Product: All-CBuilder, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Why aren't all of the new features and types supported in the new version of the MSSQL SQL Links driver?

Answer:

Please see the BDEREADME.TXT for additional information regarding BDE and SQL Links v5.01.

New MS-SQL Server 7 Driver

-----  
The SQL Links (not available with all editions of Inprise programming tools) driver for Microsoft SQL Server now supports version 7, in addition to support in the same driver for version 6.5.

SQL Links uses DBLIB (native API for MS-SQL Server). DBLIB only implements the MS-SQL Server 6.5 feature set. This means that new types in MS-SQL Server 7 like GUID, Unicode, and CHAR columns longer than 255 characters are not supported. Microsoft will not be adding support for these new types to DBLIB, so the SQL Links driver does not support these new MS-SQL Server 7 types.

Both Microsoft and Inprise strongly recommend that you use the client software appropriate for the version of MS-SQL Server used. That is, use version 6.x client software only with 6.x server software and version 7 client software only

with version 7 server software.

## Article #19566: SQL Explorer left pane cannot be resized.

Question and Answer Database

FAQ: FAQ4566B - SQL Explorer left pane cannot be resized.

Category: Delphi 4

Platform: All-32Bit

Product: All-32Bit,

Question:

When I launch DB/SQL Explorer the left pane does not display anything and I cannot resize it anymore. What can I do to fix this?

Answer:

Search your registry for all references to DbX.MainSplit and change the value to something greater than 0 (zero).

This is the registry entry for DB Explorer when it is launched from the Delphi 4 IDE:

```
[HKEY_CURRENT_USER\Software\Borland\Delphi\4.0\DbXForm]
"DbX.MainSplit"="300"
```

## Article #19602: Computer freezes at splash screen when Delphi is started.

Question and Answer Database

FAQ4602D.txt - Computer freezes at splash screen when Delphi is started.

Category :Install Issues  
Platform :Windows 95 & 98  
Product :Delphi4.x, Delphi5.x,

### Question:

When I start Delphi I see the splash screen, then my system freezes. How can I fix this?

### Answer:

This is most likely a compatibility conflict with the video driver. Borland tests its products against generic S3 drivers provided by Microsoft or S3 Inc. Any drivers compliant with this standard should be okay. Video drivers that do not fully comply with this standard may or may not function correctly with Delphi.

To verify that you have a video driver issue try changing the hardware acceleration in the display properties to 'None'. To do this go to Control Panel\DisplaySettings\Advanced Properties\Performance (a setting in the middle may work also). Restart the computer and try opening Delphi. If the problem is gone then you know it is a video driver issue.

### If the system still freezes:

In Windows 95 try starting in safe mode.

In Windows 98, in the SYSTEM.INI file under the [display] section, add the line 'BusThrottle = 1' (no quotes). Save the file, reboot and try running Delphi again.

Here are some more permanent solutions:

1. Install the Delphi 4 service pack 3. This offers a work-around by changing the way the component palette icon image list is loaded at startup. This fix is included in Delphi 5.

2. Start Delphi with the "-ns" switch: At the Run command line type "delphi32.exe" -ns. Make sure the -ns is outside the quotes (It may be necessary to type the entire path to the delphi32.exe file inside the quotes). This will bypass the splash screen.
3. Try going into the menu Component|Install Packages and remove some packages for components you don't need.
4. Install a new video driver.

## Article #19603: Computer freezes when Delphi is started under Windows 98

Question and Answer Database

FAQ4603D.txt - Computer freezes when Delphi is started under Windows 98

Category :Install Issues  
Platform :Windows 98  
Product :Delphi4.x,

### Question:

My system freezes when I start Delphi ? I don't even see the splash screen.

How can I fix this?

### Answer:

Delphi 4 will not run on Windows 98 if the display is set to 16 colors or less.

This may cause the system to freeze during installation also.

This can be fixed by changing the display color palette.

Go to Control Panel/Display/Settings/, change the color palette setting to

something greater than 16 color, such as 256 color, High Color (16-bit) or

True Color (32-bit). If you do not have these options you may need to

update your video driver.

## Article #19614: Safe Mode and VGA mode.

Question and Answer Database

FAQ: FAQ4614D - Safe Mode and VGA mode.

Category: Install Issues

Platform: Windows 95, Windows 98, Windows NT, Windows ME, Windows 2000, Windows XP

Product: All32Bit,

Question:

What is Safe Mode or VGA mode?

Answer:

Safe mode is the method for booting into a simple system configuration under Windows 95/98/ME/2000/XP.

VGA mode is the diagnostic mode under Windows NT.

When Windows boots into Safe mode or VGA mode, it uses basic default settings that will run the operating system with minimal functionality, meaning it loads a bare bones operating system. Hardware, like your CD-ROM drive, may not function in Safe mode or VGA mode because the drivers are not loaded. Because of this it may be necessary to copy the Delphi/C++Builder installation files to the hard drive before restarting in safe mode (See FAQ titled "Installing Delphi 4 from a Hard Drive").

## Article #19615: Starting in Safe Mode or VGA mode.

Question and Answer Database

FAQ: FAQ4615D - Starting in Safe Mode or VGA mode.

Category: Install Issues

Platform: All Windows

Product: All32Bit,

Question:

How do I start my computer in Safe Mode or VGA mode?

Answer:

SAFE MODE (Windows 95):

There are two ways:

1. Hold down the SHIFT key as you restart until the Windows screen comes up.
2. When you restart, watch the screen for the text "Starting Windows 95".

When you see this hit F8 and choose Safe Mode from the option menu which comes up.

VGA MODE (Windows NT):

Windows NT should offer a menu at start up where you can select VGA mode.

If you do not see this option it may not be installed. Look at Control Panel->

System-> StartupShut Down->System Startup for a list of the operating systems installed on you computer.

## Article #19616: Delphi 4 running slowly.

Question and Answer Database

FAQ: FAQ4616D - Delphi 4 running slowly.

Category: IDE

Platform: All Windows

Product: Delphi4.x,

Question:

Why is Delphi 4 running slower than Delphi 3?

Answer:

Make sure the Delphi 4 Update Pack 2 has been installed. The debugger hooks were slow starting and finishing which caused slowness. Update Pack 3 is also available but should not significantly alter the execution speed.

## Article #19618: Error "Can't find PVCS" when installing Delphi Professional.

Question and Answer Database

FAQ: FAQ4618D - Error "Can't find PVCS" when installing Delphi Professional.

Category: Install Issues

Platform: All Windows

Product: Delphi4.x,

Question:

What does the error "Can't find PVCS" when installing Delphi Professional version mean?

Answer:

This is an error in the install program and can be ignored. The version control software (PVCS) comes with Delphi Client/Server but not Delphi Professional. However PVCS can be installed into Delphi professional if you own the standalone version of PVCS (available from intersolve).

## Article #19652: Creating a lookup field in a TDBGrid for Builder

Question and Answer Database

FAQ: FAQ4652C - Creating a lookup field in a TDBGrid for Builder

Category: Database Issues

Platform: All Windows

Product: All-CBuilder,

Question:

How do I create a lookup field in a TDBGrid in C++ Builder

Answer:

1. Drop 2-TTable's, 1-TDataSource and 1-TDBGrid on a form.
2. Connect Table1 to DataSource1 to DBGrid1: In the object inspector, set these attributes.
  - a. DataSource1.DataSet = Table1
  - b. DBGrid1.DataSource = DataSource1
3. Setup Table1: In the object inspector for Table1, set these attributes.
  - a. DatabaseName = BCDEMOS
  - b. TableName = Customer
  - c. Active = True
4. Setup Table2: In the object inspector for Table2, set these attributes.
  - a. DatabaseName = BCDEMOS
  - b. TableName = Orders
  - c. Active = True
5. Add all of the fields for Table1 by bringing up the Fields Editor:
  - a. Double click on Table1
  - b. Right click on Fields Editor
  - c. Add Fields. Add all of them
6. Add a new field for Table1.
  - a. Right click on Fields Editor, and select New Field.

7. Specify the following parameters for the newly added field.
  - a. Name: CustOrder
  - b. Type: String
  - c. Size: 30
  - d. Select Lookup
  - e. Key Fields: CustNo - Field in Table1 to store value
  - f. DataSet: Table2 - Table lookup is being done on
  - g. LookUpKeys: CustNo - This Key gets copied to KeyField
  - h. Result Field: OrderNo - Value to display to the user in the drop down box

8. Run the application

## Article #19655: SET NOCOUNT ON causes "Couldn't perform the edit because another user changed the record" error

Question and Answer Database

FAQ: FAQ4655B - SET NOCOUNT ON causes "Couldn't perform the edit because another user changed the record" error

Category: Database (MSSQL)

Platform: All Windows

Product: BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

How come after I execute SET NOCOUNT ON on MSSQL server all updates result in the error

"Couldn't perform the edit because another user changed the record"?  
BDE error 10259.

Answer:

The BDE uses rows effected to determine if an UPDATE is successful. SET NOCOUNT ON tells MSSQL to return 0 for rows effected for all UPDATE statements and thereby causing all UPDATES to fail.

7/28/99 9:07:21 AM

Last Modified: 01-SEP-99

## Article #19657: FoxPro IDX files

Question and Answer Database

FAQ: FAQ4657B - FoxPro IDX files

Category: Database (FoxPro)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Does the BDE support FoxPro IDX files?

Answer:

The BDE supports FoxPro tables via its native driver up to version 2.6. IDX files were added in a FoxPro version after 2.6. Because of this the native driver does not support IDX files. If you have ODBC driver which can be configured to open IDX files whenever a table is opened then this would be a viable alternative.

## Article #19658: How do I get the version information for a file?

Question and Answer Database

FAQ: FAQ4658D - How do I get the version information for a file?

Category: Windows API

Platform: All-32Bit

Product: All32Bit,

Question:

How do I get the version information for a file?

Answer:

In order to get the file version information for a file you have to make several API calls. Here is an example that checks your version of shell32.dll and returns True if it is greater than or equal to 4.71.

```
function TForm1.CheckShell32Version: Boolean;

    procedure GetFileVersion(FileName: string; var Major1, Major2,
        Minor1, Minor2: Integer);
    { Helper function to get the actual file version information }
    var
        Info: Pointer;
        InfoSize: DWORD;
        FileInfo: PVSFixedFileInfo;
        FileInfoSize: DWORD;
        Tmp: DWORD;
    begin
        // Get the size of the FileVersionInformation
        InfoSize := GetFileVersionInfoSize(PChar(FileName), Tmp);
        // If InfoSize = 0, then the file may not exist, or
        // it may not have file version information in it.
        if InfoSize = 0 then
            raise Exception.Create('Can't get file version information for
            '
                + FileName);
        // Allocate memory for the file version information
```

```

GetMem(Info, InfoSize);
try
    // Get the information
    GetFileVersionInfo(PChar(FileName), 0, InfoSize, Info);
    // Query the information for the version
    VerQueryValue(Info, '\', Pointer(FileInfo), FileInfoSize);
    // Now fill in the version information
    Major1 := FileInfo.dwFileVersionMS shr 16;
    Major2 := FileInfo.dwFileVersionMS and $FFFF;
    Minor1 := FileInfo.dwFileVersionLS shr 16;
    Minor2 := FileInfo.dwFileVersionLS and $FFFF;
finally
    FreeMem(Info, FileInfoSize);
end;
end;

var
    tmpBuffer: PChar;
    Shell32Path: string;
    VersionMajor: Integer;
    VersionMinor: Integer;
    Blank: Integer;
begin
    tmpBuffer := AllocMem(MAX_PATH);
    // Get the shell32.dll path
    try
        GetSystemDirectory(tmpBuffer, MAX_PATH);
        Shell32Path := tmpBuffer + '\shell32.dll';
    finally
        FreeMem(tmpBuffer);
    end;

    // Check to see if it exists
    if FileExists(Shell32Path) then
        begin
            // Get the file version
            GetFileVersion(Shell32Path, VersionMajor, VersionMinor, Blank,
Blank);
            // Do something, such as require a certain version
            // (such as greater than 4.71)
            if (VersionMajor >= 4) and (VersionMinor >= 71) then
                Result := True
            else
                Result := False;
        end
    end
end

```

```
else
  Result := False;
end;
```

## Article #19660: Access and QuickReports

Question and Answer Database

FAQ: FAQ4660B - Access and QuickReports

Category: Database (MSACCESS)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

How come whenever I preview a QuickReport using the Access Native driver I crash?

Answer:

QuickReports uses threads when previewing reports. The Microsoft DAO which the BDE uses for its native Access driver is not thread safe. If your application requires previewing of QuickReports or any sort of threading support and you use an Access database you must use ODBC instead.

## Article #19661: How do I set the Wallpaper on Windows98/2000 when ActiveDesktop is turned on?

Question and Answer Database

FAQ: FAQ4661D - How do I set the Wallpaper on Windows98/2000 when ActiveDesktop is turned on?

Category: Miscellaneous

Platform: Windows98/2000

Product: All32Bit,

Question:

How do I set the Wallpaper on Windows98/2000 when ActiveDesktop is turned on?

Answer:

You may have noticed that using SystemParametersInfo to change the wallpaper when ActiveDesktop is turned on doesn't work. The reason is because you need to use the IActiveDesktop COM interface. Using SystemParametersInfo still works, but it doesn't update the wallpaper.

Note that the IActiveDesktop interface requires a Shell32.dll version  $\geq 4.71$ . The document titled "Get a File Version" demonstrates how to check the file version and uses the shell32.dll as an example.

Here is an example of using IActiveDesktop to work with the wallpaper. It assumes that you have 3 labels on a form and two buttons with the default names.

uses

```
ComObj, // For CreateComObject and Initialization/Finalization of COM
```

```
ShlObj; // For IActiveDesktop
```

```
{ The CLASS ID for ActiveDesktop is not defined in ShlObj, while the IID is so we define it here. }
```

```
const
```

```
CLSID_ActiveDesktop: TGUID = '{75048700-EF1F-11D0-9888-006097DEACF9}';
```

```
{ Demonstrate getting the Wallpaper }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
ActiveDesktop: IActiveDesktop;
```

```
CurrentWallpaper: string;
```

```
CurrentPattern: string;
```

```
WallpaperOptions: TWallpaperOpt;
```

```
tmpBuffer: PWideChar;
```

```
begin
```

```
    // Create the ActiveDesktop COM Object
```

```
    ActiveDesktop := CreateComObject(CLSID_ActiveDesktop) as  
IActiveDesktop;
```

```
    // We now need to allocate some memory to get the current Wallpaper.
```

```
    // However, tmpBuffer is a PWideChar which means 2 bytes make
```

```
    // up one Char. In order to compensate for the WideChar, we
```

```
    // allocate enough memory for MAX_PATH*2
```

```
tmpBuffer := AllocMem(MAX_PATH*2);
```

```
try
```

```
    ActiveDesktop.GetWallpaper(tmpBuffer, MAX_PATH*2, 0);
```

```
    CurrentWallpaper := tmpBuffer;
```

```
finally
```

```
    FreeMem(tmpBuffer);
```

```
end;
```

```
if CurrentWallpaper <> '' then
```

```
    Label1.Caption := 'Current Wallpaper: ' + CurrentWallpaper
```

```
else
```

```
    Label1.Caption := 'No Wallpaper set';
```

```
    // Now get the current Wallpaper options.
```

```
    // The second parameter is reserved and must be 0.
```

```
WallpaperOptions.dwSize := SizeOf(WallpaperOptions);
```

```
ActiveDesktop.GetWallpaperOptions(WallpaperOptions, 0);
```

```
case WallpaperOptions.dwStyle of
```

```
    WPSTYLE_CENTER: Label2.Caption := 'Centered';
```

```
    WPSTYLE_TILE: Label2.Caption := 'Tiled';
```

```
    WPSTYLE_STRETCH: Label2.Caption := 'Stretched';
```

```
    WPSTYLE_MAX: Label2.Caption := 'Maxed';
```

```
end;
```

```
    // Now get the desktop pattern.
```

```
    // The pattern is a string of decimals whose bit pattern
```

```
// represents a picture. Each decimal represents the on/off state
// of the 8 pixels in that row.
tmpBuffer := AllocMem(256);
try
  ActiveDesktop.GetPattern(tmpBuffer, 256, 0);
  CurrentPattern := tmpBuffer;
finally
  FreeMem(tmpBuffer);
end;
if CurrentPattern <> '' then
  Label3.Caption := CurrentPattern
else
  Label3.Caption := 'No Pattern set';
end;
```

```
{ Demonstrate setting the wallpaper }
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
  ActiveDesktop: IActiveDesktop;
begin
  ActiveDesktop := CreateComObject(CLSID_ActiveDesktop)
    as IActiveDesktop;
  ActiveDesktop.SetWallpaper('c:\downloads\images\test.bmp', 0);
  ActiveDesktop.ApplyChanges(AD_APPLY_ALL or AD_APPLY_FORCE);
end;
```

## Article #19662: "Invalid Row ID" when migrating from Oracle 7 to Oracle 8

Question and Answer Database

FAQ: FAQ4662D - "Invalid Row ID" when migrating from Oracle 7 to Oracle 8

Category: Database(Oracle8)

Platform: All-32Bit

Product: All32Bit,

Question:

I just upgraded from Oracle 7 to Oracle 8 and now I occasionally get an "Invalid Row Id" error. I am using the new Oracle 8 Row Id's. How can I fix this error?

Answer:

This error may occur when posting to tables that contain LONG/Blob fields. More than likely, you are using the old SQL Link driver. Insure that you have the BDE 5.01 installed. In the BDE Administrator go to the Configuration tab and select Drivers->Native->Oracle. Make sure that the DLL32 is set to SQLORA8.DLL and the VENDOR INIT is set to OCI.DLL. Another possible solution may be to set the TTable or TQuery's UpdateMode property to upWhereKeyOnly.

## Article #19666: SQL Anywhere and Blobs>32K when RequestLive=False

Question and Answer Database

FAQ: FAQ4666B - SQL Anywhere and Blobs>32K when RequestLive=False

Category: Database (ODBC)

Platform: All-32Bit

Product: BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

If I RequestLive=False with a TQuery, can I get blob data from SQL Anywhere greater than 32K?

Answer:

Not at this time. SQL Anywhere is not a certified driver and operates differently than any driver Inprise has certified.

With other drivers, if Blob Size is set large enough, Data is Fetched successfully. With SQL Anywhere, even if Blob Size is large enough, the driver returns an error and fetching the data is unsuccessfull.

TQueries with RequestLive=True appear to work because the exact size of the buffer is requested. Whereas when requestlive=false, your blobsize setting is used. If buffersize is too large, SQL Anywhere returns an error, whereas other ODBC Datasources do not.

## Article #19667: Invalid Field Type when creating ODBC DataSource

Question and Answer Database

FAQ: FAQ4667B - Invalid Field Type when creating ODBC DataSource

Category: Database (ODBC)

Platform: All Windows

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

I'm using BatchMove to create a table in an ODBC DataSource. How come I'm getting the error "Invalid Field Type"?

Answer:

This error occurs for ODBC drivers where SQLGetTypeInfo(SQL\_DOUBLE) returns a result set. In this case, the result is float is attempted to be created on the DataSource even though the DataSource does not support floats. A classic example of this is Microsoft or Oracle's ODBC driver for Oracle.

There two possible solutions:

1. Use the Native driver (SQL Links) driver for the Database if one exists
2. Create the table yourself and use BatchAppend instead of BatchCopy.

Last Modified: 01-SEP-99

## Article #19669: Oracle 7 faster than Oracle 8

Question and Answer Database

FAQ: FAQ4669B - Oracle 7 faster than Oracle 8

Category: Database (Oracle)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

I've noticed that fetching data against Oracle 7 is faster than Oracle 8. How come?

Answer:

If you are not using Object types the Oracle 8 driver can see improved performance turning off OBJECT MODE in BDE Administrator.

The Oracle 8 driver performs at the same level as Oracle 7 driver when the Oracle 7 driver has ROWSET SIZE set to 1. However, the Oracle 7 driver can have marked performance by increasing this parameter. The Oracle 8 driver does not support this parameter at this time and so therefore cannot reach the performance of the Oracle 7 driver at this time.

## Article #19674: Shared Memory Conflict error

Question and Answer Database

FAQ: FAQ4674B - Shared Memory Conflict error

Category: Database (Miscellaneous)

Platform: All Windows

Product: All-CBuilder, BC++4.5x, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

When I launch my second BDE application I'm getting the error Shared Memory Conflict (\$210D, 8461). How can I solve this?

Answer:

This error occurs when the memory location the BDE is attempting load at is being used another application. In most cases, this happens under Windows

NT. When this error occurs you need to changed the Shared Memory Location in BDE Administrator. While it is theoretically possible that many different

memory adresses exist that may resolve the problem, under Windows NT the address which we have found to always work in the past is 7000.

If 7000 does

not work try 7F00. For Windows 95/98, the best address to try is 1000.

Platform: All-32Bit

Product: Delphi3.x, Delphi4.x,

Question:

I'm using ClientDatasets and my query has results from 2 tables. How come when I insert, delete or update records I get the error "Unable to resolve records. Table name not found"? I've run SQL Monitor and notice that the UPDATE statement just says WHERE w.

Answer:

To update multiple tables you must generate the SQL yourself. If you have Delphi 3, you can use an UpdateSQLProvider. If you have Delphi 4 you must create 3 TQueries (One each for INSERT, DELETE and UPDATE statements). From the TProviders BeforeUpdateRecord event determine which query to use by the updatekind parameter and then execute the appropriate query (populating the parameters along the way).

## Article #19694: "Invalid field type" database error with MSSQL server 7

### Question:

When I try to activate my Table/Query I get an error stating "invalid field type". What does this mean?

### Answer:

Microsoft no longer supports DB-LIB with the release of MS SQL Server 7. This means DB-LIB doesn't have support for the 4 new data types that MS SQL 7 offers: NTEXT, NCHAR, NVARCHAR and UNIQUEIDENTIFIER (a GUID). In order to successfully use new types offered by SQL Server 7 and above you'll need to use CT-LIB. With Delphi 5 we recommend you use ADO.

It is possible that you are using one of these datatypes inadvertently. For example when you use the replication feature in MS SQL 7 a new field called "rowguid" of type UNIQUEIDENTIFIER is automatically added. Since this will cause the invalid field type error in the BDE, replication cannot be used with the BDE.

**Article #19698: Oracle wrapped stored procedure and the Oracle SQL Links driver.**

Question and Answer Database

FAQ: FAQ4698B - Oracle wrapped stored procedure and the Oracle SQL Links driver.

Category: Database (Oracle)

Platform: All-32Bit

Product: All-CBuilder, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Can the Oracle SQL Links driver use Oracle procedures that have been "wrapped".

Answer:

Yes.

Oracle wrapped stored procedures behave just like "unwrapped" procedures.

The client application knows nothing about the fact that the procedure has been encoded by Oracle's WRAP23.EXE (or WRAP80.EXE).

Please refer to your Oracle documentation for information on the PL/SQL Wrapper utility.

## Article #19699: Database Desktop and the number of displayed digits after the decimal point.

Question and Answer Database

FAQ: FAQ4699B - Database Desktop and the number of displayed digits after the decimal point.

Category: BDE

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x,

Question:

Why does SQL Explorer display all digits to the right of the decimal point where Database Desktop does not?

Answer:

The Database Desktop uses your computer's Regional Settings | Number setting to determine the display format for numbers.

Run Control Panel | Regional Settings and click on the Number tab. Adjust the "No. of digits after decimal" to the desired number of digits that you wish displayed.

## Article #19700: Obtaining a list of available BDE language drivers

Question and Answer Database

FAQ: FAQ4700B - Obtaining a list of available BDE language drivers

Category: BDE

Platform: All-32Bit

Product: Delphi2.x, Delphi3.x, Delphi4.x,

Question:

How can I retrieve a list of available BDE language drivers?

Answer:

The following Delphi procedure returns a formatted list of available BDE language drivers.

The procedure can be called as shown in the buttonclick method below.

Add BDE and DBTables to your unit's uses clause.

```
procedure GetLdList(Lines: TStrings);
var
  hCur: hDBICur;
  LD: LDDesc;
  cnt: integer;
begin
  // get a cursor to the in-mem table containing language
  // driver information...
  cnt:=0;
  check(dbiinit(nil));
  Check(DbiOpenLdList(hCur));
  try
    while (DbiGetNextRecord(hCur, dbiNOLOCK, @LD, nil) =
      DBIERR_NONE) do begin
      cnt:=cnt+1;
      Lines.Add(format('%4d %-6s%-10s %-10s%5s %-10s %-10s',
        [cnt, 'Name:', LD.szName, 'Code Page:', IntToStr(LD.iCodePage),
        'Description:', LD.szDesc]));
    end;
  end;
end;
```

```
    end;
finally
    Check(DbiCloseCursor(hCur));
    check(dbiexit);
end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
getldlist(memo1.lines);
end;

end.
```

## Article #19701: Unrecognized Database Format error when opening Access table

Question and Answer Database

FAQ: FAQ4701B - Unrecognized Database Format error when opening Access table

Category: Database (MSACCESS)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, Delphi2.x, Delphi3.x, VdBase7.x,

Question:

How come I'm getting a recognized Database Format error when opening an Access table with BDE?

Answer:

The table is probably an Access 2000 table. Another possibility is corrupted table.

The BDE uses DAO which has not been updated by MicroSoft since 1997. Access 2000 does not use DAO but uses ADO instead. Access 97 and BDE use the same DAO engine. Opening the table in Access 97 should result in the same error.

## Article #19727: \$2B05 "Permission denied." MS Terminal Server, application using the Borland Database Engine

Question and Answer Database

FAQ: FAQ4727B - \$2B05 "Permission denied." MS Terminal Server, application using the Borland Database Engine

Category: BDE

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

After logging into the Terminal Server the application is loaded which is followed by the BDE error:  
11013 \$2B05 "Permission denied."

Answer:

Terminal Server appears to create a temp folder for each user including appropriate rights. If the server is not brought down properly then the temp dir is not deleted and a subsequent user that logs in may be assigned an existing temp dir with someone else's rights.

A possible solution would be to delete all files and temp directories in the temp directory when the NT server boots up each time.

## Article #19742: ODBC Connections via Microsoft ODBC Text driver

Question and Answer Database

FAQ: FAQ4742B - ODBC Connections via Microsoft ODBC Text driver

Category: Database (ODBC)

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

Whenever I open a table via Microsoft's ODBC Text driver I get the error "Invalid table name". How come?

Answer:

The BDE calls SQLTables to determine whether a table name exists. The BDE does not expect table names returned by SQLTables to have an extension, but

Microsoft's Text driver does include extensions (Because unlike other drivers, it allows for tables with different extensions within the same database.)

and therefore the tablename cannot be verified.

There are two possible workarounds to the problem:

1. Use text files without extensions. To configure Microsoft's ODBC Text driver to do this run ODBC Administrator, configure your DSN, click Options, and \*. as an extension.
2. Use the BDE Native Text driver instead.

## Article #19744: Unable to use IDE tools to access and/or update tables in Informix database

Question and Answer Database

FAQ: FAQ4744J - Unable to use IDE tools to access and/or update tables in Informix database

Category: Database (Informix)

Platform: All Windows

Product:

Question:

I am unable to access my Informix database via most of the IDE database tools (e.g. JDBC Explorer, SQL Builder, and Browse Table functionality is lost)

Answer:

It appears that with older Informix JDBC drivers (problem reported against 1.22.JC1 specifically), there is a communication breakdown that causes an invalid schema name, "informix", to be returned on the table. As most of the IDE database tools rely on the schema name when internally querying the table, this results in poor behavior:

1) one will experience errors of the type: "the specified table (informix.  
) is not in the database" when attempting to open the table via JDBC Explorer's "Data" page 2) the table will appear to have no columns defined when inspecting via the "browse tables" dialog or the database tree in the left-hand pane of the JDBC Explorer Note that queries can still be performed successfully either via code or via the "Enter SQL" page of JDBC Explorer. The workaround for this problem is to update your JDBC driver to the latest available from the vendor. Visit the download area of Informix's website (<http://www.informix.com>), or go directly to <http://www.intraware.com:81/shop/product.html?PLNE=000148> for more information on the latest JDBC

drivers for Informix. 8/4/99 2:09:45 PM

## Article #19773: External Exception EEFACE under Winnt 4.0

Question and Answer Database

FAQ: FAQ4773C - External Exception EEFACE under Winnt 4.0

Category: Database Issues

Platform: Windows NT

Product: All-CBuilder,

Question:

When I try to connect a MS Access table to my TTable component I get the External Exception "EEFACE". Is there any way to work around this?

Answer:

A solution is to modify your registry.

- 1) Run regedit
- 2) Open HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows NT  
\Currentversion\Image file execution options
- 3) Create a new key for your application. For example "Project1.exe"
- 4) Create a new value:  
Value Name: DisableHeapLookAside  
Data Type: REG\_SZ

You should now be able to connect to the table.

## Article #19778: Editing record generates BDE Error 10259 (\$2813)

Question and Answer Database

FAQ: FAQ4778B - Editing record generates BDE Error 10259 (\$2813)

Category: BDE Features

Platform: All Windows

Product: Delphi4.x,

Question:

How come when I edit a record with more than 15 digits after the decimal place I get BDE error 10259 (\$2813) "Couldn't perform the edit because another user changed the record."?

Answer:

The BDE has a limit of 15 decimal digits after the decimal place. What is happening to cause this error is that the BDE refetches the row the before you edit it to make sure it still exists. To do so, it uses the data it originally fetched. It only fetches up to 15 digits, so the data the BDE has and data on the server don't match. The server returns that the fetch returned no records which causes the BDE to generate its error.

## Article #19779: Character fields from Access ODBC connection are reported as being double their true size

Question and Answer Database

FAQ: FAQ4779B - Character fields from Access ODBC connection are reported as being double their true size

Category: Database (ODBC)

Platform: All-32Bit

Product: All-CBuilder, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

How come when I use Microsoft's latest ODBC driver for Access the BDE returns the field size for character fields as being double their actual size?

Answer:

This problem occurs because the BDE calls SQLCOLUMNS and then looks at BUFFER\_LENGTH to determine the size of a column. With this driver BUFFER\_LENGTH is returned as double what the COLUMN\_SIZE is.

Here is what Microsoft used to document what BUFFER\_LENGTH should return:

The length in bytes of data transferred on an SQLGetData, SQLFetch, or SQLFetchScroll operation if SQL\_C\_DEFAULT is specified. For numeric data, this size may be different than the size of the data stored on the data source.

This value is the same as the COLUMN\_SIZE column for character or binary data.

Here is what Microsoft now documents what BUFFER\_LENGTH should return:

The length in bytes of data transferred on an SQLGetData, SQLFetch,

or  
SQLFetchScroll operation if SQL\_C\_DEFAULT is specified. For numeric data, this size may be different than the size of the data stored on the data source.  
This value might be different than COLUMN\_SIZE column for character data.

Inprise has verified this problem to exist in versions 4.00.3711.08 and 4.00.4202.00 of the Access ODBC driver. Inprise has contacted Microsoft and they have confirmed this new change in the ODBC specification. Inprise is currently evaluating how to resolve this issue in a future release that does not effect other ODBC drivers adversely.

Errors that may be caused by problem are "Record/Key Deleted" and "Size Mismatch".

