUserName API call to accomplish this task in Delphi 3 or higher:

```
function GetCurrentUserName: string;
var
  Len: Cardinal; { This will have to be Integer, not cardinal, in
Delphi 3. }
begin
  Len := 255; { arbitrary length to allocate for username string,
plus one for null terminator }
  SetLength(Result, Len - 1); { set the length }
  if GetUserName(PChar(Result), Len) then { get the username }
    SetLength(Result, Len - 1) { set the exact length if it
succeeded }
  else
  begin
    RaiseLastWin32Error; { raise exception if it failed }
  end;
end;
```

In Delphi 2, use a function like the following:

```
function GetCurrentUserName2: string;
var
  Len: integer;
  buf: array [0..255] of char;
```

```
begin
  Len := SizeOf(buf);
  if GetUserName(@buf,Len) then
  begin
    Result := buf;
  end
  else
  begin
    Raise Exception.Create('Win32 Error: ' + IntToStr(GetLastError));
    { You could use FormatMessage to translate the error code into an
    error message }
  end;
end;
```

## Article #15603: Changing the papersize of a print job.

Question and Answer Database

FAQ603D.txt - Changing the papersize of a print job.

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How can I change the papersize of my print job?

Answer:

One way to change printer settings at the start of a print job is to change the printer's devicemode structure.

See: TDEVMODE in the Delphi 1.02 help file or DEVMODE in the Delphi 2.01 help file for other settings you can change (providing the print driver supports the change).

The following example, contains code to change the papersize and the paper bin that is used:

```
procedure TForm1.Button1Click(Sender: TObject);
var
Device : array[0..255] of char;
Driver  : array[0..255] of char;
Port    : array[0..255] of char;
hDMode  : THandle;
PDMode  : PDEVMODE;
begin
  Printer.PrinterIndex := Printer.PrinterIndex;
  Printer.GetPrinter(Device, Driver, Port, hDMode);
  if hDMode <> 0 then begin
    pDMode := GlobalLock(hDMode);
    if pDMode <> nil then begin

      {Set to legal}
      pDMode^.dmFields := pDMode^.dmFields or dm_PaperSize;
```

```
pDMode^.dmPaperSize := DMPAPER_LEGAL;
```

```
{Set to custom size}
```

```
pDMode^.dmFields := pDMode^.dmFields or  
DM_PAPERSIZE or  
DM_PAPERWIDTH or  
DM_PAPERLENGTH;
```

```
pDMode^.dmPaperSize := DMPAPER_USER;
```

```
pDMode^.dmPaperWidth := 100 {SomeValueInTenthsOfAMillimeter};
```

```
pDMode^.dmPaperLength := 100 {SomeValueInTenthsOfAMillimeter};
```

```
{Set the bin to use}
```

```
pDMode^.dmFields := pDMode^.dmFields or DMBIN_MANUAL;
```

```
pDMode^.dmDefaultSource := DMBIN_MANUAL;
```

```
GlobalUnlock(hDMode);
```

```
end;
```

```
end;
```

```
Printer.PrinterIndex := Printer.PrinterIndex;
```

```
Printer.BeginDoc;
```

```
Printer.Canvas.TextOut(100,100, 'Test 1');
```

```
Printer.EndDoc;
```

```
end;
```

## Article #15615: Creating a rotated font.

Question and Answer Database

FAQ615D.txt Creating a rotated font.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I create a rotated font?

Answer:

Rotating fonts is a straight forward process, so long as the Windows font mapper can supply a rotated font based on the font you request.

Note: Using a TrueType font virturally guarantees success.

Here is an example of creating a font that is rotated 45 degrees:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  lf : TLogFont;
  tf : TFont;
begin
  with Form1.Canvas do begin
    Font.Name := 'Arial';
    Font.Size := 24;
    tf := TFont.Create;
    tf.Assign(Font);
    GetObject(tf.Handle, sizeof(lf), @lf);
    lf.lfEscapement := 450;
    lf.lfOrientation := 450;
    tf.Handle := CreateFontIndirect(lf);
    Font.Assign(tf);
    tf.Free;
    TextOut(20, Height div 2, 'Rotated Text!');
  end;
end;
```

## Article #15627: Making text background transparent

Question and Answer Database

FAQ627D.txt Making text background transparent

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I make the text background transparent?

Answer:

Use the Windows API function SetBkMode().

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  OldBkMode : integer;
begin
  with Form1.Canvas do begin
    Brush.Color := clRed;
    FillRect(Rect(0, 0, 100, 100));
    Brush.Color := clBlue;
    TextOut(10, 20, 'Not Transparent!');
    OldBkMode := SetBkMode(Handle, TRANSPARENT);
    TextOut(10, 50, 'Transparent!');
    SetBkMode(Handle, OldBkMode);
  end;
end;
```

## Article #15633: Getting user name and company info from Windows.

Question and Answer Database

FAQ633D.txt Getting user name and company info from Windows.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I retrieve the user name and company information from Windows?

Answer:

This information is stored under the "HKEY\CURRENT USER" section of the Windows registry. The task of retrieving this entry is greatly simplified by using the TRegIniFile component.

Example:

```
uses Registry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    reg: TRegIniFile;
```

```
begin
```

```
    reg := TRegIniFile.create('SOFTWARE\MICROSOFT\MS SETUP (ACME)\');
```

```
    Mem1.Lines.Add(reg.ReadString('USER INFO',
```

```
        'DefName',
```

```
        'Frank Borland'));
```

```
    Mem1.Lines.Add(reg.ReadString('USER INFO',
```

```
        'DefCompany',
```

```
        'A Valued Borland Customer'));
```

```
    reg.free;
```

```
end;
```

Question and Answer Database

FAQ639D.txt Getting the serial number of a disk.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I retrieve the serial number of a disk?

Answer:

You can use the Windows API function `GetVolumeInformation()`

```
procedure TForm1.Button1Click(Sender: TObject);
var
  VolumeSerialNumber : DWORD;
  MaximumComponentLength : DWORD;
  FileSystemFlags : DWORD;
  SerialNumber : string;
begin
  GetVolumeInformation('C:\',
                      nil,
                      0,
                      @VolumeSerialNumber,
                      MaximumComponentLength,
                      FileSystemFlags,
                      nil,
                      0);
  SerialNumber := IntToHex(HiWord(VolumeSerialNumber), 4) +
                  '-' +
                  IntToHex(LoWord(VolumeSerialNumber), 4);
  Mem1.Lines.Add(SerialNumber);
end;
```

## Article #15645: Executing a program from my application

Question and Answer Database

FAQ645D.txt Executing a program from my application

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I execute a program from my application?

Answer:

Using the WinExec function is the easiest way to execute an program from your application.

To execute a standard program, simply use:

```
WinExec('C:\WINDOWS\notepad.exe', SW_SHOWNORMAL);
```

To add a command line, use:

```
WinExec('C:\WINDOWS\notepad.exe C:\WINDOWS\win.ini', SW_SHOWNORMAL);
```

To pop up a DOS box, use:

```
WinExec('command.com', SW_SHOWNORMAL);
```

To execute a DOS command, use:

```
WinExec('command.com /c dir *.*', SW_SHOWNORMAL);
```

## Article #15651: Writing a raw string of data to the printer.

Question and Answer Database

FAQ: FAQ651D - Writing a raw string of data to the printer.

Category: Printing

Platform: All-32Bit

Product:

Question:

How do I write a raw string of a data to the printer?

Answer:

Under Win16, you can use the SpoolFile function, or the Passthrough escape if the printer supports it. This is detailed in TI3196 - Direct Commands to Printer - Passthrough/Escape available from the Borland web site. Under Win32, you should use WritePrinter.

The following is an example of opening a printer and writing a raw string of data to the printer. Note that you must send the correct printer name, such as "HP LaserJet 5MP" for the function to succeed. You are also responsible for embedding any necessary control codes that the printer may require.

```
uses WinSpool;
```

```
procedure WriteRawStringToPrinter(PrinterName:String; S:String);
var
  Handle: THandle;
  N: DWORD;
  DocInfol: TDocInfol;
begin
  if not OpenPrinter(PChar(PrinterName), Handle, nil) then
  begin
    ShowMessage('error ' + IntToStr(GetLastError));
    Exit;
  end;
  with DocInfol do begin
```

```
pDocName := PChar('test doc');  
pOutputFile := nil;  
pDataTyPe := 'RAW';
```

```
end;  
StartDocPrinter(Handle, 1, @DocInfo1);  
StartPagePrinter(Handle);  
WritePrinter(Handle, PChar(S), Length(S), N);  
EndPagePrinter(Handle);  
EndDocPrinter(Handle);  
ClosePrinter(Handle);  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  WriteRawStringToPrinter('HP', 'Test This');  
end;
```

## Article #15657: Multi-Threaded ISAPI DLLs

Question and Answer Database

FAQ657D.txt - Multi-Threaded ISAPI DLLs

Category :Internet/WEB  
Platform :All-32Bit  
Product :

Question:

Why can't my ISAPI DLL created in Delphi 3 handle multiple connections.

Answer:

Although the ISAPI DLL wizard in Delphi 3 creates a DLL that is multi-thread safe, there is an omission in the source code which fails to set a flag telling the application that the DLL is multi-thread safe. This shortcoming can be overcome by simply adding the line:

```
IsMultiThread := TRUE;
```

as the first line of your DPR's begin-end block.

## Article #15663: InterBase access from a web server application

Question and Answer Database

FAQ663D.txt - InterBase access from a web server application

Category :Internet/WEB

Platform :All-32Bit

Product :

Question:

How can I access Local Interbase from a web server application?

I'm using NT and getting the error message "Unknown user name or password." when attempting to access Local Interbase from a Web server application. How do I fix the problem?

Answer:

Make the following changes to your configuration:

?

?

1. Interbase must be running as a service (not as an app w/ tray icon). Which you can change by clicking on the Properties for the tray icon for IB.

?

2. Both the Interbase server and WWW Server must have the following right set: Control Panel | Services | InterBase Server | Startup make sure "Allow Service to Interact with Desktop is checked".

?

Question and Answer Database

FAQ687D.txt - Benefits to AS/400 developers and users

Category :AS400  
Platform :All  
Product :

Question:

What are the key benefits to AS/400 developers and users?

Answer:

The main benefit of Delphi/400 Client/Server Suite to the AS/400 community, is that this solution will extend and enhance the life of their current AS/400 investments. For example their existing applications can be accessed via Delphi, rather than being re-written from scratch. Delphi also provides an easy to use GUI interface allowing new applications to be developed in the shortest possible time. More and more users are wishing to access corporate information combined with rapid reporting. Delphi's Internet enablement, will also allow these companies to start developing both Internet and Intranet applications immediately.

Question and Answer Database

FAQ705D.txt - Minimum Hardware and Software Requirements

Category :AS400  
Platform :All  
Product :

Question:

What are the minimum hardware and software requirements?

Answer:

Delphi/400 Client/Server Suite:

Intel 486/25-based PC or higher  
Microsoft Windows 95 or Windows NT  
8Mb(12Mb recommended)  
50Mb hard disk space  
CD-ROM Drive  
Mouse or other Windows pointing device

ClientObjects/400:

All the AS/400s except those of the AS/Entry series.  
OS/400 Version 2.3 or later.

Supported Routers:

IBM, Client Access for Windows 95 Vn. 2.3  
Netsoft, NS Bundle Vn. 5.0  
Microsoft, SNA Server Vn. 2.11/3.0  
Wall Data, Rumba Access for Windows 95/Windows NT

## Article #15711: Displaying the selected row of a DBGrid in a different color

Question and Answer Database

FAQ711D.txt    Displaying the selected row of a DBGrid in a different color

Category       :Database/VCL

Platform       :All

Product        :Delphi 3.x

Question:

How can I show selected row in a dbgrid in a different color without using dgRowSelect (because I need to edit the data)?

Answer:

If you want to color the selected row in a DBGrid but you don't want to use the dgRowSelect option because you want to be able to edit the data you can use the following technique on the DBGrid.OnDrawColumnCell event:

```
type
  TCustomDBGridCracker = class(TCustomDBGrid);

procedure TForm1.DBGrid1DrawColumnCell(Sender: TObject;
  const Rect: TRect; DataCol: Integer; Column: TColumn;
  State: TGridDrawState);
begin
  with Cracker(Sender) do
    if DataLink.ActiveRecord = Row - 1 then
      Canvas.Brush.Color := clRed
    else
      Canvas.Brush.Color := clWhite;
  DefaultDrawColumnCell(Rect, DataCol, Column, State);
end;
```

## Article #15717: inserting contents of a file at current position in TMemo

Question and Answer Database

FAQ717D.txt inserting contents of a file at current position in TMemo

Category :VCL  
Platform :All  
Product :All 32 bit

Question:

How can I insert the contents of a file at the current position in a TMemo component?

Answer:

Use a TMemoryStream to read the file, then use the TMemo's SetSelTextBuf() method to insert the text;

```
var
  TheMStream : TMemoryStream;
  Zero : char;
begin
  TheMStream := TMemoryStream.Create;
  TheMStream.LoadFromFile('C:\AUTOEXEC.BAT');
  TheMStream.Seek(0, soFromEnd);
  //Null terminate the buffer!
  Zero := #0;
  TheMStream.Write(Zero, 1);
  TheMStream.Seek(0, soFromBeginning);
  Mem1.SetSelTextBuf(TheMStream.Memory);
  TheMStream.Free;
end;
```

## Article #15729: Using the LzExpand functions in your applications

Question and Answer Database

FAQ729D.txt Using the LzExpand functions in your applications

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I use the LzExpand functions in my application?

Answer:

Here is an example that will decompress a file that was compressed using the Microsoft compress.exe utility utilizing the -r (rename) command line switch. Note: If you already know the expanded name of the file, or it was not compressed with the -r command line switch, then simply omit the code associated with the GetExpandedName function, and directly hard code the file name as needed.

```
uses LzExpand;
```

```
{ $IFDEF WIN32 }
```

```
const MAX_PATH = 144;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var lpDstFileName : PChar;
```

```
    SrcFile : integer;
```

```
    DstFile : integer;
```

```
    SrcOs : TOFSTRUCT;
```

```
    DstOs : TOFSTRUCT;
```

```
begin
```

```
    GetMem(lpDstFileName, MAX_PATH);
```

```
    GetExpandedName('C:\TestFile.bi_', lpDstFileName);
```

```
    SrcFile := LZOpenFile('C:\TestFile.bi_', SrcOs, OF_READ);
```

```
    DstFile := LZOpenFile(lpDstFileName, DstOs, OF_CREATE);
```

```
    LZCopy(SrcFile, DstFile);
```

```
    LZClose(SrcFile);
```

```
    LZClose(DstFile);
```

```
    FreeMem(lpDstFileName, MAX_PATH);
```

```
end;
```

## Article #15735: Changing the display mode settings in code.

Question and Answer Database

FAQ735D.txt Changing the display mode settings in code.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I change the display mode settings in code?

Answer:

You can use the Windows API function EnumDisplaySettings() to get a list of valid mode settings, and use the Windows API function ChangeDisplaySettings() to actually change the display setting. Note that many drivers will not perform the reset without rebooting the computer, even though they are capable of doing so.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
Dialogs, StdCtrls, Spin;
```

```
type
```

```
PdmArray = ^TDmArray;  
TDmArray = array[0..0] of TDeviceMode;
```

```
type
```

```
TForm1 = class(TForm)  
    Memo1: TMemo;  
    SpinEdit1: TSpinEdit;  
    Button1: TButton;  
    procedure FormCreate(Sender: TObject);  
    procedure FormDestroy(Sender: TObject);
```

```

    procedure Button1Click(Sender: TObject);
private
    lpDmArray : PDmArray;
    NumModes : integer;
    { Private declarations }
public
    { Public declarations }
end;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.FormCreate(Sender: TObject);
var
    i : integer; // auto-initialized to zero
    MoreModes : bool;
    dm : TDeviceMode;

begin
    Mem1.Lines.Clear;
    MoreModes := True;

    while MoreModes do begin
        MoreModes :=
            EnumDisplaySettings(nil,
                                i,
                                dm);
        Mem1.Lines.Add('Mode ' +
            IntToStr(i) + ': ' +
            IntToStr(dm.dmBitsPerPel) + ' Bits Per Pixel ' +
            IntToStr(dm.dmPelsWidth) + ' x ' +
            IntToStr(dm.dmPelsHeight));
        Inc(i);
    end;

    NumModes := i;
    SpinEdit1.MinValue := 0;
    SpinEdit1.MaxValue := NumModes;

    GetMem(lpDmArray, sizeof(TDeviceMode) * NumModes);
    FillChar(lpDmArray^, sizeof(TDeviceMode) * NumModes, #0);

```

```

{$IFOPT R+}
  {$DEFINE CKRANGE}
  {$R-}
{$ENDIF}
  for i := 0 to (NumModes - 1) do
    EnumDisplaySettings(nil,
                        i,
                        lpDmArray[i]);

{$IFDEF CKRANGE}
  {$UNDEF CKRANGE}
  {$R+}

## Article #15741: How many colors will my display mode support

Question and Answer Database

FAQ741D.txt    How many colors will my display mode support

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I find the number of colors the current display mode supports?

Answer:

You can find the color depth of a display context in the following manner:

```
GetDeviceCaps(Form1.Canvas.Handle, BITSPIXEL) *
```

```
GetDeviceCaps(Form1.Canvas.Handle, PLANES)
```

Will give you the total number of bits used to color a pixel. possible  
Return values of:

1 = 2 colors bpp

4 = 16 colors bpp

8 = 256 colors bpp

15 = 32768 colors (will return 16 on most drivers) bpp

16 = 65535 colors bpp

24 = 16,777,216 colors bpp

32 = 16,777,216 colors (same as 24) bpp

You can use:

```
NumberOfColors := (1 shl  
    (GetDeviceCaps(Form1.Canvas.Handle, BITSPIXEL) *  
    GetDeviceCaps(Form1.Canvas.Handle, PLANES)));
```

to calculate the total number of colors.

## Article #15747: Generating a Windows Console Application

Question and Answer Database

FAQ747D.txt     Generating a Windows Console Application

Category     :Windows API

Platform     :All

Product      :All 32 bit

Question:

How do I generate a Windows Console Application?

Answer:

Create a new application, then, from the View... Menu option, start the "Project Manager", and remove all units from the project. When asked if you would like to save, Click on the 'NO' button. Then from the View... menu option, select "Project Source" and edit it so it looks like the below example. Note: You can add and use additional units, so long as you do not use any VCL components.

Example:

```
program Project1;

uses
  Windows;

{$R *.RES}

begin
  Writeln('A Console Applicaiton');
  SetConsoleTextAttribute(GetStdHandle(
    STD_OUTPUT_HANDLE),
    FOREGROUND_RED OR
    BACKGROUND_BLUE);
  Writeln('Red text on a blue background ');
  SetConsoleTextAttribute(GetStdHandle(STD_OUTPUT_HANDLE),
    FOREGROUND_BLUE OR BACKGROUND_RED);
  writeln('Blue text on a red background ');
  {White text on black background}
  SetConsoleTextAttribute(      GetStdHandle(STD_OUTPUT_HANDLE),
```

```
BACKGROUND_GREEN OR  
BACKGROUND_RED OR  
BACKGROUND_BLUE);
```

```
Writeln('Press Enter To End');
```

```
Readln;
```

```
end.
```

## Article #15765: Parameter value not in allowed range

Question and Answer Database

FAQ765D.txt Parameter value not in allowed range

Category :Miscellaneous

Platform :All

Product :All 32 bit

### Question:

When I run my console application or execute a DOS box, I sometimes get an undocumented message "Parameter value not in allowed range" that displays in the window. The message seems to be posted before the first line of code is run since it is there even when I use "trace into" to start the program. How can I get around this?

### Answer:

On some Win95 OSR2 systems, there is an invalid value contained in the "Initial Environment" setting in the \_DEFAULT.PIF, and CONAGENT.PIF file that Windows uses for dos box defaults. Opening the properties dialog for these files, and making a change to the "Initial Environment" setting (located on the Memory tab) seems to correct the problem.

## Article #15771: Mapping a DLL into another process

Question and Answer Database

FAQ771D.txt Mapping a DLL into another process

Category :Windows API

Platform :All

Product :All 32 bit

Question:

Is it possible to map a DLL into another process under Win32?

Answer:

Yes, the following details one method of forcing a DLL to be mapped into a different process under both Windows NT, and Windows 95.

?

?

1. Install a global WH\_GETMESSAGE hook which is implemented by the DLL. Note that you must store the HHOOK variable returned by the SetWindowsHookEx() function (and any other global variables that are used in the DLL) into a memory mapped file to be able to access it in the target process. Note that any global variables contained in the DLL will not be mapped into the other process, and will contain uninitialized values when referenced while the DLL is mapped into the other process(s).

?

2. PostMessage a custom message (WM\_USER + something) to a window in the target process.

?

3. When the hook traps the message the DLL will be mapped into the target process during the processing of the message.

?

## Article #15777: Deleting a directory and all the directories files

Question and Answer Database

FAQ777D.txt    Deleting a directory and all the directories files  
Category        :VCL  
Platform        :All  
Product         :All 32 bit

Question:

How can I delete a directory and all the directories files?

Answer:

The following example demonstrates deleting all the files in a directory and then the directory itself. Additional processing would be required to delete read only files and files that are in use.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  DirInfo: TSearchRec;
  r : Integer;
begin
  r := FindFirst('C:\Download\Test\*..*', FaAnyfile, DirInfo);
  while r = 0 do begin
    if ((DirInfo.Attr and FaDirectory <> FaDirectory) and
        (DirInfo.Attr and FaVolumeId <> FaVolumeID)) then
      if DeleteFile(pChar('C:\Download\test\' + DirInfo.Name))
         = false then
        ShowMessage('Unable to delete : C:\Download\test\' +
                    DirInfo.Name);
    r := FindNext(DirInfo);
  end;
  SysUtils.FindClose(DirInfo);
  if RemoveDirectory('C:\Download\Test') = false then
    ShowMessage('Unable to delete direcotry : C:\Download\test');
end;
```

## Article #15783: Changing the default width/height of the editor

Question and Answer Database

FAQ783D.txt Changing the default width/height of the editor

Category :IDE

Platform :All

Product :All 32 bit

Question:

How can I change the default width and height of the IDE's Editor window?

Answer:

The following steps will allow you to change the default size of the IDE's editors window:

- 1) Run the Windows registry editor program "RegEdit.exe".

Depending on the version of the compiler you are using, open one of the following keys:

HKEY\_CURRENT\_USER\Software\Borland\Delphi\2.0\Editor

HKEY\_CURRENT\_USER\Software\Borland\Delphi\3.0\Editor

HKEY\_CURRENT\_USER\Software\Borland\C++Builder\1.0\Editor

- 2) Right click on the Editor folder in the left window pane, and choose "New -> String Value" from the popup menu. A new item titled "New Value #1" will appear in the right window pane.

- 3) Right click on the new item that was added in the right window pane, select "Rename" from the popup menu, can change the name of the new item to "DefaultWidth".

- 4) Right click on the new item that you renamed to "DefaultWidth", and select "Modify" from the pop up window. Now type in the value in pixels that you wish the IDE's Editor Window default width to be.

- 5) Repeat the above steps starting with step #2, but this time add a second item called "DefaultHeight".

- 6) Close the "regedit.exe" program.

Note that the change will not be effective until you exit the IDE and restart it.

## Article #15795: Adding a document to the Windows 95 Start Button's documents

Question and Answer Database

FAQ795D.txt Adding a document to the Windows 95 Start Button's documents

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I add a document to the Windows 95 Start Button's documents menu?

Answer:

Use the Shell function SHAddToRecentDocs.

Example:

```
uses ShlOBJ;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  s : string;
```

```
begin
```

```
  s := 'C:\Download\ntkfaq.html';
```

```
  SHAddToRecentDocs(SHARD_PATH, pChar(s));
```

```
end;
```

## Article #15801: Retrieving the program that is associated with a given extension

Question and Answer Database

FAQ801D.txt    Retrieving the program that is associated with a given extension

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How can I retrieve the program that is associated with a given extension?

Answer:

The following example demonstrates retrieving the file associated with a file extension.

Example:

```
uses
{$IFDEF WIN32}
    Registry; {We will get it from the registry}
{$ELSE}
    IniFiles; {We will get it from the win.ini file}
{$ENDIF}

{$IFDEF WIN32}
    const MAX_PATH = 144;
{$ENDIF}

function GetProgramAssociation (Ext : string) : string;
var
{$IFDEF WIN32}
    reg: TRegistry;
    s : string;
{$ELSE}
    WinIni : TIniFile;
    WinIniFileName : array[0..MAX_PATH] of char;
    s : string;
{$ENDIF}
```

```

begin
{$IFDEF WIN32}
  s := '';
  reg := TRegistry.Create;
  reg.RootKey := HKEY_CLASSES_ROOT;
  if reg.OpenKey('.') + ext + '\shell\open\command',
    false) <> false then begin
{The open command has been found}
  s := reg.ReadString('');
  reg.CloseKey;
end else begin
{perhaps thier is a system file pointer}
  if reg.OpenKey('.') + ext,
    false) <> false then begin
    s := reg.ReadString('');
    reg.CloseKey;
    if s <> '' then begin
{A system file pointer was found}
  if reg.OpenKey(s + '\shell\open\command',
    false) <> false then
{The open command has been found}
    s := reg.ReadString('');
    reg.CloseKey;
    end;
  end;
end;
end;
{Delete any command line, quotes and spaces}
if Pos('%', s) > 0 then
  Delete(s, Pos('%', s), length(s));
if ((length(s) > 0) and
  (s[1] = '"')) then
  Delete(s, 1, 1);
if ((length(s) > 0) and
  (s[length(s)] = '"')) then
  Delete(s, Length(s), 1);
while ((length(s) > 0) and
  ((s[length(s)] = #32) or
  (s[length(s)] = '"'))) do
  Delete(s, Length(s), 1);
{$ELSE}
  GetWindowsDirectory(WinIniFileName, sizeof(WinIniFileName));
  StrCat(WinIniFileName, '\win.ini');
  WinIni := TIniFile.Create(WinIniFileName);
  s := WinIni.ReadString('Extensions',
    ext,

```

```
'' );
```

```
WinIni.Free;
```

```
{Delete any command line}
```

```
if Pos(' ^', s) > 0 then
```

```
    Delete(s, Pos(' ^', s), length(s));
```

```
{$ENDIF}
```

```
result := s;
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    ShowMessage(GetProgramAssociation('gif'));
```

```
end;
```

## Article #15807: Using Ampersands inside Delphi.

Question and Answer Database

FAQ807D.txt Using Ampersands inside Delphi

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I make a Window control's text property contain an ampersand character?

Answer:

Use two ampersand characters. The Windows default text handling for controls interprets a single Ampersand character as meaning the next character is a hot key.

Example:

```
Button1.Caption := 'This && That';
```

## Article #15812: "Error reading symbol file." error

Question and Answer Database

FAQ812D.txt "Error reading symbol file." error

Category :IDE

Platform :All

Product :All 32 bit

Question:

Q) When I open a project, I get the message "Error reading symbol file." then the project file wont compile. How can I get around this?

Answer:

A) This usually occurs when you move a project to another drive or directory. Simply deleting the project's .DSM and .DSK files should remedy the situation.

## Article #15830: Creating a delay without a timer.

Question and Answer Database

FAQ830D.txt Creating a delay without a timer.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I create a delay without using a TTimer component, and without locking up the system?

Answer:

Here is an example of using a loop that checks the time and calls `Application.ProcessMessages` to allow Windows messages to be processed during the loops execution.

```
procedure Delay(ms : longint);
var
  TheTime : LongInt;
begin
  TheTime := GetTickCount + ms;

  while GetTickCount < TheTime do
    Application.ProcessMessages;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage('Start Test');
  Delay(2000);
  ShowMessage('End Test');
end;
```

## Article #15836: Converting a color to its VCL string value

Question and Answer Database

FAQ836D.txt    Converting a color to its VCL string value

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I convert a color to its VCL string value?

Answer:

The graphics.pas file has a ColorToString() function that will convert a valid TColor value to it's string representation using a predefined constant (if possible) or a hexadecimal string. The StringToColor() function provides the reciprocal function, taking a predefined color constant string or hexadecimal string and returning the TColor value.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Mem1.Lines.Add(ColorToString(clRed));
  Mem1.Lines.Add(IntToStr(StringToColor('clRed')));
end;
```

## Article #15842: Using escape codes with the format() function

Question and Answer Database

FAQ842D.txt Using escape codes with the format() function

Category :VCL

Platform :All

Product :All 32 bit

Question:

I want to insert escape codes when using the Format() function. I'm trying to create a tab-delimited string. In "C" I could do something like `sprintf(buffer, "%s\t%s", str);`. How might I accomplish this in Pascal?

Answer:

The Pascal Format function does not use escape codes. Instead, you should insert the actual characters into the string using their ASCII representations:

Note that embedded character codes must be placed outside of the quotes.

Examples:

```
Buffer := Format('%s'#9's', [Str1, Str2]);
```

```
ShowMessage(Format('%s'#9's', ['Column1', 'Column2']));
```

## Article #15854: Working with Floating Point, Double, Single, Real, Extended types

Question and Answer Database

FAQ854D.txt Working with Floating Point, Double, Single, Real, Extended types

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

I have two floating point values that are the same, yet when I compare them using " if d1 = d2 then .. " or " if d1 <> d2 then .. " the results are incorrect. Is this a bug?

Answer:

No. Unlike integers, IEEE floating point numbers are only approximates, not exact numbers. You should never use = or <> to compare two floating point numbers. Instead, subtract the two numbers and compare them against a very small number. Example:

```
if abs(d1-d2) < 0.00001 then  
ShowMessage('D1 and D2 are equal');
```

## Article #15866: Displaying the first frame of an AVI File

Question and Answer Database

FAQ866D.txt    Displaying the first frame of an AVI File

Category       :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I display the first frame of an AVI File?

Answer:

The following demonstrates a hard core technique to get the MediaPlayer to reliably show the first frame of an AVI file.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Application.ProcessMessages;
  MediaPlayer1.Open;
  Application.ProcessMessages;
  MediaPlayer1.Step;
  Application.ProcessMessages;
  MediaPlayer1.Previous;
end;
```

## Article #15872: How can I retrieve a list of assigned properties

Question and Answer Database

FAQ872D.txt How can I retrieve a list of assigned properties

Category :IDE

Platform :All

Product :All 32 bit

Question:

How can I easily retrieve a list of assigned properties and events for a given component in text form?

Answer:

Select a component on the form and select copy from the Edit menu. The text representation of the component and its non-default properties can now be pasted into the code window in Delphi, or any text editor.

Example:

```
object MediaPlayer1: TMediaPlayer
  Left = 48
  Top = 32
  Width = 253
  Height = 30
  Cursor = crHelp
  ColoredButtons =
    [btPlay, btStop, btNext, btPrev, btStep, btBack, btRecord, btEject]
  ParentShowHint = False
  ShowHint = True
  TabOrder = 2
  OnClick = MediaPlayer1Click
end
```

## Article #15878: Save and load metafiles in a BLOB field without using DBImage

Question and Answer Database

FAQ878D.txt     Save and load metafiles in a BLOB field without using DBImage

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I save and load metafiles in a BLOB field without using the DBImage component?

Answer:

The following example demonstrates saving metafile images to a database as they exist on the disk, preserving any Placeable metafile headers that may be present in the Metafile. The image is displayed from the database in a TImage component.

Example:

```
unit Unit1;
```

```
interface
```

```
{ $IFDEF WIN32 }
```

```
  uses
```

```
    Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
    Dialogs, StdCtrls, ExtCtrls, DBCtrls, Grids, DBGrids, Db,  
    DBTables;
```

```
{ $ELSE }
```

```
uses
```

```
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,  
  Forms, Dialogs, DBTables, DB, Grids, DBGrids, ExtCtrls, StdCtrls;
```

```
{ $ENDIF }
```

```
type
```

```
  TForm1 = class(TForm)
```

```
    Table1: TTable;
```

```

## Article #15884: How can I test if a given string contains a valid number?

Question and Answer Database

FAQ884D.txt    How can I test if a given string contains a valid number?

Category       :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

How can I test if a given string contains a valid number?

Answer:

Use one of the string to number function inside a try except block, and test for an exception.

Example:

```
function IsStrANumber(NumStr : string) : bool;
begin
    result := true;
    try
        StrToInt(NumStr);
    except
        result := false;
    end;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    if IsStrANumber(Edit1.Text) then
        ShowMessage(Edit1.Text) else
        ShowMessage('Not a Number');
end;
```

## Article #15890: Creating a palette with more than one entry

Question and Answer Database

FAQ890D.txt     Creating a palette with more than one entry  
Category        :Windows API  
Platform        :All  
Product         :All 32 bit

### Question:

The RTL defines the TLogPalette as having only one palette entry. How can I create a palette with more than one entry?

### Answer:

The RTL defines the TLogPalette as having only one entry to allow you to dynamically create a palette with the number of palette entries you wish. To access the additional entries, range checking must be turned off (this can be done in code), and you must access the palette entry index using a variable.

The following example demonstrates dynamically creating a logical palette structure with 256 entries, turns off range checking (if it is on), accesses the palette entries by filling them with gray shades, turns range checking back on (if it was off), creates a handle to palette, and then cleans up the allocated resources.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  lpPalette : PLogPalette;
  hPal      : hPalette;
  i         : integer;
begin
  {Allocate the memory used by the palette}
  GetMem(lpPalette,
         sizeof(TLogPalette) + (255 * sizeof(TPaletteEntry)));

  {Fill out the palette header}
  lpPalette^.palVersion := $300;
```

```

lpPalette^.palNumEntries := 256;

{Turn range checking off if it is on and}
{remember the range checking state}
{$IFOPT R+}
  {$DEFINE CKRANGE}
  {$R-}
{$ENDIF}

{Fill in the palette structure color table with shades of gray}
for i := 0 to 255 do begin
  lpPalette^.PalPalEntry[i].peRed := i;
  lpPalette^.PalPalEntry[i].peGreen := i;
  lpPalette^.PalPalEntry[i].peBlue := i;
end;

{Turn range checking back on if it was on when we started}
{$IFDEF CKRANGE}
  {$UNDEF CKRANGE}
  {$R+}
{$ENDIF}

{Create a palette handle}
hPal := CreatePalette(lpPalette^);

{Free the memory use by the palette structure}
FreeMem(lpPalette,
        sizeof(TLogPalette) + (255 * sizeof(TPaletteEntry)));

{Do something with the palette here}

{Delete the palette handle after use}
DeleteObject(hPal);
end;

```

## Article #15896: How can I easily move a Window control at runtime?

Question and Answer Database

FAQ896D.txt How can I easily move a Window control at runtime?

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I easily move a Window control at runtime?

Answer:

The following example shows how to move a window control at runtime by holding down the control key and clicking the left mouse button. This method will not work with non-window controls such as TLabel components.

Example:

```
procedure TForm1.Button1MouseDown(Sender: TObject; Button:
  TMouseButton; Shift: TShiftState; X, Y: Integer);
{$IFDEF WIN32}
var
  pt : TPoint;
{$ENDIF}
begin
  if ssCtrl in Shift then begin
    ReleaseCapture;
    SendMessage(Button1.Handle, WM_SYSCOMMAND, 61458, 0);
{$IFDEF WIN32}
    GetCursorPos(pt);
    SendMessage(Button1.Handle,
      WM_LBUTTONUP,
      MK_CONTROL,
      Longint(pt));
    {$ENDIF}
  end;
end;
```

## Article #15902: Detecting what direction a printer will rotate for a portrait

Question and Answer Database

FAQ902D.txt - Detecting what direction a printer will rotate for a portrait

Category :Printing  
Platform :All-32Bit  
Product :

### Question:

Some printers seems to rotate the portrait orientation to achieve a landscape page differently than others. This seems to affect the direction of a rotated font. How can I tell what direction a printer will rotate output on a landscape page, and if landscape mode is available on a given printer?

### Answer:

The following example demonstrates how to call the Windows API function DeviceCapabilities(), to find out how a portrait page is rotated to achieve a landscape page, enabling you to adjust your output accordingly. Generally, a print driver will rotate a landscape page either 90 degrees, or 270 degrees from its portrait orientation.

### Example:

```
uses Printers;

{$IFDEF WIN32}
function DeviceCapabilitiesA(pDevice : PAnsiChar;
    pPort : PAnsiChar;
    fwCapability : Word;
    pOutput : PAnsiChar;
    DevMode : PDeviceModeA): Integer stdcall;
    external 'winspool.drv' name 'DeviceCapabilitiesA';

function DeviceCapabilitiesW(pDevice : PWideChar;
    pPort : PWideChar;
    fwCapability: Word;
    pOutput: PWideChar;
```

```

                                DevMode: PDeviceModeW): Integer stdcall;
external 'winspool.drv' name 'DeviceCapabilitiesW';

function DeviceCapabilities(pDevice : PChar;
                            pPort : PChar;
                            fwCapability : Word;

## Article #15908: Removing a forms caption bar?

Question and Answer Database

FAQ908D.txt Removing a forms caption bar?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I get rid of a forms caption bar?

Answer:

Reset the form style, then reset the height of the form. Note: You will need to add a method to terminate the application, as there will no longer be title bar buttons or a system menu.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    SetWindowLong(Form1.Handle,
                  GWL_STYLE,
                  GetWindowLong(Handle,GWL_STYLE) and not WS_CAPTION);
    Height := ClientHeight;
end;
```

7/16/98 4:31:28 PM

Last Modified: 01-SEP-99

```

        nil,
        256,
        @a);
{$ELSE}
  if Escape(Dc,
            QUERYESCSUPPORT,
            sizeof(TestInt),
            @TestInt,
            Nil) > 0 then begin
    Err := Escape(Dc,
                  GetTechnology,
                  0,
                  nil,
                  @a);
  {$ENDIF}
    if Err > 0 then begin
      s := UpperCase(StrPas(a));
      if Pos('POSTSCRIPT', s) > 0 then
        result := true;
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  if PrintDialog1.Execute then
    if IsPostScriptPrinter(Printer.Handle) then
      ShowMessage('This is a Postscript Printer') else
      ShowMessage('This is not a Postscript Printer');
end;

```

## Article #15919: How can I create a dynamic array of TPoints to draw a polygon?

Question and Answer Database

FAQ919D.txt    How can I create a dynamic array of TPoints to draw a polygon?

Category       :Object Pascal

Platform       :All

Product        :All 32 bit

Question:

How can I create a dynamic array of TPoints to draw a polygon?

Answer:

The easist way is to declare a type of array that has only one element, turn range checking off, access the array through the use of a variable, and call the Windows API function Polygon().

Example:

```
type
  TPtArray = array[0..0] of TPoint;
  PPtArray = ^TPtArray;

procedure DrawDynamicPolyArray(NumPoints : integer;
                               Canvas : TCanvas);

var
  p : PPtArray;
  i : integer;
begin
  {$IFOPT R+}
  {$DEFINE CKRANGE}
  {$R-}
  {$ENDIF}
  GetMem(p, sizeof(TPoint) * NumPoints);
  Randomize;
  for i := 0 to (NumPoints -1) do begin
    p^[i].x := Random(Form1.Width);
    p^[i].y := Random(Form1.Height);
  end;
  Polygon(Canvas.Handle, p, NumPoints);
  FreeMem(p, sizeof(TPoint) * NumPoints);
```

```
{ $IFDEF CKRANGE }  
  { $UNDEF CKRANGE }  
  { $R+ }  
{ $ENDIF }  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  Form1.Canvas.Brush.Color := clWhite;  
  Form1.Canvas.FillRect(Rect(0, 0, Form1.Width, Form1.Height));  
  Form1.Canvas.Brush.Color := clRed;  
  DrawDynamicPolyArray(SpinEdit1.Value,  
                        Form1.Canvas);  
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
  SpinEdit1.MinValue := 2;  
  SpinEdit1.MaxValue := 1000;  
  SpinEdit1.Value := 100;  
end;
```

end.

## Article #15924: How can I prevent the user from moving or sizing my form?

Question and Answer Database

FAQ924D.txt    How can I prevent the user from moving or sizing my form?

Category     : Object Pascal

Platform     : All

Product      : All 32 bit

Question:

How can I prevent the user from moving or sizing my form?

Answer:

Trap the Windows WM\_WINDOWPOSCHANGING message and "or" the flags of the WindowPos structure passed in the message's lParam parameter with the predefined constants SWP\_NOMOVE and SWP\_NOSIZE.

Example:

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
    procedure WMPosChange(var Message: TWMWINDOWPOSCHANGING);
      message WM_WINDOWPOSCHANGING;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMPosChange(var Message: TWMWINDOWPOSCHANGING);
begin
  PWindowPos(TMessage(Message).lParam).Flags :=
    PWindowPos(TMessage(Message).lParam).Flags or
    SWP_NOMOVE or
```

SWP\_NOSIZE;

end;

## Article #15930: Detecting if the PrintScreen key has been pressed

Question and Answer Database

FAQ930D.txt Detecting if the PrintScreen key has been pressed

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I tell if the PrintScreen key has been pressed?

Answer:

The PrintScreen system key is not processed during the TForm keydown event. The following example tests if the PrintScreen key has been pressed by calling the Windows API function GetAsyncKeyState() during the Application.OnIdle event.

Example:

```
type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
    procedure AppIdle(Sender: TObject; var Done: Boolean);
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnIdle := AppIdle;
end;
```

```
procedure TForm1.AppIdle(Sender: TObject; var Done: Boolean);
begin
  if GetAsyncKeyState(VK_SNAPSHOT) <> 0 then
    Form1.Caption := 'SnapShot';
  Done := True;
end;
```

## Article #15936: Setting the MaxPage property of the PrintDialog component

Question and Answer Database

FAQ936D.txt     Setting the MaxPage property of the PrintDialog component

Category     : Object Pascal

Platform     : All

Product      : All 32 bit

Question:

When I set the MaxPage property of the PrintDialog component, the VCL always adds one to the number of pages shown in the dialog, and after execution, the Max page property does not change. Is this a bug?

Answer:

The VCL simply wraps the Windows common print dialog. You should fill in all the fields before executing the dialog, and after execution. Check the PrintDialog's FromPage and ToPage properties for the pages to print.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  PrintDialog1.Options := [poPageNums];
  PrintDialog1.PrintRange := prPageNums;
  PrintDialog1.MinPage := 1;
  PrintDialog1.MaxPage := 5;
  PrintDialog1.FromPage := 1;
  PrintDialog1.ToPage := 5;
  if PrintDialog1.Execute then begin
    ShowMessage(IntToStr(PrintDialog1.FromPage));
    SdshowMessage(IntToStr(PrintDialog1.ToPage));
  end;
end;
```

## Article #15942: Trap scrolling messages for the ScrollBars of a TScrollBar

Question and Answer Database

FAQ942D.txt    Trap scrolling messages for the ScrollBars of a TScrollBar

Category       :VCL  
Platform       :All  
Product        :All 32 bit

Question:

How can I trap the scrolling messages for the ScrollBars of a TScrollBar component?

Answer:

The following example traps the scrolling messages for a TScrollBar component, keeping the two scroll bars in sync. If either of the scroll bars are scrolled, then the position of the other scroll bar is changed to the same value. The scroll messages are trapped by subclassing the scroll box's WinProc.

Example:

```
type
{$IFDEF WIN32}
    WParameter = LongInt;
{$ELSE}
    WParameter = Word;
{$ENDIF}
    LParameter = LongInt;

{Declare a variable to hold the window procedure we are replacing}
var
    OldWindowProc : Pointer;

function NewWindowProc(WindowHandle : hWnd;
                        TheMessage   : WParameter;
                        ParamW       : WParameter;
                        ParamL       : LParameter) : LongInt
{$IFDEF WIN32} stdcall; {$ELSE} ; export; {$ENDIF}
var
```

```

TheRangeMin : integer;
TheRangeMax : integer;
TheRange : integer;
begin

if TheMessage = WM_VSCROLL then begin
{Get the min and max range of the horizontal scroll box}
  GetScrollRange(WindowHandle,
                  SB_HORZ,
                  TheRangeMin,
                  TheRangeMax);
{Get the vertical scroll box position}
  TheRange := GetScrollPos(WindowHandle,
                           SB_VERT);
{Make sure we wont exceed the range}
  if TheRange < TheRangeMin then
    TheRange := TheRangeMin else
  if TheRange > TheRangeMax then
    TheRange := TheRangeMax;
{Set the horizontal scroll bar}
  SetScrollPos(WindowHandle,
               SB_HORZ,
               TheRange,
               true);

end;

if TheMessage = WM_HSCROLL then begin
{Get the min and max range of the horizontal scroll box}
  GetScrollRange(WindowHandle,
                  SB_VERT,
                  TheRangeMin,
                  TheRangeMax);
{Get the horizontal scroll box position}
  TheRange := GetScrollPos(WindowHandle,
                           SB_HORZ);
{Make sure we wont exceed the range}
  if TheRange < TheRangeMin then
    TheRange := TheRangeMin else
  if TheRange > TheRangeMax then
    TheRange := TheRangeMax;
{Set the vertical scroll bar}
  SetScrollPos(WindowHandle,
               SB_VERT,
               TheRange,
               true);

```

```

end;

{ Call the old Window procedure to }
{ allow processing of the message. }
NewWindowProc := CallWindowProc(OldWindowProc,
                                WindowHandle,
                                TheMessage,
                                ParamW,
                                ParamL);

end;

procedure TForm1.FormCreate(Sender: TObject);
begin
{ Set the new window procedure for the control }
{ and remember the old window procedure.      }
OldWindowProc := Pointer(SetWindowLong(ScrollBar1.Handle,
                                       GWL_WNDPROC,
                                       LongInt(@NewWindowProc)));
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
{ Set the window procedure back }
{ to the old window procedure.  }
SetWindowLong(ScrollBar1.Handle,
              GWL_WNDPROC,
              LongInt(OldWindowProc));
end;

```

## Article #15960: adjusting the tab location in a TMemo component

Question and Answer Database

FAQ960D.txt adjusting the tab location in a TMemo component

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I adjust the tab location in a TMemo component?

Answer:

Send a EM\_SETTABSTOPS message to the Memo control. The following example sets the first 5 tab stops to 20 pixels.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  DialogUnitsX : LongInt;
  PixelsX : LongInt;
  i : integer;
  TabArray : array[0..4] of integer;
begin
  Mem1.WantTabs := true;
  DialogUnitsX := LoWord(GetDialogBaseUnits);
  PixelsX := 20;
  for i := 1 to 5 do begin
    TabArray[i - 1] :=
      ((PixelsX * i ) * 4) div DialogUnitsX;
  end;
  SendMessage(Mem1.Handle,
              EM_SETTABSTOPS,
              5,
              LongInt(@TabArray));
  Mem1.Refresh;
end;
```

## Article #15966: The TDateTime component commonly ignores key input

Question and Answer Database

FAQ966D.txt    The TDateTime component commonly ignores key input  
Category     :Object Pascal  
Platform     :All  
Product      :All 32 bit

### Question:

The TDateTime component commonly ignores key input. For example, when I key in "49" in the minute field, it inputs a "4" then a "9", when I clearly want "49". Is this a bug?

### Answer:

No. The VCL simply wraps the Windows DateTime control. To input a multiple digit number, quickly enter the first number twice, followed by the additional numbers you wish to input. In the case of "49", enter "449"

## Article #15972: Color reduction techniques for graphics.

Question and Answer Database

FAQ972D.txt Color reduction techniques for graphics.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I accurately (and automatically) display HiColor and True Color (16 and 24 bit) images on a 256 color display?

Answer:

Generally, you cannot. This requires sophisticated color reduction techniques, and not all will work well on all images. Most all color reduction methods work by weighing the average of similar colored pixels in a given area of the image, and combining them. Consider an image of a person standing in a park with green grass, flowers, trees and a blue sky. You would need to remap potentially millions of colors to fit into the Windows palette (236 colors). While this can usually be done in a professional paint program with some trial and error, a single function would have much trouble remapping the colors to faithfully reproduce all images. This is the reason why paint programs that can accurately reduce colors give so many choices in the method used to reduce the color.

In the above example, you could combine many shades of blue and green, and dedicate more colors to faithfully reproduce the person's flesh tones. This method would probably produce an acceptable image, since the shades of the sky, grass, and trees are far less important than the shades necessary to reproduce flesh tones. On the other hand, if the purpose of the image was to show a spectacular panorama of a canyon, you might want to put less emphasis on the exact color of a house that might be in the picture, and instead concentrate on the colors of the canyon. As you can see, where one color reduction function may work well on one image, it would most likely have trouble with others.

Some paint programs use a "Color Wash" palette, that sometimes can display with fair accuracy a colorful 24 bit photograph. This is done by creating a palette that contains a wash of colors that are generally useful for displaying most images. Again, pixels are compared by area, and remapped to a color that is reasonably close to the original if possible.

## Article #15978: Changing the font style of a dbgrid row

Question and Answer Database

FAQ978D.txt Changing the font style of a dbgrid row

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How can I change the font style of one particular row in a dbgrid (one record)?

Answer:

Paste the code below into the OnDrawDataCell event of the dbgrid.

Note: The code below uses the DBDEMOS table "CUSTOMER.DB", a TDBGrid, a TDataSource and a TTable.

```
procedure TForm1.DBGrid1DrawDataCell(Sender: TObject; const Rect:
TRect;
  Field: TField; State: TGridDrawState);
begin
// If the record's CustNo is 1351 draw the entire row with a
// line through it. (set the font style to strike out)
  if (Sender as TDBGrid).DataSource.DataSet.FieldByName('CustNo').
AsString = '1351' then
    with (Sender as TDBGrid).Canvas do begin
      FillRect(Rect);
      // Set the font style to StrikeOut
      Font.Style := Font.Style + [fsStrikeOut];
      // Draw the cell right aligned for floats + offset
      if (Field.DataType = ftFloat) then
        TextOut(Rect.Right-TextWidth(Field.AsString)-3,
          Rect.Top+3, Field.AsString)
      // Otherwise draw the cell left aligned + offset
      else
        TextOut(Rect.Left+2,Rect.Top+3,Field.AsString);
    end;
end;
```

## Article #15984: Get a count and list all the controls on a TNoteBook

Question and Answer Database

FAQ984D.txt    Get a count and list all the controls on a TNoteBook  
Category       :VCL  
Platform        :All  
Product         :All 32 bit

Question:

How can I get a count and list all the controls on a TNoteBook component?

Answer:

The following example demonstrates getting a list of the pages in a TNotebook component, and listing the controls on each page of the Notebook component. The list is added into a Listbox component.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  n: integer;
  p: integer;
begin
  ListBox1.Clear;
  with Notebook1 do begin
    for n := 0 to ControlCount - 1 do begin
      with TPage(Controls[n]) do begin
        ListBox1.Items.Add('Notebook Page: ' +
                           TPage(Notebook1.Controls[n]).Caption);
        for p := 0 to ControlCount - 1 do
          ListBox1.Items.Add(Controls[p].Name);
        ListBox1.Items.Add(EmptyStr);
      end;
    end;
  end;
end;
```

## Article #15996: Displaying a 24 bit True Color bitmap image on a 256 color display

Question and Answer Database

FAQ996D.txt    Displaying a 24 bit True Color bitmap image on a 256 color display

Category       :VCL

Platform       :All

Product        :All 32 bit

Question:

How can I display a 24 bit True Color bitmap image on a 256 color Display under Delphi 3?

Answer:

You can take advantage of the new graphics capabilities of the TBitmap and TJpegImage components of Delphi 3. When Delphi 3 loads a bitmap image, it keeps a copy of the device independent bitmap image it loads from a file in the background. The TJPEGImage component is very good at color reducing a full color image down to 256 colors. By Loading the bitmap, then assigning the image to a Jpeg and saving it to a temporary ".JPG" file, you can then load the temporary file back into a TImage with much better results than simply loading the bitmap file unconverted. The following example demonstrates the necessary steps to achieve these results.

Example:

```
uses JPEG;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  JP : TJPEGImage;
```

```
  IM : TImage;
```

```
  TempFileName : string;
```

```
begin
```

```
  {Pop up a Open Dialog}
```

```
  OpenDialog1.Options := [ofNoChangeDir, ofFileMustExist];
```

```
  OpenDialog1.Filter := 'Bitmap Files (*.bmp)|*.bmp';
```

```
  if OpenDialog1.Execute then begin
```

```
    {Create a temporary TImage}
```

```
    IM := TImage.Create(nil);
```

```
{Load the bitmap file}
  IM.Picture.LoadFromFile(OpenDialog1.FileName);
{Create a temporary TJPEGImage}
  JP := TJPEGImage.Create;
{Priority on quality}
  JP.Performance := jpBestQuality;
{Assign the bitmap to the JPEG}
  JP.Assign(IM.Picture.Graphic);
{Free the temp image}
  IM.Free;
{Make a temp file name with the extension of .jpg}
  TempFileName := 'test.jpg';
{Save the JPEG to a temp file}
  JP.SaveToFile(TempFileName);
{Free the JPEG}
  JP.Free;
{Load the temp file to an image on the form}
  Image1.Picture.LoadFromFile(TempFileName);
{Delete the temp file}
  DeleteFile(TempFileName);
end;
end;
```

## Article #16002: Data segment too large error.

Question and Answer Database

FAQ1002D.txt Data segment too large error.

Category :Compiler

Platform :All

Product :All 32 bit

Question:

When I add a large number of typed constants to my application, my data segment grows too large. How can I get around this?

Answer:

Typed constants are added to the Program's data segment. Untyped constants are added to the code segment of the application only if they are used. Unless you are going to reassign the value of a typed constant, you should use an untyped constant instead. Typed constants should be replaced with initialized variables to be compatible with future versions of the compiler.

Example:

```
{This adds the constant to the data segment}
const SomeTypedString : string = 'Test';
const SomeTypedInt : integer = 5;
```

```
{This adds the constant to the code segment if used}
const SomeUnTypedString = 'Test';
const SomeUnTypedInt = 5;
```

## Article #16008: Turning an low power compliant monitor off?

Question and Answer Database

FAQ1008D.txt Turning an low power compliant monitor off?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I turn an low power compliant monitor off?

Answer:

You can send a `wm_SysCommand` message with the `WParam` parameter set to `SC_MonitorPower` and the `LParam` parameter set to 0 to turn the monitor off, and -1 to turn the monitor back on. The following example turns the monitor off for a 10 second interval.

Example:

type

```
TForm1 = class(TForm)
  Button1: TButton;
  Timer1: TTimer;
  procedure FormCreate(Sender: TObject);
  procedure Timer1Timer(Sender: TObject);
  procedure Button1Click(Sender: TObject);
private
  { Private declarations }
public
  MonitorOff : bool;
  { Public declarations }
end;
```

var

```
Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  Timer1.Enabled := false;
  Timer1.Interval := 10000;
  MonitorOff := false;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  if MonitorOff then begin
    MonitorOff := false;
    SendMessage(Application.Handle,
      wm_SysCommand,
      SC_MonitorPower,
      -1);
    Timer1.Enabled := false;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MonitorOff := true;
  Timer1.Enabled := true;
  SendMessage(Application.Handle,
    wm_SysCommand,
    SC_MonitorPower,
    0);
end;
```

## Article #16019: Intercepting the Ctrl-V key in a TMemo

Question and Answer Database

FAQ1019D.txt Intercepting the Ctrl-V key in a TMemo

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I intercept the Ctrl-V key in a TMemo component and paste custom text that is not currently on the clipboard?

Answer:

The following example demonstrates trapping the Ctrl-V key in a TMemo component.

Example:

```
uses ClipBrd;
```

```
procedure TForm1.Memo1KeyDown(Sender: TObject; var Key: Word;  
  Shift: TShiftState);
```

```
begin
```

```
  if ((Key = ord('V')) and (ssCtrl in Shift)) then begin
```

```
    if Clipboard.HasFormat(CF_TEXT) then
```

```
      Clipboard.Clear;
```

```
      Memo1.SelText := 'Delphi is RAD!';
```

```
      key := 0;
```

```
    end;
```

```
end;
```

## Article #16025: Subclass the window procedure for a TForm

Question and Answer Database

FAQ1025D.txt      Subclass the window procedure for a TForm

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I subclass the window procedure for a TForm?

Answer:

Override the WinProc procedure for the form. The following example overrides the window procedure for the form, and responds to the WM\_CANCELMODE message, indicating that a messagebox or other dialog box has been executed.

Example:

```
type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure WndProc (var Message: TMessage); override;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WndProc (var Message: TMessage);
begin
  if Message.Msg = WM_CANCELMODE then begin
    Form1.Caption := 'A dialog or message box has popped up';
```

```
end else
  inherited
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage('Test Message');
end;
```

## Article #16037: How can I capture an image from a video source?

Question and Answer Database

FAQ1037D.txt     How can I capture an image from a video source?

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How can I capture an image from a video source?

Answer:

For a complete example, you need to get the Microsoft Video for Windows SDK. The following simple example shows how to open the default video capture device, grab a frame from the device, save a frame from the device to the disk as a .BMP (device independent bitmap) file, record a .AVI file (with sound, but without preview), and close the device. Note: You must have a video capture device installed for this example to work.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs, ExtCtrls, StdCtrls;
```

```
type
```

```
  TForm1 = class(TForm)  
    Panell: TPanel;  
    OpenVideo: TButton;  
    CloseVideo: TButton;  
    GrabFrame: TButton;  
    SaveBMP: TButton;  
    StartAVI: TButton;  
    StopAVI: TButton;  
    SaveDialog1: TSaveDialog;  
    procedure FormCreate(Sender: TObject);
```

```
procedure OpenVideoClick(Sender: TObject);
procedure CloseVideoClick(Sender: TObject);
procedure GrabFrameClick(Sender: TObject);
procedure SaveBMPClick(Sender: TObject);
procedure StartAVIClick(Sender: TObject);
procedure StopAVIClick(Sender: TObject);
```

```
private
```

```
{ Private declarations }
```

```
hWndC : THandle;
```

```
CapturingAVI : bool;
```

```
public
```

```
{ Public declarations }
```

```
end;
```

```
var
```

```
Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
const WM_CAP_START           = WM_USER;
const WM_CAP_STOP           = WM_CAP_START + 68;
const WM_CAP_DRIVER_CONNECT = WM_CAP_START + 10;

## Article #16043: Control Panel Applets

Question and Answer Database

FAQ1043D.txt Control Panel Applets

Category :Miscellaneous

Platform :All

Product :Delphi 3.x

Question:

How do I create a Control Panel Applet?

Answer:

Creating a Control Panel Applet is a straight forward process. Simply create a Dynamic Link Library with the extension of .cpl (Control Panel Library) and place it in the Windows system directory. Each cpl file can support multiple control panel applets. The cpl will have a single function entry point called CPLApplet() that must be exported by name. All the following control panel messages will come through this single entry point:

Message:

CPL\_INIT - Sent to indicate CPLApplet() was found. Return TRUE to continue the loading process.

CPL\_GETCOUNT - Return the number of applets supported by the cpl.

CPL\_INQUIRE - Sent for information about each applet supported by the cpl. lParam1 contains the zero based applet number for the inquiry. lParam2 points to a TCplInfo structure. The idIcon field of the TCplInfo structure should be initialized with the resource id for an icon to display, and the idName and idInfo fields should be initialized with the resource string id for the name and description string id. lData can contain applet defined data for use by the applet.

CPL\_SELECT - Sent when the applet's icon has been selected by the user. lParam1 contains the applet number that was selected. lParam2 contains the applet's user defined lData value.

CPL\_DBLCLK - Sent when the applet's icon has been double-clicked. lParam1 contains the applet number. lParam2 contains the applet's

user defined lData value. This message initiates the display of the applet's dialog box.

CPL\_STOP - Sent for each applet when the control panel is exiting. lParam1 contains the applet number. lParam2 contains the applet's user defined lData value. Any applet specific cleaning up should be performed during this call.

CPL\_EXIT - Sent prior to the control panel call to FreeLibrary. Non-applet specific cleaning up should be performed during this call.

CPL\_NEWINQUIRE - Same as CPL\_INQUIRE except lParam2 is a pointer to a NEWCPLINFO structure.

Your control panel library will need some additional resources to function. You will need to create a resource file containing a string table containing both the name and description of your applet(s) and icons for each applet in your cpl. You can create a res file from a .rc (resource script file) using the BRCC.EXE or BRCC32.EXE command line resource compiler, or a WYSIWYG resource editor like Borland's Resource Workshop.

Example .rc file containing a string table with two strings and a pointer to a icon file resource:

```
STRINGTABLE
{
  1, "TestApplet"
  2, "My Test Applet"
}

2 ICON C:\SOMEPATH\CHIP.ICO
```

To compile the .rc file to a .res file that can be linked with your application, simply type on the dos command line the full path to the resource compiler, and the full path to the name of the .rc file to compile. Here is an example:

```
c:\Delphi\Bin\brcc32.exe c:\Delphi\MyRes.rc
```

When the compiler is finished, you should have a new file with the same name as the .rc file you've compiled, only with an extension of ".res".

If you are developing for multiple platforms, you should create both a

16 and 32 bit res file for linkage with your application.

The following is an example of a control panel applet that executes a secondary executable in response to the CPL\_DBLCLK message. You can adapt the code to show a form or dialog box as well. The example is coded to compile for Win16 and Win32 environments.

To build the project, you will need to compile the above .rc file to a res file named either: TCPL32.RES or TCPL16.RES.

Example:

```
library TestCpl;
```

```
{ $IFDEF WIN32 }
```

```
uses
```

```
    SysUtils,
```

```
    Windows,
```

```
    Messages;
```

```
{ $ELSE }
```

```
uses
```

```
    SysUtils,
```

```
    WinTypes,
```

```
    WinProcs,
```

```
    Messages;
```

```
{ $ENDIF }
```

```
{ $IFDEF WIN32 }
```

```
    { $R TCPL32.RES }
```

```
{ $ELSE }
```

```
    { $R TCPL16.RES }
```

```
{ $ENDIF }
```

```
const NUM_APPLETS = 1;
```

```

## Article #16055: Avoiding an Application Error when using EM\_POSFROMCHAR

Question and Answer Database

FAQ1055D.txt      Avoiding an Application Error when using EM\_POSFROMCHAR

Category        :VCL

Platform        :All

Product         :Delphi 3.x

Question:

How can I avoid an Application Error when using the EM\_POSFROMCHAR and EM\_POSFROMCHAR in a RichEdit control?

Answer:

The definitions for EM\_CHARFROMPOS and EM\_POSFROMCHAR are different in the RichEdit and Messages units:

RichEdit unit:

```
EM_POSFROMCHAR                = WM_USER + 38;  
EM_CHARFROMPOS                = WM_USER + 39;
```

Messages unit:

```
EM_POSFROMCHAR                = 214;  
EM_CHARFROMPOS                = 215;
```

To avoid confusion, these constants have been removed from the RichEdit unit in Delphi 3.

When using the EM\_POSFROMCHAR message, WParam should contain the address of the point structure that will receive the coordinates, and LParam should contain the zero based offset of the character. The return value is not initialized. Note that the y coordinate can be zero or negative.

When using EM\_CHARFROMPOS, wparam is not used, and LParam should contain the address of the point structure that will receive the coordinates. The return value should contain the required character index.

## Article #16067: CopyCursor

Question and Answer Database

FAQ1067D.txt CopyCursor

Category :Windows API

Platform :All

Product :Delphi 3.x

Question:

Where is the Windows API function CopyCursor defined in 32-Bit versions of Delphi and C++ Builder?

Answer:

While the call is documented in the Win32 help file, the function is simply mapped to the Windows API function CopyIcon(). Note that the 32 bit version of COpy icon does not take a hInstance parameter.

## Article #16073: Selection rectangle

Question and Answer Database

FAQ1073D.txt Selection rectangle

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I create a selection rectangle for use with selecting portions of an image for editing?

Answer:

The easiest way to do this is to use the Windows API function DrawFocusRect. The DrawFocusRect function uses the XOR function when drawing, so drawing the rectangle twice in the same location erases the rectangle, and the rectangle will always be visible when drawing over different colors.

Example:

type

```
TForm1 = class(TForm)
  procedure FormMouseDown(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
  procedure FormMouseMove(Sender: TObject; Shift: TShiftState; X,
    Y: Integer);
  procedure FormMouseUp(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
private
  { Private declarations }
  Capturing : bool;
  Captured : bool;
  StartPlace : TPoint;
  EndPlace : TPoint;
public
  { Public declarations }
end;
```

var

```
Form1: TForm1;
```

```
implementation

## Article #16079: Draw on frame

Question and Answer Database

FAQ1079D.txt Draw on frame

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to draw on the frame of a form?

Answer:

Create a message handler for the Windows Message WM\_NCPAINT message. The following example paints a 1 pixel red border around the frame of the form.

Example:

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
    procedure WMNCPaint(var Msg : TWMNCPaint); message WM_NCPAINT;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMNCPaint(var Msg: TWMNCPaint);
var
  dc : hDc;
  Pen : hPen;
  OldPen : hPen;
  OldBrush : hBrush;
begin
```

```
inherited;  
dc := GetWindowDC(Handle);  
msg.Result := 1;  
Pen := CreatePen(PS_SOLID, 1, RGB(255, 0, 0));  
OldPen := SelectObject(dc, Pen);  
OldBrush := SelectObject(dc, GetStockObject(NULL_BRUSH));  
Rectangle(dc, 0,0, Form1.Width, Form1.Height);  
SelectObject(dc, OldBrush);  
SelectObject(dc, OldPen);  
DeleteObject(Pen);  
ReleaseDC(Handle, Canvas.Handle);  
end;
```

## Article #16085: Object Inspector and Enter Key

Question and Answer Database

FAQ1085D.txt Object Inspector and Enter Key

Category :IDE

Platform :All

Product :All 32 bit

Question:

How can I place a return character in a string at design time from the object inspector?

Answer:

You cannot, but there is a work around available in Delphi 3.

Enter the text you want without the enter key, then right click on the form, and choose the "View as text" option. Find the string and change it to something like this:

```
Hint = 'LineOne'+#13+LineTwo'
```

## Article #16091: EnumFontFamilies()

Question and Answer Database

FAQ1091D.txt - EnumFontFamilies()

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How do I use the Windows API callback function EnumFontFamilies()?

Answer:

The following example adds the list of fonts and sizes for the current printer to a TMemo component.

Example:

```
uses Printers;
```

```
function EnumFontFamilyProc(var lf : TLogFont;  
                           var tm : TNewTextMetric;  
                           FontType : integer;  
                           var Memo : TMemo) : integer  
{ $IFDEF WIN32 } stdcall; { $ELSE } ; export; { $ENDIF }  
begin  
  Memo.Lines.Add(StrPas(@lf.lfFaceName) +  
                #32 + IntToStr(lf.lfHeight));  
  result := 1;  
end;
```

```
function EnumFontFamiliesProc(var lf : TLogFont;  
                              var tm : TNewTextMetric;  
                              FontType : integer;  
                              var Memo : TMemo) : integer  
{ $IFDEF WIN32 } stdcall; { $ELSE } ; export; { $ENDIF }  
begin  
  if FontType = TRUETYPE_FONTTYPE then begin  
    Memo.Lines.Add(StrPas(@lf.lfFaceName) + #32 + 'All Sizes');  
  end else
```

```
EnumFontFamilies(Printer.Handle,  
                  @lf.lfFaceName,  
                  @EnumFontFamilyProc,  
                  LongInt(@Memo));  
  
result := 1;  
end;  
  
procedure TForm1.Button1Click(Sender: TObject);  
var  
    tm : TTextMetric;  
    i : integer;  
begin  
    if PrintDialog1.Execute then begin  
        EnumFontFamilies(Printer.Handle,  
                          nil,  
                          @EnumFontFamiliesProc,  
                          LongInt(@Memo1));  
    end;  
end;
```

## Article #16097: How can I assign a file variable in a Record?

Question and Answer Database

FAQ1097D.txt How can I assign a file variable in a Record?

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I assign a file variable in a Record?

Answer:

While the Object Pascal language does not allow a direct assignment of a file variable, you can use the Move() procedure to move the contents of the variable to another variable. Note: If you save the record to a file for recall at a later date, you will need to re-initialize the file variable.

Example:

```
TMyRec = Record
  f : file;
  OtherField : integer;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  f : file;
  MyRec : TMyRec;
begin
  AssignFile(f, 'SomeFile.txt');
  {This line will not compile}
  MyRec.f := f;
  {This line will!}
  Move(f, MyRec.f, sizeof(f));
  Rewrite(MyRec.f);
  CloseFile(MyRec.f);
end;
```

## Article #16103: Creating a flashing icon

Question and Answer Database

FAQ1103D.txt Creating a flashing icon

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I create a flashing icon?

Answer:

You can call the Windows API function `FlashWindow()`:

Example:

```
var
    Flash : bool;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
    FlashWindow(Form1.Handle, Flash);
    FlashWindow(Application.Handle, Flash);
    Flash := not Flash;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
    Flash := False;
end;
```

## Article #16109: Getting the Printer driver and port name from TPrinter's

Question and Answer Database

FAQ1109D.txt - Getting the Printer driver and port name from TPrinter's

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How can I get the Printer driver and port name from TPrinter's GetPrinter() method?

Answer:

Sometimes, these parameters will return blank string. You can use the Windows API function GetProfileString() to retrieve the associated driver and port from the Windows.ini file.