The workarounds to this problem are:

1. Use an older version of the ODBC driver.
2. Use the BDE Access Native driver.
3. Use ADO with Delphi 5.

## Article #19781: BatchMove from TEXT doesn't create Time or TimeStamp fields.

Question and Answer Database

FAQ: FAQ4781B - BatchMove from TEXT doesn't create Time or TimeStamp fields.

Category: BDE Features

Platform: All Windows

Product: All-CBuilder, BC++4.5x, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, dBaseDOS, Delphi2.x, Delphi3.x, Delphi4.x,

Question:

How when I use MatchMode BatCopy of BatchMove and the source is a text file with time or timestamp data I always get Alpha data in the destination table?

Answer:

The text driver doesn't support time or timestamp data types. You must alter the table once batchmove is complete and change the field type yourself.

## Article #19785: Dates with single digit years operate differently with a leading zero

Question and Answer Database

FAQ: FAQ4785B - Dates with single digit years operate differently with a leading zero

Category: BDE Features

Platform: All-32Bit

Product: All-CBuilder, BC++5.x, C++Builder1.0, C++Builder3.x, C++Builder4.x, Delphi2.x, Delphi3.x, Delphi4.x, VdBase7.x,

Question:

If I have a Paradox alpha field in which I restructure it and change the field to a date or datetime field, how come 1/1/1 results in 1/1/0001 whereas the date 1/1/01 results in the date 1/1/2001?

Answer:

The BDE treats 2 digit years specially. 2 digits years of 50-99 are in 20th Century (1900's). 2 digits years of 0-49 are in the 21st Century (2000's).

## Article #20073: How to avoid "Random" Exceptions being raised when using TJPEGImage or the JPEG unit.

### How to avoid "Random" Exceptions being raised when using TJPEGImage or the JPEG unit.

#### Question:

Sometimes when I try to load a JPEG into a TImage, I get an exception message even though I wrap the LoadFromFile call in a try...except. How can I avoid such exceptions, and why do they happen?

#### Answer:

When loading a JPEG from a file, sometimes it will load fine, but contain a corrupt JPEG image. When an attempt is made to draw the image, an exception will be raised. Quite often, the programmer may try to suppress errors with a procedure such as:

```
procedure TForm1.btnOpenDefaultClick(Sender: TObject);
begin
    if OpenPictureDialog1.Execute then
        try
            Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName);
        except end;
    end;
```

But, unexpectedly, JPEG's sometimes display an exception message and it appears that the creator of the JPEG unit hard-coded a ShowMessage to display the exception. The problem is that the LoadFromFile procedure executes fine, and the actual drawing of the JPEG to the TImage is what is causing the problem. The drawing of the image is implicitly called after the image has loaded from the file.

The way around this problem is to explicitly control when any possible errors happen. You can capture any errors that happen in the loading of the image, and/or in the drawing of the image.

Below is an example of how to do this. The project consists of a unit (called MainFrm.pas). It has a TImage and an OpenPictureDialog placed on the form. Two buttons are also placed on it, one named btnOpenCatch and another called btnOpenDefault. The btnOpenCatchClick procedure demonstrates how each exception can be caught and displayed the the user. Alternatively, the exception could be "eaten" with an empty except section. The btnOpenDefaultClick displays the default way of opening an image and trying to eat an exception, which may still display a JPEG error. Also notice the addition of the JPEG unit to the uses clause.

To create a corrupt JPEG that displays this error, open a JPEG image in a hex editor and change the first few bytes or the last few bytes.

```
unit MainFrm;
```

```
interface
```

## uses

Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms, Dialogs, ExtDlgs, ExtCtrls, StdCtrls, JPEG;

## type

```
TForm1 = class(TForm)
  btnOpenCatch: TButton;
  Image1: TImage;
  OpenPictureDialog1: TOpenPictureDialog;
  btnOpenDefault: TButton;
  procedure btnOpenCatchClick(Sender: TObject);
  procedure btnOpenDefaultClick(Sender: TObject);
```

## private

```
  { Private declarations }
```

## public

```
  { Public declarations }
```

```
end;
```

## var

```
Form1: TForm1;
```

## implementation

```
{$R *.DFM}
```

```
procedure TForm1.btnOpenCatchClick(Sender: TObject);
```

## var

```
  Picture: TPicture;
  Bitmap: TBitmap;
```

## begin

```
  if OpenPictureDialog1.Execute then
```

## begin

```
  Picture := TPicture.Create;
```

## try

```
  // Try to load the picture from a file.
  // I'm wrapping it in a try..except to capture
  // any exceptions that happen in loading the image from
  // a stream.
```

## try

```
  Picture.LoadFromFile(OpenPictureDialog1.FileName);
```

## except

```
  on E: EInvalidGraphic do
```

## begin

```
  ShowMessage('Capturing Load Error: ' + E.Message);
```

```
  Exit; // Exit the procedure
```

```
  end;
```

```
end;
```

```

Bitmap := TBitmap.Create;
try
  try
    // Assign the Graphic to the Bitmap; any drawing errors/exceptions
    // will happen here, and will be captured and shown to the user
    Bitmap.Assign(Picture.Graphic);
  except
    // Eat invalid graphic messages (which may be raised
    // when a jpeg is being drawn)
    on E: EInvalidGraphic do
      begin
        ShowMessage('Capturing Assign (Drawing) Error: ' + E.Message);
        Exit; // Exit the procedure
      end;
    end;
  // Now draw the picture on the screen's TImage
  Image1.Picture.Bitmap.Assign(Bitmap);
finally
  Bitmap.Free;
end;
finally
  Picture.Free;
end;
end; // OpenPictureDialog1.Execute
end;

procedure TForm1.btnOpenDefaultClick(Sender: TObject);
begin
  if OpenPictureDialog1.Execute then
    try
      Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName);
    except end;
  end;
end.

```

Another thing to notice is that the OpenPictureDialog does not contain this fix. It will display some JPEG error messages when you click on a corrupt JPEG and it attempts to display a preview image.

Last Modified: 03-JAN-00

## Article #20090: System Resource Capacities in Windows 95

Running out of system resources in Windows 95 can give the Delphi exception "EWin32Error" with further details such as "in VCL40.DPL". EWin32Error is raised when Windows returns an error code. Following are some Windows 95 limits. The logical pens and brushes limit is probably the most significant for Delphi users since it will limit the number of visual components an application can create simultaneously. These were found on the Microsoft web page at: <http://msdn.microsoft.com/library/winresource/dnwin95/s70b0.htm>

```
*****
Windows 95 System Limits
*****
Windows Menu handles      32K
Timers                    Unlimited
COM and LPT ports        Unlimited
Items per listbox        32K
Data per listbox         Unlimited
Data per edit control    Unlimited
Regions                  Unlimited
Physical pens and brushes Unlimited
Logical pens and brushes All in 64K segment
Logical fonts            750 - 800
Installed fonts          1000
Device contexts          16K
*****
```

## Article #20100: "Expected type..." error using ADO to access numbers in Oracle Table.

### Question:

Why am I getting "Expected type was..." error using ADO to access numbers in an Oracle table?

### Answer:

The problem lies in the fact that Integer fields in Oracle are being represented as TFloatfield in Delphi. The root of this issue is the translation done by the OLE DB PROVIDER. NUMBER and INTEGER fields in Oracle are being translated as DBTYPE\_NUMERIC by the OLE DB PROVIDER. This can be verified by looking at the MDAC SDK documentation, which is available off the Microsoft web page. If the provider never returns an Integer OLE DB Data Type, you'll never get a TField that is a TIntegerField type.

Last Modified: 11-OCT-00

## **Article #20158: Hidden or missing IDE**

Occasionally in Delphi 5 the IDE will 'disappear'. This is to say you will launch Delphi, and most or all of your IDE will not be visible. Delphi is clearly running and working, as you can still use your hot keys and run and compile a program, you just can't see such useful items such as the object inspector or your component tool bar.

This is caused by Delphi saving bogus information in its desktop preference files, or '.dsk' files. Delphi saves information about your environment options and settings in these files. In order to see your IDE again, all you need to do is delete these offending files. This will in no way harm Delphi or your project, as Delphi will dynamically generate these files as it needs them. You will however lose any environment settings that you had set previously.

Last Modified: 30-NOV-99

## Article #20179: How do I execute a stored procedure with TIBSQL?

### QUESTION:

How do I execute a stored procedure with TIBSQL?

### ANSWER:

To take advantage of the light weight TIBSQL component for executing stored procedures, execute the procedure with the SQL statement 'execute procedure procedure\_name'. The results are passed back through a TIBXSQLEDA object. A TIBXSQLEDA is an object which encapsulates an InterBase API data type and contains all of the return parameters for the stored procedure. TIBSQL.Current returns the current TIBXSQLEDA object associated with the TIBSQL.

The following code example executes a stored procedure, new\_key, that does not take any parameters but does return a value. The 'new\_key' procedure is defined as follows:

```
create procedure new_key returns (newkey integer)
as
begin
    newkey = gen_id(vote_pui_gen, 1);
end
```

For more information on creating stored procedures refer to the InterBase "Data Definition Guide", and "Programmer's Guide".

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    IBSQL1.SQL.Clear;
    IBSQL1.SQL.Add('execute procedure new_key');
    IBSQL1.ExecQuery;
    Form1.Caption := IBSQL1.Current.Vars[0].AsString;
end;
```

If the procedure returns multiple parameters, you can iterate through the Vars array to extract all of the parameters.

## **Article #20180: Garbage added to end of Memo field with ODBC connection**

When the BDE inserts blob data into a table via an ODBC connection it indicates the length of the blob via a size parameter. Some ODBC drivers ignore this parameter and attempt to determine the size by looking for a NULL character instead. ODBC drivers which are reported to operate this way are Advantage and PostgreSQL. This may result in garbage appearing at the end of the blob. To resolve the problem obtain an updated ODBC driver from the ODBC vendor which determines the size via the parameter, not by looking for a NULL.

Last Modified: 01-DEC-99

## Article #20195: "Cannot load an IDAPI service library" error with a message of "SQLORA8.DLL"

### Question:

I recently moved from Oracle 7 to 8, and when I try to open my alias up in the BDE administrator, I get a "Cannot load an IDAPI service library" error with a message of "SQLORA8.DLL". How do I fix this?

### Answer:

There are several things that can cause this problem. The first thing to make sure of is that you have the Oracle 8 client installed. If you can use the Oracle 8 client tools (such as SQL Plus) to successfully connect, then you may have a path issue. The easiest way to test this is to copy the SQL Plus EXE from the Oracle bin directory to your desktop and see if you can run it. The SQL Plus EXE is typically in your c:\ORANT\BIN or c:\ORA95\BIN directory (depending on the OS, and assuming it is installed on the C drive). If you try to run it from the desktop and you get an error about it not finding a DLL, then you have a path issue.

The way to fix a path issue is to right click on the file c:\autoexec.bat and select Edit. Look for the line that starts with something like:

```
set PATH=C:\....
```

Add REM to the start of that line to comment it out, and add a new line that looks like this:

For Windows NT:

```
set PATH=C:\ORANT\BIN;
```

For Windows 95/98:

```
set PATH=C:\ORA95\BIN;
```

After that, reboot your machine and it should work fine.

**Article #20234: TeamSource Error(4): Invalid extension, in file '...\Archives\root.tsdata'**

**QUESTION:**

Why am I getting Error(4): Invalid extension, in file 'C:\Teamsource\Archives\root.tsdata' when I try to open the Remote screen in TeamSource?

**ANSWER:**

This is caused by a bug in TeamSource. The documentation for Productions states that a Production can be Defined with Source = \*.RC and Target = \*.RES, but after these values are entered TeamSource adds a period in front of them so the result is '.\*.RC' and '.\*.RES'. These values are accepted but unfortunately cause the error when the project is reopened in the future.

**WORKAROUND:**

Do not use the asterisk notation, just enter the extension. If you've already entered this notation you can recover by deleting the 'root.tsdata.z' file, but you will then need to re-do check ins.

## Article #20243: Conflict between IntelliMouse driver v2.2d and TDBLookupComboBox

### QUESTION:

Why is my application freezing when I pass the IntelliMouse pointer over a TDBLookupComboBox?

### ANSWER:

There is a conflict between the IntelliMouse driver v2.2d and TDBLookupComboBox. The error is reproduced by running an application which has a TDBLookupComboBox on a machine with IntelliMouse v2.2d. Click on the arrow in the box to show the dropdown list. Now move the mouse wheel, and the application freezes. The application must be killed to recover.

This issue does not occur with a TComboBox because TDBLookupComboBox is not a TComboBox descendent.

### WORKAROUND

This issue was fixed in Delphi 5. Here is a workaround for Delphi 4 which requires adding two lines to DBCTRLS.PAS. The .DCU file will need to be rebuilt after adding these lines:

```
// This line takes care of the AV. ListLink.DataSet could be  
// nil after the WM_MOUSEWHEEL wasn't handled and the Intellimouse  
// driver decided to send a WM_VSCROLL
```

```
procedure TDBLookupListBox.WMVScroll(var Message: TWMVScroll);  
begin
```

```
    SearchText := '';  
(* ** * ADD THIS LINE * ** *)  
    if ListLink.DataSet = nil then Exit;
```

```
    with Message, ListLink.DataSet do  
end;
```

```
// This takes care of the "hang". The control is getting a  
// WM_KILLFOCUS immediately after the *second* WM_MOUSEWHEEL.  
// Focus is retained by the drop-down list, making it appear  
// that the application had stopped responding }
```

```
procedure TDBLookupComboBox.CloseUp(Accept: Boolean);
```

```
var  
    Msg: TMsg;  
    ListValue: Variant;
```

```
begin
  if FListVisible then
    begin
      if GetCapture <> 0 then SendMessage(GetCapture, WM_CANCELMODE, 0, 0);
      (**** ADD THIS LINE ****)
      SetFocus;

      ListValue := FDataList.KeyValue;
    ...
  end;
```

Last Modified: 28-DEC-00

**Article #20330: BDE Administrator not responding.**

**QUESTION:**

Why after loading BDE 5.0 on Windows '98 machine with SR2, does the BDE Administrator not respond? There is no error message, it just freezes. Delphi is running fine.

**ANSWER:**

This is due to a conflict with Microsoft's generic SVGA video driver. If you switch to the card manufacture's updated driver, make sure you have 256 colors. This should solve the problem. You may need to experiment with different drivers.

Last Modified: 17-DEC-99

**Article #20362: "Could not perform corba dispatch, no interface repository found" error.**

**QUESTION:**

Why am I getting the error "Could not perform corba dispatch, no interface repository found"?

**ANSWER:**

There was an issue between Visibroker 3.4 which comes with JBuilder 3, and Delphi 5 which resulted in the loss of some CORBA functionality in Delphi when connecting to a JBuilder 3 server.

A new version of Visibroker 3.3 for Delphi 5 Enterprise is now available which resolves this. The update is for Delphi 5 Enterprise only and is available for free download from our web site at:

<http://www.borland.com/visibroker/delphi/>

This release includes an IDL2PAS compiler. IDL2PAS is a tool which implements isiBroker's IDL to Pascal compiler. IDL2PAS takes one or more IDL files as input and generates the corresponding Pascal classes for the client side, including the client stubs. Visit the URL above for more details.

## Article #20386: The integrated debugger and NT

### QUESTION:

My simple database application works on Windows 95 and 98, but gives me access violations on NT. I can run the files I create from the desktop in NT, but not from the IDE, why?

### ANSWER:

In order to solve this issue, you must go to Delphi's 'Tools | Debugging Options' on the main menu and locate the 'General' tab. On this page you will find a checkbox that reads 'Integrated Debugger'. You will want to make sure that this is turned off. After this Delphi should run normally.

## **Article #20393: Parameters to Access Long Text fields limited to 255 characters**

A TQuery that updates an Access LongText field via a Parameter or a TUpdateSQL Component that does the same will fail if number of characters in the parameter is more than 255. If the connection is done via ODBC it will result in a BDE error of "General SQL Error" and then an error from the ODBC of "String data, right truncated (null)". If the connection is done via the BDE Native driver it will result in an error of "External Exception EEFACE".

The reason the ODBC driver error occurs is because the Access ODBC driver has a limit of 255 characters for parameters.

The reason the error occurs with the Native driver is the DAO limits parameters to 255 characters and the BDE uses the Microsoft DAO client to use Access tables.

The best workaround to this problem is to use ADO with Delphi 5.

Another partial solution is to use a TQuery with requestlive=true, or a TTable.

## Article #20420: Parameter "ParamName" Not Found error when using an ADOQuery and Parameters

### Question:

When using an ADOQuery with Parameters, and trying to access the Parameters with: `ADOQuery.Parameters.ParamByName('ParamName').Value` I get a 'Parameter "ParamName" Not Found' error. How can I fix this?

### Answer:

You can easily fix this by creating the parameters before calling `ADOQuery.Parameters.ParamByName('ParamName').Value` by calling: `ADOQuery.Parameters.ParseSQL(ADOQuery.SQL.Text, True)`.

## Article #20433: Interpreting Cryptic Jpeg Error Number's

### Interpreting Cryptic Jpeg Error Number's

By Corbin Dunn

If you have used the TJpegImage class you may be familiar with the "JPEG error #xx" error that comes up on occasion. You may want to know exactly what went wrong, and how to get more information based on that number.

Luckily, the TJpegImage pascal source is included on the Delphi CD. Looking at the source, you will notice that it is a wrapper around some C code. There is one particular file called "jerror.h" which contains an enumeration of error strings. Based on the offset in this enum, you can find out what a given error number means.

For ease of use, I converted the "jerror.h" file to pascal in the unit JpegErrors.pas. To use this unit, simply reference the string array cJpegErrors, passing a given error number to find the error string, such as:

```
Label1.Caption := cJpegErrors[StrToInt(Edit1.Text)]
```

Note that the JpegErrors.pas unit was based on the Jpeg source that comes with Delphi 5. If the order of the error messages in "jerror.h" ever changes, the JpegErrors.pas will not be in sync with it and has to be updated.

[Download a sample program and the JpegErrors.pas unit](#)

## **Article #20559: General SQL Error when accessing a memo field in MS SQL 6.5.**

### **Question:**

When connecting to MS SQL Server 6.5, and trying to access long text data (a memo field) with something such as "FieldByName('FieldName')", I get a "General SQL Error."

### **Answer:**

This could be caused by not having the proper service packs installed on MS SQL Server. Installing Service Pack 4 has been known to fix this issue.

A "General SQL Error" is returned when the database server returns some message that the BDE does not know how to handle.

Last Modified: 23-FEB-00

## Article #20566: Master/Detail relationships with data-aware controls.

### Question:

Why are my Master/Detail relationships not showing the correct detail in the data-aware controls when I scroll through the master?

### Answer:

This is a known bug in Delphi 5 and will be fixed. It seems to only happen with queries. Using persistent fields will make it worse. Here is a good workaround which was posted on the borland newsgroup. It requires editing and recompiling the file 'dbctrls.pas' which comes with Delphi.

First find the file 'dbctrls.dcu' on your machine. If you did a default install it should be at 'C:\Program Files\Borland\Delphi5\Source\Vcl'. Rename this to something like 'dbctrls\_ORIGINAL.dcu' so you can get it back later if you want. Next start a new, blank application and open the file 'C:\Program Files\Borland\Delphi5\Source\Vcl\dbctrls.pas'. Add Dbctrls to the uses clause of the blank project. Find the definition for procedure TFieldDataLink.UpdateField; and change the code to the following. You may want to just comment out the code that is there in order to save it.

```
procedure TFieldDataLink.UpdateField;
var
  TempField : TField;
begin
  if Active and (FFieldName <> '') then
  begin
    if Assigned(FControl) then
      TempField := GetFieldProperty(DataSource.DataSet, FControl, FFieldName)
    else
      TempField := DataSource.DataSet.FieldByName(FFieldName);
    if TempField <> FField then
      SetField(TempField)
    else
      begin
        FField := NIL;
        SetField(TempField);
      end;
  end
  else
    SetField(nil);
end;
```

Finally, save and Build All Projects (Projects menu). If you get an error that 'dbctrls.dcu' cannot be found then you need to go into Tools|Environment Options|Library and add the path C:\Program Files\Borland\Delphi5\Source\Vcl (or whatever your actual path to the Vcl directory is) to the Library Path.

Now you should be able to compile and create a new 'dbctrls.dcu' file, and your data-aware controls should be

updating.

## Article #20580: How SQL Links determines if an MSSQL table can refreshed.

Q. How does SQL Links determine if an MSSQL Table can be refreshed or not?

A. The following query is run when the table is opened:

```
select x.name, x.indid, x.status, INDEX_COL('owner.tablename', x.indid, c.colid) from sysindexes x,
syscolumns c where x.id = object_id ('owner.tablename') and indid between 1 and 254 and x.id = c.id
and c.colid <= x.keycnt order by x.indid, c.colid ASC
```

Note that owner and tablename are case sensitive.

Another query that is useful in working on this problem is listing all index for a table. The following query will do so:

```
SELECT b.* from dbo.sysobjects a, sysindexes b, sysusers c where a.name='tablename' and a.id=b.id
and c.uid=a.uid and c.name='ownername'
```

Note that tablename and username are case sensitive.

## Article #20590: Stored Procedures not working in MS-SQL 7

### Question:

Why can't I use my MS-SQL 6.5 stored procedures in MS-SQL 7.0?

### Answer:

Although the BDE can be used to connect to MS-SQL 7 tables, it only supports MS-SQL 6.5 features. Here's why.

In this case the new feature in MS-SQL 7 that is not supported is the ability to have two stored procedures with the same name and different parameters. You will notice Stored Procedures in MS-SQL 7 have a ;1 or ;2 after the name. If you have a procedure with a ;1 after it you should be able to remove the ;1 and use it without a problem. If it has a ;2 or higher after it you should rename the procedures which have the same name, and remove the ;# and then it should work okay.

## Article #20641: How do I change an ISAPI DLL project to a CGI project, or vice-versa?

### Building Web Applications

By Corbin Dunn

**Question:** How do I change an ISAPI dll project to a CGI project, or vice-versa?

**Answer:** The easiest way to do this is with conditional build and defining the target in the source. By simply commenting the {\$define dll} line, you can build an EXE instead of a DLL.

Create a new Web Server Application by choosing "File->New, Web Server Application", and selecting a "ISAPI/NSAPI Dynamic Link Library." After the project has been created, save it, and click "Project->View Source." Copy and paste the sample code from below into the project source.

#### Download a sample project

#### Sample Code

```
// Comment or uncomment the line below to change from an ISAPI dll
// to a CGI app or vice-versa
//{$define dll}

{$ifndef dll}
program Project1;
{$APPTYPE CONSOLE}
{$else}
library Project1;
{$endif}

uses
  WebBroker,
  {$ifdef dll}
  ISAPIApp,
  {$else}
  CGIApp,
  {$endif}
  Unit1 in 'Unit1.pas' {WebModule1: TWebModule};

{$R *.RES}

{$ifdef dll}
```

**exports**

```
    GetExtensionVersion,  
    HttpExtensionProc,  
    TerminateExtension;  
{$endif}
```

**begin**

```
    Application.Initialize;  
    Application.CreateForm(TWebModule1, WebModule1);  
    Application.Run;  
end.
```

Last Modified: 23-FEB-00

**Article #20644: Loading an ISAPI DLL with Informix results in Error.**

Q. Why, when I load an ISAPI DLL that opens a connection to an Informix database, do I get the error "The dynamic link library ISQLT09A.dll could not be found in the specified path", or "The dynamic link library ISQLT07C.dll could not be found in the specified path", yet when I connect in any other BDE application I can connect fine?

A. IDAPI DLLs use the IUSR\_computername user account and therefore don't have access to the user path. The error indicates that the Informix client can't be found in the path for the IUSR\_computername account. To solve the problem, add the Informix and Informix/bin directories to your System path using the System control panel and reboot.

Last Modified: 01-MAR-00

## **Article #20646: ISAPI DLL when connecting to Informix gives sql.iem error**

Q. Why, when my ISAPI DLL connects an Informix database, do I get the error "Cannot open file 'sql. iem'", yet in any other BDE application I cannot connect fine?

A. ISAPI DLLs use the IUSR\_computername account. The problem here is that the IUSR\_computername account can't see the appropriate registry entries. To resolve the problem run regedit and copy HKEY\_CURRENT\_USERSoftwareInformix to HKEY\_USERS. DEFAULTSoftwareInformix.

Last Modified: 25-FEB-00

**Article #20659: Delphi 5 trial edition premature expiration**

**QUESTION:**

Why has my trial version of Delphi 5 expired before the 60 days are up?

**ANSWER:**

There is a bug in the trial edition timer which can cause it to expire early on some machines. We have a fix available for this. In order to receive a copy of the fix please go [here](#) and submit an install web case. We will then email you the fix.

Last Modified: 26-JUN-01

## **Article #20661: "Operation not applicable" when opening ClientDataSet.**

### **QUESTION:**

Why am I getting the error "Operation not applicable" when I open a TClientDataset with many master-detail datasets?

### **ANSWER:**

There is a limit of 15 master-detail relationships when using nested datasets.

There are two ways you can set up master/detail relationships in client datasets using nested tables.

One is to define them explicitly using the Fields Editor. At design time, right click the client dataset and choose Fields Editor. Add a new persistent field to your client dataset by right-clicking and choosing Add Fields. Define your new field with type DataSet Field. In the Fields Editor, define the structure of your detail table.

A second way that you may not be aware of is to obtain records that contain nested details from a provider component. When a provider component represents the master table of a master/detail relationship, it automatically creates a nested dataset field to represent the details for each record.

## Article #20689: How do I set the desktop icon color in code, or make the text behind them transparent?

**Question:** How do I set the desktop icon color in code, or make the text behind them transparent?

**Answer:** To do this, you will have find the "SysListView32" window (which is the desktop icon list view window). First, you will have to find the main parent window called "Progman". It has a child window called "SHELLDLL\_DefView" that has the "SysListView32". You can use the API call `FindWindow` to find the "Progman" window, and then `FindWindowEx` to find the child window. When you finally have the right handle to the "SysListView32" window, you can use the `ListView` macro's `ListView_SetTextBkColor` and `ListView_SetTextColor` to set the color's to whatever you want.

Below is a sample unit that does this for you. Simply use the procedure `SetDesktopIconColor` to set the desktop icon color. If the parameter `Trans` is true, it makes the background transparent, otherwise it used the given `Background` color.

### Download the DeskIcons.pas file

#### DeskIcons.pas Unit

```
unit DeskIcons;  
  
interface  
uses Graphics; // Definition of TColor  
  
procedure SetDesktopIconColor(Foreground, Background: TColor; Trans: Boolean);  
procedure SetDefaultIconColors;  
  
implementation  
uses Windows, CommCtrl; // Definition of HWND and ListView_XXXXX  
  
procedure SetDesktopIconColor(Foreground, Background: TColor; Trans: Boolean);  
{  
  This procedure set's the desktop icon text color  
  to a given color with the option to add a transparent background.  
}  
var  
  Window: HWND;  
begin  
  // Find the right window with 3 calls  
  Window := FindWindow('Progman', 'Program Manager');  
  // FindWindowEx is used to find a child window  
  Window := FindWindowEx(Window, HWND(nil), 'SHELLDLL_DefView', '');  
  // SysListView32 is the desktop icon list view  
  Window := FindWindowEx(Window, HWND(nil), 'SysListView32', '');  
  // Use the macro to set the background color to clear  
  if Trans then
```

```

    ListView_SetTextBkColor(Window, $ffffffff) // back color
else
    ListView_SetTextBkColor(Window, Background); // back color
    ListView_SetTextColor(Window, Foreground); // foreground color
    // now send a redraw to the icons to redraw the new color
    ListView_RedrawItems(Window, 0, ListView_GetItemCount(Window) - 1);
    UpdateWindow(Window); // force the redraw to take effect immediatly
end;

procedure SetDefaultIconColors;
{ This set's the colors to be whatever is currently
  stored by windows }
var
    Kind: Integer;
    Color: TColor;
begin
    Kind := COLOR_DESKTOP;
    Color := GetSysColor(COLOR_DESKTOP);
    SetSysColors(1, Kind, Color);
end;

end.

```

Last Modified: 23-FEB-00

## Article #20716: Customizing the time/date display of the TDateTimePicker

### Question:

The TDateTimePicker's time display defaults to showing hours, minutes, and seconds. I would prefer not to show seconds, but there doesn't seem to be a way of changing the format. Is there a way?

### Answer:

The underlying API control can be customized using the DTM\_SETFORMAT window message. Use the Perform message to send this message and its parameters to the control.

### Example in C++:

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    DateTimePicker1->Perform(DTM_SETFORMAT, NULL, "hh:mm tt");
    // will yeild a display without seconds, like this: "8:30 PM"
}
```

### Example in Object Pascal:

```
procedure TForm1.Button1Click(Sender: TObject);
var
    s: String;
begin
    s := 'hh:mm tt';
    DateTimePicker1.Perform(DTM_SETFORMAT, DWord(nil) ,DWord(s));
end;
```

Consult the Windows API documentation [here](#) for further information on formatting strings.

Note: This technique bypasses the VCL wrapper around the date time picker by sending a message directly to the Windows control. This causes one problem. If you send a message that sets the formatting to show date elements while the Kind property is set to dtkTime (or vice versa), the date elements will display correctly, but the user may not be able to change those elements (or elements will change incorrectly). Therefore, it is suggested that you be sure the elements you display correspond to the control's Kind.

**Article #20755: Does the BDE use Client side or server side cursors for MSSQL?**

Q. Does the BDE SQL Links driver to MSSQL use client side or server side cursors?

A. Server side cursors are used. The driver does not use the client side cursor API at all.

## **Article #20802: Access Violation when opening any Access Table**

Q. If I attempt to get a list of tables in SQL Explorer against an Access database, or just execute a SQL statement I get an Access violation, even though the Microsoft Access product works just fine. What can cause this?

A. In general terms your DAO install is bad in some regard. Obtaining a newer version of DAO350.DLL or OLEAUT32.DLL generally solves the problem. See <http://support.microsoft.com/support/kb/articles/Q231/8/41.ASP?LNG=ENG&SA=ALLKB> for additional information.

Last Modified: 29-FEB-00

**Article #20903: Missing icons for the office components on the Server tab.**

**QUESTION:**

Why am I missing icons for the office components on the Server tab?

**ANSWER:**

This was caused by an import error, and has been fixed in Delphi 5 update pack 1 which is currently available for download from our website at

<http://www.borland.com/devsupport/delphi/downloads>.

Last Modified: 11-OCT-00

## **Article #21480: Why can't I connect to an Access database using the BDE and native MSACCESS driver?**

### **Question:**

Why can't I connect to an Access database using the BDE and native MSACCESS driver?

### **Answer:**

#### ***Access 2000:***

You cannot connect to an Access 2000 database using the BDE's native MSACCESS driver. It is recommended that you upgrade to Delphi 5 and use ADO. You could also connect using the BDE with ODBC.

#### ***Access 95 or 97:***

You may get the message "BDE error 13059" and "General SQL error". If you are trying to connect to Access 95 or 97 databases using the BDE's native MSACCESS driver, then you need to have DAO 3.0 installed for Access 95 or DAO 3.5 for Access 97 (DAO = Data Access Objects for Visual Basic). You can install the DAO by doing a custom installation of MS Office and selecting only to install Data Access Objects for Visual Basic. You must also have the correct DLL32 setting in the BDE Administrator for the DAO you have installed: IDDA3532.DLL for Access 97, IDDAO32.DLL for Access 95.

Last Modified: 03-AUG-01

## **Article #21484: How do I prevent my application's main window from showing when my application loads?**

### **Question:**

How do I prevent my application's main window from showing when my application loads?

### **Answer:**

There are some cases in which you may not want the application's main window to show unless a certain criteria is met (i.e. successful user/password authentication, successful connection to database, etc.) or you may not want the window to show at all. To do this, set the Application's ShowMainForm property to false (`Application.ShowMainForm := false`) in the main project file before `Application.Run`, the `OnCreate` of one of your auto-created forms, or in the initialization section of one of your units.

## Article #21516: How to capture the URL and title of the current webpage being viewed.

### Question:

## How can I see if Netscape is running and capture the current URL?

### Answer:

This code sample will allow you to see if Netscape is running. Also, it will put the URL and page title into one string. This code will also work for IExplorer. Just replace the Netscape with IExplorer. Place a TEdit component on the form, to view the current URL and page title.

Uses

```
DdeMan;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  DDE: TDdeClientConv;
```

```
begin
```

```
  DDE := TDdeClientConv.Create(self);
```

```
  if DDE.SetLink( 'Netscape', 'WWW_GetWindowInfo' ) then
```

```
    Edit1.Text := DDE.RequestData( '0xFFFFFFFF', sURL, sTitle' )
```

```
  else
```

```
    ShowMessage( 'Netscape is not running' );
```

```
  DDE.Free;
```

```
end;
```

## Article #21519: Items disappearing from the Uses tab in the Type Library editor.

### Question:

Why are Type Libraries disappearing from the Uses tab in the Type Library editor?

### Answer:

The Delphi type library editor is designed to remove type libraries listed on the Uses tab which are not actually used by the type library currently open. Unfortunately there is a bug with this process which does not account for indirect dependencies. For example, library A uses an interface from library B and library B uses an interface from library C. Library A also has a function with a return type which is defined in C. Because Library A does not explicitly use any interfaces from C, C is removed from the Uses tab, but then subsequently refreshing and compiling a unit which uses library A's pas file, A\_TLB.pas, will result in a compiler error along the lines of "Undeclared identifier".

Fortunately there is a simple work around for this. Any type libraries which need to remain on the Uses tab, but are being automatically removed, can be forced to remain by creating a dummy interface which uses an interface from that type library. To do this open your type library and go to the Uses tab. Add the libraries you need. Now create a new interface and call it something like Dummy1. Select a parent interface from the type library you wish to retain. This will force it to remain on the Uses tab. On the Flags tab check 'hidden'. Now refresh and you should be all set.

## Article #21543: How do I get a list of CDROM drives on a computer?

### Question:

How do I get a list of CDROM drives on a computer?

### Answer:

```
procedure GetCDROMDrives(list: TStrings);  
var  
    DriveBits: set of 0..25;  
    Drives,DriveNum: integer;  
    DriveLetter: string;  
begin  
    list.Clear;  
    Drives := GetLogicalDrives;  
    if Drives <> 0 then  
    begin  
        integer(DriveBits) := Drives;  
        for DriveNum := 0 to 25 do  
        begin  
            if (DriveNum in DriveBits) then  
            begin  
                DriveLetter := char(DriveNum+Ord('A'))+':';  
                if GetDriveType(PChar(DriveLetter)) = DRIVE_CDROM then  
                    list.Add(DriveLetter);  
            end;  
        end;  
    end;  
end;
```

## **Article #21548: New Interbase driver configuration parameter COMMIT RETAIN.**

### **Question:**

What is the COMMIT RETAIN property and why can't I see it in the BDE Administrator?

### **Answer:**

COMMIT RETAIN is a new Interbase driver configuration parameter. It was introduced for explicit transactions to retain cursors on commit. It will not appear in existing aliases but should appear in new Interbase aliases, along with two other new parameters - WAIT ON LOCKS and ROLE NAME.

If these new properties do not appear when creating a new Interbase alias try this fix: After installing the latest version of the BDE, run BDE Administrator and select Object|Merge Configuration. In the Open dialog, enter SQL\_INT.CNF as the file name. This file should be in the main BDE directory. See the BDE help for more information.

**Article #21549: Code sample to detect if there is a sound device present on a computer.**

**Question:**

**How can I detect if a sound device is present on the computer were my application is running?**

**Answer:**

Use this code sample to detect if there is a sound device on the machine your application is running on. Make sure you add the unit MMSystem to your uses clause.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    if waveOutGetNumDevs > 0 then
        ShowMessage( 'Wave-Device present' )
    else
        ShowMessage( 'No Wave-Device present' );
end;
```

## Article #21552: RichEdit in a COM server is not being correctly created

### Question:

I have a RichEdit control in my COM Server application that uses the tmFree threading model for COM objects, and the RichEdit control is not being created. How can I get around this?

### Answer:

This is related to a bug in the VCL for Delphi 5 and you can [click here to read more about it](#). (It is also mentioned in the readme file for Delphi 5).

One possible workaround given was to override CreateParams for a TRichEdit and add the ES\_EX\_NOCALLOLEINIT style to it. However, this may not always work. Another possible solution is to capture the WM\_NCCREATE message and set the proper params at that point. Below is a component that will do that for you.

### [Download FixedRichEdit.pas](#)

#### Sample Code

```
unit FixedRichEdit;  
  
interface  
  
uses  
    Windows, Messages, Classes, Controls, RichEdit, ComCtrls;  
  
type  
    TFixedRichEdit = class(TRichEdit)  
    protected  
        procedure WMNCCreate(var message: TWMNCCreate); message WM_NCCREATE;  
    end;  
  
procedure Register;  
  
implementation  
  
procedure TFixedRichEdit.WMNCCreate(var message: TWMNCCreate);  
var  
    gwLEx : Longint;  
begin  
    gwLEx := GetWindowLong(WindowHandle, GWL_EXSTYLE);  
    gwLEx := gwLEx or ES_EX_NOCALLOLEINIT;  
    message.CreateStruct^.dwExStyle := gwLEx;  
end;
```

```
    inherited;  
end;  
  
procedure Register;  
begin  
    RegisterComponents('Samples', [TFixedRichEdit]);  
end;  
  
end.
```

Last Modified: 05-APR-00

## Article #21553: Getting "unmapped SQL error code 10038" when connecting to MS SQL.

### Question:

Why am I getting the error "Unmapped SQL error code 10038 - Attempt to initiate new SQL server operation with results pending"?

### Answer:

One reason we have found for this error is an incomplete connection to the server via a VPN and/or proxy server. We have Debugged the BDE code up to the point of a dialup connection to a server failing with the 10038 error. It failed during the single MS DBLIB function call to connect to the server. There aren't any changes that can be made or options that can be set that will "fix" this. It seems to do with how a MS DBLIB connection behaves across a firewall and/or VPN. Each subsequent action against the server (executing an sql statement of any kind) resulted in the "...results pending error".

You might find that other tools don't do this. MS's Windows ISQL is a good example. The main difference there is that it will try to reconnect when the initial connection appears to been dropped or failed to succeed. The BDE does not do this because many of its operations rely on a persistent connection to carry out supported features."

There is now a way to work around this. There is a new TDatabase param called "CANCEL QUERY". It can be set to either "dbcancel" or "dbcquery". In addition to params like:

```
USER NAME=varick  
PASSWORD=mypass
```

a TDatabase's params list can include

```
CANCEL QUERY=dbcquery
```

"dbcancel" is the default. "dbcquery" was added to take care of those situations where the MSSQL server is unable to process a "dbcancel" of pending results which may be the case when getting this error.

But before this property can be used in a TDatabase the parameter must be added for the MSSQL driver. This can be done by adding the following registry entry to the DB OPEN section of the MSSQL driver (using REGEDIT.EXE):

```
HKEY_LOCAL_MACHINE\SOFTWARE\Borland\Database Engine\Settings\DRIVERS\MSSQL\DB  
OPEN
```

```
Name: CANCEL QUERY Data: ""
```

Without the registry change the CANCEL QUERY param in the TDatabase has no affect (always dbcancel). Once the registry entry had been made to the MSSQL driver the CANCEL QUERY param could be used to control the cancel mode (dbcancel or dbcanquery).

Another possible workaround might be to use ODBC instead as it does not use DBLIB.

## Article #21564: Initializing an array or record to null.

### Question:

How Do I initialize an array or record to null?

### Answer:

By using the FillChar procedure. Here is an example:

```
procedure TForm1.Button1Click(Sender: TObject);  
type  
  TIntRec = record  
    i1: integer;  
    i2: integer;  
    i3: integer;  
    i4: integer;  
    i5: integer;  
  end;  
var  
  IntArray: array[0..4] of integer;  
  i: integer;  
  s: string;  
  IntRec: TIntRec;  
begin  
  // the array:  
  FillChar(IntArray,SizeOf(IntArray),0); // if you comment out this  
line, you will have random values in the array  
  for i := low(IntArray) to high(IntArray) do  
    s := s+IntToStr(IntArray[i]);  
  form1.Caption := 'IntArray: '+s;  
  // the record:  
  FillChar(IntRec,SizeOf(IntRec),0); // if you comment out this line,  
you will have random values in the record  
  form1.Caption := form1.Caption+' '+IntToStr(IntRec.i1)  
+IntToStr(IntRec.i2)+IntToStr(IntRec.i3)+IntToStr(IntRec.i4)+IntToStr  
(IntRec.i5);  
end;
```

## **Article #21573: Why is my system freezing when I start Delphi, just after closing the Just-in-time debugging dialog box?**

### **Question:**

Why does my system freeze after I see the message "The Just-in-time debugger is set to ". In order for it to work correctly, it needs to be changed to "C:\Program Files\Borland\Delphi5\Bin" -aargs %ld %ld"?

### **Answer:**

This issue probably has nothing to do with Just-in-time debugging. It is most likely a video driver issue that happens to be showing up right after the just-in-time dialog box closes. To verify this try turning off the hardware acceleration on your machine under display properties (Win 95 and Win 98 only), restart your machine and restart Delphi. If this fixes the issue you know it was caused by the video driver. See the following for further explanation:

## Article #21592: A final prompt, asking user if they really want to exit.

### Question:

How do I prompt a user, after they select a close method, for a response that they really want to close down the application?

### Answer:

Put this sample code into the OnCloseQuery event of your form. After a close method has been invoked on the form, a message will pop up asking the user if they really want to exit. If the user selects yes, the application will close normally, if they say no, the application will stay open.

```
procedure TForm1.FormCloseQuery(Sender: TObject; var CanClose:
Boolean);
begin
  if (mrNo = MessageDlg('You really want to exit?', mtInformation,
[mbYes, mbNo], 0)) then
    begin
      CanClose := False;
    end;
end;
```

## Article #21701: Clearing a console window screen

### Question:

How do I clear a console screen?

### Answer:

```
function ClearConsoleScreen: boolean;
const
    BUFSIZE = 80*25;
var
    Han,Dummy: LongWord;
    buf: string;
    coord: TCoord;
begin
    Result := false;
    Han := GetStdHandle(STD_OUTPUT_HANDLE);
    if Han <> INVALID_HANDLE_VALUE then
        begin
            if SetConsoleTextAttribute(han, FOREGROUND_RED or
FOREGROUND_GREEN or FOREGROUND_BLUE) then
                begin
                    SetLength(buf, BUFSIZE);
                    FillChar(buf[1], Length(buf), ' ');
                    if WriteConsole(han, PChar(buf), BUFSIZE, Dummy, nil) then
                        begin
                            coord.X := 0;
                            coord.Y := 0;
                            if SetConsoleCursorPosition(han, coord) then
                                Result := true;
                        end;
                    end;
                end;
            end;
        end;
end;
```

## **Article #21703: Oracle 8 problems introduced in BDE 5.1.1.**

Previous to BDE 5.1.1, setting ROWSET SIZE for an alias connected to Oracle 8 did nothing. BDE 5.1.1 added this as a new feature as a performance enhancement to improve the speed when many records are fetched.

However, this new feature introduces 3 new problems:

- When the number of rows returned from a TTable or TQuery matches a multiple of the setting of ROWSET SIZE data will be displayed twice.
- If the last row of a TTable or TQuery has fields which are blank (NULL), the corresponding field in the first record will be blank as well. This problem does not occur when using the Oracle 8.1.5 client (8i). When using the Oracle 8.0.4 client R&D has determined this problem to be caused by a bug in the Oracle 8.0.4 client. Therefore, ROWSET SIZE must be set to 0 when using the 8.0.4 client.
- Getting a list of tables in SQL Explorer may result in the error "Translate Error. Value out of Bounds."

The workaround for all of these problems at this time to set ROWSET SIZE to 0.

## Article #21721: Loading Params for some Stored Procs in Oracle Packages causes AV

As of BDE 5.1.0, Developer Support has seen a number of conditions where a Stored Proc is created correctly inside of a package, yet it will not operate correctly. This problem was introduced in version 5.1.0 as a result of fixing a bug where you crashed loading params for a stored proc with greater than 10 parameters. The conditions where this problem occur are:

- In SQL Explorer the valid property for the package and the package body returns Yes.
- Either the Oracle 8.0.4 or 8.1.5 client is used against a database of the same version.
- In the BDE Administrator settings for the Oracle native driver, DLL32 is set to SQLORA8.DLL and Vendor Init is set to OCI.DLL.
- Either Prepare is called for the Stored Proc, or the Params editor is accessed in Delphi or C++ Builder.

Under these conditions you either get an AV, or are exited from the IDE of Delphi or C++ Builder.

As of this time we don't have an exact description for what Stored Procedures work and which one do not. However; our observation is that most work. For those that have this problem, the workaround is to move the Stored Procedure out of a package and into a standalone Stored Procedure.

As of this time we believe this problem to be in the Oracle client. It is possible a future version of the Oracle client may resolve the problem.

Last Modified: 24-OCT-00

## **Article #21725: Closing and reopening a prepared query with Oracle 8 causes memory leak.**

### **Question:**

When I close and reopen a query with Oracle 8 I notice a memory leak. What causes this?

### **Answer:**

Every open of a Prepared query with Oracle 8 causes the HeapSize as reported from DbGetSysInfo to grow. When HeapSize equals MemSize an Out of Memory exception occurs. The only workaround at this time is UnPrepare the query after every execution of the Query.

This error is know to occur with BDE 5.0, 5.0.1, 5.1.0 and 5.1.1. with Oracle clients 8.0.4 and 8.1.5.

At this time, we believe this problem to be caused by a memory leak in the Oracle client. A future version of the Oracle client may resolve this error.

Last Modified: 12-APR-00

## Article #21726: Logging in with an incorrect login results in different errors with Oracle 7 and 8

### Question:

Why do I get different errors, when I login with an incorrect user name or password, using Oracle 7 vs. Oracle 8.

### Answer:

When connecting to Oracle 7, DLL32 in BDE Administrator is normally set to SQLORA32.DLL. When connecting to Oracle using SQLORA32.DLL the connection is made via calling the Oracle OCI function ologon.

When connecting to Oracle 8, DLL32 in BDE Administrator is normally set to SQLORA8.DLL. When connecting to Oracle using SQLORA8.DLL the connection is made via calling the Oracle OCI function OciBegin Session.

The reason SQLORA8.DLL and SQLORA32.DLL raise different errors is because ologon and OciBeginSession generate different errors when an incorrect login is attempted.

If you connecting to an Oracle 8 database, but like the errors that SQLORA32.DLL generates, here is a way to get the most out of SQLORA8.DLL and SQLORA32.DLL.

```
//Place this code it the location where connecting to the database
occurs
var
  DriverParams : TStringList;
begin
  DriverParams := TStringList.Create;
  try
    DriverParams.Add('DLL32=SQLORA32.DLL');
    Session.ModifyDriver('Oracle', DriverParams);
    Databasel.Open;
    //if no exception is raised, then close database and reopen with
SQLORA8.DLL
    Databasel.Close;
    DriverParams.Clear;
    DriverParams.Add('DLL32=SQLORA8.DLL');
    Session.ModifyDriver('Oracle', DriverParams);
    Databasel.Open;
  finally
    DriverParams.Free;
  end;
end;
```

## Article #21727: General SQL Error when connecting to MSSQL

### Question:

I can connect to MSSQL using ODBC, ADO and Enterprise Manager. Yet when I try to connect with BDE I get a General SQL Error. What is wrong?

### Answer:

It appears the Database Name property of your alias is invalid. To simply test whether you can connect, make the database name property blank. This will cause you to connect to the default MSSQL database on the server.

Last Modified: 13-APR-00

## Article #21728: Application Taskbar Button

### Question:

Why do operations I attempt to perform on the taskbar button for my main VCL form have no effect? (e.g. FlashWindow)

### Answer:

When calling Win32 functions or handling window messages associated with an application's taskbar button, you must use the global TApplication's window handle (TApplication::Handle).

This window handle is the parent of all the application's forms' handles. Many Win32 functions require window handles that are not that of child windows. FlashWindow is an example of such a function. It can flash the title bar and/or the task bar button of a window. If the window is a child window, then it can only flash the title bar of the window. Supplying Application->Handle for the HWND parameter of FlashWindow will allow flashing of the taskbar.

Last Modified: 02-MAY-00

## Article #21742: TTable.Edit always executes SELECT statement

### Question:

Whenever I start editing a record, even with Cached Updates ON, why is a SELECT statement executed?

### Answer:

The BDE needs to know what the current values are in the record so that when it goes to do an UPDATE it knows what record to change.

Last Modified: 25-APR-00

**Article #21773: Delphi 3 Midas apps not usable with BDE 5.1.1.**

The IDAPI32.DLL file included with BDE 5.1.1 does not include two exports, DsProviderGetDataPacket and dsResolver. This will cause Midas applications written in Delphi 3 to fail when used with it.

The workaround at this time is to use the IDAPI32.DLL file that comes with BDE 5.1.0.

Last Modified: 27-APR-00

**Article #21774: Read only access to FoxPro is recommended.**

Based on extended testing of the Native BDE FoxPro driver, Inprise/Borland advises against any use of this driver other than for read only access. Usage other than read only may result in crashes, Access Violations or corruption of indexes.

Last Modified: 02-AUG-00

## Article #21821: BDE uses small packet sizes

### Question:

I've noticed that the BDE uses small packet sizes. Is there are way to adjust this?

### Answer:

While the BDE does not explicitly request or know about packet sizes, the end result is that they are always small. In a LAN environment this works out fine. However, in a WAN environment this can result in a serious degradation of performance. Using BDE to ODBC or ADO may cause less degradation to occur.

## Article #22086: How to tell if a form has been created (or any object)?

### Question:

How to determine if a form has been created (or any object)?

### Answer:

If you creating and freeing an object several times, and you need to be able to tell if the object is currently created or freed, set the object's reference to nil everytime you free it. For example:

```
MyObject.Free;  
MyObject := nil;
```

Or in Delphi 5 or higher:

```
FreeAndNil(MyObject);
```

Then you can simply use the Assigned function to test if the object is nil or not.

## Article #22101: How to embed Adobe Acrobat into your application.

### Question:

How can I embed Adobe Acrobat into my application so users can read PDF files?

### Answer:

This document describes the process on how to use Adobe Acrobat to display files inside of your application.

1. First, you will have to ensure that you have the latest version of Acrobat on your machine. You can [download it from Adobe](#).
2. Next you will need to import the type library for Acrobat, and be sure to click the Install button to install it into the IDE:

Import Picture

3. You can now drop a TPDF component onto your form and use it however you like.

### -- Tips --

---

To set the file that you want open, use the src property, such as:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    // This example assumes that you have a TOpenDialog  
    // and TPDF dropped onto your form  
    OpenFileDialog.Filter := 'PDF Files (*.pdf)|*.pdf';  
    if OpenFileDialog.Execute then  
        Pdf1.src := OpenFileDialog.FileName;  
end;
```

---

If you don't want the Acrobat toolbar to be shown, you can call **Pdf1.setShowToolbar(false);**. You can then have custom buttons that allow the user to navigate through the PDF document by calling **gotoFirstPage**, **gotoLastPage**, **setZoom(percent: Single)**, etc. To find out a list of all the functions you can call, open the file that you imported (it is probably called PdfLib\_TLB.pas), and look at all the functions in the class **TPdf = class(TOLEControl)**. To easily browse to this file, you can place the cursor over the PdfLib\_TLB name in the uses clause and press Ctrl-Enter.

## Article #22113: Indices Vs. Keys

**Question:** When dealing with databases, what is the difference between keys and indices?

**Answer:** An index is a marker in a table which other tables can operate upon. A key is a value that a table uses internally to order its data.

Imagine you had a table of customers, working with a table of orders. Your orders would be keyed by their order numbers, and your customers by their customer numbers.

This is fine until we want to view our orders in terms of which customers made them. We would then use an index into the orders table. Using this index, we could find all of the orders which were made by a certain customer, even though the table itself isn't ordered in this fashion.

## Article #22114: How to use sets in code, such as adding to TDBGrid.Options, at run time

**Question:** I know how to use the object inspector to change the value of a set, such as TDBGrid.Options, but how do I manipulate sets in code?

**Answer:** To use sets, you will have to use square brackets to refer to set elements. Sets can have at most 256 elements in them. Here is an example of using and declaring sets:

### Sample Code

```
type
// Here are some examples of declaring set types.
// A variable of TMyMonth can take one and only one of
// one of its members.
TMyMonth = (Jan, Feb, Mar, Apr, May);
// TMyMonthSet can be an empty set (no months in it), or
// contain any combination of the above months.
TMyMonthSet = set of TMyMonth;
// TMySubMonthSet is a subset of the above set, only able
// to take on the first 3 months
TMySubMonthSet = set of Jan..Mar;

// TMyIntSet can be an empty set, or any combination of integers
// in the range of 1 to 15.
TMyIntSet = set of 1..15;
// TMySubIntSet can be an empty set, or any combination of integers
// in the range of 1 to 5.
TMySubIntSet = set of 1..5;

// Here are some examples of declaring set variables
var
  MyMonth: TMyMonth; // can only be one month (NOT a set)
  MyMonthSet: TMyMonthSet; // can be more than one month
  MyIntSet: TMyIntSet; // can be a combination of ints from 1 to 15 only
begin
  // The TMyMonth type can only take on one value at a time
  MyMonth := May;

  // Sets can take on more than one value, and notice the use of square
  // brackets
  MyMonthSet := [Jan, Mar, May];
  // MySubMonths can only take the values Jan..Mar. If you try to set it
  // to May, you won't get a compile time error, but the set will be empty.

  MyIntSet := [20]; // 20 is past the range for the set..so this should do nothing!
  if MyIntSet = [] then
    ShowMessage('MyIntSet is empty! (as expected...)');

  // Here are some common operations you can do with sets:
  // + Union operator
  MyMonthSet := MyMonthSet + [Feb, Apr]; // Add 2 months to the set
```

```
// - Difference operator
MyMonthSet := MyMonthSet - [MyMonth]; // Remove May from the set
MyMonthSet := MyMonthSet - [Jan..Apr]; // Remove Jan through Apr
// The set should now be empty (use the equality operator = to test sets)
if MyMonthSet = [] then
    ShowMessage('MyMonthSet is empty! (as expected...)');

// * Intersection operator
MyMonthSet := [Jan, Feb] * [Jan, Apr];
if MyMonthSet = [Jan] then
    ShowMessage('MyMonthSet is Jan! (as expected...)');

// <= Subset operator
if [Jan, Apr] <= [Jan..Apr] then
    ShowMessage('[Jan, Apr] <= [Jan..Apr], as expected...');
// <= Subset operator is the opposite of the above

// To test if an ordinal is in the set, us the "in" operator
if Jan in [Jan..Feb] then
    ShowMessage('Jan in set [Jan..Feb]');
end.
```

## Article #22115: Setting default value for decimal places in the BDE.

### Question:

How can I control the number of decimal places in a floating point number when I do a BatchMove to a text file?

### Answer:

Field formats in a text file are stored in a schema file which has the same name as the text file with a .sch extension. When doing a batch move to a text file (batCopy) a .sch file is automatically created. All floating point fields are provided by default with two decimal places of accuracy. After the schema file is created you can edit it and change the number of decimal places to another value. This new value will be used in future batch moves.

The default number of decimal places is controlled by the BDE parameter DECIMALDIGITS which can be found in the BDE administrator under: Configuration | System | Formats | Number. Since this is a BDE parameter it can also be changed at runtime by changing the value in the registry at:

HKEY\_LOCAL\_MACHINE\SOFTWARE\Borland\Database Engine\Settings  
\SYSTEMFORMATSNUMBER

## **Article #22213: Non-TThread Threading in Delphi, Access Violation, Invalid Pointer Operation.**

### **Question:**

Why do I get "Access violation" or "invalid pointer operation" when doing multi-threading in Delphi when not using the TThread class or the BeginThread function (i.e. using the CreateThread API function, or writing an Entera server)?

### **Answer:**

If you use non-Delphi threads (not using TThread or BeginThread) in a Delphi application, then you must manually set the IsMultiThread variable from the System unit to true. See "IsMultiThread variable" in the online help files for more information.

Last Modified: 19-JUN-00

## Article #22269: Delphi 5 on Windows 2000 and Windows ME

### Question:

Can I use Delphi 5 with Windows 2000?

### Answer:

Delphi 5 is not fully certified to be used on Windows 2000 because it came out before Windows 2000. This means that officially we cannot support it, however there are many people using it without a problem. We have heard of only a couple isolated cases of people having issues that did not occur on Windows NT. The same is true for Windows ME although we've not seen as many cases where people are using it.

Be sure to install [Delphi 5 update pack 1](#) as there were a couple Win2K modifications made.

Last Modified: 14-DEC-00

## Article #22390: Auto-Increment fields in InterBase

### Question:

I have an InterBase table, but I can't figure out how to make an Auto-Increment field for it. How do I do this?

### Answer:

InterBase doesn't have a convenient AutoInc datatype like Paradox, so we have to do a little bit of work to get this functionality. Start out by creating an Integer field that is appropriate for the size of the values you want in your AutoInc field. From there, we need a trigger to calculate the value for the field:

```
CREATE TRIGGER autoinc FOR tablename
BEFORE INSERT AS
BEGIN
    NEW.autoinc_field_name = GEN_ID(generator_name, 1);
END
```

We aren't done yet. We need a persistent location to store the current AutoInc value. InterBase's way to deal with this is called a generator:

```
CREATE GENERATOR generator_name;
SET GENERATOR generator_name TO x;
```

GEN\_ID() is a built-in InterBase function specially designed to increment the generator specified by the first parameter by the value in the second parameter. The SET GENERATOR statement initializes the generator to the value provided by *x*. This is useful if your database is based on something like a customer number, and you want this customer number to start at a specific value rather than zero. And that is all there is to it. From here on, you can insert away and this trigger will stick the correct value into autoinc\_field\_name. For further information on how to work with Auto-Increment fields in your application, read the TI "Working With Auto-increment Field Types" at <http://community.borland.com/article/0,1410,16123,00.html>.

## Article #22391: Row-Level Locking in MSSQL 7

### Question:

I'm having a hard time trying to make my application acquire one of those neat row-level locks that were introduced in MSSQL 7. How do I do this?

### Answer:

Row-level locking is definitely a powerful feature that was recently added to MSSQL server. Unfortunately, the current version of the BDE (5.11) does not support this functionality. The only way to get this out of your SQL Server is to bypass the BDE entirely with, for example, an ADO connection. In that situation, the lock is acquired by this simple SQL statement:

```
SELECT * FROM tablename WITH (UPDLOCK ROWLOCK) WHERE condition
```

*tablename* is the name of your table and *condition* is a conditional statement that should force only one record to be returned. The WITH clause will cause all rows returned to be locked with a row level lock, but if you need multiple rows locked you might want to look at another type of lock. This statement must be run in the context of a transaction, and this lock will persist until that transaction is committed or rolled back.

If you then run the MSSQL stored procedure `sp_lock()` during the timeframe of the transaction, you will see that your table has a lock of type RID, which denotes a row level lock. If you were to fire this exact SQL statement in a BDE application, `sp_lock()` would show a lock of either type TAB (table level) or PAG (page level).

**Article #22506: Delphi 1 no longer available.**

**Question:**

Why is Delphi 1 no longer shipped with the latest version of Delphi?

**Answer:**

Delphi 1 was shipped with Delphi 2,3 and 4 because it could still be used to create 16 bit applications for Windows 3.1, but it was not shipped with Delphi 5. This is because Delphi 1 has not been Y2K tested and is not considered Y2K compliant.

**Article #22584: With an inproc server that uses Sharemem, the caller AV's on exit.**

**QUESTION:**

Why is the caller getting an Access Violation on exit, when I use Sharemem?

**ANSWER:**

The problem is a call made to borlndmm.dll. The unload sequence on Win95 machines is at fault. The code runs fine on Win98, WinNT4, and Win2K. Linking the following unit will resolve the issue and the DLL does get unloaded.

```
unit Win95ShareMemFix;

interface

implementation

uses
  Windows, ActiveX, Sysutils;

initialization

  if (Win32Platform = VER_PLATFORM_WIN32_WINDOWS)
    and (Win32MajorVersion = 4) and (Win32MinorVersion <= 0) then
      Win32Check(CoLoadLibrary('borlndmm.dll', true) <> 0);

end.
```

Last Modified: 31-JUL-00

**Article #22586: Activating the clientdataset closes the query.**

**QUESTION:**

Why does my query close when I activate my clientdataset component?

**ANSWER:**

This is normal behavior in Delphi 5. When the clientdataset is activated and it is reading it's data from a query, the client dataset will close the query after it is done reading in the data. This is different from Delphi 4 because Delphi 4 uses Midas 2 which is not stateless, and Delphi 5 uses Midas 3 which is stateless. So Midas applications written in Delphi 4 may need to be redesigned to adhere to the stateless aspect of Midas 3.

**Article #22597: When Quick Report printer settings are changed during a preview at run time, they will have no affect.**

**QUESTION:**

Why don't my printer setting take affect at run time?

**ANSWER:**

The Quick Report set up dialog of the report preview only works on the current print job. The setting are loaded and cannot be changed until the printing is done. You will need to change the settings again for the second print out. The settings are not saved and will need to be changed for each consecutive print.

## Article #22609: Changing Quick Report BandType at runtime.

### QUESTION:

How do I change the BandType property of QRBand at run time?

### ANSWER:

Once you have assigned a BandType to a QRBand, you need to deactivate the band before you can change it's band type:

```
theReport.Bands.HasPageFooter := FALSE;  
theReport.Bands.PageFooter := nil;  
QRBand1.BandType := rbPageFooter;  
theReport.Bands.HasPageFooter := TRUE;  
theReport.Bands.HasPageFooter := QRBand1;
```

Last Modified: 31-JUL-00

**Article #22610: How to assign the Delphi global printer object, to the Quick Reports global printer object.**

**QUESTION:**

How do I assign the Delphi global printer object, to the Quick Report global printer object?

**ANSWER:**

If you are using Quick Reports and want to use Delphi's print dialogs, then you need to assign Delphi's global printer object to Quick Report's global printer object. Here is a code snippet that shows how to do this.

```
uses Printers;  
  
ReportForn.QuickRepl.PrinterSettings.PrinterIndex := Printer.PrinterIndex;
```

Last Modified: 14-AUG-00

## Article #22696: Error: "Type mismatch"

### QUESTION:

Why am I getting type mismatch error when I try to query my oracle table?