Example:

```
uses Printers;
```

```
{ $IFDEF WIN32 }
```

```
const MAX_PATH = 144;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  pDevice : pChar;
```

```
  pDriver  : pChar;
```

```
  pPort    : pChar;
```

```
  hDMode   : THandle;
```

```
begin
```

```
  if PrintDialog1.Execute then begin
```

```
    GetMem(pDevice, cchDeviceName);
```

```
    GetMem(pDriver, MAX_PATH);
```

```
    GetMem(pPort, MAX_PATH);
```

```
    Printer.GetPrinter(pDevice, pDriver, pPort, hDMode);
```

```
    if lstrlen(pDriver) = 0 then begin
```

```
      GetProfileString('Devices', pDevice, '', pDriver, MAX_PATH);
```

```
    pDriver[pos(',', pDriver) - 1] := #0;
end;
if lStrLen(pPort) = 0 then begin
    GetProfileString('Devices', pDevice, '', pPort, MAX_PATH);
    lStrCpy(pPort, @pPort[lStrLen(pPort)+2]);
end;
Mem1.Lines.Add('Device := ' + StrPas(pDevice));
Mem1.Lines.Add('Driver := ' + StrPas(pDriver));
Mem1.Lines.Add('Port := ' + StrPas(pPort));
FreeMem(pDevice, cchDeviceName);
FreeMem(pDriver, MAX_PATH);
FreeMem(pPort, MAX_PATH);
end;
end;
```

## Article #16115: Getting the printing margin of the page

Question and Answer Database

FAQ1115D.txt - Getting the printing margin of the page

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How can I get the printing margin of the page?

Answer:

Under Win16, call the Windows API function `Escape()`, passing the constant `GETPRINTINGOFFSET`. Under Win32, simply call the Windows API function `GetDeviceCaps()` passing the predefined constants `PHYSICALOFFSETX` and `PHYSICALOFFSETY`. Since there is no guarantee a given escape is supported, always call `Escape` with the `QUERYESCSUPPORT` constant to make sure a given escape is implemented. The following example returns the margin of a given printer under both WIN16 and WIN32, accounting for the fact that not all printers will support the escape code `GETPRINTINGOFFSET` (under WIN16). If this is the case, the printing offset is approximated by getting the page size, subtracting the physical resolution of the device, and then dividing by two.

Example:

```
uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  EscapeCode : integer;
  Margin : TPoint;
begin
  if PrintDialog1.Execute then begin
    {$IFDEF WIN32}
      Margin.x :=GetDeviceCaps(Printer.Handle, PHYSICALOFFSETX);
      Margin.y :=GetDeviceCaps(Printer.Handle, PHYSICALOFFSETY);
    {$ELSE}
      EscapeCode := GETPRINTINGOFFSET;
```

```

if Escape(Printer.Handle,
    QUERYESCSUPPORT,
    sizeof(EscapeCode),
    @EscapeCode,
    nil) <> 0 then
if Escape(Printer.Handle,
    GETPRINTINGOFFSET,
    0,
    nil,
    @Margin) < 1 then begin
EscapeCode := GETPHYSPAGESIZE;
if Escape(Printer.Handle,
    QUERYESCSUPPORT,
    sizeof(EscapeCode),
    @EscapeCode,
    nil) <> 0 then
if Escape(Printer.Handle,
    GETPHYSPAGESIZE,
    0,
    nil,
    @Margin) > 0 then begin
Margin.x := (Margin.x -
    GetDeviceCaps(Printer.Handle, HorzRes)) div 2;
Margin.y := (Margin.y -
    GetDeviceCaps(Printer.Handle, VertRes)) div 2;
end else begin
Margin.x := 0;
Margin.y := 0;
end;
end;
{$ENDIF}
Mem1.Lines.Add(IntToStr(Margin.x));
Mem1.Lines.Add(IntToStr(Margin.y));
end;
end;

```

## Article #16121: Retrieving the line number that a memo's cursor is on.

Question and Answer Database

FAQ1121D.txt Retrieving the line number that a memo's cursor is on.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I retrieve the line number that a memo's cursor is on?

Answer:

The zero based location of the cursor can be retrieved by sending an EM\_LINEFROMCHAR message. WParam contains the character number that you wish the line number for, or -1 for the current line (where the caret is located or the beginning of a text selection).

Example:

```
LineNumber := Mem1.Perform(EM_LINEFROMCHAR, -1, 0);
```

## Article #16127: How can I avoid an access violation when using the move procedure

Question and Answer Database

FAQ1127D.txt    How can I avoid an access violation when using the move procedure

Category        :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

How can I avoid an access violation when using the move procedure with pointers?

Answer:

You must dereference the pointers, otherwise you are moving the address of the pointers and possibly corrupting other memory locations.

Example

```
procedure TForm1.Button1Click(Sender: TObject);
var
  p1 : pointer;
  p2 : pointer;
begin
  GetMem(p1, 128);
  GetMem(p2, 128);
  {This line may cause an access violation}
  Move(p1, p2, 128);
  {This line is correct}
  Move(p1^, p2^, 128);
  FreeMem(p1, 128);
  FreeMem(p2, 128);
end;
```

## Article #16133: Using Resident Font

Question and Answer Database

FAQ1133D.txt Using Resident Font

Category :VCL

Platform :All

Product :All 32 bit

Question:

Instead of printing graphics, how can I get TPrinter to use the default resident font in the printer?

Answer:

Use the Windows API function GetStockObject() to retrieve the device default font handle, and assign it to Printer.Font.Handle.

Example:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    tm : TTextMetric;
```

```
    i : integer;
```

```
begin
```

```
    if PrintDialog1.Execute then begin
```

```
        Printer.BeginDoc;
```

```
        Printer.Canvas.Font.Handle := GetStockObject(DEVICE_DEFAULT_FONT);
```

```
        GetTextMetrics(Printer.Canvas.Handle, tm);
```

```
        for i := 1 to 10 do begin
```

```
            Printer.Canvas.TextOut(100,
```

```
                i * tm.tmHeight +
```

```
                tm.tmExternalLeading,
```

```
                'Test');
```

```
        end;
```

```
        Printer.EndDoc;
```

```
    end;
```

```
end;
```

## Article #16139: Printing in Delphi without using the TPrinter Unit

Question and Answer Database

FAQ1139D.txt - Printing in Delphi without using the TPrinter Unit

Category :Printing  
Platform :All Windows  
Product :

Question:

How can I print in Delphi without using the TPrinter Unit?

Answer:

The following example uses the Windows API function `PrintDlg()` to allow the user to choose a printer and prints two pages using the returned `dc`.

Example:

```
uses CommDlg;
```

```
{ $IFDEF WIN32 }
```

```
const MAX_PATH = 144;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    Pd : TPrintDlg;
```

```
    DocInfo: TDocInfo;
```

```
begin
```

```
    FillChar(Pd, sizeof(Pd), #0);
```

```
    Pd.lStructSize := sizeof(Pd);
```

```
    Pd.hWndOwner := Form1.Handle;
```

```
    Pd.Flags := PD_RETURNDC;
```

```
    if PrintDlg(pd) then begin
```

```
        FillChar(DocInfo, sizeof(DocInfo), #0);
```

```
        DocInfo.cbSize := SizeOf(DocInfo);
```

```
        GetMem(DocInfo.lpszDocName, 32);
```

```
        GetMem(DocInfo.lpszOutput, MAX_PATH);
```

```
        lStrCpy(DocInfo.lpszDocName, 'My Document');
```

```
        {Add this line to print to a file }
```

```
lStrCpy(DocInfo.lpszOutput, 'C:\Download\Test.doc');
StartDoc(Pd.hDc, DocInfo);
StartPage(Pd.hDc);
TextOut(Pd.hDc, 100, 100, 'Page 1', 6);
EndPage(Pd.hDc);
StartPage(Pd.hDc);
TextOut(Pd.hDc, 100, 100, 'Page 2', 6);
EndPage(Pd.hDc);
EndDoc(Pd.hDc);
FreeMem(DocInfo.lpszDocName, 32);
FreeMem(DocInfo.lpszOutput, MAX_PATH);
end;
end;
```

Question and Answer Database

FAQ1145D.txt Arrow and Function Keys

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I trap the Arrow and Function Keys?

Answer:

Check for the correct virtual key in the KeyDown event for the form.

Example:

```
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
begin
  if Key = VK_RIGHT then
    Form1.Caption := 'Right';
  if Key = VK_F1 then
    Form1.Caption := 'F1';
end;
```

## Article #16163: Adjusting form size to accommodate a required client size

Question and Answer Database

FAQ1163D.txt     Adjusting form size to accommodate a required client size

Category     :Miscellaneous  
Platform     :All  
Product      :All 32 bit

Question:

How do I adjust my form size to accommodate a required client size?

Answer:

You can make a call to the Windows API function `AdjustWindowRectEx()`. This function takes in a rectangle of your requested client size in screen space, and returns a rectangle containing the required window size and position to accommodate the request.

Notes: 1) The returned rectangle may be larger than the screen. 2) The form's client area may be reduced by the automatic addition of scroll bars. 3) Windows containing title bars have a minimum size allowed by the system, and cannot be made smaller. 4) Menus may form multiple menu bars if the Window is sized too small for the menu to display on a single line. The `AdjustWindowRect()` function does not take this into account.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  pt : TPoint;
  r : TRect;
begin
  pt := ClientToScreen(Point(0, 0));
  r.Left := pt.x;
  r.Top := pt.y;
  pt := ClientToScreen(Point(128, 128));
  r.Right := pt.x;
  r.Bottom := pt.y;
```

```
AdjustWindowRectEx(r,  
                  GetWindowLong(Form1.Handle, GWL_STYLE),  
                  Form1.Menu = nil, {if Form1 has a menu}  
                  GetWindowLong(Form1.Handle, GWL_EXSTYLE));  
Form1.Top := r.Top;  
Form1.Left := r.Left;  
Form1.Width := r.Right - r.Left;  
Form1.Height := r.Bottom - r.Top;  
end;
```

## Article #16169: Querying the Audio Cd Autorun feature of Win32

Question and Answer Database

FAQ1169D.txt    Querying the Audio Cd Autorun feature of Win32

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How can I query the Audio Cd Autorun feature of Win32, and how can I set this value?

Answer:

This setting is stored under the two following Windows registry keys:

HKEY\_LOCAL\_MACHINE\SOFTWARE\Classes\AudioCD\Shell

HKEY\_CLASSES\_ROOT\AudioCD\Shell

The value will be the string "play" if the Autorun feature is enabled.

The following example demonstrates both reading and writing these key values.

Example:

```
function IsAudioCdAutoRunOn : bool;
var
  reg: TRegistry;
  Classes : string;
  ClassesRoot : string;
  i : integer;
begin
  reg := TRegistry.Create;
  reg.RootKey := HKEY_LOCAL_MACHINE;
  reg.OpenKey('SOFTWARE\Classes\AudioCD\Shell',
             false);
  Classes := reg.ReadString('');
```

```

reg.CloseKey;
reg.RootKey := HKEY_CLASSES_ROOT;
reg.OpenKey('AudioCD\Shell',

## Article #16175: Testing/setting the CD autorun option under Win32

Question and Answer Database

FAQ1175D.txt     Testing/setting the CD autorun option under Win32  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

### Question:

How can I test and set the CD autorun option under 32 bit versions of Windows?

### Answer:

You can check the 4 byte value in the Windows registry under:

```
Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\  
NoDriveTypeAutoRun
```

Setting the following bit numbers of the value of this key will cause Windows not to use any auto run capabilities that may be present for the device denoted by the bit number.

```
DRIVE_UNKNOWN = bit # 0  
DRIVE_NO_ROOT_DIR = bit #1  
DRIVE_REMOVABLE= Bit # 2  
DRIVE_FIXED = Bit #3  
DRIVE_REMOTE= Bit #4  
DRIVE_CDROM= Bit #5  
DRIVE_RAMDISK= Bit #6
```

You can also set this value to test the autorun capability of a program you are developing from a floppy or network drive, by setting the value to boot the autorun program from a floppy disk (DRIVE\_REMOVABLE) or network drive (DRIVE\_REMOTE). If the device does not have auto-insert detection capabilities, simply inserting the disk and pressing F-5 from the Windows explorer should cause the autorun program to boot.

The following example demonstrates the ability to check if the autorun detection of the CD is enabled, and also demonstrates the ability of turning the autorun detection both on and off

for the CD.

Example

```
uses
  Registry;

function IsCdAutoRunOn : bool;
var
  reg: TRegistry;
  AutoRunSetting : integer;
begin
  reg := TRegistry.Create;
  reg.RootKey := HKEY_CURRENT_USER;
  reg.OpenKey(
    'Software\Microsoft\Windows\CurrentVersion\Policies\Explorer',
    false);
  reg.ReadBinaryData('NoDriveTypeAutoRun',
    AutoRunSetting,
    sizeof(AutoRunSetting));

  reg.CloseKey;
  reg.free;
  result := not ((AutoRunSetting and (1 shl 5)) <> 0);
end;

procedure SetCdAutoRun(bOn : bool);
var
  reg: TRegistry;
  AutoRunSetting : integer;
begin
  reg := TRegistry.Create;
  reg.RootKey := HKEY_CURRENT_USER;
  reg.LazyWrite := false;
  reg.OpenKey(
    'Software\Microsoft\Windows\CurrentVersion\Policies\Explorer',
    false);
  reg.ReadBinaryData('NoDriveTypeAutoRun',
    AutoRunSetting,
    sizeof(AutoRunSetting));

  if bOn then
    AutoRunSetting := AutoRunSetting and not (1 shl 5)
  else
    AutoRunSetting := AutoRunSetting or (1 shl 5);
  reg.WriteBinaryData('NoDriveTypeAutoRun',
    AutoRunSetting,
```

```
                sizeof(AutoRunSetting));
    reg.CloseKey;
    reg.free;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    if IsCdAutoRunOn then
        ShowMessage('CD AutoRun Is On') else
        ShowMessage('CD AutoRun Is Off');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
    SetCdAutoRun(True);
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
    SetCdAutoRun(False);

## Article #16181: Storing/Playing an .AVI file in a database

Question and Answer Database

FAQ1181D.txt Storing/Playing an .AVI file in a database

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How can I store an AVI file in a database and then play AVI files?

Answer:

AVI files can be stored in BLOB (binary large object) fields. The easiest way to play an AVI file stored in a BLOB is to write the BLOB data to a temporary file, then let the multimedia player play the file. The following example demonstrates how to store an AVI file to a BLOB field, and also play the AVI file from the BLOB field.

Example:

```
var
  FileName : string;

{This function gets a temporary file name form the system}
function GetTemporaryFileName : string;
{$IFDEF WIN32}
  const MAX_PATH = 144;
{$ENDIF}
var
  {$IFDEF WIN32}
    lpPathBuffer : PChar;
  {$ENDIF}
  lpbuffer : PChar;
begin
  {Get the file name buffer}
  GetMem(lpBuffer, MAX_PATH);
  {$IFDEF WIN32}
  {Get the temp path buffer}
  GetMem(lpPathBuffer, MAX_PATH);
```

```

{Get the temp path}
  GetTempPath(MAX_PATH, lpPathBuffer);
{Get the temp file name}
  GetTempFileName(lpPathBuffer,
                  'tmp',
                  0,
                  lpBuffer);
{Free the temp path buffer}
  FreeMem(lpPathBuffer, MAX_PATH);
{$ELSE}
{Get the temp file name}
  GetTempFileName(GetTempDrive('C'),
                  'tmp',
                  0,
                  lpBuffer);
{$ENDIF}
{Create a pascal string containg}
{the temp file name and return it}
  result := StrPas(lpBuffer);
{Free the file name buffer}
  FreeMem(lpBuffer, MAX_PATH);
end;

{Read a AVI file into a blob field}
procedure TForm1.Button1Click(Sender: TObject);
var
  FileStream: TFileStream; {to load the avi file}
  BlobStream: TBlobStream; {to save to the blob}
begin
  {Allow the button to repaint}
  Application.ProcessMessages;
  {Turn off the buttons}
  Button1.Enabled := false;
  Button2.Enabled := false;
  {Assign the avi file name to read}
  FileStream := TFileStream.Create(
    'C:\PROGRA~1\BORLAND\DELPHI~1\DEMOS\COOLSTUF\COOL.AVI',
    fmOpenRead);
  Table1.Edit;
  {Create a BlobStream for the TField Table1AVI}
  BlobStream := TBlobStream.Create(Table1AVI, bmReadWrite);
  {Seek to the Beginning of the stream}
  BlobStream.Seek(0, soFromBeginning);
  {Delete any data that may be there}
  BlobStream.Truncate;

```

```

{Copy from the FileStream to the BlobStream}
  BlobStream.CopyFrom(FileStream, FileStream.Size);
{Free the streams}
  FileStream.Free;
  BlobStream.Free;
{Post the record}
  Table1.Post;
{Enable the buttons}
  Button1.Enabled := true;
  Button2.Enabled := true;
end;

```

```

{Read an avi stored in a blob, and play it}
procedure TForm1.Button2Click(Sender: TObject);

```

```

var
  FileStream: TFileStream; {a temp file}
  BlobStream: TBlobStream; {the AVI Blob}
begin
  {Create a blob stream for the AVI blob}
  BlobStream := TBlobStream.Create(Table1.AVI, bmRead);
  if BlobStream.Size = 0 then begin
    BlobStream.Free;
    Exit;
  end;
  {Close the media player}
  MediaPlayer1.Close;
  {Reset the file name}
  MediaPlayer1.FileName := '';
  {Refresh the play window}
  MediaPlayer1.Display := Panell1;
  Panell1.Refresh;
  {if we have a temp file then erase it}
  if FileName <> '' then
    DeleteFile(FileName);
  {Get a temp file name}
  FileName := GetTemporaryFileName;
  {Create a temp file stream}
  FileStream := TFileStream.Create(FileName,
                                  fmCreate or fmOpenWrite);
  {Copy the blob to the temp file}
  FileStream.CopyFrom(BlobStream, BlobStream.Size);
  {Free the streams}
  FileStream.Free;
  BlobStream.Free;
  {Setup the Media player to play the AVI file}

```

```
MediaPlayer1.FileName := filename;
MediaPlayer1.DeviceType := dtAviVideo;
MediaPlayer1.Open;
MediaPlayer1.Play;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  {Unassign the temp file from the media player}
  MediaPlayer1.Close;
  MediaPlayer1.FileName := '';
  {Erase the temp file}
  if FileName <> '' then
    DeleteFile(FileName);
end;
```

## Article #16193: Setting comm port configuration programmatically under Win95

Question and Answer Database

FAQ1193D.txt    Setting comm port configuration programmatically under Win95

Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

Question:

How can I set the comm ports configuration programmatically under Windows 95?

Answer:

The following example demonstrates setting the comm port under Windows95.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  CommPort : string;
  hCommFile : THandle;
  Buffer : PCommConfig;
  size : DWORD;
begin
  CommPort := 'COM1';
  {Open the comm port}
  hCommFile := CreateFile(PChar(CommPort),
                        GENERIC_WRITE,
                        0,
                        nil,
                        OPEN_EXISTING,
                        FILE_ATTRIBUTE_NORMAL,
                        0);
  if hCommFile=INVALID_HANDLE_VALUE then
  begin
    ShowMessage('Unable to open '+ CommPort);
    exit;
  end;
  {Allocate a temporary buffer}
```

```
GetMem(Buffer, sizeof(TCommConfig));

{Get the size of the CommConfig structure}
{as it may be different than documented}
size := 0;
GetCommConfig(hCommFile, Buffer^, size);

{Free the temporary buffer}
FreeMem(Buffer, sizeof(TCommConfig));

{Allocate the CommConfig structure}
GetMem(Buffer, size);
GetCommConfig(hCommFile, Buffer^, size);

{Change the baud rate}
Buffer^.dcb.BaudRate := 1200;

{Set the comm port to the new configuration}
SetCommConfig(hCommFile, Buffer^, size);

{Free the buffer}
FreeMem(Buffer, size);

{Close the comm port}
CloseHandle(hCommFile);
end;
```

## Article #16199: Changing com port config via Win95 CommConfig Dialog

Question and Answer Database

FAQ1199D.txt Changing com port config via Win95 CommConfig Dialog  
Category :Miscellaneous  
Platform :All  
Product :All 32 bit

### Question:

When I use the Windows 95 CommConfig Dialog box, the settings entered do not seem to change the com port's configuration. How can I set the comm ports configuration using the CommConfig Dialog box?

### Answer:

The following example demonstrates setting the comm port under Windows95 using the CommConfig Dialog box. Note: Any changes made to the dialog are not updated in the system. You are responsible for updating the com ports configuration.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  CommPort : string;
  hCommFile : THandle;
  Buffer : PCommConfig;
  size : DWORD;
begin
  CommPort := 'COM1';
  {Open the comm port}
  hCommFile := CreateFile(PChar(CommPort),
                        GENERIC_WRITE,
                        0,
                        nil,
                        OPEN_EXISTING,
                        FILE_ATTRIBUTE_NORMAL,
                        0);
  if hCommFile=INVALID_HANDLE_VALUE then
  begin
```

```

    ShowMessage('Unable to open '+ CommPort);
    exit;
end;
{Get a temporary buffer}
    GetMem(Buffer, sizeof(TCommConfig));
{Get the size of the CommConfig structure}
{as it may be different than documented}
    size := 0;
    GetCommConfig(hCommFile, Buffer^, size);
{Free the temporary buffer}
    FreeMem(Buffer, sizeof(TCommConfig));
{Get the CommConfig structure}
    GetMem(Buffer, size);
    GetCommConfig(hCommFile, Buffer^, size);

{Pop up the comm port config dialog}
    if CommConfigDialog(PChar(CommPort),
        Form1.Handle,
        Buffer^) = true then begin
        {Set the com port to the values entered}
        {in the dialog if the user pressed ok}
        SetCommConfig(hCommFile, Buffer^, size);
    end;

{Free the buffer}
    FreeMem(Buffer, size);

{Close the comm port}
    CloseHandle(hCommFile);
end;

```

## Article #16211: Sending an image to the printer

Question and Answer Database

FAQ1211D.txt      Sending an image to the printer

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How can I reliably print an image to the printer?

Answer:

Sending a bitmap based on the screen to the printer is an invalid operation that will usually fail, unless the print driver has been designed to detect this error condition and compensate for the error. This means you should use the VCL canvas methods `Draw`, `StretchDraw`, `CopyRect`, `BrushCopy`, and the like to transfer a bitmap to the printer, since the underlying bitmap is based on the screen, and is device dependent. The only way to reliably print an image is to use DIBs (Device Independent Bitmaps). Getting a valid DIB can be difficult, as there are many Windows API functions that must be used correctly. Further, many video drivers incorrectly fill in the DIB structure in regards to the color table in the DIB.

The following example demonstrates an attempt to overcome some of these problems and limitations. The example should compile successfully under all versions of Delphi/C++ Builder.

The core function in the example, `BlttBitmapAsDib()`, accepts a handle to a device to image to, the x and y coordinates you wish the bitmap to be imaged at, the width and height you wish the image to be (stretching and shrinking is acceptable), and the `TBitmap` you wish to image.

Example:

```
uses Printers;
```

```
type
```

```
  PPalEntriesArray = ^TPalEntriesArray; {for palette re-construction}
```

```
TPalEntriesArray = array[0..0] of TPaletteEntry;
```

```
procedure BltTBitmapAsDib(DestDc : hdc;      {Handle of where to blt}
                          x : word;        {Bit at x}
                          y : word;        {Blt at y}
                          Width : word;    {Width to stretch}
                          Height : word;   {Height to stretch}
                          bm : TBitmap);   {the TBitmap to Blt}

var
  OriginalWidth : LongInt;                {width of BM}
  dc : hdc;                                {screen dc}
  IsPaletteDevice : bool;                 {if the device uses palettes}

## Article #16217: Using TClientDataSet with local data

Question and Answer Database

FAQ1217D.txt Using TClientDataSet with local data  
Category :Multitier/Remote Datasets  
Platform :All  
Product :Delphi 3.x

Question:

Is it possible to use a TClientDataSet in a Local application with paradox tables without using a TProvider and a TRemoteServer?

Answer:

You can't get rid of the Provider, but you can use it in a single-tier application. In order to open the Client DataSet you assign the provider manually.

```
CDS.Provider := Table1.Provider;  
CDS.Open;
```

Also, make sure you include BDEProv in the uses clause.

## Article #16223: 'Duplicate resource' error

Question and Answer Database

FAQ1223D.txt 'Duplicate resource' error

Category :Compiler

Platform :All

Product :All 32 bit

Question:

When I try to add a resource to my project's .res file, I get a "Duplicate Resource" error when linking. The resource I have added is a unique resource. How can I successfully add the resource to my project?

Answer:

The projects resource file is generated by the IDE wizard, and is not intended to be modified. To add additional resources to your project, create a separate resource file with a unique name that does not conflict with either the project or any of the unit names. Then to add the resource file to Delphi, simply add the following line to any unit file in the project:

```
{ $R MyRes.Res }
```

(where MyRes.Res is the name of the resource file).

To add the resource to Borland's C++ Builder, add the resource from the project manager.

## Article #16229: Adding hint windows to applications

Question and Answer Database

FAQ1229D.txt Adding hint windows to applications

Category :Miscellaneous

Platform :All

Product :All 32 bit

Question:

How can I pop up a hint window?

Answer:

You can either programmatically move the mouse pointer over the control with the hint, or you can display a hint window of your own;

Example # 1 - programmatically moving the mouse.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  pt : TPoint;
begin
  {Let the button repaint}
  Application.ProcessMessages;
  {Get the screen coordinates of the center of the button}
  pt := ClientToScreen(Point(Button1.Left + Button1.Width div 2,
                             Button1.Top + Button1.Height div 2));
  {Position the cursor at the center of the button}
  SetCursorPos(Pt.x, Pt.y);
end;
```

Example #2 - Creating you own hint window. For this example, you will need a TPanel and a TTimer component. The Panel will be used as the hint window, and will be invisible untill called. The timer will hide the panel after a specified duration.

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Timer1.Enabled := false;
  Panell.Visible := false;
  Panell.BevelInner := bvNone;
```

```
Panel1.BevelOuter := bvNone;
Panel1.BorderStyle := bsSingle;
Panel1.Color := clWhite;
Button1.Hint := 'Hint test';
end;
```

```
procedure TForm1.ShowAHint(x : integer;
                           y : integer;
                           Caption : string;
                           Duration : LongInt);
```

```
var
  dc : hdc;
  OldFont : hFont;
  pt : TSize;
  p : pChar;
begin
  if Timer1.Enabled <> false then
    Timer1.Enabled := false;
  Timer1.Enabled := false;
  if Panel1.Visible <> false then
    Panel1.Visible := false;
  if Caption = '' then exit;
  Panel1.Caption := caption;
  {Get the width of the caption string}
  GetMem(p, Length(Panel1.Caption) + 1);
  StrPCopy(p, Panel1.Caption);
  dc := GetDc(Panel1.Handle);
  OldFont := SelectObject(dc, Panel1.Font.Handle);
  GetTextExtentPoint32(dc, p, Length(Panel1.Caption), pt);
  SelectObject(dc, OldFont);
  ReleaseDc(Panel1.Handle, Dc);
  FreeMem(p, Length(Panel1.Caption) + 1);
  {Position and show the panel}
  Panel1.Left := x;
  Panel1.Top := y;
  Panel1.Width := pt.cx + 6;
  Panel1.Height := pt.cy + 2;
  Panel1.Visible := true;
  {Fire off the timer to hide the panel}
  Timer1.Interval := Duration;
  Timer1.Enabled := true;
end;
```

```
procedure TForm1.Timer1Timer(Sender: TObject);
begin
```

```
if Panell1.Visible <> false then
    Panell1.Visible := false;
    Timer1.Enabled := false;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    {Let the button repaint}
    Application.ProcessMessages;
    ShowAHint(Button1.Left,
              Button1.Top + Button1.Height + 6,
              Button1.Hint,
              2000);
end;
```

## Article #16235: Using InvalidateRect()to repaint the entire form

Question and Answer Database

FAQ1235D.txt Using InvalidateRect()to repaint the entire form

Category :Windows API

Platform :All

Product :All 32 bit

Question:

When I resize my form, the paint area is clipped, but I need to repaint the whole area. The form's ClipRect is read only.

How can I get around this?

Answer:

During the resize event, make a call to the Windows API function InvalidateRect(). Passing nil as the second parameter will cause the clipping rect of the form to include the entire client area of the form. The third parameter denotes if the background of the form should be erased and repainted. Simply calling the invalidate method of the form may result in a clipping region and possibly the background getting erased.

Example:

```
procedure TForm1.FormResize(Sender: TObject);
begin
  InvalidateRect(Form1.Handle, nil, false);
end;
```

## Article #16241: Using mouse\_event() to simulate mouse events

Question and Answer Database

FAQ1241D.txt Using mouse\_event() to simulate mouse events

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I use the mouse\_event() procedure to simulate a mouse event?

Answer:

The following example demonstrates using the Windows API function mouse\_event() to simulate a mouse event. When Button2 is clicked, the example code places the mouse over Button1 and clicks it. Mouse Coordinates given are in "Mickey's", where their are 65535 "Mickey's" to a screen's width.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage('Button 1 clicked');
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  Pt : TPoint;
begin
  {Allow Button2 to repaint it's self}
  Application.ProcessMessages;
  {Get the point in the center of button 1}
  Pt.x := Button1.Left + (Button1.Width div 2);
  Pt.y := Button1.Top + (Button1.Height div 2);
  {Convert Pt to screen coordinates}
  Pt := ClientToScreen(Pt);
  {Convert Pt to mickeys}
  Pt.x := Round(Pt.x * (65535 / Screen.Width));
  Pt.y := Round(Pt.y * (65535 / Screen.Height));
  {Move the mouse}
  Mouse_Event(MOUSEEVENTF_ABSOLUTE or
              MOUSEEVENTF_MOVE,
```

```
Pt.x,
```

```
Pt.y,
```

```
0,
```

```
0);
```

```
{Simulate the left mouse button down}
```

```
  Mouse_Event(MOUSEEVENTF_ABSOLUTE or
```

```
    MOUSEEVENTF_LEFTDOWN,
```

```
    Pt.x,
```

```
    Pt.y,
```

```
    0,
```

```
    0);;
```

```
{Simulate the left mouse button up}
```

```
  Mouse_Event(MOUSEEVENTF_ABSOLUTE or
```

```
    MOUSEEVENTF_LEFTUP,
```

```
    Pt.x,
```

```
    Pt.y,
```

```
    0,
```

```
    0);;
```

```
end;
```

## Article #16247: Painting a rainbow color spectrum onto a form

Question and Answer Database

FAQ1247D.txt     Painting a rainbow color spectrum onto a form

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How do I paint the color spectrum of a rainbow, and if the spectrum is clicked on, how do I calculate what color was clicked on?

Answer:

The following example demonstrates painting a color spectrum, and calculating the color of a given point on the spectrum. Two procedures are presented: PaintRainbow() and ColorAtRainbowPoint(). The PaintRainbow() procedure paints a spectrum from red to magenta if the WrapToRed parameter is false, or paint red to red if the WrapToRed parameter is true. The rainbow can progress either in a horizontal or vertical progression. The ColorAtRainbowPoint() function returns a TColorRef containing the color at a given point in the rainbow.

Example:

```
procedure PaintRainbow(Dc : hDc; {Canvas to paint to}
                      x : integer; {Start position X}
                      y : integer; {Start position Y}
                      Width : integer; {Width of the rainbow}
                      Height : integer {Height of the rainbow};
                      bVertical : bool; {Paint vertically}
                      WrapToRed : bool); {Wrap spectrum back to red}
var
  i : integer;
  ColorChunk : integer;
  OldBrush : hBrush;
  OldPen : hPen;
  r : integer;
  g : integer;
```

```

b : integer;
Chunks : integer;
ChunksMinus1 : integer;
pt : TPoint;
begin
  OffsetViewportOrgEx(Dc,
                     x,
                     y,
                     pt);

  if WrapToRed = false then
    Chunks := 5 else
    Chunks := 6;
  ChunksMinus1 := Chunks - 1;

  if bVertical = false then
    ColorChunk := Width div Chunks else

## Article #16253: Notifying applications that the registry has changed

Question and Answer Database

FAQ1253D.txt    Notifying applications that the registry has changed  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

### Question:

When I make a change to the registry, some applications do not seem to acknowledge the changes until they are restarted. How can I get the applications to respond to the changes?

### Answer:

Broadcast a WM\_WININICHANGE message to the system, sending a null terminated string detailing the registry section that changed. Most well written applications should respond to the WM\_WININICHANGE message.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    SendMessage(HWND_BROADCAST,
                WM_WININICHANGE,
                0,
                LongInt(PChar('RegistrySection')));
end;
```

## Article #16277: Creating temporary canvas

Question and Answer Database

FAQ1277D.txt Creating temporary canvas

Category :VCL

Platform :All

Product :All 32 bit

### Question:

I need a temporary canvas to draw to, but when I attempt to create one, I get several application errors. How do I do this?

### Answer:

Create a Bitmap, and use the TBitmap's canvas property to draw on. The following example creates a Bitmap, draw on its' canvas, draws the canvas to the form's background, and then free the bitmap.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  bm : TBitmap;
begin
  bm := TBitmap.Create;
  bm.Width := 100;
  bm.Height := 100;
  bm.Canvas.Brush.Color := clRed;
  bm.Canvas.FillRect(Rect(0, 0, 100, 100));
  bm.Canvas.MoveTo(0, 0);
  bm.Canvas.LineTo(100, 100);
  Form1.Canvas.StretchDraw(Form1.ClientRect,
                           Bm);

  bm.Free;
end;
```

## Article #16283: TTimer not firing at correct interval

Question and Answer Database

FAQ1283D.txt TTimer not firing at correct interval

Category :VCL

Platform :All

Product :All 32 bit

### Question:

When I create the TTimer component, it does not fire at the correct specified time. How can I get more accurate results?

### Answer:

Windows timer event were not designed to accommodate hi-resolution timing. In other words, while you may set the timer to fire every 1000 milliseconds, it may fire sometimes at intervals longer than 1000 milliseconds. Values below 55 milliseconds will never fire on time under Windows, since this is the Timer components minimum resolution. You can get the time during the timer event and compare it to the last time the event fired to receive a better timing resolution.

Question and Answer Database

FAQ1289D.txt     Error Setting Exception Debug Hook

Category        :IDE

Platform        :All

Product         :All 32 bit

### Question:

Sometimes when I run my program from the IDE and have an exception, when I fix the problem and attempt to re-run the application, I get a message "Error Setting Exception Debug Hook", then Delphi refuses to run the application. I then have to restart Delphi. Is there any way around this?

### Answer:

Yes! If you see the message, just cancel the dialog and press Ctrl-F2 to reset the program. Then do a "build all" and re-run your application.

## Article #16295: Working with objects and functions in other units

Question and Answer Database

FAQ1295D.txt Working with objects and functions in other units

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I call a function or procedure in another unit, or retrieve and set the value of a variable in another unit?

Answer:

Anything defined in the interface section of a unit is visible and callable from another unit that uses that unit. This includes Types, Constants, Classes, Functions, and Procedures. You should simply add the unit's name you want to use to the uses clause of the unit you wish to use it from. Unless necessary, you should define the uses clause in the implementation section, to help avoid circular reference errors. This is where two units depend on each other in their interface sections.

If you have a function in the current unit that has the same name as a function in another unit your wish to call, you can preface the function name with the unit name to fully qualify it.

The following example demonstrates calling functions and procedures and accessing variables in another unit:

Example:

```
{Code for unit2}
```

```
unit Unit2;
```

```
interface
```

```
procedure SomeProcedure(i : integer);
```

```
function SomeFunction(i : integer) : integer;
```

```
var
  SomeInteger : integer;

implementation

procedure SomeProcedure(i : integer);
begin
  SomeInteger := i;
end;

function SomeFunction(i : integer) : integer;
begin
  Result := SomeInteger;
  SomeInteger := i;
end;

end.
```

```
{Code for unit1's implementation section:}
```

```
implementation
```

```
uses
```

```
  Unit2;
```

```
{$R *.DFM}
```

```

## Article #16301: Programmatically closing another application

Question and Answer Database

FAQ1301D.txt Programmatically closing another application

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I programmatically close another application?

Answer:

You can send the application a WM\_QUIT message;

Example:

```
PostMessage(FindWindow(nil, 'window caption'), WM_QUIT, 0, 0);
```

Where "window caption" is the caption of the window that you are sending the message to.

## Article #16307: Formatting a drive under Win32

Question and Answer Database

FAQ1307D.txt     Formatting a drive under Win32

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How can I format a drive under Win32?

Answer:

You can use the ShellAPI funciton ShFormatDrive().

Example:

```
const SHFMT_DRV_A = 0;
const SHFMT_DRV_B = 1;

const SHFMT_ID_DEFAULT = $FFFF;

const SHFMT_OPT_QUICKFORMAT = 0;
const SHFMT_OPT_FULLLFORMAT = 1;
const SHFMT_OPT_SYSONLY = 2;

const SHFMT_ERROR = -1;
const SHFMT_CANCEL = -2;
const SHFMT_NOFORMAT = -3;

function SHFormatDrive(hWnd : HWND;
                      Drive : Word;
                      fmtID : Word;
                      Options : Word) : Longint
  stdcall; external 'Shell32.dll' name 'SHFormatDrive';

procedure TForm1.Button1Click(Sender: TObject);
var
  FmtRes : longint;
begin
  try
    FmtRes:= ShFormatDrive(Handle,
```

```
SHFMT_DRV_A,  
SHFMT_ID_DEFAULT,  
SHFMT_OPT_QUICKFORMAT);
```

```
case FmtRes of  
  SHFMT_ERROR : ShowMessage('Error formatting the drive');  
  SHFMT_CANCEL :  
    ShowMessage('User canceled formatting the drive');  
  SHFMT_NOFORMAT : ShowMessage('No Format')  
else  
  ShowMessage('Disk has been formatted');  
end;  
except  
end;
```

```
end;
```

## Article #16313: Disabling the Win95 start button

Question and Answer Database

FAQ1313D.txt Disabling the Win95 start button

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I hide and disable the Win95 start button?

Answer:

The following example both hides and unhides the Windows start button, and also enables and disables the start button.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Rgn : hRgn;
begin
  {Hide the start button}
  Rgn := CreateRectRgn(0, 0, 0, 0);
  SetWindowRgn(FindWindowEx(FindWindow('Shell_TrayWnd', nil),
                               0,
                               'Button',
                               nil),
               Rgn,
               true);
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  {Turn the start button back on}
  SetWindowRgn(FindWindowEx(FindWindow('Shell_TrayWnd', nil),
                               0,
                               'Button',
                               nil),
               0,
```

```

end;
true);

procedure TForm1.Button3Click(Sender: TObject);
begin
  {Disable the start button}
  EnableWindow(FindWindowEx(FindWindow('Shell_TrayWnd', nil),
                                0,
                                'Button',
                                nil),
                false);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  {Enable the start button}
  EnableWindow(FindWindowEx(FindWindow('Shell_TrayWnd', nil),
                                0,
                                'Button',
                                nil),
                true);
end

```

## Article #16319: Determining minor version number

Question and Answer Database

FAQ1319D.txt Determining minor version number

Category :Windows API

Platform :All

Product :All 32 bit

### Question:

The Delphi/Borland C++ Builder cd's are not marked with the minor version. How can I tell the version number of the CD?

### Answer:

You can tell the version number from the timestamp of the Bcb.exe, Delphi.exe or Delphi32.exe files found from the cd in the bin subdirectory of RunImage, or in the installed directory.

The time listed on the file will be the version number.

## Article #16325: Inserting a file at the cursor

Question and Answer Database

FAQ1325D.txt     Inserting a file at the cursor

Category        :IDE

Platform        :All

Product         :All 32 bit

Question:

Is there any way to insert the contents of a file at the cursor?

Answer:

Yes! Depending on your editor setting in the IDE environment options, the following keystrokes will insert the contents of a file at the cursor:

Default and Classic: Ctrl+K+R

Brief: Alt+R

Epsilon: None

## Article #16337: Controlling shortcut keystrokes in a string grid

Question and Answer Database

FAQ1337D.txt     Controlling shortcut keystrokes in a string grid  
Category        :Windows API  
Platform        :All  
Product         :All 32 bit

### Question:

I have a string grid that is read only. I am trapping any keystrokes sent to the string grid. I have a button that has a caption of E&xit. When ever the user presses the x key (even if the alt key is not pressed) in the string grid, the button click is executed. How can I prevent this?

### Answer:

The following example demonstrates trapping the CM\_DIALOGCHAR message at the form level. This will give you an opportunity to respond to a dialog character only if the alt key is held down, preventing the default handling of the character shortcuts.

### Example:

```
type
  TForm1 = class(TForm)
    Button1: TButton;
    StringGrid1: TStringGrid;
    procedure FormCreate(Sender: TObject);
    procedure Button1Click(Sender: TObject);
    procedure StringGrid1KeyDown(Sender: TObject; var Key: Word;
      Shift: TShiftState);
  private
    { Private declarations }
    procedure CMDialogChar(var Message: TCMDialogChar);
      message CM_DIALOGCHAR;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
  Button1.Caption := 'E&xit';  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  Application.Terminate;  
end;
```

```
procedure TForm1.StringGrid1KeyDown(Sender: TObject;  
var Key: Word; Shift: TShiftState);  
begin  
  ShowMessage('Grid keypress = ' + Char(Key));  
  Key := 0;  
end;
```

```
procedure TForm1.CMDDialogChar(var Message: TCMDDialogChar);  
begin  
  if ssAlt in KeyDataToShiftState(Message.KeyData) then  
    inherited;  
end;
```

## Article #16343: Disabling ALT-F4 to prevent form closing

Question and Answer Database

FAQ1343D.txt Disabling ALT-F4 to prevent form closing

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I disable the Alt+F4 key combination to keep my form from closing?

Answer:

If the intent is to make sure the user doesn't exit prematurely before performing some required task, use the OnCloseQuery event of the form and set the CanClose property appropriately.

If you need to override the default behavior for normal form handling and prevent the Alt+F4 keystrokes from being responded to, then set the forms KeyPreview property to true and trap the key during the forms KeyDown event.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := true;
end;
```

```
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
begin
  if ((ssAlt in Shift) and (Key = VK_F4)) then
    Key := 0;
end;
```

## Article #16349: Prevent window update

Question and Answer Database

FAQ1349D.txt Prevent window update

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I temporarily prevent any given window from updating?

Answer:

Make a call to the Windows API function LockWindowUpdate with the handle of the Window you wish to lock as a parameter. Send a zero as a parameter to enable updating and to restore the drawing.

```
LockWindowUpdate(Mem01.Handle);
```

```
.
```

```
.
```

```
LockWindowUpdate(0);
```

## Article #16355: Preventing multiple application instances

Question and Answer Database

FAQ1355D.txt Preventing multiple application instances

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I guarantee that only one instance of my program executes? Is it possible to restore the previous instance and shut down if I start more than one instance?

Answer:

Under Win16, you can check the value of `hPrevInst` at startup. If it is non-zero, then another instance of your application is running, and you can take steps to abort the current instance. Under Win32, `hPrevInst` is always zero and cannot be relied upon. You should attempt to create a uniquely named mutex. If the creation fails, then there is another instance running.

The following example attempts to create a named mutex. If the mutex fails, a unique system wide custom windows message is registered with the system, and is then broadcast to all top level windows. The second instance then shuts down. The previous instance has also registered this unique custom system wide message, and has trapped the window procedure of `Form1` to respond to this message. If the message is received, then `Form1` is restored (if minimized) and then made to be the top level window. Care is taken in the example to minimize the effect of Delphi/Borland C++ Builder's hidden application window, and its effect on the task bar icon for `Form1`.

Example:

```
{The code for OneInstance.dpr}
```

```
program OneInstance;
```

```
uses
```

```
    Windows,
```

```

Forms,
Unit1 in 'Unit1.pas' {Form1};

{$R *.RES}

begin
  {Attempt to create a named mutex}
  CreateMutex(nil, false, 'MyApp');
  {if it failed then there is another instance}
  if GetLastError = ERROR_ALREADY_EXISTS then begin
    {Send all windows our custom message - only our other}
    {instance will recognise it, and restore itself}
    SendMessage(HWND_BROADCAST,
                RegisterWindowMessage('MyApp'),
                0,
                0);
    {Lets quit}
    Halt(0);
  end;
  Application.Initialize;
  {Tell Delphi to un-hide it's hidden application window}
  {This allows our instance to have a icon on the task bar}
  Application.ShowMainForm := true;
  ShowWindow(Application.Handle, SW_RESTORE);
  Application.CreateForm(TForm1, Form1);
  Application.Run;
end.

{The code for unit1.pas}

unit Unit1;

interface

uses

Windows, Messages, SysUtils, Classes, Graphics, Controls,
Forms, Dialogs;

type
  TForm1 = class(TForm)
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }

```

```
end;  
  
procedure TForm1.FormDestroy(Sender: TObject);  
begin  
  {Set form1's window proc back to it's original procedure}  
  SetWindowLong(Form1.Handle,  
                GWL_WNDPROC,  
                LongInt(OldWindowProc));  
end;  
  
begin  
  {Tell Delphi to hide it's hidden application window for now to avoid}  
  {a "flash" on the taskbar if we halt due to another instance}  
  ShowWindow(Application.Handle, SW_HIDE);  
end.
```

## Article #16361: Programatically installing printer driver

Question and Answer Database

FAQ1361D.txt     Programatically installing printer driver

Category     :Windows API

Platform     :All

Product      :All 32 bit

Question:

My application uses a custom print dirver. Is it possible to silently install a print driver in Windows 3.1 or Windows 95 without user intervention?

Answer:

The following example silently installs a print driver. You will need to copy the print driver files to the Windows\System directory and add the following entries to the Win.Ini file.

Notes:

In the follwong example:

```
DriverName = Name of the driver;  
DRVFILE - Filename of the driver minus the extension  
         (unless it is not ".drv").
```

Example:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
  s : array[0..64] of char;  
begin  
  WriteProfileString('PrinterPorts',  
                    'DriverName',  
                    'DRVFILE,FILE:,15,45');  
  WriteProfileString('Devices',  
                    'DriverName',  
                    'DRVFILE,FILE:');  
  StrCopy(S, 'PrinterPorts');  
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@S));  
  StrCopy(S, 'Devices');  
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@S));  
end;
```

## Article #16367: Simultaneous printing to multiple printers

Question and Answer Database

FAQ1367D.txt - Simultaneous printing to multiple printers

Category :Printing  
Platform :All Windows  
Product :

Question:

Is it possible to print to more than one printer at a given time?

Answer:

Yes! The following example demonstrates how to print to more than one printer at a given time. The exmple does not use TPrinter, since TPrinter does not support printing to multiple printers at a given time.

Example:

```
unit multiprn;

interface

{$IFDEF WIN32}
    uses
        Windows, Messages, SysUtils, Classes, Graphics, Controls,
        Forms, Dialogs, StdCtrls;
{$ELSE}
    uses
        SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,
        Controls, Forms, Dialogs, StdCtrls;
{$ENDIF}

type
    TForm1 = class(TForm)
        Button1: TButton;
        ListBox1: TListBox;
        ListBox2: TListBox;
        ListBox3: TListBox;
```

```

procedure FormCreate(Sender: TObject);
procedure ListBox1Click(Sender: TObject);
procedure ListBox2Click(Sender: TObject);
procedure ListBox3Click(Sender: TObject);
procedure Button1Click(Sender: TObject);
private
  { Private declarations }
  procedure GetTheListOfPrinters;
public
  { Public declarations }
end;

```

```

var
  Form1: TForm1;

```

```

implementation

```

```

{$R *.DFM}

```

```

type

## Article #16373: Stack Overflow, Runtime error 202;

Question and Answer Database

FAQ1373D.txt Stack Overflow, Runtime error 202;

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I avoid getting a Stack overflow runtime error 202?

Answer:

Simply put, stack overflows are caused by putting too much on the stack. Usually, they are caused by recursive procedures that never end. A good example would be creating an event handler for the TMemo's onChange event, and making a change to the Memo during the processing of the event. Every time the OnChange event gets fired, another change is made, so the OnChange event gets fired again in an almost endless loop. The loop finally ends when the stack overflows, and the application crashes.

Here is an example of a recursive procedure:

```
procedure RecursiveBlowTheStack;  
begin  
  RecursiveBlowTheStack;  
end;
```

Sometimes, a stack overflow is caused by too many large procedures. Each procedure calls another procedure, until the stack simply overflows. This can be remedied by breaking up large procedures into smaller ones. A good rule of thumb in regard to a procedures size is if the procedure's source code takes up more than a screen, its time to break it down into smaller procedures.

Finally, stack overflows can be caused by creating very large local variables inside a procedure, or passing a large variable by value to another procedure. Consider the passing of string variables. If the string is 255 characters (plus the length byte), if passed by value, you are actually taking up 256 bytes off the stack. If the procedure you are calling passes the string by value to yet another procedure,

the string now takes 512 bytes of stack space. Passing the string (or other variable) as a var or const parameter takes only 4 bytes, since var and const parameters are simply pointers to the actual data. You can also create large variables on the heap by dynamic allocation of the memory;

The following code demonstrates two procedures BlowTheStack(), and NoBlowTheStack(). The BlowTheStack procedure attempts to allocate a large local variable designed to be large enough to crash the application. The NoBlowTheStack() procedure allocates the same large variable but allocates it on the heap so the function will succeed.

```
type
  PBigArray = ^TBigArray;
{$IFDEF WIN32}
  TBigArray = array[0..10000000] of byte;
{$ELSE}
  TBigArray = array[0..64000] of byte;
{$ENDIF}
```

```
procedure BlowTheStack;
```

```
var
```

```
  BigArray : TBigArray;
```

```
begin
```

```
  BigArray[0] := 10;
```

```
end;
```

```
procedure NoBlowTheStack;
```

```
var
```

```
  BigArray : PBigArray;
```

```
begin
```

```
  GetMem(BigArray, sizeof(BigArray^));
```

```
  BigArray^[0] := 10;
```

```
  FreeMem(BigArray, sizeof(BigArray^));
```

```
end;
```

Finally, the following code demonstrates creating procedures that accept large variables as parameters. The PassByValueAnCrash() procedure is designed to crash since the value parameter is too large for the stack. The PassByVar(), PassByPointer(), and PassByConst will succeed, since these procedures only use 4 bytes of stack space. Note that you cannot modify a parameter passed as const, as a const parameter is assumed to be read only.

Example:

```
procedure PassByValueAnCrash(BigArray : TBigArray);  
begin  
    BigArray[0] := 10;  
end;
```

```
procedure PassByVar(var BigArray : TBigArray);  
begin  
    BigArray[0] := 10;  
end;
```

```
procedure PassByPointer(BigArray : PBigArray);  
begin  
    PBigArray^[0] := 10;  
end;
```

```
procedure PassByConst(const BigArray : TBigArray);  
begin  
    ShowMessage(IntToStr(BigArray[0]));  
end;
```

## Article #16379: Closing popup menu in system tray application

Question and Answer Database

FAQ1379D.txt Closing popup menu in system tray application

Category :Windows API

Platform :All

Product :All 32 bit

Question:

Sometimes, my popup menu in my tray application does not close when it loses focus. How can I get it to close?

Answer:

When processing the message to pop up the menu, you need to set the foreground window, then send a WM\_NULL message after the menu popup.

```
procedure TForm1.WndProc(var Msg : TMessage);
```

```
var
  p : TPoint;
begin
  case Msg.Msg of
    WM_USER + 1:
      case Msg.lParam of
        WM_RBUTTONDOWN: begin
          SetForegroundWindow(Handle);
          GetCursorPos(p);
          PopupMenu1.Popup(p.x, p.y);
          PostMessage(Handle, WM_NULL, 0, 0);
        end;
      end;
    end;
  inherited;
end;
```

## Article #16385: Keeping a glyph's transparent area transparent.

Question and Answer Database

FAQ1385D.txt Keeping a glyph's transparent area transparent.

Category :VCL

Platform :All

Product :All 32 bit

Question:

Under some video modes, the transparent area of the standard TBitBtn glyphs turns gold or maroon. How can I keep the standard TBitBtn's glyph transparent?

Answer:

The following example demonstrates a technique where the transparent portion of the glyph is filled with the background color of the button, making the glyph appear transparent.

Example:

```
function InitStdBitBtn(BitBtn : TBitBtn;
                      kind : TBitBtnKind) : bool;
var
  Bm1 : TBitmap;
  Bm2 : TBitmap;
begin
  Result := false;
  if Kind = bkCustom then exit;
  Bm1 := TBitmap.Create;
  case Kind of
    bkOK : Bm1.Handle := LoadBitmap(hInstance, 'BBOK');
    bkCancel : Bm1.Handle := LoadBitmap(hInstance, 'BBCANCEL');
    bkHelp : Bm1.Handle := LoadBitmap(hInstance, 'BBHELP');
    bkYes : Bm1.Handle := LoadBitmap(hInstance, 'BBYES');
    bkNo : Bm1.Handle := LoadBitmap(hInstance, 'BBNO');
    bkClose : Bm1.Handle := LoadBitmap(hInstance, 'BBCLOSE');
    bkAbort : Bm1.Handle := LoadBitmap(hInstance, 'BBABORT');
    bkRetry : Bm1.Handle := LoadBitmap(hInstance, 'BBRETRY');
    bkIgnore : Bm1.Handle := LoadBitmap(hInstance, 'BBIGNORE');
    bkAll : Bm1.Handle := LoadBitmap(hInstance, 'BBALL');
  end;
end;
```

```
Bm2 := TBitmap.Create;
Bm2.Width := Bm1.Width;
Bm2.Height := Bm1.Height;
bm2.Canvas.Brush.Color := ClBtnFace;
bm2.Canvas.BrushCopy(Rect(0, 0, bm2.Width, bm2.Height),
                    Bm1,
                    Rect(0, 0, Bm1.Width, Bm1.Height),
                    bm1.Canvas.Pixels[0,0]);

bml.Free;
LockWindowUpdate(BitBtn.Parent.Handle);
BitBtn.Kind := kind;
BitBtn.Glyph.Assign(bm2);
LockWindowUpdate(0);
bm2.Free;
Result := true;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    InitStdBitBtn(BitBtn1, bkOk);
end;
```

## Article #16390: Transparent property to work for a CoolBar background bitmap

Question and Answer Database

FAQ1390D.txt      Transparent property to work for a CoolBar background  
bitmap

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I get the transparent property to work for a background  
bitmap assigned to a CoolBar component?

Answer:

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    Bm1 : TBitmap;
```

```
    Bm2 : TBitmap;
```

```
begin
```

```
    Bm1 := TBitmap.Create;
```

```
    Bm2 := TBitmap.Create;
```

```
    Bm1.LoadFromFile('c:\download\test.bmp');
```

```
    Bm2.Width := Bm1.Width;
```

```
    Bm2.Height := Bm1.Height;
```

```
    bm2.Canvas.Brush.Color := CoolBar1.Color;
```

```
    bm2.Canvas.BrushCopy(Rect(0, 0, bm2.Width, bm2.Height),
```

```
                          Bm1,
```

```
                          Rect(0, 0, Bm1.width, Bm1.Height),
```

```

## Article #16395: How can I determining if a given machine has a math coprocessor.

Question and Answer Database

FAQ1395D.txt    How can I determining if a given machine has a math coprocessor.

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I determine in code if a given machine either has a math coprocessor or if Windows is supplying emulation?

Answer:

Contrary to popular belief, not all 486/586/686/ and Pentium clones have floating point units. Under Windows 3.1, applications could take advantage of this knowledge and choose to do fixed point math or use other means to improve performance. The following example shows how to check for the existance of a floating point unit under both Win16 and Win32.

Example:

```
{ $IFDEF WIN32 }
  uses Registry;
{ $ENDIF }
```

```
function HasCoProcessor : bool;
```

```
{ $IFDEF WIN32 }
```

```
var
```

```
  TheKey : hKey;
```

```
{ $ENDIF }
```

```
begin
```

```
  Result := true;
```

```
{ $IFNDEF WIN32 }
```

```
  if GetWinFlags and Wf_80x87 = 0 then
```

```
    Result := false;
```

```
{ $ELSE }
```

```
  if RegOpenKeyEx(HKEY_LOCAL_MACHINE,
```

```
    'HARDWARE\DESCRIPTION\System\FloatingPointProcessor',
```

```
    0,
```

```
KEY_EXECUTE,  
TheKey) <> ERROR_SUCCESS then result := false;  
RegCloseKey(TheKey);  
{ $ENDIF }  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  if HasCoProcessor then  
    ShowMessage('Has CoProcessor') else  
    ShowMessage('No CoProcessor - Windows Emulation Mode');  
end;
```

## Article #16400: How can I dial out through the modem under Win32?

Question and Answer Database

FAQ1400D.txt    How can I dial out through the modem under Win32?

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How can I dial out through the modem under Win32?

Answer:

You can use the Windows API function CreateFile() to get a handle to the com port, and use standard file I/O to communicate with the given port.

Example:

```
var
  hCommFile : THandle;

procedure TForm1.Button1Click(Sender: TObject);
var
  PhoneNumber : string;
  CommPort    : string;
  NumberWritten : LongInt;
begin
  PhoneNumber := 'ATDT 1-555-555-1212' + #13 + #10;
  CommPort    := 'COM2';
  {Open the comm port}
  hCommFile := CreateFile(PChar(CommPort),
                          GENERIC_WRITE,
                          0,
                          nil,
                          OPEN_EXISTING,
                          FILE_ATTRIBUTE_NORMAL,
                          0);

  if hCommFile=INVALID_HANDLE_VALUE then
  begin
    ShowMessage('Unable to open '+ CommPort);
    exit;
```

```
end;
```

```
{Dial the phone}
```

```
NumberWritten:=0;
```

```
if WriteFile(hCommFile,
```

```
    PChar(PhoneNumber)^,
```

```
    Length(PhoneNumber),
```

```
    NumberWritten,
```

```
    nil) = false then begin
```

```
    ShowMessage('Unable to write to ' + CommPort);
```

```
end;
```

```
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
```

```
begin
```

```
    {Close the port}
```

```
    CloseHandle(hCommFile);
```

```
end;
```

## Article #16405: Retrieving BDE system information

Question and Answer Database

FAQ1405D.txt Retrieving BDE system information

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How can I get BDE system status such as size of buffer and heap used, or number of currently loaded drivers, active clients, sessions, databases or cursors?

Answer:

Use the BDE api call DbiGetSysInfo. The following example outputs the results to a text log file.

implementation

```
uses dbierrs, dbiprocs, dbitypes;
```

```
{ $R *.DFM }
```

```
procedure LogDbiSysInfo(const LogFile: string);
```

```
var
```

```
    Info: SYSInfo;
```

```
begin
```

```
    DbiGetSysInfo(Info);
```

```
    with TStringList.Create do
```

```
    try
```

```
        Clear;
```

```
        Add(Format('BUFFER SPACE: %d', [Info.iBufferSize]));
```

```
        Add(Format('HEAP SPACE: %d', [Info.iHeapSpace]));
```

```
        Add(Format('DRIVERS: %d', [Info.iDrivers]));
```

```
        Add(Format('CLIENTS: %d', [Info.iClients]));
```

```
        Add(Format('SESSIONS: %d', [Info.iSessions]));
```

```
        Add(Format('DATABASES: %d', [Info.iDatabases]));
```

```
        Add(Format('CURSORS: %d', [Info.iCursors]));
```

```
        SaveToFile('c:\logcurs.txt');
```

```
    finally
```

```
        Free;
```

```
end;  
end;  
  
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    table1.Open;  
    table2.open;  
    table3.Open;  
    LogDbiSysInfo('c:\logcurs.txt');  
end;  
  
end.
```

Output for logcurs.txt:

-----

```
BUFFER SPACE: 128  
HEAP SPACE:   160  
DRIVERS:      2  
CLIENTS:      2  
SESSIONS:     2  
DATABASES:    4  
CURSORS:      3
```

## Article #16409: What does the error 'Token not found'

Question and Answer Database

FAQ1409C.txt    What does the error 'Token not found'

Category        :Database Issues

Platform        :All

Product         :C++Builder 1.x

Question:

I have a TQuery and TDataSource. In the TStrings property of the TQuery I have 'SELECT \* FROM dbo.AnyTable' where dbo is the database on my SQL server. When I set active to TRUE I get the error: 'Token not found. Token :dbo. line number:1'.

What's wrong?

Answer:

If the RequestLive property is set to true, then enclose the owner and tables names in quotes:

Ex:

```
SELECT * FROM "dbo.table"
```

If request live is false, don't use quotes.

Ex:

```
SELECT * FROM dbo.table
```

## Article #16410: How can I use a true DWORD value passed to my Delphi application?

Question and Answer Database

FAQ1410D.txt     How can I use a true DWORD value passed to my Delphi application?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I use a true DWORD value passed to my Delphi application?

Answer:

One solution is to convert the DWORD to a comp.

Example:

```
{ $IFOPT Q+ }
  { $DEFINE OVERFLOWSON }
  { $Q- }
{ $ENDIF }

function DWordToComp(dw : longint) : comp;
var
  c : comp;
begin
  if u >= 0 then
    c := dw else begin
    c := $7FFFFFFF;
    if dw = -1 then
      c := c + c + 1
    else
      c := c + abs($7FFFFFFF - dw);
    end;
  result := c;
end;

{ $IFDEF OVERFLOWSON }
  { $UNDEF OVERFLOWSON }
  { $Q+ }
{ $ENDIF }
```

## Article #16420: Changing the input caret

Question and Answer Database

FAQ1420D.txt Changing the input caret

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to change the caret in an edit or other windows control capable of accepting keyboard input in response to a keyboard action?

Answer:

Yes! The following example demonstrates how to create two color bitmaps: a "smiley" and a "frowny" face bitmap, and attach them to the caret of an edit control. The edit control's window procedure must be trapped to do this to create a superclass condition when responding to windows focus messages. To do this we will replace the address of the Edit control's main window procedure with our own, and make calls to the Edit control's old window procedure as necessary. The example shows the "smiley" face caret when normally typing, and displays a "frowning" face caret when you backspace.

Example:

```
unit caret1;
```

```
interface
```

```
{ $IFDEF WIN32 }
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs, StdCtrls;
```

```
{ $ELSE }
```

```
uses
```

```
  WinTypes, WinProcs, Messages, SysUtils, Classes, Graphics,  
  Controls, Forms, Dialogs, StdCtrls;
```

```
{ $ENDIF }
```

```

type
  TForm1 = class(TForm)
    Edit1: TEdit;

## Article #16425: Is there any way to record a keyboard macro in the IDE?

Question and Answer Database

FAQ1425D.txt Is there any way to record a keyboard macro in the IDE?

Category :IDE

Platform :All

Product :All 32 bit

Question:

Is there any way to record a keyboard macro in the IDE?

Answer:

Yes! Depending on your editor setting in the IDE environment options, the following keystrokes will record and play back macros:

Default

Ctrl+Shift+P Plays back a key macro

Ctrl+Shift+R Starts and stops the recording a key macro

Classic

Ctrl+Shift+P Plays back a keyboard macro

Ctrl+Shift+R Starts and stops the recording a key macro

Brief

F7 Starts and Stops the recording a key macro

F8 Plays back a keyboard macro

Epsilon

Ctrl+X+( Records a keyboard macro

Ctrl+X+) Ends a keyboard macro recording

Ctrl+X+e Plays back the the last keyboard macro recorded

Ctrl+X+E Plays back the the last keyboard macro recorded

## Article #16430: How can I tell in code if my application is running on Windows NT

Question and Answer Database

FAQ1430D.txt    How can I tell in code if my application is running on Windows NT

Category        :VCL  
Platform        :All  
Product         :All 32 bit

Question:

How can I tell in code if my application is running on Windows NT?

Answer:

The following example demonstrates how to detect if your application is running under Windows NT. Note that the code will compile under both 16 and 32 bit platforms.

Example:

```
{ $IFDEF WIN32 }
  const WF_WINNT = $4000;
{ $ENDIF }

function IsNT : bool;
{ $IFDEF WIN32 }
  var
    osv : TOSVERSIONINFO;
{ $ENDIF }
begin
  result := true;
{ $IFDEF WIN32 }
  GetVersionEx(osv);
  if osv.dwPlatformId = VER_PLATFORM_WIN32_NT then exit;
{ $ELSE }
  if ((GetWinFlags and WF_WINNT) = WF_WINNT ) then exit;
{ $ENDIF }
  result := false;
end;

procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  if IsNt then
    ShowMessage('Running on NT')
  else
    ShowMessage('Not Running on NT');
end;
```

## Article #16435: How can I detect if a given key was pressed during application during startup?

Question and Answer Database

FAQ1435D.txt How can I detect if a given key was pressed during application during startup?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I detect if a given key was pressed during application startup?

Answer:

Use the Windows API function `GetKeyState()` to determine if a key is pressed in the main project source. To get to the main project's source file, select from the IDE's main menu, select "View">>"ProjectSource".

Example:

```
program Project1;

uses
  Windows,
  Forms,
  Unit1 in 'Unit1.pas' {Form1};

{$R *.RES}

begin
  if GetKeyState(vk_F8) < 1 then
    MessageBox(0, 'F8 was pressed during startup', 'MyApp', mb_ok);
  Application.Initialize;
  Application.CreateForm(TForm1, Form1);
  Application.Run;
end.
```

## Article #16440: Duplicate resource errors

Question and Answer Database

FAQ1440D.txt Duplicate resource errors

Category :Miscellaneous

Platform :All

Product :All 32 bit

### Question:

How can I avoid getting duplicate resource errors when linking a language dependent resource file under Delphi 3.0 or Borland C++ Builder?

### Answer:

If the resource identifier has an even number of characters, you may get duplicate resource errors. Rename the resource to a name that has an odd number of characters.

Example resource scripts:

```
{This compiles fine}
LANGUAGE LANG_ENGLISH,SUBLANG_ENGLISH_US
Hello BITMAP "hienglsh.bmp"
```

```
LANGUAGE LANG_SPANISH, SUBLANG_SPANISH_MEXICAN
Hello BITMAP "hispansh.bmp"
```

```
{This does not compile}
LANGUAGE LANG_ENGLISH,SUBLANG_ENGLISH_US
Helo BITMAP "hienglsh.bmp"
```

```
LANGUAGE LANG_SPANISH, SUBLANG_SPANISH_MEXICAN
Helo BITMAP "hispansh.bmp"
```

## Article #16445: How can I detect if a non-menu key has been pressed?

Question and Answer Database

FAQ1445D.txt How can I detect if a non-menu key has been pressed?

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I detect if a non-menu key has been pressed while a menu is displayed?

Answer:

Create a message handler for the WM\_MENUCHAR character message.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs, Menus;
```

```
type
```

```
  TForm1 = class(TForm)
```

```
    MainMenu: TMainMenu;
```

```
    One1: TMenuItem;
```

```
    Two1: TMenuItem;
```

```
    Three1: TMenuItem;
```

```
  private
```

```
    { Private declarations }
```

```
    procedure WmMenuChar(var m : TMessage); message WM_MENUCHAR;
```

```
  public
```

```
    { Public declarations }
```

```
end;
```

```
var
```

```
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.WmMenuChar(var m : TMessage);  
begin  
  Form1.Caption := 'Non standard menu key pressed';  
  m.Result := 1;  
end;  
  
end.
```

## Article #16455: Getting bin names from your printer

Question and Answer Database

FAQ1455D.txt - Getting bin names from your printer

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How do I retrieve the bin names of all bins for a particular printer using DeviceCapabilities?

Answer:

Here's a very simple app to do this. Just start a brand new project in Delphi and drop down a TButton and a TMemo. Then double click the button and paste this code snippet over the corresponding code in the implementation of Unit1.

```
uses
  WinSpool;

const
  PName = 'DELPHI III';
  PPort = '\\CONAN\DELPHI_III';

procedure TForm1.Button1Click(Sender: TObject);
var
  i : Integer;
  p : PChar;
begin
  GetMem(p,24*DeviceCapabilities(PName,PPort,DC_BINNAMES,nil,nil));
  with Mem01, Lines do begin
    Clear;
    for i:=1 to DeviceCapabilities(PName,PPort,DC_BINNAMES,p,nil) do
      Add(p+24*(i-1));
    end;
  FreeMem(p);
end;
```

## Article #16460: Changing the port of a printer

Question and Answer Database

FAQ1460D.txt - Changing the port of a printer

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How can I change the port a given printer will use in code?

Answer:

You can use the SetPrinter method of TPrinter to change the port. The following example demonstrates changing the port to print to a file.

Example:

```
uses Printers;

{$IFDEF WIN32}
  const MAX_PATH = 144;
{$ENDIF}

procedure TForm1.Button1Click(Sender: TObject);
var
  pDevice : pChar;
  pDriver : pChar;
  pPort   : pChar;
  hDMode  : THandle;
  PDMode  : PDEVMODE;
begin
  if PrintDialog1.Execute then begin
    GetMem(pDevice, cchDeviceName);
    GetMem(pDriver, MAX_PATH);
    GetMem(pPort, MAX_PATH);
    Printer.GetPrinter(pDevice, pDriver, pPort, hDMode);
    Printer.SetPrinter(pDevice, PDriver, 'FILE:', hDMode);
    FreeMem(pDevice, cchDeviceName);
```

```
FreeMem(pDriver, MAX_PATH);  
FreeMem(pPort, MAX_PATH);  
Printer.BeginDoc;  
Printer.Canvas.TextOut(100, 100, 'Delphi Is RAD!');  
Printer.EndDoc;  
end;  
end;
```

## Article #16465: Getting the actual size of a TComboBox

Question and Answer Database

FAQ1465D.txt Getting the actual size of a TComboBox

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I tell the actual size of a TComboBox in it's dropped down state before it drops down?