### ANSWER:

The numeric type that oracle uses allows a length field and a precision field. So declaring a field to be Numeric (10,4) specifies a number with 10 digits, 4 of which to be used for precision.

```
Declaration    | Valid input  
-----
```

```
Numeric (5,2)  | 345.23
```

```
Numeric(3)    | 345      *
```

\*Note: This Declaration appears to be an integer but is actually a floating-point number.

In both cases these numbers are stored as floating point Numbers. If your tables have type TIntegerField where a numeric field was declared, then you will get an error on activation. Technically the BDE handles Numeric fields as floats, even if they look like integers. If you are sure that the values in table are integers then you can use the Trunc function, which returns an Int64.

## Article #22866: How to send a response early in a web application action.

### Question:

How to send a response early in a web application action.

### Answer:

Typically, with web applications, you set `Response.Content` to something in an Action and let the content be sent after the action is done. But what if you want to constantly stream out data to the client web browser? To do this, you will have to use `TWebRequest.WriteString` in combination with `TWebResponse.SendResponse`.

The trick is to not set `Response.Content` before calling `Response.SendResponse`. Setting `Response.Content` to a string and then calling `SendResponse` causes the Response to send a "Content-Length:" to the web browser client. The web browser will then expect nothing longer than the `Response.Content` and will close the connection early.

To keep the connection open, the first thing you should do is send `Response.SendResponse`. This properly fills up the Response header, but doesn't set the "Content-Length:". You can then use `Request.WriteString` to write individual strings directly to the web browser at any time.

Here is an example action that should give you an idea of how to do this:

```
// This example doesn't add the proper HTML starting  
// tags for simplicity  
procedure TWebModule1.WebModule1WebActionItem1Action(Sender: TObject;  
    Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);  
var  
    I: Integer;  
    S: string;  
begin  
    // Important that this is first!  
    Response.SendResponse;  
    S := 'About to send time stamps<br>';  
    // Send the content early by accessing the Request  
    // directly and writing to it.  
    Request.WriteString(S);  
    // Send some Responses and pause to simulate lengthy operations  
    for I := 1 to 3 do  
    begin  
        // Pause for about 3 secs  
        Sleep(3000);
```

```
// Set another response  
S := TimeToStr(Now) + '<br>';  
Request.WriteString(S);  
end;  
end;
```

## Article #22867: How to turn off ISAPI DLL caching on Windows 2000 and IIS5

### Question:

How do I turn off ISAPI DLL caching on Windows 2000 and Internet Information Services 5 (IIS5)?

### Answer:

You may want to turn off DLL caching to allow you to better debug ISAPI DLL's. Note that if you do turn it off, it is best to turn it back on when you are ready to use your DLL as it greatly improves performance.

Click on Start->Settings->Control Panel->Administrative Tools->Internet Services Manager. Right click on your website and select Properties:

IIS Manager Screen Shot

Select the "Home Directory" tab, and click on Configuration...:

Configuration

Uncheck "Cache ISAPI applications":

uncheck cache extensions

## Article #22940: Can you drag and drop existing SQL structures directly onto a form?

**Question:** What is the easiest way to implement SQL Tables, Sequences, Procedures, etc. that have already been created, into the Data Access components?

**Answer:** By dragging and dropping pre-created SQL structures onto Builder/Delphi forms.

Once the structures have been created, they may be accessible from within the components themselves. To do this, right-click on your Data Access Component and choose "Explore." This will open the SQL Explorer.

Next, navigate and open the database alias you are working with. You should be presented with a list of whatever structure groups are currently available. Within these are the structures themselves. Find the specific structure you would like to implement and drag it over to your Builder/Delphi form and drop it. A component will be created and its properties filled in with the applicable data. This is much easier than typing in the properties by hand, and is an efficient way to eliminate implementation errors that could occur.

## Article #22985: Error "Unable to write to registry" during Interbase 5.5 install.

### Question:

Why did my Interbase 5.5 installation stop around 10% with the error 'unable to write to registry'?

### Answer:

Another possible error message is "Failed to open registry key". Here are 3 possible solutions:

1) InterBase 5.5 expecting the following registry key to exist and it has not yet been created:

HKEY\_LOCAL\_MACHINE-->Software-->Microsoft-->Windows-->CurrentVersion-->SharedDLLs

2) Other software has added enough values to this key to hit some OS limit to the number of values that can be registered for this key. Check to see if there are extraneous or duplicate values under this key and delete them.

3) A path length over 128 characters can cause problems when installing Interbase but it usually gives a different error message (see the file Install.txt which comes with Delphi for more information).

## Article #23006: Passing nil to a variable parameter.

### QUESTION:

How do I pass nil to a variable parameter of a method?

### ANSWER:

Create the pointer type, assign it nil and pass it in by dereferencing it.

```
var
  value: PInt;
begin
  value := nil;
  NextVal(value^);
end;
```

Now to use the passed in parameter you will have to check for nil first by getting the address of the Integer.

```
function NextVal(var value: Integer): HRESULT; stdcall;
begin
  if @value <> nil then
    ShowMessage('value ' + IntToStr(value))
  else
    ShowMessage('passed nil');

  Result := 0;
end;
```

**Article #23007: How to access more than one table with the QuickRep component.**

**QUESTION:**

I have more than table that I need my QuickRep component to access, what other Dataset can I use?

**ANSWER:**

The QuickRep component can only be connected to one dataset at a time. If you have data from more than one table that needs to be accessible to the QuickRep component, use a TQuery with a join statement.

Last Modified: 15-SEP-00

## Article #23008: Variable alignment problems in record type.

### Question:

Why am I getting garbage returned from my record variables?

### Answer:

This is most likely a problem with field alignment. If you are using an application in Delphi 5 that was migrated from an earlier version you should know that alignment changed in Delphi 5. See Delphi 5 help under *Contents / Upgrading to Delphi 5 / Compatibility issues / Default alignment*.

If this is not your issue there is also a bug in Delphi 5 you should be aware of. If no compiler directive is specified the default is `{ $ALIGN ON }` or simply `{ $A+ }`. Aligned means the record is unpacked and each field takes a fixed amount of space in memory based on the datatype. Packing is done to save memory.

The bug in Delphi can cause packing or inconsistent alignment to occur even when alignment is on, `{ $A+ }`. It occurs when multiple record fields are declared in the same line. Moreover, this alignment is not consistent, varying between 2, 4 and 6.

The solution is easy; declare each field in a new line. Here's an example that demonstrates the issue with Extended types. Since they are all Extended types they should all use the same amount of space in memory. Therefore the difference between each of the memory addresses should all be the same, but notice they are not. We've only observed this behavior with Extended and Real48 types. We've heard reports of it happening with other data types but have not been able to reproduce it.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  test1 : record
    field1, field2 : Extended;    // Packed
    field3 : Extended;          // Not packed
    field4 : Extended;          // Not packed
  end;
begin
  showmessage('Address of field1: ' + IntToStr(longint(@test1.field1))
+ #10#13
+ 'Address of field2: ' + IntToStr(longint(@test1.field2))
+ #10#13
+ 'Address of field3: ' + IntToStr(longint(@test1.field3))
+ #10#13
+ 'Address of field4: ' + IntToStr(longint(@test1.field4)));
end;
```

Last Modified: 11-OCT-00

## Article #23009: Auto Increment Fields in a ClientDataSet

### QUESTION:

How can I auto increment my field in a dataset using TClientDataSet?

### ANSWER:

If you are using a TClientDataSet to create local data set, which will be saved locally to disk, then there are a couple of ways to automatically increment a field. The first technique requires the use of an aggregate.

Examine the code below:

```
.
.
var
    NewID: Integer;
begin
    //Assuming that your table has been created
    with ClientDataSet do
    begin
        AggregatesActive := False;
        Aggregates.Clear;
        with Aggregates.Add do
        begin
            Expression := 'Max(AField)';
            AggregateName := 'Runtime';
            Active := True;
        end;

        AggregatesActive := True;

    try
        NewID := Aggregates[0].Value;
        // ...or alternatively
        // NewID := Aggregates.Find('Runtime').Value;
        Inc(NewID);
    except
        on E: Exception do SomeHandle; //Probably shouldn't throw exception
    end;

    // Next set field value to NewID
    Insert;
    FieldByName('AField').AsInteger := NewID;
end;
```

In this example we first deactivate any aggregates, as well as clearing them. Clearing them is optional, if you choose not to clear then be sure to use the proper index value when indexing into `Aggregates[]`. When we add the new aggregate we set the `Expression` to `Max('AField')`, give it a name, and activate it. This aggregate will keep track of the maximum value in your auto incremented field. So when you insert a new record you can set the value of the auto incremented field to the current value of the aggregate, add 1.

The second technique of auto incrementing requires changing the current index of the `TClientDataSet`. The first thing to do is to create an `Index` with the value of its `Fields` property set to the field name for which you want to auto increment. Once the index is created you need to set it to the `ClientDataSet.IndexName` property. This will cause the resulting data set to order itself in descending order based on the values in the column. You can then call `Last()` to move the cursor to the end of this data set. Next, get the value out of the field and add 1. This will be the value of your next of the next record's auto increment field.

## Article #23011: Using the requery method in place of the refresh method.

### QUESTION:

How can I speed up ADO's slow refresh for my table?

### ANSWER:

Use the requery method, this will update your tables faster. Call requery to refresh the recordset by re-executing the original command or SQL statement that produced the record set. Here is an example on how to implement requery:

```
procedure TFrmListOpen.TableRefresh;
var
  SavePlace : TBookmark;
begin
  {Using a standard refresh takes too long.  This code will perform a }
  {refresh much quicker.}
  SavePlace := DM.TableOpenEvents.GetBookmark;
  DM.TableOpenEvents.Requery;
  DM.TableOpenEvents.GotoBookMark(SavePlace);
  DM.TableOpenEvents.FreeBookMark(SavePlace);
end;
```

Last Modified: 08-SEP-00

## Article #23012: Checking the BDE version programmatically.

### QUESTION:

How can I check for the BDE version programmatically?

### ANSWER:

Your application might need a certain version of the BDE to run properly. So you will want to make sure that version is installed. Here is a code sample that shows you how to check which version of the BDE is installed.

```
uses
  Forms,
  DB,
  BDE,
  Dialogs,
  SysUtils;

{$R *.RES}

var
  ThisVersion : SYSVersion;
begin
  DbtGetSysVersion(ThisVersion);
  ShowMessage('BORLAND DATABASE ENGINE VERSION = ' + IntToStr(ThisVersion.iVersion));
end.
```

Last Modified: 15-SEP-00

## Article #23175: Finding all files (or files of a certain type) in a given directory

### Question:

Given a directory name, how do I find all files in that directory (or files of a specific type, such as \*.jpg)? How to I optionally search through all subdirectories?

### Answer:

You can use FindFirst and FindNext functions in SysUtils. Here is an example:

```
{ procedure GetFiles -
  Parameters:
    ADirectory: string; // A directory to search for files
    Files: TStringList; // The list of files to put the result in
    SubFolders: Boolean; // If True, it searches subfolders too }

procedure GetFiles(const ADirectory: string; Files: TStringList;
SubFolders: Boolean);
    // Helper function to remove any slashes or add them if needed
function SlashSep(const Path, S: string): string;
begin
    if AnsiLastChar(Path) ^ <> '\' then
        Result := Path + '\' + S
    else
        Result := Path + S;
    end;
var
    SearchRec: TSearchRec;
    nStatus: Integer;
begin
    // First find all the files in the current directory
    // You could put something else instead of *.* , such as *.jpeg or *.
gif
    // to find only files of those types.
    nStatus := FindFirst(PChar(SlashSep(ADirectory, '*.*')), 0,
SearchRec);
    while nStatus = 0 do
        begin
            Files.Add(SlashSep(ADirectory, SearchRec.Name));
            nStatus := FindNext(SearchRec);
        end;
    FindClose(SearchRec);
    // Next look for subfolders and search them if required to do so
```

```

if SubFolders then
begin
    nStatus := FindFirst(PChar(SlashSep(ADirectory, '*.*')),
faDirectory,
    SearchRec);
    while nStatus = 0 do
    begin
        // If it is a directory, then use recursion
        if ((SearchRec.Attr and faDirectory) <> 0) then
        begin
            if ( (SearchRec.Name <> '.') and (SearchRec.Name <> '..') )
then
                GetFiles(SlashSep(ADirectory, SearchRec.Name), Files,
SubFolders);
            end;
            nStatus := FindNext(SearchRec)
        end;
        FindClose(SearchRec);
    end;
end;

```

[Click here to download the source and sample program from Code Central.](#)

**NOTE:** Delphi 4's FindClose function has a bug in it and can make this code run in an infinite loop. You will need to change the FindClose function in SysUtils.pas to look like this:

```

procedure FindClose(var F: TSearchRec);
begin
    if F.FindHandle <> INVALID_HANDLE_VALUE then
    begin
        Windows.FindClose(F.FindHandle);
        F.FindHandle := INVALID_HANDLE_VALUE;
    end;
end;

```

Last Modified: 07-NOV-00

## Article #25128: Creating a BDE alias programmatically from Delphi

Problem:

Need to create a BDE alias programmatically

Solution:

When you create a delphi project and include the DB unit it creates an instance of a TSession component called Session. This component has methods to allow the creation of a BDE alias.

If your application includes any of the database components the DB unit is automatically included in the project. If you do NOT use any of the database components you will have to manually add the DB unit to have access to the Session variable. Alternatively you could add your own TSession variable to your project. (TSession is a component in the Data Access tab of the component palette).

The following is a code fragment from an program that creates a new BDE alias:

----- Begin Code Fragment -----

```
{ procedure to create new BDE alias }
{ it creates an InterBase alias with the specified }
{ database and username }
{ All BDE parameters not specified will use the defaults }

procedure TForm1.Button1Click(Sender: TObject);
var
    AParams: TStringList;
begin
    AParams := TStringList.Create;

    AParams.add('Server Name=' + 'lurch:d:c:ibtmprestored.gdb');
    AParams.add('User Name=' + 'SYSDBA');
    Session.AddAlias('NewAlias', 'INTRBASE', AParams);
```

```
Session.SaveConfigFile;  
AParams.Free;
```

```
end;
```

## Article #25183: Handling the "Capability not supported" error

### Problem:

An application written using the BDE, Delphi, or C++ Builder may return an error "Capability not supported."

### Solution:

This error is returned by the BDE when the BDE parses an SQL string to be sent to a server and the syntax of the string is not supported by the BDE.

See below for more information on how the BDE sends pass through SQL strings to DBMS servers and ODBC data sources.

The BDE, and Delphi and C++ Builder applications that use data-aware components send SQL strings to DBMS servers and ODBC data sources depending on the setting of the SQLQRYMODE parameters.

The settings of the SQLQRYMODE parameter are listed in the BDE Administrator Help (formerly known as the BDE Configuration Help) file, and are paraphrased below:

- The SQL string is sent to the server or ODBC data source first. If an error is returned the string is then parsed and ran by the BDE.

SERVER - The SQL string is sent to the server or ODBC data source, if an error is returned then the error is placed on the BDE error stack and the appropriate BDE error is returned.

LOCAL - The SQL string is parsed and ran by the BDE.

When the BDE parses and runs the SQL string due to the SQLQRYMODE being set to blank or LOCAL, if the SQL string to be parsed is not supported by the BDE the error "Capability not supported" is returned.

The SQLQRYMODE parameter is found in both BDE alias definitions and in BDE driver definitions. The BDE will look for this parameter first in the alias definition, if it is not found or the entry not a recognized value or is corrupted then the BDE will

look at this parameter in the driver definition. Alias definitions can be created by using TDatabase component, by using the DbOpenDatabase() and DbAddAlias() BDE API calls, and by using the BDE Administrator (formerly the BDE Configuration) utility.

## Article #25187: An EDatabase Exception is generated by a Delphi or C++ Builder application

### Problem:

A Delphi generated application is generating an EDatabase exception.

### Solution:

An exception was generated in the Delphi application code, or in the Delphi VCL Source code.

To locate the cause of the exception do the following steps from within the Delphi development environment:

Set the "Break on exception" checkbox and the "Integrated debugging" checkbox in the Tools | Options | Preferences menu to checked. In Delphi 1.0 the menu choices are: Option | Environment | Preferences. Run the "Build All" in the Project menu to generate debug information. Run the application and repeat the steps that produced the EDatabase exception.

When the error occurs and the cause is not obvious from within the application source code it is possible to go inside the VCL source code and have the debugger stop the application on the line of the VCL source that generates the EDatabase exception. To do this requires having the Enterprise or Client/Server edition of Delphi or C++ Builder.

If these versions of are not owned, obtaining the source code to the VCL components requires upgrading to the versions of Delphi mentioned above, or purchasing the RTL source code. To do either of the two choices consult the Borland Website at [www.borland.com](http://www.borland.com)

for the Borland Customer Service phone number.

To use the VCL source code to further track down the source of the EDatabase exception do the following:

Look up the help topic for the component that is generating the error. On this page in the upper left is a line that says "Unit". On the line underneath is the source file that contains the VCL source. Copy the source file noted on the help page from the Program Files\Delphi\Source\Vcl directory to the application directory. Copy the files db.pas and dbtables.pas as well, since these files are used extensively by the TDatabase, TTable and TQuery components. Repeat the steps above for reproducing the exception.

## Article #25188: Handling BDE Engine Errors

### Problem:

A Delphi or C++ Builder generated application produces a BDE Engine exception.

### Solution:

An exception was produced in the Delphi generated application due to an error from the RDBMS server (i.e InterBase), the BDE or an ODBC driver.

Using the Borland BDE Configuration Utility (BDECFG.EXE, or BDEADMIN.EXE)

to examine the SQLQRYMODE property of the InterBase or Visigneic ODBC alias being used in the application. If the setting is or set to LOCAL change the setting to SERVER. Save the changes and exit the utility.

If the application is using a TDatabase component, bring the application up in Delphi and left double-click the mouse on the TDatabase component to bring up the Database Login dialog. Change the SQLQRYMODE property in the parameters list box to SERVER, if the property is present. Save and do a Build All.

At this point exiting the Delphi IDE and starting it again may be required so that the new changes in the BDE aliases will be re-read and accounted for.

### SQLQRYMODE

#### Settings

=====

: The BDE sends the SQL query string to the RDBMS server or the ODBC data

source and if an error is returned the BDE will then parse the string itself and

will send the parsed string (or strings) to the server.

LOCAL: The BDE will parse the strings and send the parsed string (or strings) to the

server.

SERVER: The BDE will send the SQL query string to the RDBMS SERVER or the ODBC datasource. If an error occurs then this will be returned through the BDE.

By changing the setting to SERVER the error returned will be in direct relation to the SQL query that was requested by the Delphi application. Next, run the application and try to reproduce the exception.

When the exception is reproduced the BDE will take the resulting error from the server and will map it through one of its existing error codes and messages. If the error is "General SQL Error: " this indicates that an error occurred on the server and the BDE did not have a comparable or corresponding error message to map it to so it returned this error. The

portion will be the error string that is returned from the server (or ODBC datasource). This is the easy case, match the error string with the errors listed in the InterBase Language Reference, or with a listing of ODBC errors.

If another error is produced then it is uncertain if the error is from the server, the BDE, or an ODBC driver, this is the not-so-easy case. Delphi provides a way to look at where the error is coming from, follow the instructions in the following paragraphs.

To further track down the source of the exception start by placing a memo on the main form. This memo will be used to display further information that is available in the BDE Engine Exception object. Next implement the following code snippet into the main form of the application:

```
unit dbughelp;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
Dialogs,
  StdCtrls, DB;
```

```
type
```

```
  TForm1 = class(TForm)
    Memo1: TMemo;
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
    procedure MyHandler(Sender: TObject; E:Exception);
  end;
```

```
var
```

```
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := MyHandler;
end;
```

```
procedure TForm1.MyHandler(Sender: TObject; E: Exception);
```

```
var
```

```
  i: Word;
  F: EBDEEngineError;
```

```
begin
```

```
  Memo1.Lines.Add('== Begin Entries for Exceptions ==');
  Memo1.Lines.Add(E.ClassName);
  if (E is EBDEEngineError) then begin
    F := EBDEEngineError(E);
    Memo1.Lines.Add('ErrorCount = ' + IntToStr(F.ErrorCount));
    for i := 0 to F.ErrorCount - 1 do begin
      Memo1.Lines.Add(' ');
      Memo1.Lines.Add('-----');
      Memo1.Lines.Add(' ');
      Memo1.Lines.Add('NativeError = ' + IntToStr(F.Errors[i].
NativeError));
      Memo1.Lines.Add('Message = ' + F.Errors[i].Message);
      Memo1.Lines.Add('ErrorCode = ' + IntToStr(F.Errors[i].
```

```
ErrorCode));  
    end;  
end;  
Memo1.Lines.Add('== End Entries for Exceptions ==');  
end;
```

end.

In the FormCreate procedure (i.e OnCreate event) the application global exception handler is re-routed to a custom exception handler, the Myhandler procedure. Within the MyHandler procedure the error information in the BDE Engine Exception object is placed in the memo component. After the BDE Engine Exception information is placed in the memo look for the NativeError codes. The errors will follow a specific pattern for InterBase , the BDE and for ODBC. The patterns of the error messages are:

InterBase: The errors will follow the pattern of -xxx, like a -902 error.

Use the InterBase Language Reference manual to look up the error and the error message.

BDE: Download the DBI Error checking utility from the BDE Technical Support pages of the [www.borland.com](http://www.borland.com) website. Run the utility and type in the error number, the corresponding error message will be returned.

ODBC: Try consulting an ODBC reference for the error code.

## Article #25207: Automatically Generating Data to Create Large Tables Using Delphi

### Problem:

In testing applications, sometimes a large table is desired for a variety of reasons.

Some of the reasons might be to test performance, backing up and restoring sets of data, and reporting statistical data. Creating a large table by hand, or by several persons can be a time-consuming task that can be automated and performed quickly by using the approach given below.

### Solution:

The approach given below uses Delphi to connect to the InterBase server, however it could easily be modified for any database.

Before starting to construct the program that will generate records, if they are to be viewed in the Delphi generated application, run the BDE Configuration Utility. On the InterBase alias that will be used change the Enable BCD property to TRUE. This step not required but is recommended for tables with NUMERIC and DECIMAL columns. BDE will treat NUMERIC and DECIMAL columns differently based upon the setting of this property, the chart below will illustrate how BDE treats these columns:

	ENABE BCD is FALSE	ENABLE BCD is TRUE
NUMERIC(4)	TSmallIntField	TSmallIntField
NUMERIC(9)	TIntegerField	TBCDField
NUMERIC(10)	TFloatField	TBCDField
DECIMAL(4)	TIntegerField	TBCDField
DECIMAL(9)	TIntegerField	TBCDField
DECIMAL(10)	TFloatField	TBCDField

The ENABLE BCD setting affects how the BDE retrieves data from

InterBase by use of a SELECT statement. When the columns are translated into the TSmallIntField and TIntegerField types the decimal data is truncated, otherwise if the columns are translated to TFloatField or TBCDField types then the whole and decimal values are retained. The ENABLE BCD setting has no bearing on the INSERT statement that will be used later on to insert data into the table.

In the application the Interface section of the .pas will look similar to:

```
unit gendatal;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs,
  StdCtrls, DB, DBTables;

type
  TForm1 = class(TForm)
    Query1: TQuery;
    Button1: TButton;
    Edit1: TEdit;
    Edit2: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormClose(Sender: TObject; var Action: TCloseAction);
  private
    procedure gen_alpha      (var in_string:   String; in_length: Word);

    procedure gen_smallint  (var in_smallint: Smallint);
    procedure gen_integer   (var in_integer:  Integer);
    procedure gen_float     (var in_float:    Single);
    procedure gen_double    (var in_double:   Double);
    procedure gen_decimal   (var in_decimal:  Double; precision,
      scale: Word);
    procedure gen_integer_range (var in_integer: Integer; in_low,
      in_high: Integer);
    procedure gen_date_1900   (var in_date:   TDateTime);

    function  gen_rand: Extended;
  end;
end;
```

```
public
end;
```

```
var
  Form1: TForm1;
```

The application is divided up into several functions that perform the generation of fictitious data.

The functions are as follows:

```
// Generate CHAR and VARCHAR data for strings that are from 1 to
// 255 characters in width
procedure gen_alpha      (var in_string:   String; in_length: Word);

// Generate a SMALLINT value
procedure gen_smallint  (var in_smallint: Smallint);

// Generate an INTEGER value
procedure gen_integer   (var in_integer:  Integer);

// Generate a FLOAT value
procedure gen_float     (var in_float:    Single);

// Generate a DOUBLE PRECISION value
procedure gen_double    (var in_double:   Double);

// Generate a date in the 1900's range (i.e 20th Century)
procedure gen_date_1900(var in_date:     TDateTime);

// Generate a DECIMAL or a NUMERIC value
procedure gen_decimal   (var in_decimal:  Double; precision,
  scale: Word);

// Generate a value used by the procedures gen_integer, gen_float,
// gen_double, and gen_decimal
function  gen_rand: Extended;

// Generate a value used by gen_decimal, and gen_1900_date
procedure gen_integer_range (var in_integer: Integer; in_low,
  in_high: Integer);
```

The functions used in the interface of this application and the TQuery component that is used to

insert the data into the table will be covered later. The code for each procedure is shown below:

In this procedure an array of possible characters to include in the character string is constructed private to this procedure. In this array the blank space character is available twice, at the beginning and the end, and the comma character is available. What is not included here is the period character and other punctuation character, include these punctuation characters as desired. Please note that in Delphi 1.0 (16-bit) strings are limited to 255 characters. In Delphi v3.0 and higher, (32-bit) strings can be up to 4Gig in size, though InterBase supports CHAR and VARCHAR types only up to 32,767 (32k) bytes in length.

```
procedure TForm1.gen_alpha(var in_string: String; in_length: Word);
const
  char_array_size: Word = 55;
  char_array: Array[0..54] of Char =
    (' ', ' ', 'A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K',
     'L', 'M', 'N', 'O', 'P', 'Q', 'R', 'S', 'T', 'U', 'V', 'W', 'X',
     'Y', 'Z', 'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k',
     'l', 'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x',
     'y', 'z', ' ');
var
  i, j: Word;
begin
  // CHAR and VARCHAR types cannot exceed 32767, these lines of
  // code ensure this limit is not exceeded.
  if (in_length > 32767) then
    in_length := 32767;

  j := Random(in_length - 1) + 1;
  SetLength(in_string, j);
  for i := 1 to j do
    in_string[i] := char_array[Random(char_array_size)];
end;

procedure TForm1.gen_smallint(var in_smallint: Smallint);
begin
  // This calculation provides a range of
  // -32,768 to 32,767, the range of a smallint
```

```
in_smallint := 32767 - Trunc(65536 * gen_rand);  
end;
```

In generating a random integer value and extended variable is used internally in the procedure.

An extended variable is used because the internal algorithm uses a value that ranges from 0 to 4,294,967,295 and integer values above 2147483647 are not supported in Delphi (i.e. Delphi does not support unsigned long values).

```
procedure TForm1.gen_integer(var in_integer: Integer);  
var  
    temp_extended: Extended;  
begin  
    // This calculation provides a range of  
    // -2,147,483,648 to 2,147,483,647, the range of a integer  
  
    temp_extended := 4294967295.0 * gen_rand;  
    if temp_extended <= 2147483647 then  
        in_integer := Integer(2147483647 - Trunc(temp_extended))  
    else  
        in_integer := -1 * Integer(Trunc(temp_extended - 2147483647));  
end;
```

In generating a random float value the format of the float value as defined in the Object Pascal Language Guide is used to construct the float value. Specifically, the s, e, and f components are separately obtained and then placed in an integer variable (which is of the same size as a float), and then once this is done the value is copied into the float. Please note in constructing a float value it is possible to create a NAN (not a number), infinity, and minus infinity values. The procedure below does not create these values, if it did this would raise an exception in Delphi.

```
procedure TForm1.gen_float(var in_float: Single);  
var  
    s, e:      Byte;  
    f:        Longint;  
    temp_integer: Integer;
```

```

begin
  temp_integer := 0;

  // Obtain values for the component elements of in_float
  s := Trunc(2* gen_rand);
  e := Trunc(255 * gen_rand);

  f := Trunc(8388608 * gen_rand);

  // Place the components in the proper location in in_float
  temp_integer := temp_integer or s;
  temp_integer := temp_integer shl 8;
  temp_integer := temp_integer or e;
  temp_integer := temp_integer shl 23;
  temp_integer := temp_integer or f;

  // Move the data into the float variable
  Move(temp_integer, in_float, sizeof(temp_integer));
end;

```

In generating random double precision values the format double precision type that is defined in the Object Pascal Language Guide is used. Specifically the s, e, and f components are separately generated. Since a double precision value is 64-bits wide two long integers, which are 32-bits in length, are used to hold the values during computation of the double precision value. To this end the s, e, and 20 bits of the f components are held in one integer, and the remaining 32-bits of f are held in the other integer. In the final stages the contents of the two integers are copied to the correct locations inside the double precision number to produce a random value. Please note in constructing a double precision value it is possible to create a NAN (not a number), infinity, and minus infinity values. The procedure below does not create these values, if it did this would raise an exception in Delphi.

```

procedure TForm1.gen_double(var in_double: Double);
var
  e, s: Word;

```

```

f_low, low_integer, hi_integer: Integer;
temp_char_array: array[0..7] of char;
begin

    low_integer := 0;
    hi_integer := 0;

    // Get s component of double
    s := Trunc(2 * gen_rand);
    low_integer := low_integer or s;

    // Get e component of double
    low_integer := low_integer shl 11;
    e := Trunc(2046 * gen_rand);
    low_integer := low_integer or e;

    // Low 20 bits of f component of double
    low_integer := low_integer shl 20;
    f_low := Trunc(2097152 * gen_rand);
    low_integer := low_integer or f_low;

    // High 32 bits of f component of double
    gen_integer(hi_integer);

    Move(hi_integer, temp_char_array[0], 4);
    Move(low_integer, temp_char_array[4], 4);
    Move(temp_char_array, in_double, 8);
end;

```

```

procedure TForm1.gen_date_1900      (var in_date: TDateTime);
var
    days, millisecs: Integer;
begin
    gen_integer_range(days, Integer(0), Integer(36524));
    gen_integer_range(millisecs, 1, 99999);

    in_date := StrToFloat(FormatFloat('00000', days) + '.' +
        FormatFloat('00000', millisecs));
end;

```

In this procedure the range array is used to signify the range of numbers to generate using the `gen_integer_range` procedure when generating integers within a certain

range. The double\_format array is used to indicate a specific string formatting used in the algorithm used to generate the DECIMAL or NUMERIC value.

```
procedure TForm1.gen_decimal (var in_decimal: Double; precision,
scale: Word);
const
  range: array[1..9] of Integer = (9, 99, 999, 9999, 99999, 999999,
9999999,
                                99999999, 999999999);
  double_format: array[1..16] of String =
    ('0', '00', '000', '0000', '00000', '000000', '0000000',
'000000000',
    '0000000000', '00000000000', '000000000000', '0000000000000',
'000000000000000',
    '0000000000000000', '00000000000000000', '000000000000000000');
var
  whole, decimal:      Word;
  whole_int, decimal_int: Integer;
  whole_double, decimal_double: Double;
begin
  if ((precision > 15) or (precision < 1) or (scale > 15) or (scale <
1)) then begin
    in_decimal := 0.0;
    exit;
  end;

  if (scale > precision) then begin
    in_decimal := 0.0;
    exit;
  end;

  whole := precision - scale;
  decimal := scale;

  // generate whole number portion
  if (whole = 0) then
    whole_int := 0
  else begin
    if (whole <= 9) then begin
      gen_integer_range(whole_int, -1 * range[whole], range[whole]);
      whole_double := whole_int;
    end
    else begin
```

```

    gen_integer_range(whole_int, -1 * range[9], range[9]);
    whole_double := Int(whole_int * exp((whole - 9)*ln(10)));
    gen_integer_range(whole_int, 0, (whole - 9));
    whole_double := whole_double + whole_int;
end;
end;

// generate decimal number portion
if (decimal = 0) then
    decimal_int := 0
else begin
    if (decimal <= 9) then begin
        gen_integer_range(decimal_int, 0, range[decimal]);
        decimal_double := decimal_int;
    end
    else begin
        gen_integer_range(decimal_int, 0, range[9]);
        decimal_double := Int(decimal_int * exp((decimal - 9)*ln(10)));
        gen_integer_range(decimal_int, 0, (decimal - 9));
        decimal_double := decimal_double + decimal_int;
    end;
end;
end;

in_decimal := StrToFloat(FormatFloat(double_format[whole+1],
whole_double) +
    '.' + FormatFloat(double_format[decimal], decimal_double));
end;

```

This procedure is used internally by other procedures that require generating a random integer value within a certain range.

```

procedure TForm1.gen_integer_range (var in_integer: Integer; in_low,
in_high: Integer);
var
    low, hi, delta: Integer;
begin
    if (in_low <= in_high) then begin
        low := in_low;
        hi := in_high;
    end
    else begin
        low := in_high;
        hi := in_low;
    end;
end;

```

```

end;

if ((hi - low) > 2147483647) then begin
    in_integer := 0;
    Exit;
end;

delta := hi - low + 1;
in_integer := Trunc(delta * gen_rand) + low;
end;

```

Place each procedure and function shown above in the Implementation section of the .pas file. Next, place a TQuery, two TEdit, and a TButton Component on the form. Give the TQuery component focus on the form and in the Object Inspector make the entry in the SQL property similar to the following entry:

```

INSERT INTO InputTble
(Col1, Col2, Col3)
VALUES
(:parm1, :parm2, :parm3)

```

The names of the columns and their data type in the table depend on the structure of the table. Next, set data type of the parm variables in the Params property. The InterBase data types will match up with the following BDE data types:

InterBase Type:	BDE Type:
=====	=====
CHAR	String
VARCHAR           String	
SMALLINT	Smallint
INTEGER	Integer
FLOAT	Float
DOUBLE PRECISION	Float
NUMERIC           Float	
DECIMAL	Float
DATE	Date

One data type is missing here, the BLOB data type. BDE v3.5 and previous does not accept blob parameters to pass to InterBase BLOB columns. This is also why there

is no procedure the  
generate random BLOB data.

For the TButton component set up an OnClick event and have the OnClick event look like:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i:          Longint;
  in_string:  String;
  in_integer: Integer;
  in_decimal86: Double;
begin
  in_integer := 0;
  in_decimal := 0;
  Databasel.StartTransaction;
  try
    for i := 0 to StrToInt(Edit1.Text) - 1 do begin
      gen_alpha(in_string, 128);
      gen_integer(in_integer);
      gen_decimal(in_decimal86, 8, 6);
      Query1.ParamByName('parm1').AsString := in_string;
      Query1.ParamByName('parm2').AsInteger := in_integer;
      Query1.ParamByName('parm3').AsFloat := in_decimal86;
      Query1.ExecSQL;
      Edit2.Text := IntToStr(i);
      Application.ProcessMessages;
    end;
  except
    else Databasel.Rollback;
  end;
  if Databasel.InTransaction then
    Databasel.Commit;
end;
```

Using the Object Inspector, set up an OnCreate and an OnClose event for the form and have them look similar to:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  // Start up the random number generator in the runtime library
  Randomize;
end;
```

```
procedure TForm1.FormClose(Sender: TObject; var Action: TCloseAction);
begin
    // Free the form upon closing
    Action := caFree;
end;
```

When running the application type the number of records that are desired to be generated in the Edit1 control and click on the Button12 control to start the process of adding records.

The Edit2 control will display the number of records added.

## Article #25213: Handling "General SQL error: violation of FOREIGN KEY constraint . . ." error

### Problem:

When using a master-detail relationship the error "General SQL error: violation of FOREIGN KEY constraint . . ." error messages appear when I try to simultaneously post records in the master and detail table.

### Solution:

The VCL code posts the records to the detail table first, then posts the records to the master table.

This is done for local tables (dBASE, Paradox, and ASCII), ODBC data sources, InterBase, Oracle, and other supported RDBMS servers. In posting the details records first, since the master record is not yet in the table, an error is generated on the server and passed to the BDE. In case of local tables the error is generated in the BDE.

One easy way of overcoming the exception is to do the following:

- In the BeforeEdit event of the detail TTable or TQuery object place the following lines of code:

```
// If using TQuery object replace "TTable" with "TQuery"

if ((DataSet as TTable).MasterSource.State = dsInsert) then
    (TTable(DataSet).MasterSource as TTable).Post;
```

What this will do is that when record data is typed in on the detail table, the detail table will switch its state into dsInsert mode. The BeforeInsert event will fire off the above code that will place the new master record in the master table. If the new record in the detail table is aborted and the new record remains in the master table. What will happen in the application is that the new master is still added first (no change here), the only difference is that the new master and

detail records are not added at the click of a "Post" button or other such triggering UI component.

Two other alternatives that are more difficult to implement are suggested below:

- Remove the foreign key constraint and require that the client applications check for the key in the master table.
- Do not use the MasterSource and MasterFields properties in the TTable and TQuery objects and manage the master-detail relationship in the application code.

## Article #25223: Converting Data in Paradox Tables to InterBase Using Delphi

### Problem:

I would like to transfer data from Paradox tables to InterBase. I do not want to use SQL to perform their conversion from Paradox to InterBase. What are my options?

### Solution:

One option is to use database desktop's Tools| Utilities | Copy menu choices to convert the Paradox table to InterBase.

Another option is to use the Data Pump.

A 3rd option is to export the table into ASCII and use SQL for the conversion manually. Note that this option will not bring in blob fields.

Note: While these steps have been written with Paradox and InterBase tables in mind, they will work for any database.

Last Modified: 02-OCT-00

## Article #25238: How to retrieve an InterBase Blob in Delphi using SaveToFile?

### Problem:

This is an example of how to retrieve an InterBase Blob in Delphi.

### Note:

While this example was designed specifically for Interbase, it can easily be made to apply to any database.

### Solution:

IB V4.x

Delphi 3.0

There are several ways of retrieving InterBase Blob data within Delphi.

This example uses the SaveToFile method.

- \* Put TDatabase, TQuery, TDataSource and TDBGrid on the form.
- \* set the TDatabase's fields as follow:
  - > Alias name to the BDE Alias.
  - > DatabaseName to something you wish.
  - > Connected to true
- \* Set the TQuery fields as follow:
  - > SQL to the sql statement to be executed, ie select \* from table1
  - > DatabaseName to the same name you've named in the previous step.
- \* Set the TDataSource field DataSet to the name of the Tquery component. Default is query1.
- \* Set the TDBGrid field DataSource to the name of the TDataSource component. Default is Datasource1.
- \* Go back to TQuery component and double click.
- \* Right click on the blank space on the windows said "form1.query". And choose add fields.
- \* Select all the fields in the list and added.
- \* Drop a TButton on the form.
- \* Double click on the Tbutton.
- \* Add the following lines between begin and end;

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
querylimage.savetofile('c:testimage.jpg');
end;
```

Note: image is the field name defined as blob.  
And c:testimage.jpg is where the location of the  
image file to be created.

- \* Save the project/form/unit. and Run.
- \* Click on the Button will retrieve a blob entry and create file  
image.jpg.

Last Modified: 02-OCT-00

## Article #25249: Calling an IB stored procedure using TStoredProc

### Problem:

Looking for an example of how to call an InterBase stored procedure using Delphi's TStoredProc component.

### Solution:

The information in this article applies to:

- \* InterBase v4.x
- \* InterBase v5.x
- \* Delphi 1.x, 2.x, 3.x, 4.x

Here is an example of how to call an InterBase stored procedure using Delphi's TStoredProc component.

The stored procedure retrieves and returns the next value from a generator. You must create this stored procedure and generator in the database.

### Creating the generator:

```
=====
create generator cust_no_gen;
```

### Here is the InterBase Stored procedure:

```
=====
create procedure procl returns(e_no integer)
as begin
    e_no=gen_id(cust_no_gen,1);
end
```

-----  
-----  

### Here are the steps to accomplish the task in Delphi:

- \* Put TDatabase, TStoredProc, TButton, TLabel components on the form.
- \* Set the following properties for TDatabase component:
  - > AliasName to the BDE alias pointing to the database created
  - > Fill in DatabaseName to be used by other database components

> Connected to True

\* Set the following properties for TStoredProc component:

- > Databasename to the name you set for your TDatabase component
- > StoredProcName to the name of the stored procedure in the database (You can select from drop down list)

\* Double click on the TButton component and add the following code in between begin and end.

```
storedproc1.execproc;  
labell1.caption:=storedproc1.parambyname('e_no').asstring;
```

The result would look like this:

=====

```
procedure TForm1.Button2Click(Sender: TObject);  
begin  
storedproc1.execproc;  
labell1.caption:=storedproc1.parambyname('e_no').asstring;  
end;  
end.
```

- \* Save the project/form/unit and Run.
- \* Click on the Button and the next generated number will be displayed.

Some benefits of getting the gen id first before inserting it:

=====

- \* The next generated number will be visible, so it is known exactly what's inserted.
- \* Using trigger to call the generator in Delphi often results in error "Record Key Deleted". Calling the generator using TstoredProc is a workaround for this error.

Last Modified: 02-OCT-00

## Article #25276: Vendor Initialization Failed error when trying to start InterBase application

### Problem:

When an application tries to start it gets the error:

```
Vendor Initialization Failed
Idapi Service Library
```

And complains that it cannot find gds32.dll

### Solution:

Things to check are:

1) check Registry for InterBase entries:

```
HKEY_LOCAL_MACHINESOFTWAREBorlandInterBaseCurrentVersion
```

2) Make sure gds32.dll is in the propert location (It should be in the windowssystem

```
directory for win95 and the winntsystem32 directory for NT)
```

3) Make sure that the gds32.dll is the correct version for the installed kit.

The registry entries for InterBase will tell you the installed version. Make

sure that the gds32.dll has the same version. In win95 and NT4.0 you can

right mouse click on the gds32.dll file and select the properties menu option.

This will bring up a dialog which will tell you the version of the dll.

4) Make sure that the file msvcrt40.dll exists in the system directory. This file

is required for InterBase to operate. This file is installed by the operating

system on NT4.0, but not with NT 3.51 or win95. The InterBase installation

will install this file on these operating systems.

BDE specific suggestions:

-----

- 1) connect with wisql to see if InterBase is setup properly. If the wisql connection is successful that would suggest that the BDE is improperly configured.
  
- 2) Make sure that the database and InterBase files reside on local drives. InterBase will not operate when either the InterBase files or the database file reside on a mapped drive.

## Article #25287: SQL Monitor

Problem:

What is SQL Monitor?

Solution:

SQL monitor is one of the tools shipped the Enterprise versions of C++ Builder and Delphi.

SQL monitor is used to display and debug the information sent through the

BDE. It allows you see what is actually happening behind the scenes and make sure that your BDE applications are being efficient.

If installed in the default location, SQL Monitor will be located in the (bin) directory of the Borland tool.

Last Modified: 11-OCT-00

## Article #25294: Insufficient memory to complete operation

### Problem:

Why am I getting the message insufficient memory to complete operation?

### Solution:

You may have hit one of the BDE fixed, but configurable, memory limitations.

Use the BDE Administrator (BDEADMIN.EXE) to increase MEMSIZE and SHAREDMEMSIZE settings.

You may also wish to re-evaluate the application hitting this limitation because it is likely that the application is a major resource hit on the machine.

Not using auto-create forms and opening tables and queries as needed can free up some of these resources.

Last Modified: 12-OCT-00

## Article #25337: When installing BDE based products they overwrite IB v5 gds32.dll with v4.2.1 dl

### Problem:

If you have installed and are running InterBase version 5.0 on Windows NT/95 and then install a BDE based product will over write the IB v5 gds32.dll with the IB v4.2.1 gds32.dll.

### Solution:

Until the BDE changes their installation programs to locate our software in its new registry location this will continue to happen.

### Default Registry Entries:

#### v4.21:

```
HKEY_LOCAL_MACHINE
  SOFTWARE
    Borland
      InterBase
```

#### v5.00:

```
HKEY_LOCAL_MACHINE
  SOFTWARE
    InterBase Corp
      InterBase
```

To avoid this problem you must:

- a) Safely shut down the InterBase server.
- b) Rename the gds32.dll to gds32.500 (or something you like)
- c) Install the BDE based product
- d) Rename the gds32.dll to gds32.421 (or something you like)
- e) Rename gds32.500 to gds32.dll
- f) Restart the InterBase server.

## Article #25360: Setting the BDE DRIVER FLAGS parameter for individual aliases

### Problem:

How do I set the BDE DRIVER FLAGS parameter to different values for different aliases?

I have several BDE aliases defined and I want the DRIVER FLAGS parameter to be set differently for each of the BDE aliases.

### Solution:

There is NO way to set the DRIVER FLAGS parameter for individual BDE aliases.

The only way to set it is for the InterBase SQL Links driver. This change affects ALL BDE aliases created using this driver.

Last Modified: 18-OCT-00

## Article #25364: How to insert an InterBase BLOB in Delphi using LoadFromFile?

### Problem:

There is no example of how to insert an InterBase Blob in Delphi.

### Solution:

The information in this article applies to:

- \* InterBase v4.x
- \* InterBase v5.x
- \* Delphi all releases thru 4.x

This is one way of inserting BLOB in Delphi. There are several ways to accomplish this task. This example is just one way of doing it. This example is using the LoadFromFile method.

Create a table in InterBase with a field that can store non-text Blobs:

```
create table table1 (images blob sub_type 0);
```

- 
- \* Put TQuery and a Button on the form.
  - \* Set the TQuery's properties:
    - > Alias name to the BDE Alias pointing to the database.
    - > SQL to the sql statement to be executed,  
i.e. select images from table1
    - > RequestLive to True.
    - > Active to true.
  - \* Go back to TQuery component and double click which will bring up a window titled "form1.query".
  - \* Right click on the blank space of form1.query and choose add fields.
  - \* Select images in the list and add.
  - \* Double click on the TButton.
  - \* Add the following lines

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
  query1.append;  
  query1images.loadfromfile('c:testimage.bmp');  
  query1.post;  
end;
```

Note: images is the field name defined as blob.

And c:testimage.bmp is where the location of the image file to be inserted.

- \* Save the project/form/unit and Run.
- \* Click on the Button will insert a blob entry.

To verify the Blob is inserted:

- \* Drop a Tdatasource and TDBImage component on the form.
- \* Set the properties of Tdatasource:
  - > Dataset to "query1"
- \* Set the properties of TDBImage:
  - >Datasource to "datasource1"
  - >Datafield to images
- \* Save the project and run. You should see the images displayed.

Note: By default, DBImage will only display bitmaps.

## **Article #25382: Error installing from InterBase: String variable is not large enough for strin**

### Problem:

Trying to install InterBase from various products may result in the error " String variable is not large enough for string. Check the string declarations. Error: 401"

In most cases, this is a benign error. You can just click the OK box and continue. This error usually occurs when you have a very long path statement. In most cases, the only way to make it not occur is to shorten your path statement.

In some other conditions, checking the PATH value for the registry key: HK\_Current\_userenvironment and if it's a hex value delete it or convert it to a character string may resolve the problem as well.

Last Modified: 01-NOV-00

## Article #25392: Getting 'Error creating cursor handle' when using TStoredProc

### Problem:

When using TStoredProc and try to execute an InterBase stored procedure the error 'Error creating cursor handle' is generated.

### Solution:

This error is the message that accompanies an ENoResultSet exception thrown by the BDE. This error occurs, because the application tried to execute an SQL statement and retrieve a result set that did not exist.

When using TStoredProcs with InterBase execute procedures the application must use the TStoredProc.ExecProc method instead of the TStoredProc.Open method (or setting active property to true).

(See Data Definition Guide for more information on execute stored procedures)

Last Modified: 27-OCT-00

## Article #25433: Using BLOBs in Stored Procedures through the BDE

Problem:

Example using Blobs in Stored Procedures, then accessing them via BDE and Delphi

Solution:

Test case done with

IB V5.0  
Delphi 3.0  
BDE 4.51

```
----- IB CODE -----  
  
/* start procedure */  
set term ^^;  
  
create procedure t2_get_call_details_proc(call_no integer)  
returns (customer_no integer,  
        phone_no varchar(20),  
        ib_version char(20),  
        os_version varchar(20),  
        problem blob sub_type text segment size 80,  
        comment blob sub_type text segment size 100)  
as  
begin  
  
begin  
  for select customer_no,  
            phone_no,  
            gds_version,  
            operating_sys_version,  
            problem_description,  
            comment  
from call_logs  
where call_log_no = :call_no  
into :customer_no,  
      :phone_no,  
      :ib_version,  
      :os_version,  
      :problem,
```

```
      :comment
```

```
do  
suspend;  
end
```

```
end^^  
commit^^
```

```
set term ;^^  
/* end procedure */
```

```
commit;
```

```
----- DELPHI CODE -----
```

```
procedure TfrmMain.cmdGetDetailsClick(Sender: TObject);  
begin  
  // Close details  
  begin  
    qyGetDataCallLog_2.Close;  
    qyGetDataCallLog_2.UnPrepare;  
  end;  
  // Get Call Details  
  begin  
    db1.StartTransaction;  
    qyGetDataCallLog_2.SQL.Clear;  
    qyGetDataCallLog_2.SQL.Add  
      ('select * from t2_get_call_details_proc(:call_no);');  
    qyGetDataCallLog_2.Prepare;  
    qyGetDataCallLog_2.Params[0].AsInteger := StrToInt(edtCall_No.  
Text);  
    qyGetDataCallLog_2.Open;  
    db1.Commit;  
  end;  
end;
```

Last Modified: 18-OCT-00

## **Article #25435: Can a Delphi Application Connect to an InterBase Database on Any Platform?**

### Problem:

I want to develop a Delphi application using InterBase as a backend. I need it to be able to connect to an InterBase database on whatever operating system it happens to reside.

### Solution:

The information in this article applies to:

- \* All InterBase Versions

Yes, this is possible with a Delphi application using either the BDE/SQL Links or ODBC. Depending on how transportable you want the application to be, you may need to programmatically make it possible for the user to set up their own datasources.

The InterBase client library will connect to an InterBase database running on any supported platform. Because the BDE/SQLLinks driver uses the InterBase client, Delphi applications are able to connect to InterBase databases on any of the supported platforms.

Last Modified: 26-OCT-00

## Article #25493: How to connect to an InterBase database using the BDE API

### Problem:

Sometimes it is necessary to remove the VCL layer of code in a Delphi or C++ Builder application in order to track down a connection problem. To do this requires writing to the BDE API.

### Solution:

The following example below are some excerpts from a Delphi application that uses the BDE API to directly connect to an InterBase database. In order to run this example add the following units to the uses clause:

```
DB, DBTables, BDE
```

In the example the OnCreate event of the form is used to initialize the BDE engine, and to create a BDE alias in memory. The OnClose event shuts down the BDE engine. The OnClick event of a pushbutton is used to perform the connection to the database. If an error is returned by the BDE API function then the Check() function will generate an EDBEngineError exception and the appropriate error dialog will be shown.

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  DbiInit(nil);
  Check(DbiAddAlias(nil,
                   'TempIB',           // This is the name of the
in-memory alias
                   'INTRBASE',
                   'SERVER NAME: myserver:/usr/interbase/examples.v4/
employee.gdb; USER NAME: SYSDBA; PASSWORD: masterkey',
                   True));
end;
```

// NOTE: The formatting of the SERVER NAME indicates what protocol to use:

```
//
```

```
// Local connection:
// TCP/IP connection:      :
// NetBEUI connection:    ///  
// SPX connection:        @
```

```
procedure TForm1.FormClose(Sender: TObject; var Action: TCloseAction);  
begin  
    Check(DbiExit);  
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Check(DbiOpenDatabase('TempIB',  
                           'INTRBASE',  
                           dbiREADWRITE,  
                           dbiOPENSHARED,  
                           'masterkey',  
                           0,  
                           nil,  
                           nil,  
                           hDb));  
end;
```

```
// The memory variable hDb is defined as follows:      hDb: hDBIDb;
```

```
end.
```

Last Modified: 26-OCT-00

## Article #25594: Is it possible to connect to InterBase from a Delphi app without using the BDE?

### Problem:

For performance reasons, some customers would like to avoid using the BDE

or ODBC to connect to InterBase from thier Delphi or C++Builder apps. Is this possible?

### Solution:

Yes, it is possible to program directly to the InterBase API using C or C++

(API = Application Program Interface) Please refer to the Programmer's Guide in the InterBase documentation.

There are also two third-party libraries available for download from our website, that were designed for this purpose.

Greg Deatz' FreeIBComponents ( <http://www.interbase.com/download/components.html> )

is a Delphi add-on which directly accesses the InterBase API.

With Jason Wharton's IB Objects ( <http://www.ibobjects.com/> )

"you can eliminate both the BDE and ODBC from your applications. Access will be direct to the InterBase API."

As of Delphi 5 and C++ Builder 5 you can also you InterBase Express (IBX).

## Article #25617: Performance techniques when using BDE and Delphi TTables with InterBase

### Problem:

With the default BDE configuration of the native InterBase driver, when the Delphi component TTable is used in order to fetch a set of rows, an InterBase cursor is setup in order to track the specific row that is being referenced in the dataset. When any modification to the rows is made (insert/update/delete), the Interbase API function `isc_commit_transaction()` is called resulting in a commit of the data and a loss of cursor.

The closing of the InterBase cursor triggers a Delphi "fetchall" which reloads all of the data accross the connection.

Other actions against the selected data, such as `locatelist`, `recordcount`, and using filters also result in a "fetchall" command in the default environment (driver flags set to NULL or 0).

With large data sets, this can be a very slow and network intensive operation. Multiple users doing this against the same datasets simultaneously can easily slow down the server significantly.

### Solution:

There are several possibilities for reducing the impact of using TTable components with large data sets.

Some of those suggested are :

1. In the BDE Configuration utility, you can set the `MaxRows` parameter to a restrictive value so that only the specified number of rows will be fetched.

This is, in general a good idea when it is possible for the user, in advance, to narrow down the search so that it is very likely that the specified number of rows will contain the desired information.

To make this user friendly, it may be necessary to code the search such that the next set of rows after the current set

can be easily obtained (such as a "Show Next" button).

2. It is possible to modify the InterBase driver flags on a global level to change the driver options for record locking and cursor retention. Since these flags are global to an application, care is required in order to ensure correct behavior.

If the BDE -> Configuration -> Drivers -> Native -> Intrbase ->drivers

flag is set to 4096 or 4608, the InterBase API call upon commit will

typically be changed from `isc_commit_transaction` to `isc_commit_retaining`. This will not close the InterBase cursor, hence avoiding the resultant "fetchall".

Note: the `TDatabase.commit` method ignores this flag and issues an `isc_commit_transaction` which will close the cursor and trigger the "fetchall".

Sideeffects:

=====

Setting the driver flag to 4096

-----

This may lead to potential deadlocks of multiple users attempt to modify the same row at the same time.

If it is likely that multiple users will attempt to modify the same rows frequently, this solution is not workable.

Also, when the user is done with the information, a hard commit should be done to free up the locks established on the table.

Setting the driver flag to 4608

-----

Any changes to data made by other users during the time this transaction is open will not be available since the transaction is scoped as read-committed at the time of the original request to fetch this information.

If it is important for one user to see changes made by another user in a timely manner, this solution is not suitable.

When a user is done with modifications, a hard commit will allow other changes to the database to be viewed.

See article in InterCom Vol 1 Number 2 (about handling deadlocks) for more information on possible driver flags.

Last Modified: 26-OCT-00

## **Article #25619: Do I need Local InterBase on the client machines along with my BDE application?**

### Problem:

Do I need to install Local Interbase on the client machines, or does InstallShield install the necessary parts on the client machine to allow them to use the local database?

### Solution:

Depending which version of Delphi you are using (the Professional or the Enterprise version) here is what the InstallShield version of both is able to do in terms of distributing and installing InterBase along with applications:

#### Professional:

InstallShield Express distributes applications, the BDE and a local version of the InterBase SQL Link driver (remote connections are not permitted). It does not distribute any of the other SQL Link drivers (DLL's). As such the BDE engine can only access ASCII, Paradox, dBASE and local InterBase files directly. Contact Inprise Corp. for information on obtaining the remote InterBase SQL Links driver. The BDE can also go through ODBC drivers, but InstallShield Express does not automatically distribute ODBC drivers.

#### Client/Server:

In the Enterprise version of Delphi and C++ Builder the InstallShield Express has all of the capabilities that are present in the Professional version plus some added capabilities. The SQL Link drivers can optionally be bundled in with the BDE, this includes the remote SQL Link driver for InterBase. When the InterBase SQL Link driver is included in the distributable install, the InterBase Client software is automatically bundled in as part of the SQL Link.

The InterBase Client software is freely distributable with no

royalties required and no copy limitations.

To distribute the Local InterBase Server requires obtaining the InterBase Deployment Kit which will license the purchaser to be able to distribute the Local InterBase Server to up to 20 seats or 100 seats depending on the Deployment kit that is purchased.

Last Modified: 25-OCT-00

## Article #25620: An Introduction to the TBatchMove Component in Delphi and C++ Builder

### Problem:

What is the TBatchMove component and how do I use it with InterBase (or any other database)?

### Solution:

An Introduction to the TBatchMove component

=====

#### 1. What is it?

TBatchMove is a VCL component that lets you perform operations on groups of records in a table.

The operations are named with intuitive names that basically tell what they do.

Listed below are the operations or "modes" that the TBatchMove component supports.

- batAppend => appends all records from the source table to the end of the destination table.

- batAppendUpdate => Appends all records from the source table to the end of the destination

table and updates

those records with the same primary index in the

destination table with

the same records from the source table.

- batCopy => Copies a table and its records to a new table

- batDelete => Delete all records in the destination table that also appear in the source table.

- batUpdate => Update existing records in the destination table with their counterparts

in the source table.

#### 2. How do I use it?

Listed below are steps to setup and run a TBatchMove component to

upsized Paradox data to InterBase.

- a. Put two TTable objects on the form, one for source and one for destination.
  1. Click on "Data Access" tab.
  2. Click on table icon.
  3. Click on form.
  4. Press  to go to the Object Inspector.
  5. Define the Database property for table1 to be the BDE alias that points to the directory where Paradox tables are located. In this case, we are using the DBDEMOS alias that is installed by default when you do a full install of Delphi 3.
  6. Define the TableName property in object inspector for table1 to be the Paradox table name, In this example, the table name will be the "orders" sample table that comes with Delphi. Since we have already specified the location of the tables, you can easily fill in the TableName property setting by selecting the table from the picklist of the TableName property.
  7. Repeat steps 2.a.1 - 2.a.4 for table2
  8. Define the database on table2 to be an alias that points to the InterBase database, in this case employee.gdb, by selecting the BDE alias that points to the employee database.
  9. Define TableName property for table2 to be the table name you want created in InterBase. For simplicity, call it "orders" as well.
  10. Configure the TBatchMove component
    - a. Put the TBatchMove component on the form.
      1. Click on the Mode property's edit box.
      2. Click on the BatchMove icon.

3. Click on the form.
- b. Define the source and destination for TBatchMove
  1. Hit `F4` to go to the object inspector.
  2. Set the Source property of TBatchMove to be table1.
  3. Set the Destination property of TBatchMove to be table2.
- d. Specify the mode for TBatchMove
  1. Click on the Mode property's edit box.
  2. Click on the down arrow that appears to get a picklist of modes to choose from.
  3. Click on "batCopy" to select it from the list.
- d. Activate TBatchMove
  1. Right click on TBatchMove component
  2. Click on "Execute" on the pop-up menu that appears.
- e. What happens when TBatchMove fails?

You can tell TBatchMove to document what happened when you run a batch move operation by setting the following properties. They tell Delphi to create a local Paradox table containing records that were not successfully part of the batchmove operation.

ChangedTablename => Records that were modified by the batch move operation

KeyvioltableName => Records that could not be added because they violated a uniqueness constraint.

ProblemTableName => Records that could not be added for one reason or another.

## Article #25621: How to create an About Box in Delphi or C++ Builder

Problem:

What are the steps to create an about box?

Solution:

Go to the Main Menu

Click on File | New Form

Go to the Object Inspector

Click on the Name property & Type: AboutBox

Click on the Caption property & Type: About This Program

Click on the BorderStyle property and select bsDialog

ADD 3 TEXT LABELS

Click on the Standard Tab

\*PROGRAM NAME

Click on the Label (giant A in your component palette) and place it on your form.

Go to the Object Inspector

Click on the Caption property & Type: The name of your program

\*VERSION

Click on the Label (giant A in your component palette) and place it on your form.

Go to the Object Inspector

Click on the Caption property & Type: The Version of your program

\*COPYRIGHT STATEMENT

Click on the Label (giant A in your component palette) and place it on your form.

Go to the Object Inspector

Click on the Caption property & Type: Your copyright statement

(To type the ? hold down the ALT KEY and type: 0169 and release the ALT KEY)

CREATE ICON

Click on the Additional Tab in the Component Palette

Click on the Image Button (Light Blue Horizon picture) and place it on the left side of your form

(You should see an empty square on your

form at this point)

Go to Object Inspector

Click on AutoSize property and change it to True

Click on: Picture property

Double click: the Value column.- The Picture Editor dialog box is displayed

Click: Load button

Navigate to: Common Files | Borland Shared | Images | Icons & select an icon

Click: OK

#### \*OK BUTTON

Click on the Additional Tab in the Component Palette

Click on the OK Button & place near the bottom of your form

Go to Object Inspector

Click on Kind - Change to bkok

#### \*BEVEL FRAME

Click on the Additional Tab in the Component Palette

Click on the Bevel Button and carefully move to the form and drag it around the 3 text lines & release

Go to Object Inspector

Click on the Shape property and change to bsFrame. You now have a 3D frame.

## Article #25625: How to Set Up a C++ Builder or Delphi Form to View InterBase Data

### Problem:

This document gives step by step instructions on how to view data in an InterBase table from a C++ Builder form.