Answer:

During the FormShow event, send the combo box a CB\_SHOWDROPDOWN message twice, once to drop it down, and once to retract it. Then send a CB\_GETDROPPEDCONTROLRECT message, passing the address of a TRect. When the SendMessage call returns, the TRect will contain the rectangle that would enclose the ComboBox in it's dropped down state, relative to the screen. You can then call ScreenToClient to convert the TRect's coordinates to be relative to the client area of the form.

Example:

```
var
  R : TRect;

procedure TForm1.FormShow(Sender: TObject);
var
  T : TPoint;
begin
  SendMessage(ComboBox1.Handle,
              CB_SHOWDROPDOWN,
              1,
              0);
  SendMessage(ComboBox1.Handle,
              CB_SHOWDROPDOWN,
              0,
              0);
  SendMessage(ComboBox1.Handle,
              CB_GETDROPPEDCONTROLRECT,
```

```
        0,  
        LongInt(@r));  
t := ScreenToClient(Point(r.Left, r.Top));  
r.Left := t.x;  
r.Top := t.y;  
t := ScreenToClient(Point(r.Right, r.Bottom));  
r.Right := t.x;  
r.Bottom := t.y;  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Form1.Canvas.Rectangle(r.Left,  
                           r.Top,  
                           r.Right,  
                           r.Bottom );  
end;
```

## Article #16470: Converting a number from one base to another

Question and Answer Database

FAQ1470D.txt     Converting a number from one base to another  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

Question:

How can I convert a number from one base to another base?

Answer:

The following function will convert a number from one base to a number of another base:

```
procedure RadixStr(NumStr : pChar;  
                  Radix  : LongInt;  
                  ResultStr : pChar;  
                  NewRadix : LongInt;  
                  var ErrorCode : LongInt);
```

The RadixStr() function takes a pointer to a null terminated string containing a number of one base, and fills a buffer with a null terminated string containing the number converted to another base.

Parameters:

NumStr: A pointer to a null terminated string containing the numeric string to convert:

Radix: The base of the number contained in the NumStr parameter. The base must be in the range of 2 to 36;

ResultStr : A pointer to a null terminated string buffer to place the resulting numeric string. The buffer should be sufficiently large to hold the resulting string.

NewRadix: The base to use in the conversion. The base must be in the range of 2 to 36;

ErrorCode: Upon return, contains the return code 0 if successful, or the character number of the offending character contained in the buffer NumStr.

Examples of calling the RadixStr() function:

```
{Convert Hex to Decimal}
RadixStr('FF',
        16,
        lpBuffer,
        10,
        Code);
```

Should return the string '255' in lpbuffer^.

```
{Convert Decimal to Binary}
RadixStr('255',
        10,
        lpBuffer,
        2,
        Code);
```

Should return the string '11111111' in lpbuffer^.

```
{Convert Hex to Octal}
RadixStr('FF',
        16,
        lpBuffer,
        8,
        Code);
```

Should return the string '377' in lpbuffer^.

```
{Function code}
```

```
procedure RadixStr(NumStr : pChar;
                  Radix : LongInt;
                  ResultStr : pChar;
                  NewRadix : LongInt;
                  var ErrorCode : LongInt);
```

```
var
    RadixChar : array[0..35] of Char;
    v : LongInt;
    i : LongInt;
    p : LongInt;
```

```

    c : Integer;
begin
    if ((Abs(Radix) < 2) or
        (Abs(Radix) > 36)) then begin
        ErrorCode := p;
        Exit;
    end;
    StrLCopy(ResultStr, NumStr, StrLen(NumStr));
    for i := 0 to 35 do begin
        if i <= 9 then
            RadixChar[i] := Char(48 + (i))
        else
            RadixChar[i] := Char(64 + (i - 9))
        end;
    end;
    v := 0;
    for i := 0 to (StrLen(ResultStr) - 1) do begin
        ResultStr[i] := UpCase(ResultStr[i]);
        p := Pos(ResultStr[i], PChar(@RadixChar)) - 1;
        if ((p < 0) or
            (p >= Abs(Radix))) then begin
            ErrorCode := i;
            Exit;
        end;
        v := v * Abs(Radix) + p;
    end;
    if v = 0 then begin
        ResultStr := '0';
        ErrorCode := 0;
        exit;
    end else begin
        i:=0;
        repeat
            ResultStr[i] := RadixChar[v mod NewRadix];
            v := v div NewRadix;
            Inc(i)
        until v = 0;
        if Radix < 0 then begin
            ResultStr[i] := '-';
            ResultStr[i + 1] := #0
        end else
            ResultStr[i] := #0;
        p := StrLen(ResultStr);
        for i := 0 to ((p div 2) - 1) do begin
            ResultStr[i] := Char(Byte(ResultStr[i]) xor
                Byte(ResultStr[(p - i) - 1]));

```

```
ResultStr[(p - i) - 1] := Char(Byte(ResultStr[(p - i) - 1]) xor  
                                Byte(ResultStr[i]));
```

```
ResultStr[i] := Char(Byte(ResultStr[i]) xor  
                    Byte(ResultStr[(p - i) - 1]))
```

```
end;
```

```
ResultStr[p] := #0;
```

```
ErrorCode := 0;
```

```
end;
```

```
end;
```

## Article #16475: Getting printer capabilities

Question and Answer Database

FAQ1475D.txt - Getting printer capabilities

Category :Printing  
Platform :All  
Product :

Question:

How can I detect if a printer is capable of printing graphics, large bitmaps, and DIBs?

Answer:

You can call the `GetDeviceCaps` function and test the capability against the `RASTERCAPS` capability. Note that if the Device does support graphics, but does not support another raster capability such as "StretchDib", Windows will handle the call by using lower level graphic primitives to accomplish the task.

Example:

```
if (GetDeviceCaps(Printer.Canvas.Handle, RASTERCAPS) and
    RC_NONE) = RC_NONE then
NoGraphics := True;

if (GetDeviceCaps(Printer.Canvas.Handle, RASTERCAPS) and
    RC_STRETCHDIB) = RC_STRETCHDIB then
DeviceDirectly SupportsStretchDIB := True else
WindowsWillSimulateStretchDIB := True;
```

## Article #16485: Getting property information

Question and Answer Database

FAQ1485D.txt    Getting property information

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I tell if a given object has a given property at runtime?

Answer:

The following example shows how to determine if an object has a property available, and if so, how to change the property:

```
function HasProperty(Obj : TObject;
                    Prop : string) : PPropInfo;
begin
  Result := GetPropInfo(Obj.ClassInfo, Prop);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  p : pointer;
begin
  p := HasProperty(Button1, 'Color');
  if p <> nil then
    SetOrdProp(Button1, p, clRed) else
    ShowMessage('Button has no color property');

  p := HasProperty(Label1, 'Color');
  if p <> nil then
    SetOrdProp(Label1, p, clRed) else
    ShowMessage('Label has no color property');

  p := HasProperty(Label1.Font, 'Color');
  if p <> nil then
    SetOrdProp(Label1.Font.Color, p, clBlue) else
    ShowMessage('Label.Font has no color property');
end;
```

## Article #16490: Moving controls at runtime

Question and Answer Database

FAQ1490D.txt Moving controls at runtime

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I move a control at runtime using the mouse?

Answer:

You can trap the OnMouseDown event, remembering the x and y coordinates of the mouse and set the mouse capture. You can then track mouse movements with the OnMouseMove event, moving the control until the OnMouseUp event is fired. You then will want to place the control in it's final position and release capture of the mouse.

The following example shows how to move a TButton component around on the form using the mouse. The movement is initiated by the user holding down the control key when the mouse button is activated.

Example:

type

```
TForm1 = class(TForm)
  Button1: TButton;
  procedure Button1MouseDown(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
  procedure Button1MouseMove(Sender: TObject; Shift: TShiftState; X,
    Y: Integer);
  procedure Button1MouseUp(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
private
  { Private declarations }
public
  { Public declarations }
  MouseDownSpot : TPoint;
```

```

    Capturing : bool;
end;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.Button1MouseDown(Sender: TObject;
Button: TMouseButton; Shift: TShiftState; X, Y: Integer);
begin
    if ssCtrl in Shift then begin
        SetCapture(Button1.Handle);
        Capturing := true;
        MouseDownSpot.X := x;
        MouseDownSpot.Y := Y;
    end;
end;

procedure TForm1.Button1MouseMove(Sender: TObject;
Shift: TShiftState; X, Y: Integer);
begin
    if Capturing then begin
        Button1.Left := Button1.Left - (MouseDownSpot.x - x);
        Button1.Top := Button1.Top - (MouseDownSpot.y - y);
    end;
end;

procedure TForm1.Button1MouseUp(Sender: TObject; Button: TMouseButton;
Shift: TShiftState; X, Y: Integer);
begin
    if Capturing then begin
        ReleaseCapture;
        Capturing := false;
        Button1.Left := Button1.Left - (MouseDownSpot.x - x);
        Button1.Top := Button1.Top - (MouseDownSpot.y - y);
    end;
end;

```

## Article #16495: re-mark a Delphi 16-Bit executable to be a Windows 4.0 application

Question and Answer Database

FAQ1495D.txt - re-mark a Delphi 16-Bit executable to be a Windows 4.0 application

Category :Delphi 1.x  
Platform :All Windows  
Product :

Question:

Is it possible to re-mark a Delphi 16-Bit executable to be a Windows 4.0 application, and why have I been instructed to do this? Is it also possible to tell what kind of executable image a given file is and it's expected windows version before I load it?

Answer:

There are several reasons why you would want to mark a 16-Bit executable to be a Windows 4.0 application.

- 1) Thunks created using the Microsoft Thunk Compiler will not work unless the 16-bit thunk DLL is marked for version 4.0.
- 2) Print drivers and other sub system driver files created for Windows 95 must be marked for version 4.0 even though they may be 16-bit executable images.
- 3) All standard control windows owned by a version 4.0 application are drawn with a chiseled 3D look.
- 4) Applications marked for Windows version 4.0 receive the full benefit of new user interface features available in Windows 95.
- 5) New window messages, such as WM\_STYLECHANGED, are sent to applications that are marked as a version 4.0 application.
- 6) Printer DCs are reset during StartPage() in version 4.0 applications.
- 7) Executables marked as a Windows version 4.0 executable will load on Windows 95, Windows NT versions 3.5, Win32s version 1.15, and all

later versions, but will not load on earlier versions of Windows such as Windows 3.1.

Note: Windows applications marked as 3.1 executables allow other applications to share GDI resources such as font or bitmap handles. Windows 95 does not clean up objects left undeleted by a 16-bit version 3.x application. Objects created by a 16-bit version 4.0-based applications are not shared, and are freed automatically when the application terminates.

The following is an example of how to read, examine, and remark the expected windows version of any Windows executable, dynamic link library, or .vxd file. Note: Any non-zero file checksums are not recalculated. You cannot mark a file that is currently in use. To build the project, you will need to create a form that contains two buttons, one label, an OpenFileDialog component, and two spin edit components.

Example:

```
unit Unit1;

interface

{$IFDEF WIN32}
uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, StdCtrls, Spin;
{$ELSE}
uses
  WinTypes, WinProcs, Messages, SysUtils, Classes, Graphics, Controls,
  Forms, Dialogs, StdCtrls, Spin;
{$ENDIF}

type
  TForm1 = class(TForm)
    SpinEdit1: TSpinEdit;
    SpinEdit2: TSpinEdit;
    Button1: TButton;
    Button2: TButton;
    OpenFileDialog: TOpenDialog;
    Label1: TLabel;
  procedure FormCreate(Sender: TObject);
  procedure Button1Click(Sender: TObject);
  procedure Button2Click(Sender: TObject);
```

```
private
  { Private declarations }
  ExeType : word;
  hdroffset : longint;
  procedure GetExeHeader(FileName : string);
  procedure RemarkExeHeader(FileName : string);
public
  { Public declarations }
end;
```

```
var
  Form1: TForm1;
```

## Article #16500: Does Delphi have an equivalent to the Visual Basic SendKeys function?

Question and Answer Database

FAQ1500D.txt Does Delphi have an equivalent to the Visual Basic SendKeys function?

Category :VCL

Platform :All

Product :All 32 bit

Question:

Does Delphi have an equivalent to the Visual Basic SendKeys function?

Answer:

The following example demonstrates procedures that provide the capability of sending keystrokes to any window control capable of receiving keyboard input. You may use this technique to toggle the num lock, caps lock, and scroll lock keys under Windows NT. This same technique works for toggling caps lock and scroll lock keys under Windows 95, but it will not work for num lock.

Note that there are four procedures provided: SimulateKeyDown(), SimulateKeyUp(), SimulateKeystroke(), and SendKeys(), to allow greater control in your ability to send keystrokes.

The SimulateKeyDown(), SimulateKeyUp(), and SimulateKeystroke() procedures expect a virtual key code (like VK\_F1).

The SimulateKeystroke() procedure accepts an extra parameter that is useful when simulating the PrintScreen key. When extra is set to zero, the entire screen will be captured to the windows clipboard. When extra is set to one, only the active window will be captured.

The four button click methods demonstrate the use of these functions:

ButtonClick1 - Toggles the cap lock.

ButtonClick2 - Captures the entire screen to the clipboard.

ButtonClick3 - Capture the active window to the clipboard.

ButtonClick4 - Set the focus to an edit control and sends it a string.

Example:

```
procedure SimulateKeyDown(Key : byte);
```

```

begin
    keybd_event(Key, 0, 0, 0);
end;

procedure SimulateKeyUp(Key : byte);
begin
    keybd_event(Key, 0, KEYEVENTF_KEYUP, 0);
end;

procedure SimulateKeystroke(Key : byte;
                             extra : DWORD);
begin
    keybd_event(Key,
                extra,
                0,
                0);
    keybd_event(Key,
                extra,
                KEYEVENTF_KEYUP,
                0);
end;

procedure SendKeys(s : string);
var
    i : integer;
    flag : bool;
    w : word;
begin
    {Get the state of the caps lock key}
    flag := not GetKeyState(VK_CAPITAL) and 1 = 0;
    {If the caps lock key is on then turn it off}
    if flag then
        SimulateKeystroke(VK_CAPITAL, 0);
    for i := 1 to Length(s) do begin
        w := VkKeyScan(s[i]);
        {If there is not an error in the key translation}
        if ((HiByte(w) <> $FF) and
            (LoByte(w) <> $FF)) then begin
            {If the key requires the shift key down - hold it down}
            if HiByte(w) and 1 = 1 then
                SimulateKeyDown(VK_SHIFT);
            {Send the VK_KEY}
            SimulateKeystroke(LoByte(w), 0);
            {If the key required the shift key down - release it}
            if HiByte(w) and 1 = 1 then

```

```

        SimulateKeyUp(VK_SHIFT);
    end;
end;
{if the caps lock key was on at start, turn it back on}
if flag then
    SimulateKeystroke(VK_CAPITAL, 0);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    {Toggle the cap lock}
    SimulateKeystroke(VK_CAPITAL, 0);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
    {Capture the entire screen to the clipboard}
    {by simulating pressing the PrintScreen key}
    SimulateKeystroke(VK_SNAPSHOT, 0);
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
    {Capture the active window to the clipboard}
    {by simulating pressing the PrintScreen key}
    SimulateKeystroke(VK_SNAPSHOT, 1);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
    {Set the focus to a window (edit control) and send it a string}
    Application.ProcessMessages;
    Edit1.SetFocus;
    SendKeys('Delphi Is RAD!');
end;

```

## Article #16505: Using Tapi

Question and Answer Database

FAQ1505D.txt Using Tapi

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I use TAPI to dial the telephone for a voice call?

Answer:

The following example shows how to interface with tapi to make a voice call.

Example:

```
{tapi Errors}
const TAPIERR_CONNECTED          = 0;
const TAPIERR_DROPPED           = -1;
const TAPIERR_NOREQUESTRECIPIENT = -2;
const TAPIERR_REQUESTQUEUEFULL  = -3;
const TAPIERR_INVALIDDESTADDRESS = -4;
const TAPIERR_INVALIDWINDOWHANDLE = -5;
const TAPIERR_INVALIDDEVICECLASS = -6;
const TAPIERR_INVALIDDEVICEID    = -7;
const TAPIERR_DEVICECLASSUNAVAIL = -8;
const TAPIERR_DEVICEIDUNAVAIL    = -9;
const TAPIERR_DEVICEINUSE        = -10;
const TAPIERR_DESTBUSY           = -11;
const TAPIERR_DESTNOANSWER       = -12;

## Article #16510: Setting custom tabstops in a ListBox.

Question and Answer Database

FAQ1510D.txt     Setting custom tabstops in a ListBox.

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I set custom tab stops in a TListbox control?

Answer:

You will need to send a LB\_SETTABSTOPS message to the Listbox.

Note: The Listbox tabwidth property must be set to a number other than zero for the LB\_SETTABSTOPS message to work.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
```

```
  ListBox1.TabWidth := 1;
```

```
  ListBox1.Items.Add('one'+#9+'one');
```

```
  ListBox1.Items.Add('two'+#9+'two');
```

```
  ListBox1.Items.Add('three'+#9+'three');
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  DialogUnitsX : LongInt;
```

```
  PixelsX : LongInt;
```

```
  i : integer;
```

```
  TabArray : array[0..4] of integer;
```

```
begin
```

```
  DialogUnitsX := LoWord(GetDialogBaseUnits);
```

```
  PixelsX := SpinEdit1.Value;
```

```
  for i := 1 to 5 do begin
```

```
    TabArray[i - 1] :=
```

```
      ((PixelsX * i) * 4) div DialogUnitsX;
```

```
  end;
```

```
  if SendMessage(ListBox1.Handle,
```

```
      LB_SETTABSTOPS,
```

```
5,  
    LongInt(@TabArray)) = 0 then  
    ShowMessage('Tabs Not Set');  
    Listbox1.Refresh;  
end;
```

## Article #16515: Compile Error: Too many files open

Question and Answer Database

FAQ1515D.txt     Compile Error: Too many files open

Category        :IDE

Platform        :All

Product         :All 32 bit

### Question:

I have a large project consisting of many units. I added a unit and now I get an error "Too many files open". How can I work around this?

### Answer:

Move your project to a directory with a short path name, or use the dos subst command to substitute a drive letter for the directory name. If you move the project to another directory, be sure to only move the necessary files used to compile the application. Borland's Ti3214 - "Moving Projects Between Machines or Directories" is also a helpful resource. ie: .dpr, .pas, .res etc.. Note: Do not move the .dsm files, as they have path information built into them, and will be automatically regenerated.

## Article #16520: How can I create a transparent form?

Question and Answer Database

FAQ1520D.txt    How can I create a transparent form?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I create a transparent form?

Answer:

The following example demonstrates how to create a transparent form.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Form1.Brush.Style := bsClear;
  Form1.BorderStyle := bsNone
end;
```

```
procedure TForm1.BitBtn1Click(Sender: TObject);
begin
  Application.Terminate;
end;
```

## Article #16525: Using WM\_COPYDATA.

Question and Answer Database

FAQ1525D.txt Using WM\_COPYDATA.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I use the WM\_COPYDATA message to pass information between 16-bit and 32-bit applications?

Answer:

The following example shows how to use the WM\_COPYDATA message to send a record containing data between a 16-bit and 32-bit application. This method can also be used to call 16-bit or 32-bit dll from a 16-bit or 32-bit application (known as thunking). Thunking can be accomplished by creating an invisible window to respond to the WM\_COPYDATA message, and call the dll in your behalf.

Compile the following unit source code under both 16-bit and 32-bit versions of Delphi. Use separate directories for the two projects. Each project will require a form, a button, and a memo component on it's form.

To use the WM\_COPYDATA message, you must send the address of a TCopyDataStruct to the receiving window. The dwData parameter of the TCopyDataStruc is a user defined parameter that allows you to store any 32 bit value you wish, for additional information. The cbData member of the TCopyDataStruc contains the size of the data pointed to by the lpData member of the TCopyDataStruc. The lpData parameter of the TCopyDataStruct can point to any data structure you wish.

Note that any pointers contained in the structure you send will not be valid from the receiving application since windows has no way to convert them. Note that the data that is passed to the receiving application is only valid during the call. If the receiving application needs to retain the information passed, it should make a copy of the data that is local to the receiving application. The receiving application should not modify the data that is passed during the call. If modifications are necessary, the receiving application

should make a local copy of the data, and send a WM\_COPYDATA message back to the sending application using the modified copy.

It's worth noting that the WM\_COPYDATA message will work going to and from any combination of 16/32 bit applications. Finally, be aware that the call to SendMessage will not return until the message is processed. Also be aware that you should never use PostMessage() with the WM\_COPYDATA message.

```
unit Unit1;
```

```
interface
```

## Article #16530: Selecting a cell in a DBGrid

Question and Answer Database

FAQ1530D.txt     Selecting a cell in a DBGrid

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

How can I programmatically place a grid into edit mode and move the cursor to a predetermined position in the edit box?

### Answer:

Place the grid in editor mode, then get a handle to the edit box and send a EM\_SETSEL message, passing the initial position where you want the cursor to appear, and the position of the ending selection (if you wish to highlight text).

The following example sets the cursor to the second character in the edit control, and does not select any text.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  h : THandle;
begin
  Application.ProcessMessages;
  DbGrid1.SetFocus;
  DbGrid1.EditorMode := true;
  Application.ProcessMessages;
  h := Windows.GetFocus;
  SendMessage(h, EM_SETSEL, 2, 2);
end;
```

## Article #16535: Trapping non client areas

Question and Answer Database

FAQ1535D.txt Trapping non client areas

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I trap messages in the non client areas of my form, such as the title bar?

Answer:

Create a message handler for one of the variety of WM\_NC (non client) messages available to trap. (search the Windows API help file for WM\_NC). This example shows how to track mouse movement in all of the non client areas of the form.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs, StdCtrls;
```

```
type
```

```
  TForm1 = class(TForm)
```

```
  private
```

```
    procedure WMNCMOUSEMOVE(var Message: TMessage);
```

```
    message WM_NCMOUSEMOVE;
```

```
    { Private declarations }
```

```
  public
```

```
    { Public declarations }
```

```
  end;
```

```
var
```

```
  Form1: TForm1;
```

implementation

{ \$R \*.DFM }

```
procedure TForm1.WMNCMOUSEMOVE(var Message: TMessage);
var
  s : string;
begin
  case Message.wParam of
    HTERROR : s := 'HTERROR';
    HTTRANSPARENT : s := 'HTTRANSPARENT';
    HTNOWHERE : s := 'HTNOWHERE';
    HTCLIENT : s := 'HTCLIENT';
    HTCAPTION : s := 'HTCAPTION';
    HTSYSTEMMENU : s := 'HTSYSTEMMENU';
    HTSIZE : s := 'HTSIZE';
    HTMENU : s := 'HTMENU';
    HTHSCROLL : s := 'HTHSCROLL';
    HTVSCROLL : s := 'HTVSCROLL';
    HTMINBUTTON : s := 'HTMINBUTTON';
    HTMAXBUTTON : s := 'HTMAXBUTTON';
    HTLEFT : s := 'HTLEFT';

## Article #16545: Changing the printer setup between pages

Question and Answer Database

FAQ1545D.txt - Changing the printer setup between pages

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How can I change the printer setup between printed pages?

Answer:

This is normally accomplished by retrieving a copy of the device mode structure that is associated with the current printer, making the necessary changes to the device independent portion of the structure, and then calling the Windows API function `ResetDc()` in between pages.

Since the `ResetDc()` function is disabled by Windows during the printing of a page, and the `TPrinter` unit does not have an event that is fired between pages, a work around is required.

While it is possible to insert and modify code directly in the implementation section of `TPrinter`, it is not possible to make changes to the interface portion of `TPrinter` and still maintain stability in the VCL and other third party components. With the advent of packages, rebuilding the main VCL package is also not an ideal solution. Finally, `TPrinter` is one of the few VCL classes that does not lend itself to subclassing, making it difficult to add an event that would fire between pages.

Before the advent of packages, the work around consisted of creating an additional unit that sat between `TPrinter` and the unit(s) containing your printing code. A `uses` statement was added to the `TPrinter` unit in the implementation section that pointed to the new unit (avoiding any change to `TPrinter`'s interface section). Finally, code was added to the `TPrinter` unit that would call a function pointer in the new unit between each printed page. You could then hook into `TPrinter` by adding the new unit to the `uses` clause of the unit(s) you

are printing from, and reassigning the function pointer to point to a function in your unit. While this may sound complex, in practice, it was a clean solution to an interesting problem, that worked well with both VCL components and custom printing code produced directly in your application.

With the advent of packages, a new solution is needed, since the TPrinter unit is compiled into the main VCL system package, where rebuilding is not recommended. Here we will provide such a solution in the form of a single unit that encapsulates both the work around and the printing code. The code is designed so it will compile under all versions of Delphi and Borland's C++ Builder. Since there will be no hooks added to the TPrinter unit, this solution will only work with custom printing code provided from your application, and not work with VCL and other "non-aware" third part components that offer a print method, or code utilizing the AssignPrn() function.

The solution presented allows changes to the page setup by making direct calls to the Windows API to simulate TPrinter's NewPage method, and calling the Windows API function ResetDc() between pages. Note that not all printers support the ResetDc() escape. Under 16 bit versions of Windows, testing for escape support by calling Escape(QueryEscapeSupport...) returns the correct value for the ResetDc undocumented escape code #128, but Windows 95 instead steals the call, and returns true even if the driver does not support it. The only way to test if the ResetDc() function is supported is to make a call directly to the function itself. To avoid printing blank pages in the event of an error, the example calls the ResetDC function and passes Printer.Handle as the DC before the printing actually starts to test for support of the function. This is ok, as the call is transformed by Windows to an escape to the print driver, and the dc is not actually passed but is instead used by Windows to identify the driver. If the print driver does not support the ResetDc() escape, we will accomplish changing the printer's settings by printing each page as separate print job. Since we are bypassing TPrinter's NewPage method, and since the print job may be accomplished by printing separate pages, the PageNumber property of TPrinter will not remain accurate through out the print job and should be tracked by the application. Finally, if abort method of TPrinter must be called, it should be called in a section of code after only after a StartPage command.

Note: See TDEVMODE in the Delphi 1.02 help file or DEVMODE in the 32 bit versions of Delphi and C++ Builder for other settings you can change, such as the bin, paper sizes and so forth.

Example:

```
unit Unit1;

interface

{$IFDEF WIN32}
uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls,
  Forms, Dialogs, StdCtrls, Printers;
{$ELSE}
uses
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,
  Controls, Forms, Dialogs, StdCtrls, Printers, Print;
{$ENDIF}

type
  TForm1 = class(TForm)
    PrintDialog1: TPrintDialog;
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
    function PageSetup : bool;
    function NewPage : bool;
  public
    { Public declarations }
    PageNumber : integer;
    CanReset : bool;
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

## Article #16550: Text in Windows metafiles

Question and Answer Database

FAQ1550D.txt    Text in Windows metafiles

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

### Question:

Sometimes, some text in a metafile I display from my application comes up in the wrong font. The file displays properly in xyz Graphics program. Why?

### Answer:

The VCL simply wraps standard Windows functions for displaying metafiles. As the metafile is scaled, the font width and height are scaled as well. Many times, the Windows font mapper will simply substitute a different font that the font that was originally selected in an attempt to satisfy the request. This can also be seen in many graphics programs if you arbitrarily scale the metafile in different directions. Note that some "hi end" graphic programs actually read the metafile record by record, bypassing the Windows GDI entirely to overcome the effects of the Windows font mapper.

## Article #16555: How can I get the serial number of an Audio CD?

Question and Answer Database

FAQ1555D.txt     How can I get the serial number of an Audio CD?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I get the serial number of an Audio CD?

Answer:

The cd may or may not have a serial number and/or Universal Product Code embedded in the cd. The MCI Windows extension does provide this functionality through the MCI\_INFO\_MEDIA\_IDENTITY command. This command will return a unique ID string consisting of 16 hexadecimal digits.

Example:

```
uses MMSystem, MPlayer;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  mp : TMediaPlayer;
```

```
  msp : TMCI_INFO_PARMS;
```

```
  MediaString : array[0..255] of char;
```

```
  ret : longint;
```

```
begin
```

```
  mp := TMediaPlayer.Create(nil);
```

```
  mp.Visible := false;
```

```
  mp.Parent := Application.MainForm;
```

```
  mp.Shareable := true;
```

```
  mp.DeviceType := dtCDAudio;
```

```
  mp.FileName := 'D:';
```

```
  mp.Open;
```

```
  Application.ProcessMessages;
```

```
  FillChar(MediaString, sizeof(MediaString), #0);
```

```
  FillChar(msp, sizeof(msp), #0);
```

```
  msp.lpstrReturn := @MediaString;
```

```
  msp.dwRetSize := 255;
```

```
ret := mciSendCommand(Mp.DeviceId,  
                      MCI_INFO,  
                      MCI_INFO_MEDIA_IDENTITY,  
                      longint(@msp));  
  
if Ret <> 0 then begin  
  MciGetErrorString(ret, @MediaString, sizeof(MediaString));  
  Mem1.Lines.Add(StrPas(MediaString));  
end else  
  Mem1.Lines.Add(StrPas(MediaString));  
mp.Close;  
Application.ProcessMessages;  
mp.free;  
end;  
  
end.
```

## Article #16560: Error: 'Mismatch in datapacket'

Question and Answer Database

FAQ1560D.txt     Error: 'Mismatch in datapacket'

Category     :Multitier/Remote Datasets

Platform     :All

Product      :Delphi 3.x

Question:

When I use LoadFromStream on the TClientDataSet,  
I receive an EDBClient exception "Mismatch in datapacket".

Answer:

You may not be resetting the position of the stream.  
This procedure works...

```
var
Stream: TMemoryStream;
begin
  Stream := TMemoryStream.Create;
  try
    CDS.SaveToStream(Stream);
    // Reset to the beginning of the data packet.
    // Forgetting this step is one way to produce the error.
    Stream.Position := 0;
    CDS.LoadFromStream(Stream);
  finally
    Stream.Free;
  end;
end;
```

## Article #16565: Accessing new interfaces in a RemoteDataModule

Question and Answer Database

FAQ1565D.txt    Accessing new interfaces in a RemoteDataModule  
Category        :Multitier/Remote Datasets  
Platform        :All  
Product         :Delphi 3.x

Question:

If I want to support several interfaces on the same RemoteDataModule and in the typelib editor, add new interfaces, and make them members of the original coClass. How do I access these other interfaces. If I try (AppServer as IAnother) or IAnother(AppServer), I get a compilation error.

Answer:

Try the syntax:

```
(IDispatch(RemoteServer.AppServer) as IAnother)
```

Also, this will only work if you are using DCOM as the transport.

## Article #16575: Reassigning events at runtime

Question and Answer Database

FAQ1575D.txt Reassigning events at runtime

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I reassign an event at runtime?

Answer:

The following example demonstrates reassigning an event.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Button2SavedEvent : TNotifyEvent;
  Button3SavedEvent : TNotifyEvent;
begin
  {Save the events}
  Button2SavedEvent := Button2.OnClick;
  Button3SavedEvent := Button3.OnClick;

  {Clear button 2's OnClick event}
  Button2.OnClick := nil;

  {Set button 3's OnClick to Button2's old OnClick Event}
  Button3.OnClick := Button2SavedEvent;

  { Do something here }

  {Take us back to the original events}
  Button2.OnClick := Button2SavedEvent;
  Button3.OnClick := Button3SavedEvent;
end;
```

## Article #16580: Showing two forms allowing the first to retain focus

Question and Answer Database

FAQ1580D.txt Showing two forms allowing the first to retain focus

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to show a form, but allow the form showing before it to remain focused, and still positioned behind the newly shown form?

Answer:

The follow code demonstrates showing a non auto-created form without changing the focus of the original form.

```
uses Unit2;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    Form2 := TForm2.Create(Application);
```

```
    Form2.Visible := FALSE;
```

```
    ShowWindow(Form2.Handle, SW_SHOWNA);
```

```
end;
```

Question and Answer Database

FAQ1585D.txt Disabling close button of a window

Category :Windows API

Platform :All

Product :All 32 bit

Question:

Is it possible to disable the close button of any given Window?

Answer:

Yes, the following example disables the close button (and close option from the system menu) of the given Window.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  hwndHandle : THANDLE;
  hMenuHandle : HMENU;
begin
  hwndHandle := FindWindow(nil, 'Untitled - Notepad');
  if (hwndHandle <> 0) then begin
    hMenuHandle := GetSystemMenu(hwndHandle, FALSE);
    if (hMenuHandle <> 0) then
      DeleteMenu(hMenuHandle, SC_CLOSE, MF_BYCOMMAND);
  end;
end;
```

## Article #16595: Creating a Resource only DLL

Question and Answer Database

FAQ1595D.txt     Creating a Resource only DLL

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How do I create a Resource only DLL?

Answer:

Create and build an empty DLL project, that contains a resource link reference to the .res file that contains your resources.

Example:

```
library ResTest;
```

```
uses
```

```
    SysUtils;
```

```
{ $R MYRES.RES }
```

```
begin
```

```
end.
```

To use you resource only DLL, simply load the dll and the resources you wish to use:

Example:

```
{ $IFDEF WIN32 }
```

```
const BadDllLoad = 0;
```

```
{ $ELSE }
```

```
const BadDllLoad = 32;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
h : THandle;  
Icon : THandle;
```

```
begin
```

```
  h := LoadLibrary('RESTEST.DLL');
```

```
  if h <= BadDllLoad then
```

```
    ShowMessage('Bad Dll Load')
```

```
  else begin
```

```
    Icon := LoadIcon(h, 'ICON_1');
```

```
    DrawIcon(Form1.Canvas.Handle, 10, 10, Icon);
```

```
    FreeLibrary(h);
```

```
  end;
```

```
end;
```

## Article #16600: Deleting an executable while it is running

Question and Answer Database

FAQ1600D.txt Deleting an executable while it is running

Category :Miscellaneous

Platform :All

Product :All 32 bit

Question:

How can I delete my executable while it is running?

Answer:

Under Win32, unless you are running from a removable drive, you cannot delete a running executable. You can have Windows delete the executable the next time Windows is ran by adding an entry to the RunOnce key in the Windows registry under:

HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce

You can name the key anything you like, and specify a command line to another executable or to a dos command passed to command.com.

Example:

uses

Registry;

procedure TForm1.Button1Click(Sender: TObject);

var

reg: TRegistry;

begin

reg := TRegistry.Create;

with reg do begin

RootKey := HKEY\_LOCAL\_MACHINE;

LazyWrite := false;

OpenKey('Software\Microsoft\Windows\CurrentVersion\RunOnce',  
false);

WriteString('Delete Me!', 'command.com /c del FILENAME.EXT');

```
    CloseKey;  
    free;  
end;  
end;
```

Question and Answer Database

FAQ1610D.txt displaying an application associated icons

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I display the icon that is associated with a given file type?

Answer:

Use the ShellApi function `ExtractAssociatedIcon()` to retrieve the icon that is associated with the file.

Example:

```
uses ShellApi;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    Icon : hIcon;
```

```
    IconIndex : word;
```

```
begin
```

```
    IconIndex := 1;
```

```
    Icon := ExtractAssociatedIcon(HInstance,  
                                Application.ExeName,  
                                IconIndex);
```

```
    DrawIcon(Canvas.Handle, 10, 10, Icon);
```

```
end;
```

Question and Answer Database

FAQ1625D.txt - Printing a web page using the HTML control

Category :Printing  
Platform :All  
Product :

Question:

How do I print a WEB page with the HTML control?

Answer:

Use either the HTML control's AutoPrint method, or alternatively use the PrintPage method.

Example using AutoPrint:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    OldCur: TCursor;
```

```
begin
```

```
    OldCur := Screen.Cursor;
```

```
    with Printer do begin
```

```
        BeginDoc;
```

```
        HTML1.AutoPrint(handle);
```

```
        Title := HTML1.URL;
```

```
        EndDoc;
```

```
    end;
```

```
    Screen.Cursor := OldCur;
```

```
end;
```

## Article #16630: Illegal Operation, Windows Lockup, IDE

Question and Answer Database

FAQ1630D.txt Illegal Operation, Windows Lockup, IDE

Category :IDE

Platform :All

Product :All 32 bit

### Question:

How can I prevent Windows 95 from locking up when my application performs an illegal operation when run from the IDE?

### Answer:

When the dialog box announces the Illegal Operation, do not immediately press the "Done" button. Instead, go back to the IDE and select "Run->Program Reset" from the IDE menu (or press Ctrl-F2 inside the IDE) to release the Debug Hook, and then go back to the dialog box and press the "Done" button.

## Article #16635: doing work while application is Idle

Question and Answer Database

FAQ1635D.txt    doing work while application is Idle

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I have my application perform work when it is idle?

Answer:

You can create an OnIdle event to be called whenever your application is waiting for messages to be processed. Simply declare the event handler procedure in the private section of the forms declaration:

```
{ Private declarations }  
procedure IdleEventHandler(Sender: TObject; var Done: Boolean);
```

In the implementation section, define the procedure:

```
procedure TForm1.IdleEventHandler(Sender: TObject;  
  var Done: Boolean);  
begin  
  {Do a small bit of work here}  
  Done := false;  
end;
```

Then assign the Application's OnIdle event to point to your new procedure(You may do this wherever you like, but a good place would be the Forms OnCreate method):

```
Application.OnIdle := IdleEventHandler;
```

OnIdle is called only once, as the application transitions into an idle state. It is not called continuously unless Done is set to False. If Done is False, WaitMessage is not called. Applications that set Done to False consume an inordinate amount of CPU time that affects overall system performance.

You can set the boolean variable "done" to true when you want to stop the event handler from executing.

## Article #16640: passing functions/procedure to other functions/procedures

Question and Answer Database

FAQ1640D.txt    passing functions/procedure to other functions/  
procedures

Category        :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

Can I pass a function or procedure to another function or procedure?

Answer:

Yes. You must declare a procedure or function type to use as the parameter type, then you can pass the address of the procedure that you wish to pass. You must be careful to pass functions or procedures that are compatible with the function or procedure expected, as little error checking will be provided by the compiler.

Example:

```
type
  AFunctionType = function(IntIn : integer) : integer;

function AddProc(IntIn : integer) : integer;
begin
  Result := IntIn + 1;
end;

function SubProc(IntIn : integer) : integer;
begin
  Result := IntIn - 2;
end;

procedure PassAFunction(var IntIn : integer;
                        fn : AFunctionType);
begin
  IntIn := fn(IntIn);
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i : integer;

begin
  i := 10;

  PassAFunction(i, @AddProc);
  ShowMessage(IntToStr(i));

  PassAFunction(i, @SubProc);
  ShowMessage(IntToStr(i));
end;
```

## Article #16645: printing a TStringGrid or a TDBGrid

Question and Answer Database

FAQ1645D.txt - printing a TStringGrid or a TDBGrid

Category :Printing  
Platform :All  
Product :

Question:

How do I Print a TStingGrid / TDBGrid?

Answer:

You will need to create two loops, one to print each row, and one to print each column using TPrinter's TextOut method. You should determine the widest line of text in the grid you will need to accommodate and adjust your font size as necessary, or decide if you need to print some of the columns on a separate page.

## Article #16650: printing in color

Question and Answer Database

FAQ1650D.txt - printing in color

Category :Printing

Platform :All

Product :

Question:

How do I print in color?

Answer:

Generally, no special effort is required to print in color assuming the printer is a color printer and is set to its native color mode. Windows will automatically convert color to black and white if the printer does not support color. If you need to change the color mode in code, you can access the DevMode structure of the printer driver.

Example:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    Device : array[0..255] of char;
```

```
    Driver : array[0..255] of char;
```

```
    Port   : array[0..255] of char;
```

```
    hDMode : THandle;
```

```
    PDMode : PDEVMODE;
```

```
begin
```

```
    with Printer do begin
```

```
        PrinterIndex := PrinterIndex;
```

```
        GetPrinter(Device, Driver, Port, hDMode);
```

```
    if hDMode <> 0 then begin
```

```
        pDMode := GlobalLock(hDMode);
```

```
        if pDMode <> nil then begin
```

```
            pDMode.dmFields := pDMode.dmFields or dm_Color;
```

```
            pDMode.dmColor := DMCOLOR_COLOR;
```

```
GlobalUnlock(hDMode);
end;
end;

PrinterIndex := PrinterIndex;
BeginDoc;
Canvas.Font.Color := clRed;
Canvas.TextOut(100,100, 'Red As A Rose!');
EndDoc;
end;
end;
```

## Article #16655: rotating a Metafile

Question and Answer Database

FAQ1655D.txt rotating a Metafile

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I rotate a Metafile?

Answer:

You will need to enumerate through the metafile records using the Windows API functions EnumMetaFile() and EnumEnhMetaFile(). As each Metafile object is returned, you will need to rotate the coordinates of each object. Rectangles will need to be converted to polygons, and ellipses will need to be rendered to polylines under Win16 or replaced with paths under Win32. Fonts should be remapped to TrueType fonts (if necessary) since most non-TrueType fonts do not rotate.

## Article #16664: Colored text on a TStatusBar

Question and Answer Database

FAQ1664D.txt Colored text on a TStatusBar

Category :VCL

Platform :All

Product :All 32 bit

Question:

Why do changes to the StatusBar's font color not have any affect?

Answer:

The status bar is a standard Windows control, and as such, displays the font in the `clBtnText` value, which is set via the Control Panel. This color is black by default, but it can vary due to the user's color scheme. Other standard Windows controls, such as buttons, exhibit this identical behavior. The StatusBar and its associated panels have an owner-draw capability that allow you to draw text in any colors you want. Be sure to change the `Style` property of the `TStatusBar.Panels` to `OwnerDraw`.

Example:

```
procedure TForm1.StatusBar1DrawPanel(StatusBar: TStatusBar;
  Panel: TStatusBarPanel; const Rect: TRect);
begin
  if Panel = StatusBar.Panels[0] then begin
    StatusBar.Canvas.Font.Color := clRed;
    StatusBar.Canvas.TextOut(Rect.Left, Rect.Top, 'Panel - 0')
  end else begin
    StatusBar.Canvas.Font.Color := clGreen;
    StatusBar.Canvas.TextOut(Rect.Left, Rect.Top, 'Panel - 1');
  end;
end;
```

## Article #16668: Typecasting

Question and Answer Database

FAQ1668D.txt    Typecasting

Category       :Object Pascal

Platform       :All

Product        :All 32 bit

Question:

Many Windows functions claim to want PChar parameters in the documentation, but they are defined as requiring LongInts. Is this a bug?

Answer:

No, this is where "typecasting" is used. Typecasting allows you to fool the compiler into thinking that one type of variable is of another type for the ultimate in flexibility. The last parameter of the Windows API function SendMessage() is a good example. It is documented as requiring a long integer, but commonly requires a PChar for certain messages (i.e. WM\_WININICHANGE). Generally, the variable you are typecasting from must be the same size as the variable type you are casting it to. In the SendMessage example, you could typecast a PChar as a longint, since both occupy 4 bytes of memory:

Example:

```
var
  s : array[0..64] of char;
begin
  StrCopy(S, 'windows');
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@S));
end;
```

Pointers are the easiest to typecast, and are the most flexible since you can pass anything to the called procedure. They are also the most dangerous for the same reason. You can also use untyped variable parameters for convenience, although var parameters are really pointers behind the scenes.

Example:

```
type
  PBigArray = ^TBigArray;
  TBigArray = Array[0..65000] of char;

procedure ZeroOutPointerVariable(P : pointer; size : integer);
var
  i : integer;

begin
  for i := 0 to size - 1 do
    PBigArray(p)^[i] := #0;
  end;

procedure ZeroOutUntypedVariable(var v, size : integer);
var
  i : integer;

begin
  for i := 0 to size - 1 do
    TBigArray(v)[i] := #0;
  end;

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string[255];
  i : integer;
  l : longint;

begin
  s := 'Hello';
  i := 10;
  l := 2000;

  ZeroOutPointerVariable(@s, sizeof(s));
  ZeroOutPointerVariable(@i, sizeof(i));
  ZeroOutPointerVariable(@l, sizeof(l));

  s := 'Hello';
  i := 10;
  l := 2000;

  ZeroOutUntypedVariable(s, sizeof(s));
  ZeroOutUntypedVariable(i, sizeof(i));
```

```
ZeroOutUntypedVariable(1, sizeof(1));  
end;
```

## Article #16672: IDE highlighting the incorrect line

Question and Answer Database

FAQ1672D.txt IDE highlighting the incorrect line

Category :IDE

Platform :All

Product :All 32 bit

### Question:

On one project, the IDE insists on highlighting the incorrect line for different conditions. For example, when a syntax error is highlighted, the line above the error is highlighted or when I set breakpoints by choosing a blue dot in the gutter, it does not "line up" with the text line. How can I fix this?

### Answer:

This condition is usually caused by opening the file in a different editor than the editor provided by the IDE. If a line of code is somehow modified and then saved back to the disk using only a carriage return for a line terminating character (instead of a carriage return + line feed sequence), the IDE may get confused. To fix the problem, load the file into an editor that will save each line with a carriage return + line feed sequence.

## Article #16676: Determining the version/release of Delphi 3

Question and Answer Database

FAQ1676D.txt - Determining the version/release of Delphi 3

Category :Delphi 3.x  
Platform :All Windows  
Product :Delphi3.x,

Question:

How do I find out what exact version/release of Delphi 3 I have?

Answer:

You can determine the version/release of Delphi 3 by checking the modified time stamp of the file "dclldb30.dpl". Do step 1A if you want to check the version/release currently installed on your system, or step 1B if you want to check the version/release on your Delphi 3 CD. Then follow steps 2 and 3.

1A. Do a find files or folders search for "dclldb30.dpl" on the drive where Delphi 3 was installed. (by default in the "...\borland\delphi 3\bin" directory).

1B. With the Delphi 3 CD inserted, do a find files or folders search for "dclldb30.dpl" on the CD-ROM drive.

2. Right click on the file and go to properties, then read the modified time stamp.

3. Time stamp 3:00:00 A.M. is version 3.00; 3:01:00 A.M. is version 3.01; 3:02:00 A.M. is version 3.02; etc. Version 3.01 is release 1; version 3.02 is release 2; etc. At the time of this writing, the newest version of Delphi 3 was 3.02 release 2).

You can also get:

"/devsupport/delphi/download\_files/vcnp.zip" version checking utility

"/devsupport/delphi/download\_files/vcp.exe" version checking utility (Package EXE)

## Article #16680: Component Palette Corruption Problems

Question and Answer Database

FAQ1680D.txt      Component Palette Corruption Problems

Category        :Install Issues

Platform        :All

Product         :Delphi 3.x

### Question:

I installed Delphi 3 successfully; no errors occurred. Delphi 3 starts up OK, but the component palette display is corrupted: part of one icon appears on part of the next; images are "drifting" off the buttons; the wrong images on buttons, etc. Restarting the computer does not help. What's going on?

(Note: Similar cases have been reported from Delphi 2. Same workarounds/solutions may also apply to Delphi 2.)

### Answer:

USERHTML

The problem is most likely a compatibility conflict with the video driver. Borland tests its products against generic S3 drivers provided by Microsoft or S3 Inc. Any drivers compliant with this standard should not cause this problem with Delphi 3. Video drivers that do not fully comply with this standard may or may not function correctly with Delphi 3. Refer to [Part I](#) and [Part II](#) if you using any of the following high performance video card types with Delphi 3: [Matrox Millennium](#), [Diamond Viper](#), [Neo Magic](#) or a "[Non-Standard Souped-up S3 Card](#)". Otherwise, refer to [Part II](#).

### Part I.

It has been reported that certain workstation configurations that include the above high performance video cards, using their default high performance video drivers, may cause the Delphi 3 component palette to appear corrupted. Borland and cooperative video card vendors are currently investigating these reports. See [Part II](#) if the following workarounds or solutions are not successful:

## Matrox Millennium:

Borland and Matrox are investigating the issue, but neither have been able to reproduce the problem using the Matrox Millennium video card. Possible workarounds that customers have reported are:

- Turning off "Bitmap Caching" in the Matrox driver options.
- Switching to 16-bit or 24-bit Color Mode.
- (Contact Matrox for support on these workarounds.)

## Diamond Viper:

For The Diamond Viper 330, Diamond has advised using the generic S3 drivers provided by Microsoft or S3 Inc. as the solution for their video cards.

(Contact Diamond for support on this solution.)

## Neo Magic:

For The Neo Magic 128XD video card, a reported workaround is to change the video mode to 16-bit or 24-bit color.

(Contact Neo Magic for support on this workaround.)

## "Non-Standard Souped-up S3 Cards":

A "Non-Standard Souped-up S3 Card" is a video card built around the S3 chip which is running drivers to which the vendor has added performance tricks above and beyond the generic S3 drivers. S3 chips are used in several different video cards from different vendors (STB, Orchid, Number9, Diamond, etc.). Please contact your specific video card vendor about getting a compatible generic S3-compliant video driver. Also see Part II directly below.

## Part II.

Try running Delphi 3 under Safe Mode in Windows 95 or VGA Mode under Windows NT. This loads only standard-generic video drivers which are compliant with the standard S3 drivers provided by

Microsoft or S3 Inc.

If this fixes the display of the component palette, then the problem is most likely a compatibility conflict with the video driver. You should get an updated version of your video driver from your video card vendor or switch your default driver to a generic compatible driver from Microsoft or S3 Inc. (which may be available on your Windows 95 or Windows NT CD-ROM).

As of this writing, the above workarounds are the only ones known to Inprise. Since Inprise and the related video card vendors have been unable to reproduce this issue, these workarounds have been provided by Inprise users, and have not been directly tested by Inprise. If none of these workarounds solves your problem, then please post a detailed message to the [INPRISE Newsgroups](#) forum [borland.public.install.delphi](#) and/or contact your video card vendor.

## Article #16683: Runtime Error 255

Question and Answer Database

FAQ1683D.txt - Runtime Error 255

Category :Install Issues  
Platform :All-32Bit  
Product :All32Bit,

### Question:

I am getting runtime error 255 when using Delphi 3. What does it mean?

### Answer:

This error is reported if there is a hardware or other exception that isn't caught (and that is not one of the error codes listed below). As of this writing, Error 255 in Delphi 3 appears to be caused by certain video drivers, or by workstations using the AMD NexGen x586 CPU. If your PC is not using the AMD NexGen x586, then the problem is probably the video driver. Try changing driver configuration, getting a newer video driver, or using the generic S3 drivers provided by Microsoft or S3 Inc.

In the case of the AMD NexGen x586, AMD no longer officially supports it, but there is a "Windows CPU Identifier tool" reported as fixing this runtime error in a file called "winid20.exe", packaged in an Update Kit called <ftp://ftp.amd.com/pub/nexgen/updtpi31.exe>

(this "update kit" is actually a self-extracting executable file, from

which you extract, and then execute, the "winid20.exe" tool. For further

details, please refer to AMD's

<http://www.amd.com/products/cpg/nx586/support/toolbox.html>

Nx586 Processor Toolbox home page.)

Note: if your PC uses the VESA Local Bus instead of the PCI bus, you'll want to download the package <ftp://ftp.amd.com/pub/nexgen/updtvl30.exe> instead.

Listing of Delphi 3 Runtime Errors:

```
STATUS_INTEGER_DIVIDE_BY_ZERO:   ErrCode := 200;
STATUS_ARRAY_BOUNDS_EXCEEDED:   ErrCode := 201;
STATUS_FLOAT_OVERFLOW:          ErrCode := 205;
STATUS_FLOAT_INEXACT_RESULT,
STATUS_FLOAT_INVALID_OPERATION,
STATUS_FLOAT_STACK_CHECK:       ErrCode := 207;
STATUS_FLOAT_DIVIDE_BY_ZERO:    ErrCode := 200;
STATUS_INTEGER_OVERFLOW:        ErrCode := 215;
STATUS_FLOAT_UNDERFLOW,
STATUS_FLOAT_DENORMAL_OPERAND:  ErrCode := 206;
STATUS_ACCESS_VIOLATION:        ErrCode := 216;
STATUS_PRIVILEGED_INSTRUCTION:  ErrCode := 218;
STATUS_CONTROL_C_EXIT:          ErrCode := 217;
STATUS_STACK_OVERFLOW:          ErrCode := 202;
```

## Article #16687: Doing a complete reinstallation of Delphi 3

Question and Answer Database

FAQ1687D.txt - Doing a complete reinstallation of Delphi 3

Category :Install Issues  
Platform :All-32Bit  
Product :Delphi3.x, Delphi4.x,

Question:

I need to do a complete reinstallation of Delphi 3. How do I do this?

Answer:

Uninstall Delphi 3 using the following five steps:

Back up all project files;

Optional: back up aliases by backing up idapi32.cfg, using it to replace the newly installed idapi32.cfg after reinstallation;

It is recommended that all third party and custom components be reinstalled after the complete reinstallation of Delphi 3; Use the windows add/remove programs utility to remove Delphi 3, answering "yes" to remove all files; Manually remove the "Delphi 3" directory from your system.

Install Delphi 3 using the following five steps:

Insert the Delphi 3 CD into CD-ROM Drive;

If auto-play is enabled, the Delphi 3 Setup Launcher will automatically run. If the Delphi 3 Setup Launcher does not automatically run, run the file install.exe in the root directory of your Delphi 3 CD;

Follow the on screen instructions to install Delphi 3;

From Optional Uninstall #2 above: back up idapi32.cfg by copying over the newly installed idapi32.cfg;

Install all third party and custom components.

## Article #16691: Calls to the abort method fail to compile

Question and Answer Database

FAQ1691D.txt      Calls to the abort method fail to compile

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

When I use any of the BDE access units (DbiTypes, DbiProcs, DbiErrs), any attempt to raise a "silent exception" using calls to the abort procedure in my unit fail to compile, and I receive the error "Statement expected, but expression of type 'Integer' found". I have looked for the DbiTypes.pas, DbiProcs.pas, and DbiErrs.pas files to check for an inconsistency, but I am unable to find these files. Where are the files located, and how can I get around this error?

### Answer:

The DbiTypes, DbiProcs, DbiErrs units are aliased to the "BDE" unit, as declared under the IDE's main menu for Projects->Options->Directories/Conditionals->Unit Aliases. The source code for the DBE unit is located in Delphi's "doc" directory, and is named "BDE.INT". In this file, you will find that there is a constant named ABORT that has a declared value of -2. Since you want to use the procedure Abort() that is located in the SysUtils unit, you will need to fully qualify your call to the abort procedure by prefixing the name of the SysUtils unit to the Abort procedure.

### Example:

```
SysUtils.Abort;
```

## Article #16695: Changing the main form of an app. at runtime

Question and Answer Database

FAQ1695D.txt Changing the main form of an app. at runtime

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to change the main form of an application dynamically at runtime?

Answer:

It is possible to change the applications main form dynamically at runtime, but only during the applications start up. To do this, you will need to choose "View->Project Source" from the IDE's main menu, and edit the applications initialization code, changing the forms creation order in response to some condition. Note: You will need re-edit this code if you add additional forms to the project, as the IDE's code wizard will not be expecting the changes that you have made to the main project file, and you may find that the creation code for the additional forms you have added may have been inserted in an unexpected position within the code.

```
begin
  Application.Initialize;
  if SomeCondition then begin
    Application.CreateForm(TForm1, Form1);
    Application.CreateForm(TForm2, Form2);
  end else begin
    Application.CreateForm(TForm2, Form2);
    Application.CreateForm(TForm1, Form1);
  end;
  Application.Run;
end.
```

## Article #16699: Showing dbgrid is disabled

Question and Answer Database

FAQ1699D.txt Showing dbgrid is disabled

Category :VCL

Platform :All

Product :All 32 bit

Question:

Some of the database components (notably the TDBGrid component) does not turn gray or give any visual notification when the control is disabled. How can I provide this functionability?

Answer:

The following example demonstrates changing the text color of the control to clGray when the control is disabled, giving a visual indication that the control is disabled.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  DbGrid1.Enabled := false;
  DbGrid1.Font.Color := clGray;
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  DbGrid1.Enabled := true;
  DbGrid1.Font.Color := clBlack;
end;
```

## Article #16703: Detecting the full path/filename of a DLL

Question and Answer Database

FAQ1703D.txt Detecting the full path/filename of a DLL

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I detect (from a dynamic link library) the full path and file name of where the DLL is running from?

Answer:

The following example demonstrates a dll function that will detect the full path of where the dll was loaded from.

Example:

```
uses Windows;
```

```
procedure ShowDllPath stdcall;
```

```
var  
    TheFileName : array[0..MAX_PATH] of char;
```

```
begin  
    FillChar(TheFileName, sizeof(TheFileName), #0);  
    GetModuleFileName(hInstance, TheFileName, sizeof(TheFileName));  
    MessageBox(0, TheFileName, 'The DLL file name is:', mb_ok);  
end;
```

## Article #16707: Programmatically dropping down a menu

Question and Answer Database

FAQ1707D.txt Programmatically dropping down a menu

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I programmatically drop a menu down in code?

Answer:

The following example demonstrates both dropping down a menu and selecting a menu item by synthesizing menu shortcut keys. If your application does not have shortcut keys assigned to the menu items, you can send combinations of the VK\_MENU, VK\_LEFT, VK\_DOWN, and VK\_RETURN keys to programmatically navigate the menu.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
//Allow button to finish painting in response to the click
  Application.ProcessMessages;
  {Alt Key Down}
  keybd_Event(VK_MENU, 0, 0, 0);
  {F Key Down - Drops the menu down}
  keybd_Event(ord('F'), 0, 0, 0);
  {F Key Up}
  keybd_Event(ord('F'), 0, KEYEVENTF_KEYUP, 0);
  {Alt Key Up}
  keybd_Event(VK_MENU, 0, KEYEVENTF_KEYUP, 0);
  {F Key Down}
  keybd_Event(ord('S'), 0, 0, 0);
  {F Key Up}
  keybd_Event(ord('S'), 0, KEYEVENTF_KEYUP, 0);
end;
```

## Article #16711: Executing the explorer find file dialog

Question and Answer Database

FAQ1711D.txt Executing the explorer find file dialog

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I execute the Windows Explorer Find File Dialog Box?

Answer:

The following example demonstrates using DDE to execute Explorer's find file dialog. The example opens the dialog in the Directory "C:\Download".

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  with TDDEClientConv.Create(Self) do begin
    ConnectMode := ddeManual;
    ServiceApplication := 'explorer.exe';
    SetLink( 'Folders', 'AppProperties');
    OpenLink;
    ExecuteMacro('[FindFolder(, C:\DOWNLOAD)]', False);
    CloseLink;
    Free;
  end;
end;
```

## Article #16715: Radiogroups and focus

Question and Answer Database

FAQ1715D.txt Radiogroups and focus

Category :VCL

Platform :All

Product :All 32 bit

Question:

When tabbing through the controls on a form, a radio group requires two tab keystrokes if an item is selected, but only one if no item is selected. Since two tab keystrokes are required in this case one of the tab keystrokes gives no visual indication that the focused control is the RadioGroup. Is there any way to make the behavior more consistent?

Answer:

Setting the TabStop property of the RadioGroup to false should correct the problem, yet still allow the tab key to function, so long as one item is selected in the RadioGroup.

## Article #16719: Trapping the Windows system key 'PrintScreen'

Question and Answer Database

FAQ1719D.txt Trapping the Windows system key 'PrintScreen'

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I globally trap the Windows system key "PrintScreen"?

Answer:

The following example demonstrates registering a hot key with the system to globally trap the windows printscreen key.

Example:

```
type
  TForm1 = class(TForm)
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
    procedure WMHotKey(var Msg : TWMHotKey); message WM_HOTKEY;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

const id_SnapShot = 101;

procedure TForm1.WMHotKey (var Msg : TWMHotKey);
begin
  if Msg.HotKey = id_SnapShot then
```

```
    ShowMessage('GotIt');  
end;  
  
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    RegisterHotKey(Form1.Handle,  
                  id_SnapShot,  
                  0,  
                  VK_SNAPSHOT);  
end;  
  
procedure TForm1.FormDestroy(Sender: TObject);  
begin  
    UnRegisterHotKey (Form1.Handle, id_SnapShot);  
end;
```

## Article #16723: Accessing HKEY\_LOCAL\_MACHINE under NT without Admin. rights

Question and Answer Database

FAQ1723D.txt      Accessing HKEY\_LOCAL\_MACHINE under NT without Admin.  
rights

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

When using the TRegistry component under NT, a user with less than "administrator" rights is unable to access information stored in the HKEY\_LOCAL\_MACHINE. How can I work around this?

Answer:

The problem is caused by the fact that TRegistry (and the derived TRegInifile) always opens a key with KEY\_ALL\_ACCESS, even if only KEY\_READ would be needed. You can avoid this by going back to using the API registry functions (RegOpenKey et al.), or create a new class from the TRegistry component, and change the new TRegistry class to add an access property.

## Article #16727: Detecting how many jobs are in the print spooler

Question and Answer Database

FAQ1727D.txt    Detecting how many jobs are in the print spooler  
Category       :Windows API  
Platform        :All  
Product         :All 32 bit

Question:

Is there any way to detect how many jobs are in the Windows print spooler at any given time?

Answer:

The Windows print spooler regularly broadcasts a system wide WM\_SPOOLERSTATUS message each time a job is added or deleted from the spooler que. The following example demonstrates trapping for this message.

Example:

```
type
  TForm1 = class(TForm)
    Label1: TLabel;
  private
    { Private declarations }
    procedure WM_SpoolerStatus(var Msg : TWMSPOOLERSTATUS);
      message WM_SPOOLERSTATUS;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WM_SpoolerStatus(var Msg : TWMSPOOLERSTATUS);
begin
```

```
Label1.Caption := IntToStr(msg.JobsLeft) +  
                  ' Jobs currently in spooler';  
msg.Result := 0;  
end;
```

## Article #16731: Bitwise AND evaluates different under Delphi 3

Question and Answer Database

FAQ1731D.txt     Bitwise AND evaluates different under Delphi 3  
Category        :Object Pascal  
Platform        :All  
Product         :Delphi 3.x

### Question:

Under Delphi 3 (all versions), on some occasions, bitwise arithmetic using "AND" against integers does not always render the same results as Delphi 2. How can I get around this?

### Answer:

This is a known problem, where in certain circumstances, the compiler produces a sign extended negative result in a bitwise "AND" operation. The solution is to compare the result against zero, instead of comparing the result as being greater than zero. The following example demonstrates both the problem and the solution.

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    IntVal : Integer;  
begin  
    IntVal := 128 + 1;  
    if (IntVal and 128) > 0 then  
        ShowMessage('This never executes!');  
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);  
var  
    IntVal : Integer;  
begin  
    IntVal := 128 + 1;  
    if (IntVal and 128) <> 0 then  
        ShowMessage('This is correct!');  
end;
```

## Article #16735: Dialogs displaying 'No to all' button instead of mbHelp

Question and Answer Database

FAQ1735D.txt Dialogs displaying 'No to all' button instead of mbHelp  
Category :VCL  
Platform :All  
Product :Delphi 3.x

### Question:

When I upgraded to Delphi 3, some of my dialogs now display a button with a caption title of "No to all" where they used to display the mbHelp button. The Delphi help file and documentation give no mention to this additional button. What is this new button, and how can I prevent this behavior?

### Answer:

Delphi 3 introduced two new buttons for the message dialog boxes: mbNoToAll and mbYesToAll. The new button constants were inserted where mbHelp used to reside. The most likely cause of the problem is that you are using a hard coded ordinal value or perhaps are manipulating the value used to set the button type requested in a non portable fashion, instead of relying on more portable constants such as mbHelp.

## Article #16747: Local InterBase: 'Internal Error; Near: query shellmgr' error

Question and Answer Database

FAQ1747D.txt - Local InterBase: 'Internal Error; Near: query shellmgr' error

Category :Install Issues  
Platform :All-32Bit  
Product :

Question:

Local InterBase: "Internal Error; Near: query shellmgr" error:  
What is the cause and how do I fix this error?

Answer:

This is actually a problem with some Dell machines. The problem is associated with Dell Pentium Pro machines with NT 4.0 pre-installed. There is a setting in the registry that is modified so that Dell can load up an explorer extension.

Workaround:

Run Regedit

Modify the key: HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows NT  
\CurrentVersion\WinLogon\Shell

Originally this will say: Explorer.exe userhook.

Modify the key to say: Explorer.exe

Reboot the machine

This is documented on InstallShield's website and it is not a problem in the IB install.

## Article #16751: Cannot write EXE or DLL to disk.

Question and Answer Database

FAQ1751D.txt      Cannot write EXE or DLL to disk.

Category        :Compiler

Platform        :All

Product         :All 32 bit

### Question:

Occasionally, when building a dynamic link library or executable file, the IDE responds that it cannot write the exe or dll file. How can I get around this?

### Answer:

This will happen if the executable or dynamic link library is still in memory. If you have executed the file outside of the IDE, and then try to compile your project, the Windows system will not allow the compiler to overwrite the file. The only recourse is to make sure the application is not running, or your dll is not in memory when you attempt to compile the project.

## Article #16754: How can I have a TBitBtn component that has a word wrapped caption?

Question and Answer Database

FAQ1754D.txt    How can I have a TBitBtn component that has a word wrapped caption?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I have a TBitBtn component that has a word wrapped caption?

Answer:

The following example demonstrates drawing word wrapped text directly on a TBitBtn's glyph.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  R : TRect;
  N : Integer;
  Buff : array[0..255] of Char;
begin
  with BitBtn1 do begin
    Caption := 'A really really long caption';
    Glyph.Canvas.Font := Self.Font;
    Glyph.Width := Width - 6;
    Glyph.Height := Height - 6;
    R := Bounds(0, 0, Glyph.Width, 0);
    StrPCopy(Buff, Caption);
    Caption := '';
    DrawText(Glyph.Canvas.Handle,
              Buff,
              StrLen(Buff),
              R,
              DT_CENTER or DT_WORDBREAK or DT_CALCRECT);
    OffsetRect(R,
              (Glyph.Width - R.Right) div 2,
              (Glyph.Height - R.Bottom) div 2);
```

```
DrawText (Glyph.Canvas.Handle ,  
          Buff ,  
          StrLen (Buff) ,  
          R ,  
          DT_CENTER or DT_WORDBREAK) ;
```

```
end ;
```

```
end ;
```

## Article #16758: Bitmaps and captions on TBitBtn

Question and Answer Database

FAQ1758D.txt     Bitmaps and captions on TBitBtn

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

When I use BitBtn, the Caption(text) and bitmap file cannot be seen at the same time. How can I work around this?

Answer:

This can happen if the bitmap is too large. The TBitBtn class displays the bitmap first, and then displays the caption above, below, to the right, or to the left, of the bitmap (depending on the Layout property). If the bitmap is as wide as the button, then there isn't any room to display the caption.

If you are trying to use bitmaps which are the same size as your button (and you want the caption displayed on top of the bitmap), you will need to create a bitmap image with the captioned text drawn onto the bitmap's canvas.

Example:

```
var
  bm : TBitmap;
  OldBkMode : integer;
begin
  bm := TBitmap.Create;
  bm.Width := BitBtn1.Glyph.Width;
  bm.Height := BitBtn1.Glyph.Height;
  bm.Canvas.Draw(0, 0, BitBtn1.Glyph);
  OldBkMode := SetBkMode(bm.Canvas.Handle, Transparent);
  bm.Canvas.TextOut(0, 0, 'The Caption');
  SetBkMode(bm.Canvas.Handle, OldBkMode);
  BitBtn1.Glyph.Assign(bm);
end;
```

## Article #16762: Detecting print errors

Question and Answer Database

FAQ1762D.txt - Detecting print errors

Category :Printing  
Platform :All  
Product :

### Question:

How can I detect printing errors (like the printer is out of paper) when printing from my application?

### Answer:

Print jobs are generally added to the Windows print spooler, where the job will be spooled to the printer at some future time (perhaps even after your application has been shut down). Even if the spooler is not used, it is the print driver that takes the responsibility of dealing with errors at the printer level. The only way to handle printer errors at application level is to print to a dedicated printer through a custom device driver that is built for that specific printer.

## Article #16766: Disabling system menu in code

Question and Answer Database

FAQ1766D.txt Disabling system menu in code

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I disable the forms system menu and the Minimize, Maximize, and Close Buttons in code at Runtime?