### Solution:

1. Make sure SQL Link for InterBase is installed on your computer.
2. Set up a BDE alias to point to InterBase database.
  - a. Bring up BDE Administrator.
  - b. Select Object | New from the menu.
  - c. Select "INTRBASE" from the "DataBase Driver name" list.
  - d. Enter a name for the BDE alias.
  - e. Enter the path to the database in space next to "SERVER NAME"
  - f. Enter your InterBase user name in the "User Name" space.
  - g. Select Object | Apply to save the alias.
  - h. Exit BDE administrator.
2. Start C++ Builder or Delphi
3. Create a new form by selecting File | New | Form from the menu.
4. Place a Ttable object on the form.
  - a. Click on the "Data Access" tab on the component palette.
  - b. Click on the Ttable object.
  - c. Click on the form to place the Ttable object on the form.
5. Define the Ttable object to be a table in the InterBase database.
  - a. Hit `F12` to bring up the Object Inspector.
  - b. Click on the "DatabaseName" property.
  - c. Click on down arrow that appears.
  - d. Select the database alias you created in step 1.
  - e. Click on TableName property.
  - f. Select the table name from your database's list of tables.

6. Put a DataSource on the form.
  - a. Click on Data Access Tab.
  - b. Click on DataSource button.
  - c. Click on the form to place the DataSource on the form.
  - d. Hit `Enter` to get to the Object Inspector.
  - e. Click on the space next to the "DataSet" property.
  - f. Select the Ttable object created earlier from the drop down list.
  
7. Put a DBGrid on the form.
  - a. Click on "Data Controls" tab on component palette.
  - b. Click on DBGrid object.
  - c. Click on form to place the dbGrid on the form.
  - d. Hit `Enter` to get to the Object Inspector.
  - e. Click on DataSource property.
  - f. Select DataSource created earlier.
  
8. Activate the Ttable object.
  - a. Click on Ttable object.
  - b. Hit `Enter` to get to object Inspector.
  - c. Click next to "Active" property.
  - d. Select "True" from drop down list.
  
9. Press `F5` to compile and run the form.

Last Modified: 24-OCT-00

## Article #25636: Using Form Wizard to Quickly Create a Delphi Form

### Problem:

This document will show how to quickly and easily make a Delphi form that is bound to a table.

### Solution:

The steps below demonstrate how to use the Form Wizard to quickly create a form that is bound to a table in a Delphi application. It is assumed that the user has done a full install of Delphi.

1. Start Delphi.
2. Select File | New Application from the menu.
3. Select Database | Form Wizard from the menu.
4. You will now see a form with Radio buttons for selecting Form Options and DataSet options.
5. For this example, we will use the defaults of :
  - Form Options set to "Create a simple form.
  - Data Options set to "Create a form using Ttable objects"
6. Hit the button.
7. Click on the white area under "Drive or Alias Name" heading. This will bring up a list of drives and aliases to choose from.
8. Select "DBDemos" as the alias you want to work with.
9. Select the "customer" table by double clicking on it.
10. Click on the ">>" button to include all fields from the customer table in the form.
11. Click on button.
12. Click on radio button next to "In a Grid"

13. Click on
14. Click on "Form and Data Module"
15. Click on "Finish" button.
16. See the form come up.
17. Hit to see data in form

Last Modified: 24-OCT-00

## Article #25639: Connecting via ODBC using Delphi or C++ Builder

Problem:

This document will cover the followings:

- \* Setting up an ODBC data source
- \* Connecting from Delphi or C++ Builder using the ODBC data source
- \* Displaying SQL Monitor log for the ODBC connection

Solution:

Setting up an ODBC data source

In order to make a connection from 3rd party products using ODBC, an ODBC data source is needed. A data source stores connection information

such as user name, password, location of database&etc. This is how to set up a data source:

? Start up ODBC Administrator. ODBC Administrator can be started by:

- 1) Going to Control Panel and double click on 32bit ODBC. OR
- 2) Starting the utility called "32bit ODBC Administrator" if you have the ODBC SDK installed.

? Stay at the User Data Source tab and click on Add. This will bring up another window titled "Create New Data Source".

? Pick the ODBC driver that to be used. Pick the InterBase driver which is called "InterBase 5.x driver by Visigenic (\*.gdb)" and then click on Finish.

This will bring up a new window with the title "InterBase ODBC Configuration".

? Fill in the blank fields in this window:

- 1) Data Source Name: Make up a name for your data source.
- 2) Description: This is the description of the data source. It's not required.
- 3) Network Protocol: Choose the protocol from the drop down list.
- 4) Database: Fill in the physical full path to the database including the database name to server.
- 5) Server: Fill in the server name. If you choose the protocol

"local", this will default to the local server.

6) Username: Fill in the database user name.

7) Password: Fill in the password corresponding to the above user name.

Optional for the new InterSolv ODBC driver for InterBase:

8) Go to the Advanced tab and fill in the CharacterSet and Roles.

? Clicking the OK button will bring back to the main form. You should see

the newly added user data source there.

Note: A user data source is a data source visible to the user whereas a system data source is visible to the system.

### Connecting from Delphi using the ODBC data source

ODBC connection from Delphi is very similar to connecting using BDE from Delphi. Here is an example of connecting using the Tquery component.

This example will also display the results of a sql statement.

? Drop a Tquery, a Tdatasource, and a Tdbgrid component on a Delphi form.

? Set the following properties for the Tquery component:

1) DatabaseName: Pick from the list the data source name you just created in

ODBC Administrator.

2) SQL: Input the sql statement to be executed. For example: "select \* from table1".

3) Active: Set to True to connect. And supply user name and password on connection.

? Set the following properties for the Tdatasource component:

1) Data Set: Set to the name of the Tquery component, or "query1" in this case.

? Set the following properties for the TDBGrid component:

1) Data Source: Set to the name of the Tdatasource component, or "data source1"

in this case.

? Now you can see the returned results from select statement in the dbgrid area.

## Displaying SQL Monitor Log for the ODBC connection

This section will display the SQL Monitor Log for ODBC and BDE. It will show the difference of the two logs.

? To turn on the SQL Monitor log: Go to the Database and choose SQL Monitor.

? Make the Tquery's connection to active from above. And you should see a log generated in the SQL Monitor window.

Here is a sample of what it looks like:

```
1      13:57:29  Log started for: Delphi 4
2      13:57:34  SQL Prepare: InterBase InterSolv Driver (*.g -
select * from test_table
3      13:57:34  SQL Execute: InterBase InterSolv Driver (*.g -
select * from test_table
4      13:57:34  SQL Vendor: ODBC - SQLAllocStmt
5      13:57:34  SQL Vendor: ODBC - SQLExecDirect
6      13:57:34  SQL Vendor: ODBC - SQLNumResultCols
7      13:57:34  SQL Vendor: ODBC - SQLDescribeCol
8      13:57:34  SQL Vendor: ODBC - SQLDescribeCol
9      13:57:34  SQL Misc: InterBase InterSolv Driver (*.g - Set
rowset size
10     13:57:34  SQL Vendor: ODBC - SQLBindCol
11     13:57:34  SQL Vendor: ODBC - SQLBindCol
12     13:57:34  SQL Stmt: InterBase InterSolv Driver (*.g - Fetch
13     13:57:34  SQL Vendor: ODBC - SQLSetStmtOption
14     13:57:34  SQL Vendor: ODBC - SQLExtendedFetch
15     13:57:34  SQL Data Out: InterBase InterSolv Driver (*.g -
Column = 1, Name = TESTING, Type = fldTIMESTAMP, Precision = 19,
Scale = 0, Data = 3/31/1998 10:42:52:0
16     13:57:34  SQL Data Out: InterBase InterSolv Driver (*.g -
Column = 2, Name = TESTDATE, Type = fldTIMESTAMP, Precision = 19,
Scale = 0, Data = 3/30/1998 14:4:39:0
17     13:57:34  SQL Stmt: InterBase InterSolv Driver (*.g - Fetch
18     13:57:34  SQL Vendor: ODBC - SQLSetStmtOption
19     13:57:34  SQL Vendor: ODBC - SQLExtendedFetch
```

```
20      13:57:34  SQL Stmt: InterBase InterSolv Driver (*.g - EOF
21      13:57:34  SQL Stmt: InterBase InterSolv Driver (*.g - Reset
22      13:57:34  SQL Vendor: ODBC - SQLFreeStmt
```

Here is a sample SQL monitor log using the BDE for the same operation:

```
1      14:06:45  SQL Prepare: INTRBASE - select * from test_table
2      14:06:45  SQL Vendor: INTRBASE - isc_dsqli_allocate_statement
3      14:06:45  SQL Vendor: INTRBASE - isc_start_transaction
4      14:06:45  SQL Vendor: INTRBASE - isc_dsqli_prepare
5      14:06:45  SQL Vendor: INTRBASE - isc_dsqli_sql_info
6      14:06:45  SQL Vendor: INTRBASE - isc_vax_integer
7      14:06:45  SQL Transact: INTRBASE - XACT (UNKNOWN)
8      14:06:45  SQL Vendor: INTRBASE - isc_commit_retaining
9      14:06:45  SQL Execute: INTRBASE - select * from test_table
10     14:06:45  SQL Vendor: INTRBASE - isc_dsqli_execute
11     14:06:45  SQL Stmt: INTRBASE - Fetch
12     14:06:45  SQL Vendor: INTRBASE - isc_dsqli_fetch
13     14:06:45  SQL Data Out: INTRBASE - Column = 1, Name =
TESTING, Type = fldTIMESTAMP, Precision = 1, Scale = 0, Data =
3/31/1998 10:42:52:0
14     14:06:45  SQL Data Out: INTRBASE - Column = 2, Name =
TESTDATE, Type = fldTIMESTAMP, Precision = 1, Scale = 0, Data =
3/30/1998 14:4:39:0
15     14:06:45  SQL Stmt: INTRBASE - Fetch
16     14:06:45  SQL Vendor: INTRBASE - isc_dsqli_fetch
17     14:06:45  SQL Stmt: INTRBASE - EOF
18     14:06:45  SQL Stmt: INTRBASE - Reset
19     14:06:45  SQL Vendor: INTRBASE - isc_dsqli_free_statement
20     14:06:45  SQL Transact: INTRBASE - XACT Commit
21     14:06:45  SQL Vendor: INTRBASE - isc_commit_transaction
```

Note: What's after SQL Vendor is the layer beyond Delphi. For ODBC, it's ODBC and for BDE is the "INTRBASE". Also pay special attention to the function follows the name. ODBC uses ODBC function calls and where as BDE uses InterBase api function calls.

Last Modified: 27-OCT-00

## Article #25644: What are Delphi and C++ Builder Action Lists and how do I use them?

Problem:

What are Delphi and C++ Builder Action Lists and how do I use them?

Solution:

What are Action Lists?

Action lists are a way of linking controls that perform similar tasks.

Why use Action Lists?

This is a time saver. Once controls are linked, changes made to an action list item will propagate to all components tied to that action item.

Action List Demo Objective:

To make the File | New command use an action list item

Start	New application
Add	MainMenu component to the form
Double click	MainMenu component - To import File Menu template
Right click	Form1.MainMenu
Select	Insert from Template
Select	File Menu
Click	OK
Add	ActionList component to the form
Double click	ActionList component This will display the Action
List editor	
Click	New Action - This action will be responsible for
the New File	
Click	Object Inspector
Click Name	Change to: actNewFile
Click Caption	Change to: &New
Click Shortcut	Change to: CTRL+N
Double click	MainMenu component
Click	Object Inspector
Click Action	Change to: actNewFile You can also use the down
arrow to select this	
Go to	Action List Editor

Double click      actNewFile  
Click             Object Inspector  
Click             Events tab    This will display 3 properties:  
OnExecute, OnHint, & OnUpdate  
Double click      OnExecute  
Enter             ShowMessage( Create New File );  
Save All

If we ran the application now, selecting File | New would trigger the message Create New File

The benefit of saving time occurs when you have multiple components.

Add             Button component to the form  
Click             Properties tab of the Object Inspector  
Click Action     Change to: actNewFile - You can also use the down  
arrow to select this  
Add             CheckBox component to the form  
Click             Object Inspector  
Click Action     Change to: actNewFile

Doing the above will now tie the Button and CheckBox component properties to that action

Run the application

Change one line of code, save all, and then run the application again.

That change will propagate to all components in the action list we created.

Last Modified: 24-OCT-00

## Article #25645: A possible explanation for 'Name not Unique in this context' errors

### Problem:

My app was working fine, when I went to add some fields into one of my tables. When I try to add the fields using the field editor, I get an error message stating 'Name is not unique in this context'.

What happened?

### Solution:

The information in this document is relevant to all versions of C++Builder and Delphi.

The error, 'Name is not unique in this context' means there's already a component (field or otherwise) on the form with the same name.

One instance where this error can occur is if you have a form that is descended from another form.

If you create the field on the parent form, then try to explicitly add the field to the child form as well, rather than inheriting it, this error can occur.

source: list serve

## Article #25647: Using Variables & For Loops in Delphi

### Problem:

Using Variables & For Loops in Delphi to cause a piece of code to get executed a certain number of consecutive iterations based on certain criteria.

### Solution:

The information in this article applies to:

\* All versions of Delphi

1. From the Standard tab of the Component Palette drop a Button & a Memo Field on the Form.
2. Enlarge the Memo Field vertically by dragging the top & bottom edges.
3. Double click the Button to open the Event Handler.
4. Enter the code as shown in the procedure body:

```
procedure TForm1.Button1Click(Sender: TObject); // this line is pre-
coded in the event handler
```

```
var {this declares a section of code where you can define variables}
I : Integer; {define 'I' as an Integer variable}
```

```
Begin // This line is pre-coded in the event handler
```

```
Mem1.Lines.Clear; {clears characters previously displayed in memo
field}
```

```
For I := 0 to 5 do {incremental 'For Loop'}
  Mem1.Lines.Add('This is iteration ' + IntToStr(I)); {display
string}
{'IntToStr' converts the increment variable from an integer to a
string so that it can be displayed}
```

```
Mem1.Lines.Add(' '); {display blank line}
```

```
For I := 5 downto 0 do {decremental 'For Loop'}
  Mem1.Lines.Add('This is iteration ' + IntToStr(I));
```

end;

end.

5. Click the 'Run' button on the Toolbar (or press F9).

Last Modified: 24-OCT-00

## Article #25648: Peep Show Picture Viewer

### Problem:

Creating a graphics viewing application for viewing bitmap, icon, and metafiles (\*.bmp, \*.ico, \*.mtf).

### Solution:

The information in this article applies to:

#### Creating the Main Form

Step 1: Select File|New Application from the File Menu.

Step 2: For the main form, change the Name property to 'MainForm'.

Step 3: Change the Caption property to 'Peep Show'.

Step 4: Change the Height to 450 and the Width to 575 (or other suitable values for you display resolution).

Step 5: Change the FormStyle to fsMDIForm.

#### Adding a Menu

Step 1: Click the Standard tab of the Component palette and click the MainMenu button.

Step 2: Click on the form to place a MainMenu component on the form.  
(position unimportant doesn't  
show at runtime)

Step 3: Change the Name property to MainMenu.

Step 4: Double-click the MainMenu component to display the Menu Designer.

Step 5: Place your cursor over the Menu Designer and click you right mouse button. Choose Insert  
from Template from the context menu. The Insert  
Template dialog box appears.

Step 6: Chosse MDI Frame Menu and click OK. The menu is displayed in

the Menu Designer.

Step 7: Click the system close box on the Menu Designer to close it.

### Configuring the File|Open and File|Save Dialog Boxes

Step 1: Click the Dialogs tab on the Component palette. Choose an `OpenPictureDialog` component and place it on the form. The `OpenPictureDialog` component's icon can be placed anywhere on the form.

Step 2: Change the Name property of the Open dialog box to `OpenPictureDialog`.

Step 3: Change the title property to `Open a Picture for Viewing`.

Step 4: Add a `SavePictureDialog` component.

Step 5: Change the Name property of the component to `SavePictureDialog` and the Title property to `Save a Picture`.

### Coding the File|Open and File|Save As Menu Items

Step 1: On the main form, choose `File|Open` from the menu. An event handler is created for that menu item and the Code Editor is displayed.

Step 2: Type code so that the event handler looks like this:

```
procedure TmainForm.Open1Click(Sender: TObject);
var
    Child : TChild;
begin
    If OpenPictureDialog.Execute then begin
Child := Tchild.Create(Self);
with Child.Image.Picture do begin
    LoadFromFile(OpenPicturedialog.FileName);
    Child.Clientwidth := Width;
        Child.ClientHeight := Height;
end;
Child.Caption := ExtractFileName(OpenPictureDialog.
FileName);
Child.Show;
```

```
        end;  
    end;
```

Step 3: Press F12 to switch back to the form. Now choose File|Save As from the menu. The File|Save As event handler is displayed.

Step 4: Type code so that the File|Save As event handler looks like this:

```
    procedure TmainForm>SaveAs1Click(Sender: TObject);  
    begin  
        if SavePictureDialog>Execute then  
with ActiveMDIChild as Tchild do  
        Image.Picture.SaveToFile(SavePictureDialog.FileName);  
        end;
```

(Choose File|Save All to save project)

## Coding the Window Menu

Step 1: Switch back to the form by pressing F12. Choose Window|Tile from the form's menu.

Step 2: You need to enter only a single line of code for the event handler: Tile;

Step 3: Switch back to the form and repeat the process for Window|Cascade: Cascade;

Step 4: Repeat the steps for the Window|Arrange All: ArrangeIcons;

## Creating the MDI Child Form

Step 1: Create a new form using the toolbar button or the File menu.

Step 2: Change the Name property to Child. The Caption property can be ignored because you will be setting the dialog box's caption at runtime.

Step 3: Change the FormStyle property to fsMDIChild. This is necessary for the form to be treated as an MDI child window.

Step 4: Click the Additional tab on the Component palette. Click the

Image button and place an  
Image component anywhere on the form.

Step 5: Change the Name property to Image.

Step 6: Change the Stretch property to True.

Step 7: Change the Align property to alClient. The Image component expands to fill the client area of the form.

Step 8: Choose File|Save and save the form's unit as MDIChild.

Step 9: Switch to the Code Editor. Click the PctViewU tab. Now choose File|Use Unit from the main menu, select the MDIChild unit, and click OK.

## Finishing Touches

To prevent the child window from being created at start up do the following:

Step 1: Choose Project|Options from the main menu.

Step 2: If necessary, click the Forms tab. The list of forms to auto-create is displayed.

Step 3: Click the child from and then click the > button. This removes the child from from the auto-create list and puts it in the Available froms list.

To make the close button actually close the window instead of minimizing it (the MS default) do the following:

Step 1: Bring up the child window from int the Form Designer. Be sure the form itself is selected and not the Image component on the form (choose the Child from the Component Selector at the top of the object Inspector, if necessary).

Step 2: Double-click the Value column next to the OnClose event in the Object Inspector. Add a line of code to the event havndler so that it looks

like this:

```
procedure Tchild.FormClose(Sender: TObject; var Action: TCloseAction);  
begin  
    Action := caFree;  
end;
```

The End!

Last Modified: 24-OCT-00

## Article #25665: Handling exceptions in Delphi

This article provides some information on setting up error handling with Delphi.

One of the big advantages of using exceptions is that you do not have to check the result of every function call that you make. Typical C programming involves making a function call (such as `allocmem`) and checking the result to see if the function succeeded or not. More than likely, the function will always work. Having an exception being raised when an error does happen, makes less work for the programmer.

The best way to catch exceptions is by defensive programming. Any code which could possibly raise an exception can be wrapped in one of two blocks: a **try ... except** block or a **try ... finally** block.

Here is an example of using **try ... except**:

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    try  
        // Some code which may raise an exception  
    except  
        on E: EConvertError do  
            begin  
                // Handle only EConvertError, or any derived classes  
            end;  
        on E: Exception do  
            begin  
                // Handle only Exception, or any derived classes  
            end;  
        end;  
end;
```

Once an exception is raised, the exception handler jumps immediately to the nearest **except** (or **finally**) block. Notice how you can pick exactly what exceptions you want to handle. Also, notice that `EConvertError` derives from `Exception`. You must list more specific (derived) exceptions before generic exceptions. Also, if you do not catch the exception (such as, if we had not put **E: Exception** in the handler), then the exception would continue to propagate outside of the **try ... except** block, and be caught else where.

The big difference between a **try ... except** block and a **try ... finally** block is that the **try ... except** block is only executed if an exception was raised, while the **try ... finally** is **always** executed. Because **finally** blocks are always executed, it doesn't make sense to catch specific exceptions with the **on** keyword, so this is not possible in them. **Try ... finally**'s are typically used 3 to 1 times over **try ...**

**except**'s, as handling for an exceptional case it is much rarer than simply doing resource management. Normal resource management with a **try ... finally** block typically looks like this:

```
procedure TForm1.FormCreate(Sender: TObject);  
var  
    Form: TForm1;  
begin  
    Form := TForm1.Create(Self); // Allocate some memory  
    try  
        // Some code which may raise an exception  
        Form.DoSomethingWhichMayRaiseAnException;  
    finally  
        Form.Free; // Always free the memory.  
    end;  
end;
```

The Form will always be freed. One may ask why the line **Form := TForm1.Create(Self);** is not inside the **try ... finally** block. The reason is simple: what if Create raised an exception? Then you would be freeing the Form variable when it was never allocated! Now, the compiler is smart enough to realize this, and would give you a warning if you put the Form inside the block:

```
[Warning] Unit1.pas(34): Variable 'Form' might not have been  
initialized
```

The next question may be what to do with the exception once you catch it. Sometimes, you may want to ignore certain exceptions (such as EConvertError), or execute certain code when an exception has been raised. If you don't handle the exception (or catch with a try...except block), then the default exception handler will show a dialog with the exception's message. You can customize this for your entire application by placing a **TApplicationEvents** component on your form and writing code for the **OnException** event. A reason for doing this might be to log the exception do a file. Or, you may want to display a custom dialog. I have an application which automatically closes the dialog after 15 seconds with no mouse clicks. Very handy!

Now, raising an exception is simple:

```
raise Exception.Create('some exception!');
```

Notice that it is possible to raise an exception inside of a **try...except/finally** block. If you want to re-raise the current exception, you can simply use **raise**:

```
procedure TForm1.FormCreate(Sender: TObject);  
var  
    Form: TForm1;  
begin
```

```
Form := TForm1.Create(Self); // Allocate some memory
try
  // Some code which may raise an exception
  Form.DoSomethingWhichMayRaiseAnException;
except
  on E: Exception do
    raise; // re-raise the currently caught exception
end;
end;
```

Note that it is wrong to try and re-raise it with:

```
raise E; // DON't DO THIS!
```

After you catch an exception, it is implicitly freed by the compiler (since, it has to be freed at some time!). Re-raising it with just **raise** doesn't free the current exception object. Calling **raise E**, where E is the caught exception, means that the compiler will implicitly free E twice!

This should give you a pretty good overview as to how to handle exceptions with Delphi.

## Article #25669: Can I create stored procedures via Delphi or C++ Builder?

### Problem:

Can I create InterBase stored procedures in my InterBase database using Delphi or C++ Builder?

### Solution:

\*\*\*\*\*

This document refers to:

- \* InterBase versions 4.X and above.

\*\*\*\*\*

Yes, you can create stored procedures via Delphi. You can use the TQuery component to pass the SQL statements needed to create the stored procedure on the InterBase server. One caveat you will want to be aware of is that you need to have two colons in front of memory variables instead of one when you call the stored procedure.

Listed below are steps to create an example of defining stored Procedures via Delphi or C++ Builder:

1. Select File | New Application from the menu.  
--This will bring up a new application with a blank form.
2. Click on the button icon on the standard tab of the component palette.
3. Click on the "Data Access" tab.
4. Click on the Query icon.
5. Hit  to bring up the Object Inspector.
6. Set the DatabaseName property to your InterBase alias.
7. Click on the three dots in the space next to the "SQL" property.
8. You can now enter the text of your stored procedure.
9. Type in the text of the stored procedure definition code:

```
create procedure myproc returns (a integer)
  as
  begin
    a=5;
  end
```

10. After you have entered the code for your stored procedure, click on the button.
11. Next, you will need to tell Delphi to run your stored procedure code. To that, do the steps listed below:
  - a. Click on the button.
  - b. Hit to bring up the Object Inspector.
  - c. Click on the Events tab.
  - d. DoubleClick on the space next to "OnClick"
  - e. Enter in the following code after the line with the word 'begin' on it:  
query1.execSQL;
12. Push to run the program.

## Article #25670: How to Use Delphi or C++ Builder to Run a Query in a Text file

### Problem:

I would like to run a query saved in a text file using Delphi or C++ Builder. How do I do that?

### Solution:

### Step by Step Instructions on How to Run a Query from a File Using Delphi

=====

1. Create an alias in the BDE to point to the database.
2. Create a file called 'myquery.sql' in your c: root directory that contains the following line:  

```
select * from employee
```
3. Start Delphi.
4. File | New Application
5. Place a button on the form. You can do this by clicking on the button icon on the Standard page of the component palette and then clicking on the form.
6. Click on the Data Access tab of the component palette.
7. Click on TQuery icon and then on the form to place a TQuery on the form.
8. Hit `Alt+O` to bring up the Object Inspector.
9. Define the TQuery's DatabaseName property to be the alias that points to the employee database.
10. Click on DataSource icon and then on the form to place a DataSource on the form.
11. Hit `Alt+O` to bring up the Object Inspector.

12. Define the DataSet property of the DataSource object to be Query1.
13. Click on the Data Controls tab on the component palette.
14. Click on DBGrid icon and then on the form to place a DBGrid on the form.
15. Hit `Alt+V` to go back to the Object Inspector.
16. Define the DBGrid's DataSource property to be DataSource1.
17. Click on the button again.
18. Hit `Alt+V` to go to the Object Inspector.
19. Click on the 'Events' tab.
20. Double Click in the white space next to the OnClick event.
21. Place the following code in the button's OnClick event code:

```
Query1.Close;
Query1.SQL.Clear;
Query1.SQL.LoadFromFile('C:MYQUERY.SQL');
Query1.Open;
```
22. Run the application by hitting `F5`.
23. Press the button to see the query run.

Note: You can also read a query into the TQuery object with SQL Builder.

Use the File | Import from file menu in SQL Builder choices to do this.

For more information about accessing SQL Builder, please refer

to document number 25679.

## **Article #25671: Where are the Delphi 4 InterBase Certificate Keys and IDs located?**

### Problem:

Can't find the Certificate Key and ID for installing InterBase from the Delphi 4 CD.

### Solution:

The information in this article applies to:

- \* Delphi 4
- \* C++Builder 3

As with the InterBase installation from the C++Builder CD, the license keys are located in the IB5 directory on the Delphi 4 CD in a file named `ibkey.txt`.

Last Modified: 23-OCT-00

## Article #25679: How to create SQL queries with SQL Builder

### Problem:

Here is a quick walk-through of creating a query with SQL Builder. SQL Builder is an interactive tool that is included with Delphi and C++ Builder. It allows a user to create an SQL query using a graphical interface. Complete instructions on displaying results using a dbGrid component is also covered.

### Solution:

\*\*\*\*\*

Note: The information in this document was tested with C++ Builder 3.0.

\*\*\*\*\*

#### A. Setup Display Components

=====

1. File | New Application
2. Click on the Data Access tab.
3. Click on the Query icon and then on form to place Tquery component on the form.
4. Hit `F4` to go to the Object Inspector.
5. Click on space next to DatabaseName.
6. Select the alias you will be using from the pull down menu,  
For this example, we will use the "DBDEMOS" alias that ships with the BDE.
7. Click on DataSource icon and then on form to place DataSource on the form.
8. Hit `F4` to go to the object Inspector.
9. Click on the space next to the "DataSet" property.
10. Enter "Query1" (without the quotation marks) as the DataSet.
11. Click on Data Controls tab.
12. Click on DBGrid icon and then on the form.
13. Hit `F4` to go to the Object Inspector.

14. Click on space next to the "DataSource" property.

15. Click on downarrow and select "DataSource1".

## B. Set Up Query

=====

1. Right click on query component.

2. Select SQL Builder from menu.

3. Click on down arrow next to "Table" drop down list.

4. Select "customer" from the list.

5. See the list of fields in customer table appear in a box.

6. Click on checkbox next to the table name.

7. Notice that this checks all the fields.

8. If you hit the SQL button at this time, you can see the SQL statement that was generated for you.

9. Click on File | Exit to get out of the SQL Builder.

10. When prompted to save changes to the query, click on "Yes"

11. Your SQL query is now built and stored in the tquery component. You can see that the query got built by looking at the SQL property of the Tquery component.

12. To see the results of the query, you will need to set the active property on the

Tquery to true. Here are the steps to do that:

- a. Right click on the tquery component
- b. Hit to get to the Object Inspector.
- c. Click on space next to Active property.
- d. Select True from the list.

11. Hit to run the form. You will see the results of your query in a grid.

## Article #25682: Delphi Training: Accepting User Input Using An Edit Box

### Problem:

An example of using an Edit Box to accept user input with Delphi.

### Solution:

EDIT BOX (Accepting User Input)

Wayne Shaddock

October 2, 1998

### This demo uses:

- A TForm
- A TButton
- A TEdit
- 2 TLabel

It demonstrates the use of an edit box to take input from the console and display to the user some information about the input data.

1. Open a new project.
2. From the Standard tab on the Component Palette place a button, 2 labels, and an edit box on the form.
3. Arrange the components as desired. (The first label will display some instructions when the button is clicked so it should be placed above the edit box. The second label will give information about the user's input, so it should be placed below or to the right of the edit box)
4. Double click the button to create an event handler and type in the following code in the body of the Button1.Click procedure:

```
Label1.Caption := 'Enter an integer';
```

5. Double-click the edit box and create a variable declaration section right before the body of the procedure. Declare the following variable:

```
X : Integer;
```

6. Type the following code in the body of the Edit1.Change procedure:

```
X := StrToInt(Edit1.Text);  
if X > 10 then  
    Label2.Caption := 'You entered a number greater than 10'  
else if  
X <= 10 then  
    Label2.Caption := 'You entered a number less than or equal to 10';
```

7. Click the 'Run' arrow on the toolbar to compile and run the program.

Last Modified: 23-OCT-00

## Article #25683: Using Control Characters With Delphi

### Problem:

An example of using control characters with Delphi to format text displayed in a label component.

### Solution:

Using Control Characters With Delphi

Wayne Shaddock

?1998

#### 1) Open a new project:

From the 'File' menu select New Application

#### 2) Place two buttons on the form:

From the Standard tab of the Component Pallet double-click the button icon twice

#### 3) Place two labels on the form:

From the Standard tab of the Component Pallet double-click the label icon twice

#### 4) Change the captions of the two buttons:

Click Button1 to select it and change the 'Caption' property to 'No Control Character' (without the single quotes)

Click Button2 to select it and change the 'Caption' property to 'Control Character' (without the single quotes)

#### 5) Change the captions of the two labels:

Click Label1 to select it and change the 'Caption' property to 'Without Carraige Return Control Character' (without the single quotes)

Click Label1 to select it and change the 'Caption' property to 'With Carraige Return Control Character'

(without the single quotes)

6) Code the Event Handler for Button1:

Double-click Button1 to invoke the Event Handler. Declare a variable declaration section by typing the keyword 'var' between the keyword 'procedure' and 'begin'.

Declare a string variable by typing the following below the keyword 'var':

```
S1 : string;
```

Type the following code in the body of the procedure:

```
S1 := 'This is a string with no carriage return control character.';
Label1.Caption := S1;
```

7) Code the Event Handler for Button2:

Following the example for the first button enter the code for the event handler as follows:

```
procedure TForm1.Button2Click(Sender: TObject);
var
  S1, S2 : string;
begin
  S1 := 'This is a string with';
  S2 := 'a carriage return control character.';
  Label2.Caption := S1 + #10 + S2;
end;
```

9) Compile and run the project: press the F9 key.

Pressing the button labeled 'No Control Character' results in the first label displaying a text string as a single line. Pressing the other button results in a text string being displayed in the second label on two lines because of the inclusion of the control character '#10' in the code for Button2's event handler.

## Article #25704: InterBase array datatype and the BDE

### Problem:

I have just created a table that contains a field with an array of integers defined as one of the fields. How can I access it from my Delphi or C++ Builder application using the BDE?

### Solution:

\*\*\*\*\*

The information in this article applies to:

\*InterBase versions 3.3, 4.X, and 5.X

\*Delphi versions 1.X, 2.X, 3.X, and 4.0

\*\*\*\*\*

Delphi and C++ Builder's data aware components do not support arrays. One has to use

InterBase API calls to get data into and out of the arrays. Thus you must either write your own array handling code, or use a component set which already does this.

Last Modified: 23-OCT-00

## Article #25707: Creating a Worker Thread for Background Processing

Problem:

Creating a Worker Thread for Background Processing

Solution:

This information in this document applies to:

- \* InterBase 5.x
- \* Delphi 32-bit

\*\*\*\*\*

Steps to Create a Background Thread

\*\*\*\*\*

1. Create new Application

2. Create a descendant of TThread (we'll call it TWorkerThread). You can do this by

selecting the File | New menu option and choosing the "Thread Object" item.

3. Save your unit (we'll call it WorkerThreadUnit)

4. Add WorkerThreadUnit to interface uses section of TMainForm. This is added to the

interface section, opposed to the implementation section, because we are going to

create a variable of this class and need this when declaring the main form's class.

```
{ begin code snippet }  
interface
```

```
uses
```

```
    WorkerThreadUnit;
```

```
{ end code snippet }
```

5. Create a variable of TWorkerThread. Here is a code snippet showing a variable of

type TWorkerThread being declared.

```

{ begin code snippet }
type
  TMainForm = class(TForm)
  private
  public
    { Public declarations }
    workerThread: TWorkerThread;
  end;
{ end code snippet }

```

6. Add TMainForm's unit (MainUnit) to the implementation section of WorkerThreadUnit. We add it to the implementation section, because we will use it in our classes declaration, not its definition.

```

{ begin code snippet }
implementation

  uses SysUtils, MainUnit;
{ end code snippet }

```

7. Fill in the Execute method of TWorkerThread to do what you want when thread is created. This method will be called when you create an instance of your thread.

```

{ begin code snippet }
procedure TWorkerThread.Execute;
begin
  { Place thread code here }
  .
  .
  .
end;
{ end code snippet }

```

8. Create a method to be used for all your user interface code. This needs to be in a separate method so that we can invoke it with the Synchronize method of the TThread class (we'll call it UpdateUI)

```

{ begin code snippet }
procedure TWorkerThread.UpdateUI;
begin

```

```

    { do user interface stuff here }
    .
    .
    .
end;
{ end code snippet }

```

9. In TWorkerThread's Execute method call the Synchronize method and pass it the UpdateUI method as a parameter.

```

{ begin code snippet }
procedure TWorkerThread.Execute;
begin
    { Place thread code here }
    FreeOnTerminate := true;
    Synchronize(UpdateUI);
end;
{ end code snippet }

```

10. Now, in your main form create an instance of your TWorkerThread class where ever you need a new thread. Here is an example showing an instance of our

TWorkerThread class being created when Button1 is clicked.

```

{ begin code snippet }
procedure TMainForm.Button1Click(Sender: TObject);
begin
    workerThread := TWorkerThread.Create(false);
end;
{ end code snippet }

```

\*\*\*\*\*

Notes

\*\*\*\*\*

\* Delphi requires (there are a few exceptions) that all user interface code be executed in the context of the application's primary thread.

\* TThread provides a method called Synchronize to allow some of its methods to be executed in the context of the application's primary thread.

\* TThread is an object pascal object that encapsulates a Win32 API thread object.

The parameter to the TThread.Create method controls whether the thread is created

in a suspended state. If true is passed in then the thread will be created, but its execute

will be suspended. If false is passed in the thread will be created and will execute

immediately. In the above example I passed in false so that the worker thread would

execute as soon as it was created.

\* The thread associated with a TThread object will be terminated as soon as the

TThread.Execute method is done executing.

\* However, the TThread object will not automatically be destroyed when the

underlying thread terminates. To destroy the TThread object you can:

- \* Explicitly call the TThread.Destroy method

- \* Set the TThread's property FreeOnTerminate to true in the TThread.Execute

method. If FreeOnTerminate is true then the TThread object will be

automatically destroyed when the underlying thread is terminated.

## Article #25745: Why can't I display data in descending order in Delphi?

### Problem:

Why can't I display data in descending order in Delphi or C++ Builder?

### Solution:

If you are using a TTable, descending indexes can be a problem. A way around this

is to use TQuery and specify the SQL order by clause. The downside to this method

is refresh is not automated.

Last Modified: 23-OCT-00

## Article #25774: I am getting permission denied errors when I run a Delphi or C++ Builder data-aware application.

Problem:

The errors are:

Cannot find file e:tempdboxusers.lck

Permission Denied

Solution:

In some sequences of events BDE will store data in temporary Paradox tables. Some of the scenarios where BDE creates temporary Paradox tables

are with heterogeneous joins, and with CachedUpdates. BDE will look to where the Paradox PrivateDir is set to be. This will be based on the drive and directory that the application is launched from. If the application is launched from a networked or mapped drive then the temporary Paradox tables will be created on that drive and network rights will be an issue. In most cases it will be sufficient to route the Paradox PrivateDir setting to the local drive. The code snippets below show two possible approaches to doing this in Delphi. These approaches require the use of the Session object, specifically the Session.PrivateDir member of the object. This also requires having DBTables in the Uses clause. One approach is to reassign the Session.PrivateDir to the Windows temporary directory, by calling the GetTempPath() Windows API function call. Add Windows to the Uses clause

so that GetTempPath() can be called. The other approach is to assign a hard coded path to Session.PrivateDir.

Uses Windows, DBTables

```
const
    temp_path_len = 512;
var
    temp_path: array[1 .. 512] of char;

//
// Place this code snippet at the
// appropriate place in the code
//
GetTempPath(temp_path_len, @temp_path);
Session.PrivateDir := StrPas(@temp_path);
```

```
//  
// or  
//  
// Session.PrivateDir := 'C:Temp';
```

## Article #25807: Purpose of the interbase Client32 files

### Problem:

What is the purpose of the interbase Client32 files in the Pro versions of C++Builder and Delphi?

### Solution:

This information applies to InterBase 5.x for Win95 and NT

To allow you to have a pre-made install of the Client-only software with a predefined license key. You can install this on as many workstations as you want.

Source: Bill Karwin

Last Modified: 12-OCT-00

## Article #25831: How do I use the InterBase API security functions to add, modify and delete users

### Problem:

Since there are no VCL controls to add, modify, or delete users for an InterBase server I am not sure how to do this task. The BDE also does not allow me to add, modify or delete users. I need to be able to do this task within a program? How do I do it?

### Solution:

InterBase has surfaced the following functions to add, modify and delete users:

```
ISC_STATUS isc_add_user(ISC_STATUS *status, USER_SEC_DATA *
user_sec_data)
```

```
ISC_STATUS isc_modify_user( ISC_STATUS *status, USER_SEC_DATA
*user_sec_data)
```

```
ISC_STATUS isc_delete_user( ISC_STATUS *status, USER_SEC_DATA
*user_sec_data)
```

The following program below shows how to define these functions in a Delphi program and how to call them in a Delphi application:

```
unit add_user1;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
Dialogs,
StdCtrls, ExtCtrls;
```

```
const
```

```
    sec_uid_spec = $01;
    sec_gid_spec = $02;
    sec_server_spec = $04;
    sec_password_spec = $08;
    sec_group_name_spec = $10;
    sec_first_name_spec = $20;
    sec_middle_name_spec = $40;
```

```
    sec_last_name_spec = $80;  
sec_dba_user_name_spec = $100;  
    sec_dba_password_spec = $200;
```

```
    sec_protocol_tcpip = 1;  
sec_protocol_netbeui = 2;  
    sec_protocol_spx = 3;  
    sec_protocol_local = 4;
```

```
type
```

```
    ISC_STATUS = Integer;  
P_ISC_STATUS = ^ISC_STATUS;
```

```
    USER_SEC_DATA = record  
        sec_flags: Smallint;  
        uid: Integer;  
        gid: Integer;  
        protocol: Integer;

    user_sec_data1.sec_flags := sec_password_spec or sec_server_spec or
                             sec_dba_user_name_spec or
sec_dba_password_spec;

    result := isc_modify_user(p_status, @user_sec_data1);
end;

function TForm1.del_user_by_name_password(user_name: PChar; password:
PChar): ISC_STATUS;
var

```

```

p_status: P_ISC_STATUS;
status: array[0..19] of ISC_STATUS;
user_sec_data1: USER_SEC_DATA;
begin
  // have p_status point at the ISC_STATUS array
  p_status := @status[0];

  // set up the USER_SEC_DATA elements
  user_sec_data1.protocol      := sec_protocol_tcpip;
  user_sec_data1.server       := 'aquaman';
  user_sec_data1.user_name    := user_name;
  user_sec_data1.password     := password;
  user_sec_data1.dba_user_name := 'sysdba';
  user_sec_data1.dba_password := 'masterkey';

  user_sec_data1.sec_flags := sec_password_spec or sec_server_spec or
                             sec_dba_user_name_spec or
sec_dba_password_spec;

  result := isc_delete_user(p_status, @user_sec_data1);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  add_user_by_name_password(@add_user_name.Text[1], @add_password.
Text[1]);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  mod_user_by_name_password(@mod_user_name.Text[1], @mod_password.
Text[1]);
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  del_user_by_name_password(@del_user_name.Text[1], @del_password.
Text[1]);
end;

end.

```

## Article #25849: Displaying 4 digit years in Delphi applications

### Problem:

When date fields are displayed in the data aware controls the year is always displayed with 2 digits. How can I display years with 4 digits instead?

### Solution:

The information in this article applies to:

- \* BDE
- \* InterBase Express (IBX)
- \* ADO

When connecting to an InterBase database date datatypes are always returned to the client using InterBase's date format: ISC\_QUAD. All other databases have their own way of representing 4 digit years. It is the client's responsibility to display the date information in a format suitable for the particular application.

When using Delphi with either the BDE or IBX year data is displayed with 2 digits by default.

There are many ways to change this behavior and customize the displayed date format. Two such ways will be explained here.

### Changing Regional Settings for the System

-----

One way to adjust the display format of date fields is to change the system's settings for displaying dates. In the control panel applet "Regional Settings" there is a Date tab that allows the system's date format to be customized. You can change the value for the combo box "Short date style"

### Changing the Short Date Format for the Application

-----

Another way to adjust the display formats for dates is to set the variable ShortDateFormat. This variable is defined in the Sysutils unit. You can customized the date display format for the application by setting this variable. For more information search on ShortDateFormat in the Delphi help.

Here is an example that sets the variable to display 4 digit years

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    ShortDateFormat := 'mm/dd/yyyy';
end;
```

## Changing the Date Display Format for a Particular Field

---

You can also customize the date display format for individual fields. This is accomplished by creating a persistent field component for the field and setting the `DisplayFormat` property for the component.

The easiest way to create a persistent field is to use the Fields editor in Delphi. After dropping your dataset component on a form, right click on the component and select "Fields Editor...". Right clicking in the Fields editor brings up a menu which allows you to "Add all fields"

Once the fields are created you can customize the properties for the date field.

Select the date field's `Field` object from the list. Then in the object inspector you can set the `DisplayFormat` property for the date field. You can also change the property in code as demonstrated in the following snippet of code.

Note: `Query1HIRE_DATE` is the field component that was created from the Fields editor.

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    Query1HIRE_DATE.DisplayFormat := 'mm-dd-yyyy';
end;
```

## Article #25870: How do I use the InterBase Express (IBX) SQL monitor?

### Problem:

Use the TIBSQLMonitor component to monitor the dynamic SQL that passes through the InterBase server. You can write an application that can view only its own SQL statements, or you can write a generic SQL monitor application that monitors the dynamic SQL of all applications built with InterBase Express (IBX).

Use the TIBSQLMonitor component to watch dynamic SQL taking place in all InterBase data access applications both before and after they have been compiled.

### Solution:

To build a simple SQL monitoring application, follow these steps:

1. Open a new form in Delphi.
2. Add a Memo component to the form and clear the Lines property.
3. Add a TIBSQLMonitor component to the form
4. Double-click the OnSQL event and add the following line of code:  
`Mem1.Lines.Add(EventText);`
5. Compile the application.

You can now start another IBX application and monitor the code.

**Article #25915: BDE Merge Module now available.**

A BDE Merge Module is now available for download from our ftp site at:

<ftp://ftp.borland.com/pub/bde/devsupport/updates/>

There are two files available here:

bdemm5ent.exe

bdemm5pro.exe

for the Enterprise and Professional versions of Delphi. French and German versions are also available:

bdemm5pf.exe

bdemm5ef.exe

bdemm5pg.exe

bdemm5eg.exe

This BDE merge module provides support for the Microsoft Windows Installer (MSI). The Merge Module contains all the BDE files, along with registry and configuration information needed to install those files.

Last Modified: 11-OCT-00

## Article #25954: Where are my components?

### Question

Where are my components?

### Answer

Windows NT and 2000:

Most likely Delphi was installed by an administrator or a user with administrator rights and the user currently logged on does not have administrator rights. The component library is failing to load because it does not have the registry keys available that indicate where the packages are located. Install first as Admin, then do a 'Registry Settings Only' install for each user to get all the necessary DLL's and registry key entries to run Delphi under a specific user profile.

To do this login as the user and run the Delphi install. Around 3 screens in you'll get to the screen where you need to choose the install directories. At the bottom of this screen is a check box to select for Registry Settings Only. Complete the install as usual. It should be much faster since no files are copied.

If it looks like the components are there but the bitmap images are missing then try uninstalling and reinstalling each package. This can be done very easily by going into the Delphi menu option Component | Install Packages. Uncheck each of the packages and then check it again. Say "Yes" to any message boxes that appear asking about the removal of related packages. I recommend you start by removing "Borland Database Components" since this will remove several others as well.

## Article #26068: Resolving DFM corruption issues with CVS.

Many developers have complained of problems using source control with their Builder/Delphi projects. After checking their form files out of source control systems such as CVS and attempting to open the form in Builder or Delphi, the IDE reports an error "Invalid stream format." and refuses to display the form. After some research, it was found that CVS was adding bytes to the form's DFM file, inserting a line-feed (integer value of 10) character before each carriage return character (integer value of 13).

The cause is CVS opening and closing this file as if it were a text file. In Builder/Delphi 4, DFM files were stored as binary files, reason being that a binary DFM could be rendered to a form in the Builder/Delphi IDE faster than a text file could. Through the IDE, a developer could view and edit the DFM as a text file, but it was still stored in binary format.

Version 5 of Builder and Delphi now store DFM files as plain text by default, giving you the option of storing DFMs in binary format. Projects converted from version 4 to version 5 continue to store their DFMs in binary format until set differently.

To prevent your forms from being corrupted by CVS, you should either store your DFMs as text or let CVS know that your DFMs are binary files (consult the CVS documentation for these settings).

If your DFM files have already been corrupted, it might be possible to fix them using this tool: [FIXDFM.EXE](#). This tool is unsupported by Borland so don't send any email if you have problems with it. What it does is search your corrupted binary DFM file for the byte pattern 10 13 (linefeed, carriage return) and removes the 10. Keep in mind the possibility that the program will modify cr/lf combos that were in the DFM originally and not added by CVS.

**Article #26072: Delphi 5 is unable to start due to problems with a missing export in a .BPL file.**

**Question:**

When I try to start Delphi 5, I get an error about:

"The VCLX5.BPL file is linked to missing export VCL50.BPL:@Forms@Finilization\$qqrv"  
or something very similar to this. How can I fix this problem?

**Answer:**

This problem typically occurs when you have a corrupted .bpl file on your system. The solution is to uninstall Delphi, search for any BPL's on your system (a good search query would be: \*50.bpl), and delete the files. If you don't want to delete them (because you may have some custom .bpl's on your system), copy them to a temporary folder that is on your desktop (it will not be on your system path so they won't cause any problems). Then, reinstall Delphi.

## Article #26107: Where is the file dsgnintf.pas?

### Question:

I'm looking for dsgnintf.pas - where is it?

### Answer:

This file comes on the Delphi 5 Professional and Enterprise version CD. It is listed under the directory Runimage\Delphi50\Source\Toolsapi

This file does not come with the Delphi trial version and is not available for download. Please note that this is a design time package and should not be in a run time unit. The Borland/Delphi license agreement prohibits distribution of this file in run time code.

Last Modified: 28-DEC-00

## Article #26111: Manually uninstalling Delphi

### Question:

How do I manually uninstall Delphi?

### Answer:

When uninstalling a program it is best to use the utility Add/Remove Programs found in the Control Panel in Windows, but sometimes this does not work properly. Here is a guide to help you uninstall Delphi manually.

There are four major areas where you will need to delete: The Delphi directory, the Borland Shared directory, the System32 directory and the Windows Registry.

1. The Delphi directory is easy. Just go into Windows Explorer and delete the entire directory called Delphi5. This should be under the directories Program Files\Borland.
2. The Borland Shared directory has more than one possible location but the most common is Program Files\Common Files\Borland Shared. If you are removing all Borland software that uses the BDE from your machine (i.e. Delphi and C++ Builder) you may be able to just delete the entire directory. Be aware that there may be other programs that use the BDE such as Corel paradox. It may be a good idea to always leave the BDE directory unless you are certain.
3. The System32 directory is located in your operating system directory, for example WINNT \System32. It will be the trickiest because it contains many files and only a portion of them are used by Delphi. The key here is to look on your Delphi CD for the System32 directory to find which files to delete. The files contained under the Runimage directory on the CD are in more or less the same directory structure as they are on your machine. The main exception is that the Windows\System32 directory located under Runimage\Delphi50\ on the CD contains items that are actually contained in the OS directory on your machine.

One tip is that Delphi files of the same version have the same date and time, so if you go into the System32 directory and sort by 'Modified' you should be able to group all the Delphi files together so you can delete them all at once.

4. In order to make changes to the registry you must open to utility regedit.exe. Go to the Start menu and select run, then type 'regedit'. Once in the registry open the entry HKEY\_LOCAL\_MACHINE \SOFTWARE\Borland\Delphi. Right click on the version of Delphi you are deleting such as 5.0 and select delete. If desired remove other directories under here as well. Now you should simply do a search on the registry for 'delphi' and 'borland' and make your own judgment as to whether there are other entries you want to delete.

One final step you may want to take is to remove all the file extension associations with Delphi. If you

did a search on the registry in step four then you may have already done this. It can be done by opening Windows Explorer and going to the menu View | Options. The extensions associated with Delphi 5 are: dfm, dpr, dpk and pas.

## Article #26151: Unable to install Delphi 5 after having the Trial edition fully uninstalled

### Question:

After uninstalling the Delphi 5 Trial Edition, I went to install a purchased copy of Delphi 5, but it keeps telling me to uninstall the Trial Edition. How can I get around this problem?

### Answer:

The registry did not properly get cleared by the Delphi 5 Trial uninstaller. Click Start->Run, and type "regedit". Expand HKEY\_CURRENT\_USER, Software, Borland, and then Delphi. Select the key (a folder in the left panel) labeled 5.0 and press delete. You will be prompted to delete the key (select Yes). Next, expand HKEY\_LOCAL\_MACHINE, Software, Borland, and then Delphi. Select the key (a folder in the left panel) labeled 5.0 and press delete. *WARNING: Be very careful when using regedit to not delete any other keys as it can make your system unstable.*

## Article #26402: How to print an HTML document from inside of your application

### Developing Internet Applications

By [Corbin Dunn](#)

Delphi Developer Support

**Question:** How do I print an HTML document from inside an application? Or, how do I print from a TWebBrowser control?

**Answer:** Using Internet Explorer 5 makes this very simple to do, but involves a little work to get it done. Let's say that you want to allow your program to print HTML documents - either from the web directly, or from a file. The main problem programmers encounter is that TWebBrowser does not have a Print method. If you have ever looked inside of MSHTML.pas you will notice that IHTMLWindow3 has a print method that we can call - the only trick is in acquiring an IHTMLWindow3 interface from a TWebBrowser. This can be done by using TWebBrowser component (it doesn't have to be visible), calling WebBrowser.Navigate to go the location you want to print, and then in the NavigateComplete event doing the print:

```
procedure TForm1.WebBrowser_V1NavigateComplete(Sender: TObject;  
    const pDisp: IDispatch; var URL: OleVariant);  
var  
    HTMLDoc: IHTMLDocument2;  
    HTMLWnd: IHTMLWindow2;  
    HTMLWindow3: IHTMLWindow3;  
begin  
    HTMLDoc := (Sender as TWebBrowser).Document as IHTMLDocument2;  
    if HTMLDoc = nil then  
        raise Exception.Create('Couldn't convert the WebBrowser to an  
IHTMLDocument2');  
    HTMLWnd := HTMLDoc.parentWindow;  
    HTMLWindow3 := HTMLWnd as IHTMLWindow3;  
    // Finally, we get to the print method  
    HTMLWindow3.print;  
end;
```

## Article #26407: Dynamically changing the MainForm of an Application when it starts.

### Developing Applications

By [Corbin Dunn](#)

Delphi Developer Support

**Question:** I want to dynamically change the MainForm for my Application based on a command line switch or registry setting. How can I do this?

**Answer:** The MainForm for your Application will be the first form created with a call to `Application.CreateForm`. Whenever this form is closed, your whole application will close. You may want to change which form this is based on a command line switch or registry setting. Here is a code sample from the Application source on how to do this:

```
program Project1;

uses
  Forms,
  Classes, // For TComponentClass
  SysUtils, // For FindCmdLineSwitch
  Unit1 in 'Unit1.pas' {Form1},
  Unit2 in 'Unit2.pas' {Form2};

{$R *.RES}

var
  InstanceClass: TComponentClass;
  FormReference: TForm;

begin
  Application.Initialize;

  if FindCmdLineSwitch('second', ['-','/'], True) then
  begin
    InstanceClass := TForm2;
    FormReference := Form2;
  end
  else
  begin
    InstanceClass := TForm1;
    FormReference := Form1;
  end;
end;
```

```
Application.CreateForm( InstanceClass, FormReference );  
Application.Run;
```

**end.**

**Article #26408: Help pages are coming up blank in Delphi.**

**Question:**

Why are my help topics coming up blank?

**Answer:**

There is a Windows imposed limit to the number of help files that can be opened in one help screen. To fix this, in Delphi, go into Help | Customize and remove help files that you do not think you will need. You should remove them from the Link and Index screens.

## Article #26416: How to move a string into a TMemoryStream or TFileStream.

**Question:** How do I move a string into a TMemoryStream (or a TFileStream)?

**Answer:** Here is a code sample of how to do this with a TMemoryStream. It could easily be extended to work with a TFileStream too:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    SourceString: string;  
    MemoryStream: TMemoryStream;  
begin  
    SourceString := 'Hello, how are you doing today?';  
    MemoryStream := TMemoryStream.Create;  
    try  
        // Write the string to the stream. We want to write from  
SourceString's  
        // data, starting at a pointer to SourceString (this returns a  
pointer to  
        // the first character), dereferenced (this gives the actual  
character).  
        MemoryStream.WriteBuffer(Pointer(SourceString)^, Length  
(SourceString));  
        // Go back to the start of the stream  
        MemoryStream.Position := 0;  
        // Read it back in to make sure it worked.  
        SourceString := 'I am doing just fine!';  
        // Set the length, so we have space to read into  
        SetLength(SourceString, MemoryStream.Size);  
        MemoryStream.ReadBuffer(Pointer(SourceString)^, MemoryStream.  
Size);  
        Caption := SourceString;  
    finally  
        MemoryStream.Free;  
    end;  
end;
```

## **Article #26523: Is Turbo Pascal still available?**

### **Question**

Is Turbo Pascal available for purchase or free download?

### **Answer**

We are no longer selling 16 bit development tools because they are not considered to be Y2K compliant. This includes Turbo Pascal 7 and Turbo Pascal for Windows 1.5 (the latest version of each). Copies of these products may still be available in some stores.

However, Turbo Pascal 5.5 is available for free download from our community site [here](#). Please note this product is no longer supported.

Delphi 5 is our current Pascal windows development tool. It is a descendent of Turbo Pascal and is capable of creating console applications as well as Windows apps. The Standard version of Delphi 5 costs about the same as Turbo Pascal did and is available from our web site at [shop.borland.com](http://shop.borland.com).

Last Modified: 04-JAN-01

## Article #26563: How do I split the editor?

### Question:

How do I split the editor? I want to be able to compare two files side by side.

### Answer:

The editor in C++Builder 5 and Delphi 5 do not directly support this functionality, but by using multiple edit windows and the Save Desktop feature, you can accomplish the same feat.

### Try this:

On Builder/Delphi's main menu, click "View" | "New Edit Window". A new edit window should appear. Close any docked windows you don't need, such as the Class Explorer, and arrange your two edit windows such that they are side by side.

Naturally, you don't want to take the time to rearrange the windows every time you need a split view, so why not save this desktop configuration?

Click "View" | "Desktops" | "Save Desktop...", enter a name such as "Split View", and click OK.

Now, by using either "View" | "Desktops" or the Desktop pull-down menu (it's one of the menu bands on the Builder/Delphi main menu), you can switch between standard single editor view, and split view with a couple of mouse clicks.

## Article #26609: BORDBK50.DLL is missing or not registered.

### Question:

What do I do about the error "BORDBK50.DLL is missing or not registered"?

### Answer:

If the installation does not complete then the cause of the problem is likely due to a software conflict. Some anti-virus software and certain NT Internet Services have been known to prevent bordbk50.dll from being registered with the operating system. In this case the best solution is to try eliminating the software in question and then try reinstalling Delphi 5.

If that is not a viable solution, try manually registering the bordbk50.dll (or borbdk51.dll if you have installed the update pack). Search for this file on your machine to verify that you have it. It is most likely in the folder C:\Program Files\Common Files\Borland Shared\Debugger. Run TREGSVR manually to register the dll. TREGSVR can be found in the Delphi5\bin directory. To register the DLL open a DOS window and change to the directory where bordbk50.dll is located, then type:

```
tregsvr bordbk50.dll
```

You may also need to include the full path to the location of tregsvr.

Last Modified: 11-JAN-01

## Article #26634: What is "Error 113" during installation?

### Question:

What is installation error 113?

### Answer:

This error occurs when there are problems reading files from the CD. Delphi requires a 32-bit CD-ROM driver in order to read long file names. If you have a 16-bit CD-ROM driver you will need to update to 32-bit. The reason this happens with Delphi (and usually not with other programs) is because Delphi installs by copying the Runimage directory, which contains long file names, from the CD to the hard drive. Typically, other installation programs unpack a compressed file. Contact the manufacturer's web site for an update.

To verify that you have a 16-bit driver:

- Check device manager in Control Panel - if no CD-ROM then it's 16-bit.
- Go to Explorer and view the Runimage directory on the CD. If there is a tilde (~) in any of the file names then the name is long and is being truncated.

Possible fix:

- Autoexec.bat and Config.sys - remove any reference to the 16-bit CD-ROM and restart. Windows might load new drivers. If not, manually add the new drivers.

Other Issues:

- This error can happen when someone is installing off of a network and has not actually mapped a drive to the correct location (they simply share the folder). Setup needs to see the Install and Runimage folders in the ROOT directory of a drive. Right click My Computer->Map Network Drive...
- This can also happen if you are trying to do a hard drive install, but have not put the files in the ROOT of the drive.

**Article #26667: Saving your project's breakpoint settings.**

**Question:**

Whenever I close and re-open my project, all of my breakpoints are lost. Is there any way to save my breakpoints?

**Answer:**

Yes. Under **Tools/Environment Options/AutoSave options** check the box labeled **Project Desktop**. The IDE online help says that this option saves what editor files you had open, but does not tell you it also saves your breakpoint options.

Last Modified: 14-MAR-02

## Article #26668: How to set the default form font in Delphi.

### Question:

How can I set the default form font in Delphi?

### Answer:

The value for the default font is stored in the registry. Open the registry editor by entering **regedit** at the RUN prompt. Go to the key

HKEY\_CURRENT\_USER\Software\Borland\Delphi\5.0

Here you will add a new key called FormDesign (with no space). To do right click on the 5.0 and chose New | Key. Name the key **FormDesign**. Now right click on this new key and choose New | String Value. Name this string value **DefaultFont** (no space). Now right click on this new string value entry in the right window and choose Modify. Enter the name of the default font you would like, followed by a comma and the default size. For example:

Arial,10

Now the next time you open Delphi this should be the default font for your forms. You can even go a little further with this if you wish by adding other font properties such as

Arial,10, bold, italic

## Article #26731: How to display the current user name.

### QUESTION:

How can I get the name of the user currently logged onto the system.

### ANSWER:

The code sample below displays the current user's name.

```
function CurrentUserName:String;  
var  
    u: array[0..127] of Char;  
    sz:DWord;  
begin  
    sz:=SizeOf(u);  
    GetUserName(u,sz);  
    Result:=u;  
end;  
  
procedure TForm1.Button1Click(Sender:  
TObject);  
begin  
    ShowMessage(CurrentUsername);  
end;
```

Last Modified: 02-FEB-01

**Article #26735: How to use the Find Error entry under the search heading of the menu bar.**

**QUESTION:**

How do I use the Find Error tool?

**ANSWER:**

If you are getting an AV, and are not sure what line this is happening on. You can use this feature to help scope down where this error might be occurring. This is especially helpful for tracking down, those irregular AV's.

The first thing to do when the AV occurs, is to write down the address. This Hex address we are interested in is the number that occurs in this sentence: "Access violation at address 0043F156 in module..." However, to use this properly, the application must be in Debug mode.

You can put the application into debug mode; by setting a break point some place in the application. Next, go to Search -> Find Error, after selecting this, a dialog window will show up. Put the Hex address number in the box "0043F156".

You actually don't need to put in the 004; this number specifies the preferred load address of the compiled image. You can check this number by going to Project->Options, then viewing the linker tab. It will appear in the Memory sizes portion off of the Linker tab.

Now hit the OK button, it should stop on the line that caused the error.

## Article #26752: How to detect if the current user is logged in administrator.

### QUESTION:

How can I check if the current user is logged in as administrator?