Answer:

The following demonstrates disabling the buttons and system menu on the form's caption bar.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  {Disable}
  Form1.BorderIcons := Form1.BorderIcons -
                        [biSystemMenu, biMinimize, biMaximize];
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  {Enable}
  Form1.BorderIcons := Form1.BorderIcons +
                        [biSystemMenu, biMinimize, biMaximize];
end;
```

## Article #16770: Avoiding flicker on DrawCell

Question and Answer Database

FAQ1770D.txt     Avoiding flicker on DrawCell

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

When I set the font color on a DrawGrid's DrawCell event using  
Font.Color := clRed; I get an endless loop of flicker. How can I get  
around this?

Answer:

Be sure to fully qualify the canvas that you are using.

Example:

```
    If (Row = 0) then begin
        DrawGrid1.Canvas.Font.Color := clRed;
        DrawGrid1.Canvas.TextOut(Rect.Left,Rect.Top, IntToStr(Col));
    end;
```

## Article #16774: How can I determine the names of the installed comm ports?

Question and Answer Database

FAQ1774D.txt    How can I determine the names of the installed comm ports?

Category        :Windows API  
Platform        :All  
Product         :All 32 bit

Question:

How can I determine the names of the installed comm ports?

Answer:

The following example demonstrates enumerating the communications ports that are installed and listed in the Win32 registry.

Example:

```
uses Registry;

procedure TForm1.Button1Click(Sender: TObject);
var
  reg : TRegistry;
  ts : TStringList;
  i : integer;
begin
  reg := TRegistry.Create;
  reg.RootKey := HKEY_LOCAL_MACHINE;
  reg.OpenKey('hardware\devicemap\serialcomm',
             false);
  ts := TStringList.Create;
  reg.GetValueNames(ts);
  for i := 0 to ts.Count -1 do begin
    Mem1.Lines.Add(reg.ReadString(ts.Strings[i]));
  end;
  ts.Free;
  reg.CloseKey;
  reg.free;
end;
```

## Article #16778: Extracting Icons

Question and Answer Database

FAQ1778D.txt     Extracting Icons

Category        :Windows API

Platform        :All

Product         :All 32 bit

### Question:

How can I use the undocumented ShellAPI function `ExtractIconEx()` to extract the small and large icons from a given file?

### Answer:

You can use the undocumented ShellAPI function `ExtractIconEx()` to extract both large and small icons from an executable file, dynamic-link library (DLL), or icon file.

The function is prototyped as:

```
function ExtractIconEx(lpszFile: PAnsiChar;
                       nIconIndex: Integer;
                       phiconLarge : PhIconArray;
                       phiconSmall: PhIconArray;
                       nIcons: UINT): UINT; stdcall;
```

### Parameters

#### `lpszFile`:

Pointer to a null-terminated string specifying the name of the executable, DLL, or icon file to extract the icon from.

#### `nIconIndex`:

Specifies the index of the icon to retrieve. If this value is 0, the function returns the handle of the first icon in the specified file. If the value is -1 and `phiconLarge` and `phiconSmall` are both nil, the function returns the total number of icons in the executable, DLL, or icon file to extract the icon from. If the file is an executable or DLL file, the return value is the number of `RT_GROUP_ICON` resources. If the file is an .ICO file, the return value is 1.

phiconLarge:

Pointer to an array of icon handles for the large icons returned. This parameter can be nil if only one icon is to be extracted.

phiconSmall

Pointer to an array of icon handles for the small icons returned. This parameter can be nil if only one icon is to be extracted.

nIcons

Specifies the number of icons to extract.

Return Value

The return value is the handle to an icon if only one icon is to be extracted. If there were no icons found in the file, the return value is 0.

The following example demonstrates using the ExtractIconEx() function. Note that the functions are prototyped differently than as prototyped in the ShellAPI unit, to allow the full usage of the function.

```
type ThIconArray = array[0..0] of hIcon;
type PhIconArray = ^ThIconArray;
```

```
function ExtractIconExA(lpszFile: PAnsiChar;
    nIconIndex: Integer;
    phiconLarge : PhIconArray;
    phiconSmall: PhIconArray;
    nIcons: UINT): UINT; stdcall;
external 'shell32.dll' name 'ExtractIconExA';
```

```
function ExtractIconExW(lpszFile: PWideChar;
    nIconIndex: Integer;
    phiconLarge: PhIconArray;
    phiconSmall: PhIconArray;
    nIcons: UINT): UINT; stdcall;
external 'shell32.dll' name 'ExtractIconExW';
```

```
function ExtractIconEx(lpszFile: PAnsiChar;
    nIconIndex: Integer;
    phiconLarge : PhIconArray;
    phiconSmall: PhIconArray;
    nIcons: UINT): UINT; stdcall;
```

```
external 'shell32.dll' name 'ExtractIconExA';
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    NumIcons : integer;  
    pTheLargeIcons : phIconArray;  
    pTheSmallIcons : phIconArray;  
    LargeIconWidth : integer;  
    SmallIconWidth : integer;  
    SmallIconHeight : integer;  
    i : integer;  
    TheIcon : TIcon;  
    TheBitmap : TBitmap;
```

```

## Article #16782: Adjusting number and with of columns in a TFileListBox

Question and Answer Database

FAQ1782D.txt Adjusting number and with of columns in a TFileListBox

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to adjust the number of columns and width of columns in a TFileListBox component?

Answer:

The following example demonstrates casting a FileListBox component to a TDirectoryListBox component so additional columns can be added and sized.

Example:

```
with TDirectoryListBox(FileListBox1) do begin
  Columns := 2;
  SendMessage(Handle,
    LB_SETCOLUMNWIDTH,
    Canvas.TextWidth('WWWWWWWWW.WWW'),
    0);
end;
```

## Article #16786: Notifying forms of global changes

Question and Answer Database

FAQ1786D.txt     Notifying forms of global changes

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I tell all created (and even hidden), forms of an application that some global option has changed?

Answer:

One way is to create a user message, and use the preform method to send the message to all forms in the Screen.Forms array.

Example:

```
{Code for Unit1}
```

```
const
  UM_MyGlobalMessage = WM_USER + 1;

type
  TForm1 = class(TForm)
    Label1: TLabel;
    Button1: TButton;
    procedure FormShow(Sender: TObject);
    procedure Button1Click(Sender: TObject);
    { Private declarations }
  private
    procedure UMMyGlobalMessage(var AMessage: TMessage); message
      UM_MyGlobalMessage;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
```

implementation

{ \$R \*.DFM }

uses Unit2;

procedure TForm1.FormShow(Sender: TObject);

begin

    Form2.Show;

end;

procedure TForm1.UMMyGlobalMessage(var AMessage: TMessage);

begin

    Label1.Left := AMessage.WParam;

    Label1.Top := AMessage.LParam;

    Form1.Caption := 'Got It!';

end;

procedure TForm1.Button1Click(Sender: TObject);

var

    f: integer;

begin

    for f := 0 to Screen.FormCount - 1 do

        Screen.Forms[f].Perform(UM\_MyGlobalMessage, 42, 42);

end;

{Code for Unit2}

const

    UM\_MyGlobalMessage = WM\_USER + 1;

type

    TForm2 = class(TForm)

        Label1: TLabel;

    private

        { Private declarations }

        procedure UMMyGlobalMessage(var AMessage: TMessage); message

            UM\_MyGlobalMessage;

    public

        { Public declarations }

end;

var

```
Form2: TForm2;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm2.UMMyGlobalMessage(var AMessage: TMessage);  
begin  
  Label1.Left := AMessage.WParam;  
  Label1.Top  := AMessage.LParam;  
  Form2.Caption := 'Got It!';  
end;
```

## Article #16790: How can I activate different hints for each cell in a grid

Question and Answer Database

FAQ1790D.txt    How can I activate different hints for each cell in a grid

Category        :VCL  
Platform        :All  
Product         :All 32 bit

Question:

How can I activate different hints for each cell in a grid control?

Answer:

The following example demonstrates tracking the mouse movements in a StringGrid component. If the mouse moves to a different cell in the grid, a new hint window is displayed, showing the row and column numbers of the cell.

Example:

```
type
  TForm1 = class(TForm)
    StringGrid1: TStringGrid;
    procedure StringGrid1MouseMove(Sender: TObject;
      Shift: TShiftState; X, Y: Integer);
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
    Col : integer;
    Row : integer;
  public
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Hint := '0 0';
  StringGrid1.ShowHint := True;
end;

procedure TForm1.StringGrid1MouseMove(Sender: TObject;
Shift: TShiftState; X, Y: Integer);
var
  r : integer;
  c : integer;
begin
  StringGrid1.MouseToCell(X, Y, C, R);
  if ((Row <> r) or
    (Col <> c)) then begin
    Row := r;
    Col := c;
    Application.CancelHint;
    StringGrid1.Hint := IntToStr(r) + #32 + IntToStr(c);
  end;
end;
```

## Article #16794: Dynamically drawing a transparent image

Question and Answer Database

FAQ1794D.txt Dynamically drawing a transparent image

Category :VCL

Platform :All

Product :All 32 bit

Question:

How do I use a TImageList component to dynamically draw a transparent image?

Answer:

The following example demonstrates the dynamic creation of a TImageList component used to draw a transparent bitmap.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  bm : TBitmap;
  il : TImageList;
begin
  bm := TBitmap.Create;
  bm.LoadFromFile('C:\Download\TEST.BMP');
  il := TImageList.CreateSize(bm.Width,
                             bm.Height);

  il.DrawingStyle := dsTransparent;
  il.Masked := true;
  il.AddMasked(bm, clRed);
  il.Draw(Form1.Canvas, 0, 0, 0);
  bm.Free;
  il.Free;
end;
```

## Article #16798: Porting strings from 16 to 32-bit

Question and Answer Database

FAQ1798D.txt Porting strings from 16 to 32-bit

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

When I port my code from 16 to 32 bit, record types that contain strings do not function correctly. What has happened?

Answer:

Traditionally, strings that are defined with no length parameter would default to having a length of 255 characters. With the advent of 32 bit Delphi, strings with no defined length default to a long string. Long strings are pointers to a reference counted AnsiString. Long string types are not recommended for use in structures that are intended to be written or read from a disk file. To port your code correctly, you need to explicitly set the expected length of the string in the record, otherwise, a long string is used in place of the original string in the record, leading to unexpected results.

Example:

```
ShortStringRec : record
  s : string[255]; {this uses a short string - ok}
end;
```

```
LongStringRec : record
  s : string; {this uses a long string - not ok}
end;
```

## Article #16802: Overwrite in TMemo and TEdit

Question and Answer Database

FAQ1802D.txt Overwrite in TMemo and TEdit

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I get the TEdit and TMemo controls to have a overwrite capability?

Answer:

The Windows TEdit and TMemo controls have no overwrite capability. It is possible to emulate this behavior however, by setting the SelLength property of the edit or memo control to one during the processing of the KeyPress event. This causes the character at the current position of the caret to be overwritten.

The following example demonstrates emulation of an overwrite capability of a TMemo component. The state of the overwrite mode can be toggled by pressing the insert key.

Example:

```
type
  TForm1 = class(TForm)
    Mem1: TMemo;
    procedure Mem1KeyDown(Sender: TObject; var Key: Word;
      Shift: TShiftState);
    procedure Mem1KeyPress(Sender: TObject; var Key: Char);
  private
    { Private declarations }
    InsertOn : bool;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.Mem1KeyDown(Sender: TObject; var Key: Word;  
  Shift: TShiftState);
```

```
begin
```

```
  if (Key = VK_INSERT) and (Shift = []) then
```

```
    InsertOn := not InsertOn;
```

```
end;
```

```
procedure TForm1.Mem1KeyPress(Sender: TObject; var Key: Char);
```

```
begin
```

```
  if ((Mem1.SelLength = 0) and
```

```
    (not InsertOn)) then
```

```
    Mem1.SelLength := 1;
```

```
end;
```

## Article #16806: Small bitmaps in a TPopUpMenu

Question and Answer Database

FAQ1806D.txt Small bitmaps in a TPopUpMenu

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I place small bitmaps in a TPopUpMenu component?

Answer:

The following example demonstrates adding a bitmap to a PopUpMenu item using the Windows API function `SetMenuItemBitmaps()`. This function takes a handle to the popup menu, the zero based position of the menu item you wish to add the bitmaps to, and two bitmap handles, (one bitmap specifying the image to be shown in the menu unchecked state, and another specifying the image to be shown in the menu checked state).

type

```
TForm1 = class(TForm)
  PopupMenu1: TPopupMenu;
  Pop11: TMenuItem;
  Pop21: TMenuItem;
  Pop31: TMenuItem;
  procedure FormCreate(Sender: TObject);
  procedure FormDestroy(Sender: TObject);
  procedure FormMouseUp(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
```

private

```
{ Private declarations }
  bmUnChecked : TBitmap;
  bmChecked : TBitmap;
```

public

```
{ Public declarations }
```

end;

var

```
Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  bmUnchecked := TBitmap.Create;
  bmUnchecked.LoadFromFile(
    'C:\Program Files\Borland\BitBtns\ALARMRNG.BMP');
  bmChecked := TBitmap.Create;
  bmChecked.LoadFromFile(
    'C:\Program Files\Borland\BitBtns\CHECK.BMP');
  {Add the bitmaps to the item at index 1 in PopUpMenu}
  SetMenuItemBitmaps(PopUpMenu1.Handle,
    1,
    MF_BYPOSITION,
    BmUnchecked.Handle,
    BmChecked.Handle);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  bmUnchecked.Free;
  bmChecked.Free;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  pt : TPoint;
begin
  pt := ClientToScreen(Point(x, y));
  PopUpMenu1.Popup(pt.x, pt.y);
end;
```

## Article #16814: Explanation of rounding

Question and Answer Database

FAQ1814D.txt    Explanation of rounding

Category       :Object Pascal

Platform       :All

Product        :All 32 bit

Question:

Since Delphi's Round() function uses "bankers rounding" where the value is rounded to the nearest even number, how can I round a floating point number using the more traditional means, where fractional values less than .5 round down, and fractional values of .5 and greater round up?

Answer:

The following function demonstrates rounding down numbers with fractional values of less than .5, and rounding up numbers with fractional values of .5 and greater.

Example:

```
function RoundUp(X: Extended): Extended;
begin
  Result := Trunc(X) + Trunc (Frac(X) * 2);
end;
```

## Article #16818: StretchDraw on an icon

Question and Answer Database

FAQ1818D.txt     StretchDraw on an icon

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

When I attempt to use the TCanvas.StretchDraw method to draw a zoomed view of an Icon, the size does not change. How can I get around this?

### Answer:

Icons always draw at the system default icon size. To display a zoomed view of an icon image, copy the icon image to a bitmap, then use the TCanvas.StretchDraw method.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  TheBitmap : TBitmap;
begin
  TheBitmap := TBitmap.Create;
  TheBitmap.Width := Application.Icon.Width;
  TheBitmap.Height := Application.Icon.Height;
  TheBitmap.Canvas.Draw(0, 0, Application.Icon);
  Form1.Canvas.StretchDraw(Rect(0,
                                0,
                                TheBitmap.Width * 3,
                                TheBitmap.Height * 3),
    TheBitmap);

  TheBitmap.Free;
end;
```

## Article #16822: How can I determine the week number of a given day in the year?

Question and Answer Database

FAQ1822D.txt    How can I determine the week number of a given day in the year?

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

How can I determine the week number of a given day in the year?

Answer:

This is a highly debated subject, as the first week of the year may be considered to be before or after Jan 1. The following function provides a starting point for WeekOfYear calculations.

Example:

```
function WeekOfYear(ADate : TDateTime) : word;
var
  day : word;
  month : word;
  year : word;
  FirstOfYear : TDateTime;
begin
  DecodeDate(ADate, year, month, day);
  FirstOfYear := EncodeDate(year, 1, 1);
  Result := Trunc(ADate - FirstOfYear) div 7 + 1;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(IntToStr(WeekOfYear(Date)));
end;
```

## Article #16825: How do I change a specific IDAPI configuration setting?

Question and Answer Database

FAQ1825C.txt    How do I change a specific IDAPI configuration setting?

Category        :Database Issues

Platform        :All

Product         :C++Builder 1.x

Question:

How do I change a specific IDAPI configuration setting?

How do I know the current settings?

Answer:

The settings change depending on the database or server. To find the current settings, you can display the TStringList returned from GetAliasParams in a TMemo, then you can modify the alias by replacing specific indexed strings within the TStringList.

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    TStringList MyList;

    MyList = new TStringList();

    Session1->GetAliasParams('DBDEMOS', MyList);
    Session1->Memo1->Lines->Assign(MyList);
    Session1->MyList->Strings[0] = "PATH=d:\\borland\\BCB\\Demos\\
\\Data';
    Session1->ModifyAlias('DBDEMOS', MyList);

    delete MyList;
}
```

## Article #16826: Sending a message to all controls on a form

Question and Answer Database

FAQ1826D.txt      Sending a message to all controls on a form

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

Is there a way to send a message to all the controls on a form?

Answer:

You can use `Screen.Forms[i].Broadcast(msg);` where `[i]` is the index of the form you wish to broadcast the message to. `Broadcast` works with all `TWinControls` components, and sends messages to all children in the `Controls` array. If one of your children wants to handle the message and have `Broadcast` exit, then set `Msg.Result` to a `NonZero` value during the processing of the message.

## Article #16830: Resizing an array

Question and Answer Database

FAQ1830D.txt     Resizing an array

Category     :Compiler

Platform     :All

Product      :All 32 bit

Question:

How can I resize an array?

Answer:

You cannot resize a non-dynamic array in Pascal. You can create and resize a dynamically created array. To do this, you must create the dynamic array, turn range checking off, and access the array members via a variable only, or you will receive runtime and compile time errors. Since you will access the array through a pointer variable, you can dynamically resize the array by creating a new array in memory, copy all the valid elements of the original array to the new array, free the memory for the original array, and assign the new array's pointer back to the original array pointer.

Example:

```
type
  TSomeArrayElement = integer;
  PSomeArray = ^TSomeArray;
  TSomeArray = array[0..0] of TSomeArrayElement;

procedure CreateArray(var TheArray : PSomeArray;
                     NumElements : longint);
begin
  GetMem(TheArray, sizeof(TSomeArrayElement) * NumElements);
end;

procedure FreeArray(var TheArray : PSomeArray;
                   NumElements : longint);
begin
  FreeMem(TheArray, sizeof(TSomeArrayElement) * NumElements);
end;
```

```

procedure ReSizeArray(var TheArray : PSomeArray;
                     OldNumElements : longint;
                     NewNumElements : longint);
var
    TheNewArray : PSomeArray;
begin
    GetMem(TheNewArray, sizeof(TSomeArrayElement) * NewNumElements);
    if NewNumElements > OldNumElements then
        Move(TheArray^,
             TheNewArray^,
             OldNumElements * sizeof(TSomeArrayElement)) else
        Move(TheArray^,
             TheNewArray^,
             NewNumElements * sizeof(TSomeArrayElement));
    FreeMem(TheArray, sizeof(TSomeArrayElement) * OldNumElements);
    TheArray := TheNewArray;
end;

```

```

procedure TForm1.Button1Click(Sender: TObject);
var
    p : PSomeArray;
    i : integer;
begin
    {$IFOPT R+}
    {$DEFINE CKRANGE}
    {$R-}
    {$ENDIF}

    CreateArray(p, 200);
    for i := 0 to 199 do
        p^[i] := i;
    ResizeArray(p, 200, 400);
    for i := 0 to 399 do
        p^[i] := i;
    ResizeArray(p, 400, 50);
    for i := 0 to 49 do
        p^[i] := i;
    FreeArray(p, 50);

    {$IFDEF CKRANGE}
    {$UNDEF CKRANGE}

Question and Answer Database

FAQ1838D.txt Timed beeps from the PC speaker

Category :Windows API

Platform :All

Product :All 32 bit

### Question:

How can I beep the PC Speaker several times in a row, and have a small delay between beeps that is reliable across different machines with different clock speeds?

### Answer:

The following demonstrates using a delay function that can be used to beep the PC speaker.

### Example:

```
procedure Delay(ms : longint);
{$IFDEF WIN32}
var
  TheTime : LongInt;
{$ENDIF}
begin
{$IFDEF WIN32}
  Sleep(ms);
{$ELSE}
  TheTime := GetTickCount + ms;
  while GetTickCount < TheTime do
    Application.ProcessMessages;
{$ENDIF}
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MessageBeep(word(-1));
  Delay(200);
  MessageBeep(word(-1));
  Delay(200);
end;
```

```
MessageBeep(word(-1));  
end;
```

Question and Answer Database

FAQ1842D.txt    How can I place a bitmap in a Metafile?

Category        :VCL

Platform        :All

Product        :All 32 bit

Question:

How can I place a bitmap in a Metafile?

Answer:

The following example demonstrates drawing a bitmap into a metafile.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  m : TmetaFile;
  mc : TmetaFileCanvas;
  b : tbitmap;
begin
  m := TMetaFile.Create;
  b := TBitmap.create;
  b.LoadFromFile('C:\SomePath\SomeBitmap.BMP');
  m.Height := b.Height;
  m.Width := b.Width;
  mc := TMetafileCanvas.Create(m, 0);
  mc.Draw(0, 0, b);
  mc.Free;
  b.Free;
  m.SaveToFile('C:\SomePath\Test.emf');
  m.Free;
  Image1.Picture.LoadFromFile('C:\SomePath\Test.emf');
end;
```

## Article #16845: What are IDAPI and SQL links

Question and Answer Database

FAQ1845C.txt    What are IDAPI and SQL links

Category        :Database Issues

Platform        :All

Product         :C++Builder 1.x

Question:

What is the definition of 'IDAPI'? What is 'SQL Links'?

Answer:

IDAPI is the Integrated Database Application Program Interface. BDE is a way to access multiple data sources with a consistent API. The distinction is in the terminology: IDAPI is the API for the BDE. It includes all the functions necessary to access, manipulate, etc. the data; BCB, dBASE for Windows, Quattro Pro, and Paradox for Windows use these functions to access data: You can use them yourself in your programs. If you look at the BCB source you will see these functions used. They are prefaced with "Dbi" (e.g. DbiCreateTable).

SQL Links is a collection of native drivers that enable you to connect to remote database servers.

## Article #16846: Images conflicts between different versions of IE

Question and Answer Database

FAQ1846D.txt Images conflicts between different versions of IE  
Category :Miscellaneous  
Platform :All  
Product :All 32 bit

### Question:

If I create an application on a machine with Internet Explorer 4 and deploy on machines without Internet Explorer 4, they see no images in my Toolbar and/or Coolbar. How can I get my images to be visible?

### Answer:

The Imagelist streaming implementation and other features of the Coolbar and Toolbar have changed between Internet Explorer 3.02 and Internet Explorer 4. Applications using Win32 common controls developed under Internet Explorer 4.0 may not work correctly under Internet Explorer 3.02 (and vice-versa).

The way to work around the imagelist streaming problem is to not stream the images to the .dfm. Instead, place the bitmaps in a resource file, then load them into the imagelist at runtime using the following code:

```
procedure LoadResourcedBMP(ID: string; Images: TImageList);
var
  B: TBitmap;
begin
  B := TBitmap.Create;
  try
    B.LoadFromResourceName(hInstance, ID);
    Images.AddMasked(B, B.TransparentColor);
  finally
    B.Free;
  end;
end;
```

## Article #16854: Big-endian and little-endian formatted integers

Question and Answer Database

FAQ1854D.txt Big-endian and little-endian formatted integers

Category :Compiler

Platform :All

Product :All 32 bit

Question:

How can I create big-endian and little-endian formatted integers?

Answer:

The big-endian and little-endian format simply swaps the HiByte and LoBytes and HiWords and LoWords of a given integer or word value. The following demonstrates swapping the values of a given word or longint. Calling the Endian functions a second time reverts the values back to their original format.

```
function EndianWord(w : word) : word;
begin
    result := swap(w);
end;

function EndianInt(i : integer) : integer;
begin
    result := swap(i);
end;

function EndianLong(L : longint) : longint;
begin
    result := swap(L shr 16) or
              (longint(swap(L and $ffff)) shl 16);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
    w : word;
    i : integer;
    l : LongInt;
begin
    w := 10;
```

```
i := -10;
l := 1024;
w := EndianWord(w);
i := EndianInt(i);
l := EndianLong(l);
{again!}
w := EndianWord(w);
i := EndianInt(i);
l := EndianLong(l);
Mem1.Lines.Add(IntToStr(w));
Mem1.Lines.Add(IntToStr(i));
Mem1.Lines.Add(IntToStr(l));
end;
```

## Article #16861: Mask edit for TDBEdit controls

Question and Answer Database

FAQ1861C.txt Mask edit for TDBEdit controls

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

How to I create a mask for a TDBEdit control?

Answer:

Edit masks are applied to the fields in the table (TField components) and not in the data controls themselves.

Double-click on the TTable icon and add all the fields you want from your table. When a field is highlighted, its properties show up in the object inspector, including an edit mask. Linking the TDBEdit and any of the other data controls to this dataset will follow the edit mask rules for the fields set this way.

## Article #16865: Packing dBase tables

Question and Answer Database

FAQ1865C.txt     Packing dBase tables

Category     :Database Issues

Platform     :All

Product      :C++Builder 1.x

Question:

Is there a BDE API or a DLL available to pack a dBASE table?

Answer:

The BDE includes a function to pack dBASE tables, called `DbiPackTable()`.

Include the `BDE.HPP` header file. Then call the BDE function as follows:

```
DBIPackTable(Table1->DbHandle, Table1->Handle,  
             "TABLENAME.DBF", szDBASE, TRUE);
```

Note: The table must be opened in exclusive mode.

## Article #16866: MaxLength property of a DBEdit is not automatically set

Question and Answer Database

FAQ1866D.txt    MaxLength property of a DBEdit is not automatically set  
Category        :Database/VCL  
Platform        :All  
Product         :Delphi 3.x

### Question:

In Delphi 1.0 and 2.0, the TDBEdit control would automatically set the max field length (MaxLegth) and wouldn't allow you to enter more characters than the size specified for the TField Object. Why has Delphi 3 removed this "feature"?

### Answer:

This new behavior allows you to set the value different than the field size. Delphi 1 and Delphi 2 overrided a change and put back the field size length. In Delphi 3 though, the maximum length is set, by default, to zero and will allow you to specify and enter any MaxLength for a TDBEdit, but it only writes as many characters to the database as the actual TField size property allows.

## Article #16870: How can I get the default Windows folders

Question and Answer Database

FAQ1870D.txt How can I get the default Windows folders

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I get the default Windows folders?

Answer:

The following example demonstrates retrieving the entire list of default shell folders to a TMemo component. The folders retrieved should include: Favorites, Desktop, Programs, Fonts, SendTo, Start Menu, Templates, Startup, Recent and NetHood.

Example:

```
uses Registry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    reg : TRegistry;
```

```

## Article #16873: Getting current record from a TDBGrid

Question and Answer Database

FAQ1873C.txt Getting current record from a TDBGrid

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

How do you tell which record and which field of a TDBGrid is current?

Answer:

Here is a method to keep track of the current column and row. The following code in the method `MyDBGridDrawDataCell` updates the variables `Col` and `Row` (which must not be local to the method) every time the grid is redrawn. Using this code you can assume that `Col` and `Row` point to the current column and row respectively.

```
int Col, Row;

void __fastcall TForm1::DBGrid1DrawDataCell(TObject *Sender,
      const TRect &Rect, TField *Field, TGridDrawState State)
{
    int RowHeight;
    if (State.Contains(gdFocused)
        {
            RowHeight = Rect.Bottom - Rect.Top;
            Row = (Rect.Top / RowHeight) - 1;
            Col = Field->Index;
        }
    }
```

## Article #16874: Changing the font in a hint window

Question and Answer Database

FAQ1874D.txt Changing the font in a hint window

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I change the font of a hint window?

Answer:

The following example traps the `Application.OnShowHint` event and changes the font.

Example:

```
type
  TForm1 = class(TForm)
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
  public
    procedure MyShowHint(var HintStr: string;
                        var CanShow: Boolean;
                        var HintInfo: THintInfo);
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.MyShowHint(var HintStr: string;
                            var CanShow: Boolean;
                            var HintInfo: THintInfo);

var
  i : integer;
```

```
begin
  for i := 0 to Application.ComponentCount - 1 do
    if Application.Components[i] is THintWindow then
      with THintWindow(Application.Components[i]).Canvas do begin
        Font.Name      := 'Arial';
        Font.Size      := 18;
        Font.Style     := [fsBold];
        HintInfo.HintColor := clWhite;
      end;
    end;
  end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnShowHint := MyShowHint;
end;
```

## Article #16878: Converting a TColor value to a HTML Color string

Question and Answer Database

FAQ1878D.txt - Converting a TColor value to a HTML Color string

Category :Internet/WEB

Platform :All-32Bit

Product :

Question:

How can I convert a TColor value to a HTML Color string?

Answer:

The following example demonstrates converting a TColor to a RGB color, and formatting the RGB color to be shown as hexadecimal digits.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  TheRgbValue : TColorRef;
begin
  if ColorDialog1.Execute then begin
    TheRgbValue := ColorToRGB(ColorDialog1.Color);
    ShowMessage(Format( '%.2x%.2x%.2x' ,
                        [GetRValue(TheRGBValue),
                         GetGValue(TheRGBValue),
                         GetBValue(TheRGBValue)]));
  end;
end;
```

## Article #16881: What is the equivalent in BCB to a Pdox TCursor

Question and Answer Database

FAQ1881C.txt    What is the equivalent in BCB to a Pdox TCursor

Category        :Database Issues

Platform        :All

Product         :C++Builder 1.x

Question:

What is the equivalent in BCB of Paradox's TCursor and what is a TCursor in Paradox?

Answer:

The TTable component.

A TCursor in Paradox is a pointer to the data in a table, a pointer that enables you to manipulate data at the table level, record level, and field level without having to display the table.

## Article #16882: Using JPEGs from resource files

Question and Answer Database

FAQ1882D.txt Using JPEGs from resource files

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I load a JPEG image from a resource file that is linked with my application?

Answer:

The following demonstrates creating a resource file containing a JPEG image, and loading the JPEG file from the resource file. The resulting JPEG image is displayed in a Image component.

1) Create a text file with the extension of ".rc". The text file should be named something different than the project name or any unit name in your application to avoid any confusion for the compiler. The text file should contain the following line:

```
MYJPEG JPEG C:\DownLoad\MY.JPG
```

Where:

"MYJPEG" is the name you wish to name the resource

"JPEG" is the user defined resource type.

"C:\DownLoad\MY.JPG" is the path and filename of the JPEG file.

For our example we will name the file "foo.rc" .

Now run the BRCC32.exe (Borland Resource CommandLine Compiler) program found in the Delphi/C++ Builders bin directory giving the full path to the rc file:

```
C:\DelphiPath\BIN\BRCC32.EXE C:\ProjectPath\F00.RC
```

You should now have a compiled resource file named the same as the ".rc" file you compiled with the extension of ".res".

The following demonstrates using the embedded JPEG in your application

```
{Link the res file}  
{$R FOO.RES}
```

```
uses Jpeg;
```

```
procedure LoadJPEGFromRes(TheJPEG : string;  
                          ThePicture : TPicture);
```

```
var
```

```
  ResHandle : THandle;  
  MemHandle : THandle;  
  MemStream : TMemoryStream;  
  ResPtr     : PByte;  
  ResSize    : Longint;  
  JPEGImage : TJPEGImage;
```

```
begin  
  ResHandle := FindResource(hInstance, PChar(TheJPEG), 'JPEG');  
  MemHandle := LoadResource(hInstance, ResHandle);  
  ResPtr     := LockResource(MemHandle);  
  MemStream := TMemoryStream.Create;  
  JPEGImage := TJPEGImage.Create;  
  ResSize := SizeOfResource(hInstance, ResHandle);  
  MemStream.SetSize(ResSize);  
  MemStream.Write(ResPtr^, ResSize);  
  FreeResource(MemHandle);  
  MemStream.Seek(0, 0);  
  JPEGImage.LoadFromStream(MemStream);  
  ThePicture.Assign(JPEGImage);  
  JPEGImage.Free;  
  MemStream.Free;
```

```
end;  
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  LoadJPEGFromRes('MYJPEG', Image1.Picture);  
end;
```

## Article #16885: error Index out of range with TTable FindNearest or FindKey

Question and Answer Database

FAQ1885C.txt error Index out of range with TTable FindNearest or FindKey

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

Why do I get 'Index out of range' when I use TTable::FindNearest and TTable::FindKey on a dBASE table with an expression index?

Answer:

FindKey and FindNearest are not meant to work with dBASE expression indexes. Instead, use TTable::GoToKey and TTable::GotoNearest, which will work fine with dBASE expression indexes.

## Article #16890: Playing MPEG files in Delphi apps

Question and Answer Database

FAQ1890D.txt    Playing MPEG files in Delphi apps

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I play an MPEG file in Delphi apps?

Answer:

Providing the Windows MMSYSTEM layer has a MPEG decoder installed, you can easily use the MultiMedia play a MPEG file by setting the filename to the path of the MPEG file.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  MediaPlayer1.FileName := 'C:\Download\rsgrow.mpg';
  MediaPlayer1.Open;
  MediaPlayer1.Display := Panel1;
  MediaPlayer1.DisplayRect := Panel1.ClientRect;
  MediaPlayer1.Play;
end;
```

Question and Answer Database

FAQ1894D.txt    Running apps on Windows startup

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How can I get my application to run every time Windows starts?

Answer:

The following demonstrates how to add your application to the Windows boot sequence. Code is demonstrated for both the Win32 and Win16 platforms.

uses

```
  Registry, {For Win32}  
  IniFiles; {For Win16}
```

```
{$IFDEF WIN32}
```

```
  const MAX_PATH = 144;
```

```
{$ENDIF}
```

```
{For Win32}
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  reg: TRegistry;
```

```
begin
```

```
  reg := TRegistry.Create;
```

```
  reg.RootKey := HKEY_LOCAL_MACHINE;
```

```
  reg.LazyWrite := false;
```

```
  reg.OpenKey('Software\Microsoft\Windows\CurrentVersion\Run',  
              false);
```

```
  reg.WriteString('My App', Application.ExeName);
```

```
  reg.CloseKey;
```

```
  reg.free;
```

```
end;
```

```
{For Win16}
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
  WinIni : TIniFile;
  WinIniFileName : array[0..MAX_PATH] of char;
  s : string;
begin
  GetWindowsDirectory(WinIniFileName, sizeof(WinIniFileName));
  StrCat(WinIniFileName, '\win.ini');
  WinIni := TIniFile.Create(WinIniFileName);
  s := WinIni.ReadString('windows',
                        'run',
                        '');
  if s = '' then
    s := Application.ExeName else
    s := s + ';' + Application.ExeName;
  WinIni.WriteString('windows',
                    'run',
                    s);
  WinIni.Free;
end;
```

## Article #16898: Alloting CPU time

Question and Answer Database

FAQ1898D.txt Alloting CPU time

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I change the amount of CPU time that is allotted to my application?

Answer:

The following example demonstrates changing the CPU priority given an application. Care should be taken when changing the applications priority, as values that are too high may cause the system to become unresponsive. For more information, please see the Win32 help file for the `SetThreadPriority()` function.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  ProcessID : DWORD;
  ProcessHandle : THandle;
  ThreadHandle : THandle;
begin
  ProcessID := GetCurrentProcessID;
  ProcessHandle := OpenProcess(PROCESS_SET_INFORMATION,
                              false,
                              ProcessID);
  SetPriorityClass(ProcessHandle, REALTIME_PRIORITY_CLASS);
  ThreadHandle := GetCurrentThread;
  SetThreadPriority(ThreadHandle, THREAD_PRIORITY_TIME_CRITICAL);
end;
```

## Article #16905: creating indexes with the TTable create function

Question and Answer Database

FAQ1905C.txt    creating indexes with the TTable create function  
Category       :Database Issues  
Platform        :All  
Product         :C++Builder 1.x

Question:

Why is it that when I create a table using the TTable component's CreateTable method it creates the fields correctly but does not create the indexes even though I do a

```
NewTable->IndexDefs->Assign(Table1->IndexDefs)?
```

Answer:

This is the correct way to transfer the index definition to NewTable, however, the IndexDefs property of Table1 may not be up-to-date so you need to call the Update method of Table1's IndexDefs property prior to its assignment to NewTable as shown in this example:

```
NewTable->Active = false;  
NewTable->DatabaseName = "DBDEMOS";  
NewTable->TableName = "Temp";  
NewTable->TableType = ttParadox;  
NewTable->FieldDefs->Assign(Table1->FieldDefs);  
NewTable->Table1->IndexDefs->Update();     // Do an update first  
NewTable->IndexDefs->Assign(Table1->IndexDefs);  
NewTable->CreateTable();
```

## Article #16906: Reducing the resource requirements of TNotebook and TTabbedNotebook

Question and Answer Database

FAQ1906D.txt Reducing the resource requirements of TNotebook and TTabbedNotebook  
Category :VCL  
Platform :All  
Product :All 32 bit

Question:

Is there any way to reduce the resource requirements of the TNotebook and TTabbedNotebook components?

Answer:

Yes. It is possible to reduce the requirements of the pages in the TNotebook and TTabbedNotebook components by destroying the handles of the components that are not on the current page. The following example demonstrates calling the protected DestroyHandle method of the page, by subclassing the notebook to get access to the protected method.

```
type TMyTabbedNotebook = class(TTabbedNotebook);
type TMyNotebook = class(TNotebook);

procedure TForm1.TabbedNotebook1Change(Sender: TObject;
                                       NewTab: Integer;
                                       var AllowChange: Boolean);
begin
    with TabbedNotebook1 do
        TMyTabbedNotebook(
            TWinControl(Pages.Objects[PageIndex])).DestroyHandle;
end;

procedure TForm1.TabSet1Change(Sender: TObject; NewTab: Integer;
                               var AllowChange: Boolean);
begin
    with Notebook1 do
        TMyNotebook(TWinControl(Pages.Objects[PageIndex])).DestroyHandle;
    Notebook1.PageIndex := NewTab;
end;
```

```
    AllowChange := true  
end;
```

## Article #16910: Changing the root key

Question and Answer Database

FAQ1910D.txt Changing the root key

Category :VCL

Platform :All

Product :All 32 bit

Question:

According to the documentation for the TRegIniFile component, I should be able to change the root key. I have tried, but the key does not change. How can I change the root key?

Answer:

The following demonstrates changing the root key for the TRegIniFile component.

Example:

```
uses Registry;

procedure TForm1.Button1Click(Sender: TObject);
var
  WinIni : TRegIniFile;
begin
  WinIni := TRegIniFile.Create('');
  WinIni.RootKey := HKEY_LOCAL_MACHINE;
  WinIni.WriteString('Frank',
                    'Borland',
                    'Writes Fast Code!');

  WinIni.Free;
end;
```

## Article #16914: Show a AVI clip in full screen zoom mode

Question and Answer Database

FAQ1914D.txt     Show a AVI clip in full screen zoom mode  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

Question:

How can I show a AVI clip in full screen zoom mode?

Answer:

The following example demonstrates playing a AVI file in full screen mode by displaying the AVI on a second form that has the form border style set to bsNone and has no border icons. Note that the second form has a panel with it's alignment set to alClient, and a MediaPlayer component that has a Notify event. We will show the second form maximized, and when the AVI file has played, the Notify event will close the form.

Example:

```
{Code for Form 1}
```

```
uses Unit2;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Form2.Show;  
    Form2.WindowState := wsMaximized;  
    Form2.MediaPlayer1.Notify := false;  
    Form2.MediaPlayer1.Display := Form2.Pane11;  
    Form2.MediaPlayer1.FileName := 'C:\TheWall\DELCAR2.AVI';  
    Form2.MediaPlayer1.Open;  
    Form2.MediaPlayer1.DisplayRect := Form2.ClientRect;  
    Form2.MediaPlayer1.Play;  
end;
```

```
{Code for Form 2}
```

```
procedure TForm2.MediaPlayer1Notify(Sender: TObject);  
begin  
    if MediaPlayer1.NotifyValue = nvSuccessful then  
        Form2.Close;  
end;
```

## Article #16918: Play an AVI file that has sound, silently

Question and Answer Database

FAQ1918D.txt    Play an AVI file that has sound, silently  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

Question:

How can I play an AVI file that has sound silently without adjusting the volume?

Answer:

The following example demonstrates playing an AVI file silently by turning off the MCI audio channels in code.

Example:

```
uses MMSystem;

procedure SetMediaAudioOff(DeviceID : word);
var
  SetParm : TMCISetParams;
begin
  SetParm.dwAudio := MCI_SET_AUDIO_ALL;
  mciSendCommand(DeviceID,
                 MCI_SET,
                 MCI_SET_AUDIO or MCI_SET_OFF,
                 Longint(@SetParm));
end;

Procedure SetMediaAudioOn(DeviceID : word);
var
  SetParm : TMCISetParams;
begin
  SetParm.dwAudio := MCI_SET_AUDIO_ALL;
  mciSendCommand(DeviceID,
                 MCI_SET,
                 MCI_SET_AUDIO or MCI_SET_ON,
                 Longint(@SetParm));
```

```
end;  
  
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  {Play AVI file silently}  
  MediaPlayer1.FileName := 'C:\TheWall\DELCAR2.AVI';  
  MediaPlayer1.Display := Panel1;  
  MediaPlayer1.Open;  
  MediaPlayer1.Play;  
  SetMediaAudioOff(MediaPlayer1.DeviceId);  
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);  
begin  
  {Play AVI with sound}  
  MediaPlayer1.FileName := 'C:\TheWall\DELCAR2.AVI';  
  MediaPlayer1.Display := Panel1;  
  MediaPlayer1.Open;  
  MediaPlayer1.Play;  
  SetMediaAudioOn(MediaPlayer1.DeviceId);  
end;
```

## Article #16925: TTable AddIndex() with ixUnique and Paradox tables

Question and Answer Database

FAQ1925C.txt TTable AddIndex() with ixUnique and Paradox tables

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

Why can't I use the ixUnique option when creating indexes for Paradox tables with the AddIndex method of the TTable component?

Answer:

The index options used in the AddIndex method of the TTable component are table specific. For example, the ixUnique option works with dBASE tables but not Paradox. The following table shows how these options apply to dBASE and Paradox tables.

Index Options	dBASE	Paradox
ixUnique	*	
ixDescending	*	*
ixNonMaintained	*	*
ixPrimary		*
ixCaseInsensitive		*

## Article #16926: Flush binary file from disk cache to disk

Question and Answer Database

FAQ1926D.txt Flush binary file from disk cache to disk

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I guarantee that information I have written to a binary file is flushed from the disk cache and actually written to the disk?

Answer:

The following example demonstrates flushing the disk cache of given binary file, so that data is guaranteed to be written to the disk.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  f : file;
  i : integer;
begin
  i := 10;
  AssignFile(f, 'C:\Download\Test.Bin');
  Rewrite(f, 1);
  BlockWrite(f, i, sizeof(i));
  FlushFileBuffers(TFileRec(f).Handle);
  CloseFile(f);
end;
```

## Article #16929: How do I do a locate on a non-indexed field?

Question and Answer Database

FAQ1929C.txt    How do I do a locate on a non-indexed field?

Category     :Database Issues

Platform     :All

Product      :C++Builder 1.x

Question:

How do I do a locate on a non-indexed field?

Answer:

The following function can be added to your to your unit and called as follows:

```
bool __fastcall Locate(const TTable *oTable, const TField *oField,
                      const Char* SvALUE);
```

Table1 is your table component, Table1LName is TField you've added with the fields editor (double click on the table component) and 'Beman' is the name you want to find.

```
// Locate will find SValue in a non-indexed table
bool __fastcall Locate(const TTable *oTable, const TField *oField,
                      const Char* SvALUE)
{
    TBookmark bmPos;
    bool Locate, bFound;

    Locate = false;
    bFound = false;

    if (!oTable->Active)
        return;

    if (oTable->FieldDefs->IndexOf(oField->FieldName) < 0)
        return;

    bmPos = oTable->GetBookmark;

    oTable->DisableControls;
```

```
oTable->First;

while(!oTable->EOF)
{
    if(oField->AsString == sValue)
    {
        Locate = true;
        bFound = true;
        break;
    }
    else
        oTable->Next;
}

if (!bFound)
    oTable->GotoBookMark(bmPos);

oTable->FreeBookMark(bmPos);
oTable->EnableControls;
}
```

## Article #16930: Determine the last access time of a given file

Question and Answer Database

FAQ: FAQ1930D - Determine the last access time of a given file

Category: Windows API

Platform: All Windows

Product:

Question:

How can I determine the last access time of a given file?

Answer:

The following example demonstrates retrieving the last date and time a given file was accessed. Note: Not all file systems support the last access time.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  SearchRec : TSearchRec;
  Success : integer;
  DT : TFileTime;
  ST : TSystemTime;
begin
  Success := SysUtils.FindFirst('C:\autoexec.bat',
                                faAnyFile,
                                SearchRec);

  if (Success = 0) and
     (( SearchRec.FindData.ftLastAccessTime.dwLowDateTime <> 0)
     or ( SearchRec.FindData.ftLastAccessTime.dwHighDateTime <> 0))
  then
    begin
      FileTimeToLocalFileTime(SearchRec.FindData.ftLastAccessTime,DT);
      FileTimeToSystemTime(DT,ST);
      Mem1.Lines.Clear;
      Mem1.Lines.Add('AutoExec.Bat was last accessed at:');
```

```
Mem1.Lines.Add('Year := ' + IntToStr(st.wYear));
Mem1.Lines.Add('Month := ' + IntToStr(st.wMonth));
Mem1.Lines.Add('DayOfWeek := ' + IntToStr(st.wDayOfWeek));
Mem1.Lines.Add('Day := ' + IntToStr(st.wDay));
Mem1.Lines.Add('Hour := ' + IntToStr(st.wHour));
Mem1.Lines.Add('Minute := ' + IntToStr(st.wMinute));
Mem1.Lines.Add('Second := ' + IntToStr(st.wSecond));
Mem1.Lines.Add('Milliseconds := ' + IntToStr(st.wMilliseconds));
end;
SysUtils.FindClose(SearchRec);
end;
```

## Article #16933: using return instead of tab or mouse to move off a control

Question and Answer Database

FAQ1933C.txt using return instead of tab or mouse to move off a control

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

Is there a way to use the return key for data entry, instead of tab or the mouse?

Answer:

Use this code for an Edit's OnKeyPress event.

```
void __fastcall TForm1::Edit1KeyPress(TObject *Sender, Char *Key)
{
    if (Key == "#13")
    {
        SelectNext(dynamic_cast (Sender), true, true );
        Key = "#0";
    }
}
```

This causes Enter to behave like tab. Now, select all controls on the form you'd like to exhibit this behavior (not Buttons) and go to the Object Inspector and set their OnKeyPress handler to EditKeyPress. Now, each control you selected will process Enter as Tab. If you'd like to handle this at the form (as opposed to control) level, reset all the controls OnKeyPress properties to blank, and set the \_form\_'s OnKeyPress property to EditKeyPress. Then, change Sender to ActiveControl and set the form's KeyPreview property to true:

```
void __fastcall TForm1::Edit1KeyPress(TObject *Sender, Char *Key)
{
    if (Key == "#13")
    {
        SelectNext(dynamic_cast (ActiveControl), true, true );
        Key = "#0";
    }
}
```

```
}  
}
```

This will cause each control on the form (that can) to process  
Enter as Tab.

## Article #16934: Formatting and displaying integers with commas

Question and Answer Database

FAQ1934D.txt    Formatting and displaying integers with commas  
Category        :Object Pascal  
Platform        :All  
Product         :All 32 bit

Question:

How can I easily display an integer value with commas every three digits?

Answer:

The following example demonstrates displaying an integer value with thousand separators. Note that the actual character used to separate the digits will depend on the local (country) system settings.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i : integer;
begin
  i := 12345678;
  Mem1.Lines.Add(FormatFloat('#, ', i));
end;
```

Question and Answer Database

FAQ1938D.txt Create hints for Menu items

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I create hints for Menu items?

Answer:

The following example demonstrates adding a hint handler to your application for handling menu selections. Hints will be displayed in the status panel's caption.

Example:

```
type
  TForm1 = class(TForm)
    Panel1: TPanel;
    MainMenu: TMainMenu;
    MenuItemFile: TMenuItem;
    MenuItemOpen: TMenuItem;
    MenuItemClose: TMenuItem;
    OpenDialog1: TOpenDialog;
    procedure FormCreate(Sender: TObject);
    procedure MenuItemCloseClick(Sender: TObject);
    procedure MenuItemOpenClick(Sender: TObject);
  private
    { Private declarations }
    procedure HintHandler(Sender: TObject);
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    Panell.Align := alBottom;  
    MenuItemFile.Hint := 'File Menu';  
    MenuItemOpen.Hint := 'Opens A File';  
    MenuItemClose.Hint := 'Closes the Application';  
    Application.OnHint := HintHandler;  
end;
```

```
procedure TForm1.HintHandler(Sender: TObject);  
begin  
    Panell.Caption := Application.Hint;  
end;
```

```
procedure TForm1.MenuItemCloseClick(Sender: TObject);  
begin  
    Application.Terminate;  
end;
```

```
procedure TForm1.MenuItemOpenClick(Sender: TObject);  
begin  
    if OpenFileDialog1.Execute then  
        Form1.Caption := OpenFileDialog1.FileName;  
end;
```

## Article #16942: Native Access driver and ISAPI/NSAPI

Question and Answer Database

FAQ1942D.txt - Native Access driver and ISAPI/NSAPI

Category :Internet/WEB

Platform :All-32Bit

Product :

Question:

Why can't I use the native Access driver in an ISAPI/NSAPI DLL?

Answer:

Because neither DAO 3.0 or DAO 3.5 are thread-safe.

A web server (such as IIS) will always spawn different threads and load the ISAPI DLL in the context of the thread. The ISAPI DLL is then talking to the BDE which talks to the DAO engine (not thread-safe).

So, if you need to write an ISAPI/NSAPI DLL talking to Access 95/97 tables, you'll need to use Microsoft's ODBC driver. The ODBC driver doesn't use the DAO engine, and is thread-safe.

## Article #16945: Problems with MS Access

Question and Answer Database

FAQ1945C.txt Problems with MS Access

Category :Database Issues

Platform :All

Product :BC++ 5.x

### Question:

I'm having trouble with using BDE 3.5 to talk to a Microsoft Access table. Specifically, if the table has a primary key, and I create a secondary key which uses one of the fields in the primary key, my C++ program no longer recognizes the primary key. What do I need to do?

### Answer:

You need to have a secondary key which uses the `_first record_` in the primary key. It is not necessary that all secondary keys do this, just that one of them does.

## Article #16949: Clearing the window in a console application

Question and Answer Database

FAQ1949D.txt Clearing the window in a console application

Category :Miscellaneous

Platform :All

Product :All 32 bit

Question:

How can I guarantee to clear my window in a console application?

Answer:

The following example demonstrates clearing the console window by using the screensize information passed back from the Windows API function `GetConsoleScreenBufferInfo()` to write several blank lines.

Example:

```
program Project1;

{$APPTYPE CONSOLE}

uses
  Windows;

{$R *.RES}

var
  sbi : TConsoleScreenBufferInfo;
  i : integer;
begin
  Writeln('A Console Applicaiton');
  Writeln('Press Enter To Clear The Screen');
  GetConsoleScreenBufferInfo(GetStdHandle(STD_OUTPUT_HANDLE),
    sbi);
  Readln;
  GetConsoleScreenBufferInfo(GetStdHandle(STD_OUTPUT_HANDLE),
    sbi);
  for i := 0 to sbi.dwSize.y do
    writeln;
  Writeln('Press Enter To End');
```

Readln;  
end.

## Article #16957: Accessing a grid's column/row by name

Question and Answer Database

FAQ1957D.txt    Accessing a grid's column/row by name

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

Is it possible to access a grid row or column by name?

Answer:

The following example presents two functions: `GetGridColumnByName()` and `GetGridRowByName()` that return the given column or row that contains the specified caption.

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    StringGrid1.Rows[1].Strings[0] := 'This Row';
    StringGrid1.Cols[1].Strings[0] := 'This Column';
end;

function GetGridColumnByName(Grid : TStringGrid;
                             ColName : string): integer;

var
    i : integer;
begin
    for i := 0 to Grid.ColCount - 1 do
        if Grid.Rows[0].Strings[i] = ColName then begin
            Result := i;
            exit;
        end;
    Result := -1;
end;

function GetGridRowByName(Grid : TStringGrid;
                           RowName : string): integer;

var
    i : integer;
begin
    for i := 0 to Grid.RowCount - 1 do
```

```
    if Grid.Cols[0].Strings[i] = RowName then begin
        Result := i;
        exit;
    end;
Result := -1;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
    Column : integer;
    Row : integer;
begin
    Column := GetGridColumnByName(StringGrid1, 'This Column');
    if Column = -1 then
        ShowMessage('Column not found') else
        ShowMessage('Column found at ' + IntToStr(Column));
    Row := GetGridRowByName(StringGrid1, 'This Row');
    if Row = -1 then
        ShowMessage('Row not found') else
        ShowMessage('Row found at ' + IntToStr(Row));
end;
```

## Article #16960: Converting ASCII files to Paradox tables

Question and Answer Database

FAQ1960C.txt     Converting ASCII files to Paradox tables

Category     :Database Issues

Platform     :All

Product      :C++Builder 1.x

Question:

How do I import my ASCII file into a Paradox table? Can the Database Desktop do it?

Answer:

No, the Database Desktop can't do it.

Drop 1 TBatchMove and 2 TTables on a form. Set BatchMove1::Mode to batCopy, and Source and Destination to Table1 and Table2, respectively. Set Table1::TableName to an empty Paradox table created with the same structure as the Ascii file. Set Table2::TableName to any non-existent table name such as FOO.TXT, and set Table2::TableType to ttASCII. Double-click on the form and type, BatchMove1->Execute() into the created OnCreate method. Press F9 to build and run. The files FOO.TXT and FOO.SCH should be created.

Now copy the ASCII text file to the directory where FOO.TXT is located. Open FOO.SCH and changed the first line to read the name of the name of the ASCII data file instead of "FOO". Add statements for delimiter and separator, and change Filetype= to "varying" if appropriate. Rename FOO.SCH to the name of the ASCII data file .SCH. Back in your program, change Table2::TableName to the name of your ASCII data file. Change BatchMove1::Source to Table2 and BatchMove1::Destination to Table1. F9 to rebuild and run.

You can now open the paradox table in Database Desktop and see your data. If the data did not splice correctly into the target fields, you will need to modify your schema file (.sch).

Also see the file ASCII DRV.TXT in Delphi3, or TI2844 "Using The

ASCII Driver With Comma-delimited Files", or Delphi3\Help\Examples

## Article #16965: Assigning a comp type to an integer

Question and Answer Database

FAQ1965D.txt     Assigning a comp type to an integer

Category     : Object Pascal

Platform     : All

Product      : All 32 bit

### Question:

I am using a comp type (64 bit integer) and would like to assign the value to an integer. Using the Trunc function is too slow. Is there a better way?

### Answer:

The VCL defines a type called TLargeInteger that is a comp type that is broken down into the integer components Low and High. You could simply cast the comp as a TLargeInteger and access one of it's members, and avoid using floating point functions to get at it's underlying integer value.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  c : comp;
  i : integer;
begin
  c := $FFFFFF;
  // i := c; This won't work - incompatible types!
  i := Trunc(c); // This works but has additional overhead;
  i := TLargeInteger(c).LowPart;
end;
```

## Article #16977: Changing the default form size

Question and Answer Database

FAQ1977D.txt Changing the default form size

Category :IDE

Platform :All

Product :All 32 bit

### Question:

How can I change the default form size that Delphi / C++ Builder uses?

### Answer:

While the default form size is hard coded in the IDE, you can simply create a form to your liking, and save the form template in the repository for future reuse.

To add a form to the repository, create your new form and save it to a directory (usually to the Objrepos directory located in the Delphi or CBuilder directory), then right click on the form and choose "Add to repository". After completing the information requested in the repository dialog, you will be able to add your new default form to any project by selecting "File->New" from the IDE's main menu, and choosing your new form.

## Article #16981: Getting the handle of a Window containing a DOS box

Question and Answer Database

FAQ1981D.txt    Getting the handle of a Window containing a DOS box  
Category       :Windows API  
Platform        :All  
Product         :All 32 bit

### Question:

How can I get the handle of the Window containing a DOS box or other console mode application?

### Answer:

The following example demonstrates using the Windows API function FindWindow() to retrieve the handle of a console mode application. Note that the WndClass of a console window is different under Windows 95 and Windows NT, and the title of the Window may contain a full path name under Windows NT.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  info : TOSVersionInfo;
  ClassName : string;
  Title : string;
begin
  {See if we're running on Win95 or NT.}
  info.dwOSVersionInfoSize := sizeof(info);
  GetVersionEx(info);
  if (info.dwPlatformId = VER_PLATFORM_WIN32_NT) then begin
    ClassName := 'ConsoleWindowClass';
    Title := 'Command Prompt';
  end else begin
    ClassName := 'tty';
    Title := 'MS-DOS Prompt';
  end;
  ShowMessage(IntToStr(FindWindow(PChar(ClassName), PChar(Title))));
end;
```

## Article #16985: Refreshing the TDriveComboBox drive list

Question and Answer Database

FAQ1985D.txt Refreshing the TDriveComboBox drive list

Category :VCL

Platform :All

Product :All 32 bit

### Question:

How can I get the TDriveComboBox component to refresh its' list, given that networked drives can be added, deleted, and remapped, and drives can be hot swapped by using plug and play devices?

### Answer:

The following example demonstrates surfacing the protected BuildList() method of the TDriveComboBox component to regenerate the list of current disk drives.

### Example:

```
type
  TNewDriveComboBox = class(TDriveComboBox)
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  Drive : char;
begin
  Drive := DriveComboBox1.Drive;
  TNewDriveComboBox(DriveComboBox1).BuildList;
  DriveComboBox1.Drive := Drive;
end;
```

## Article #16989: Removing drives listed in a TDriveComboBox

Question and Answer Database

FAQ1989D.txt Removing drives listed in a TDriveComboBox

Category :VCL

Platform :All

Product :All 32 bit

### Question:

On many laptop computers, there is a possibility that no floppy drive is installed. Is it possible to remove drives that are listed in the TDriveComboBox component to avoid listing non existent drives?

### Answer:

The following example demonstrates removing drives that are not ready for use from the TDriveComboBox component. Note that on many computers, there will be a significant delay in checking for a plug and play floppy drive.

### Example:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i : integer;
  OldErrorMode : Word;
  OldDirectory : string;
begin
  OldErrorMode := SetErrorMode(SEM_NOOPENFILEERRORBOX);
  GetDir(0, OldDirectory);
  i := 0;
  while i <= DriveComboBox1.Items.Count - 1 do begin
    {$I-}
    ChDir(DriveComboBox1.Items[i][1] + ':\');
    {$I+}
    if IoResult <> 0 then
      DriveComboBox1.Items.Delete(i) else
      inc(i);
  end;
  ChDir(OldDirectory);
  SetErrorMode(OldErrorMode);
```

end;

## Article #16993: Determining if you have Delphi v3.02 installed

Question and Answer Database

FAQ1993D.txt - Determining if you have Delphi v3.02 installed

Category :Delphi 3.x  
Platform :All-32Bit  
Product :Delphi3.x,

### Question:

I am updating many machines in our office to Delphi 3.02. How can I determine if a given machine has been upgraded?

### Answer:

Check the Bin directory for DELPHI.EXE. If it's file time is listed as 3:00, you have 3.0. If it's file time is listed 3:01, you may have either 3.01 or 3.02. In this case, check the time stamp of TLIBIMP.EXE. If it's file time is listed as 3.02, then you have 3.02.

You can also get:

```
"/devsupport/delphi/download_files/vcnp.zip">version checking utility  
"/devsupport/delphi/download_files/vcp.exe">version checking utility  
(Package EXE)
```

## Article #16996: Defining PRIMARYLANGID(), SUBLANGID(), and MAKELANGID() macros

Question and Answer Database

FAQ1996D.txt Defining PRIMARYLANGID(), SUBLANGID(), and MAKELANGID()  
( ) macros

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I define the PRIMARYLANGID(), SUBLANGID() and MAKELANGID() macros that are used with the Windows API functions that accept language identifiers?

Answer:

The follow example demonstrates functional equivalents for the PRIMARYLANGID(), SUBLANGID(), and MAKELANGID() macros.

```
function PRIMARYLANGID(lgid : Word) : LongInt;
begin
    result := lgid and $3FF;
end;
```

```
function SUBLANGID(lgid : Word) : LongInt;
begin
    result := lgid shr 10;
end;
```

```
function MAKELANGID(sPrimaryLanguage : Word;
                   sSubLanguage : Word) : Word;
begin
    result := (sSubLanguage shl 10) or
              sPrimaryLanguage;
end;
```

## Article #17000: Forcing edit mode in a TListView via a keypress

Question and Answer Database

FAQ2000D.txt Forcing edit mode in a TListView via a keypress

Category :VCL

Platform :All

Product :All 32 bit

### Question:

When the user clicks on a caption in the listview, it goes into edit mode. How can I force the edit mode by pressing F2 or a similar key?

### Answer:

The following example demonstrates trapping the F2 key in a Listview control and forcing the caption into edit mode.

### Example:

```
procedure TForm1.ListView1KeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
begin
  if Ord(Key) = VK_F2 then
    ListView1.Selected.EditCaption;
end;
```

## Article #17004: Differences between Create(Self) and Create(Application)

Question and Answer Database

FAQ2004D.txt Differences between Create(Self) and Create  
(Application)

Category :VCL

Platform :All

Product :All 32 bit

Question:

What's the difference between TForm.Create(Self) and  
TForm.Create(Application)?

Answer:

Self is an implicit variable which can only be used within class  
methods, and refers to the current class instance. So "Self" within a  
method of the TForm1 class refers to the current instance of TForm1.

When you create a form or component, you pass its owner in the  
constructor. When a form or component is freed, it automatically frees  
all the components which it owns as well.

So if you pass an Application as the owner when you create a form  
instance, the form instance will be automatically freed when the  
Application is freed.

If you pass a form instance as the owner when you create another form  
instance, the second form will be freed when the first is freed.

## Article #17008: Using the Shell API function SHBrowseForFolder()

Question and Answer Database

FAQ2008D.txt Using the Shell API function SHBrowseForFolder()  
Category :Windows API  
Platform :All  
Product :All 32 bit

Question:

How can I use the Shell API function SHBrowseForFolder() to let the user browse for a folder?

Answer:

The following example demonstrates using the SHBrowseForFolder() function to allow the user to select a given directory object.

Example:

```
uses ShellAPI, ShlObj;

procedure TForm1.Button1Click(Sender: TObject);
var
  TitleName : string;
  lpItemID : PItemIDList;
  BrowseInfo : TBrowseInfo;
  DisplayName : array[0..MAX_PATH] of char;
  TempPath : array[0..MAX_PATH] of char;
begin
  FillChar(BrowseInfo, sizeof(TBrowseInfo), #0);
  BrowseInfo.hwndOwner := Form1.Handle;
  BrowseInfo.pszDisplayName := @DisplayName;
  TitleName := 'Please specify a directory';
  BrowseInfo.lpszTitle := PChar(TitleName);
  BrowseInfo.ulFlags := BIF_RETURNONLYFSDIRS;
  lpItemID := SHBrowseForFolder(BrowseInfo);
  if lpItemID <> nil then begin
    SHGetPathFromIDList(lpItemID, TempPath);
    ShowMessage(TempPath);
    GlobalFreePtr(lpItemID);
  end;
end;
```

end;

## Article #17012: Adding accelerator characters to TTabsheets

Question and Answer Database

FAQ2012D.txt Adding accelerator characters to TTabsheets

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I make an accelerator character work for a Tabsheet?

I put accelerator characters in the captions for each Tabsheet of a PageControl, but when I try to tab the pages using accelerator key, it beeps and does nothing.

Answer:

The following example demonstrates trapping the CM\_DIALOGCHAR message to surface the accelerator messages for the tab sheets of a PageControl.

Example:

```
type
  TForm1 = class(TForm)
    PageControl1: TPageControl;
    TabSheet1: TTabSheet;
    TabSheet2: TTabSheet;
    TabSheet3: TTabSheet;
  private
    { Private declarations }
    procedure CMDialogChar(var Msg:TCMDialogChar);
      message CM_DIALOGCHAR;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.CMDDialogChar(var Msg:TCMDDialogChar);
var
  i:Integer;
begin
  with PageControll do begin
    if Enabled then
      for i := 0 to PageControll.PageCount - 1 do
        if ((IsAccel(Msg.CharCode, Pages[i].Caption)) and
          (Pages[i].TabVisible)) then begin
          Msg.Result:=1;
          ActivePage := Pages[i];
          exit;
        end;
      end;
    end;
  inherited;
end;
```

## Article #17016: Limiting the amount of text entered in a TEdit

Question and Answer Database

FAQ2016D.txt Limiting the amount of text entered in a TEdit

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I limit the amount of text that is entered into a TEdit control so the text entered does not exceed the width of the TEdit control?

Answer:

The following two examples demonstrate limiting the text in a edit control to the amount of text that fits in the client area of the control to avoid scrolling text. The first example sets the MaxLength property to the number of "W" characters that will fit in the control. The "W" character is chosen, since it is most likely to be the widest character in the font. This method will work well for fixed pitch fonts, but will produce less than desirable effects when using a variable width font. The second method traps the edit control's key press method, and measures the text width of the current string in the edit control and the width of the character that will be added. If the width exceeds the client area of the edit control, the key is discarded, and a MessageBeep is produced.

Examples:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  cRect : TRect;
  bm : TBitmap;
  s : string;
begin
  Windows.GetClientRect(Edit1.Handle, cRect);
  bm := TBitmap.Create;
  bm.Width := cRect.Right;
  bm.Height := cRect.Bottom;
  bm.Canvas.Font := Edit1.Font;
  s := 'W';
```

```
while bm.Canvas.TextWidth(s) < CRect.Right do
  s := s + 'W';
if length(s) > 1 then begin
  Delete(s, 1, 1);
  Edit1.MaxLength := Length(s);
end;
end;
```

{Alternatively}

```
procedure TForm1.Edit1KeyPress(Sender: TObject; var Key: Char);
var
  cRect : TRect;
  bm : TBitmap;
begin
  if ((Ord(Key) <> VK_TAB) and
    (Ord(Key) <> VK_RETURN) and
    (Ord(Key) <> VK_LEFT) and
    (Ord(Key) <> VK_BACK)) then begin
    Windows.GetClientRect(Edit1.Handle, cRect);
    bm := TBitmap.Create;
    bm.Width := cRect.Right;
    bm.Height := cRect.Bottom;
    bm.Canvas.Font := Edit1.Font;
    if bm.Canvas.TextWidth(Edit1.Text + Key) > CRect.Right then begin
      Key := #0;
      MessageBeep(-1);
    end;
    bm.Free;
  end;
end;
```

## Article #17020: Detecting if the system time has been changed

Question and Answer Database

FAQ2020D.txt Detecting if the system time has been changed

Category :Windows API

Platform :All

Product :All 32 bit

Question:

Is it possible to detect if the system time has been changed by another application?

Answer:

The following example demonstrates trapping the WM\_TIMECHANGE message. Note: Applications that change the system time should broadcast a WM\_TIMECHANGE message to all top level windows.

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
    procedure WMTIMECHANGE(var Message: TWMTIMECHANGE);
      message WM_TIMECHANGE;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMTIMECHANGE(var Message: TWMTIMECHANGE);
begin
  Form1.Caption := 'Time Changed';
end;
```

Last Modified: 01-SEP-99

## Article #17024: Trapping for when a user is done resizing a window

Question and Answer Database

FAQ2024D.txt Trapping for when a user is done resizing a window

Category :Windows API

Platform :All

Product :All 32 bit

Question:

I want to trap when the user is finished sizing or moving my window. I trapped the WM\_SIZE and the WM\_MOVE messages, but I receive many of these messages, and seems impossible to tell when the user has completed the operation. How can I tell when the user is finished moving and sizing the window?

Answer:

The following example demonstrates trapping the WM\_EXITSIZEMOVE message to determine when the user has exited a Window sizing or moving event. Although the message is documented as available only under Windows NT, it does work equally as well under Windows 95. Note that you can also trap the WM\_ENTERSIZEMOVE to determine when the user is initiating a window move or size operation.

Example:

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
  public
    procedure WMEXITSIZEMOVE(var Message: TMessage);
      message WM_EXITSIZEMOVE;
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.WMEXITSIZEMOVE(var Message: TMessage);  
begin  
    Form1.Caption := 'Finished Moving and sizing';  
end;
```

## Article #17028: Using the WIN API high resolution performance counter

Question and Answer Database

FAQ2028D.txt Using the WIN API high resolution performance counter

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I make use of the high resolution performance counter available under Win32?

Answer:

The following example demonstrates using the TLargeInteger type to query the performance counter. Note that the TLargeInteger type (64 bit integer) can be converted and referenced as a whole by casting it to a Comp type.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  li : TLARGEINTEGER;
begin
  QueryPerformanceFrequency(li);
  ShowMessage(FloatToStr(Comp(li)));
  QueryPerformanceCounter(li);
  ShowMessage(FloatToStr(Comp(li)));
  QueryPerformanceCounter(li);
  ShowMessage(FloatToStr(Comp(li)));
end;
```

## Article #17032: Keyboard shortcut to a component that has no caption

Question and Answer Database

FAQ2032D.txt    Keyboard shortcut to a component that has no caption  
Category        :VCL  
Platform        :All  
Product         :All 32 bit

### Question:

How can I create a keyboard shortcut to a component that has no caption?

### Answer:

One work around is to leverage the FocusControl property of TLabel. The following example demonstrates using an invisible label control to create a keyboard shortcut to a memo control. The shortcut will respond to the Alt+M key combination. To use this example, place a label, a memo, and several other controls that receive focus. Run the application, move focus to a control other than "Memo1", and key in -M. You should see focus move to Memo1.

### Example:

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    Label1.Visible := false;  
    Label1.Caption := '&M';  
    Label1.FocusControl := Memo1;  
end;
```

## Article #17036: Getting modem status under Win32

Question and Answer Database

FAQ2036D.txt Getting modem status under Win32

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I get the modem status under Win32?

Answer:

The following example demonstrates retrieving the current state of the modem control-register values under Win32.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  CommPort : string;
  hCommFile : THandle;
  ModemStat : DWord;
begin
  CommPort := 'COM2';

  {Open the comm port}
  hCommFile := CreateFile(PChar(CommPort),
                        GENERIC_READ,
                        0,
                        nil,
                        OPEN_EXISTING,
                        FILE_ATTRIBUTE_NORMAL,
                        0);

  if hCommFile = INVALID_HANDLE_VALUE then
  begin
    ShowMessage('Unable to open '+ CommPort);
    exit;
  end;

  {Get the Modem Status}
```

```
if GetCommModemStatus(hCommFile, ModemStat) <> false then begin
  if ModemStat and MS_CTS_ON <> 0 then
    ShowMessage('The CTS (clear-to-send) is on.');
```

if ModemStat and MS\_DSR\_ON <> 0 then  
 ShowMessage('The DSR (data-set-ready) is on.');

if ModemStat and MS\_RING\_ON <> 0 then  
 ShowMessage('The ring indicator is on.');

if ModemStat and MS\_RLSD\_ON <> 0 then  
 ShowMessage('The RLSD (receive-line-signal-detect) is  
on.');

```
end;
```

```
{Close the comm port}
  CloseHandle(hCommFile);
end;
```

## Article #17039: BDE 4.51 causes Application Error

Question and Answer Database

FAQ2039C.txt BDE 4.51 causes Application Error

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

when building a program that interacts with MS Access using the BDE 4.51 and C++Builder, I find that programs I run under the debugger crash with an exception. The programs work fine when run from windows, and I can access the data fine at designtime. What is happening?

Answer:

The DAO, like the VCL, uses exceptions internally to propogate information and control structures. The C++Builder debugger is designed so as to trigger a user interrupt when a certain number of internal exceptions have been tracked. That interrupt causes the exception message to appear.

The program being debugged has not crashed, and it is perfectly reasonable to resume execution without doing anything other than clicking on the exception message box. The interruption is only intended to serve as a notification about what is happening behind the scenes.

Question and Answer Database

FAQ2044D.txt Click a speed button in code

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I click a SpeedButton component in code? I tried using SendMessage but it does not work since Speedbuttons do not have handles.

Answer:

The following example demonstrates using the Perform method of TControl to send the message.

Example:

```
procedure TForm1.SpeedButton1Click(Sender: TObject);
begin
  ShowMessage('clicked');
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  SpeedButton1.Perform(WM_LBUTTONDOWN, 0, 0);
  SpeedButton1.Perform(WM_LBUTTONUP, 0, 0);
end;
```

## Article #17052: Using an instance of TPrinter

Question and Answer Database

FAQ2052D.txt Using an instance of TPrinter

Category :VCL

Platform :All

Product :All 32 bit

Question:

When I create an instance of TPrinter using TPrinter.Create, I get an exception. How can I get around this?

Answer:

There is no need to create an instance of TPrinter using TPrinter.Create, as an instance of TPrinter (called Printer) is automatically created when you use the Printers unit.

Example:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    Printer.BeginDoc;
```

```
    Printer.Canvas.TextOut(100, 100, 'Hello World!');
```

```
    Printer.EndDoc;
```

```
end;
```

## Article #17056: Customizing TTrackBar

Question and Answer Database

FAQ2056D.txt Customizing TTrackBar

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I create a trackbar where the track has a thin line on which the slider moves along, rather than a rather big white space which the slider moves along?

Answer:

The following example demonstrates creating a descendant of the TTrackbar component that overrides the CreateParams method, and clears the TBS\_ENABLESELRANGE flag from the params style. This results in a Trackbar component that has a small thin track for the slider to move upon. Note that the TBS\_ENABLESELRANGE constant is declared in the CommCtrl unit.

Example:

```
uses CommCtrl, ComCtrls;
```

```
type TMyTrackBar = class(TTrackBar)
```

```
  procedure CreateParams(var Params: TCreateParams); override;  
end;
```

```
procedure TMyTrackBar.CreateParams(var Params: TCreateParams);  
begin  
  inherited;  
  Params.Style := Params.Style and not TBS_ENABLESELRANGE;  
end;
```

```
var  
  MyTrackbar : TMyTrackbar;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin
```

```
MyTrackBar := TMyTrackbar.Create(Form1);  
MyTrackbar.Parent := Form1;  
MyTrackbar.Left := 100;  
MyTrackbar.Top := 100;  
MyTrackbar.Width := 150;  
MyTrackbar.Height := 45;  
MyTrackBar.Visible := true;  
end;
```

## Article #17060: Detecting tab key press

Question and Answer Database

FAQ2060D.txt Detecting tab key press

Category :VCL

Platform :All

Product :All 32 bit

Question:

Since the KeyPress and the KeyDown events do not get called for the tab key, how do I trap the tab key at the form level?

Answer:

At form level, the tab key is generally handled by Windows. The following example demonstrates creating a CM\_Dialog message handler to trap for Dialog keys. The code surfaces the tab character through the KeyPress event.

Example:

```
type
  TForm1 = class(TForm)
  private
    procedure CMDialogKey( Var msg: TCMDialogKey );
    message CM_DIALOGKEY;
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.CMDialogKey(var msg: TCMDialogKey);
begin
  if msg.Charcode <> VK_TAB then
    inherited;
end;
```

```
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
begin
  if Key = VK_TAB then
    Form1.Caption := 'Tab Key Down!';
end;
```

## Article #17064: adding system menu items to a form

Question and Answer Database

FAQ2064D.txt adding system menu items to a form

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I add a custom item to the system menu of my application?

Answer:

The following example demonstrates using the Windows API function `AppendMenu()` to append a new menu item to the system menu. We will define a new system command

constant : `SC_MyMenuItem` that will be used to identify our new item to the system. After adding the menu item, we will trap the `WM_SYSCOMMAND` message to test if our new menu item was selected.

Example:

```
type
  TForm1 = class(TForm)
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
    procedure WMSysCommand(var Msg: TWMSysCommand);
      message WM_SYSCOMMAND;
  public
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
const
```

```
SC_MyMenuItem = WM_USER + 1;
```

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
  AppendMenu(GetSystemMenu(Handle, FALSE), MF_SEPARATOR, 0, '');  
  AppendMenu(GetSystemMenu(Handle, FALSE),  
    MF_STRING,  
    SC_MyMenuItem,  
    'My Menu Item');  
end;
```

```
procedure TForm1.WMSysCommand(var Msg: TWMSysCommand);  
begin  
  if Msg.CmdType = SC_MyMenuItem then  
    ShowMessage('Got the message') else  
    inherited;  
end;
```

Question and Answer Database

FAQ2068D.txt Resizing StringGrid Columns

Category :VCL

Platform :All

Product :All 32 bit

Question:

Is it possible to automatically size a column in a TStringGrid component to fit the text of the largest string in the column?

Answer:

The following example demonstrates auto sizing a column in a TStringGrid Component.

Example:

```
procedure AutoSizeGridColumn(Grid : TStringGrid;
                             column : integer);
var
  i : integer;
  temp : integer;
  max : integer;
begin
  max := 0;
  for i := 0 to (Grid.RowCount - 1) do begin
    temp := Grid.Canvas.TextWidth(grid.cells[column, i]);
    if temp > max then max := temp;
  end;
  Grid.ColWidths[column] := Max + Grid.GridLineWidth + 3;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  AutoSizeGridColumn(StringGrid1, 1);
end;
```

## Article #17071: Endless looping with the TMediaPlayer

Question and Answer Database

FAQ2071D.txt    Endless looping with the TMediaPlayer

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I get an AVI to loop continually with the TMediaPlayer?

Answer:

The following example demonstrates looping an AVI file by taking advantage of the MediaPlayer's Notify event to play the AVI file again... and again... and again!

Example:

```
procedure TForm1.MediaPlayer1Notify(Sender: TObject);
begin
  with MediaPlayer1 do
    if NotifyValue = nvSuccessful then begin
      Notify := True;
      Play;
    end;
end;
```

## Article #17075: Frame count of an AVI

Question and Answer Database

FAQ2075D.txt     Frame count of an AVI

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I tell how many frames are in a given AVI file and how long the AVI file will play?

Answer:

The TMediaPlayer provides this information by setting the TimeFormat property and querying the Length property. The following example demonstrates retrieving the number of frames and the play time of a given AVI file.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  MediaPlayer1.TimeFormat := tfFrames;
  ShowMessage('Number of frames = ' +
    IntToStr(MediaPlayer1.Length));
  MediaPlayer1.TimeFormat := tfMilliseconds;
  ShowMessage('Number of milliseconds = ' +
    IntToStr(MediaPlayer1.Length));
end;
```

## Article #17079: drawing transparent text onto a TBitmap

Question and Answer Database

FAQ2079D.txt drawing transparent text onto a TBitmap

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I draw transparent text on a TBitmap?

Answer:

The following example demonstrates drawing transparent text on the canvas of a TBitmap.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  OldBkMode : integer;
begin
  Image1.Picture.Bitmap.Canvas.Font.Color := clBlue;
  OldBkMode := SetBkMode(Image1.Picture.Bitmap.Canvas.Handle,
                        TRANSPARENT);
  Image1.Picture.Bitmap.Canvas.TextOut(10, 10, 'Hello');
  SetBkMode(Image1.Picture.Bitmap.Canvas.Handle,
            OldBkMode);
end;
```

## Article #17083: displaying seconds, minutes, tracks of an AVI

Question and Answer Database

FAQ2083D.txt displaying seconds, minutes, tracks of an AVI

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I display the real time track selection and current play time of an Audio CD track?

Answer:

The following example demonstrates displaying the current track and play time of an AudioCD, updating the values every second by utilizing a timer event.

Example:

```
uses
    MMSystem;

procedure TForm1.Timer1Timer(Sender: TObject);
var
    Trk : Word;
    Min : Word;
    Sec : Word;
begin
    with MediaPlayer1 do begin
        Trk := MCI_TMSF_TRACK(Position);
        Min := MCI_TMSF_MINUTE(Position);
        Sec := MCI_TMSF_SECOND(Position);
        Label1.Caption := Format('%.2d', [Trk]);
        Label2.Caption := Format('%.2d:%.2d', [Min, Sec]);
    end;
end;
```

## Article #17091: Shift, Ctrl, Alt key checking

Question and Answer Database

FAQ2091D.txt    Shift, Ctrl, Alt key checking

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I determine if the Shift, Alt, or Ctrl key is depressed at any given time?

Answer:

The following example demonstrates checking if the Shift key is pressed during a menu item selection. The example presents functions for testing the status of the Alt, Ctrl, and shift keys.

Example:

```
function CtrlDown : Boolean;
var
  State : TKeyboardState;
begin
  GetKeyboardState(State);
  Result := ((State[vk_Control] And 128) <> 0);
end;
```

```
function ShiftDown : Boolean;
var
  State : TKeyboardState;
begin
  GetKeyboardState(State);
  Result := ((State[vk_Shift] and 128) <> 0);
end;
```

```
function AltDown : Boolean;
var
  State : TKeyboardState;
begin
  GetKeyboardState(State);
```

```
Result := ((State[vk_Menu] and 128) <> 0);  
end;
```

```
procedure TForm1.MenuItem12Click(Sender: TObject);  
begin  
  if ShiftDown then  
    Form1.Caption := 'Shift' else  
    Form1.Caption := '';  
end;
```

## Article #17095: making a Delphi DLL with as little in the uses clause as possible

Question and Answer Database

FAQ2095D.txt making a Delphi DLL with as little in the uses clause as possible

Category :VCL  
Platform :All  
Product :All 32 bit

Question:

I want to create a small dynamic link library that contains only a few small functions. I do not need any additional units, but Delphi insists that the uses clause is incorrect if I remove the standard uses clause. The code does compile to a very small dll if I do remove the uses clause. May I disregard the error when I load the project?

Answer:

While it is ok to disregard the error, it would be better to create a unit that would contain the code for your functions. This way the main project file can have a uses statement that will satisfy the IDE.

Example:

```
(* Main project file *)

library Project1;

uses
  Unit1;

exports
  AddLong index 1 name 'ADDLONG' resident;

begin
end.

(* unit1's code *)

unit Unit1;
```

interface

```
function AddLong(a : longint;  
                b : longint) : longint  
{ $IFDEF Win32 } stdcall; { $ELSE } ; export; { $ENDIF }
```

implementation

```
function AddLong(a : longint;  
                b : longint) : longint;
```

```
begin  
  AddLong := a + b;  
end;
```

end.

## Article #17099: Moving a form by clicking in its client area

Question and Answer Database

FAQ2099D.txt Moving a form by clicking in its client area

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I make a form move by clicking and dragging in the client area instead of on the caption bar?

Answer:

You could trap the mouse move messages, and move the form based on the net movement of the mouse. An easy way to achieve the same result is to make Windows believe the caption bar was clicked on by trapping and modifying the WM\_NCHITTEST message.

Example:

type

```
TForm1 = class(TForm)
private
  { Private declarations }
public
  procedure WMNCHitTest(var M: TWMNCHitTest);
    message WM_NCHITTEST;
  { Public declarations }
end;
```

var

```
Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.WMNCHitTest(var M: TWMNCHitTest);
begin
```

```
inherited;  
{If the client has been clicked, make Windows believe}  
{it was the caption bar that was clicked on}  
  if M.Result = htClient then  
    M.Result := htCaption;  
end;
```

## Article #17103: Keeping an application minimized

Question and Answer Database

FAQ2103D.txt Keeping an application minimized

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I keep my application minimized as an icon?

Answer:

The following example demonstrates trapping the WM\_QUERYOPEN message to prevent the application from restoring from an iconized state. Note that the Window state of the form must be set to Minimized in the object inspector for this method to work.

Example:

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
    procedure WMQueryOpen(var Msg : TWMQueryOpen);
      message WM_QUERYOPEN;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMQueryOpen(var Msg : TWMQueryOpen);
begin
  Msg.Result := 0;
end;
```

FAQ2107D.txt Clearing the recent Documents from the Start Menu

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I clear the list of recent documents in the Windows Start menu?

Answer:

Call the Windows API function SHAddToRecentDocs() passing nil as the filename parameter.

Example:

uses

ShlOBJ;

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
  SHAddToRecentDocs(SHARD_PATH, nil);
```

```
end;
```

## Article #17110: Changing RichEdit Font styles with HotKey combinations

Question and Answer Database

FAQ2110D.txt Changing RichEdit Font styles with HotKey combinations

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I change the RichEdit font style in response to a dedicated keystroke combination?

Answer:

The following example demonstrates changing the font style in a TRichEdit component the following key combinations are pressed:

Ctrl + B - Turns on and off Bold styling

Ctrl + I - Turns on and off Italic styling

Ctrl + S - Turns on and off Strikeout styling

Ctrl + U - Turns on and off Underline styling

Note: It is possible to set the font to include multiple styles.

Example:

```
const
  KEY_CTRL_B = 02;
  KEY_CTRL_I = 9;
  KEY_CTRL_S = 19;
  KEY_CTRL_U = 21;

procedure TForm1.RichEdit1KeyPress(Sender: TObject; var Key: Char);
begin
  case Ord(Key) of
    KEY_CTRL_B: begin
      Key := #0;
      if fsBold in (Sender as TRichEdit).SelAttributes.Style then
        (Sender as TRichEdit).SelAttributes.Style :=
          (Sender as TRichEdit).SelAttributes.Style - [fsBold] else
        (Sender as TRichEdit).SelAttributes.Style :=
```

```

        (Sender as TRichEdit).SelAttributes.Style + [fsBold];
end;
KEY_CTRL_I: begin
    Key := #0;
    if fsItalic in
        (Sender as TRichEdit).SelAttributes.Style then
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style - [fsItalic]
        else
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style + [fsItalic];
        end;
KEY_CTRL_S: begin
    Key := #0;
    if fsStrikeout in
        (Sender as TRichEdit).SelAttributes.Style then
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style - [fsStrikeout]
        else
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style + [fsStrikeout];
        end;
KEY_CTRL_U: begin
    Key := #0;
    if fsUnderline in
        (Sender as TRichEdit).SelAttributes.Style then
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style - [fsUnderline]
        else
            (Sender as TRichEdit).SelAttributes.Style :=
                (Sender as TRichEdit).SelAttributes.Style + [fsUnderline];
        end;
    end;

## Article #17114: using the Lookup method to return values from multiple columns

Question and Answer Database

FAQ2114D.txt using the Lookup method to return values from multiple columns

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How do I use the Lookup method to return values from multiple columns?

Answer:

The result is a variant array -- one index to the array for every column specified in the KeyValues parameter:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  MyResults: Variant;
  MyKeyFields, MyKeyValues: String;
  MySearchForValue: Integer;
begin
  MyKeyFields := 'CustNo';
  MySearchForValue := 1351;
  MyReturnColumns := 'Company;Addr1';
  MyResults := Table1.Lookup(MyKeyFields, MySearchForValue,
                             MyKeyValues);
  if not VarIsNull(MyResults) then
    ShowMessage('Company: ' + MyResults[0] + ' Address: ' +
                MyResults[1]);
  { With DBDemos data this returns
    "Company: Sight Diver Address: 1 Neptune Lane" }
end;
```

## Article #17118: Copying files using the Standard Windows Copy file dialog box

Question and Answer Database

FAQ2118D.txt Copying files using the Standard Windows Copy file dialog box

Category :Windows API  
Platform :All  
Product :All 32 bit

Question:

Is there any way to copy a group of files and use the same file copy animation dialog box that the Windows Explorer uses?

Answer:

The following example demonstrates using the SHFileOperation function to copy a group of files and display a progress dialog. You can also use the following flags to delete, move and rename a group of files.

TO\_COPY  
FO\_DELETE  
FO\_MOVE  
FO\_RENAME

Note: The buffer that contains the file names to copy must end with a double null terminating character;

Example:

```
uses ShellAPI;

procedure TForm1.Button1Click(Sender: TObject);
var
  Fo      : TSHFileOpStruct;
  buffer  : array[0..4096] of char;
  p       : pchar;

begin
  FillChar(Buffer, sizeof(Buffer), #0);
  p := @buffer;
  p := StrECopy(p, 'C:\Download\1.ZIP') + 1;
```

```
p := StrECopy(p, 'C:\Download\2.ZIP') + 1;
p := StrECopy(p, 'C:\Download\3.ZIP') + 1;
StrECopy(p, 'C:\Download\4.ZIP');

FillChar(Fo, sizeof(Fo), #0);
Fo.Wnd      := Handle;
Fo.wFunc    := FO_COPY;
Fo.pFrom    := @Buffer;
Fo.pTo      := 'D:\';
Fo.fFlags   := 0;
if ((SHFileOperation(Fo) <> 0) or
    (Fo.fAnyOperationsAborted <> false)) then
    ShowMessage('Cancelled')
end;
```

## Article #17126: Getting stronger type checking

Question and Answer Database

FAQ2126D.txt    Getting stronger type checking

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

How can I get Delphi to perform stronger type checking on user defined types. Example: If I create a user defined type that descends from a double, I can pass a variable of this new type to any function that expects a double. I want Delphi to provide stronger type checking and produce a warning in this instance.

### Answer:

The following example demonstrates Delphi's new Strong type checking types, allowing you to define types that require stronger type checking at compile time.

### Example:

```
type TStrongType = type Double;
type TWeakType = Double;

procedure AddWeakType(var d : TWeakType);
begin
  d := d + 1;
end;

procedure AddStrongType(var d : TStrongType);
begin
  d := d + 1;
end;

procedure AddDoubleType(var d : Double);
begin
  d := d + 1;
end;

procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  d : Double;
  s : TStrongType;
  w : TWeakType;
begin
  AddDoubleType(d);           { compiles fine }
  AddDoubleType(w);           { compiles fine }
  AddDoubleType(s);           { <- compile error }
  AddDoubleType(double(s));   { compiles fine }

  AddWeakType(d);             { compiles fine }
  AddWeakType(w);             { compiles fine }
  AddWeakType(s);             { <- compile error }
  AddWeakType(TWeakType(s)); { compiles fine }

  AddStrongType(d);           { <- compile error }
  AddStrongType(TStrongType(d)); { compiles fine }
  AddStrongType(w);           { <- compile error }
  AddStrongType(TStrongType(w)); { compiles fine }
  AddStrongType(s);           { compiles fine }
end;
```

Question and Answer Database

FAQ2134D.txt Getting the path to the directory where Windows was installed from

Category :VCL  
Platform :All  
Product :All 32 bit

Question:

I need to install some files from the Windows Setup disk in code. On many computers, the Windows setup files reside in CAB files that are installed on the user's hard drive and in other cases, the system is installed from a CD. Where can I find where Windows was originally installed from?

Answer:

The following example demonstrates retrieving the source of the Windows setup files.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  reg: TRegistry;
begin
  reg := TRegistry.Create;
  reg.RootKey := HKEY_LOCAL_MACHINE;
  reg.OpenKey('Software\Microsoft\Windows\CurrentVersion\SETUP',
             false);
  ShowMessage(reg.ReadString('SourcePath'));
  reg.CloseKey;
  reg.free;
end;
```

## Article #17138: responding when the user minimizes or maximizes a Form

Question and Answer Database

FAQ2138D.txt    responding when the user minimizes or maximizes a Form

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I respond to the user minimizing or maximizing my form before the resizing actually takes place?

Answer:

The following example demonstrates trapping the Windows WM\_SYSCOMMAND message. If the command specifies to minimize or maximize the form, we will beep the PC speaker instead;

Example:

```
type
  TForm1 = class(TForm)
  private
    { Private declarations }
    procedure WMSysCommand(var Msg: TWMSysCommand);
      message WM_SYSCOMMAND;
  public
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.WMSysCommand;
begin
  if (Msg.CmdType = SC_MINIMIZE) or
    (Msg.CmdType = SC_MAXIMIZE) then
```

```
    MessageBeep(0) else
inherited;
end;
```

## Article #17142: Creating a custom word break procedure

Question and Answer Database

FAQ2142D.txt Creating a custom word break procedure

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I create a custom word break procedure for the TEdit, TMemo, or the TRichEdit components?

Answer:

The following example implements a custom work break procedure and attaches it to a TMemo component. Note that the implementation of the word break proc simply returns that it is ok to break the word at the current character. Additional custom handling can be further implemented. For additional information, please see the documentation for the EM\_SETWORDBREAKPROC message in the Win32 Help File.

```
var
  OriginalWordBreakProc : pointer;
  NewWordBreakProc : pointer;

function MyWordBreakProc(LPTSTR  : pchar;
                        ichCurrent : integer;
                        cch : integer;
                        code : integer) : integer
  {$IFDEF WIN32} stdcall; {$ELSE} ; export; {$ENDIF}
begin
  result := 0;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  OriginalWordBreakProc := Pointer(
    SendMessage(Mem1.Handle,
                EM_GETWORDBREAKPROC,
                0,
                0));
```

```
{$IFDEF WIN32}
  NewWordBreakProc := @MyWordBreakProc;
{$ELSE}
  NewWordBreakProc := MakeProcInstance(@MyWordBreakProc,
                                       hInstance);
{$ENDIF}
SendMessage(Mem1.Handle,
            EM_SETWORDBREAKPROC,
            0,
            longint(NewWordBreakProc));
```

end;

```
procedure TForm1.FormDestroy(Sender: TObject);
begin
  SendMessage(Mem1.Handle,
              EM_SETWORDBREAKPROC,
              0,
              longint(@OriginalWordBreakProc));
```

```
{$IFNDEF WIN32}
  FreeProcInstance(NewWordBreakProc);
{$ENDIF}
```

end;

## Article #17146: Creating a Lookup field at runtime

Question and Answer Database

FAQ2146D.txt Creating a Lookup field at runtime

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How can I create a lookup field at runtime?

Answer:

Creating a lookup field at runtime differs in only a few ways from creating any standard TField object. Three properties of a field that must be set in order to function as a Lookup field are LookUpDataset, LookUpKeyFields and LookUpResultField. The sample code below demonstrates how to create a Lookup field at runtime using the two DBDEMOS tables 'customer.DB' and 'orders.DB'.

Example:

uses

```
Forms, Classes, Controls, StdCtrls, Db, DBTables, DBCtrls;
```

type

```
TForm1 = class(TForm)
```

```
Table1: TTable; // DBDemos customer table
```

```
Table2: TTable; // DBDemos orders table
```

```
Button1: TButton;
```

```
DBLookupComboBox1: TDBLookupComboBox;
```

```
DataSource1: TDataSource;
```

```
Table2CustNo: TFloatField; // CustNo key field object used for
```

Lookup

```
procedure Button1Click(Sender: TObject);
```

```
private
```

```
{ Private declarations }
```

```
public
```

```
{ Public declarations }
```

```
end;
```

```
var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.Button1Click(Sender: TObject);
begin
  with TStringField.Create(Table2) do begin
    FieldName := 'MyLookup';
    FieldKind:= fkLookup;
    DataSet := Table2;
    Name := DataSet.Name + FieldName;
    KeyFields:= 'CustNo';
    LookUpDataset:= Table1;
    LookUpKeyFields:= 'CustNo';
    LookUpResultField:= 'Company';
    DbLookupComboBox1.DataField:= FieldName;
    DataSource1.DataSet:= DataSet;
    Table2.FieldDefs.Add(Name, ftString, 20, false);
  end;
  DbLookupComboBox1.DataSource:= DataSource1;
  Table1.Active:= True;
  Table2.Active:= True;
end;

end.
```

Product :Delphi 3.x

Question:

I'm getting "Object not found" error when opening a STANDARD alias with a TDatabase. What is wrong?

Answer:

Delphi 3.0 is attempting to get information on an alias parameter that does not exist on the STANDARD database alias you are trying to open. With the BDE Administrator (BDEADMIN.EXE), delete and re-create the alias.

## Article #17154: Sharing data dictionaries

Question and Answer Database

FAQ2154D.txt      Sharing data dictionaries

Category        :Database/VCL

Platform        :All

Product         :All 32 bit

Question:

How do I share data dictionaries?

Answer:

The data dictionary is merely a table created in any database. To create, right click on the DB Explorer Dictionary tab, provide a unique dictionary name, select a database from the list to create the dictionary table in, provide a unique table name (you can leave BDESDD), and description is optional. Once the dictionary is created, you can see on the dictionary table exists on the Databases tab, under the database you specified. To share, the database and table specified in dictionary creation must exist in a shareable location, such as on an SQL server. At the second location, select from the Dictionary menu, Register. Provide any name for Dictionary name (using a company standard of some sort and everyone use the same name here is recommended), select the database table that contains the previously created dictionary table, table name, and description is once again optional. In cases where database tables are qualified with an owner name, the datadictionary table will also have this same feature/limitation. The same issue will be true for each table field being described -- i.e. if the field is myownerA.field1, table myownerb.field1 will not see the attributes described.

## Article #17158: 'Your application is not enabled for use with this driver' error

Question and Answer Database

FAQ2158D.txt 'Your application is not enabled for use with this driver' error

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

What is the cause and how do I fix this error?

Answer:

This error will be raised if an application created with Delphi Standard or Delphi Professional attempts to use any SQL Link driver (InterBase, Oracle, Informix, Sybase, MS-SQL). This error can also be raised if an application created with Delphi Standard attempts to use an ODBC driver. In order to create programs that use Borland's SQL Links, you must have Delphi Client / Server and to use ODBC, you must have at least Delphi Professional.

## Article #17162: open or create a project using the TReport component

Question and Answer Database

FAQ2162D.txt open or create a project using the TReport component

Category :Database/VCL

Platform :All

Product :Delphi 3.x

Question:

How can I open or create a project using the TReport ReportSmith component. Also, can I open an existing project from Delphi 2 in Delphi 3?

Answer:

Yes. The TReport component is included in Delphi 3, but by default it is not included on the palette. If you wish to use the TReport component to create a new project you need to make it available for use on the palette. To do this choose Component | Configure Palette and move the TReport component from [Hidden] to a visible Palette (ie QReport).

NOTE: Delphi 3 does not ship with ReportSmith. You will need to install ReportSmith from your Delphi 2 CD.

NOTE: report.dcu and rsconsts.dcu are not in the search path by default. These files are located in "Delphi 3\Lib\Delphi2" directory and can either be moved to the "Delphi 3\Lib" directory or the path can be added to Delphi's search directory.

## Article #17166: Specify a DefaultExpression for a TField object

Question and Answer Database

FAQ2166D.txt Specify a DefaultExpression for a TField object

Category :Database/VCL

Platform :All

Product :Delphi 3.x

Question:

How do I specify a DefaultExpression for a TField object?

Answer:

If you set up a field attribute set and associate that set with a field in your table that will work. If you set the value in the object inspector it will let you enter in a string but it will not reflect the value at runtime. If you try to set the TField.DefaultExpression property at runtime like this:

```
MyField.DefaultExpression := 'MyValue';
```

It will compile but you will not get a default value at runtime when you create a new record in the table by, say, clicking on the + on the DBNavigator. To get the default value to take at runtime the code assignment needs to be:

```
MyField.DefaultExpression := ''MyValue'';
```

In the Object Inspector. You just need to put 'MyValue'. Use single quotes in the Object Inspector.

## Article #17170: Getting values in a TDBGrid before they are posted

Question and Answer Database

FAQ2170D.txt Getting values in a TDBGrid before they are posted

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How do I know what is being typed into the grid?

Answer:

You can see what is being typed into a TDBGrid by looking at the TInPlaceEdit control of the TDBGrid. Care should be taken to make sure that the TInPlaceEdit control is created before trying to use it. The following function will show the data in the column of the grid that is being edited:

```
procedure TForm1.DBGrid1KeyUp(Sender: TObject;
    var Key: Word; Shift: TShiftState);
var
    B: byte;
begin
    for B := 0 to DBGrid1.ControlCount - 1 do
        if DBGrid1.Controls[B] is TInPlaceEdit then
            begin
                with DBGrid1.Controls[B] as TInPlaceEdit do
                    begin
                        Labell.Caption := 'Text = ' + Text;
                    end;
            end;
    end;
```

Please reference TInPlaceEdit in the Delphi 3 help file for more information on it's functionality.

## Article #17178: 'Cannot load IDAPI service library' error during connect

Question and Answer Database

FAQ2178D.txt 'Cannot load IDAPI service library' error during connect

Category :Multitier/Remote Datasets

Platform :All

Product :Delphi 3.x

Question:

I try to connect to my Remote Server and I get a "Cannot load IDAPI service library" error message on the client machine. What is wrong?

Answer:

This error is being propagated from the server where the actual problem resides. This error is a good indication that IDPROV32.DLL has not been properly installed on the server. Copy this file to the BDE directory on the server and register it through the use of a proper tool like TRegSvr.exe or RegSrv32.exe.

## Article #17206: Blank form at design or run time

Question and Answer Database

FAQ2206D.txt Blank form at design or run time

Category :Quick Reports

Platform :All

Product :Delphi 3.x

### Question:

Using QuickReports 2, I have a report with only a title band and some QRLabels, at design or run time I can not print or preview the form (It is blank). What is wrong?

### Answer:

Most likly, QuickReport doesn't think you any Data to print or preview. At runtime you can tell QR to print using this techinque: On the Report's OnNeedData event, add this code:

```
If Form1.tag = 0 then
begin
    MoreData := True;
    Form1.Tag := 1;
end else
    MoreData := False;
```

This tells the QR component that it got data, go ahead and print. Then the component on the next time into the event to stop - no longer needs data avoiding an infinite loop. Of course Form1's tag property is simple being used as a flag, thus can be replaced by any other flaging scheme.

## Article #17218: Automating Word 7

Question and Answer Database

FAQ2218D.txt Automating Word 7  
Category :ActiveX/OLE/COM/ActiveForm  
Platform :All  
Product :All 32 bit

Question:  
How do I automate Word 7?

Answer:  
You can get to any of the interfaces exposed by the word automation server. These can be found by loading MSWORD8.OLB into Delphi which will display the type library information. You can also use the Application's WordBasic property to get at the VB used in Word. The following sample demonstrates both avenues:

```
implementation

uses ComObj;

{$R *.DFM}

var
  V: OleVariant;

procedure TForm1.Button1Click(Sender: TObject);
begin
  V := CreateOleObject('Word.Application');
  V.ShowMe;
  V.WordBasic.FileNew;
  V.WordBasic.Insert('test');
  V.Run('mymac');
  V.WordBasic.FileSave;
end;

end.
```

## Article #17221: How to use Access97 drivers with BDE 4.51

Question and Answer Database

FAQ2221C.txt     How to use Access97 drivers with BDE 4.51

Category     :Database Issues

Platform     :All

Product      :C++Builder 3.x

Question:

How do I use the native Access drivers with the BDE 4.51 that is shipping with BCB3?

Answer:

Redeploying application with Access 97

1. In BDE Administrator open idapi.cnf from the InstallShield redist directory. Under the Configuration tab, set DLL32 to IDDA3532.DLL for the MSACCESS driver. Apply changes.

2. Copy idapi.cnf to idapi32.cnf in the InstallShield redist directory.

3. In InstallShield Groups & Files dialog, add IDDA3532.DLL to the BDE/IDAPI File Group.

## Article #17222: New methods not showing in code insight window

Question and Answer Database

FAQ2222D.txt    New methods not showing in code insight window

Category        :ActiveX/OLE/COM/ActiveForm

Platform        :All

Product         :Delphi 3.x

### Question:

I'm writing an in-process server and I'm adding some methods to it. However, they do not show up in the code-insight window, and my code doesn't compile. What is wrong?

### Answer:

You need to either reimport the type library into the client, or just use the type library wrapper (myserver\_tlb.pas) that was created for you when you rebuilt the in-process server. If you imported the type library from the server and then modified the server, the wrapper for the server's type library will be out-dated.

## Article #17226: 'EOleSys..operation unavailable' error

Question and Answer Database

FAQ2226D.txt 'EOleSys..operation unavailable' error

Category :ActiveX/OLE/COM/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

EOleSys..operation unavailable" error using GetActiveOleObject.  
What is the cause and how do I resolve this error?

Answer:

This occurs when using a Delphi automation server, or when the automation server (such as word.basic) is not running.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  V: OleVariant;
begin
  V := GetActiveOleObject('Word.Basic');
  V.FileNew;
  V.Insert('test');
end;
```

GetActiveOleObject is defined in ComObj.pas. It converts the classname to a guid, and passes the guid to the Windows api call GetActiveObject.

```
function GetActiveOleObject(const ClassName: string): IDispatch;
var
  ClassID: TCLSID;
  Unknown: IUnknown;
begin
  ClassID := ProgIDToClassID(ClassName);
  OleCheck(GetActiveObject(ClassID, nil, Unknown));
  OleCheck(Unknown.QueryInterface(IDispatch, Result));
end;
```

The GetActiveOleObject uses an interface called IRunningObjectTable. We're not automatically registering to this table, so to have this functionality you must get

this interface and use it's methods to register.

## Article #17242: ActiveForm not displaying in Internet Explorer

Question and Answer Database

FAQ2242D.txt    ActiveForm not displaying in Internet Explorer  
Category        :ActiveX/OLE/COM/ActiveForm  
Platform        :All  
Product         :Delphi 3.x

Question:

Why do ActiveX or ActiveForm sometimes not display in Internet Explorer? All that shows up is the .htm page with a blank square with a little red X in it.

Answer:

Its likely that you selected the licensing option when you created the ActiveForm and you are not deploying the .LIC file with your .OCX file.

Usually licensing is not used with ActiveForm/ActiveXs that are being used to enhance a web site because you are giving the control away for free.

To disable the design time licensing locate the initialization section in your ActiveForm's XXXImpl file and replace the second to last parameter of the TActiveXControlFactory.Create call to an empty string like so:

```
initialization
  TActiveXControlFactory.Create(
    ComServer,
    TAnimateX,
    TAnimate,
    Class_AnimateX,
    1,
    '',      0);
end.
```

So, when should you use Design-Time Licensing?

Your control should use design-time only when you want to sell the ActiveX or ActiveForm to other developers who will then sell

their finished applications to end-users. That is, the control works in a design-time environment (ie, Delphi, C++Builder, VB, etc.) when the LIC file is present, but it only works in a run-time environment (ie, the end-user application) when the .LIC file is not present.

If you're deploying your ActiveX over the web, then you are by definition deploying to end-users (as opposed to developers) and you should never require a design-time license.

Also, if the ActiveForm is unsigned, the Internet Explorer must have its "Active content security" level set to medium. To do this, go to the control panel and select Internet. Go to the security tab and then press the Safety Level button. Make sure the level is set to medium.

NOTE: This is only advised when designing your own controls. Potentially rogue ActiveX controls could damage data on the machine!

## Article #17245: Keeping the Local IBServer from starting up automatically

Question and Answer Database

FAQ2245C.txt Keeping the Local IBServer from starting up automatically

Category :Database Issues

Platform :All

Product :C++Builder 1.x

Question:

How can I keep the Local InterBase Server from automatically starting when I start Windows?

Answer:

There are three methods that you can use:

- 1) Right click on the Local InterBase Server icon and select "Startup Configuration" then select "Manual Startup".
- 2) Try taking the Local InterBase Server out of you Startup Menu, or comment it from the run/load lines of your Win.ini file.
- 3) Run REGEDIT.EXE, find the key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run

and remove manually the IBSERVER entry.

## Article #17250: 'TActiveFormX declaration missing or incorrect' error

Question and Answer Database

FAQ2250D.txt 'TActiveFormX declaration missing or incorrect' error

Category :ActiveX/OLE/COM/ActiveForm

Platform :All

Product :Delphi 3.x

Question:

What does this error mean and how do I solve the problem?

Answer:

This is usually caused by changing the name of an ActiveForm in the incorrect order (see README.TXT). If the name of the CoClass is changed first and then does a refresh, an AV will occur.

Proceeding to use the Object Inspector to change the name of the form will cause "TActiveFormX declaration missing or incorrect".

To fix this he will need to open the .DFM file and change the line:

```
object ActiveFormX: TActiveFormX
```

```
to,
```

```
object MyForm: TMyForm
```

## Article #17254: Missing ProviderName in TClientDataSet

Question and Answer Database

FAQ2254D.txt - Missing ProviderName in TClientDataSet

Category :DCOM/MultiTier/ActiveForm  
Platform :All-32Bit  
Product :

Question:

I don't see entries in the TClientDataSet ProviderName property.  
What's wrong?

Answer:

On your server application, in the remote data module, right click your dataset (TTable, Tquery, etc) and select "Export [MyDataset] from data module". Rebuild the server application. You should now see the provider supplied in the list of the TClientDataSet.

"Exporting from data module" adds a "Get\_MyDataset" function to the protected section of the remote datamodule's CoClass that returns an IProvider interface.

## Article #17258: Propagating constraints from middle-tier to client

Question and Answer Database

FAQ2258D.txt - Propagating constraints from middle-tier to client

Category :Multi-tier  
Platform :All-32Bit  
Product :

Question:

How do I propagate constraints from Middle-tier to Client?

Answer:

This example uses the demos found in  
\Delphi 3\Demos\DB\CLIENTDS\Empedit.dpr and \server.dpr.  
Empedit.dpr represents the client tier, server.dpr runs on  
the middle tier, and the database, DBDEMOS, is located also on  
the middle tier, but in a real world scenario would be an SQL  
database running on yet a third machine. This example uses the  
Employee.db table. In order to use the following, you will need  
to set up DCOM and have the two examples running before adding  
the complication of constraints to the mix.

The general steps are:

Define constraints in the data dictionary  
Associate the data dictionary attributes to a TField  
Access the TField from a ClientDataSet.

First, define an attribute set in the data dictionary that  
includes a constraint. For instance, an attribute set called  
EmpNoA could have a CustomConstraint of "EmpNo > 100" and a  
ConstraintErrorMessage of "EmpNo is less than 100". Define  
static TFields in Server.dpr. Bring up the EmpServer datamodule  
and double click EmpQuery to bring up the fields editor. In the  
fields editor, right-click the EmpNo TField, select Associate  
Attributes, and select EmpNoA from the Associate Attributes  
dialog. Now when selecting the EmpNo TField in the fields  
editor you should see CustomConstraint and  
ConstraintErrorMessage matching the data dictionary entry. Open  
EmpEdit.dpr and add a TDBEdit to EmployeeForm. Set the

DataField property to EmpNo and the DataSource property to EmpData (the TClientDataSet). Compile and run Server.dpr on the middle tier machine, then on the client machine run the EmpEdit example application. Attempt to post a record where EmpNo is greater than 100; your custom error message will appear.

## Article #17262: 'DAX Error: Unexpected failure.' error

Question and Answer Database

FAQ2262D.txt 'DAX Error: Unexpected failure.' error  
Category :ActiveX/OLE/COM/ActiveForm  
Platform :All  
Product :Delphi 3.x

Question:

How do I resolve this error?

Answer:

This usually happens when the application server has raised an exception during initialization. Add exception handling to your server.

## Article #17266: Determining Drive Type

Question and Answer Database

FAQ2266D.txt Determining Drive Type

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can my application tell if a given drive is a CD, Network, Ramdisk, or Removable drive?

Answer:

Use the Windows API function `GetDriveType()`.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  case GetDriveType('C:\') of
    0          : ShowMessage('The drive type cannot be
determined');
    1          : ShowMessage('The root directory does not exist');
    DRIVE_REMOVABLE: ShowMessage('The disk can be removed');
    DRIVE_FIXED   : ShowMessage('The disk cannot be removed');
    DRIVE_REMOTE  : ShowMessage('The drive is remote (network
drive');
    DRIVE_CDROM   : ShowMessage('The drive is a CD-ROM drive');
    DRIVE_RAMDISK : ShowMessage('The drive is a RAM disk');
  end;
end;
```

## Article #17270: Client launching

Question and Answer Database

FAQ2270D.txt - Client launching

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All-32Bit  
Product :

### Question:

What do I need to do to make my client launch and access my server through DCOM?

### Answer:

One setup that usually work is if you install Service Pack 3 on all NT 4.0 machines. If you are going to use any Win95 clients then you'll have to install DCOM for Win95 on those machines. You'll also need Microsoft Internet Explorer 3.02 on the client machines. On the machine were the application server is going to run (an NT 4.0 machine) you'll do each of the following:

Enable the Guest account. This is disabled by default.  
Make sure the application server is on a local drive on the machine.  
Run the application server once to register it.  
In DCOM Config (dcomcnfg.exe) for the specific server object:

On the Identity tab, select "The interactive user".  
On the Security tab, select Custom Access Permissions, and make sure Everyone is added and allowed access.  
On the Security tab, select Custom Launch Permissions, and make sure Everyone is added and allowed to launch.

## Article #17282: Old ActiveForm information displayed

Question and Answer Database

FAQ2282D.txt - Old ActiveForm information displayed

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All-32Bit  
Product :

### Question:

I updated my ActiveForm and I hit my web page in Internet Explorer, but I get the old ActiveForm. What am I doing wrong?

### Answer:

Even if you use version info, you'll see this happening in some cases. Usually it goes away if you unregister the OCX (in C:\WINDOWS\OCCACHE\ or C:\WINNT\OCCACHE) using REGSVR32.EXE.

The recommended way of doing this is:

Exit Internet Explorer.

Run "regsvr32.exe /u c:\windows\occache\MyActiveX.ocx"

Restart Internet Explorer and hit the web page again.

If you deploy extra files that you ActiveX is using you might be helped by knowing that all the stuff is being pulled down to your OCCACHE directory and if Internet Explorer determines that there is a conflict - it'll put some files in OCCACHE\CONFLICT.x (x is a number) directories.

## Article #17286: What directory is the ActiveForm in

Question and Answer Database

FAQ2286D.txt - What directory is the ActiveForm in

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All-32Bit  
Product :

Question:

I need to know the exact directory that my ActiveForm is located in; How do I get that information?

Answer:

GetModuleFilename(HInstance, ModuleName, SizeOf(ModuleName)).  
ModuleName can be declared as an array [0..255] of Char for instance. For your information:

Application.ExeName gives you the path to IEXPLORE.EXE.  
GetCurrentDirectory usually gives you C:\Windows\Desktop.

## Article #17294: 'Invalid filename' error

Question and Answer Database

FAQ: FAQ2294D - 'Invalid filename' error

Category: Internet/WEB

Platform: All-32Bit

Product: All32Bit,

Question:

When a client hits my ISAPI DLL it says "Invalid filename". My Paradox/dBASE tables are on a Novell server. What's wrong?

Answer:

You're missing the drive mapping for your IUSR\_XXX account. Your tables are on the Novell server, so you need a drive mapping to get there.

Background information:

Your webserver is running IIS as a service. Nobody is logged in interactively.

A client hits the web page with the ISAPI DLL. IIS is logging you in on the server as IUSR\_XXX. In order for the ISAPI DLL to see your tables on the Novell server, you will need the drive mapping for that user.

## Article #17298: 'Invalid configuration parameter for alias

Question and Answer Database

FAQ: FAQ2298D - 'Invalid configuration parameter for alias

Category: Internet/WEB

Platform: All-32Bit

Product: All32Bit,

Question:

"Invalid configuration parameter for alias {alias\_name}"  
error with ODBC: I get this error when trying to access a  
database thru an ODBC DSN connection on the ISAPI/NSAPI server.  
What am I doing wrong?

Answer:

In order for ODBC to be used as a service and to be accessed by  
all users (IIS guest account), you need to create a non-standard  
SYSTEM DSN, not the default USER DSN.

## Article #17302: Conditional defines for all Delphi versions

Question and Answer Database

FAQ2302D.txt - Conditional defines for all Delphi versions

Category :Compiler  
Platform :All-32Bit  
Product :All32Bit,

Question:

What are the conditional defines for Delphi

Answer:

Delphi defines the following standard conditional symbols.

VER80 - Delphi 1.x  
VER90 - Delphi 2.x  
VER93 - CBuilder 1.0  
VER100 - Delphi 3.x

For example the following would compile in the correct uses statement in Delphi 2 and Delphi 3 respectively.

```
{$IFDEF VER90}  
uses system, windows, oleaut;  
{$ENDIF}
```

```
{$IFDEF VER100}  
uses system, windows, comobj;  
{$ENDIF}
```

The version numbers for Delphi 1, 2 and 3 correspond to version 8.0, 9.0 and 10.0 of the Object Pascal compiler. For additional information on conditional compiles and compiler directives see appendix B in the Delphi 3 users guide.

Question and Answer Database

FAQ2306D.txt - Launching a web browser

Category :Internet/WEB  
Platform :All-32Bit  
Product :

Question:

How can I launch the computer's current web browser with a specific web site URL?

Answer:

Call the Win32 API function called HlinkNavigateString which is declared in the UrlMon unit.

Example call:

```
HlinkNavigateString(nil, 'http://www.borland.com');
```

If you're calling this from an ActiveForm then call it like this:

```
HlinkNavigateString(ComObject, 'http://www.borland.com');
```

## Article #17310: TClientSocket and TServerSocket

Question and Answer Database

FAQ2310D.txt - TClientSocket and TServerSocket

Category :Internet/WEB  
Platform :All-32Bit  
Product :

Question:

Why don't the Sockets receive more than 8k worth of data?

Answer:

Because the IP layer breaks a stream of data into 8k chunks, the developer must explicitly insert a length integer at the beginning of the stream telling the receiving end how much data to expect, more importantly, how many 8k packets to receive.

Because the Socket components are just wrappers for the WinSock and not Protocols with header information (as mentioned above), the developer must concern themselves with said "padding" of data. This requires:

NOTE: The implementation can vary by the developer so this will remain generic.

padding the data at the source with a length integer,  
extracting the length integer at the destination,  
counting the number of bytes received at the destination  
and matching those with the length integer.

If TotalBytesReceived <> LengthInteger then know the next packet is a continuation, otherwise know the next packet is a different stream altogether.

NOTE: This is handled in HTTP & FTP protocols via header information (ie, 'Content\Length:').

## Article #17314: Installing old Delphi 2 components

Question and Answer Database

FAQ2314D.txt - Installing old Delphi 2 components

Category :Miscellaneous

Platform :All-32Bit

Product :

Question:

When installing a component into a package in Delphi 3, why is Delphi 3 complaining about not finding an associated PAS file? All I should need is the DCU file.

Answer:

That's true only if the component was compiled using Delphi 3. If it's a Delphi 2 DCU file, it will tell you "Fatal Error" and complain about not finding an associated PAS file. In order to install such a component, you will need the source code and recompile the PAS file.

There are two solutions to the problem:

Have the vendor of the component re-compile the component with Delphi 3.

If you have the source to the component, re-compile the component with Delphi 3 and use the resultant DCU.

Question and Answer Database

FAQ2322D.txt - Using Visual Basic arrays in Delphi

Category :Miscellaneous  
Platform :All-32Bit  
Product :

Question:

How do I pass arrays from VB to Delphi?

Answer:

Arrays can be passed as variants:

VB module code:

```
Attribute VB_Name = "Module1"  
Declare Function TestMin Lib "c:\windows\system\NoelSArr"  
    (Nums As Variant) As Integer
```

VB form code:

```
Dim A As Variant  
Private Sub Command1_Click()  
    A = Array(4, 3)  
    MsgBox (TestMin(A))  
End Sub
```

Delphi DLL code:

```
library NoelSArray;  
.  
.  
function TestMin(const Nums: Variant): integer; export; stdcall;  
var  
    p1: Variant;  
begin  
    p1 := VarArrayCreate([0, 1], VT_I4);  
    p1:= Nums;  
    if (p1[0] < p1[1]) then  
        result:= p1[0]  
    else  
        Result:= p1[1];
```

end;

## Article #17354: Component palette shown incorrectly - Matrox Millenium card

Question and Answer Database

FAQ2354D.txt - Component palette shown incorrectly - Matrox Millenium card

Category :Install Issues  
Platform :All-32Bit  
Product :

Question:

How do I solve the problem?

Answer:

This problem has occurred on a few Matrox Millennium boards and Diamond Stealth 3D 2000 boards. The workaround is to try a different version of the vendor's video driver or try to use Windows' version (even VGA/SVGA) of the video driver.

One solution for the Matrox Millennium board may be the following:

download the latest version of video-driver  
(v3.70 as of October 3rd)  
do normal installation  
deactivate the "Use device bitmap caching" in the  
"MGA PowerDesk Settings"

## Article #17358: Using FindFirst to search for files.

Question and Answer Database

FAQ2358D.txt Using FindFirst to search for files.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I handle the memory loss when I use the example for FindFirst to search for files?

Answer:

You need to qualify calls to FindFirst, FindNext, and FindClose to include the SysUtils unit.

Example:

```
begin
  Result := SysUtils.FindFirst(Path, Attr, SearchRec);
  while Result = 0 do
  begin
    ProcessSearchRec(SearchRec);
    Result := SysUtils.FindNext(SearchRec);
  end;
  SysUtils.FindClose(SearchRec);
end;
```

## Article #17362: Getting an handle to a window in another application.

Question and Answer Database

FAQ2362D.txt Getting an handle to a window in another application.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get the handle of another application's window and make that window the active window?

Answer:

Using the Windows API function `FindWindow()` is the simplest and most straightforward method of locating a given window provided you know the exact window caption or class name. If you know only part of the window's caption (ie: 'Netscape - ' + 'Some Unknown URL', you need to use the Windows `EnumWindows()` function to enumerate all the active windows, then call the Windows API functions `GetWindowText()` and `GetClassName` to see if you find a match for the window that you are searching for.

The following example returns the window handle of the first window enumerated that contains a partial match of the window title and an exact match of the window's `ClassName` (if given) and brings that window to the foreground.

```
type
  PFindWindowStruct = ^TFindWindowStruct;
  TFindWindowStruct = record
    Caption : string;
    ClassName : string;
    WindowHandle : THandle;
  end;

function EnumWindowsProc(hWindow : hWnd;
                        lParam : LongInt) : Bool
{$IFDEF Win32} stdcall; {$ELSE} ; export; {$ENDIF}
var
  lpBuffer : PChar;
```

```

WindowCaptionFound : bool;
ClassNameFound : bool;

begin
  GetMem(lpBuffer, 255);
  Result := True;
  WindowCaptionFound := False;
  ClassNameFound := False;

  try
    if GetWindowText(hWnd, lpBuffer, 255) > 0 then
      if Pos(PFindWindowStruct(lParam).Caption, StrPas(lpBuffer)) > 0
        then WindowCaptionFound := true;

    if PFindWindowStruct(lParam).ClassName = '' then
      ClassNameFound := True else
      if GetClassName(hWnd, lpBuffer, 255) > 0 then
        if Pos(PFindWindowStruct(lParam).ClassName, StrPas
(lpBuffer))
          > 0 then ClassNameFound := True;

    if (WindowCaptionFound and ClassNameFound) then begin
      PFindWindowStruct(lParam).WindowHandle := hWnd;
      Result := False;
    end;

  finally
    FreeMem(lpBuffer, sizeof(lpBuffer^));
  end;
end;

function FindAWindow(Caption : string;
                    ClassName : string) : THandle;
var
  WindowInfo : TFindWindowStruct;

begin
  with WindowInfo do begin
    Caption := Caption;
    ClassName := ClassName;
    WindowHandle := 0;
    EnumWindows(@EnumWindowsProc, LongInt(@WindowInfo));
    FindAWindow := WindowHandle;
  end;
end;

```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  TheWindowHandle : THandle;
begin
  TheWindowHandle := FindAWindow('Netscape - ', '');
  if TheWindowHandle = 0 then
    ShowMessage('Window Not Found!') else
    BringWindowToTop(TheWindowHandle);
end;
```

## Article #17366: Using an AVI file with TAnimate

Question and Answer Database

FAQ2366D.txt - Using an AVI file with TAnimate

Category :Miscellaneous  
Platform :All-32Bit  
Product :

Question:

How can I resource an AVI so the TAnimate control doesn't have to rely upon an external file?

Answer:

There is an AVI Type, which is not used often, called 'AVI' and if you create a .RES file, Resource file, with this type it will allow you to use the resource as an AVI.

The steps are:

Create a new RES file. (Resource Workshop is good but it must be a 32-bit resource file)  
Add the AVI to the RES Project as a New Type specified as 'AVI'. (ie File | "Add to project..." in Resource Workshop and followed by clicking on the "New Type" button)

NOTE:Make sure to edit the Name of the Resource (from 'AVI\_1') to a more meaningful name before saving the project. (maybe 'About') - case sensitive.

Save the RES Project to a name (ie RORY.RES)  
Back in Delphi 3, add the RES file in with the \$R Compiler directive (ie {\$R 'C:\AVI\RORY.RES' } )  
Programmatically, set the TAnimate's RESName property to the Resource name. (Not the Type; AVI)

Example:

```
Animat1.RESName := 'About';  
Animat1.Active := True;
```

## Article #17370: Migrating a project from Delphi 1 or 2 to Delphi 3

Question and Answer Database

FAQ2370D.txt Migrating a project from Delphi 1 or 2 to Delphi 3

Category :Miscellaneous

Platform :All

Product :Delphi 3.x

Question:

What files should I move when migrating a project from Delphi 1 or 2 to Delphi 3?

Answer:

The files required to move a project from Delphi 1 or Delphi 2 to Delphi 3 are just the DFM, PAS, and DPR. It is also important to move any resource files (.res), that have custom resources like cursors, icons, strings, etc. All the other files are going to be recreated by the compiler when a build all is done inside of Delphi 3. It is especially important not to bring over the DCU files as the format changes from version to version. You may get unknown identifier errors or other strange behaviors if you try to bring over DCU files.

## Article #17378: Checking drive ready status.

Question and Answer Database

FAQ2378D.txt    Checking drive ready status.

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I check to see if a drive is ready without triggering a Windows error dialog box?

Answer:

You can use the Windows API function SetErrorMode() to suppress the Window's critical Error dialog.

Example:

```
function IsDriveReady(DriveLetter : char) : bool;
var
  OldErrorMode : Word;
  OldDirectory : string;
begin
  OldErrorMode := SetErrorMode(SEM_NOOPENFILEERRORBOX);
  GetDir(0, OldDirectory);
  {$I-}
  ChDir(DriveLetter + ':\');
  {$I+}
  if IoResult <> 0 then
    Result := False
  else
    Result := True;

  ChDir(OldDirectory);
  SetErrorMode(OldErrorMode);

## Article #17382: External function failure when passing boolean parms.

Question and Answer Database

FAQ2382D.txt External function failure when passing boolean parms.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

Why do some external functions fail when passed a boolean parameter of True?

Answer:

In Delphi 3, the value "True" for data types ByteBool, WordBool, and LongBool is now represented as -1 for compatibility with Microsoft Visual Basic. Note that many compilers represent "True" as either non-zero or a positive 1. When passing values to non Visual Basic applications, you should consider using the following technique to avoid incompatibilities:

```
LongBool(Abs(True));
```

When accepting boolean values from any external source, you should always test against the value "False". The following technique should always work, since the value for false is always zero:

```
if BoolValPassed <> False then DoSomething.
```

## Article #17386: No default printer selected error message.

Question and Answer Database

FAQ2386D.txt - No default printer selected error message.

Category :Printing  
Platform :All-32Bit  
Product :

Question:

What is the cause of the error message: 'No default printer selected'?

Answer:

This message may be caused by running an older version of the IBM AS400 emulation software. An update from IBM generally fixes the problem.

## Article #17390: Creating a non-VCL console project.

Question and Answer Database

FAQ2390D.txt     Creating a non-VCL console project.

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I create a small footprint, non-VCL, non-console project?

Answer:

Create a new application, then, from the View... Menu option, start the "Project Manager", and remove all units from the project. Then from the View... menu option, select "Project Source" and edit it so that it looks like the below example. Note: You can add and use additional units, so long as you do not use any VCL components.

Example:

```
program Project1;

{$R *.RES}

uses SysUtils;

var
  f : TextFile;

begin
  AssignFile(f, 'TestFile.Txt');
  ReWrite(f);
  Writeln(f, 'Test');
  Close(f);
end.
```

## Article #17394: Printing to file.

Question and Answer Database

FAQ2394D.txt - Printing to file.

Category :Printing  
Platform :All  
Product :

Question:

How do I print to a file without changing the printer's setup, or getting a prompt for a file to print to?

Answer:

To do this you simply need to change the initialization of the DocInfo structure in TPrinter from:

```
lpszOutput := nil;
```

to:

```
lpszOutput := 'C:\SomePath\SomeFileName';
```

You can make a permanent change to TPrinter, but for the ultimate in flexibility, you can create an interface unit to make the filename easy to change from your application.

{ Note: Modifications to the VCL are made at the developers risk and

any effects caused by modifications are not the responsibility of Borland International. }

The safest way to make changes to the VCL is to create a new directory called "patched", and copy the Printers.Pas unit to the new directory, then make your changes (with comments) to the copied file. The you must add the path to your patched directory to the beginning of your library path, then restart Delphi/C++ Builder, and rebuild your project after making the following changes. Note that the library path setting can be found off the main menu of:

Delphi 1 : Options... Environment... Library

Delphi 2 : Tools... Options... Library  
Delphi 3 : Tools... Environment Options... Library  
C++ Builder : Options... Environment... Library

Instructions for the patch:

1) Create a new unit in the patched directory called "PrnPage.pas" and include the following code in the unit:

```
unit PrnPage;  
  
interface  
  
var FileNameToPrintTo : Pointer;  
  
implementation  
  
begin  
    FileNameToPrintTo := nil;  
end.
```

2) Now open the Printers.Pas file in your patched directory. Search for the line that reads "uses Consts;" (or in Delphi 16 it will read "uses WinProcs, Consts;");

and add the PrnPage unit to the uses clause:

```
uses Consts, PrnPage;
```

3) Now search for line that reads "lpszOutput := nil;"

and change it to read: lpszOutput := FileNameToPrintTo;

4) Save your changes, and restart Delphi / C++ Builder.

5) To test your changes, try the following code. Note: Be sure to use the "Build All" option when compiling your project for the first time.

```
uses Printers, PrnPage;
```

```
{$IFDEF WIN32}
```

```
    const MAX_PATH = 144;
```

```
{$ENDIF}
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  lpPrnFile : pChar;
begin
  GetMem(lpPrnFile, MAX_PATH +1);

  try
    StrPCopy(lpPrnFile, 'C:\Download\TestIt.Prn');
    FileNameToPrintTo := @lpPrnFile^;

    with Printer do begin
      BeginDoc;
      Canvas.TextOut(10, 10, 'Test');
      EndDoc;
    end;

    FileNameToPrintTo := nil;

  finally
    FreeMem(lpPrnFile, MAX_PATH +1);
  end;
end;
```

## Article #17398: Getting the longfilename from a file.

Question and Answer Database

FAQ2398D.txt Getting the longfilename from a file.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get the long file name of a file or directory from the short file name?

Answer:

You can use the Win32\_Find\_Data member of TSearchRec to extract this information.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  SearchRec : TSearchRec;
  Success : integer;
begin
  Success := SysUtils.FindFirst('C:\Download\dial-u~1.htm',
                                faAnyFile,
                                SearchRec);

  if Success = 0 then begin
    ShowMessage(SearchRec.FindData.CFileName);
  end;
  SysUtils.FindClose(SearchRec);
end;
```

## Article #17406: Getting the filename and path of a local table.

Question and Answer Database

FAQ2406D.txt Getting the filename and path of a local table.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I get the full filename (including path) of a local table?

Answer:

The following example was adapted from the BDE32.HLP file, located in the Borland/CommonFiles/BDE directory:

implementation

```
{ $R *.DFM }
```

```
uses DbiTypes, DbiProcs;
```

```
function fDbiFormFullName(Tbl: TTable): String;
```

```
var
```

```
  Props: CurProps;
```

```
  Buffer1 : array[0..DBIMAXPATHLEN] of char;
```

```
  Buffer2 : array[0..DBIMAXPATHLEN] of char;
```

```
begin
```

```
  Check(DbiGetCursorProps(Tbl.Handle, Props));
```

```
  StrPCopy(Buffer1, Tbl.TableName);
```

```
  Check(DbiFormFullName(Tbl.DBHandle,
```

```
    @Buffer1,
```

```
    Props.szTableType,
```

```
    @Buffer2));
```

```
  Result := StrPas(Buffer2);
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
  Mem1.Lines.Add(fDbiFormFullName(Table1));
```

```
end;
```

Notes:

Table\_You\_Are\_Using.Active Must be True.  
Works on Local Tables.

## Article #17410: Temporarily turning off range checking.

Question and Answer Database

FAQ2410D.txt Temporarily turning off range checking.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I temporarily turn off range checking for a block of code, then turn it back on if it was originally enabled ?

Answer:

You can do this in code by using "IFOPT" and "DEFINE".

type

```
  PSomeArray = ^TSomeArray;
```

```
  TSomeArray = array[0..0] of integer;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  p : PSomeArray;
```

```
  i : integer;
```

```
begin
```

```
{ $IFOPT R+ }
```

```
  { $DEFINE CKRANGE }
```

```
  { $R- }
```

```
{ $ENDIF }
```

```
  GetMem(p, sizeof(integer) * 200);
```

```
  try
```

```
    for i := 1 to 200 do
```

```
      p[i] := i;
```

```
  finally
```

```
    FreeMem(p, sizeof(integer) * 200);
```

```
  end;
```

```
{ $IFDEF CKRANGE }
```

```
  { $UNDEF CKRANGE }
```

```
{ $R+ }  
{ $ENDIF }  
end;
```

## Article #17418: Why am I having trouble displaying and/or printing a very large bitmap?

Question and Answer Database

FAQ2418D.txt Handling bitmap display.

Category :Windows API

Platform :All

Product :All 32 bit

### Question:

I created a very large bitmap image that refuses to display or print on some systems. What can I do?

### Answer:

There are a number of factors that can affect the size of the largest displayable bitmap. Some versions of Windows can only work with a Bitmap that is no larger than 1.75 megabytes in size. The display driver can also play an important role, even during printing, as the printer driver may rely on the display driver to do some of the work. Some display drivers can only work with a bitmap that is no larger than the screen resolution, and may have trouble with bitmaps that use a different color resolution. The safest method to use when working with large bitmaps, is to create smaller bitmaps from the larger one (in code), and display the larger bitmap in sections called "bands".

## Article #17422: Copying a information from one memo field to another using TBlobStream

Question and Answer Database

FAQ2422D.txt Copying a information from one memo field to another using TBlobStream

Category :Database/VCL  
Platform :All  
Product :All 32 bit

Question:

How do I copy information from one memo field in one table to another memo field in another table?

Answer:

Here's an example using a TBlobStream:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  BS1, BS2: TBlobStream;
begin
  BS1 := TBlobStream.Create(Table1Notes,bmRead);
  try
    Table2.Edit;
    BS2 := TBlobStream.Create(Table2MyBlob,bmReadWrite);
    try
      BS2.CopyFrom(BS1,BS1.Size);
    finally
      BS2.Free;
    end;
  finally
    BS1.Free;
  end;
  Table2.Post;
end;
```

## Article #17426: Broadcasting a message.

Question and Answer Database

FAQ2426D.txt Broadcasting a message.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I broadcast a message (such as WM\_WININICHANGE) to all top level Windows?

Answer:

The Windows API function `SendMessage()` takes a 4 parameters. The first is the window handle. To broadcast to all top level Windows, use `HWND_BROADCAST`. The second parameter is the message itself, and then the `WParam` and the `LParam` parameters for the given message. For the `WM_WININICHANGE` message, `wParam` should be zero, and `LParam` should be either the address of a null terminated section name that changed, or `nil` if you want each window to examine all sections for the change. Passing a null value is not recommended unless you have modified several sections due to performance considerations.

Example:

```
var
  s : array[0..64] of char;
begin
  StrCopy(S, 'windows');
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@S));
end;
```

## Article #17430: Registering a file extension and context menu operations

Question and Answer Database

FAQ2430D.txt     Registering a file extension and context menu operations

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I register a file extension (file type) and how do I register context menu operations?

Answer:

Here's a sample that registers a sample extension (.myext). A sample application (MyApp.Exe) is going to handle this extension. It also registers one default action as well as two other context menu operations. You may have to logout and login in after running this code to get the icon to show up correctly.

uses

  Registry;

procedure TForm1.Button1Click(Sender: TObject);

var

  R : TRegIniFile;

begin

  R := TRegIniFile.Create('');

  with R do begin

    RootKey := HKEY\_CLASSES\_ROOT;

    WriteString('.myext', '', 'MyExt');

    WriteString('MyExt', '', 'Some description of MyExt files');

    WriteString('MyExt\DefaultIcon', '', 'C:\MyApp.Exe,0');

    WriteString('MyExt\Shell', '', 'This\_Is\_Our\_Default\_Action');

    WriteString('MyExt\Shell\First\_Action', '', 'This is our first action');

    WriteString('MyExt\Shell\First\_Action\command', '',

      'C:\MyApp.Exe /LotsOfParamaters %1');

    WriteString('MyExt\Shell\This\_Is\_Our\_Default\_Action', '',

```
    'This is our default action');
WriteString('MyExt\Shell\This_Is_Our_Default_Action\command',
    '', 'C:\MyApp.Exe %1');
WriteString('MyExt\Shell\Second_Action', '', 'This is our second
action');
WriteString('MyExt\Shell\Second_Action\command',
    '', 'C:\MyApp.Exe /TonsOfParameters %1');
Free;
end;
end;
```

## Article #17434: Custom InPlace Editor in StringGrid

Question and Answer Database

FAQ2434D.txt Custom InPlace Editor in StringGrid

Category :VCL

Platform :All

Product :Delphi 3.x

Question:

How can I popup my own inplace editor (such as a combobox) in a string grid cell?

Answer:

The following example demonstrates popping up a Combobox as an inplace editor to a Stringgrid component.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  {The combobox height is not settable, so we will}
  {instead size the grid to fit the combobox!}
  StringGrid1.DefaultRowHeight := ComboBox1.Height;
  {Hide the combobox}
  ComboBox1.Visible := False;
end;
```

```
procedure TForm1.ComboBox1Change(Sender: TObject);
begin
  {Get the ComboBox selection and place in the grid}
  StringGrid1.Cells[StringGrid1.Col,
                    StringGrid1.Row] :=
    ComboBox1.Items[ComboBox1.ItemIndex];
  ComboBox1.Visible := False;
  StringGrid1.SetFocus;
end;
```

```
procedure TForm1.ComboBox1Exit(Sender: TObject);
begin
  {Get the ComboBox selection and place in the grid}
```

```

StringGrid1.Cells[StringGrid1.Col,
                    StringGrid1.Row] :=
    ComboBox1.Items[ComboBox1.ItemIndex];
ComboBox1.Visible := False;
StringGrid1.SetFocus;
end;

procedure TForm1.StringGrid1SelectCell(Sender: TObject; Col,
    Row: Integer; var CanSelect: Boolean);
var
    R: TRect;
begin
    if ((Col = 3) AND
        (Row <> 0)) then begin
        {Size and position the combo box to fit the cell}
        R := StringGrid1.CellRect(Col, Row);
        R.Left := R.Left + StringGrid1.Left;
        R.Right := R.Right + StringGrid1.Left;
        R.Top := R.Top + StringGrid1.Top;
        R.Bottom := R.Bottom + StringGrid1.Top;
        ComboBox1.Left := R.Left + 1;
        ComboBox1.Top := R.Top + 1;
        ComboBox1.Width := (R.Right + 1) - R.Left;
        ComboBox1.Height := (R.Bottom + 1) - R.Top;
        {Show the combobox}
        ComboBox1.Visible := True;
        ComboBox1.SetFocus;
    end;
    CanSelect := True;
end;

```

## Article #17438: Delphi startup failure.

Question and Answer Database

FAQ2438D.txt Delphi startup failure.

Category :IDE

Platform :All

Product :All 32 bit

### Question:

I was working on a project, and shut down Delphi/C++ Builder after saving the project. Now Delphi/C++ Builder will not start up. What should I do?

### Answer:

Check to make sure the path to the project (including file names) did not contain any unusual characters (such as a comma). If you find that the path did contain an unusual character, use `regedit.exe` to edit the keys:

HKEY\_CURRENT\_USER/Software/Borland/C++Builder/1.0/ClosedProjects

HKEY\_CURRENT\_USER/Software/Borland/C++Builder/1.0/Closed Files

or if you were running Delphi go to

HKEY\_CURRENT\_USER/Software/Borland/Delphi/2.0/ClosedProjects

HKEY\_CURRENT\_USER/Software/Borland/Delphi/2.0/Closed Files

or

HKEY\_CURRENT\_USER/Software/Borland/Delphi/2.0/ClosedProjects

HKEY\_CURRENT\_USER/Software/Borland/Delphi/2.0/Closed Files

and modify the paths containing the unusual characters. You can replace the offending characters with any usual character.

Shut down RegEdit, and Delphi/C++ Builder should now start.

## Article #17442: Creating Non-Visual Components Without Icons

Question and Answer Database

FAQ2442D.txt      Creating Non-Visual Components Without Icons

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How I do to create a nonvisual component that does not show up on the component palette at design time (such as a TField)?

Answer:

Nonvisual components without icons are useful for components that are always subcomponents associated with other components.      Use RegisterNoIcon instead of RegisterComponent, and then create the component as you would normally.

## Article #17482: Getting the Windows version in code?

Question and Answer Database

FAQ2482D.txt Getting the Windows version in code?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I retrieve the Windows version in code?

Answer:

Here is an example that should work under all versions of Windows.

```
{ $IFDEF WIN32 }
function GetVersionEx(lpOs : pointer) : BOOL; stdcall;
  external 'kernel32' name 'GetVersionExA';
{ $ENDIF }

procedure GetWindowsVersion(var Major : integer;
                             var Minor : integer);

var
  { $IFDEF WIN32 }
  lpOS, lpOS2 : P OSVersionInfo;
  { $ELSE }
  l : longint;
  { $ENDIF }
begin
  { $IFDEF WIN32 }
  GetMem(lpOS, SizeOf(T OSVersionInfo));
  lpOS^.dwOSVersionInfoSize := SizeOf(T OSVersionInfo);
  while getVersionEx(lpOS) = false do begin
    GetMem(lpOS2, lpOS^.dwOSVersionInfoSize + 1);
    lpOS2^.dwOSVersionInfoSize := lpOS^.dwOSVersionInfoSize + 1;
    FreeMem(lpOS, lpOS^.dwOSVersionInfoSize);
    lpOS := lpOS2;
  end;
  Major := lpOS^.dwMajorVersion;
  Minor := lpOS^.dwMinorVersion;
  FreeMem(lpOS, lpOS^.dwOSVersionInfoSize);
```

```
{$ELSE}  
  l := GetVersion;  
  Major := LoByte(LoWord(l));  
  Minor := HiByte(LoWord(l));  
{$ENDIF}  
end;  
  
procedure TForm1.Button1Click(Sender: TObject);  
var  
  Major : integer;  
  Minor : integer;  
begin  
  GetWindowsVersion(Major, Minor);  
  Mem1.Lines.Add(IntToStr(Major));  
  Mem1.Lines.Add(IntToStr(Minor));  
end;
```

## Article #17486: How do I create a power function?

Question and Answer Database

FAQ2486D.txt    How do I create a power function?

Category        :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

How do I create a power function?

Answer:

The following example shows how to use the example power function to raise three to the power of 2:

```
function Power(x, y : extended) : extended;
begin
  result := exp(y*ln(x));
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(FloatToStr(Power(3, 2)));
end;
```

## Article #17490: Local Interbase Startup Configuration.

Question and Answer Database

FAQ2490D.txt - Local Interbase Startup Configuration.

Category :Install Issues  
Platform :All-32Bit  
Product :

Question:

How can I keep the Local InterBase Server from automatically starting when I start Windows?

Answer:

There are three methods that you can use:

Right click on the Local InterBase Server icon and select "Startup Configuration" then select "Manual Startup".

Try taking the Local InterBase Server out of you Startup Menu, or comment it from the run/load lines of your Win.ini file.

Run REGEDIT.EXE and activate the key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run and remove manually the IBSERVER entry.

## Article #17494: Preventing Components from Resizing

Question and Answer Database

FAQ2494D.txt Preventing Components from Resizing

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I prevent resizing of my component at design-time?

Answer:

Have your constructor set the default size of the object. Override the SetBounds method, and then check the component state. If it is in design mode (csDesigning in ComponentState) simply pass the default values for width and heights to the inherited SetBounds, otherwise you pass the parameters unchanged.

Example:

```
procedure TVu.SetBounds(ALeft : integer;
                       ATop : integer;
                       AWidth : integer;
                       AHeight : integer);
begin
  if csdesigning in componentstate then begin
    AWidth := 50;
    AHeight := 50;
    inherited;
  end;
```

## Article #17498: Embedding a quote in a string.

Question and Answer Database

FAQ2498D.txt Embedding a quote in a string.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I embed a quote in a string since it is a reserved delimiter?

Answer:

You can either use two single quote characters where a single quote is required, or define a constant whose value is character number 39. If you have many quotes to embed (this can happen in a complex SQL statement), the second method is preferred.

Example:

```
const Quote = #39;
```

```
{This line will not compile}
```

```
ShowMessage('The smith's yard is greener than ours');
```

```
{This line will compile}
```

```
ShowMessage('The smith's yard is greener than ours');
```

```
{This line will compile}
```

```
ShowMessage('The smith' + Quote + 's yard is greener than ours');
```

## Article #17502: How do I restart Windows in code.

Question and Answer Database

FAQ2502D.txt    How do I restart Windows in code.

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I restart Windows in code?

Answer:

The Windows API function `ExitWindows()` is incorrectly documented. There are three constants available for the first parameter, and the second parameter is used when exiting Windows to start a DOS program:

`EW_RESTARTWINDOWS`

`EW_REBOOTSYSYSTEM`

`EW_EXITANDEXECAPP`

Example:

```
ExitWindows(EW_RESTARTWINDOWS, 0 );
```

## Article #17506: Implementing the VB TwipsPerPixel in Delphi

Question and Answer Database

FAQ: FAQ2506D - Implementing the VB TwipsPerPixel in Delphi

Category: VCL

Platform: All Windows

Product:

Question:

I need the equivalent of the VB TwipsPerPixel functions.  
How can I implement the same functionality in Delphi?

Answer:

The following example demonstrates two functions  
(TwipsPerPixelX, and TwipsPerPixelY) that implement  
the same functionality in Delphi.

Example:

```
function TwipsPerPixelX(Canvas : TCanvas) : Extended;
begin
    result := 1440 /
        GetDeviceCaps(Canvas.Handle,
            LOGPIXELSX);
end;

function TwipsPerPixelY(Canvas : TCanvas) : Extended;
begin
    result := 1440 /
        GetDeviceCaps(Canvas.Handle,
            LOGPIXELSY);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    ShowMessage(FloatToStr(TwipsPerPixelX(Form1.Canvas)));
    ShowMessage(FloatToStr(TwipsPerPixelY(Form1.Canvas)));
end;
```

end;

## Article #17510: Converting 16bit resource to 32bit.

Question and Answer Database

FAQ2510D.txt     Converting 16bit resource to 32bit.

Category     :Object Pascal

Platform     :All

Product     :All 32 bit

Question:

How can I convert a 16-bit resource file to a 32 bit resource file?

Answer:

If you have the original source file (.rc) then you can simply recompile the .rc file to a .res file using the Borland Resource Command Line Compiler (brcc32.exe) located in the Delphi/C++ Builders bin directory. If you only have a .res file to work with, you will need to use a quality resource compiler/decompiler such as Borland's Resource Workshop. Versions of the Borland's Resource Workshop later than 4.5 can extract, compile, and decompile both 16 and 32 bit resource files from a variety of sources including .res, .exe, .dll, drv, and .cpl files. The Borland Resource Workshop version 4.5 ship with the Borland RAD Pack product line.

## Article #17514: Creating resource files.

Question and Answer Database

FAQ2514D.txt Creating resource files.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

What are my options for creating resource files?

Answer:

You can use the Borland Command Line Resource Compiler (BRCC.EXE and BRCC32.EXE) that ships with Delphi and C++ Builder, or a WYSIWYG resource editor such as Borland's Resource Workshop 5.0 that ships with the Borland RAD Pack. The Resource Workshop 5.0 can compile and decompile both 16 and 32 bit resources from .rc, .res, .exe, .dll, .drv, .vbx, .cpl, .ico, .bmp, .rle, .dlg, fnt, and cur files.

## Article #17518: Using the WinApi GetObject to get a bitmap.

Question and Answer Database

FAQ2518D.txt Using the WinApi GetObject to get a bitmap.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How to I gain access to the TBitmap types used by the Windows API function GetObject()?

Answer:

The WinTypes/Windows, and Graphics units have two different definitions of TBitmap. You can qualify the one you want by prefacing the unit name like this:

var

```
AWindowsTBitmap : Windows.TBitmap;
```

```
AVclTBitmap : Graphics.TBitmap;
```

## Article #17522: calling windows Beep() function

Question and Answer Database

FAQ2522D.txt calling windows Beep() function

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

I want to call the Windows Beep() function, but I get the error "Too many parameters" when compiling. How can I get around this?

Answer:

The Beep() procedure is declared both in the SysUtils unit and the Windows unit. The following example demonstrates calling both procedures.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    SysUtils.Beep;
    Windows.Beep(100, 1000);
end;
```

## Article #17526: Performing undo on an edit control.

Question and Answer Database

FAQ2526D.txt Performing undo on an edit control.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I programmatically undo changes in an edit type control?

Answer:

You can use:

```
Mem1.Perform(EM_UNDO, 0, 0);
```

If you want to check whether undo is available, so you can enable or disable a menu item choice, you can check the "Undo status" like this:

```
If Mem1.Perform(EM_CANUNDO, 0, 0) <> 0 then begin  
  {Undo is possible}  
end;
```

To perform a "Redo" simply "Undo" a second time.

## Article #17533: Embedding a copyright symbol in a string?

Question and Answer Database

FAQ2533D.txt Embedding a copyright symbol in a string?

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I embed a copyright symbol in a caption?

Answer:

For most fonts, typing ALT+0169 in the (object inspector) will produce a copyright symbol. In code, use `chr(169)` to produce a copyright symbol. If you are using the symbol font, the char code will be 211.

## Article #17537: Adding TrueType fonts to windows in code.

Question and Answer Database

FAQ2537D.txt Adding TrueType fonts to windows in code.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I add a TrueType font to Windows 95 in code;

Answer:

You should copy the file to the Windows\Fonts directory, then add an entry to the registry key:

```
"Software\Microsoft\Windows\CurrentVersion\Fonts".
```

The entry will be the font name and the path (if different than the Windows\Fonts directory). Once the registry entry is written, you should make a call to the Windows API function `AddFontResource()`, then broadcast a system-wide `WM_FONTCHANGE` message. Finally, you should make a call to the Windows API function `RemoveFontResource()`, to remove the resource lock on the font file, and broadcast a second system-wide `WM_FONTCHANGE` message.

Here is an example:

```
uses Registry;

procedure TForm1.Button1Click(Sender: TObject);
var
  reg: TRegistry;
  b : bool;
begin
  CopyFile('C:\DOWNLOAD\FP000100.TTF',
          'C:\WINDOWS\FONTS\FP000100.TTF', b);
  reg := TRegistry.Create;
  reg.RootKey := HKEY_LOCAL_MACHINE;
  reg.LazyWrite := false;
```

```
reg.OpenKey('Software\Microsoft\Windows\CurrentVersion\Fonts',
            false);
reg.WriteString('TESTMICR (TrueType)', 'FP000100.TTF');
reg.CloseKey;
reg.free;
{Add the font resource}
AddFontResource('c:\windows\fonts\FP000100.TTF');
SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
{Remove the resource lock}
RemoveFontResource('c:\windows\fonts\FP000100.TTF');
SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
end;
```

## Article #17544: Converting resources from 16bit to 32bit.

Question and Answer Database

FAQ2544D.txt     Converting resources from 16bit to 32bit.

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I convert a 16 bit res file to a 32 bit res file?

Answer:

Use Borland's WYSIWYG Resource Workshop 5.0 resource editor that ships with the Borland RAD Pack to decompile the 16 bit .res file to a .rc file. Once you have a .rc file, you can close the project, set your preferences in Resource Workshop to "Win32", reload the .rc file, then save as a .res file. Note: The Resource Workshop 5.0 can compile and decompile both 16 and 32 bit resources from .rc, .res, .exe, .dll, .drv, .vbx, .cpl, .ico, .bmp, .rle, .dlg, fnt, and cur files.

## Article #17547: TDateTime does not set the field out of 1900

Question and Answer Database

FAQ2547C.txt     TDateTime does not set the field out of 1900  
Category        :Database Issues  
Platform        :All  
Product         :C++Builder 3.x

### Question:

I have a Table, assume paradox but the issue is the same with all tables, and one of the fields is a DATE field. I get to the date field by using `TDataSet.FieldName ("MyDateField").AsString` I read the string into a `AnsiString` and then create the `TDateTime` with the `AnsiString` (`TDateTime dt (AnsiString)`). then I decode the `TDateTime` to change the year to something in the 2000 and then set it back to the dataset using `TDataSet.FieldName ("MyDateField").AsString=dt.DateString();` The field is then not set to the 2000 year but back to the 1900 year. What the heck is the problem. Is `TDateTime` not year 2000 compliant?

### Answer:

No, `TDateTime` is absolutely year 2000 compliant. The problem is that you are setting the field as a string and something is being lost in the process. What you need to do is read in the `TDateTime` as a `TDateTime` by using a `TDateField` or a `TDateTimeField`. Instead of this:

```
AnsiString as = DataSet->FieldName ("FieldName")->AsString;
TDateTime dt (as, TDateTime::Date);
short int y, m, d;
dt.DecodeDate (&y, &d, &y);
y = 2001;
TDateTime dt2 (y, m, d);
DataSet->Edit ();
DataSet->FieldName ("FieldName")->AsString = dt2.DateString();
```

Do this:

```
TDateField *df = (TDateField*)DataSet->FieldName ("FieldName");
```

```
TDateTime dt = df->AsDateTime;  
short int y, m, d;  
dt.DecodeDate (&y, &d, &y);  
y = 2001;  
TDateTime dt2 (y, m, d);  
DataSet->Edit ();  
df->AsDateTime = dt2;
```

It will now work fine.

Y.T.

## Article #17548: Copying contents of a control to the clipboard.

Question and Answer Database

FAQ2548D.txt Copying contents of a control to the clipboard.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get a control in another window to copy it's contents to the Windows clipboard?

Answer:

Send a WM\_COPY message to the active window to tell it to copy its contents to the clipboard. If the control does not support the message, it is simply ignored, and no exception is raised.

Example:

```
SendMessage(Edit1.handle, WM_COPY, 0, 0);
```

## Article #17552: Checking available disk space on large drives.

Question and Answer Database

FAQ2552D.txt      Checking available disk space on large drives.

Category       :Windows API

Platform       :All

Product        :All 32 bit

Question:

How do I check for available disk space on a drive larger than 2 gigabytes?

Answer:

You will need to call the Windows API function `GetDiskFreeSpaceEx()` and convert the returned integers to doubles, since integers greater than 2 gigabytes are not supported in Delphi.

Example:

```
function GetDiskFreeSpaceEx(lpDirectoryName: PAnsiChar;
  var lpFreeBytesAvailableToCaller : Integer;
  var lpTotalNumberOfBytes: Integer;
  var lpTotalNumberOfFreeBytes: Integer) : bool;
  stdcall;
  external kernel32
  name 'GetDiskFreeSpaceExA';
```

```
procedure GetDiskSizeAvail(TheDrive : PChar;
  var TotalBytes : double;
  var TotalFree : double);
var
  AvailToCall : integer;
  TheSize : integer;
  FreeAvail : integer;
begin
  GetDiskFreeSpaceEx(TheDrive,
    AvailToCall,
    TheSize,
    FreeAvail);
```

```

{$IFOPT Q+}
{$DEFINE TURNOVERFLOWON}
{$Q-}
{$ENDIF}
if TheSize >= 0 then
    TotalBytes := TheSize else
if TheSize = -1 then begin
    TotalBytes := $7FFFFFFF;
    TotalBytes := TotalBytes * 2;
    TotalBytes := TotalBytes + 1;
end else
begin
    TotalBytes := $7FFFFFFF;
    TotalBytes := TotalBytes + abs($7FFFFFFF - TheSize);
end;

if AvailToCall >= 0 then
    TotalFree := AvailToCall else
if AvailToCall = -1 then begin
    TotalFree := $7FFFFFFF;
    TotalFree := TotalFree * 2;
    TotalFree := TotalFree + 1;
end else
begin
    TotalFree := $7FFFFFFF;
    TotalFree := TotalFree + abs($7FFFFFFF - AvailToCall);
end;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
    TotalBytes : double;
    TotalFree : double;
begin
    GetDiskSizeAvail('C:\',
                    TotalBytes,
                    TotalFree);
    ShowMessage(FloatToStr(TotalBytes));
    ShowMessage(FloatToStr(TotalFree));
end;

```

## Article #17555: Dropping a combobox's list in code.

Question and Answer Database

FAQ2555D.txt Dropping a combobox's list in code.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get a ComboBox to drop down its list box in code?

Answer:

Send the ComboBox a CB\_SHOWDROPDOWN message, passing a 1 (true) in the WParam parameter to drop the list down, or a 0 (false) to hide it.

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    SendMessage(ComboBox1.Handle,  
                CB_SHOWDROPDOWN,  
                1,  
                0);
```

```
    ComboBox1.SetFocus;
```

```
end;
```

## Article #17559: Setting a form's maxwidth in code.

Question and Answer Database

FAQ2559D.txt    Setting a form's maxwidth in code.

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I get a Form's width to be less than 120 (approx) pixels?

Answer:

This is controlled and overridden by Windows. Under some versions of Windows, you may be successful by creating a message handler to respond to the WM\_GETMINMAXINFO message:

Example:

```
{Place this code in the private section of the Form declaration}
procedure WMGetMinMaxInfo(var Message: TWMGetMinMaxInfo);
  message WM_GETMINMAXINFO;
```

```
{Place this code in the Form implementation section}
procedure TForm1.WMGetMinMaxInfo(var Message: TWMGetMinMaxInfo);
begin
  with message do begin
    MinMaxInfo^.ptMaxSize.x := 20;
    MinMaxInfo^.ptMaxSize.y := 20;
    MinMaxInfo^.ptMinTrackSize.x := 20;
    MinMaxInfo^.ptMinTrackSize.y := 20;
  end;
end;
```

## Article #17563: Getting the windows directory.

Question and Answer Database

FAQ2563D.txt Getting the windows directory.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I determine where the Windows directory is?

Answer:

You can make a call to the Windows API function

GetWindowsDirectory().

If you want the system directory, simply call the Windows API function

GetSystemDirectory().

Example:

```
{ $IFDEF WIN32 }
```

```
const MAX_PATH = 144;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  a : Array[0..MAX_PATH] of char;
```

```
begin
```

```
  GetWindowsDirectory(a, sizeof(a));
```

```
  ShowMessage(StrPas(a));
```

```
  GetSystemDirectory(a, sizeof(a));
```

```
  ShowMessage(StrPas(a));
```

```
end;
```

## Article #17567: Getting the size of the desktop.

Question and Answer Database

FAQ2567D.txt Getting the size of the desktop.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I find the size of the Desktop minus the taskbar?

Answer:

Call the Windows API function `SystemParametersInfo()` passing the `SPI_GETWORKAREA` parameter along with the address of the rectangle structure to receive the coordinates.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  r : TRect;
begin
  SystemParametersInfo(SPI_GETWORKAREA,
                      0,
                      @r,
                      0);
  Mem1.Lines.Add(IntToStr(r.Top));
  Mem1.Lines.Add(IntToStr(r.Left));
  Mem1.Lines.Add(IntToStr(r.Bottom));
  Mem1.Lines.Add(IntToStr(r.Right));
end;
```

## Article #17571: Hiding the windows taskbar.

Question and Answer Database

FAQ2571D.txt Hiding the windows taskbar.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I hide the Windows Task Bar?

Answer:

First call the Windows API function `FindWindow()` to retrieve the handle to the TaskBar Window, then call the Windows API function `ShowWindow()` passing the predefined constant `SW_HIDE`.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  hTaskBar : THandle;
begin
  hTaskbar := FindWindow('Shell_TrayWnd', Nil);
  ShowWindow(hTaskBar, SW_HIDE);
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
  hTaskBar : THandle;
begin
  hTaskbar := FindWindow('Shell_TrayWnd', Nil);
  ShowWindow(hTaskBar, SW_SHOWNORMAL);
end;
```

## Article #17575: Keeping an application in a minimized state?

Question and Answer Database

FAQ2575D.txt Keeping an application in a minimized state?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I keep my application in a iconized (minimized) state?

Answer:

First, you must set the WindowState property of the form to Minimized. Then you must create a message handler to respond to the Windows WM\_QueryOpen message, to let Windows know that you do not want the form to resize.

Example:

{Place this code in the private section of the Form declaration}

```
procedure WMQueryOpen(VAR Msg : TWMQueryOpen); message WM_QUERYOPEN;
```

{Place this code in the Form implementation section}

```
procedure TForm1.WMQueryOpen(VAR Msg : TWMQueryOpen);
```

```
begin
```

```
    Msg.Result := 0;
```

```
end;
```

## Article #17582: Getting the current line number of a TMemo?

Question and Answer Database

FAQ2582D.txt Getting the current line number of a TMemo?

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I determine the current line number of a TMemo?

Answer:

You can use the Windows EM\_LINEFROMCHAR message to get the current (zero based) line number (position of the caret) of any edit control.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  LineNumber : integer;
begin
  LineNumber := SendMessage(Memo1.Handle,
                           EM_LINEFROMCHAR,
                           word(-1),
                           0);
  ShowMessage(IntToStr(LineNumber));
end;
```

## Article #17591: Calling DeleteFile function

Question and Answer Database

FAQ2591D.txt     Calling DeleteFile function

Category     :Object Pascal

Platform     :All

Product      :All 32 bit

Question:

I want to call the Windows DeleteFile() function, but I get the error "Incompatible types: 'string' and 'Pointer'" when compiling. How can I get around this?

Answer:

The DeleteFile() procedure is declared both in the SysUtils unit and the Windows unit. The following example demonstrates calling both procedures. The version declared in the SysUtils unit accepts strings, and the Windows version accepts PChars.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
  a : array[0..MAX_PATH - 1] of char;
begin
  s := 'C:\SomeFile';
  SysUtils.DeleteFile(s);
  a := 'C:\SomeFile';
  Windows.DeleteFile(@a);
end;
```

## Article #17595: Using far pointers.

Question and Answer Database

FAQ2595D.txt Using far pointers.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I instruct the compiler that I require a far pointer instead of a near pointer?

Answer:

In 16 bit versions of Delphi, all pointers are far pointers. When running in a 32 bit environment, all pointers are considered to be huge near pointers as there is no concept of far pointer that cross process address space without thunking.

## Article #17599: String Trim functions.

Question and Answer Database

FAQ2599D.txt String Trim functions.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

Where are the equivalent functions for the Visual Basic Trim functions?

Answer:

There are many ways to implement these and similar functions. The following example is a great start for a string handling unit add to your programming tool box.

```
unit StrFunc;

interface

procedure LTrim(var s : string);

procedure RTrim(var s : string);

procedure Trim(var s : string);

implementation

{$R *.DFM}

procedure LTrim(var s : string);
begin
  while ((length(s) > 0) and
        (s[1] = #32)) do
    Delete(s, 1, 1);
end;

procedure RTrim(var s : string);
begin
```

```
while ((length(s) > 0) and
      (s[length(s)] = #32)) do
  Delete(s, Length(s), 1);
end;
```

```
procedure Trim(var s : string);
begin
  LTrim(s);
  RTrim(s);
end;
```

end.

## Article #17603: Virtual key constants.

Question and Answer Database

FAQ2603D.txt Virtual key constants.

Category :VCL

Platform :All

Product :All 32 bit

Question:

Where are the VK\_Key constants A-Z and 0-9 declared?

Answer:

They are not declared in Delphi, since they are simply the ordinal value for those keys.

VK\_0 thru VK\_9 are the same as ASCII '0' thru '9' (\$30 - \$39)

VK\_A thru VK\_Z are the same as ASCII 'A' thru 'Z' (\$41 - \$5A).

## Article #17607: Changing the Windows wallpaper in code?

Question and Answer Database

FAQ2607D.txt - Changing the Windows wallpaper in code?

Category :Windows API  
Platform :All-32Bit  
Product :

Question:

How do I change the Windows wallpaper in code?

Answer:

Call the Windows API function `SystemParametersInfo()` passing the `SPI_SETDESKWALLPAPER` parameter along with the filename of the new bitmap to use.

Example:

```
SystemParametersInfo(SPI_SETDESKWALLPAPER,  
                    0,  
                    PChar('C:\SOME_PATH\SOME.BMP'),  
                    SPIF_SENDWININICHANGE);
```

Question and Answer Database

FAQ2610D.txt    Passing TPrinter handle to GetDeviceCaps()

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

Is there any way to call the GetDeviceCaps() function before I start my print job?

Answer:

Yes, You can pass the Printer.Handle property to the GetDeviceCaps() function instead of the Printer.Canvas.Handle property.

Example:

```
{Before BeginDoc;}
HRes := GetDeviceCaps(Printer.Handle, HORZRES);
VRes := GetDeviceCaps(Printer.Handle, VERTRES);

Printer.BeginDoc;

{After BeginDoc;}
InchX := GetDeviceCaps(Printer.Canvas..Handle, LOGPIXELSX);
InchY := GetDeviceCaps(Printer.Canvas.Handle, LOGPIXELSY);

Printer.Canvas.TextOut(InchX, InchY, 'Delphi Is RAD!');

Printer.EndDoc;
```

## Article #17618: Changing windows default printer in code.

Question and Answer Database

FAQ2618D.txt - Changing windows default printer in code.

Category :Printing  
Platform :All-32Bit  
Product :

Question:

How do I change the default Windows printer?

Answer:

You need to change the printer, driver, and port as listed in the device key of the Windows section in the Windows.ini file, then broadcast a system wide WM\_WININICHANGE message.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  WinIni : TIniFile;
  WinIniFileName : array[0..MAX_PATH] of char;
  s : array[0..64] of char;
begin
  GetWindowsDirectory(WinIniFileName, sizeof(WinIniFileName));
  StrCat(WinIniFileName, '\win.ini');
  WinIni := TIniFile.Create(WinIniFileName);
  try
    WinIni.WriteString('windows',
                      'device',
                      'HP LaserJet Series II,HPPCL,LPT1:');
  finally
    WinIni.Free;
  end;

  StrCopy(s, 'windows');
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@s));
end;
```

## Article #17622: Raster operations.

Question and Answer Database

FAQ2622D.txt Raster operations.

Category :VCL

Platform :All

Product :All 32 bit

### Question:

When using a canvas, the return value from the pixels property returns an invalid color of -1 or hex \$FFFFFFFF. How can I get around this?

### Answer:

This can happen if the requested pixel is not in the current clipping region. This can also happen on devices that do not support the Windows API functions GetPixel() and SetPixel(). You should check the return value from the GetDeviceCaps() to check to see if a device supports raster operations before using these functions. A printer and/or metafile canvas is a likley candidate for a device that the pixels property may fail on.

### Example:

```
if (GetDeviceCaps(Printer.Canvas.Handle, RASTERCAPS)
    and RC_NONE) = RC_NONE then
NoRasterOperations := True;
```

## Article #17626: How do I create a Resource only DLL?

Question and Answer Database

FAQ2626D.txt    How do I create a Resource only DLL?

Category        :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

How do I create a Resource only DLL?

Answer:

Create and build an empty DLL project, that contains a resource link reference to the .res file that contains your resources.

Example:

```
library ResTest;
```

```
uses
```

```
    SysUtils;
```

```
{ $R MYRES.RES }
```

```
begin
```

```
end.
```

To use you resource only DLL, simply load the dll and the resources you wish to use:

Example:

```
{ $IFDEF WIN32 }
```

```
const BadDllLoad = 0;
```

```
{ $ELSE }
```

```
const BadDllLoad = 32;
```

```
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
h : THandle;  
Icon : THandle;
```

```
begin
```

```
  h := LoadLibrary('RESTEST.DLL');
```

```
  if h <= BadDllLoad then
```

```
    ShowMessage('Bad Dll Load')
```

```
  else begin
```

```
    Icon := LoadIcon(h, 'ICON_1');
```

```
    DrawIcon(Form1.Canvas.Handle, 10, 10, Icon);
```

```
    FreeLibrary(h);
```

```
  end;
```

```
end;
```

## Article #17634: Trying to delete a running .exe?

Question and Answer Database

FAQ2634D.txt Trying to delete a running .exe?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I delete my executable while it is running?

Answer:

Under Win32, unless you are running from a removable drive, you cannot delete a running executable. You can have Windows delete the executable the next time Windows is ran by adding an entry to the RunOnce key in the Windows registry under:

HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce

You can name the key anything you like, and specify a command line to another executable or to a dos command passed to command.com.

Example:

uses

Registry;

procedure TForm1.Button1Click(Sender: TObject);

var

reg: TRegistry;

begin

reg := TRegistry.Create;

with reg do begin

RootKey := HKEY\_LOCAL\_MACHINE;

LazyWrite := false;

OpenKey('Software\Microsoft\Windows\CurrentVersion\RunOnce',  
false);

WriteString('Delete Me!', 'command.com /c del FILENAME.EXT');

```
    CloseKey;  
    free;  
end;  
end;
```

## Article #17641: Access97 ODBC with BDE 4.51

Question and Answer Database

FAQ2641C.txt      Access97 ODBC with BDE 4.51

Category        :Database Issues

Platform        :All

Product         :C++Builder 3.x

### Question:

I have BCB Pro 1.0, Upgraded BDE to 4.5, and have Office 97 installed on my machine.

When i attempt to connect to the access97 database, i get :

Cannot load an IDAPI service library.

File : C:\Program Files\Common Files\Microsoft Shared\DAO\dao3032.dll

Alias : AliasName

### Answer:

Office 97 comes with DAO3.5, but the BDE4.51 defaults to the DAO3.0 driver. Open the BDE Admin and goto the native access driver and change the dll32 to IDDA3532.dll. The Registry change is only necessary if you wish to use DAO3.0

FAQ2646D.txt    Displaying a file's associated icon.

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I display the icon that is associated with a given file type?

Answer:

Use the ShellApi function `ExtractAssociatedIcon()` to retrieve the icon that is associated with the file.

Example:

```
uses ShellApi;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    Icon : hIcon;
```

```
    IconIndex : word;
```

```
begin
```

```
    Icon := ExtractAssociatedIcon(HInstance,  
                                  'C:\SomePath\SomeFile.ext',  
                                  IconIndex);
```

```
    DrawIcon(Form1.Canvas.Handle, 10, 10, Icon);
```

```
end;
```

Question and Answer Database

FAQ2657D.txt - Printing a WEB page with the HTML control?

Category :Internet/WEB  
Platform :All-32Bit  
Product :

Question:

How do I print a WEB page with the HTML control?

Answer:

Use either the HTML control's AutoPrint method, or alternatively use the PrintPage method.

Example using AutoPrint:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
var
```

```
    OldCur: TCursor;
```

```
begin
```

```
    OldCur := Screen.Cursor;
```

```
    with Printer do begin
```

```
        BeginDoc;
```

```
        HTML1.AutoPrint(handle);
```

```
        Title := HTML1.URL;
```

```
        EndDoc;
```

```
    end;
```

```
    Screen.Cursor := OldCur;
```

```
end;
```

## Article #17665: Using the Application's OnIdle Event.

Question and Answer Database

FAQ2665D.txt Using the Application's OnIdle Event.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How do I have my application perform work when the computer is idle?

Answer:

You can create an OnIdle event to be called whenever your application is waiting for messages to be processed. Simply declare the event handler procedure in the private section of the forms declaration:

```
{ Private declarations }  
procedure IdleEventHandler(Sender: TObject; var Done: Boolean);
```

In then implementation section, define the procedure:

```
procedure TForm1.IdleEventHandler(Sender: TObject;  
    var Done: Boolean);  
begin  
    {Do a small bit of work here}  
    Done := false;  
end;
```

Then assign the Application's OnIdle event to point to your new procedure(You may do this wherever you like, but a good place would be the Forms OnCreate method):

```
Application.OnIdle := IdleEventHandler;
```

OnIdle is called only once, as the application transitions into an idle state. It is not called continuously unless Done is set to False If Done is False, WaitMessage is not called. Applications that set Done to False consume an

inordinate amount of CPU time that affects overall system performance.

You can set the boolean variable "done" to true when you want to stop the event handler from executing.

## Article #17677: Passing a function to a procedure or vice versa.

Question and Answer Database

FAQ2677D.txt Passing a function to a procedure or vice versa.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

Can I pass a function or procedure to another function or procedure?

Answer:

Yes. You must declare a procedure or function type to use as the parameter type, then you can pass the address of the procedure that you wish to pass. You must be careful to pass functions or procedures that are compatible with the function or procedure expected, as little error checking will be provided by the compiler.

Example:

```
type
  AFunctionType = function(IntIn : integer) : integer;

function AddProc(IntIn : integer) : integer;
begin
  Result := IntIn + 1;
end;

function SubProc(IntIn : integer) : integer;
begin
  Result := IntIn - 2;
end;

procedure PassAFunction(var IntIn : integer;
                        fn : AFunctionType);
begin
  IntIn := fn(IntIn);
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i : integer;
begin
  i := 10;

  PassAFunction(i, @AddProc);
  ShowMessage(IntToStr(i));

  PassAFunction(i, @SubProc);
  ShowMessage(IntToStr(i));
end;
```

## Article #17685: How do I print in color?

Question and Answer Database

FAQ2685D.txt    How do I print in color?

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I print in color?

Answer:

Generally, no special effort is required to print in color assuming the printer is a color printer and is set to its native color mode. Windows will automatically convert color to black and white if the printer does not support color. If you need to change the color mode in code, you can access the DevMode structure of the printer driver.

Example:

```
uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  Device : array[0..255] of char;
```

```
  Driver : array[0..255] of char;
```

```
  Port   : array[0..255] of char;
```

```
  hDMode : THandle;
```

```
  PDMode : PDEVMODE;
```

```
begin
```

```
  with Printer do begin
```

```
    PrinterIndex := PrinterIndex;
```

```
    GetPrinter(Device, Driver, Port, hDMode);
```

```
  if hDMode <> 0 then begin
```

```
    pDMode := GlobalLock(hDMode);
```

```
    if pDMode <> nil then begin
```

```
      pDMode.dmFields := pDMode.dmFields or dm_Color;
```

```
      pDMode.dmColor := DMCOLOR_COLOR;
```

```
      GlobalUnlock(hDMode);
```

```
    end;  
end;  
  
PrinterIndex := PrinterIndex;  
BeginDoc;  
Canvas.Font.Color := clRed;  
Canvas.TextOut(100,100, 'Red As A Rose!');  
EndDoc;  
end;  
end;
```

Product :All 32 bit

Question:

When I try to set the selected property of a ListBox component, I receive an exception that the Index is out of bounds. How do I get around this?

Answer:

The selected property should only be used with ListBox components that have the MultiSelect property set to true. If you are working with a ListBox that has the MultiSelect property set to false, use the ItemIndex property to select the item.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items.Add('1');
  ListBox1.Items.Add('2');
  {This will fail on a single selection ListBox}
  // ListBox1.Selected[1] := true;
  ListBox1.ItemIndex := 1; {This is ok}
end;
```

## Article #17700: Getting a list of valid time zones from windows.

Question and Answer Database

FAQ2700D.txt Getting a list of valid time zones from windows.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I retrieve a list of valid time zones from the system?

Answer:

The following example lists the time zones known to Windows.

Example:

```
uses Registry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    reg : TRegistry;
```

```
    ts : TStringList;
```

```
    i : integer;
```

```
begin
```

```
    reg := TRegistry.Create;
```

```
    reg.RootKey := HKEY_LOCAL_MACHINE;
```

```
    reg.OpenKey(
```

```
'SOFTWARE\Microsoft\Windows\CurrentVersion\Time Zones',  
        false);
```

```
    if reg.HasSubKeys then begin
```

```
        ts := TStringList.Create;
```

```
        reg.GetKeyNames(ts);
```

```
        reg.CloseKey;
```

```
        for i := 0 to ts.Count - 1 do begin
```

```
            reg.OpenKey(
```

```
'SOFTWARE\Microsoft\Windows\CurrentVersion\Time Zones\' +  
                ts.Strings[i],
```

```
                false);
```

```
            Mem1.Lines.Add(ts.Strings[i]);
```

```
            Mem1.Lines.Add(reg.ReadString('Display'));
```

```
    Mem1.Lines.Add(reg.ReadString('Std'));
    Mem1.Lines.Add(reg.ReadString('Dlt'));
    Mem1.Lines.Add('-----');
    reg.CloseKey;
end;
ts.Free;
end else
reg.CloseKey;
reg.free;
end;
```

## Article #17707: Deploying the BDE: InstallShield can't find BDE drivers

Question and Answer Database

FAQ2707C.txt    Deploying the BDE:    InstallShield can't find BDE drivers

Category        :Database Issues

Platform        :Windows 95

Product         :    C++Builder3.x

Question:

I'm trying to deploy a full version of the BDE with my application. When I use InstallShield Express, though, when I create a new BDE alias there is a page entitled: Step 3 of 4. On this page, there is a combo box entitled type. This combo box is supposed to contain driver types, but it's empty. When I look at the help, it says that InstallShield is looking for driver information from a key in the registry called HKEY\_LOCAL\_MACHINE\SOFTWARE\Borland\Database Engine\Settings\DRIVERS. This key isn't there!

Answer:

The reason for this problem is that the BDE configuration settings are set up for Windows 95/NT AND Windows 3.1. This means that all the driver information is stored in the idapi.cfg file, and none of it is put into the registry.

To change this:

1. Go into the BDE Administration
2. Go to Object\Options and change the setting from Win3.1 and Win95/NT to Win95/NT only.
3. Go to Object\Save As Configuration and save over the old Idapi.cfg file.
4. Check your registry. The DRIVERS key should have been added.
5. Uninstall InstallShield
6. Reinstall InstallShield

Now you should see the drivers listed in that combo box.

## Article #17708: BCD Number Truncate to only 4 Decimal Places

Question and Answer Database

FAQ2708D.txt - BCD Number Truncate to only 4 Decimal Places

Category :Database/VCL

Platform :All-32Bit

Product :

Question:

When I use the BDE setting ENABLE BCD, all my data is truncated to 4 decimal places. Is this as designed?

Answer:

Delphi uses the Delphi Currency type for holding the BCD values internally. This is actually a signed 64 bit integer (comp) with the last 4 digits used for the decimal places.

If a BCD value from BDE that contains more than 4 decimals, an exception is raised.

The only way to work with more decimal places than 4 is to call GetData on the field and work directly with the FMTBCD structure.

## Article #17716: Changing font color on standard win controls.

Question and Answer Database

FAQ2716D.txt Changing font color on standard win controls.

Category :VCL

Platform :All

Product :All 32 bit

Question:

Why do changes to the StatusBar's font color not have any affect?

Answer:

The status bar is a standard Windows control, and as such, displays the font in the `clBtnText` value, which is set via the Control Panel. This color is black by default, but it can vary due to the user's color scheme. Other standard Windows controls, such as buttons, exhibit this identical behavior. The StatusBar and its associated panels have an owner-draw capability that allow you to draw text in colors you want.

Example:

```
procedure TForm1.StatusBar1DrawPanel(StatusBar: TStatusBar;
  Panel: TStatusPanel; const Rect: TRect);
begin
  if Panel = StatusBar.Panels[0] then begin
    StatusBar.Canvas.Font.Color := clRed;
    StatusBar.Canvas.TextOut(Rect.Left, Rect.Top, 'Panel - 0')
  end else begin
    StatusBar.Canvas.Font.Color := clGreen;
    StatusBar.Canvas.TextOut(Rect.Left, Rect.Top, 'Panel - 1');
  end;
end;
```

## Article #17720: Typecasting a PChar to a longint.

Question and Answer Database

FAQ2720D.txt    Typecasting a PChar to a longint.

Category       :Windows API

Platform       :All

Product        :All 32 bit

Question:

Many Windows functions claim to want PChar parameters in the documentation, but they are defined as requiring LongInts. Is this a bug?

Answer:

No, this is where "typecasting" is used. Typecasting allows you to fool the compiler into thinking that one type of variable is of another type for the ultimate in flexibility. The last parameter of the Windows API function SendMessage() is a good example. It is documented as requiring a long integer, but commonly requires a PChar for some messages (WM\_WININICHANGE). Generally, the variable you are typecasting from must be the same size as the variable type you are casting it to. In the SendMessage example, you could typecast a PChar as a longint, since both occupy 4 bytes of memory:

Example:

```
var
  s : array[0..64] of char;
begin
  StrCopy(S, 'windows');
  SendMessage(HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(@S));
end;
```

Pointers are the easiest to typecast, and are the most flexible since you can pass anything to the called procedure, and the most dangerous for the same reason. You can also use untyped variable parameters for convenience, although var parameters are really pointers behind the scenes.

Example:

```

type
  PBigArray = ^TBigArray;
  TBigArray = Array[0..65000] of char;

procedure ZeroOutPointerVariable(P : pointer; size : integer);
var
  i : integer;

begin
  for i := 0 to size - 1 do
    PBigArray(p)^[i] := #0;
  end;

procedure ZeroOutUntypedVariable(var v, size : integer);
var
  i : integer;

begin
  for i := 0 to size - 1 do
    TBigArray(v)[i] := #0;
  end;

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string[255];
  i : integer;
  l : longint;

begin
  s := 'Hello';
  i := 10;
  l := 2000;

  ZeroOutPointerVariable(@s, sizeof(s));
  ZeroOutPointerVariable(@i, sizeof(i));
  ZeroOutPointerVariable(@l, sizeof(l));

  s := 'Hello';
  i := 10;
  l := 2000;

  ZeroOutUntypedVariable(s, sizeof(s));
  ZeroOutUntypedVariable(i, sizeof(i));
  ZeroOutUntypedVariable(l, sizeof(l));

```

end;

## Article #17724: How do I use Paths and Geometric Pens?

Question and Answer Database

FAQ2724D.txt How do I use Paths and Geometric Pens?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I use Paths and Geometric Pens?

Answer:

You will need to call the Windows API function `ExtCreatePen()` to create a geometric pen style, and use the `Canvas.Handle` property to use the Windows Path functions.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  lb : TLogBrush;
begin
  lb.lbStyle := BS_SOLID;
  lb.lbColor := RGB(255, 0, 0);
  lb.lbHatch := 0;
  Form1.Canvas.Pen.Handle :=
    ExtCreatePen(PS_GEOMETRIC or
                PS_INSIDEFRAME or
                PS_ENDCAP_SQUARE or
                PS_JOIN_BEVEL,
                20,
                lb,
                0,
                nil);
  BeginPath(Form1.Canvas.Handle);
  Form1.Canvas.MoveTo(100, 30);
  Form1.Canvas.LineTo(200, 100);
  Form1.Canvas.LineTo(300, 30);
  EndPath(Form1.Canvas.Handle);
  StrokePath(Form1.Canvas.Handle);
```

```
Form1.Canvas.Pen.Width := 1;  
end;
```

## Article #17728: How do I convert a color to a shade of gray?

Question and Answer Database

FAQ2728D.txt How do I convert a color to a shade of gray?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I convert a color to a shade of gray?

Answer:

The following example shows how to convert an RGB color to the equivalent color of gray using the same method that a black and white television would render a color broadcast:

```
function RgbToGray(RGBColor : TColor) : TColor;
var
  Gray : byte;
begin
  Gray := Round((0.30 * GetRValue(RGBColor)) +
                (0.59 * GetGValue(RGBColor)) +
                (0.11 * GetBValue(RGBColor)));
  Result := RGB(Gray, Gray, Gray);
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Shape1.Brush.Color := RGB(255, 64, 64);
  Shape2.Brush.Color := RgbToGray(Shape1.Brush.Color);
end;
```

## Article #17732: Overcomming Stream read error.

Question and Answer Database

FAQ2732D.txt Overcomming Stream read error.

Category :VCL

Platform :All

Product :All 32 bit

Question:

When I start 16 Bit Delphi, I get the error "Stream Read Error" or "Invalid Stream Format". How can I get Delphi to start properly?

Answer:

This is usually caused by a corrupt "Delphi.dmt" file located in Delphi's \Bin\ directory. To replace the file, simply copy the file:

D:\DELPHI16\RUNIMAGE\Delphi\BIN\Delphi.DMT

from the CD to Delphi's \Bin\ directory, then clear the read only attribute from the file.

## Article #17736: Drawing in scale without using Windows Mapping Modes?

Question and Answer Database

FAQ2736D.txt Drawing in scale without using Windows Mapping Modes?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I draw in scale without using Windows Mapping Modes?

Answer:

You will need to use the Windows API function `GetDeviceCaps()` to retrieve the "logical" number of pixels per inch for the display in both the X and y directions, and multiply your coordinates by the returned values. Screen measurements are based on a concept of "Logical Pixels" and may not always reflect a true measurement. Printers should give satisfactory results when measurement are compared against a ruler. When printing, delete the lines for `GetDc()` and `ReleaseDc()` and simply pass `Printer.Canvas.Handle` to the `GetDeviceCaps()` function.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  dc : hdc;
  InchX : integer;
  InchY : integer;
begin
  dc := GetDc(0);
  InchX := GetDeviceCaps(dc, LOGPIXELSX);
  InchY := GetDeviceCaps(dc, LOGPIXELSY);
  ReleaseDC(0, dc);
  Form1.Canvas.Rectangle(Round(0 * InchX),
                        Round(0 * InchY),
                        Round(1.5 * InchX),
                        Round(1.5 * InchY));
end;
```

## Article #17740: How can I eject a CD-ROM in code?

Question and Answer Database

FAQ2740D.txt    How can I eject a CD-ROM in code?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How can I eject a CD-ROM in code?

Answer:

You can use the Windows API function `GetDriveType()` to test if the drive is a CD-ROM drive then use the `TMediaPlayer` (even if the CD is not an Audio CD) to eject the CD.

Example:

```
function IsDriveCD(Drive : char) : longbool;
var
  DrivePath : string;
begin
  DrivePath := Drive + ':\';
  result := LongBool(GetDriveType(PChar(DrivePath)) and DRIVE_CDROM);
end;

function EjectCD(Drive : char) : bool;
var
  mp : TMediaPlayer;
begin
  result := false;
  Application.ProcessMessages;
  if not IsDriveCD(Drive) then exit;
  mp := TMediaPlayer.Create(nil);
  mp.Visible := false;
  mp.Parent := Application.MainForm;
  mp.Shareable := true;
  mp.DeviceType := dtCDAudio;
  mp.FileName := Drive + ':\';
  mp.Open;
```

```
Application.ProcessMessages;  
mp.Eject;  
Application.ProcessMessages;  
mp.Close;  
Application.ProcessMessages;  
mp.free;  
result := true;  
end;  
  
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    if not EjectCD('D') then  
        ShowMessage('Not A CD Drive');  
end;
```

## Article #17744: Extracting RGB components of a color.

Question and Answer Database

FAQ2744D.txt     Extracting RGB components of a color.

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I extract the Red, Green, and Blue components of a given color?

Answer:

Use the Window API functions `GetRValue()`, `GetGValue()`, and `GetBValue()`.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Form1.Canvas.Pen.Color := clRed;
  Mem1.Lines.Add('Red := ' +
                 IntToStr(GetRValue(Form1.Canvas.Pen.Color)));
  Mem1.Lines.Add('Red := ' +
                 IntToStr(GetGValue(Form1.Canvas.Pen.Color)));
  Mem1.Lines.Add('Blue := ' +
                 IntToStr(GetBValue(Form1.Canvas.Pen.Color)));
end;
```

## Article #17748: How do I create an icon from a bitmap?

Question and Answer Database

FAQ2748D.txt     How do I create an icon from a bitmap?

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I create an icon from an bitmap?

Answer:

You must create two bitmaps, a mask bitmap (called the "AND" bitmap) and a image bitmap (called the XOR bitmap). You can pass the handles to the "AND" and "XOR" bitmaps to the Windows API function `CreateIconIndirect()` and use the returned icon handle in your application.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  IconSizeX : integer;
  IconSizeY : integer;
  AndMask : TBitmap;
  XOrMask : TBitmap;
  IconInfo : TIconInfo;
  Icon : TIcon;
begin
  {Get the icon size}
  IconSizeX := GetSystemMetrics(SM_CXICON);
  IconSizeY := GetSystemMetrics(SM_CYICON);

  {Create the "And" mask}
  AndMask := TBitmap.Create;
  AndMask.Monochrome := true;
  AndMask.Width := IconSizeX;
  AndMask.Height := IconSizeY;

  {Draw on the "And" mask}
```

```

AndMask.Canvas.Brush.Color := clWhite;
AndMask.Canvas.FillRect(Rect(0, 0, IconSizeX, IconSizeY));
AndMask.Canvas.Brush.Color := clBlack;
AndMask.Canvas.Ellipse(4, 4, IconSizeX - 4, IconSizeY - 4);

{Draw as a test}
Form1.Canvas.Draw(IconSizeX * 2, IconSizeY, AndMask);

{Create the "XOr" mask}
XOrMask := TBitmap.Create;
XOrMask.Width := IconSizeX;
XOrMask.Height := IconSizeY;

{Draw on the "XOr" mask}
XOrMask.Canvas.Brush.Color := ClBlack;
XOrMask.Canvas.FillRect(Rect(0, 0, IconSizeX, IconSizeY));
XOrMask.Canvas.Pen.Color := clRed;
XOrMask.Canvas.Brush.Color := clRed;
XOrMask.Canvas.Ellipse(4, 4, IconSizeX - 4, IconSizeY - 4);

{Draw as a test}
Form1.Canvas.Draw(IconSizeX * 4, IconSizeY, XOrMask);

{Create a icon}
Icon := TIcon.Create;
IconInfo.fIcon := true;
IconInfo.xHotspot := 0;
IconInfo.yHotspot := 0;
IconInfo.hbmMask := AndMask.Handle;
IconInfo.hbmColor := XOrMask.Handle;
Icon.Handle := CreateIconIndirect(IconInfo);

{Destroy the temporary bitmaps}
AndMask.Free;
XOrMask.Free;

{Draw as a test}
Form1.Canvas.Draw(IconSizeX * 6, IconSizeY, Icon);

{Assign the application icon}
Application.Icon := Icon;

{Force a repaint}
InvalidateRect(Application.Handle, nil, true);

```

```
{Free the icon}  
  Icon.Free;  
end;
```

## Article #17752: How do I create a bitmap from an icon?

Question and Answer Database

FAQ2752D.txt     How do I create a bitmap from an icon?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I create a bitmap from an icon?

Answer:

Use `Bitmap.Canvas.Draw` to draw the icon on the `Bitmap`.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  TheIcon : TIcon;
  TheBitmap : TBitmap;
begin
  TheIcon := TIcon.Create;
  TheIcon.LoadFromFile('C:\Program Files\Borland\IcoCur32\EARTH.ICO');
  TheBitmap := TBitmap.Create;
  TheBitmap.Height := TheIcon.Height;
  TheBitmap.Width := TheIcon.Width;
  TheBitmap.Canvas.Draw(0, 0, TheIcon);
  Form1.Canvas.Draw(10, 10, TheBitmap);
  TheBitmap.Free;
  TheIcon.Free;
end;
```

## Article #17756: Does my CD-ROM Drive contain an Audio CD?

Question and Answer Database

FAQ2756D.txt Does my CD-ROM Drive contain an Audio CD?  
Category :VCL  
Platform :All  
Product :All 32 bit

Question:

How can I tell if a given CD-ROM Drive contains an Audio CD?

Answer:

You can use the Windows API function `GetDriveType()` to test if the drive is a CD-ROM drive then use the Windows API function `GetVolumeInformation()` to test if the VolumeName is 'Audio CD'.

Example:

```
function IsAudioCD(Drive : char) : bool;
var
  DrivePath : string;
  MaximumComponentLength : DWORD;
  FileSystemFlags : DWORD;
  VolumeName : string;
begin
  Result := false;
  DrivePath := Drive + ':\';
  if GetDriveType(PChar(DrivePath)) <> DRIVE_CDROM then exit;
  SetLength(VolumeName, 64);
  GetVolumeInformation(PChar(DrivePath),
                      PChar(VolumeName),
                      Length(VolumeName),
                      nil,
                      MaximumComponentLength,
                      FileSystemFlags,
                      nil,
                      0);
  if lStrCmp(PChar(VolumeName), 'Audio CD') = 0 then result := true;
```

```
end;

function PlayAudioCD(Drive : char) : bool;
var
  mp : TMediaPlayer;
begin
  result := false;
  Application.ProcessMessages;
  if not IsAudioCD(Drive) then exit;
  mp := TMediaPlayer.Create(nil);
  mp.Visible := false;
  mp.Parent := Application.MainForm;
  mp.Shareable := true;
  mp.DeviceType := dtCDAudio;
  mp.FileName := Drive + ':';
  mp.Shareable := true;
  mp.Open;
  Application.ProcessMessages;
  mp.Play;
  Application.ProcessMessages;
  mp.Close;
  Application.ProcessMessages;
  mp.free;
  result := true;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  if not PlayAudioCD('D') then
    ShowMessage('Not an Audio CD');
end;
```

## Article #17759: How can I tell if the mouse is over my form?

Question and Answer Database

FAQ2759D.txt How can I tell if the mouse is over my form?

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I tell if the mouse is over my form?

Answer:

You can use the `GetCapture()` windows API function to capture the mouse. See the Windows documentation for additional information and limitations on mouse capturing.

Example:

```
procedure TForm1.FormDeactivate(Sender: TObject);
begin
    ReleaseCapture;
end;
```

```
procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X,
    Y: Integer);
begin
    If GetCapture = 0 then
        SetCapture(Form1.Handle);
    if PtInRect(Rect(Form1.Left,
                    Form1.Top,
                    Form1.Left + Form1.Width,
                    Form1.Top + Form1.Height),
                ClientToScreen(Point(x, y))) then
        Form1.Caption := 'Mouse is over form' else
        Form1.Caption := 'Mouse is outside of form';
end;
```

## Article #17763: Is my machine connected to the network.

Question and Answer Database

FAQ2763D.txt Is my machine connected to the network.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can my application tell if the machine is connected to a network under Windows 95?

Answer:

You can call the Windows API function `GetSystemMetrics()` and pass the `SM_NETWORK` flag.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  if GetSystemMetrics(SM_NETWORK) AND $01 = $01 then
    ShowMessage('Machine is attached to network') else
    ShowMessage('Machine is not attached to network');
end;
```

## Article #17767: Storing icons in your application for use at runtime?

Question and Answer Database

FAQ2767D.txt Storing icons in your application for use at runtime?

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I store icons in my application and use them at runtime?

Answer:

Create a resource file containing the icons you wish to use, then use the Windows API function LoadIcon(),

Example:

```
{ $R MYRES.RES }
```

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    h : hIcon;  
begin  
    h := LoadIcon(hInstance, 'ICON_1');  
    Application.Icon.Handle := h;  
    InvalidateRect(Application.Handle, nil, true);  
end;
```

## Article #17771: How do I draw using LoEnglish Mapping Modes?

Question and Answer Database

FAQ2771D.txt      How do I draw using LoEnglish Mapping Modes?

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I draw using LoEnglish Mapping Modes?

Answer:

You will need to call the Windows API functions `SetMapMode()` and `SetViewportOrgEx()` to change the mapping mode and the origin, then draw using coordinates that are oriented from the bottom of the canvas.

Notes:

- 1) Change the drawing mode back as soon as you are finished drawing, or you may get unexpected results.
- 2) Screen measurements are based on a concept of "Logical Pixels" and may not always reflect a true measurement. Printers should give satisfactory results when measurement are compared against a ruler.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  OldMapMode : integer;
  OldOrigin : TSize;
  Inch : integer;
begin
  Inch := 100;
  with Form1.Canvas do begin
    SetViewportOrgEx(Handle,
                     0,
                     ClientHeight,
                     @OldOrigin);
```

```
OldMapMode := SetMapMode(Handle,  
                           MM_LOENGLISH);  
Rectangle(1 * inch, 1 * inch,  
          0 * inch, 0 * inch);  
SetMapMode(Handle,  
            OldMapMode);  
SetViewportExtEx(Handle,  
                  OldOrigin.cx,  
                  OldOrigin.cy,  
                  nil);
```

end;

end;

## Article #17774: Non VCL Bitmap buffering

Question and Answer Database

FAQ2774D.txt Non VCL Bitmap buffering

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I create a non VCL memory display context and bitmap for additional drawing performance?

Answer:

You will need to use low level Windows API functions.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  dc : hdc;
  MemDc : hdc;
  MemBitmap : hBitmap;
  OldMemBitmap : hBitmap;
begin
  {Get the handle to the screen's dc}
  dc := GetDc(0);

  {Create and retrieve a handle to a memory dc based on the screen}
  MemDc := CreateCompatibleDc(dc);

  {Create a bitmap that is compatible with the display.}
  {Note: if you pass "MemDc" to CreateCompatibleBitmap()}
  {instead of "dc", you will get a monochrome bitmap!}
  MemBitmap := CreateCompatibleBitmap(dc, 100, 100);

  {Release the screen dc}
  ReleaseDc(0, dc);

  {Select the bitmap surface into the MemDc}
```

```
{remembering the default bitmap}
  OldMemBitmap := SelectObject(MemDc, MemBitmap);

{Draw on the MemoryDc}
  PatBlt(MemDc, 0, 0, 100, 100, WHITENESS);
  Ellipse(MemDc, 0, 0, 100, 100);

{Copy the MemDc to the Form Canvas}
  BitBlt(Form1.Canvas.Handle,
        100, 100,
        100, 100,
        MemDc,
        0, 0,
        SRCCOPY);

{Select the default bitmap back into the memory dc}
  SelectObject(MemDc, OldMemBitmap);

{Note: You can now use the memory bitmap handle with}
{functions such as GetDiBits()}

{Delete the Memory Bitmap}
  DeleteObject(MemBitmap);

{Delete the MemoryDc}
  DeleteDc(MemDc);

end;
```

## Article #17777: Positioning the caret in an edit control.

Question and Answer Database

FAQ2777D.txt    Positioning the caret in an edit control.

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I position the cursor (caret) in an edit or similar type control?

Answer:

You can use the Delphi SelStart() and SelectLength() methods.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    Edit1.SetFocus;
    {Move the caret to the second character}
    Edit1.SelStart := 2;
    {Do not select any text}
    Edit1.SelLength := 0;
end;
```

## Article #17780: Color problems in 256 color mode.

Question and Answer Database

FAQ2780D.txt    Color problems in 256 color mode.

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

When I am drawing graphics with my application in 256 color mode (or less), some pen and text colors do not match my brush colors.

### Answer:

Unless you are using a palette, Windows will attempt to convert pen and text colors to the nearest pure color available. You can determine the nearest pure color, a given color will map to, by calling the Windows API function `GetNearestColor()`. If you wish to use dithered colors for a pen, you can also set the pen style to the `psInsideFrame` style. When using this style, the pen draws lines within the frame of closed shapes that specify a bounding rectangle instead of centering the line over the shape. For the `psInsideFrame` style to have an effect, the pen width must be larger than 1 pixel.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var NearestColor : TColorRef;
begin
  Form1.Canvas.Brush.Color := RGB(143, 53, 22);
  Form1.Canvas.Pen.Color := RGB(143, 53, 22);
  Form1.Canvas.Pen.Width := 10;
  Form1.Canvas.Ellipse(10, 10, 100, 100);
  Form1.Canvas.Pen.Style := psInsideFrame;
  Form1.Canvas.Ellipse(10, 110, 100, 200);
  Mem1.Lines.Add(
    'The nearest displayable color to RGB(143, 53, 22) is:');
  NearestColor :=
```

```
    GetNearestColor(Form1.Canvas.Handle,  
                    RGB(143, 53, 22));  
Mem1.Lines.Add('Red := ' +  
               IntToStr(GetRValue(NearestColor)));  
Mem1.Lines.Add('Red := ' +  
               IntToStr(GetGValue(NearestColor)));  
Mem1.Lines.Add('Blue := ' +  
               IntToStr(GetBValue(NearestColor)));  
end;
```

## Article #17784: How do I recurse sub directories?

Question and Answer Database

FAQ2784D.txt    How do I recurse sub directories?

Category       :Object Pascal

Platform        :All

Product         :All 32 bit

Question:

How do I recurse sub directories?

Answer:

You will need to use Delphi's FindFirst() and FindNext() procedures to create a list of all the sub directories in a directory. For each sub directory, you will need to use Delphi's FindFirst() and FindNext() procedures, again to add any sub directories of the found directories to the list. Continue working down the list until all the directories have been processed.

Example:

```
procedure GetDirectories(const DirStr : string;
                        ListBox : TListBox);

var
  DirInfo: TSearchRec;
  r : Integer;
begin
  r := FindFirst(DirStr + '\*.*', FaDirectory, DirInfo);
  while r = 0 do begin
    Application.ProcessMessages;
    if ((DirInfo.Attr and FaDirectory = FaDirectory) and
        (DirInfo.Name <> '.') and
        (DirInfo.Name <> '..')) then
      ListBox.Items.Add(DirStr + '\' + DirInfo.Name);
    r := FindNext(DirInfo);
  end;
  SysUtils.FindClose(DirInfo);
end;

procedure GetFiles(const DirStr : string;
```

```
        ListBox : TListBox);
```

```
var
  DirInfo: TSearchRec;
  r : Integer;
begin
  r := FindFirst(DirStr + '\*.*', FaAnyfile, DirInfo);
  while r = 0 do begin
    Application.ProcessMessages;
    if ((DirInfo.Attr and FaDirectory <> FaDirectory) and
        (DirInfo.Attr and FaVolumeId <> FaVolumeID)) then
      ListBox.Items.Add(DirStr + '\' + DirInfo.Name);
    r := FindNext(DirInfo);
  end;
  SysUtils.FindClose(DirInfo);
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  i : integer;
begin
  ListBox1.Items.Clear;
  ListBox2.Items.Clear;
  ListBox1.Items.Add('C:\Delphi');
  GetDirectories('C:\Delphi', ListBox1);
  i := 1;
  while i < ListBox1.Items.Count do begin
    GetDirectories(ListBox1.Items[i], ListBox1);
    Inc(i);
  end;
end;
```

```
procedure TForm1.ListBox1Click(Sender: TObject);
```

```
begin
  ListBox2.Clear;
  GetFiles(ListBox1.Items[ListBox1.ItemIndex],
           ListBox2);
end;
```

Note: Recursing directories can take up a lot of memory. It is suggested that you consider creating a linked list or a temporary file to store your list entries instead of using a component (such as a Memo or StringList), as there are limits to the number of entries these components can have.

## Article #17787: Sending a file to the Windows Recycle Bin?

Question and Answer Database

FAQ2787D.txt Sending a file to the Windows Recycle Bin?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I send a file to the Windows Recycle Bin?

Answer:

Use the ShellAPI function SHFileOperation().

```
uses ShellAPI;
```

```
procedure SendToRecycleBin(FileName: string);
```

```
var
```

```
    SHF: TSHFileOpStruct;
```

```
begin
```

```
    with SHF do begin
```

```
        Wnd := Application.Handle;
```

```
        wFunc := FO_DELETE;
```

```
        pFrom := PChar(FileName);
```

```
        fFlags := FOF_SILENT or FOF_ALLOWUNDO;
```

```
    end;
```

```
    SHFileOperation(SHF);
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    SendToRecycleBin('c:\Download\Test.gif');
```

```
end;
```

## Article #17791: Justifying edit text.

Question and Answer Database

FAQ2791D.txt Justifying edit text.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I create a single line edit control that is right or centered justified?

Answer:

You can use a TMemo component, since the TEdit component does not directly support center and right justification. In addition, you will need to prevent the user from pressing the Enter, Ctrl-Enter, and a variety of arrow key combinations to prevent more than one line to be added to the memo. This can be accomplished by scanning the TMemo's text string for carriage return and line feed characters and deleting them during the TMemo's Change and KeyPress events. Optionally, you could replace any carriage returns with spaces to accommodate a multi-line paste operation.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    Memo1.Alignment := taRightJustify;
    Memo1.MaxLength := 24;
    Memo1.WantReturns := false;
    Memo1.WordWrap := false;
end;
```

```
procedure MultiLineMemoToSingleLine(Memo : TMemo);
var
    t : string;
begin
    t := Memo.Text;
    if Pos(#13, t) > 0 then begin
```

```
while Pos(#13, t) > 0 do
  delete(t, Pos(#13, t), 1);
while Pos(#10, t) > 0 do
  delete(t, Pos(#10, t), 1);
Memo.Text := t;
end;
end;

procedure TForm1.Memo1Change(Sender: TObject);
begin
  MultiLineMemoToSingleLine(Memo1);
end;

procedure TForm1.Memo1KeyPress(Sender: TObject; var Key: Char);
begin
  MultiLineMemoToSingleLine(Memo1);
end;
```

## Article #17798: Read and BlockRead file function failure in 32bit.

Question and Answer Database

FAQ2798D.txt Read and BlockRead file function failure in 32bit.

Category :Object Pascal

Platform :All

Product :All 32 bit

### Question:

When I port my code from 16 bit Delphi to 32 bit Delphi, the read and BlockRead function no longer seem to work correctly.

Is this a bug?

### Answer:

No. In 32 bit environments, records are automatically aligned on 32 bit boundaries when the \$A+ compiler directive is in effect. This is done by padding the record so each record will be located on a 32 bit boundary. If you are reading in data from a file containing non-aligned records, the data may not be read in correctly if you are using automatic record alignment. To turn off automatic record alignment for a given record type, use the "packed" record attribute. Globally turning off record alignment with the \$A- is not recommended, as much of the system requires record alignment to be on. The following example demonstrates the size difference of a packed and unpacked record.

### Example:

```
type TSomeRec = record
    w1 : word;
    b1 : byte;
    w2 : word;
end;
```

```
type TSomePackedRec = packed record
    w1 : word;
    b1 : byte;
    w2 : word;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  r : TSomeRec;
  s : TSomePackedRec;
begin
  ShowMessage(IntToStr(SizeOf(r))); {displays 6}
  ShowMessage(IntToStr(SizeOf(s))); {displays 5};
end;
```

## Article #17800: Record alignment in 32bit pascal.

Question and Answer Database

FAQ2800D.txt Record alignment in 32bit pascal.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

When I try to call a function in a DLL and pass a record, the field members are not aligned in the same way the dll expects. The DLL was constructed with a C compiler using record member alignment. How can I achieve a like record alignment with Delphi?

Answer:

The following example demonstrates padding a record to 32 bit boundaries. Adjustments will need to be made to interface with the compiler directives that were in place when the dll was built, as there are differing rules that can be in force during compile time in regards to record alignment. Some compilers may have options to (for instance) guarantee that every field is not only 32 bit aligned, but each field will also be located on an even 32 bit boundary. It may even be possible that the given compiler guarantees that the entire record is aligned to an even number of 32 bit "chunks".

```
type SomeAlignedRecord = {$IFDEF WIN32} packed {$ENDIF} record
    AByteField : byte;
    {add three bytes to align field to 32 bits}
    UnusedPaddingA : array[1..3] of byte;
    AWordField : word;
    {add two bytes to align field to 32 bits}
    UnusedPaddingB : array[1..2] of byte;
    ACharField : char;
    {add three bytes to align field to 32 bits}
    UnusedPaddingC : array[1..3] of byte;
    {align record to an even number of 32 bit chunks}
    FinalUnusedPadding : array[1..4] of byte;
end;
```

## Article #17804: Calling windows RegisterClass function.

Question and Answer Database

FAQ2804D.txt Calling windows RegisterClass function.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

I want to call the Windows RegisterClass() function, but I get the error "Incompatible types: 'TPersistentClass' and 'TWndClassA'" when compiling. How can I get around this?

Answer:

The RegisterClass() function is declared both in the Classes unit and the Windows unit. To call the Windows version, simply prefix the call with the unit name.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
  wc : TWndClass;
begin
  Windows.RegisterClass(wc)
end;
```

## Article #17807: Sending keystroke #255 to a windows control.

Question and Answer Database

FAQ2807D.txt      Sending keystroke #255 to a windows control.

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

Since the `keybd_event()` function only accepts key values up to 254, how can I send the keystroke #255 to a Windows control?

Answer:

This can be very useful for entering a value in an edit control for a foreign, symbol, or wingding character. The following example shows how to stuff the keyboard with the #255 character and direct it to any Window control. Note: This method should not be used to enter characters that could normally be processed by the `keybd_event()` function.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  KeyData : packed record
    RepeatCount : word;
    ScanCode : byte;
    Bits : byte;
  end;
begin
  {Let the button repaint}
  Application.ProcessMessages;
  {Set the focus to the window}
  Edit1.SetFocus;
  {Send a right so the char is added to the end of the line}
  SimulateKeyStroke(VK_RIGHT, 0);
  {Let the app get the message}
  Application.ProcessMessages;
  FillChar(KeyData, sizeof(KeyData), #0);
  KeyData.ScanCode := 255;
  KeyData.RepeatCount := 1;
```

```
SendMessage(Edit1.Handle, WM_KEYDOWN, 255,
    LongInt(KeyData));
KeyData.Bits := KeyData.Bits or (1 shl 30);
KeyData.Bits := KeyData.Bits or (1 shl 31);
SendMessage(Edit1.Handle, WM_KEYUP, 255,
    LongInt(KeyData));
KeyData.Bits := KeyData.Bits and not (1 shl 30);
KeyData.Bits := KeyData.Bits and not (1 shl 31);
SendMessage(Edit1.Handle, WM_CHAR, 255,
    LongInt(KeyData));
Application.ProcessMessages;
end;
```

## Article #17811: Freeing an object stored in a list.

Question and Answer Database

FAQ2811D.txt Freeing an object stored in a list.

Category :VCL

Platform :All

Product :All 32 bit

Question:

When I add an object to a TStrings component, how should I free the object?

Answer:

Simply call the objects free method. The following example attaches a icon object to the strings property of a listbox during the forms creation, and frees the icon when the form is destroyed.

Example:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  Icon: TIcon;
begin
  Icon := TIcon.Create;
  Icon.LoadFromFile('C:\Program Files\BorlandImages\CONSTRUC.ICO');
  ListBox1.Items.AddObject('Item 0', Icon);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  ListBox1.Items.Objects[0].Free;
end;
```

## Article #17834: Covert string of (zeros and ones) to binary.

Question and Answer Database

FAQ2834D.txt Covert string of (zeros and ones) to binary.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I convert a string of zeros and ones to the integer it represents?

Answer:

The following example shows how to convert a "BinaryString" to a long integer by using the shl (shift bits left) macro.

Example:

```
function BinStringToLongInt(BinString : string) : longint;
var
  i : integer;
  Num : longint;
begin
  Num := 0;
  for i := 1 to length(BinString) do
    if BinString[i] = '1' then
      Num := (Num shl 1) + 1 else
      Num := (Num shl 1);
  Result := Num;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Mem1.Lines.Add(IntToStr(BinStringToLongInt('11111111')));
end;
```

## Article #17836: Bad PC First port on line1

Question and Answer Database

FAQ2836D.txt - Bad PC First port on line1

Category :AS400  
Platform :All-32Bit  
Product :

Question:

What does the error "Bad PC First port on line1" installing with TCP/IP proptocol to Delphi/400?

Answer:

You must enter a port number in the the edit box labled "1st port pc". In the TCP/IP configuration for the AS/400, default values for the 1st pc port can read 5103, NB PC Port can read 5203.

## Article #17841: Linking an animated cursor to a resource file.

Question and Answer Database

FAQ2841D.txt Linking an animated cursor to a resource file.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How do I link an animated cursor to a resource file, then load it from my application?

Answer:

You will need to save the ani file into a res file as user data, (detailed in Borland's Technical information article Ti-3209 - "How to use a user defined resource"). Once you have successfully linked the resource to your application, you will need to save the data to a temporary file, then use the LoadImage command to get a handle to the animated cursor.

## Article #17849: Adding install to Win95 Add/Remove programs.

Question and Answer Database

FAQ2849D.txt Adding install to Win95 Add/Remove programs.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I get my program listed in the control panels  
"Add/Remove programs" applet?

Answer:

You can use Install Shield Express that ships with Delphi and C++ Builder, or you can add this in code using the TRegistry object to add a new key to the registry under the key:

```
HKEY_LOCAL_MACHINE\  
SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\  

```

The key that you add should be unique, and should reflect the name of your program: "My Program Name".

Under your new key, you will need to add two items: The name to display for your program in the control panel applet list, and the command line to your uninstall program:

Example:

```
uses Registry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    reg: TRegistry;
```

```
begin
```

```
    reg := TRegistry.Create;
```

```
    reg.RootKey := HKEY_LOCAL_MACHINE;
```

```
    reg.LazyWrite := false;
```

```
    reg.OpenKey(  
        'SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\MyProgam',
```

```
    true);  
reg.WriteString('DisplayName', 'My Program');  
reg.WriteString('UninstallString',  
  'C:\Program Files\Borland\Delphi 3\MyUninstall.exe UninstalMe');  
reg.CloseKey;  
reg.free;  
end;
```

In addition to uninstalling you application, your uninstall program should delete the registry keys you added in the previous example.

Example:

```
uses Registry;  
  
procedure TForm1.Button1Click(Sender: TObject);  
var  
  reg: TRegistry;  
begin  
  reg := TRegistry.Create;  
  reg.RootKey := HKEY_LOCAL_MACHINE;  
  reg.LazyWrite := false;  
  reg.DeleteKey(  
'SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\MyProgam');  
  reg.free;  
end;
```

## Article #17852: Query with a string does not work properly

Question and Answer Database

FAQ2852D.txt - Query with a string does not work properly

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

Question:

I am doing a Query against the 400 where I specify a string,  
example: `SELECT * FROM CUST WHERE CUSTNAME = "Sparky"`  
But it is not working properly. What am I doing wrong?

Answer:

The 400 likes Single Quotes and not double quotes.  
You should be doing:

```
SELECT * FROM CUST
WHERE CUSTNAME = 'Sparky'
```

## Article #17855: CO400INS library created, not CO400

Question and Answer Database

FAQ2855D.txt - CO400INS library created, not CO400

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

When I'm don installing Delphi/400 the CO400INS library created, instead of the CO400 library.

### Answer:

CO400INS is a temporary library for the installation of Delphi/400. At the conclusion of a normal install, the CO400 library has been installed and CO400INS has been removed. Early versions of ClientAccess data transfer and remote command functions may not work correctly and this can prevent the installation program from creating the CO400 library and transferring data. Check with IBM for the latest PTF's relating to data transfer and remote command functions.

## Article #17857: PtInRegion pixel function

Question and Answer Database

FAQ2857D.txt PtInRegion pixel function

Category :Windows API

Platform :All

Product :All 32 bit

### Question:

I am having trouble getting the Windows API function PtInRegion() to work correctly in Windows 3.1 and Windows 95 without generating an application error or GPF. What can I do to determine if a point is in a region reliably?

### Answer:

The Windows 3.1 and Windows 95 GDI heap is limited in regards to scan converting large and complex regions such as Ellipses, Polygons, and PolyPolygons. One "Brute Force" technique is to create an "in memory" monochrome bitmap and draw the required shape in black. You can then test to see if a given point in the bitmap is black or white. If the test pixel is black, then the given point is "in" the given region.

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  bm : TBitmap;
begin
  bm := TBitmap.Create;
  bm.Monochrome := true;
  bm.Height := 100;
  bm.Width := 100;
  bm.Canvas.Brush.Color := clWhite;
  bm.Canvas.FillRect(Rect(0, 0, 100, 100));
  bm.Canvas.Brush.Color := clBlack;
  bm.Canvas.Pen.Color := clBlack;
  bm.Canvas.Ellipse(10, 10, 90, 90);
  if bm.Canvas.Pixels[20, 20] = clBlack then
    ShowMessage('Point : (20, 20) is in region') else
```

```
ShowMessage('Point : (20, 20) is not in region');  
if bm.Canvas.Pixels[50, 50] = clBlack then  
    ShowMessage('Point : (50, 50) is in region') else  
    ShowMessage('Point : (50, 50) is not in region');  
bm.Free;  
end;
```

## Article #17861: How can I close the CD Tray in code?

Question and Answer Database

FAQ2861D.txt    How can I close the CD Tray in code?

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How can I close the CD Tray in code?

Answer:

Make a call to the MMSystem function `mciSendCommand` sending the `MCI_SET_DOOR_CLOSED` command.

Example:

```
uses MMSystem;

procedure CloseCD(Drive : char);
var
  mp : TMediaPlayer;
begin
  result := false;
  Application.ProcessMessages;
  mp := TMediaPlayer.Create(nil);
  mp.Visible := false;
  mp.Parent := Application.MainForm;
  mp.Shareable := true;
  mp.DeviceType := dtCDAudio;
  mp.FileName := Drive + ':';
  mp.Open;
  Application.ProcessMessages;
  mciSendCommand(mp.DeviceID,
  MCI_SET, MCI_SET_DOOR_CLOSED, 0);
  Application.ProcessMessages;
  mp.Close;
  Application.ProcessMessages;
  mp.free;
  result := true;
end;
```

end;

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    CloseCD('D');  
end;
```

## Article #17867: Creating a file association for my application?

Question and Answer Database

FAQ2867D.txt Creating a file association for my application?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I create a file association for my application?

Answer:

In Win32, create a new registry entry under the HKEY\_CLASSES\_ROOT root key that points to the file extension, the command line to invoke, and the icon to display. Under Win16, simply file extension and the command line to invoke in the [Extensions] sections of Win.ini.

Example:

uses

Registry, {For Win32}

IniFiles; {For Win16}

{For Win32}

procedure TForm1.Button1Click(Sender: TObject);

var

reg: TRegistry;

begin

reg := TRegistry.Create;

reg.RootKey := HKEY\_CLASSES\_ROOT;

reg.LazyWrite := false;

{Add Program Support}

reg.OpenKey('.bor\shell\open\command',  
true);

{Invoke the program passing the file name as the first parameter}

reg.WriteString('',

'C:\Program Files\Borland\Delphi 3\Project1.exe %1');

{Add Icon Display}

reg.CloseKey;

```
reg.OpenKey('.bor\DefaultIcon',
            true);
{Use the first icon in the executable to display}
reg.WriteString('',
                'C:\Program Files\Borland\Delphi 3\Project1.exe,0');
reg.CloseKey;
reg.free;
end;
```

```
{For Win16}
```

```
procedure TForm1.Button2Click(Sender: TObject);
```

```
var
    WinIni : TIniFile;
    WinIniFileName : array[0..MAX_PATH] of char;
    s : array[0..64] of char;
```

```
begin
    GetWindowsDirectory(WinIniFileName, sizeof(WinIniFileName));
    StrCat(WinIniFileName, '\win.ini');
    WinIni := TIniFile.Create(WinIniFileName);
    WinIni.WriteString('Extensions',
                      'bor',
                      'C:\PROGRA~1\BORLAND\DELPHI~1\PROJECT1.EXE ^.bor');
    WinIni.Free;
    StrCopy(S, 'Extensions');
    SendMessage(HWND_BROADCAST, WM_WININICHANGE,
                0, LongInt(@S));
end;
```

## Article #17869: How to move Client Objects to a different AS/400

Question and Answer Database

FAQ2869D.txt - How to move Client Objects to a different AS/400

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

Question:

How do I move Client Object to a different AS/400?

Answer:

Install ClientObjects/400 on the second machine.

On the old AS/400 run CO400UNS. CO400UNS will clear the validation key and provide a "Reference" to allow the ClientObjects/400 license to be transferred.

Get a new validation key from Inprise or the salesperson that provided the first validation key. To get this new key you will need to supply the "Reference" (provided by CO400UNS), the serial number and the model of the new AS/400.

Run CO400INS on the new AS/400 to enter the new key.

## Article #17877: 'Setup cannot find any system', using SNA Server

Question and Answer Database

FAQ2877D.txt - 'Setup cannot find any system', using SNA Server

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

I use SNA Server. When installing the AS/400 part of Delphi/400, the setup program displays error "Setup cannot find any system".

### Answer:

Check the configuration of SNA server on NT server :

For SNA server 2.11, verify the "APPC LU PROPERTIES" and select "Member of Default Outgoing local APPC lu pool".  
For SNA server 3.0, verify the "LOCAL APPC LUs" members, one of these must have the option "Member of Default Outgoing local APPC lu pool" selected.

## Article #17879: Detecting display changes.

Question and Answer Database

FAQ2879D.txt Detecting display changes.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How do I detect, and how should I handle dynamic changes in the display?

Answer:

To detect changes in the display, create a message handler to trap the WM\_DISPLAYCHANGE message. If you have a simple application, you may need to do little in response to this message. If your application makes use of graphics, you may want to restart the application, as there may be many changes to the system that may be difficult to overcome as the screen resolution, color depth and default fonts may change.

Here is an example of of a message handler:

```
type
  TForm1 = class(TForm)
    Button1: TButton;
  private
    { Private declarations }
    procedure WMDisplayChange(var Message: TMessage);
      message WM_DISPLAYCHANGE;
  public
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.WMDisplayChange(var Message: TMessage);  
begin  
  {Do Something here}  
  inherited;  
end;
```

FAQ2881D.txt Executing and application by extention.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I execute the application that is associated with a file extension?

Answer:

Use the ShellAPI function ShellExecute().

Example:

```
uses ShellAPI;

procedure TForm1.Button1Click(Sender: TObject);
var
  DocFileName : string;
  DocFileDir  : string;
begin
  DocFileName := 'C:\Download\somefile.htm';
  DocFileDir  := ExtractFileDir(DocFileName);
  ShellExecute(Form1.Handle,
               nil,
               pChar(DocFileName),
               nil,
               pChar(DocFileDir),
               SW_SHOWNORMAL);
end;
```

## Article #17883: Handling command line params with spaces

Question and Answer Database

FAQ2883D.txt Handling command line params with spaces

Category :Object Pascal

Platform :All

Product :All 32 bit

### Question:

When I pass a file name containing spaces to my application, ParamStr(1) only shows the part of the filename before the first space. How can I retrieve file names containing spaces?

### Answer:

Since the space character is a delimiter for ParamStr, you will need to add together all the parameters that are passed to your application (using the ParamCount variable), or access the entire paramstring via the CmdLine variable, and parse out any additional commands. The following example shows how to get the entire command line including any embedded spaces:

### Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  s := StrPas(CmdLine);
  {$IFDEF WIN32}
  Delete(s, 1, Pos(' ' , s) + 1);
  {$ENDIF}
  ShowMessage(s);
end;
```

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

Is it possible to create a form that accepts additional parameters for the create method?

Answer:

Simply replace the Create constructor to your form class to accept additional parameters.

Example:

```
unit Unit2;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs;
```

```
type
```

```
  TForm2 = class(TForm)
```

```
  private
```

```
    { Private declarations }
```

```
  public
```

```
    constructor CreateWithCaption(aOwner: TComponent;  
                                  aCaption: string);
```

```
    { Public declarations }
```

```
  end;
```

```
var
```

```
  Form2: TForm2;
```

```
implementation
```

```
{ $R *.DFM }
```

```
constructor TForm2.CreateWithCaption(aOwner: TComponent;  
                                     aCaption: string);
```

```
begin  
    Create(aOwner);  
    Caption := aCaption;  
end;
```

```
uses Unit2;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin  
    Unit2.Form2 :=  
        Unit2.TForm2.CreateWithCaption(Application, 'My Caption');  
    Unit2.Form2.Show;  
end;
```

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I retrieve a DOS environment variable such as the current path?

Answer:

You can make a call to the Windows API function `GetDOSEnvironment()` under Win16 or the `GetEnvironmentStrings()` function under Win32.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  p : pChar;
begin
  Mem1.Lines.Clear;
  Mem1.WordWrap := false;
  {$IFDEF WIN32}
  p := GetEnvironmentStrings;
  {$ELSE}
  p := GetDOSEnvironment;
  {$ENDIF}
  while p^ <> #0 do begin
    Mem1.Lines.Add(StrPas(p));
    inc(p, lStrLen(p) + 1);
  end;
  {$IFDEF WIN32}
  FreeEnvironmentStrings(p);
  {$ENDIF}
end;
```

Product :DelphiAS400,

### Question:

I just upgraded my AS/400 OS from V3R6 to V3R7 and now I am getting a "Protection Error" whenever I try to access the AS/400 using CO400 from Delphi.

### Answer:

The error is raised when the Delphi/400 is installed to the AS/400 more than once. Re-run the CO400INS program and re-enter your license key.

## Article #17895: Getting the Lowest common denominator.

Question and Answer Database

FAQ2895D.txt Getting the Lowest common denominator.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How do I convert two numbers representing a ratio to a string that represents a fraction of the lowest common denominator?

Answer:

The following example demonstrates a technique based on equations originally solved by Euclid in approx. 300 B.C. :

Example:

```
function GetFracStr(Num1 : integer;
                   Num2 : integer) : string;
var
  N1 : integer;
  N2 : integer;
  Tmp : integer;
begin
  if Num1 < Num2 then begin
    N1 := Num1;
    N2 := Num2;
  end else begin
    N1 := Num2;
    N2 := Num1;
  end;
  Tmp := N2 mod N1;
  while Tmp <> 0 do begin
    N2 := N1;
    N1 := Tmp;
    Tmp := N2 mod N1;
  end;
  result := IntToStr(Num1 div N1) + '/' + IntToStr(Num2 div N1);
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Memo1.Lines.Add(GetFracStr(2, 64));  
end;
```

## Article #17897: Delphi/400 requires QSECOFR login

Question and Answer Database

FAQ2897D.txt - Delphi/400 requires QSECOFR login

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

Question:

Why does the Client Objects AS/400 piece need to be installed by QSECOFR?

Answer:

Since QSECOFR uses the Security Officer profile, this user has access to all parts of the machine as well as all other user profiles. Delphi/400 needs access to specific parts of the AS/400 for the installation of their product. These areas on the 400 may be restricted to specific users due to security reasons, so it is required that you sign on as QSECOFR

## Article #17899: Placing multiple copies of a component on a form.

Question and Answer Database

FAQ2899D.txt Placing multiple copies of a component on a form.

Category :IDE

Platform :All

Product :All 32 bit

Question:

How can I paste multiple copies of a component onto a form from the component palette?

Answer:

Hold the Shift key down when you select the component from the palette. A blue outline will appear around the border of the component. Now click several times on the form in different locations. With each click, you will get a new copy of the component. To stop this action, single click on the original component on the component palette without holding the Shift key.

## Article #17901: How do I launch a control panel applet?

Question and Answer Database

FAQ2901D.txt    How do I launch a control panel applet?

Category       :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I launch a control panel applet?

Answer:

You can launch a control panel applet by calling WinExec to execute control.exe, passing the name of the control panel applet as a command line parameter. Applets files (.cpl) can be found in the Windows system directory. Note: Some of the applet files will not be found in the Windows system directory. Those applets can be executed simply by name.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    WinExec('C:\WINDOWS\CONTROL.EXE TIMEDATE.CPL',
           sw_ShowNormal);
    WinExec('C:\WINDOWS\CONTROL.EXE MOUSE',
           sw_ShowNormal);
    WinExec('C:\WINDOWS\CONTROL.EXE PRINTERS',
           sw_ShowNormal);
end;
```

## Article #17905: Integer to 'Binary String'

Question and Answer Database

FAQ2905D.txt Integer to 'Binary String'

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I convert an integer to a string of zeros and ones representing the binary values of the bits?

Answer:

The following example shows how to convert an integer to a "BinaryString" of zeros and ones by using the "shl" (shift bits left) macro to isolate the bits, and the "and" operator to test the bits.

Example:

```
function LongIntToBinString(BinValue : longint) : string;
```

```
var
  i : integer;
  s : string;
begin
  s := '';
  for i := 31 downto 0 do
    if (BinValue and (1 shl i)) <> 0 then
      s := s + '1' else
      s := s + '0';
  Result := s;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.Add(LongIntToBinString($FF));
end;
```

## Article #17907: Detecting PlugNPlay hardware changes?

Question and Answer Database

FAQ2907D.txt Detecting PlugNPlay hardware changes?

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I correctly detect PlugNPlay hardware changes?

Answer:

You should create a WM\_DEVICECHANGE message handler to detect changes in PlugNPlay hardware.

Example:

```
type
  TForm1 = class(TForm)
    Button1: TButton;
  private
    { Private declarations }
    procedure WMDeviceChange(var Message: TMessage);
      message WM_DEVICECHANGE;
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

const DBT_DEVICEARRIVAL = $8000;
const DBT_DEVICEQUERYREMOVE = $8001;
const DBT_DEVICEQUERYREMOVEFAILED = $8002;
const DBT_DEVICEREMOVEPENDING = $8003;
const DBT_DEVICEREMOVECOMPLETE = $8004;
```

```

const DBT_DEVICETYPESPECIFIC = $8005;
const DBT_CONFIGCHANGED = $0018;

procedure TForm1.WMDeviceChange(var Message: TMessage);
var
  s : string;
begin
{Do Something here}
  case Message.wParam of
    DBT_DEVICEARRIVAL :
      s := 'A device has been inserted and is now available';
    DBT_DEVICEQUERYREMOVE: begin
      s := 'Permission to remove a device is requested';
      ShowMessage(s);
      {True grants premission}
      Message.Result := integer(true);
      exit;
    end;
    DBT_DEVICEQUERYREMOVEFAILED :
      s := 'Request to remove a device has been canceled';
    DBT_DEVICEREMOVEPENDING :
      s := 'Device is about to be removed';
    DBT_DEVICEREMOVECOMPLETE :
      s := 'Device has been removed';
    DBT_DEVICETYPESPECIFIC :
      s := 'Device-specific event';
    DBT_CONFIGCHANGED :
      s:= 'Current configuration has changed'
  else s := 'Unknown Device Message';
end;
ShowMessage(s);
inherited;
end;

```

Question and Answer Database

FAQ2909D.txt Launching your default browser on a URL.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How do I start up and pass an URL to the default browser?

Answer:

Use the ShellAPI function ShellExecute.

Example:

```
uses ShellAPI;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
```

```
    ShellExecute(Form1.Handle,  
                nil,  
                'http://www.borland.com',  
                nil,  
                nil,  
                SW_SHOWNORMAL);
```

```
end;
```

## Article #17911: Creating a Win95 Shell icon application.

Question and Answer Database

FAQ2911D.txt     Creating a Win95 Shell icon application.

Category        :Windows API

Platform        :All

Product         :All 32 bit

Question:

How do I create a Delphi/C++ Builder application that runs in the system tray?

Answer:

This is done via the ShellAPI function `Shell_NotifyIcon()`. The following example shows how to create an application that uses this function. The example application shows a different icon in the system tray every second and shows the time in the title. The application responds to a right click of the mouse by showing a menu allowing the user to display a form or quit the application. Attempts to close the form result in the form hiding, but the tray application continues to run. Note that no task bar icon is shown for the form. To compile the application, you will need to create a form with a `TPopupMenu` and a `TTimer` component. You will also need to make modifications to the main project source file (`TrayIt.dpr`).

Example:

```
{TrayIt.dpr}
```

```
program TrayIt;
```

```
uses
```

```
  Windows,
```

```
  Forms,
```

```
  TrayIt1 in 'TrayIt1.pas' {Form1};
```

```
{$R *.RES}
```

```
begin
```

```
  Application.Initialize;
```

```
Application.ShowMainForm := False;
Application.CreateForm(TForm1, Form1);
ShowWindow(Application.Handle, SW_HIDE);
Application.Run;
end.
```

```
{TrayIt1.pas}
```

```
unit TrayIt1;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
Dialogs, Menus, ShellAPI, ExtCtrls;
```

```
type
```

```
TForm1 = class(TForm)
  PopupMenu1: TPopupMenu;
  Open1: TMenuItem;
  Exit1: TMenuItem;
  Timer1: TTimer;
  procedure FormCreate(Sender: TObject);
  procedure Open1Click(Sender: TObject);
  procedure Exit1Click(Sender: TObject);
  procedure FormClose(Sender: TObject; var Action: TCloseAction);
  procedure Timer1Timer(Sender: TObject);
```

```
private
```

```
{ Private declarations }
```

```
procedure WndProc(var Msg : TMessage); override;
```

```
public
```

```
{ Public declarations }
```

```
IconData : TNotifyIconData;
```

```
IconCount : integer;
```

```
end;
```

```
var
```

```
Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.WndProc(var Msg : TMessage);
```

```
var
```

```

    p : TPoint;
begin
    case Msg.Msg of
        WM_USER + 1:
            case Msg.lParam of
                WM_RBUTTONDOWN: begin
                    GetCursorPos(p);
                    PopupMenu1.Popup(p.x, p.y);
                end
            end;
        end;
    inherited;
end;

## Article #17915: Calculating a point using angles and distance

Question and Answer Database

FAQ2915D.txt     Calculating a point using angles and distance

Category     : Object Pascal

Platform     : All

Product      : All 32 bit

Question:

How do I calculate the x and y coordinates of a point that is at some distance and angle away?

Answer:

The following example shows how to convert a polar coordinate to a rectangular coordinate:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Angle : Double;
  x : Double;
  y : Double;
  Distance : Double;
  Radians : Double;
begin
  Distance := 100;
  Angle := 270;
  Radians := Angle * DegToRad;
  x := Round(Distance * Cos(Radians));
  y := Round(Distance * Sin(Radians));
  ShowMessage(FloatToStr(x) + ' ' + FloatToStr(y));
end;
```

## Article #17917: Calculating an angle from two points

Question and Answer Database

FAQ2917D.txt     Calculating an angle from two points

Category     : Object Pascal

Platform     : All

Product      : All 32 bit

Question:

How can I tell the given angle expressed by two points?

Answer:

The following example shows how to tell the angle of a given point from the coordinate 0, 0. In this example, the caption of the form shows the current point and angle from the center of the form. The y coordinates are inverted to show a more natural north orientation where north is directly up.

Example:

```
const RADTODEG = 180 / Pi;

function AngleOfPt(pt : TPoint) : double;
begin
  Result := 0;
  if ((Pt.x = 0) and (Pt.y < 0)) then
    Result := 270 else
  if ((Pt.x = 0) and (Pt.y > 0)) then
    Result := 90 else
  if ((Pt.x > 0) and (Pt.y >= 0)) then
    Result := ArcTan(Pt.y / Pt.x) * RADTODEG else
  if ((Pt.x < 0) And (Pt.y > 0)) then
    Result := 180 - (ArcTan(Pt.y / Abs(Pt.x))* RADTODEG) else
  if ((Pt.x < 0) And (Pt.y <= 0)) then
    Result := 180 + (ArcTan(Pt.y / Pt.x) * RADTODEG) else
  if ((Pt.x > 0) and (Pt.y < 0)) then
    Result := 360 - (ArcTan(Abs(Pt.y) / Pt.x) * RADTODEG) else
  Result:=0;
end;
```

```
procedure TForm1.FormMouseMove(Sender: TObject; Shift:
TShiftState; X, Y: Integer);
var
  XYMove : TPoint;
  RotateAngle : Double;
begin
  XYMove := (Point(x - (Form1.Width div 2),
                  (Form1.Height div 2) - y));
  RotateAngle :=
    AngleOfPt(XYMove);
  Form1.Caption := IntToStr(XYMove.x) + #32 +
                  IntToStr(XYMove.y) + ' = ' +
                  FloatToStr(RotateAngle);
end;
```

```
procedure TForm1.FormPaint(Sender: TObject);
begin
  Form1.Canvas.MoveTo(Form1.Width div 2,
                      0);
  Form1.Canvas.LineTo(Form1.Width div 2,
                      Form1.Height);
  Form1.Canvas.MoveTo(0,
                      Form1.Height div 2);
  Form1.Canvas.LineTo(Form1.Width,
                      Form1.Height div 2);
end;
```

```

## Article #17921: Changing the printer port in code.

Question and Answer Database

FAQ2921D.txt Changing the printer port in code.

Category :Windows API

Platform :All

Product :All 32 bit

Question:

How can I change the port a given printer will use in code?

Answer:

You can use the SetPrinter method of TPrinter to change the port. The following example demonstrates changing the port to print to a file.

Example:

```
uses Printers;
```

```
{ $IFDEF WIN32 }  
const MAX_PATH = 144;  
{ $ENDIF }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    pDevice : pChar;
```

```
    pDriver : pChar;
```

```
    pPort   : pChar;
```

```
    hDMode  : THandle;
```

```
    PMode   : PDEVMODE;
```

```
begin
```

```
    if PrintDialog1.Execute then begin
```

```
        GetMem(pDevice, cchDeviceName);
```

```
        GetMem(pDriver, MAX_PATH);
```

```
        GetMem(pPort, MAX_PATH);
```

```
        Printer.GetPrinter(pDevice, pDriver, pPort, hDMode);
```

```
        Printer.SetPrinter(pDevice, PDriver, 'FILE:', hDMode);
```

```
        FreeMem(pDevice, cchDeviceName);
```

```
        FreeMem(pDriver, MAX_PATH);
```

```
FreeMem(pPort, MAX_PATH);
Printer.BeginDoc;
Printer.Canvas.TextOut(100, 100, 'Delphi Is RAD!');
Printer.EndDoc;
end;
end;
```

## Article #17923: TCombobox drop down size.

Question and Answer Database

FAQ2923D.txt TCombobox drop down size.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I tell the actual size of a TComboBox in it's dropped down state before it drops down?

Answer:

During the FormShow event, send the combo box a CB\_SHOWDROPDOWN message twice, once to drop it down, and once to retract it. Then send a CB\_GETDROPPEDCONTROLRECT message, passing the address of a TRect. When the SendMessage call returns, the TRect will contain the rectangle that would enclose the ComboBox in it's dropped down state, relative to the screen. You can then call ScreenToClient to convert the TRect's coordinates to be relative to the client area of the form.

Example:

```
var
  R : TRect;

procedure TForm1.FormShow(Sender: TObject);
var
  T : TPoint;
begin
  SendMessage(ComboBox1.Handle,
              CB_SHOWDROPDOWN,
              1,
              0);
  SendMessage(ComboBox1.Handle,
              CB_SHOWDROPDOWN,
              0,
              0);
  SendMessage(ComboBox1.Handle,
              CB_GETDROPPEDCONTROLRECT,
```

```
        0,  
        LongInt(@r));  
t := ScreenToClient(Point(r.Left, r.Top));  
r.Left := t.x;  
r.Top := t.y;  
t := ScreenToClient(Point(r.Right, r.Bottom));  
r.Right := t.x;  
r.Bottom := t.y;  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Form1.Canvas.Rectangle(r.Left,  
                           r.Top,  
                           r.Right,  
                           r.Bottom );  
end;
```

## Article #17928: Finding distance between two points.

Question and Answer Database

FAQ2928D.txt Finding distance between two points.

Category :Object Pascal

Platform :All

Product :All 32 bit

Question:

How can I find the distance between two points?

Answer:

The following example shows how to tell the distance between two points. In this example, the caption of the form shows the current point and distance from the center of the form. The y coordinates are inverted to show a more natural north orientation where north is directly up.

Example:

```
function Distance(Pt1 : TPoint;
                  Pt2 : TPoint) : Double;
var
  dx : LongInt;
  dy : LongInt;
begin
  dx:= pt1.x - pt2.x;
  dy:= pt1.y - pt2.y;
  Result := Sqrt((Dx * Dx) + (Dy * Dy));
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift:
TShiftState; X, Y: Integer);
var
  Pt1 : TPoint;
  Pt2 : TPoint;
  Dist : Double;
begin
  Pt1.x := Form1.Width div 2;
  Pt1.y := Form1.Height div 2;
```

```
Pt2.x := x;
Pt2.y := y;
Dist := Distance(Pt1, Pt2);
Form1.Caption := IntToStr(Pt2.x - Pt1.x) + #32 +
                 IntToStr(Pt1.y - Pt2.y) + ' = ' +
                 FloatToStr(Dist);
end;
```

```
procedure TForm1.FormPaint(Sender: TObject);
begin
  Form1.Canvas.MoveTo(Form1.Width div 2,
                      0);
  Form1.Canvas.LineTo(Form1.Width div 2,
                      Form1.Height);
  Form1.Canvas.MoveTo(0,
                      Form1.Height div 2);
  Form1.Canvas.LineTo(Form1.Width,
                      Form1.Height div 2);
end;
```

```
procedure TForm1.FormResize(Sender: TObject);
begin
  Invalidate;
end;
```

## Article #17930: Determining if an object supports a property.

Question and Answer Database

FAQ2930D.txt Determining if an object supports a property.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I tell if a given object has a given property at runtime?

Answer:

The following example shows how to determine if an object has a property available, and if so, how to change the property:

```
function HasProperty(Obj : TObject;
                    Prop : string) : PPropInfo;
begin
    Result := GetPropInfo(Obj.ClassInfo, Prop);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
    p : pointer;
begin
    p := HasProperty(Button1, 'Color');
    if p <> nil then
        SetOrdProp(Button1, p, clRed) else
        ShowMessage('Button has no color property');

    p := HasProperty(Label1, 'Color');
    if p <> nil then
        SetOrdProp(Label1, p, clRed) else
        ShowMessage('Label has no color property');

    p := HasProperty(Label1.Font, 'Color');
    if p <> nil then
        SetOrdProp(Label1.Font.Color, p, clBlue) else
        ShowMessage('Label.Font has no color property');
end;
```

## Article #17932: Determining if a combobox is in dropped state.

Question and Answer Database

FAQ2932D.txt Determining if a combobox is in dropped state.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I determine if a ComboBox is in a dropped down state?

Answer:

Send a CB\_GETDROPPEDSTATE message to the ComboBox.

Example:

```
if SendMessage(ComboBox1.Handle,  
               CB_GETDROPPEDSTATE,  
               0,  
               0) = 1 then begin  
{do something}  
end;
```

## Article #17934: How do I plot a line?

Question and Answer Database

FAQ2934D.txt    How do I plot a line?

Category        :VCL

Platform        :All

Product         :All 32 bit

Question:

How do I plot a line?

Answer:

The easiest way to step along each point in a line segment is to call the Windows API function `LineDDA()`. `LineDDA()` takes the x and y start and end points of the line you wish to plot, and the address of a function in your program, and calls this function for each pixel that needs to be drawn. `LineDDA()` accepts an additional parameter "LParam" that gets passed back to your function each time it is called. The value of LParam can be anything you wish, and is useful for passing handles and pointers. Some typecasting of this parameter may be necessary to achieve the functionality you desire.

The following example shows how to plot a line from 10,10 to 100,100, and draw a circle along the line if the x coordinate of the pixel position is an even multiple of 10.

Example:

```
procedure DDAProc(x : integer;
                 y : integer;
                 LParam : LongInt)
{$IFDEF WIN32} stdcall; {$ELSE} ; export; {$ENDIF}
begin
  if x mod 10 = 0 then
    TCanvas(LParam).Ellipse(x - 10,
                           y - 10,
                           x + 10,
                           y + 10);
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  LineDDA(10, 10,
    100, 100,
    @DDAProc,
    {$IFDEF WIN32}
    LongInt(Form1.Canvas)
    {$ELSE}
    Form1.Canvas
    {$ENDIF}
  );
end;
```

## Article #17936: Moving a control at runtime with the mouse.

Question and Answer Database

FAQ2936D.txt Moving a control at runtime with the mouse.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I move a control at runtime using the mouse?

Answer:

You can trap the OnMouseDown event, remembering the x and y coordinates of the mouse and set the mouse capture. You can then track mouse movements with the OnMouseMove event, moving the control until the OnMouseUp event is fired. You then will want to place the control in it's final position and release capture of the mouse.

The following example shows how to move a TButton component around on the form using the mouse. The movement is initiated by the user holding down the control key when the mouse button is activated.

Example:

type

```
TForm1 = class(TForm)
  Button1: TButton;
  procedure Button1MouseDown(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
  procedure Button1MouseMove(Sender: TObject; Shift: TShiftState; X,
    Y: Integer);
  procedure Button1MouseUp(Sender: TObject; Button:
    TMouseButton; Shift: TShiftState; X, Y: Integer);
private
  { Private declarations }
public
  { Public declarations }
  MouseDownSpot : TPoint;
```

```

    Capturing : bool;
end;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.Button1MouseDown(Sender: TObject;
Button: TMouseButton; Shift: TShiftState; X, Y: Integer);
begin
    if ssCtrl in Shift then begin
        SetCapture(Button1.Handle);
        Capturing := true;
        MouseDownSpot.X := x;
        MouseDownSpot.Y := Y;
    end;
end;

procedure TForm1.Button1MouseMove(Sender: TObject;
Shift: TShiftState; X, Y: Integer);
begin
    if Capturing then begin
        Button1.Left := Button1.Left - (MouseDownSpot.x - x);
        Button1.Top := Button1.Top - (MouseDownSpot.y - y);
    end;
end;

procedure TForm1.Button1MouseUp(Sender: TObject; Button:
TMouseButton; Shift: TShiftState; X, Y: Integer);
begin
    if Capturing then begin
        ReleaseCapture;
        Capturing := false;
        Button1.Left := Button1.Left - (MouseDownSpot.x - x);
        Button1.Top := Button1.Top - (MouseDownSpot.y - y);
    end;
end;

```

## Article #17938: Debugging CORBA clients and servers

Question and Answer Database

FAQ2938D.txt :Debugging CORBA clients and servers

Category :CORBA

Platform :Win95/NT

Product :

Question:

How do I debug a CORBA client and server at the same time?

Answer:

You will need two instances of Delphi 4. One will be running and debugging the server, the other will be running and debugging the client. Always make sure that you start the server before you start the client, and always make sure you shut all clients down before you shut the server down, otherwise you may get unpredictable results.

## Article #17940: Placing a grid in edit mode programatically.

Question and Answer Database

FAQ2940D.txt Placing a grid in edit mode programatically.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I programmatically place a grid into edit mode and move the cursor to a predetermined position in the edit box?

Answer:

Place the grid in editor mode, then get a handle to the edit box and send a EM\_SETSEL message, passing the initial position where you want the cursor to appear, and the position of the ending selection (if you wish to highlight text).

The following example sets the cursor to the second character in the edit control, and does not select any text.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  h : THandle;
begin
  Application.ProcessMessages;
  DbGrid1.SetFocus;
  DbGrid1.EditorMode := true;
  Application.ProcessMessages;
  h := Windows.GetFocus;
  SendMessage(h, EM_SETSEL, 2, 2);
end;
```

## Article #17942: APPC LU NAME ARE INVALID OR NOT FOUND

Question and Answer Database

FAQ2942D.txt - APPC LU NAME ARE INVALID OR NOT FOUND

Category :AS400  
Platform :All-32Bit  
Product :

Question:

How come I am getting "APPC LU NAME ARE INVALID OR NOT FOUND" when running Delphi/400.

Answer:

Reasons for this error can be:

The router was not signed on with QSECOFR authority during the install.

ClientObjects/400 is not installed to the AS/400

You are using a TCP/IP transport to use the SNA version of ClientObjects/400 or you're using an SNA router in combination with the TCP/IP version of ClientObjects/400.

If you're using SNA Server: the server is not started.

If you're using SNA Server: In the SNA Server Admin application, LU Properties, "Member Default Outgoing LU Pool" check box must be selected.

If you're using TCP/IP: TCP/IP is not started on the AS/400 (STRTCP command on the AS/400).

If you're using TCP/IP: The subsystem is not started on the AS/400 (STRSBS CO400/CO400TCP).

## Article #17944: Trapping messages in non client area of a form.

Question and Answer Database

FAQ2944D.txt Trapping messages in non client area of a form.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How can I trap messages in the non client areas of my form, such as the title bar?

Answer:

Create a message handler for one of the variety of WM\_NC (non client) messages available to trap. (search the Windows API help file for WM\_NC). This example shows how to track mouse movement in all of the non client areas of the form.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
  Dialogs, StdCtrls;
```

```
type
```

```
  TForm1 = class(TForm)
```

```
  private
```

```
    procedure WMNCMOUSEMOVE(var Message: TMessage);
```

```
    message WM_NCMOUSEMOVE;
```

```
    { Private declarations }
```

```
  public
```

```
    { Public declarations }
```

```
  end;
```

```
var
```

```
  Form1: TForm1;
```

implementation

{ \$R \*.DFM }

```
procedure TForm1.WMNCMOUSEMOVE(var Message: TMessage);
var
  s : string;
begin
  case Message.wParam of
    HTERROR : s := 'HTERROR';
    HTTRANSPARENT : s := 'HTTRANSPARENT';
    HTNOWHERE : s := 'HTNOWHERE';
    HTCLIENT : s := 'HTCLIENT';
    HTCAPTION : s := 'HTCAPTION';
    HTSYSTEMMENU : s := 'HTSYSTEMMENU';
    HTSIZE : s := 'HTSIZE';
    HTMENU : s := 'HTMENU';
    HTHSCROLL : s := 'HTHSCROLL';
    HTVSCROLL : s := 'HTVSCROLL';
    HTMINBUTTON : s := 'HTMINBUTTON';
    HTMAXBUTTON : s := 'HTMAXBUTTON';
    HTLEFT : s := 'HTLEFT';
    HTRIGHT : s := 'HTRIGHT';
    HTTOP : s := 'HTTOP';
    HTTOPLEFT : s := 'HTTOPLEFT';
    HTTOPRIGHT : s := 'HTTOPRIGHT';
    HTBOTTOM : s := 'HTBOTTOM';
    HTBOTTOMLEFT : s := 'HTBOTTOMLEFT';
    HTBOTTOMRIGHT : s := 'HTBOTTOMRIGHT';
    HTBORDER : s := 'HTBORDER';
    HTOBJECT : s := 'HTOBJECT';
    HTCLOSE : s := 'HTCLOSE';
    HTHELP : s := 'HTHELP';
    else s := '';
  end;
  Form1.Caption := s;
  Message.Result := 0;
end;

end.
```

## Article #17946: Creating a PolyPolygon using a point array.

Question and Answer Database

FAQ2946D.txt Creating a PolyPolygon using a point array.

Category :VCL

Platform :All

Product :All 32 bit

Question:

How do I create a PolyPolygon using a point array as shown in the example of Polygon?

Answer:

Polygon is a method of TCanvas, and has been adapted to use a dynamic point array as a parameter. The PolyPolygon() function is a Windows GDI function and requires a pointer to a point array.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  PtArray : array[0..9] of TPOINT;
  PtCounts : array[0..1] of integer;
begin
  PtArray[0] := Point(0, 0);
  PtArray[1] := Point(0, 100);
  PtArray[2] := Point(100, 100);
  PtArray[3] := Point(100, 0);
  PtArray[4] := Point(0, 0);
  PtCounts[0] := 5;
  PtArray[5] := Point(25, 25);
  PtArray[6] := Point(25, 75);
  PtArray[7] := Point(75, 75);
  PtArray[8] := Point(75, 25);
  PtArray[9] := Point(25, 25);
  PtCounts[1] := 5;
  PolyPolygon(Form1.Canvas.Handle,
              PtArray,
              PtCounts,
```

## Article #17948: Converting a RGB color to a CMYK color

Question and Answer Database

FAQ2948D.txt - Converting a RGB color to a CMYK color

Category :Printing  
Platform :All  
Product :

Question:

How do I convert an RGB color to a CMYK color?

Answer:

The following functions RGBTOCMYK() and CMYKTORGB() demonstrate how to convert between RGB and CMYK color spaces. Note: There is a direct relationship between RGB colors and CMY colors. In a CMY color, black tones are achieved by printing equal amounts of Cyan, Magenta, and Yellow ink. The black component in a CMY color is achieved by reducing the CMY components by the minimum of (C, M, and Y) and substituting pure black in its place producing a sharper print and using less ink. Since it is possible for a user to boost the C,M and Y components where boosting the black component would have been preferable, a ColorCorrectCMYK() function is provided to achieve the same color by reducing the C, M and Y components, and boosting the K component.

Example:

```
procedure RGBTOCMYK(R : byte;  
                   G : byte;  
                   B : byte;  
                   var C : byte;  
                   var M : byte;  
                   var Y : byte;  
                   var K : byte);  
  
begin  
  C := 255 - R;  
  M := 255 - G;  
  Y := 255 - B;
```

```

if C < M then
  K := C else
  K := M;
if Y < K then
  K := Y;
if k > 0 then begin
  c := c - k;
  m := m - k;
  y := y - k;
end;
end;

```

```

procedure CMYKTORGB(C : byte;
                   M: byte;
                   Y : byte;
                   K : byte;
                   var R : byte;
                   var G : byte;
                   var B : byte);

```

```

begin
  if (Integer(C) + Integer(K)) < 255 then
    R := 255 - (C + K) else
    R := 0;
  if (Integer(M) + Integer(K)) < 255 then
    G := 255 - (M + K) else
    G := 0;
  if (Integer(Y) + Integer(K)) < 255 then
    B := 255 - (Y + K) else
    B := 0;
end;

```

```

procedure ColorCorrectCMYK(var C : byte;
                           var M : byte;
                           var Y : byte;
                           var K : byte);

```

```

var
  MinColor : byte;
begin
  if C < M then
    MinColor := C else
    MinColor := M;
  if Y < MinColor then
    MinColor := Y;
  if MinColor + K > 255 then
    MinColor := 255 - K;

```

```

    C := C - MinColor;
    M := M - MinColor;
    Y := Y - MinColor;
    K := K + MinColor;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
    R : byte;
    G : byte;
    B : byte;
    C : byte;
    M : byte;
    Y : byte;
    K : byte;
begin
    R := 151;
    G := 81;
    B := 55;
    Mem1.Lines.Add('R = ' + IntToStr(R));
    Mem1.Lines.Add('G = ' + IntToStr(G));
    Mem1.Lines.Add('B = ' + IntToStr(B));

## Article #17952: Metafile fonts and the VCL

Question and Answer Database

FAQ2952D.txt Metafile fonts and the VCL

Category :VCL

Platform :All

Product :All 32 bit

### Question:

Sometimes, some text in a metafile I display from my application comes up in the wrong font. The file displays properly in xyz Graphics program. Is this a bug in the VCL?

### Answer:

No. The VCL simply wraps standard Windows functions for displaying metafiles. As the metafile is scaled, the font width and height are scaled as well. Many times, the Windows font mapper will simply substitute a different font that the font that was originally selected in an attempt to satisfy the request. This can also be seen in many graphics programs if you arbitrarily scale the metafile in different directions. Note that some "hi end" graphic programs actually read the metafile record by record, bypassing the Windows GDI entirely to overcome the effects of the Windows font mapper.

## Article #17958: Error 'There are no fonts installed'.

Question and Answer Database

FAQ2958D.txt     Error 'There are no fonts installed'.

Category        :VCL

Platform        :All

Product         :All 32 bit

### Question:

When I execute the FontDialog with the Device property set to fdBoth or fdPrinter, I get an error "There are no fonts installed".

### Answer:

This setting should show fonts that are compatible with either the Printer or both the Printer and the Screen. The following is an example of calling the Windows ChooseFont dialog directly to provide a list of fonts that are compatible with both the screen and the printer:

### Example:

```
uses
  Printers,
  CommDlg;

procedure TForm1.Button1Click(Sender: TObject);
var
  cf : TChooseFont;
  lf : TLogFont;
  tf : TFont;
begin
  if PrintDialog1.Execute then begin
    GetObject(Form1.Canvas.Font.Handle,
              sizeof(lf),
              @lf);
    FillChar(cf, sizeof(cf), #0);
    cf.lStructSize := sizeof(cf);
    cf.hWndOwner := Form1.Handle;
    cf.hdc := Printer.Handle;
    cf.lpLogFont := @lf;
```

```
cf.iPointSize := Form1.Canvas.Font.Size * 10;
cf.Flags := CF_BOTH or
           CF_INITTOLOGFONTSTRUCT or
           CF_EFFECTS or
           CF_SCALABLEONLY or
           CF_WYSIWYG;
cf.rgbColors := Form1.Canvas.Font.Color;
if ChooseFont(cf) <> false then begin
  tf := TFont.Create;
  tf.Handle := CreateFontIndirect(lf);
  tf.Color := cf.RgbColors;
  Form1.Canvas.Font.Assign(tf);
  tf.Free;
  Form1.Canvas.TextOut(10, 10, 'Test');
end;
end;
end;
```

## Article #17962: Making the drop-down list appear faster

Question and Answer Database

FAQ2962D.txt Making the drop-down list appear faster

Category :Database/VCL

Platform :All

Product :All 32 bit

Question:

How do I get the drop-down list (pick list) to appear faster?  
I don't want to have to click 4 times every single time.

Answer:

In your OnCellClick event handler for your TDBGrid, do this:

```
keybd_event(VK_F2,0,0,0);  
keybd_event(VK_F2,0,KEYEVENTF_KEYUP,0);  
keybd_event(VK_MENU,0,0,0);  
keybd_event(VK_DOWN,0,0,0);  
keybd_event(VK_DOWN,0,KEYEVENTF_KEYUP,0);  
keybd_event(VK_MENU,0,KEYEVENTF_KEYUP,0);
```

This is the same as pressing F2 followed by Alt+DownArrow.

## Article #17964: Why isn't a network install of Delphi 3 supported?

Question and Answer Database

FAQ2964D.txt Why isn't a network install of Delphi 3 supported?

Category :Install Issues

Platform :All

Product :Delphi 3.x

Question:

Why isn't a network install of Delphi 3 supported?

Answer:

Delphi 3 was not designed to be installed on a network. Borland makes no claims that a network install of Delphi 3 will work.

It may work for some users if all work machines install Delphi 3 to the same location on the network. This requires many rights, including:

- \* Writing shared DLLs and OCXs to NT4's System32 directory (usually C:\WinNT\System32)
- \* Writing registry entries to HKEY\_LOCAL\_MACHINE
- \* Writing registry entries to HKEY\_CURRENT\_USER
- \* Writing registry entries to HKEY\_CLASSES\_ROOT (part of registering OCXs)

Delphi 3 expects all shared DLLs, packages and OCXs to be locally installed.

Delphi 3 expects all registry entries to be local.

Many problems may arise when trying to install Delphi 3 on a network. Possibly the most important one is the network software and hardware itself. Unforeseen problems may occur with any network configuration.

For more information, please see the TI entitled "Installing and

using Delphi 3 under NT4".

## Article #17966: Getting the summary function to work

Question and Answer Database

FAQ2966D.txt Getting the summary function to work

Category :Quick Reports

Platform :All

Product :All 32 bit

Question:

I cannot get the summary function to work? What's wrong?

Answer:

Most likely you have forgot to set the Master property. Master should be pointed to the QuickRep or QRSubDetail component you want to base the aggregation upon.

## Article #17968: Adding sums of fields

Question and Answer Database

FAQ2968D.txt Adding sums of fields

Category :Quick Reports

Platform :All

Product :All 32 bit

Question:

I want to sum several fields and then sum those sums -  
how do I do this?

Answer:

Just create a entire new sum expression, adding all  
the fields together:

```
QRExpr1.Expression := Sum(Field1);  
QRExpr2.Expression := Sum(Field2);  
QRExpr3.Expression := Sum(Field1+Field2);
```

## Article #17972: Switching between different data sources

Question and Answer Database

FAQ2972D.txt     Switching between different data sources

Category     :Quick Reports

Platform     :All

Product      :All 32 bit

Question:

In QuickReport 1 all components was connected to a DataSource, now they are connected to a DataSet. The other solution made it much easier to switch between different tables. Why did this change? How do I use it?

Answer:

This change was done to improve speed, code size and to make QuickReport more stable. To switch between different tables and queries it's easiest to use the TQRExpr component to display field data. TQRExpr will pick up the field from any dataset connected to the report, regardless of its name. Then simply change the QuickRep.DataSet property.

## Article #17974: Improving performance

Question and Answer Database

FAQ2974D.txt     Improving performance

Category     :Quick Reports

Platform     :All

Product      :All 32 bit

Question:

Is there any special trick to improve performance?

Answer:

Most importantly - add persistent field objects for your tables. Create expressions with as few functions as possible. Instead of doing `Sum(Field1)+Sum(Field2)` you should do `Sum(Field1+Field2)`. The last one is a lot faster.

7/16/98 4:31:28 PM

## Article #17976: Printing Delphi controls using QuickReports

Question and Answer Database

FAQ2976D.txt - Printing Delphi controls using QuickReports

Category :Quick Reports

Platform :All-32Bit

Product :

Question:

Can I print any standard Delphi control using QR?

Answer:

No, a control has to be descending from TQRPrintable to be printed on a QuickReport.

However, if you want, you can drop a TQRImage on a QuickReport and then do something like this:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  DC : HDC;
begin
  DC := GetDC(Button1.Handle);
  BitBlt(QuickReport2.QRImage1.Canvas.Handle,0,0,
        Button1.Width,Button1.Height,DC,0,0,SrcCopy);
  ReleaseDC(Button1.Handle,DC);
  QuickReport2.Preview;
end;
```

## Article #17978: Using additional data sets in expressions

Question and Answer Database

FAQ2978D.txt Using additional data sets in expressions

Category :Quick Reports

Platform :All

Product :All 32 bit

Question:

The expressions only pick up field values from datasets referenced in my reports. How can I use additional datasets in expressions?

Answer:

In the QuickRep.BeforePrint event you can add additional datasets to the QuickRep.AllDataSets list property:

```
MyReport.AllDataSets.Add(SomeOtherTable).
```

You can now use fields from this (these) tables in your expressions.

Last Modified: 01-SEP-99

## Article #17986: Printing calculated text

Question and Answer Database

FAQ2986D.txt    Printing calculated text

Category       :Quick Reports

Platform       :All

Product        :All 32 bit

Question:

I have a calculated table field and it has line breaks in the text and those line breaks don't print.

Answer:

Delphi defines calculated table text fields as TStringfield and QuickReport handles that type of field differently than it handles actual memo fields. To output a calculated text field, use a QRMemo component and set QRMemo.Lines.Text to the value of the calculated field at runtime.

## Article #17988: Cannot find A2E table

Question and Answer Database

FAQ2988D.txt - Cannot find A2E table

Category :AS400  
Platform :All Windows  
Product :DelphiAS400,

Question:

How come I'm getting the error "Cannot find A2E table" when making TAS400.Active set to TRUE?

Answer:

This error message refers to the ASCII to EBCDIC tables contained in files in a path defined by WIN.INI in the [CO400] section. Verify the entire path exists and that the \*.EBC and \*.ASC files exist along that path. Example of WIN.INI fragment:

```
[CO400]
.
.
c:\co400\convert\us1.ebc
c:\co400\convert\us1.asc.
```

## Article #17998: No default printer selected when using Quickreports

Question and Answer Database

FAQ2998D.txt - No default printer selected when using Quickreports

Category :Quick Reports  
Platform :All-32Bit  
Product :

Question:

I get a exception error when running our application on a machine without a default printer.

Answer:

QuickReport requires that a default printer be installed. The report is prepared using information from the printer driver. The following code is one way to check and see if a default printer has been defined.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Device, Driver, Port    : array [0..255] of Char;
  Mode                   : Integer;
begin
  Printer.GetPrinter(Device,Driver,Port,Mode);
  if Device <> '' then
    ShowMessage(Device)
  else
    ShowMessage('You do not have a default printer defined');
end;
```

## Article #18002: Using a TQRExpr component at run-time

Question and Answer Database

FAQ3002D.txt Using a TQRExpr component at run-time

Category :Quick Reports

Platform :All

Product :All 32 bit

Question:

How do I check the value of QRExpr control at runtime?

Answer:

The Value property of a TQRExpr component is of type TQREvResult. You can check Value.Kind to see what the data type is. The following table shows how to retrieve the results of the expression based on the value of Value.Kind:

Value.Kind	The result is in
resInt	Value.IntResult
resDouble	Value.DblResult
resString	Value.StrResult
resBool	Value.BooResult
resError	there was an error

The constants are defined in the QRPrntr unit.

## Article #18004: Detecting if there's a disk in a drive

Question and Answer Database

FAQ3004D.txt    Detecting if there's a disk in a drive  
Category        :Miscellaneous  
Platform        :All  
Product         :All 32 bit

Question:

How do I detect if there's a disk in a drive? How do I avoid the critical error box that Windows displays?

Answer:

Here's a short example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  OldErrorMode : Integer;
  fp           : TextFile;
begin
  try
    OldErrorMode := SetErrorMode(SEM_FAILCRITICALERRORS);
    try
      AssignFile(fp, 'A:\foo.bar');
      Reset(fp);
      CloseFile(fp);
    finally
      SetErrorMode(OldErrorMode);
    end;
  except
    on E:EInOutError do
      if E.ErrorCode = 21 then
        ShowMessage('Drive A: is not ready...');
    end;
  end;
end;
```

## Article #18006: Converting strings to dates

Question and Answer Database

FAQ3006D.txt     Converting strings to dates

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

I want to convert strings to dates, but StrToDate doesn't do what I want. I want to convert "December 6, 1969" to a TDateTime. What should I do?

Answer:

StrToDate only converts numbers, so if you have month names in your string, you'll have to use VarToDateTime instead. Here are some examples:

```
var
  D1, D2, D3 : TDateTime;
begin
  D1 := VarToDateTime('December 6, 1969');
  D2 := VarToDateTime('6-Apr-1998');
  D3 := VarToDateTime('1998-Apr-6');
  ShowMessage(DateToStr(D1)+' '+DateToStr(D2)+' '+
              DateToStr(D3));
end;
```

## Article #18012: Cannot create local description file

Question and Answer Database

FAQ3012D.txt - Cannot create local description file

Category :AS400  
Platform :Win95/NT  
Product :DelphiAS400,

Question:

Why am I getting a "Can't create local description file" when I deploy my Delphi/400 program?

Answer:

This error occurs with Delphi 1 deployed applications. WIN.INI must be updated so that the [CO400] section contains an entry that provides the directory containing local description files. For example:

```
[CO400]
.
.
PATH_DDS=C:\CO400\DDS
```

## Article #18016: Protection Error, Runtime version

Question and Answer Database

FAQ3016D.txt - Protection Error, Runtime version

Category :AS400  
Platform :All-32Bit  
Product :

Question:

How come I am getting the error "Protection Error, Runtime version" with Delphi/400?

Answer:

Possible Causes:

You are trying to use the run-time Components during Design Time.

You are exceeding the limit of Developers that are licensed to use the Delphi/400 components.

Your PC may have locked up and been rebooted without killing the job on the AS/400 thus making the 400 think that there are two developers with the same key running the same job. To check for currently running jobs on the AS/400:

Close Delphi.

Execute "WRKACTJOB" on the AS/400 to see the active job. Look for the PC controller. If the controller is in "CPCW" it means that the job is running. To kill the job, choose option "4" and finally "ENTER" to confirm.

The 60 day evaluation period has expired.

Developer must have installed product using the QSECOFR sign-on. You have installed Delphi/400 twice. By default you have a temp key for two months but just for the first install.

## Article #18024: Unknown Field Name

Question and Answer Database

FAQ3024D.txt - Unknown Field Name

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

How come I'm getting the error "Unknown Field Name" with Delphi/400?

### Answer:

This error may occur when using field names that contain "#" as is common for the AS/400. This may be illegal on the PC depending on the translation table declared in the configuration of the router.

Note: SNA Server version 3 should be 3.01.1113. Early versions of 3.0 do a poor job of translating EBCDIC-ASCII for special characters.

Also note: the translation table must also accommodate the language features of the OS/400, i.e. French special characters, etc.

## Article #18028: IDAPI Service Library not Found

Question and Answer Database

FAQ3028D.txt - IDAPI Service Library not Found

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

Question:

I'm using Delphi/400. How come I'm getting an "IDAPI Service Library Not Found" error?

Answer:

This error usually occurs in deployments.  
There are two conditions where this error can occur.

IDC0400.DLL is not in the BDE directory.  
Some of client DLLs (CO40032.DLL, TCRTR32, E32TCPIP.DLL, etc)  
are in the application directory and some are in Windows\System32.

If you use the install from the Deployment CD both of these problems will not occur.

## Article #18036: Delphi/400 : Queries against \*LIBL

Question and Answer Database

FAQ3036D.txt - Delphi/400 : Queries against \*LIBL

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

Question:

Trying to execute a sql query on an alias with property  
Libraryname set to "\*LIBL" doesn't work.

Example :

MyTable is in MyLib Library and MyLib is included in \*LIBL

Select \* from MyTable. returns "invalid expresion" exception.

Answer:

Set explicitly the libraryname in your statement :

```
select * from MyLib/MyTable.
```

Question and Answer Database

FAQ3080D.txt - Delphi 3/400: ApplyUpdates doesn't work

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

I have Delphi 3/400. How come when using a MIDAS connection, ApplyUpdates doesn't work.

### Answer:

To solve this problem obtain the latest Delphi/400 patch from:  
"<http://libra.netmastersllc.com/borland400/patches.html>"

There is no way to know if a field is NULL or contains NOTHING. so, the Resolver will replace each field with no data by a NULL. In most case, this will generate a error on the AS/400. (if your fields don't allow NULL). That's why you should had something like this on the server side :

```
procedure TDemoServer.MyProviderGetData(DataSet: TClientDataSet);
var
  i:integer;
begin
  with DataSet do
    begin
      while not EOF do
        begin
          Edit;
          for i:=0 to fieldcount-1 do
            begin
              if fields[i].IsNull then
                fields[i].asString:='';
            end;
          Post;
          Next;
        end;
    end;
end;
```

end;  
end;

## Article #18082: Getting a cool menu in your app

Question and Answer Database

FAQ3082D.txt :Getting a cool menu in your app

Category :VCL

Platform :Win95/NT

Product :Delphi4.x,

Question:

I want to have a menu that looks like Delphi 4's menu in my app.  
How can I do that?

Answer:

1. Drop down a TControlBar. Align it to Client.
2. Drop down a TToolBar inside of the TControlBar.
3. Set Flat and ShowCaptions of the TToolBar to True.
4. Create as many TToolButtons on the TToolBar as you'd like.
5. Set Grouped to True for all TToolButtons. This will enable your menu to pop up menu after menu as you sweep across the menu (if a menu is already pulled down).
6. Drop down a TMainMenu, and make sure it's *\*not\** attached to the form it's on.
7. Create the entire menu, with all its entries.
8. For each TToolButton, set its MenuItem to the corresponding menu item in the TMainMenu.

## Article #18084: Running 16-bit Delphi on Windows NT4

Question and Answer Database

FAQ3084D.txt      Running 16-bit Delphi on Windows NT4

Category        :Miscellaneous

Platform        :All

Product         :All 32 bit

Question:

When running 16-bit Delphi on Windows NT 4.0, running or debugging in the IDE locks up the system. What causes this and how can it be fixed?

Answer:

USERHTML

The problem is caused by running 16-bit Delphi on a 32-bit operating system it was never intended nor certified to run on. A known conflict between 16-bit Delphi and NT 4.0 is enabling Delphi's environment options "Minimize on run" and "Integrated Debugging" at the same time. Disabling the "Minimize on run" usually solves this problem, and is recommended as a workaround.

## Article #18086: Installing Delphi from a hard drive.

### Question:

How do I install Delphi from a local hard drive?

### Answer:

You will need approximately 460 MB of hard drive space to do the hard drive install (for Delphi 5 Enterprise version). 230 MB for the complete installation and free space to hold the files temporarily while doing the installation.

1. Put the Delphi CD in the drive and choose "Browse the CD, or view the CD in Windows Explorer."
2. Copy the "Install" folder to the root directory of the local drive you will be installing from (i.e. not inside any subfolders).
3. Copy the "Runimage" folder to the root directory of the same drive. This may take a very long time. Verify that the entire folder was copied correctly. Right-click on the folder and choose properties. This folder should contain the same number of files that the one on the CD-ROM contained.
4. Copy all of the remaining files (autorun.inf, delphi.ico, deploy.txt, etc.) to the root directory of the same drive.
5. Reboot into Safe Mode or VGA mode (optional) and double click on the "Install.exe" that you now have on your hard drive and install Delphi as you normally would.
6. Restart your computer and verify that Delphi runs correctly. Once you have done this you can delete all the files that you copied over from the CD-ROM.

## Article #18090: Creating Delphi 4 Style Toolbars/Menus

Question and Answer Database

FAQ3090D.txt :Creating Delphi 4 Style Toolbars/Menus  
Category :Miscellaneous  
Platform :Win95/NT  
Product :Delphi4.x,

Question:

How do I create Delphi 4 Style toolbars (like MS Office 97)?

Answer:

Do the following:

- 1) Drop a ControlBar component onto a form.
- 2) Set the Align property of the ControlBar to alTop.
- 3) Drop a ToolBar component onto the ControlBar.
- 4) Set the Align property of the ToolBar to alNone.
- 5) Set the Flat property of the ToolBar to TRUE.
- 6) Set the ShowCaptions property of the ToolBar to TRUE.
- 7) Right Click on the ToolBar and choose New Button;  
repeat a few times.
- 8) Drop a PopUpMenu for each ToolButton you added  
to the ToolBar onto the form.
- 9) Right click on each PopUpMenu component and choose  
Menu Designer- create Menu Items for each.
- 10) Set the DropDownMenu property of each ToolButton on  
the ToolBar to its respective PopUpMenu.
- 11) Set the AutoSize property of the ToolButtons to TRUE.

## Article #18727: Merging the configuration file has failed

Question and Answer Database

FAQ: FAQ3727B - Merging the configuration file has failed

Category: Install Issues

Platform: Win95/NT

Product: BC++5.x, C++Builder1.0, C++Builder3.x, Delphi2.x, Delphi3.x,

Question:

I'm deploying my BDE application and the install generates the error "Merging the configuration file has failed". What is causing this?

Answer:

The most likely cause of this error is using a BDE Deployment tool with BDE 5 or later, such as InstallShield, that doesn't know about BDE 5 files.

Specifically what causes the error is that BDE 5.0 uses a new mechanism to for language drivers. The error occurs because the language driver being merged can't be found.

To solve the problem:

1. When you update your BDE, install to the same directory the BDE is already installed to.
2. Add BANTAM.DLL, \*.BTL and CHARSET.CVB from your BDE directory to the BDE/IDAPI Files group.

Another possible causes of this problem are:

1. Running an application that uses the BDE while deploying your application.
2. The target machine's preexisting Idapi32.cfg file is set to read-only or is in any other way inaccessible.

3. The IDAPI configuration file on the target machine is corrupt.

For additional information see document Q100670 on

## Article #18737: Oracle 8 and returning the REF CURSOR from a stored procedure

Question and Answer Database

FAQ3737B.txt Oracle 8 and returning the REF CURSOR from a stored procedure

Category :Database(Oracle8)

Platform :Win95/NT

Product : BDE 5.0 (fixed in BDE 5.01)

Question:

Using Delphi 4 (w/BDE 5) with the Oracle 8.0.4 client and the Oracle 8 SQL Link driver, I am trying to execute a stored procedure that returns a REF CURSOR type. No matter what I seem to try I get the error "General SQL error ORA-01036: illegal variable name/number" when I try to execute the procedure. What am I doing wrong?

Answer:

When using BDE 5.0 there is a known problem with returning a REF CURSOR type from a stored procedure when using the Oracle 8 SQL Link Driver (in BDE 5.0). BDE 5.01 or later resolves the problem.

## Article #18749: Unknown Internal Operating System Error

Question and Answer Database

FAQ3749B.txt      Unknown Internal Operating System Error  
Category        :BDE  
Platform        :Win95/NT  
Product        :    BC++5.x      C++Builder1.0      C++Builder3.x      Delphi2.x  
Delphi3.x      Delphi4.x

Question:

Why am I getting an Unknown Internal Operating System Error when opening a Paradox or dBASE Table?

Answer:

This error can occur when attempting to open a Paradox or dBASE table whose language driver is not installed on your computer. In most circumstances this means a bad BDE install and BDE should be reinstalled.

One way to determine a likely bad install is by running BDE administator and attempting to modify the langauge driver for the Paradox driver. If only one language driver is available, it indicates a bad install.

This problem is most likely to occur with BDE 5.0 when deploying with a deployment tool that does not know about BDE 5.0. The problem occurs because BDE 5.0 includes a new mechanism for language drivers. To deploy BDE 5.0 language driver features with an older development tool be sure include BANTAM.DLL and \*.BTL from the BDE directory on your deployment machine.

## Article #18761: Automating Word 8 (word97)

Question and Answer Database

FAQ3761D.txt :Automating Word 8 (word97)  
Category :ActiveX/OLE/COM/ActiveForm  
Platform :All Windows  
Product :All32Bit,

Question:

How do I automate word 8 (aka word97)?

Answer:

You can get to any of the interfaces exposed by the word automation server. These can be found by loading the file "MSWORD8.OLB" into Delphi which will display the type library information. The following code sample demonstrates creating a new word document and inserting text into the document via automation.

uses

ComObj;

procedure TForm1.Button1Click(Sender: TObject);

var

Word97: Variant;

begin

Word97 := CreateOLEObject('Word.Application');

Word97.Documents.Add;

Word97.Selection.TypeText('Wow BOB woW');

Word97.Visible := True;

Word97:= UnAssigned;

end;

## Article #18763: Error: Too many fields in table create

### Question:

I'm getting the error "Too many fields in table create" when either using DbiCreateTable (BDE API) or TTable.Create (Delphi) or TTable->Create (C++ Builder). What is the limit to the number of fields I can create in a table using these functions?

### Answer:

The number of fields varies by database. See <http://community.borland.com/article/0,1410,15159,00.html> for a complete listing. If your database supports a larger number of fields you may create a table with a larger number of fields using a TQuery instead.

## Article #18765: Detecting if a mouse has a wheel

Question and Answer Database

FAQ3765D.txt - Detecting if a mouse has a wheel

Category :VCL  
Platform :Win95/NT  
Product :Delphi4.x,

Question:

How can I detect if the currently installed mouse has a wheel?

Answer:

By taking advantage of the new global mouse object which contains information relating to the mouse. The mouse object has a boolean property called "WheelPresent" which is true if a mouse wheel is present or false if none is detected.

## Article #18767: Oracle's Oracle 7.x ODBC drivers, VARCHAR2 >255

Question and Answer Database

QNA :Oracle's Oracle 7.x ODBC drivers, VARCHAR2 >255  
Category :Database (ODBC)  
Platform :Win95/NT  
Product : All32Bit

### Question:

I am unable to see or edit data from my VARCHAR2 fields when they are defined as >255 in size.

### Answer:

This is a problem that has been seen with only the Oracle ODBC drivers.

"Live" TQueries can be used in this situation.

The Oracle SQL Links drivers and Intersolv Oracle ODBC drivers do not exhibit the same behavior.

As a general rule ODBC drivers should be ODBC level 2 compliant when used with the Borland Database Engine.

## Article #18770: IBM CAE 5 PTF 3 and 4 for DB2 Universal server and client

Question and Answer Database

FAQ3770B.txt IBM CAE 5 PTF 3 and 4 for DB2 Universal server and client

Category :Database (DB2)

Platform :Win95/NT

Product : All32Bit

Question:

When working with IBM's CAE v5 and IBM Universal server with the Borland DB2 SQL Link driver for Win95 and WinNT I sometimes receive unusual errors.

Answer:

While the versions of the Borland DB2 SQL Links driver <=5.0 have not been tested with IBM's CAE 5 and Universal server you should apply the IBM PTF versions 3 and/or 4 to both the CAE client and Universal server.

## Article #18772: Informix SE, errors while working with Borland Informix SQL Links

Question and Answer Database

FAQ3772B.txt Informix SE, errors while working with Borland Informix SQL Links

Category :Database (Informix)

Platform :Win95/NT

Product : All32Bit

Question:

I sometimes receive strange errors while working with an Informix SE server and the Informix SQL Links driver.

Answer:

Only versions of Informix ONLINE are certified for use with the Borland SQL Links.

Informix SE is not a tested or supported server when using the Borland

Informix SQL Links driver.

All versions ( $\geq$  V3.0) of the 32bit Informix SQL Links driver are certified against Informix 7 server. SQL Links v5 includes an Informix 9

driver that has been certified with the Informix 9 server.

While previous versions of Informix ONLINE have not been tested with the

32bit Informix SQL Links driver most functionality should be available

as implied by Informix's ESQL/C (versions 7 and 9).

## Article #18774: Microsoft SQL Server "Unexpected EOF from SQL Server"

Question and Answer Database

FAQ3774B.txt Microsoft SQL Server "Unexpected EOF from SQL Server"  
Category :Database (MSSQL)  
Platform :All Windows  
Product : All32Bit

### Question:

I receive the error "Unexpected EOF from SQL Server" 109 10008 "Bad token from SQL Server" when working with my MS SQL Server. Why am I receiving this error?

### Answer:

Banyan Vines Network, MS SQL Server 6.x, A select with an "order by" will cause a "connection is already in use..." error MS's ISQL will bring up the error "Unexpected EOF from SQL Server" Error: "109 The pipe has been ended." [OS/2 and NT] "10008 Bad token rom SQL Server: datastream processing out of sync." Often caused by an abruptly terminated network connection, which causes a damaged Tabular Data Stream token to be read by the client. Please see Microsoft's knowledge Base article Q73215 for more details on this error.

3/26/99

Last Modified: 01-SEP-99

## Article #18776: Microsoft SQL Server error 17824 Unable to write to ListenOn connection

Question and Answer Database

QNA :Microsoft SQL Server error 17824 Unable to write to ListenOn connection  
Category :Database (MSSQL)  
Platform :Win95/NT  
Product : All32Bit

### Question:

I am receiving the error "17824 Unable to write to ListenOn connection 'xxx', oginname 'xxx', hostname 'xxx'." when working with my MS SQL server.

What is causing this error?

### Answer:

Please see the Microsoft SQL server documentation for further information on this topic.

After establishing a number of concurrent application connections to the MS SQL Server the following error is encountered:

MS SQL Server error "17824 Unable to write to ListenOn connection 'xxx', loginname 'xxx', hostname 'xxx'."

### POSSIBLE CAUSE:

It is possible that the PROCEDURE CACHE percentage is set too low.

Please see your MS SQL Server documentation and NT Event Viewer for more information on debugging network errors and tuning your MS SQL Server's PROCEDURE CACHE.

Relevant SQL Server options: MAX PROCEDURE CACHE ... MAX WORKER THREADS

### PROCEDURE CACHE

The procedure cache holds entries for each procedure and other maintenance overhead.

Settings for the PROCEDURE CACHE include:

MAX PROCEDURE CACHE ACTIVE %  
MAX PROCEDURE CACHE USED%  
PROCEDURE CACHE USED%

MAX WORKER THREADS

The max worker threads option allows control over the number of threads allocated to the user pool.

## Article #18778: Sybase DBLIB, Access Violation in KERNEL32.DLL

Question and Answer Database

FAQ3778B.txt     Sybase DBLIB, Access Violation in KERNEL32.DLL  
Category        :Database (Sybase)  
Platform        :Win95/NT  
Product         :     All32Bit

### Question:

My application is crashing in KERNEL32.DLL when a connection is attempted using the SQL Links DBLIB driver (SQLSYB32.DLL) and the Sybase 11.1 Win95/NT client.

Why is this happening?

### Answer:

This problem has been addressed in BDE/SQL Links v4.01 and above.

(Please check Delphi, C Builder, and Visual dBASE Client Server product release info for more information on new versions of the BDE and SQL Links)

DBLIB and CTLIB connection types to Sybase servers through Borland SQL Links are determined by the Sybase driver DLL32 param (either SQLSYB32.DLL or SQLSSC32.DLL)

SQLSYB32.DLL     (DBLIB) - loads Sybase LIBSYBDB.DLL  
SQLSSC32.DLL     (CTLIB) - loads Sybase LIBCT.DLL

### Tested using:

Sybase 11.1 LIBSYBDB.DLL dated 9/4/96

If the 11.1 LIBSYBDB.DLL is replaced with a Sybase 10 LIBSYBDB.DLL (dated 8/2/95) then the connection is OK.

## Article #18780: Sybase CTLIB, multiple stored procedure result sets

Question and Answer Database

FAQ3780B.txt     Sybase CTLIB, multiple stored procedure result sets  
Category     : Database (Sybase)  
Platform     : Win95/NT  
Product      :     All32Bit

Question:

I wish to return result set from multiple stored procedures or open tables/tqueries after returning results from a stored procedure but receive this error instead:

```
ct_send(): user api layer: external error: This routine cannot be called because another command structure has results pending.
```

What can I do to avoid this error?

Answer:

Sybase (CTLIB SYBSSC32.DLL) SQL Links Driver, BDE 4.x

Solution:

Use a tquery to "open" the stored procedure.

(For additional info please see the topic on Sybase in the BDE32.HLP file by using the help file Index tab to search for SYBASE)

Delphi Example:

Add "BDE" to your unit's uses clause

Button Click procedure to open results from a Tquery ("exec storedproc"):

```
procedure TForm1.Button2Click(Sender: TObject);  
begin
```

```
  query1.prepare;  
  dbisetprop(hdbiobj(query1.StmtHandle), stmtEXECASCURSOR, 1);
```

```
query1.open;
```

In this example:  
the StoredProc name is LINEITEM\_RSLT:

```
CREATE PROCEDURE LINEITEM_RSLT AS  
(  
SELECT * FROM lineitem  
)
```

Tquery1 sql strings for this example would be:

```
exec LINEITEM_RSLT
```

## Article #18782: DB2 Win3.1 and Win95/WinNT combined installation.

Question and Answer Database

FAQ3782B.txt DB2 Win3.1 and Win95/WinNT combined installation.

Category :Database (DB2)

Platform :Win95/NT

Product : All32Bit

Question:

What can I do to allow connections from both the Win 3.x and Win 95/NT IBM CAE on the same PC?

Answer:

Both the 16 and 32 bit IBM CAE use a file called DB2ODBC.DLL. Each install may overwrite the copy of the previous install's version (16 vs. 32bit) of the file. If the \BIN dir of both installs is in the environment path and the corresponding copy of DB2ODBC.DLL is copied to its respective directory after each install then the \WINDOWS\SYSTEM copy of DB2ODBC.DLL can be deleted or renamed.

## Article #18784: IBM DB2 CLI driver errors SQL0551N and SQL0805N

Question and Answer Database

FAQ3784B.txt IBM DB2 CLI driver errors SQL0551N and SQL0805N

Category :Database (DB2)

Platform :Win95/NT

Product : All32Bit

Question:

```
[IBM][CLI Driver][DB2/NT] SQL0551N "MYUSERNAME" does not have the
privilege to perform "GRANT" on object "NULLID.SQLL16W4".
SQLSTATE=42501
```

What can I do to help address the cause of this error?

Answer:

The following error may appear either when trying to list tables via a DB2 alias or when a table is chosen to be viewed on an OS/2 or NT DB2 server:

```
[IBM][CLI Driver][DB2/NT] SQL0551N "MYUSERNAME" does not have the
privilege to perform "GRANT" on object "NULLID.SQLL16W4".
SQLSTATE=42501
```

```
[IBM][CLI Driver][DB2/NT] SQL0805N Package "NULLID.SQLL66W4" was not
found. SQLSTATE=51002 "GRANT" on object.
```

It may be necessary to issue the following after logging in as the DBA:

```
grant execute on package NULLID.SQLL16W4 TO PUBLIC
```

## Article #18786: BDE >=4.0, Intersolve ODBC 3.0, TQuery CachedUpdates, TUpdateSql, ApplyUpdates, null/blank string

Question and Answer Database

FAQ3786B.txt    BDE >=4.0, Intersolve ODBC 3.0, TQuery CachedUpdates, TUpdateSql, ApplyUpdates, null/blank string  
Category     : Database (ODBC)  
Platform     : Win95/NT  
Product      : All32Bit

Question:

When working with BDE 4.0, Intersolve ODBC 3.0, Delphi TQuery CachedUpdates, TUpdateSql I receive the error "General SQL error. [INTERSOLV][ODBC Oracle driver]Character, decimal, and binary parameters cannot have a precision of zero. Error in parameter n."  
What might be causing this error?

Answer:

The problem does not occur when using CachedUpdates w/TTables

"General SQL error. [INTERSOLV][ODBC Oracle driver]Character, decimal, and binary parameters cannot have a precision of zero. Error in parameter n."

Add a new string value called "Workarounds" to:

\HKEY\_CURRENT\_USER\Software\ODBC\ODBC.INI\MYODBCDSN and set its value to 1048576

Currently under investigation.

From /IVODBC/READ.ME (Intersolv 3.0 ODBC readme):

"WorkArounds=1048576. Some applications incorrectly specify a precision of 0 for character types when the value will be SQL\_NULL\_DATA. This option overrides the specified precision and sets the precision to 256."

## Article #18788: Oracle Integer to BDE or Delphi float, ENABLE INTEGER

Question and Answer Database

FAQ3788B.txt Oracle Integer to BDE or Delphi float, ENABLE INTEGER  
Category :Database (Oracle)  
Platform :Win95/NT  
Product : All32Bit

### Question:

I've created an Oracle table using the INTEGER type but the BDE shows the INTEGER field as a FLOAT even though I have ENABLE INTEGERS set to True.

### Answer:

The Oracle server will set the fields precision to '\*' and the scale to '0' (MYFIELD(\*,0) for example) when a field is created as INTEGER. This translates to an Oracle precision of 38. The maximum precision for Oracle NUMBERS INTEGERS and SMALLINTS is 38. The maximum precision for Delphi/BDE INTEGERS is 10 (-2,147,483,648 to 2,147,483,647 or 9,999,999,999).

## Article #18789: SQL LINKS >=4.0 BLOB SIZE parameter

Question and Answer Database

FAQ3789B.txt SQL LINKS >=4.0 BLOB SIZE parameter

Category :BDE Features

Platform :Win95/NT

Product : All32Bit

Question:

What is the BDE BLOB SIZE parameter used for?

Answer:

[\*Please note that the behavior described below applies only to BDE/  
SQL

Links >=4.0. The Version 4.01 BLOB SIZE param applies to viewing  
"dead"

results as well as live results containing text/blob data if BLOB  
SIZE

is set higher than 32k]

Increasing the BLOB SIZE from the default of 32 will currently  
prevent

opening "dead" (unindexed or Request Live = false) results from  
returning

text data when opening. In other words if BLOB SIZE is increased from  
32

then only TQueries that are opened as live results will return data.

From SQL Links 4.0 Help:

BLOB SIZE

Determines the fetch buffer size for dead BLOBs. Applications that  
deal with dead BLOBs using dead table opens or queries or batchmoves  
can set a maximum limit on the size of BLOBs to fetch. Setting this  
parameter to 64 means your application can fetch BLOBs of up to 64K.  
This parameter does not apply to live table opens.

Default Value: 32

Range : >32 and <1000

\*

Interbase BLOBs are always "live" and are therefore not affected by the BLOB SIZE param

\*

DB/2

Binding a large buffer for fetching dead blobs by setting the BLOB SIZE

setting to max (65535) DB2 returns SQL error "SQL0973N Not enough storage is available in the QUERY\_HEAP to process the statement. SQLSTATE=57011"

Note:

This is a vendor restriction. Increasing the QUERY\_HEAP on the server should solve the problem.

Last Modified: 01-SEP-99

## Article #18798: SQL Explorer reports Oracle 8 database as Oracle 7 database

Question and Answer Database

FAQ3798B.txt SQL Explorer reports Oracle 8 database as Oracle 7 database

Category :Database(Oracle8)

Platform :Win95/NT

Product : BC++5.x C++Builder1.0 C++Builder3.x Delphi2.x

Delphi3.x Delphi4.x

Question:

Why does SQL Explorer report the database type as Oracle 7.3.2 when I connect to an Oracle 8 database?

Answer:

SQL Explorer queries the SM\$VERSION table using the sql statement

```
"select 'Oracle ' || VERSION_TEXT from SM$VERSION"
```

to determine the version of the database and it returns 7.3.2.

To verify that you are connecting to an Oracle 8 database query GV\$VERSION.

example: select BANNER from GV\$VERSION

## Article #18804: Access Violation when opening BDE Object in DataModule of DLL

Question and Answer Database

FAQ3804B.txt    Access Violation when opening BDE Object in DataModule of DLL

Category       :Database/VCL

Platform        :All Windows

Product        :   C++Builder1.0   C++Builder3.x   Delphi2.x   Delphi3.x  
x   Delphi4.x

Question:

Why do I receive an Access Violation when I open any BDE object (Session, Database, Stored Procedure, Table) contained in a Data Module in my DLL?

Answer:

Forms and Data Modules in DataModules in DLLs are not autocreated. You instantiate them yourself. The most likely place to do this is in DLL entry point.

Where DMod is the name of your Data Module, in C++ Builder the code would look as follows:

```
if reason = DLL_PROCESS_ATTACH
    DMod = new TMod(NULL);
```

in Delphi it looks like:

```
if reason = DLL_PROCESS_ATTACH
    DMod := TMod.Create(nil);
```

## Article #18806: Sybase/"record has been modified by another user" error with datetime fields

Question and Answer Database

FAQ3806B.txt Sybase/"record has been modified by another user" error with datetime fields

Category :Database (Sybase)

Platform :Win95/NT

Product :BDE versions prior to 5.10

### Question:

I have a table in a Sybase database (version 10.x or 11.x) that has a datetime field. I was able to use/edit data in this table until I applied a patch to my Sybase client (versions affected below). Now after applying the patch, whenever I attempt to update records that were written to the table with the unpatched client I get the error "record has been modified by another user". What is wrong?

### Answer:

As of Open Client Version 11.1.1, CT-Lib now uses a small datetime as its default. (A small datetime keeps year, month, day, hour & minute). This means that the 11.1.1 client will not even attempt to send second and millisecond data to the server when you post a record. If the data was written with second and millisecond precision, there is no way of reselecting it using Open Client 11.1.1. (for example 11:30:23.111 doesn't equal 11:30:00.000) In versions earlier than this (for example 11.1.0) CT-Lib used long datetime as its default. (A long datetime keeps everything a small datetime does plus seconds and milliseconds). As a result, when you upgrade your Sybase client you will see this problem.

One possible workaround is to change your Update Mode to be WhereKeyOnly or WhereChanged, but if the datetime field is part of the key or you change the value of the datetime field you will still see this problem. You could also use small datetime fields when you are designing your tables and avoid this problem entirely. If you have a database which requires second and/or millisecond precision for the datetime fields, you have a few options:

1. Use Open Client 11.1.0 or 10.0.4 with CT-Lib
2. Use Open Client 11.1.1 with DB-Lib
3. Write your own implementation of second and millisecond times in another field and use it in conjunction with a short date.

If these alternatives are not acceptable to you, we encourage you to provide this feedback to Sybase Customer Service or your Sybase sales representative.

### Versions Affected:

Open Client 11.5, 11.1.1, 11.1 with ebf7398 applied, 10 with ebf7438.

## Article #18808: Delphi4, Oracle 7.x stored procedures with multiple parameters with one being a REF Cursor

Question and Answer Database

FAQ3808B.txt Delphi4, Oracle 7.x stored procedures with multiple parameters with one being a REF Cursor

Category :Database (Oracle)

Platform :Win95/NT

Product : Delphi4.x

Question:

I have a stored procedure on my Oracle 7.x server that has multiple parameters with one of them being a REF Cursor type. When I try to execute this procedure I get "invalid cursor" errors.

I used to be able to execute this procedure in Delphi 3, why doesn't it work in Delphi 4?

Answer:

Parameter binding behavior was changed in Delphi 4.

In Delphi 4 if you don't give a parameter a value it assumes that the value you wanted was NULL. This causes a problem for the REF Cursor type in Oracle because the server doesn't accept NULL as an input value

for a REF Cursor type. The workaround for this issue is to set the value

of the REF Cursor parameter to 0 (zero) at either design time or at runtime before the procedure is executed. This change in behavior will

be accounted for in a later version of the BDE (> 5.0).

## Article #18823: Sybase 11.5 server causes problems for SQL Explorer

Question and Answer Database

FAQ3823B.txt - Sybase 11.5 server causes problems for SQL Explorer

Category :Database (Sybase)

Platform :Win95/NT

Product :C++Builder1.0, C++Builder3.x, Delphi2.x, Delphi3.x, Delphi4.x

### Question:

When connecting to a Sybase 11.5 server the following problems occur in SQL Explorer:

1. Type is shown as SYBASE: Unknown Version: Mapping error: Bad template: SQL Server/([0-9]+).
2. Only Columns, Indices and Triggers and shown below tables in the tree.
3. Selecting the text tab of table which has a numeric field results in the error dialog "Property Precision does not exist".

### Answer:

You can solve this problem by editing the DBX.DBI file in your bin directory. Find the line the reads:

```
SYBASE:IdentityRE=SQL Server/([0-9]+).
```

change it to:

```
SYBASE:IdentityRE=[SQL Server][Adaptive Server Enterprise]/([0-9]+).
```

This will resolve the problem.

Note that this problem does not occur in Delphi 5 or later, or C++ Builder 5 or later because the DBX.DBI file has been updated to include this fix.

Last Modified: 01-MAR-00

## Article #18825: Preventing changing to a page in a page control

Question and Answer Database

FAQ3825D.txt :Preventing changing to a page in a page control  
Category :VCL  
Platform :Win95/NT  
Product :Delphi3.x, Delphi4.x,

Question:

How do I prevent a user from tabbing to a specific page in a page control?

Answer:

```
uses
  CommCtrl;

procedure TForm1.PageControl1Changing(Sender: TObject;
  var AllowChange: Boolean);
var
  Info : TTCHitTestInfo;
  Index : Integer;
begin
  with Info do begin
    GetCursorPos(pt);
    pt := PageControl1.ScreenToClient(pt);
    flags := TCHT_ONITEM;
  end;
  Index := TabCtrl_HitTest(PageControl1.Handle,@Info);
  AllowChange := Index <> 2; // Or another test that makes sense
end;
```

## Article #18827: Installing Delphi 4 From a Network Location

Question and Answer Database

FAQ3827D.txt :Installing Delphi 4 From a Network Location  
Category :Install Issues  
Platform :Win95/NT  
Product :Delphi4.x,

Question:

How do I install Delphi 4 on my machine from some place on the network?

(This does not include installing Delphi ON a network, only from a network. Delphi is intended to be installed on the machine that will be running it, not on a network server.)

Answer:

1a) Copy the needed files or the entire Delphi 4 CD to a location your machine can access on the network. The files needed for Delphi 4 installation are all of the files in the root directory of the CD (license.txt, inprise.gif, install.exe, etc.) as well as the entire Install and Runimage directories.

1b) Alternately, you could simply share the CD Drive.

2) On the machine where you will be installing Delphi, map a drive directly to that location so that the license.txt, install.exe, and other files are in the root directory of the drive. (You will get Error 113 if the files are not in the correct location).

3) Run install.exe from the drive you just mapped.

NOTE: Make sure that the filenames of the original files on the CD are not truncated when you copy them to your network, and make sure that you can read long filenames over your network.

## Article #18829: Vendor Init when using Oracle 7.2 with Delphi4/BDE5

Question and Answer Database

FAQ3829B.txt - Vendor Init when using Oracle 7.2 with Delphi4/BDE5

Category :Database (Oracle)  
Platform :Win95/NT  
Product :Delphi4.x,

### Question:

I have Delphi4/BDE5 and I am trying to connect to an Oracle server using the Oracle 7.2 client. Every time I try to connect I get a "Vendor Init error". I have read the Developer support Web pages and read the available documentation and everything is configured correctly. Why can't I connect?

### Answer:

The lowest version of the Oracle 7 client supported by BDE 5 is 7.3.x

## Article #19235: Oracle 8 and writing Data to a LOB (blob/clob) field.

Question and Answer Database

FAQ4235B.txt - Oracle 8 and writing Data to a LOB (blob/clob) field.

Category :Database(Oracle8)  
Platform :Win95/NT  
Product :Delphi4.x,

### Question:

I am using Oracle 8.0.4 as my database backend and when I attempt to write data to a Blob/Clob field I keep getting the error "ORA-22990: LOB locators cannot span

transactions". The code I am using used to work against Oracle 7 servers but against Oracle 8 it keeps raising this error. What is wrong?

### Answer:

As of Oracle 8, Oracle mandates that in order to write data to a LOB datatype ( Blobs and Clobs are subtypes of the LOB type) that you must be in a transaction. this is due to the

changes in the way oracle implemented the LOB data type. To get around this issue start a

transaction before you attempt to write data to a LOB data type.

for example if your code was (Delphi example)

```
Table1.Insert;  
Table1KEYFLD.AsInteger := new_val;  
Table1TESTFLD.LoadFromFile('D:\data\test.bmp');  
Table1.Post;
```

change it to

```
Databasel.StartTransaction;  
Table1.Insert;
```

```
Table1KEYFLD.AsInteger := new_val;  
Table1TESTFLD.LoadFromFile('D:\data\test.bmp');  
Table1.Post;  
Database1.Commit;
```

and this will get you around the issue.  
For more information on LOB data types see the Oracle 8 documentation.

## Article #19238: Date Field Precision For Borland Database Formats

Question and Answer Database

FAQ4238C.txt :Date Field Precision For Borland Database Formats  
Category :Database Issues  
Platform :All Windows  
Product :C++Builder1.0, C++Builder3.x,

Question:

What is the Date Field precision for Borland database formats?

Answer:

Date Field Precision for Paradox, Visual dBASE and InterBase are as follows:

Paradox

Date Field Range is from January 1, 9999 BC to December 31, 9999 AD. Paradox correctly handles leap years and leap centuries and checks all dates for validity. Paradox treats all BC years as leap years.

dBase

In dBASE III+ to Visual dBASE for Windows 5.5  
Date Field Range is from January 1, 0000 to December 31, 9999. For all versions of dBASE from version III+ to the current Visual dBASE for Windows 5.5, date fields are stored as a string in the format YYYYMMDD. In dBASE III+ a new SET CENTURY command was added for the approaching 21st century. SET CENTURY ON allows display and editing of the 4 digit year. SET CENTURY OFF limits display and entry of the year to 2 digits. All calculations and storage involving date fields handle the year correctly regardless of the state of SET CENTURY. With SET CENTURY OFF, the command, STORE {01/01/2000} TO MYDATE, will display the year as 00 even though it is stored correctly on disk and in memory as the string 20000101. Note that the YEAR function always returns a 4 digit year.

InterBase

Date Field Range is from January 1, 100 to December 11, 5941. InterBase supports a DATE data type that stores dates as two 32-bit longwords. An InterBase DATE data type includes information about year, month, day of the month, and time.

## Article #19240: SQL against Access tables with special characters in field names, such as #

Question and Answer Database

FAQ4240B.txt - SQL against Access tables with special characters in field names, such as #

Category :Database (MSACCESS)

Platform :All Windows

Product :C++Builder1.0, C++Builder3.x, Delphi2.x, Delphi3.x, Delphi4.x,

Question:

How do I execute SQL against an Access table that has a special character in a field name, such as a #? Whenever I try my statement I get a "General SQL Error".

Answer:

Place [] around the field name. Example:

```
SELECT * FROM Table WHERE Table.[Phone #] = '(831)431-1000'
```

## Article #19242: Vendor INIT error when connecting to DB2 Version 5

Question and Answer Database

FAQ4242B.txt - Vendor INIT error when connecting to DB2 Version 5

Category :Database (DB2)

Platform :Win95/NT

Product :BC++5.x, C++Builder1.0, C++Builder3.x, Delphi2.x,  
Delphi3.x, Delphi4.x, VdBase7.x,

Question:

I have DLL32 for my DB2 driver in BDE Admin set to SQLDB2V5.DLL. How come whenever I try to connect I get a Vendor Init error?

Answer:

The most likely cause of this error is that a minimum of DB2 Version 5, FixPack 4 is not installed. Another cause is that the DB2/BIN directory is not in your path.

## Article #19254: Interbase, cached updates and Blob not found error

Question and Answer Database

FAQ4254B.txt - Interbase, cached updates and Blob not found error

Category :Database (InterBase)  
Platform :Win95/NT  
Product :All32Bit,

Question:

My application is querying an Interbase table that contains blob fields and I am using cached updates. I can do some editing of the blob fields but after editing a few records I begin to get the error 'BLOB NOT FOUND'. Why am I getting this error and what can I do to avoid it?

Answer:

This issues arises because of the way that Interbase accesses blob fields. Interbase Blob handles are not guaranteed to stay consistent across transactions and therefore the record buffer that is cached may contain a Blob handle that is no longer valid (BLOB NOT FOUND). There are a few workarounds you can try:

1. Use a live query instead of cached updates
2. Use a TTable instead of cached updates
3. Use MIDAS
4. Refresh the query after each post (not recommended--too expensive)
5. Force an update of all blob fields when posting:

Example of #5:

```
TForm1.Query1BeforePost(DataSet: TDataSet);  
var  
    i: Integer;  
    temp: String;  
begin  
    for i := 0 to Query1.FieldCount-1 do
```

```
if (Query1.Fields[i].IsBlob) then
begin
    temp := Query1.Fields[i].AsString;
    Query1.Fields[i].AsString := temp;
end;
end;
```

This will force an update of all blob fields and refresh their handles.

## Article #19255: MS Access and tryingto detect Null blobs using TBlobField.IsNull method

Question and Answer Database

FAQ4255B.txt - MS Access and tryingto detect Null blobs using TBlobField.IsNull method

Category :Database (MSACCESS)  
Platform :Win95/NT  
Product :C++Builder3.x, Delphi3.x, Delphi4.x,

Question:

I have an MS Access table with blob fields in it. When I use the TBlobField.IsNull method it always returns True whether the blob field has data or is Null. This same test works fine with Paradox and if do a query against the MS access table to look for null blobs (for example select \* from blobtest where blob1 IS NULL) it detects and shows the records with empty blobs correctly. What is wrong and how can I work around it?

Answer:

The DAO engine does not know without opening the Blob if it is null or not. The BDE would have to open the all the Blob fields at every getrecord call for the TBlobField.IsNull

function to work correctly. This would be a huge performance hit even though IsNull may

never be used. A workaround is to use .AsString and check the length:

before:

```
(assume that Table1blob1 is a TBlobField)
if Table1blob1.IsNull then
```

after:

```
if Length(Table1blob1.AsString) = 0) then
```

## **Article #19257: Installation error -113**

Question and Answer Database

FAQ4257D.txt :Installation error -113

Category :Install Issues

Platform :All Windows

Product :Delphi

Question:

What does installation "Error ?113" mean?

Answer:

The machine that you are trying to install Delphi on has a 16-bit CD-ROM driver installed on it. The driver does not recognize long file names and therefore cannot find some of the files necessary for installation. Contact the vendor of the CD-ROM drive for an updated 32 bit driver or the computer system manufacturer (such as Dell, Micron or Gateway).

## Article #19258: Installation error -117

Question and Answer Database

FAQ4258D.txt :Installation error -117  
Category :Install Issues  
Platform :All Windows  
Product :Delphi3.x, Delphi4.x, DelphiAS400,

Question:

What is installation "Error ?117"?

Answer:

A certain batch of CDs produced by Inprise contained a strange glue-like substance on them that causes this error to popup because a track on the CD cannot be read.

The solution is to clean the CD using Windex or some equivalent cleaner to remove the offending substance. The other possible cause of this error is a damaged or scratched CD, if cleaning the CD does not make the error cease then the customer should call the order desk (800-331-0877) to order a replacement CD.

## Article #19259: Missing DATAPUMP.EXE error when deploying BDE with ISExpress

Question and Answer Database

FAQ: FAQ4259D - Missing DATAPUMP.EXE error when deploying BDE with ISExpress

Category: Miscellaneous

Platform: Win95/NT

Product: Delphi4.x,

Question:

What is this "Missing DATAPUMP.EXE" error when trying to deploy BDE with Installshield Express?

Answer:

Download and replace the files included in the installshield express update available from the Borland website at <http://www.borland.com/devsupport/delphi/downloads/> The cause of this error is that ISExpress is trying to deploy the DATAPUMP when it should not.

## Article #19260: Missing component palette under NT

Question and Answer Database

FAQ4260D.txt :Missing component palette under NT  
Category :Install Issues  
Platform :Windows NT  
Product :

### Question:

No errors during installation, but when I run Delphi there are no components on the component palette! Why?

### Answer:

Most likely you are using NT and need to use the "Registry Keys Only" installation choice as the currently logged in user to get all the necessary DLL's and registry key entries to run Delphi 4 under this user profile. Most likely Delphi 4 was installed by an administrator or a user with administrator rights and you are logged in as another user and trying to use Delphi 4.

Delphi fails to load properly because it cannot locate registry keys essential for running.

## Article #19261: Random access violations in the IDE

Question and Answer Database

FAQ4261D.txt :Random access violations in the IDE  
Category :Install Issues  
Platform :Win95/NT  
Product :Delphi4.x,

Question:

Delphi used to work fine but now I get random access violations in the IDE! Why?

Answer:

You most likely installed a bad component or package that was not written/compiled for Delphi 4. Try uninstalling custom components one by one (or package by package) until the problem goes away, then get in touch with the component vendor regarding this issue.

## Article #19262: Installation error "\_ins5176" at end of installation

Question and Answer Database

FAQ4262D.txt :Installation error "\_ins5176" at end of installation  
Category :Install Issues  
Platform :Windows 95  
Product :Delphi3.x, Delphi4.x,

### Question:

I get installation "Error \_ins5176" at the end of my installation, what does this mean?

Delphi seems to run fine after the install and reboot.

### Answer:

If the install continues and everything seems to work fine, then it can be ignored (the error happens during installation cleanup).

Otherwise, it's much more serious and there's no easy solution. Try uninstalling the product via the control panel's "Add/Remove applications" applet. This usually happens on a machine that already has another version of Delphi on it and has to do with the failure to register an OCX that is already registered.

## Article #19263: Multiple splash screens keep popping up

Question and Answer Database

FAQ4263D.txt :Multiple splash screens keep popping up  
Category :Install Issues  
Platform :Win95/NT  
Product :Delphi3.x, Delphi4.x,

Question:

Why do multiple splash screens keep popping up?

Answer:

Either you have a bad CD-ROM driver, or a slightly damaged CD that one computer may read fine but this particular computer is not as forgiving. Try a hard drive installation or update the CD-ROM driver. You will need to contact customer service in the case of a damaged CD.

## Article #19264: "ICON IMAGE IS NOT VALID" error when installing

Question and Answer Database

FAQ4264D.txt : "ICON IMAGE IS NOT VALID" error when installing  
Category : Install Issues  
Platform : Win95/NT  
Product : Delphi3.x, Delphi4.x,

Question:

What does the "ICON IMAGE IS NOT VALID" error mean?

Answer:

Chances are good that you are using a Micron(or other factory assembled system) computer which has a proprietary version of the OS (95, NT, 98). You may be able to successfully install by uninstalling and re-installing, or in the worse case scenario you may need to install a non-Micron-proprietary OS (official OEM version of 95/98/NT)

## Article #19272: IDCO400.DLL and IDCO400.CFG not marked as shared DLLs.

Question and Answer Database

FAQ4272D.txt - IDCO400.DLL and IDCO400.CFG not marked as shared DLLs.

Category :AS400  
Platform :Win95/NT  
Product :DelphiAS400,

### Question:

I have Delphi/400 Development and Deployment installed. How come when I uninstall either one of them IDCO400.DLL and IDCO400.CFG are deleted?

### Answer:

These files are not marked as shared DLLs in

HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\CurrentVersion\SharedDlls

so they are deleted during uninstall. You can either add the keys in the registry to make them be not be deleted, or make make backups before unstaill.

Note: This problem is only a problem if both the deployment and the developer installs are done on the same computer.

## Article #19274: Non-Blob column in table required to perform operation with MSSQL

Question and Answer Database

FAQ4274B.txt - Non-Blob column in table required to perform operation

Category :Database (MSSQL)

Platform :32 Bit

Product :BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, Delphi 5.x

Question:

How come I'm getting the error

"Non Blob column in table required to perform operation" when posting to my MSSQL database?

Answer:

There are two conditions where this error occurs:

1. You have an identity field and a field that is NOT NULL (required) and you post a record.

With BDE versions prior 5.10, all you can do is ignore the error and continue. The problem is resolved simply by getting BDE 5.10.

2. You have an identity field which is the primary key and a key field, you have a text field, and you post a record.

With BDE versions prior 5.10, all you can do is ignore the error and continue. If you have BDE 5.10 and Delphi, you can turn on the AutoRefresh property of your DataSet to resolve the problem.

If you have BDE 5.10 and development system other than Delphi 5, you can call DbisetProp and set curAUTOREFETCH (which is equal to 0x00050017) to true.

- o C++ Builder Example:

```
#include "bde.hpp"
#define curAUTOREFETCH 0x00050017;
Table1->Open();
DbisetProp(Table1->Handle, curAUTOREFETCH, TRUE);
```

- o Delphi version other than 5 example:

```
uses bde;  
const  
  curAUTOREFETCH = $00050017;  
...  
Table1.Open;  
DbiSetProp(hDbiObj(Table1.Handle), curAUTOREFETCH, Longint(TRUE))
```

## Article #19285: How to prevent closing of an undocked ToolBar

Question and Answer Database

FAQ4285D.txt :How to prevent closing of an undocked ToolBar

Category :Miscellaneous

Platform :Win95/NT

Product :Delphi4.x,

Question:

How do I prevent a user from closing (hiding) an undocked ToolBar?

Answer:

Here's one possible solution. You have to create your own TToolDockForm descendant, and in it you want to make sure that the border icon is gone as well as preventing Alt+F4.

type

```
TMyToolDockForm = class(TToolDockForm)
    constructor Create(AOwner: TComponent); override;
    procedure DoClose(var Action: TCloseAction); override;
end;
```

```
constructor TMyToolDockForm.Create(AOwner: TComponent);
```

```
begin
```

```
    inherited Create(AOwner);
```

```
    BorderIcons := [];
```

```
end;
```

```
procedure TMyToolDockForm.DoClose(var Action: TCloseAction);
```

```
begin
```

```
    Action := caNone;
```

```
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
var
```

```
    i : Integer;
```

```
begin
```

```
    for i:=0 to ComponentCount-1 do
```

```
        if Components[i] is TToolBar then
```

```
            TToolBar(Components[i]).FloatingDockSiteClass :=
```

```
TMyToolDockForm;  
end;
```

## Article #19288: Error: "BORDBK40.DLL is missing or not registered"

Question and Answer Database

FAQ4288D.txt :Error: "BORDBK40.DLL is missing or not registered"  
Category :Install Issues  
Platform :All  
Product :Delphi4.x,

### Question:

What does "BORDBK40.DLL is missing or not registered" error mean during installation or startup of Delphi 4?

### Answer:

If the installation does not complete the cause of the problem is likely due to a software conflict. Some anti-virus software and certain NT Internet Services have been known to prevent BORDBK40.DLL and/or HTML.OCX from being registered with the operating system. In this case the best solution is to try eliminating the software in question from the picture and then try reinstalling Delphi 4. If that doesn't pose a viable solution you can also try step 1 and 2 outlines below to manually register the BORDBK40.DLL or HTML.OCX.

If the install does complete, and you get this message when running Delphi 4:

- 1) First, try running TREGSVR manually to register the dll. TREGSVR can be found in the "Delphi 4/bin" directory.
- 2) To register the DLL you would type "tregsvr bordbk40.dll" in the directory where the DLL resides. (This works providing you have the "Delphi 4/bin" directory on your path, otherwise you would include the path to bordbk40.dll)
- 3) If TREGSVR says the dll "has been successfully registered", but Delphi 4 doesn't work, then you have probably uninstalled Delphi 4 AFTER applying Update 2, and then re-installed without applying Update 2. Hence, the DLL is installed correctly but Delphi 4.00 does not know how to use the Delphi 4.01 version of the DLL. To correct this problem install update pack 2 and then your version of Delphi 4 will correspond to the version of the DLL on your system.

## Article #19291: Paradox errors when using SQL servers and cached updates

Question and Answer Database

FAQ4291D.txt :Paradox errors when using SQL servers and cached updates

Category :Database/VCL

Platform :Win32

Product :All32Bit,

Question:

Why am I getting a paradox lock or table busy error when I'm accessing data on a SQL server in my application (not paradox)?

Answer:

You are probably using Cached Updates in you project. When the BDE caches your data it is stored inside a paradox table. This happens when an application is being run off a server and there is more then one user executing the application. It is easily fixed by setting the paradox NetFile Directory and Private Directory to a temp directory such as " C:\ " (see the documentation for TSession for PrivateDir and NetFileDir properties)

## Article #19297: Deleting all records from dBASE table may work differently between 16 bit and 32 bit.

Question and Answer Database

FAQ4297B.txt - Deleting all records from dBASE table may work differently between 16 bit and 32 bit.

Category :BDE Features  
Platform :All Windows  
Product :BC++4.5x, BC++5.x, C++Builder1.0, C++Builder3.x,  
Delphi2.x, Delphi3.x, Delphi4.x, VdBase5.5x, VdBase5.6,  
VdBase7.x,

### Question:

In 16 bit Visual dBASE, DELETE without a WHERE clause causes records to be physically deleted. In 32 bit, it just marks them for deletion.

### Example

```
USE Foo
DELETE FROM Foo
```

### Answer:

This is design change. Other 32 bit clients may be effected as well. To insure that records are physically deleted from a dBASE table always issue a pack.

## Article #19384: BatchMove of Time field from Paradox to Oracle results in timestamp in the year 3000.

Question and Answer Database

FAQ4384B.txt - BatchMove of Time field from Paradox to Oracle results in timestamp in the year 3000.

Category :Database (Oracle)

Platform :All Windows

Product :All-CBuilder, BC++4.5x, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x,

Question:

How come when I batch move my Paradox table to my Oracle table I have timestamp data in the year 3000.

Answer:

This can occur when you batchmove time fields.

Oracle does not have an exact match, so a timestamp field is created. Oracle has no Time field, so an arbitrary date is put into the DATE field with the original time.

## Article #19395: Delphi is not brought to the front when breakpoints are hit in Windows 98

Question and Answer Database

FAQ4395D.txt :Delphi is not brought to the front when breakpoints are hit in Windows 98

Category :IDE

Platform :Windows 98

Product :All32Bit,

Question:

In Windows 98, why is it that when I hit a breakpoint or an Exception occurs,

Delphi isn't brought to the front of all other windows?

All it does is blink the Delphi icon in the Windows taskbar.

Answer:

This is a Windows 98 feature. You can turn it off by editing the WIN.INI file

under the section header entitled "[Compatibility95]"

```
[Compatibility95]
```

```
(Add the line below)
```

## Article #19396: GPF in module MACXW4.DRV

Question and Answer Database

FAQ4396D.txt :GPF in module MACXW4.DRV  
Category :Install Issues  
Platform :Windows 95/98  
Product :All32Bit,

### Question:

I just installed Delphi and when I access the Environment Options or open up one of my projects, I get an error message that 'Delphi32 caused a GPF in module MACXW4.DRV at?' and then Delphi shuts down. How do I fix this?

### Answer:

This is more than likely a video driver related problem. Downloading the latest video drivers for your video card should solve the problem. You can also try turning hardware acceleration off. To turn off hardware acceleration: Right click on the desktop, select properties from the popup menu. Click on the "Settings" tab and then click on the "Advanced" button and then select the "Performance" tab. The final step is to turn the accelerator slider down to none and reboot for the changes to take effect.

## Article #19414: "Socket subsystem error" during install of InterBase

Question and Answer Database

FAQ4414C.txt : "Socket subsystem error" during install of InterBase  
Category : Database Issues  
Platform : All-32Bit  
Product : C++Builder3.x, C++Builder4.x,

### Question:

During installation of InterBase on Windows 95 or Windows NT, the configuration of the network service fails and reports the error message "Socket subsystem error."

### Answer:

This error occurs on systems that use the Novell Winsock TCP/IP driver.

InterBase 5.5 supports only the Microsoft Winsock TCP/IP driver. Some versions of the Novell Winsock TCP/IP driver are not compatible with the Microsoft driver. Installing or running InterBase on a platform with a Novell TCP/IP driver is not supported.

Remove the Novell TCP/IP protocol driver using Control Panel | Network | Protocols. Install the Microsoft TCP/IP protocol driver from the Windows NT and 95 installation media.

## Article #19417: Updating your AS/400 OS release does not effect your Delphi/400 install

Question and Answer Database

FAQ4417D.txt - Updating your AS/400 OS release does not effect your Delphi/400 install

Category :AS400  
Platform :All Windows  
Product :DelphiAS400,

Question:

I'm updating my OS release on my AS/400. Will this effect my Delphi4/00 install?

Answer:

No. The key on your AS/400 is based on the model number and serial number of your AS/400. These do not change when install a new AS/400 OS release.

## Article #19428: Error: APPC Allocate Error Security Not Valid

Question and Answer Database

FAQ4428D.txt - Error: APPC Allocate Error Security Not Valid

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

How come I'm getting the error "APPC Allocate Error Security Not Valid" when I try to connect to my AS/400 using Delphi/400.

### Answer:

This error occurs when the port number to your AS/400 is incorrect. The correct port number for Delphi 3 is 5003. The correct port number for Delphi 4 is 4003.

Delphi 2/400 and Delphi 3/400 use the CO400 library on the AS/400. Delphi 4/400 uses the CO404 library. The way Delphi 4/400 decides to use the CO404 library is by reading Version=4 from the CO400 section of WINI.INI. If Version=4 is missing it connects to the CO400 library instead.

The Delphi 4/400 Deployment install does not update WIN.INI, so by default it attempts to connect to the CO400 library. So, for Delphi 4/400 Deployments if you enter a port number of 4003 and do not update WIN.INI, you will receive the error APPC Allocate Error Security Not Valid unless you either update WIN.INI, or have the CO400 library installed.

## Article #19430: Error: Nested Transactions Not supported

Question and Answer Database

FAQ4430B.txt - Error: Nested Transactions Not supported

Category :Database (InterBase)  
Platform :All-32Bit  
Product :All, All, All,

Question:

Q. How do I update a live view inside a transaction against Interbase? I always get the error "Nested Transactions not supported".

Answer:

To update an updateable view you must use an UPDATE SQL command. Otherwise, you cannot update an updateable view inside a transaction.

## Article #19432: DbiOpenTableList does not list Informix views

Question and Answer Database

FAQ4432B.txt - DbiOpenTableList does not list Informix views

Category :Database (Informix)  
Platform :All-32Bit  
Product :All, All, All,

Question:

How come Synonyms are not listed for the tablename property of a TTable, yet they are list under Synonmys in SQL Explorer?

Answer:

A TTable uses DbiOpenTableList to get its list of tables. For Informix, Synonyms are not implemented in this function. SQL Explorer uses SQL to gets Synonym list.

## Article #19436: Access CrossTab queries queries

Question and Answer Database

FAQ4436B.txt - Access CrossTab queries queries

Category :Database (MSACCESS)  
Platform :All-32Bit  
Product :All-CBuilder, BC++5.x, Delphi2.x, Delphi3.x,  
Delphi4.x, VdBase7.x,

Question:

Can the BDE MSACCESS driver execute crosstab queries?

Answer:

Yes. Here is an example created by using the Crosstab expert from Access against the Northwind sample database.

```
TRANSFORM Count([OrderID]) AS [The Value]
SELECT [ShipVia], Count([OrderID]) AS [Total Of OrderID]
FROM Orders
GROUP BY [ShipVia]
PIVOT [ShipPostalCode];
```

## Article #19438: Incorrect Application Icon

Question and Answer Database

FAQ4438D.txt - Incorrect Application Icon

Category :Miscellaneous  
Platform :All Windows  
Product :All32Bit,

### Question:

Windows shows the wrong icon for my application in the Windows Explorer and on Short Cuts. When my application is run however, the correct icon appears on the Task Bar and in the Alt-Tab list.

### Answer:

When Windows shows the default icon for an application in a Short Cut or in the Window's Explorer it uses the first icon resource that appears in the executable file. Icon resources that are linked into an application are ordered alphabetically. The resource name that Delphi uses for an application's icon is "MAINICON". If you link additional icon resources into your application you will need to make sure to name them so that they are ordered alphabetically after the resource name "MAINICON". The correct icon appears when the application is launched because in the window creation and registration process the icon resource name for the application is specified explicitly.

## Article #19439: Creating a custom TInplaceEdit for TDBGrid

Question and Answer Database

FAQ4439D.txt - Creating a custom TInplaceEdit for TDBGrid

Category :Database/VCL  
Platform :All Windows  
Product :All32Bit,

Question:

How can I customize the cell editor for a TDBGrid?

Answer:

You should create a custom TInPlaceEdit for use within Grids.

Following is an example component:

```
unit CustomEditorGrid;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs,
  Grids, DBGrids;

type
  TMyInplaceEdit = class(TInplaceEdit)
  public
    procedure DblClick; override;
  end;

  TCustomEditorGrid = class(TDBGrid)
  private
    { Private declarations }
  protected
    { Protected declarations }
    function CreateEditor: TInplaceEdit; override;
  public
    { Public declarations }
  published
```

```
    { Published declarations }  
end;
```

```
procedure Register;
```

```
implementation
```

```
const
```

```
    SomeDefaultValue = 'Default Value';
```

```
procedure Register;
```

```
begin
```

```
    RegisterComponents('Custom', [TCustomEditorGrid]);
```

```
end;
```

```
{ TCustomEditorGrid }
```

```
function TCustomEditorGrid.CreateEditor: TInplaceEdit;
```

```
begin
```

```
    Result := TMyInplaceEdit.Create(Self);
```

```
end;
```

```
{ TMyInplaceEdit }
```

```
procedure TMyInplaceEdit.DblClick;
```

```
begin
```

```
    inherited DblClick;
```

```
    if (Text = '') then
```

```
        Text := SomeDefaultValue;
```

```
end;
```

```
end.
```

## Article #19440: Delphi 3/400 and Delphi 4/400 installed on the same machine

Question and Answer Database

FAQ4440D.txt - Delphi 3/400 and Delphi 4/400 installed on the same machine

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

I have Delphi 3/400 and Delphi 4/400 installed on the same machine. I see that the last one installed controls what library I connect to the AS/400 regardless of whether I'm using Delphi 3 or Delphi 4. For example, if I install Delphi 3/400, then Delphi 4/400, then connect using Delphi 3, I connect to the Delphi 3 library (CO400). How do I make each connect to the correct library?

### Answer:

The version= line in the CO400 section of WIN.INI controls what library is connected to for the Delphi 4/400 version. If version=4, the CO404 library is used. If the line is not found, the CO400 library is used.

So, to resolve the problem, make sure Delphi 4/400 is installed last and control which library is connected to by editing WIN.INI.

## Article #19443: Generating auxiliary tables for Local SQL

Question and Answer Database

FAQ4443B.txt - Generating auxiliary tables for Local SQL

Category :BDE Features  
Platform :All Windows  
Product :All32Bit,

Question:

When I insert or delete records with Database Desktop using Local SQL a INSERTED or DELETED table is generated. How do I do the same with any BDE tool?

Answer:

Here's a Delpi example. It assumes Query2 has a SQL statement that deletes or inserts records from a Paradox or dBASE table.

```
Query2.Prepare;  
Check(DbiSetProp(hDbiObj(Query2.stmtHandle), stmtAUXTBLS, LongInt  
(True)));  
Query2.ExecSQL;
```

## Article #19452: 0 Dates and Informix

Question and Answer Database

FAQ4452B.txt - 0 Dates and Informix

Category :Database (Informix)  
Platform :All Windows  
Product :All-CBuilder, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x,

### Question:

Informix documentation says that if you assign 0 to a date the result should be 12/31/1899, yet if I assign a 0 to an Informix date in Delphi or C++ Builder, the result is 12/30/1899. How come?

### Answer:

Delphi and C++ Builder assign a 0 based date to 12/30/1899. When they send the date to the server they do not send a zero but send a 12/30/1899 instead.

## Article #19462: Creating Floats in Access Table results in integers being created

Question and Answer Database

FAQ4462B.txt - Creating Floats in Access Table results in integers being created

Category :Database (ODBC)  
Platform :All-32Bit  
Product :All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x,

Question:

How come when I'm using ODBC to connect to ODBC Access and I create a Table with TTable.CreateTable, fields which are type float result in being type integer?

Answer:

This is a problem specific to Microsoft's implementation of the Access ODBC driver. The problem does not occur with other ODBC datasources. The solution is to either use SQL to create the table or use the Native driver instead.

## Article #19464: Fieldtypes that get translated to BCD

Question and Answer Database

FAQ4464B.txt - Fieldtypes that get translated to BCD

Category :Database (Miscellaneous)  
Platform :All Windows  
Product :All-CBuilder, BC++4.5x, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, JBuilderC/S1.0,

Question:

What fieldtypes get translated to BCD when Enable BCD is true?

Answer:

When BCD is enabled, the following data types are translated to BDE logical data type fldBCD.

Interbase:

DECIMAL, NUMERIC

Oracle

NUMBER, FLOAT

Mssql

MONEY, SMALLMONEY, DECIMAL, NUMERIC

Sybase

MONEY, SMALLMONEY, DECIMAL, NUMERIC

Dbase

NUMBER, FLOAT

Paradox

BCD

## Article #19470: Delphi/400 deployment fails if BDE partial install is deployed

Question and Answer Database

FAQ4470D.txt - Delphi/400 deployment fails if BDE partial install is deployed

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Question:

I'm trying to install the Delphi/400 Deployment and I'm getting an error indication it cannot find the BDE. What is wrong?

### Answer:

The Deployment looks in the registry at the registry entry DLLPATH in HKEY\_LOCAL\_MACHINE\SOFTWARE\Borland\Database Engine to find the BDE. If this entry is missing or pointing to an invalid directory this problem will occur.

There are four possible conditions to cause this error.

1. The BDE has not been installed.
2. Only a partial install of the BDE has performed. Partial installs do not update DLLPath.
3. The registry has been edited to point to an incorrect location.
4. The files in directory where DLLPATH points have been moved or deleted.

## Article #19490: ODBC and DB2 don't do Prepare's

Question and Answer Database

FAQ4490B.txt - ODBC and DB2 don't do Prepare's

Category :Database (DB2)

Platform :32 bit Windows

Product : ALL 32 Bit BDE

### Question:

How come I see no performance improvement when preparing a query against an ODBC datasource or a DB2 datasource?

### Answer:

IN BDE versions prior to 5.10, The BDE connection to DB2 and ODBC do not support prepare. Performing a prepare causes a no-op to occur.

BDE 5.10 and later supports Prepare in a DB2 connection. However, executing two prepared statements in a row will generate a General SQL Error. To avoid getting the General SQL Error Unprepare after each SQL execution and then Prepare again before executing the statement again.

ODBC still does not support Prepare.

## Article #19504: Special SQL syntax required to INSERT into BLOBs/CLOBs when parameters are >= 4K.

Question:

Why am I having trouble inserting/updating Oracle 8 BLOB and/or CLOB datatypes where the data >=4k?

Answer:

Oracle SQL requires a different SQL syntax when parameters to BLOBs and/or CLOBs have more than 4K worth of data. This means the following SQL statement:

```
INSERT INTO TESTBLOB (ICOMPONENTID, GIMAGE) VALUES (:CID, :GIMAGE)
```

will result in the error:

EDBEngineError with message 'General SQL error.  
ORA-22275: invalid LOB locator specified'

To resolve the problem for a blob do the following:

1. Use the following SQL statement:

```
insert into TESTBLOB (ICOMPONENTID, GIMAGE) values(:CID, empty_blob() ) returning  
GIMAGE into :GIMAGE
```

2. Make the parameter type for GIMAGE be ftOraBlob

To resolve the problem for a clob do the following:

1. Use the following SQL statement:

```
insert into TESTBLOB (ICOMPONENTID, GIMAGE) values(:CID, empty_clob() ) returning  
GIMAGE into :GIMAGE
```

2. Make the parameter type for GIMAGE be ftOraClob

## Article #19505: Sybase / MSSQL ARITHABORT ON and "Divide by zero occurred." error.

Question and Answer Database

FAQ: FAQ4505B - Sybase / MSSQL ARITHABORT ON and "Divide by zero occurred." error.

Category: Database (Sybase)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Why doesn't the Sybase SQL Link driver raise an error when a "Divide by zero" error occurs on the server?

Answer:

The MSSQL and Sybase SQL Links drivers do not raise server errors with severity levels 10 and below for the reasons explained below.

Setting ARITHABORT ON should change the severity level of arithmetic errors (see below).

With MSSQL Server "ARITHABORT ON" appears to change the severity level of the "Divide by zero" error from 10 to 16 whereas Sybase does not change its level from 10 (as expected the underlying Sybase server behavior does change though).

Both the MSSQL and Sybase documentation describe severity levels the same way (see below).

MSSQL descriptions for levels 0 through 16:

Severity Level 0 and 10: Status Information (Reported as Level 0)

These messages are not errors; they provide additional information after certain statements have executed.

[errors with levels 0 or 10 are not raised by the BDE]

Severity Levels 11 through 16

These messages indicate errors that can be corrected by the user.

Sybase:

-----  
set arithabort on  
select 1/0

Server Message: Number 3607, Severity 10  
Divide by zero occurred.  
(0 rows affected)

-----  
set arithabort off  
select 1/0

Server Message: Number 3621, Severity 10  
Command has been aborted.  
(0 rows affected)

MSSQL:

-----  
set arithabort off  
select 1/0

(null)

(1 row(s) affected)

Divide by zero occurred.

This error is documented as being  
Error: 3607  
Severity Level: 10  
Description: Divide by zero occurred.

-----  
set arithabort on  
select 1/0

Msg 8134, Level 16, State 1  
Divide by zero error encountered

Last Modified: 01-SEP-99

## Article #19506: Informix Online and ROW LEVEL LOCKING (LOCK MODE ROW)

Question and Answer Database

FAQ: FAQ4506B - Informix Online and ROW LEVEL LOCKING (LOCK MODE ROW)

Category: Database (Informix)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Is it possible to do row level locking when working with an Informix server?

Answer:

All settings and options for row level locking are done at the table and database level.

The client application does not require any modifications or specific Informix server support to benefit from Informix Online row level locking.

Please see your Informix documentation for specific server and table settings.

Example Informix table create (please see your Informix documentation for specific information):

```
CREATE TABLE ROWLOCKTEST
(
FLD1 CHAR(5),
FLD2 FLOAT
)
LOCK MODE ROW
```

LOCK MODE PAGE is the default if not specified.

ALTER TABLE can be used to change the LOCK MODE for a table.

Example:

- 1) Start a transaction from the Informix client (TDatabase.starttransaction)
- 2) Modify a row and post (do not commit yet (TDatabase.commit))
- 3) From another client or connection attempt a change to the updated, uncommitted row. The second client should time out.
- 4) All rows not currently involved in a transaction can be modified.

If the Informix table in the above example had been created or altered with

LOCK MODE PAGE then rows adjacent (within the same locked page) to the row or rows currently part of a pending transaction will also be locked.

## Article #19507: Oracle database link, cursor, ORA-03106: fatal two-task communication protocol error

Question and Answer Database

FAQ: FAQ4507B - Oracle database link, cursor, ORA-03106: fatal two-task communication protocol error

Category: Database (Oracle)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Why am I receiving the Oracle error ORA-03106: "fatal two-task communication protocol error" when using an Oracle database link and Oracle cursors?

Answer:

```
SQL> print rcl
ERROR:
ORA-03106: fatal two-task communication protocol error
ORA-02063: preceding line from MARSLNK
```

As indicated in the SQL Plus output above this problem can be reproduced without using the BDE and/or BDE clients (Delphi, BCB, etc.).

The example SQL Plus output shows examples show the creation of an Oracle database link, synonym, stored procedure, package, package body, along with the execution and "printing" of the Oracle cursor data.

=====

```
create public database link MARSLNK using 'srvr_tcp.borland.world'
```

=====

EXECUTE PROCEDURE AND FETCH DATA FROM CURSORS VIA SQL\*PLUS:

```
variable rctl refcursor;
execute cursortest_4(:rctl);
```

```
print rctl
```

```
variable rcl refcursor;
execute cursortest_2(:rcl);
```

```
print rcl
```

=====

```
create or replace procedure cursortest_4 (rcl in out DMOD.rctl) AS
```

```
begin
```

```
open rcl for
```

```
SELECT CUSTOMER_N, NAME
```

```
FROM IDXCUSTM
```

```
ORDER BY UPPER(NAME);
```

```
end;
```

=====

```
create or replace procedure cursortest_2
```

```
(rcl in out cursorpack.rctl) AS
```

```
begin
```

```
open rcl for
```

```
SELECT *
```

```
FROM IDXCUSTM;
```

```
end;

=====

create or replace package cursorpack IS

type rctl is ref cursor return IDXCUSTOM%rowtype;

end;
```

```
=====

create or replace PACKAGE DMOD

IS

type rctl is ref cursor;

end;
```

```
=====
```

Log in to the Oracle server as the administrator to create the public database link:

SQL\*Plus: Release 3.3.4.0.0 - Production on Thu Oct 22 16:36:15 1998

Copyright (c) Oracle Corporation 1979, 1996. All rights reserved.

Connected to:  
Oracle7 Server Release 7.3.4.0.0 - Production  
With the distributed, replication and parallel query options  
PL/SQL Release 2.3.4.0.0 - Production

```
SQL> CREATE PUBLIC DATABASE LINK MARSLNK USING 'srvr_tcp.borland.world';
```

Database link created.

```
=====
```

Log into the Oracle server as user to create the synonym, packages

and procedures followed by execution of the procedures and printing/fetching the cursor rows:

SQL\*Plus: Release 3.3.4.0.0 - Production on Thu Oct 22 16:40:35 1998

Copyright (c) Oracle Corporation 1979, 1996. All rights reserved.

Connected to:

Oracle7 Server Release 7.3.4.0.0 - Production

With the distributed, replication and parallel query options

PL/SQL Release 2.3.4.0.0 - Production

```
SQL> CREATE SYNONYM IDXCUSTM FOR IDXCUST@MARSLNK;
```

Synonym created.

```
SQL> create or replace PACKAGE DMOD
```

```
2
```

```
2 IS
```

```
3
```

```
3 type rctl is ref cursor;
```

```
4
```

```
4 end;
```

```
5 /
```

Package created.

```
SQL> create or replace package cursorpack IS
```

```
2
```

```
2 type rctl is ref cursor return IDXCUSTM%rowtype;
```

```
3
```

```
3 end;
```

```
4 /
```

Package created.

```
SQL> create or replace procedure cursortest_2
```

```
2
```

```
2 (rcl in out cursorpack.rctl) AS
```

```
3
```

```
3 begin
```

```
4
```

```
4 open rcl for
```

```
5
5  SELECT *
6
6  FROM IDXCUSTM;
7
7  end;
8  /
```

Procedure created.

```
SQL> create or replace procedure cursortest_4 (rc1 in out DMOD.rctl)
AS
2
2  begin
3
3  open rc1 for
4
4  SELECT CUSTOMER_N, NAME
5
5  FROM IDXCUSTM
6
6  ORDER BY UPPER(NAME);
7
7  end;
8  /
```

Procedure created.

```
SQL> variable rctl refcursor;
SQL> execute cursortest_4(:rctl);
```

PL/SQL procedure successfully completed.

```
SQL> print rctl
ERROR:
ORA-03106: fatal two-task communication protocol error
ORA-02063: preceding line from MARSLNK
```

no rows selected

```
SQL> variable rcl refcursor;
SQL> execute cursortest_2(:rcl);
```

PL/SQL procedure successfully completed.

SQL> print rc1

ERROR:

ORA-03106: fatal two-task communication protocol error

ORA-02063: preceding line from MARSLNK

no rows selected

## Article #19508: Raising MSSQL and Sybase errors with a severity <=10 do not get raised by SQL Links.

Question and Answer Database

FAQ: FAQ4508B - Raising MSSQL and Sybase errors with a severity <=10 do not get raised by SQL Links.

Category: Database (MSSQL)

Platform: All-32Bit

Product: All-32Bit,

Question:

Why don't server errors with a severity <=10 get raised by SQL Links?

Answer:

According to MS documentation severity Level 0 and 10 are for Status Information only (Reported as Level 0) These messages are not errors; they provide additional information after certain statements have executed.

Errors w/severity <=10 are also not returned by MS ODBC.

ADDITIONAL INFORMATION AND EXAMPLES

```
create procedure myerrorproc as
begin
RAISERROR ('my raiserror',11,127)
end
```

```
Using WISQL32:
exec myerrorproc
```

Returns the following:

```
Msg 50000, Level 11, State 127
my raiserror
```

```
create procedure myerrorproc2 as
begin
RAISERROR ('my raiserror',10,127)
end
```

```
Using WISQL32:
exec myerrorproc2
```

Returns the following:  
my raiserror

Info from MS SQL Server knowledgebase:

RAISERROR Statement (version 6.5):  
"Messages with severity levels 10 and under are not errors, but they do provide additional information."

Severity Levels 0 through 18

Severity Level 0 and 10: Status Information (Reported as Level 0) These messages are not errors; they provide additional information after certain statements have executed.

Severity Levels 11 through 16

These messages indicate errors that can be corrected by the user.

Severity Level 17: Insufficient Resources

These messages indicate that the statement has caused SQL Server to run out of resources (such as locks or disk space for the database) or to exceed some limit set by the SA.

These system limits include the number of databases that can be open at the same time and the number of connections allowed to SQL Server. Limits are stored in the sysconfigures table in the master database and can be changed with the sp\_configure system stored procedure. (For details about using sp\_configure, see the Microsoft SQL Server Transact-SQL Reference)

Level 17 messages that indicate you have run out of space can usually be corrected by the database owner. Other level 17 messages are best addressed by the SA.

Severity Level 18: Nonfatal Internal Error Detected  
These messages indicate that there is some type of internal software problem, but the statement finishes, and the connection to SQL Server is maintained. For example, a level 18 message occurs when SQL Server detects that a decision about the access path for a particular query has been made without a valid reason. The SA should be informed every time a level 18 message occurs.

## Article #19557: New Interbase SQL Links support in BDE 5.01 (SQLINT32.DLL v5.01.24)

Question and Answer Database

FAQ: FAQ4557B - New Interbase SQL Links support in BDE 5.01 (SQLINT32.DLL v5.01.24)

Category: Database (InterBase)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Does the Interbase SQL Links driver support Roles and additional transaction behavior?

Answer:

Please see the BDEREADME.TXT for additional information regarding BDE and SQL Links v5.01.

Please note that the new BDE ALIAS configuration parameters (COMMIT RETAIN, ROLE NAME, WAIT ON LOCKS) will show up only in newly created ALIASES.

InterBase Changes

-----  
Transaction Isolation Levels & InterBase  
-----

By adding 4096 to the setting of DRIVER FLAGS in the Borland Database Engine (BDE) configuration, you can specify that the InterBase SQL Links driver should use soft commits. Soft commits are a feature of InterBase that let the driver retain the cursor when committing changes. Soft commits improve performance on updates to large sets of data. When not used, the BDE must re-fetch all the records, even for a single record change. With soft commit the cursor is retained, and a re-fetch is not needed. Soft commits are never used in explicit transactions started by

BDE client applications. The soft commit property corresponds to the COMMIT RETAINING transaction option in the InterBase documentation.

DRIVER FLAGS	Isolation level	Commit type
-----	-----	-----
0	Read committed	hard commit
512	Repeatable read	hard commit
4096	Read committed	soft commit
4608	Repeatable read	soft commit

The 4096 driver flag bit only affects implicit transaction behavior. Use the COMMIT RETAINING property to control the default commit behavior of explicit transactions.

## Roles

-----  
InterBase allows users to log in by specifying a role. ROLE NAME is a new BDE configuration parameter that allows BDE clients to pass a role name. ROLE NAME can also be passed as an optional parameter when using a TDatabase component (Delphi and C++Builder).

This information supersedes that in the InterBase 5.5 Operations Guide, which indicates that the BDE has no property for specifying a role name.

## Transaction WAIT

-----  
Currently, the InterBase SQL Links driver uses NOWAIT when resolving lock conflicts and returns an error immediately if there is a resource conflict. Setting the WAIT ON LOCK configuration parameter allows SQL Links to use WAIT on InterBase transactions. This can also be done by setting the r/w database property dbWAITONLOCK to TRUE.

## Explicit transactions

-----  
The new BDE configuration parameter COMMIT RETAIN allows explicit transactions to use soft commit. The new database property dbCOMMITRETAIN also does this. Only explicit transactions are affected. The existing driver flags are still valid for explicit transactions.

COMMIT RETAINING = TRUE      calls isc\_commit\_retaining()

COMMIT RETAINING = FALSE    calls isc\_commit\_transaction()

## Article #19558: MSSQL SQL Links driver and the LANGDRIVER setting

Question and Answer Database

FAQ: FAQ4558B - MSSQL SQL Links driver and the LANGDRIVER setting

Category: Database (MSSQL)

Platform: All-32Bit

Product: All-32Bit,

Question:

Why might I be seeing duplicated rows being displayed in my application when using the MSSQL SQL Links driver w/MSSQL server version 6.5 or later?

Answer:

Please see the Delphi 4 README.TXT, BDEREADME.TXT, BDE32.HLP and SSQLLNK32.HLP for additional information regarding BDE language drivers and Borland SQL Links.

BDE/Microsoft SQL Server/Default Language Driver

-----  
If the LANGDRIVER parameter of a BDE alias for the Microsoft SQL Server driver is left blank, the Paradox ASCII driver will be used by default. Beginning with version 6.5, MS-SQL Server changed the default sort order from BINARY to NOCASE (52). As a result, an index created on CHAR or VARCHAR fields using the default language driver (Paradox ASCII) produces duplicate rows for an MS-SQL table if mixed case data is found in that field. Workaround: select an appropriate language driver in the LANGDRIVER parameter when configuring a BDE alias for MS-SQL (for example, US users would select the driver Borland ENG Latin-1). Note: this only applies to SQL Server version 6.5 and above, with default sort order.

## Article #19559: BDE 12550 Invalid configuration parameter error

Question and Answer Database

FAQ: FAQ4559B - BDE 12550 Invalid configuration parameter error

Category: BDE

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

What might be causing the error BDE 12550 Invalid configuration parameter?

Answer:

12550 Invalid configuration parameter.

One possible cause for the error:

ODBC ALIASES.

When creating and/or using a BDE alias that is using an ODBC DSN make sure that the ALIAS parameter "ODBC DSN" is set to the DSN that you wish to use and that has been created using ODBC Manager. Available ODBC DSN's can be chosen from the parameter's drop-down edit using the BDE Administrator.

Another possible cause:

Using ISAPI app and ODBC against NT web server. ODBC DSN on NT machine should be set to "system" instead of "user".

## Article #19560: "lock timeout" error, TIMEOUT and MAX QUERY TIME parameters.

Question and Answer Database

FAQ: FAQ4560B - "lock timeout" error, TIMEOUT and MAX QUERY TIME parameters.

Category: Database (MSSQL)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

What does the lock timeout error mean and what can I do to change the timeout?

Answer:

"lock timeout" error, TIMEOUT and MAX QUERY TIME parameters.

By default, SQL statements sent to MS SQL and Sybase servers using DB-Lib are sent using the synchronous query submission API. Earlier versions of SQL Links used the asynchronous query submission API. To use the asynchronous query submission API, add 2048 to the current value of DRIVER FLAGS or set it to 2048 if it's blank.

To control the time-out for synchronous query submission use the MSSQL and Sybase driver TIMEOUT param.

To control the time-out for Asynchronous query submission use the MSSQL and Sybase driver and ALIAS MAX QUERY TIME param.

## Article #19561: Oracle user functions, ORA-06553 expression of of wrong type

Question and Answer Database

FAQ: FAQ4561B - Oracle user functions, ORA-06553 expression of of wrong type

Category: Database (Oracle)

Platform: All-32Bit

Product: All-CBuilder, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

When using my user functions I receive the error:  
ORA-06553 expression of of wrong type.  
What might be causing this error?

Answer:

Oracle SQL Plus example:

```
SQL> SELECT MYFUNCTION('ASTRING') FROM MYTABLE
      2 /
SELECT MYFUNCTION('ASTRING') FROM MYTABLE
      *
```

ERROR at line 1:

ORA-06552: PL/SQL: Statement ignored

ORA-06553: PLS-382: expression is of wrong type

In this example the function has been defined with a return type of boolean which is not a valid field type.

In other words the return type cannot be returned as part of a sql result (see below).

USER FUNCTIONS FROM THE ORACLE 8 SQL REFERENCE:

You can write your own user functions in PL/SQL to provide functionality that is not available in SQL or SQL functions. User functions are used in a SQL statement anywhere SQL functions can be used; that is, wherever

expression can occur.

For example, user functions can be used in the following:

- the select list of a SELECT command
- the condition of a WHERE clause
- CONNECT BY, START WITH, ORDER BY, and GROUP BY clauses
- the VALUES clause of an INSERT command
- the SET clause of an UPDATE command

For a complete description on the creation and use of user functions, see Oracle8 Application Developer's Guide.

Oracle user functions, ORA-06553 expression of of wrong type