### ANSWER:

Below is a code sample to check if the current user is logged in as administrator.

```
function IsAdmin: Boolean;
var
  hAccessToken: THandle;
  ptgGroups: PTokenGroups;
  dwInfoBufferSize: DWORD;
  psidAdministrators: PSID;
  x: Integer;
  bSuccess: BOOL;
begin
  Result := False;
  bSuccess := OpenThreadToken(GetCurrentThread, TOKEN_QUERY, True,
    hAccessToken);
  if not bSuccess then
  begin
    if GetLastError = ERROR_NO_TOKEN then
      bSuccess := OpenProcessToken(GetCurrentProcess, TOKEN_QUERY,
        hAccessToken);
  end;
  if bSuccess then
  begin
    GetMem(ptgGroups, 1024);
    bSuccess := GetTokenInformation(hAccessToken, TokenGroups,
      ptgGroups, 1024, dwInfoBufferSize);
    CloseHandle(hAccessToken);
    if bSuccess then
    begin
      AllocateAndInitializeSid(SEcurity_NT_AUTHORITY, 2,
        SECURITY_BUILTIN_DOMAIN_RID, DOMAIN_ALIAS_RID_ADMINS,
        0, 0, 0, 0, 0, 0, psidAdministrators);
      {$R-}
      for x := 0 to ptgGroups.GroupCount - 1 do
```

```
    if EqualSid(psidAdministrators, ptgGroups.Groups[x].Sid) then
    begin
        Result := True;
        Break;
    end;
    {$R+}
    FreeSid(psidAdministrators);
end;
FreeMem(ptgGroups);
end;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    if isAdmin then

## Article #26754: How to detect the computer name.

### QUESTION:

How can I get the name of the computer my application is running on?

### ANSWER:

On a Form, add a TButton and a TEdit box. Declare your function and add the GetCompName code, shown below, to the implementation section of the Unit. Next, in the TButton's OnClick event add the code shown. Now run the project and click the button.

```
function GetCompName: string;

var
    Form1: TForm1;

implementation

{$R *.dfm}

function GetCompName: string;
var
    dwLength: dword;
begin
    dwLength := 253;
    SetLength(result, dwLength+1);
    if not Windows.GetComputerName(pchar(result), dwLength) then
        raise exception.create('Computer name not detected');
    result := pchar(result);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
    Edit1.Text := GetCompName;
end;
```

## Article #26889: Why does my Application run slowly under Linux?

### Question

Why does my Linux application run so much slower than my windows application?

### Answer

Linux performs fixups of external functions at runtime instead of at load time. This creates noticeable performance loss. To work around this, use static linking of your exe's.

You might also notice a significant performance improvement if you run your application without debugging turned on, or outside the IDE.

## Article #26890: Error -10 while installing

### Question

I got an Error -10 when I tried to install Kylix, why?

### Answer

The Error -10 is a generic install error. The usual cause of this is due to a previous version of Kylix that wasn't uninstalled completely. Check the RPM database to see if there are still components from Kylix installed, use the command `rpm -qa | grep kylix` to check for installed packages. If there are any packages still on the system, use `rpm -e <PACKAGE>` to remove them.

This can also be caused by a bug in the RPM manager that causes it to incorrectly check package dependencies. If this is the cause, then you can use the `-m` switch on the installer.

## Article #26891: What are the Differences in the install paths for Kylix?

### Question

What is the difference between the Install Path and the Sym Link Path?

### Answer

The Install path is where all the kylix files will be installed, whereas the symlink path is where symbolic links to those files will be installed. The links should be installed to a location that all the users of kylix will have access. Note, if you are installing as the root, the the installer will want to install Kylix to the /root/kylix directory. This is generally not the best option. Kylix should be installed to a common directory to all users that are going to be using it.

## Article #26937: Why am I getting the error "Operation must use an updateable query"?

### Question:

Why am I getting the error "Operation must use an updateable query" when editing a Paradox table using the Microsoft ODBC driver on my deployed application?

### Answer:

The Microsoft ODBC driver uses the Borland Database Engine (BDE) for updateable queries. It does not use it for read-only queries. One solution is to deploy the BDE with your application. A better solution is to use the Paradox driver that comes with the BDE.

This ODBC driver is used by Microsoft to import Paradox tables into Access. An import is read-only so it doesn't need the BDE. If you attempt to edit a Paradox table in MS Access without the BDE on your machine you should receive an error as well. We have been asked how to acquire the BDE in order to use Paradox tables in Access. Unfortunately the BDE is not sold as a stand-alone product. It is only available with Delphi and C++Builder.

If you are using ADO and TClientDataset you may receive the error: "Object or provider is not capable of performing the requested operation". This error can occur even if the BDE is on the machine. We have not verified the exact cause of this error but the solution is the same: don't use the Microsoft Paradox ODBC driver for updates - use the native Paradox driver instead.

## Article #27022: How do I get a TRichEdit to scroll in code?

### Question:

How do I get a TRichEdit to automatically scroll down as I add new lines?

### Answer:

This functionality is included in a TMemo but not a TRichEdit. You just need to add one line of code to get it to scroll down:

```
begin
  RichEdit1.Lines.Add('New text');
  RichEdit1.Perform(EM_SCROLL, SB_LINEDOWN, 0);
end;
```

## **Article #27031: Error "Application is not licensed to use this feature" when running a Delphi application.**

### **Question:**

What is the cause of the error "Application is not licensed to use this feature"?

### **Answer:**

This error occurs when you try to use components from one version of Delphi, such as Enterprise, with a different version that does not include those components, such as Standard. For example if you try to install the database components from the Enterprise version of Delphi into a Standard installation of Delphi.

Another possible cause is if you have the Standard version of Delphi installed on your machine and you install the Professional or Enterprise version without first uninstalling the Standard version. This error may also occur if you move a project from one version to another and keep the same compiled units (.dcu). It is best to delete the .dcu files and let them be recreated automatically.

*Note: It is fine to have two different release versions of Delphi on your machine, such as Delphi 4 and Delphi 5, but not two versions of the same release such as Delphi 5 Standard and Delphi 5 Enterprise.*

## Article #27039: Setting a Kylix TListView component's subitem images to nothing

**Question:** In Kylix, I have a TListView with a ViewStyle of vsReport that has the Images property set to a valid TImageList. Whenever I add subitems to an Item in the TListView, they have images (icons) set to them. How can I prevent this from happening?

**Answer:** This is due to a bug in the CLX VCL. There are two workarounds that you can do. First, you can modify the VCL source. To do this, open up QComCtrls.pas and save it in your projects current directory. Then, look for the following procedure and add the suggested lines of code:

```
procedure TCustomViewItem.ImageIndexChange(ColIndex, NewIndex:
Integer);
var
    Pixmap: QPixmapH;
begin
    if ViewControlValid and HandleAllocated and Assigned(ViewControl.
Images) then
        begin
            Pixmap := ViewControl.Images.GetPixmap(NewIndex);
            if Assigned(Pixmap) then
                QListViewItem_setPixmap(Handle, ColIndex, Pixmap)
                // Remove the ; from the last line and add the following fix:
            else
                begin
                    Pixmap := QPixmap_create;
                    QListViewItem_setPixmap(Handle, ColIndex, Pixmap);
                    QPixmap_destroy(Pixmap);
                end;
                // End of the fix
            end;
        end;
end;
```

The above solution will not work if you build with runtime packages. The fix for this must be done each time you add an item to the TListView. First, add Qt to your uses list, as we need to make some calls directly to the Qt library. Then, add the following work around whenever you add an Item to the TListView:

```
var
    Pixmap: QPixmapH;
begin
    with ListView.Items.Add do
        begin
```

```
Caption := 'Some Caption for the Item';
SubItems.Add('Some sub item');
// Work around for a bug in setting the image to nothing
Pixmap := QPixmap_create;
QListViewItem_setPixmap(Handle, 1, QPixmap);
QPixmap_destroy(Pixmap);
// End work around for the bug
end;
end;
```

The 1 passed to `QListViewItem_setPixmap` is the index of the `SubItem` that you want fixed, with the first one being 1, the second 2, etc (so, it is NOT a 0-based index, but rather a 1-based index).

## Article #27041: TIBLicensingService component not found on Component Pallet.

TIBLicensingService is not installed on the IBX component pallet. If you need to use this component in your application it must be created dynamically.

Delphi example:

```
uses IBServices;  
  
var  
    IBLicensingService1 : TIBLicensingService;  
  
...  
  
IBLicensingService1 := TIBLicensingService.Create(nil);
```

Last Modified: 19-MAR-01

## Article #27043: Trying to revoke a drop target that has not been registered with TWebBrowser.

TWebBrowser.ExecWB can generate the error "Trying to revoke a drop target that has not been registered" under 2 different conditions:

1. TWebBrowser is not yet ready to accept the command. For following may generate this error:

```
Navigate('e:\pictures\picture1.jpg');  
ExecWB(OLECMDID_PRINT, OLECMDEXECOPT_DONTPROMPTUSER);
```

To resolve the problem use QueryStatusWB and wait for it to return OLECMDF\_SUPPORTED + OLECMDF\_ENABLED. Below is an example that fixes the problem:

```
Navigate('e:\pictures\picture1.jpg');  
while QueryStatusWB( OLECMDID_PRINT) <> OLECMDF_SUPPORTED +  
OLECMDF_ENABLED do  
Forms.Application.ProcessMessages;  
ExecWB(OLECMDID_PRINT, OLECMDEXECOPT_DONTPROMPTUSER);
```

2. Even though you use QueryStatusWB, Copy and Paste may still fail. Add the following to the end of your unit to resolve the problem:

```
initialization  
OleInitialize(nil);
```

```
finalization  
OleUninitialize;
```

## Article #27067: Trouble Shooting Errors Received After Adding a Unit to the Uses Section of Your Unit

### Question:

Why am I getting the error "file not found: 'xxx.dcu' " when I add a unit to the uses section, if I know it should be there?

### Answer:

Here are some possibilities. First go to the menu option Tools | Environment Options | Library and make sure the Library Path includes \$(DELPHI)\lib.

A second possibility is that the unit name may have changed between Delphi and Kylix. For example the unit Printers is now QPrinters.

Finally, remember that Linux is case sensitive, so qprinters.dcu and Qprinters.dcu would not be found in the example above - only QPrinters.dcu.

## Article #27128: How to custom draw menu items

### Custom drawing of menu items

By [Corbin Dunn](#)

Delphi Developer Support

First, take the opportunity to [download the complete source](#) for this project from CodeCentral.

While working an application I wanted to have a custom drawn popup menu that separated the menu into a series of groups. This would allow the user to easily differentiate each group. With Delphi, this is very easy to do. I put a **TPopupMenu** on my form and set the **OwnerDraw** property to True. I then set the **OnDrawItem** event for all of my "header" menu items. Then, I added the following code:

```
procedure TForm1.CustomMenuDrawItem(Sender: TObject; ACanvas:
TCanvas;
  ARect: TRect; Selected: Boolean);
var
  LeftPos: Integer;
  TopPos: Integer;
  TextLength: Integer;
  Text: string;
begin
  Text := (Sender as TMenuItem).Caption;
  ACanvas.Brush.Color := clGray;
  ACanvas.FillRect(ARect);
  ACanvas.Font.Color := clWhite;
  ACanvas.Font.Style := [fsBold];
  // Draw right in the middle of the menu
  TopPos := ARect.Top +
    (ARect.Bottom - ARect.Top - ACanvas.TextHeight('W')) div 2;
```

```
TextLength := Length(Text);  
if TextLength > (ARect.Right - ARect.Left) then  
    LeftPos := ARect.Left + 3  
else  
    LeftPos := ARect.Left + (ARect.Right - ARect.Left -  
        ACanvas.TextWidth(Text)) div 2;  
ACanvas.TextOut(LeftPos, TopPos, Text);  
end;
```

Pretty simple!

## Article #27129: Selecting an item in a TListView when the checkbox is checked

### Selecting an item in a TListView when the checkbox is checked

By [Corbin Dunn](#)

Delphi Developer Support

You may have noticed some peculiar behavior with a TListView that has check boxes. Checking a check box does not select the underlying item. There is any easy way to solve this problem. In the **OnMouseDown** event handler of the TListView add the following code:

```
procedure TForm1.ListView1MouseDown(Sender: TObject; Button:
TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  Item: TListItem;
begin
  // Did we hit a checkbox? If so, make sure the item it
  // represents is selected.
  Item := ListView1.GetItemAt(X, Y);
  if Item <> nil then
    if ListView1.Selected <> Item then
      ListView1.Selected := Item;
end;
```

This should solve that problem!

If you want some example source code with this solution in it, [download the project](#) from CodeCentral.

## Article #27138: How to create Data Link File with Windows 2000

ADO comes installed on Windows 2000. You have to download it and install it for earlier Windows versions. When you install it, Data Link File shows up in the New Menu under Windows Explorer, making it quite easy to create a Data Link File. Below are two ways to easily create a Data Link file with Windows 2000 and Windows Explorer.

1. Select New | Text Document. Rename the resulting file to have a UDL extension. Double click on the file.
2. Open Notepad and place the following in it:

```
REGEDIT4
[HKEY_CLASSES_ROOT\.UDL\ShellNew]
@="MSDASC"
"Data"=hex:ff,fe,5b,00,6f,00,6c,00,65,00,64,00,62,00,5d,00,0d,00,0a,00,3b,00,
20,00,45,00,76,00,65,00,72,00,79,00,74,00,68,00,69,00,6e,00,67,00,20,00,61,
00,66,00,74,00,65,00,72,00,20,00,74,00,68,00,69,00,73,00,20,00,6c,00,69,00,
6e,00,65,00,20,00,69,00,73,00,20,00,61,00,6e,00,20,00,4f,00,4c,00,45,00,20,
00,44,00,42,00,20,00,69,00,6e,00,69,00,74,00,73,00,74,00,72,00,69,00,6e,00,
67,00,0d,00,0a,00,50,00,52,00,4f,00,56,00,49,00,44,00,45,00,52,00,3d,00,6d,
00,73,00,64,00,61,00,73,00,71,00,6c,00,3b,00,0d,00,0a,00
```

Save the file with a .REG extension. Double click on the file. This will cause this to be automatically be entered in the appropriate place in your registry. After restarting Windows Explorer, Microsoft Data Link will be in the New menu.

## Article #27166: Assigning an Oracle BLOB greater than 32K must be done using AsMemo

If you create a table as such:

```
create table foo  
(f1 int not null,  
f2 long)
```

then insert data such as:

```
insert into foo values (:1, :2)
```

when assigning values to the second parameter you must the AsMemo property. Failing to do this may result in an Access Violation in SQLORA32.DLL at 4D629F73.

Example:

```
var  
s : string;  
counter : integer;  
begin  
s := "";  
for counter := 1 to 32768 do  
s := s + 'A';  
with Query1 do  
begin  
Params[0].Value := 1;  
//Params[1].Value := s; //This will cause an AV when ExecSQL is executed.  
//Params[1].AsString := s; //This will cause an AV when ExecSQL is executed.  
//Params[1].AsBlob := s; //Generates Oracle Error  
Params[1].AsMemo := s;  
ExecSQL;  
end;
```

## Article #27227: WHERE clause with greater than 256 ANDs or ORs generates size of optimizer block exceeded error

Q. What can cause the error Size of optimizer block exceeded?

A. This error occurs when the WHERE clause of an UPDATE or SELECT has greater than 256 ANDs or ORs.

Example:

```
create table foo( f1 int,f2 int,f3 int,f4 int,f5 int,f6 int,f7 int,f8 int,f9 int,f10 int,f11 int,f12 int,f13 int,f14
int,f15 int,f16 int,f17 int,f18 int,f19 int,f20 int,f21 int,f22 int,f23 int,f24 int,f25 int,f26 int,f27 int,f28 int,
f29 int,f30 int,f31 int,f32 int,f33 int,f34 int,f35 int,f36 int,f37 int,f38 int,f39 int,f40 int,f41 int,f42 int,f43
int,f44 int,f45 int,f46 int,f47 int,f48 int,f49 int,f50 int,f51 int,f52 int,f53 int,f54 int,f55 int,f56 int,f57 int,
f58 int,f59 int,f60 int,f61 int,f62 int,f63 int,f64 int,f65 int,f66 int,f67 int,f68 int,f69 int,f70 int,f71 int,f72
int,f73 int,f74 int,f75 int,f76 int,f77 int,f78 int,f79 int,f80 int,f81 int,f82 int,f83 int,f84 int,f85 int,f86 int,
f87 int,f88 int,f89 int,f90 int,f91 int,f92 int,f93 int,f94 int,f95 int,f96 int,f97 int,f98 int,f99 int,f100 int,

f77=77 and f78=78 and f79=79 and f80=80 and f81=81 and f82=82 and f83=83 and f84=84 and f85=85
```

and f86=86 and f87=87 and f88=88 and f89=89 and f90=90 and f91=91 and f92=92 and f93=93 and f94=94 and f95=95 and f96=96 and f97=97 and f98=98 and f99=99 and f100=100 and f101=101 and f102=102 and f103=103 and f104=104 and f105=105 and f106=106 and f107=107 and f108=108 and f109=109 and f110=110 and f111=111 and f112=112 and f113=113 and f114=114 and f115=115 and f116=116 and f117=117 and f118=118 and f119=119 and f120=120 and f121=121 and f122=122 and f123=123 and f124=124 and f125=125 and f126=126 and f127=127 and f128=128 and f129=129 and f130=130 and f131=131 and f132=132 and f133=133 and f134=134 and f135=135 and f136=136 and f137=137 and f138=138 and f139=139 and f140=140 and f141=141 and f142=142 and f143=143 and f144=144 and f145=145 and f146=146 and f147=147 and f148=148 and f149=149 and f150=150 and f151=151 and f152=152 and f153=153 and f154=154 and f155=155 and f156=156 and f157=157 and f158=158 and f159=159 and f160=160 and f161=161 and f162=162 and f163=163 and f164=164 and f165=165 and f166=166 and f167=167 and f168=168 and f169=169 and f170=170 and f171=171 and f172=172 and f173=173 and f174=174 and f175=175 and f176=176 and f177=177 and f178=178 and f179=179 and f180=180 and f181=181 and f182=182 and f183=183 and f184=184 and f185=185 and f186=186 and f187=187 and f188=188 and f189=189 and f190=190 and f191=191 and f192=192 and f193=193 and f194=194 and f195=195 and f196=196 and f197=197 and f198=198 and f199=199 and f200=200 and f201=201 and f202=202 and f203=203 and f204=204 and f205=205 and f206=206 and f207=207 and f208=208 and f209=209 and f210=210 and f211=211 and f212=212 and f213=213 and f214=214 and f215=215 and f216=216 and f217=217 and f218=218 and f219=219 and f220=220 and f221=221 and f222=222 and f223=223 and f224=224 and f225=225 and f226=226 and f227=227 and f228=228 and f229=229 and f230=230 and f231=231 and f232=232 and f233=233 and f234=234 and f235=235 and f236=236 and f237=237 and f238=238 and f239=239 and f240=240 and f241=241 and f242=242 and f243=243 and f244=244 and f245=245 and f246=246 and f247=247 and f248=248 and f249=249 and f250=250 and f251=251 and f252=252 and f253=253 and f254=254 and f255=255 and f256=256 and f257=257;

Generates the error:

Statement failed, SQLCODE = -904

size of optimizer block exceeded

This error has been reported to occur in conjunction with the error unknown username or password. This error is not related to the problem.

A common cause for having an UPDATE statement that includes every field in a table occurs when using a TTable or TQuery with Delphi or C++ Builder and the UpdateMode property is set to UpWhereAll. Changing the UpdateMode to upWhereChanged or upWhereKeyOnly solves the problem for most applications. If you need further customizations, a TUpdateSQL component can be used in conjunction with your TQuery or TTable to further control which fields are used in the WHERE clause of your UPDATE statement.

## Article #27255: Finding the column and row of the cursor in a TRichEdit

### Finding the column and row of the cursor in a TRichEdit

By [Corbin Dunn](#)

Delphi Developer Support

You may have come across the problem of trying to find out the current column and row position of the cursor in a rich edit. This is pretty easy to do, and the best time to do it is in the **Application.OnIdle** event:

```
procedure TForm1.ApplicationEvents1Idle(Sender: TObject;  
    var Done: Boolean);  
var  
    Row, Col: Integer;  
begin  
    // Find out what line we are on, based on the current selection's  
    // end (start + length).  
    Row := SendMessage(Richedit1.Handle, EM_EXLINEFROMCHAR, 0,  
        RichEdit1.SelStart + RichEdit1.SelLength);  
    // Find the column, from the selection end, minus the char we are  
on  
    Col := RichEdit1.SelStart + RichEdit1.SelLength -  
        SendMessage(Richedit1.Handle, EM_LINEINDEX, -1, 0);  
    // Display it in a status bar  
    StatusBar1.SimpleText := IntToStr(Row+1) + ' ' + IntToStr(Col+1)  
        + ' ' + DateTimeToStr(Now);  
end;
```

**Article #27265: Corrupted help files.**

**Question:**

My Delphi 5 help files seem to be corrupted. When I use the index, and select a topic, often an entirely different topic comes up. Is there some way to repair the help system?

**Answer:**

Usually, this is the result of a bad .gid file. WinHelp creates the .gid file the first time you open the help, and stores information on how to locate topics quickly. It's a hidden file by default so you may need to go into Folder Options to select the option to see hidden files. Try deleting all .gid files in your help directory and see if the problem goes away.

**Article #27266: BDE on multiprocessor machines.**

**Question:**

Are there any know issues with the BDE on multiprocessor machines?

**Answer:**

Yes. We have had reports that in very high traffic situations the BDE can cause an application to freeze or possibly give BDE Error \$2A04. Your best solution if you are faced with this situation is probably to switch to a single processor machine or set the affinity mask of your process to run on just one processor. You may also want to consider a different form of connectivity such as ADO.

Last Modified: 27-APR-01

## Article #27267: Setting process affinity for your application.

### Question:

Is there a way to make my application run on one processor of a multiprocessor machine?

### Answer:

Yes. Here are a couple ways you can set process affinity. The first is done while your application is running. Go into the Task Manager and click the Processes tab. Right click on your process and choose Set Affinity. Clear either CPU0 or CPU1.

The second is done in code. Here is an example of setting and getting process affinity:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    vHandle : Cardinal;  
    vMaskProcess, vMaskSystem : cardinal;  
begin  
    vHandle := Form1.Handle;  
    SetProcessAffinityMask(vHandle, 0); // or 1  
    GetProcessAffinityMask(vHandle, vMaskProcess, vMaskSystem);  
    showmessage(inttostr(vMaskProcess));  
    showmessage(inttostr(vMaskSystem));  
end;
```

## Article #27298: Finding product information from Borland's website for previous versions of Delphi

### QUESTION:

**Where can I find product information for previous versions of Delphi?**

### ANSWER:

You can find information on previous versions of Delphi by following these steps:

1. Start out at Borland's Home Page: [www.borland.com](http://www.borland.com)

2. Near the top, you should see the following:

Corporate Info | Products | Downloads | Services | Support | Community

Click on [Support](#)

3. You are now at the Developer Support Main Page. To the left, you will see a listing of various products underneath Updates/Patches.

Click on [Delphi](#)

4. On the top left, underneath Corporate Info, you will see Delphi. Underneath Delphi, you will see Datasheet(PDF), What's New and various other links. Click on [Previous Versions](#)

5. You can now select the previous version of Delphi you are wanting information about and navigate accordingly.

**Article #27308: Does Delphi 5 include Resource Workshop and InstallShield Express?**

**QUESTION:**

**Does Delphi 5 include Resource Workshop and InstallShield Express?**

**ANSWER:**

InstallShield and Resource Workshop are provided with Delphi 5 Professional and Enterprise but are not included in the Standard Version.

Last Modified: 10-MAY-01

## **Article #27312: What databases can be used with dbExpress?**

### **Question**

Will dbExpress allow access to file based databases such as DBase, Paradox and FoxPro?

### **Answer**

No. It currently works with DB2, Interbase, MySQL and Oracle.

Last Modified: 10-MAY-01

## Article #27321: How to get UpdateMode to work for TQuery on a SQL Server 7.0 table.

### QUESTION:

Why are all the fields on my SQL Server table used for identifying a record even though I have UpdateMode set to upWhereKeyOnly?

### ANSWER:

The problem is that the BDE is not identifying a primary key for your table. There may be two things required to solve this problem. The first is to verify that the table has been created with a primary key declared. You can verify that a primary key exists using SQL Explorer and viewing the text of the table, or by looking at the constraints placed on that table.

If you have verified that a primary key exists and you are still getting the error then you may need to change the SQL statement that is sent to the server. Try specifying the owner of the table before the table name (separated with a . ). For example if the owner is SYSADMIN and the table is Foo, then the SQL statement might look something like:

```
select * from SYSADMIN.Foo;
```

## Article #27329: How to retrieve the position of the cursor.

### QUESTION:

How can I get the current coordinates of the mouse?

### ANSWER:

The windows unit provides a wrapper around the Windows API function, `GetCursorPos`. Passing a `TPoint` into the function will retrieve the coordinates of the cursor. The following code illustrates how to get the values of the coordinates of the cursor from a button click.

```
procedure Form1.Button1Click(Sender: TObject);
var
  foo: TPoint;
begin
  GetCursorPos(foo)
  ShowMessage( '(' + IntToStr(foo.X) + ' , ' + IntToStr( foo.Y ) + ')' );
end;
```

**Article #27349: I installed my application with InstallShield and there are files missing.**

**Question:**

When I deploy my application with Installshield and try to run it, I get an error "Can't find VCL50.bpl. What's going on?"

**Answer:**

You have built your application using runtime packages. If these packages are not installed on the target machine, it will return an error like the above. You need to either install these packages or change your Project|Options|Packages settings to build your executable without these packages.

## Article #27369: Why won't my server socket reconnect?

### Question

Why won't my server socket reconnect ?

### Answer

The Linux TCP stack has a default wait of 2 minutes before it will let you bind another server socket to that port. This can be circumvented by adding a `SetSocketOpt()` call in the `OnCreateHandle` event. The actual is as follows.

```
Var  
    I : integer;  
begin  
    SetSocketOpt(sock, SOL_SOCKET, SO_REUSEADDR, @I, sizeof(I));  
end;
```

## Article #27370: Why won't the virtual key codes work in my program?

### Question

How can I determine what virtual key was pressed in Kylix?

### Answer

First you have to add QT to the uses clause of your program, then you can start using the virtual key codes in Kylix as described in the help files, i.e. `Key_Return`.

**Article #27373: VisiBroker applications created with Delphi 5 Enterprise on Windows 2000**

**QUESTION:**

**I installed VisiBroker that comes with Delphi 5 Enterprise and I can't get my VisiBroker applications to work on Windows 2000. What is wrong?**

**ANSWER:**

The version of VisiBroker that ships with Delphi 5 Enterprise is VisiBroker 3.3 for C++. As you can see from the following supported platform page <http://www.borland.com/techpubs/visibroker/platforms/previous-platforms.html#vbcpp33> Windows 2000 is not a supported operating system. However, Delphi 6 Enterprise comes with VisiBroker 4.1 which does work on Windows 2000.

Last Modified: 05-FEB-02

**Article #27375: Can you use the Naming Service with the version of VisiBroker that comes with Delphi 5 Enterprise?**

**QUESTION:**

**I am interested in using the Naming Service with Visibroker and was wondering if this feature is supported with VisiBroker for Delphi 5 Enterprise?**

**ANSWER:**

The version of VisiBroker that ships with Delphi 5 Enterprise is VisiBroker 3.3 for C++. This means you have all the capabilities that are offered with VisiBroker 3.3, one of them being the Naming Service. For a complete listing of all the features and instructions on how to use them, please consult the VisiBroker for C++ 3.3 documentation found at: <http://www.borland.com/techpubs/books/vbcpp/vbcpp33/index.html>

## Article #27379: Install option is inactive for the Trial Version of Delphi 5

### QUESTION:

I received the install password for the Delphi 5 trial, but the Install option is inactive. Why is that?

### ANSWER:

A lot of customers have had issues with installing the trial version due to a misunderstanding of Step 2: Register Now ! People click on the Register Now option and they are routed to the Borland Community site where they create a member account. While creating a member account you choose your username and a password, however this is not the password nor the registration that is required when installing the Delphi 5 Trial. After becoming a member of the Borland Community Site, you actually have to go to the community site and log in. Only then are you presented with the next step - completing a brief survey. After completing the survey, you will be at the next step, which is where you actually obtain your Trial Edition Password. In this step you must enter the System ID that you obtained at the very beginning of your installation (Step 1: Get your System ID to unlock the Trial.) Once you enter the System ID and enter your e-mail address (be sure and enter the proper e-mail address), you will be e-mailed your trial edition password and then Step 3 of the install should be active.

Last Modified: 01-JUN-01

## Article #27394: Borland Kylix Install Frequently Asked Questions

### Error -10 when trying to install Kylix

The Error -10 is a generic install error. The usual cause of this is due to a previous version of Kylix that wasn't uninstalled completely. You will need to check the RPM database to see if there are still components from Kylix installed. This can be done with command **rpm -qa | grep kylix**. For each of the resulting packages (if there are none, then Kylix is completely uninstalled), use **rpm -e *PackageName*** to remove them. Then, try reinstalling Kylix.

If you have Kylix completely uninstalled (the **rpm -qa | grep kylix** command returns nothing), and after choosing "Begin Install" from the installation, the installer aborts with an error code -10, then the problem may be do with the your locale settings. Typing the command "locale" may show **LC\_NUMERIC="de\_DE"** (the German locale, in this case). Some versions of RPM (mostly newer ones) respect this setting and will use a comma as the decimal separator. This causes a problem for the Kylix installer. The installer needs a period as the decimal separator. The workaround is to reset the **LC\_NUMERIC** environment like this:

```
export LC_NUMERIC="en_US"
```

Once installation is finished, you can reset this value by setting it to the original locale. This problem can occur for any locale which does not use a period as the decimal separator.

### Should I install Kylix as root or a regular user?

Installing Kylix as root has the advantage of allowing all users to access the Kylix installation, provided you install it into a "shared" location. I reccomend installing Kylix as root into the directory /usr/local/kylix. However, if you are going to be the only user using Kylix, you may want to install it as that user into your home directory.

To install as root, type **su** from the command prompt and enter the super user password. Then, run the Kylix installer.

## Article #27405: Borland Delphi Presales Frequently Asked Questions

### Can Delphi output Java byte code?

No. Use [JBuilder](#) for Java development.

### Are the ADO components in Delphi compatible with Microsoft's Jet engine 4?

Yes.

### Can I use components written in an earlier version of Delphi than the one I have?

Yes, though Delphi components from previous versions must be recompiled from source code in Delphi 5. This is true for all 32bit versions of Delphi.

### What is TeamSource?

TeamSource is a workflow management tool for helping application development teams manage their daily tasks in a shared development environment. TeamSource uses a version control system, such as PVCS, for storing and retrieving shared files, but goes beyond simple version control to manage and coordinate the process of using a parallel model of source control.

### Does PVCS work with Delphi?

Yes, but PVCS does not ship with Delphi.

### What is the Integrated Translation Environment?

The Integrated Translation Environment (ITE) is a suite of tools that facilitates software localization and simultaneous development of applications for different locales. Because of its integration with the Delphi IDE, the ITE lets you manage multiple localized versions of an application as part of a single Delphi project group. The ITE ships with the Enterprise and higher editions of Delphi.

### Can I add the Integrated Translation Environment to my Professional or Standard version?

No. You will need to upgrade to the Enterprise or Architect version to get the ITE.

### What are some of the differences between Delphi Standard/Professional/Enterprise/Architect?

See <http://www.borland.com/delphi/index.html>

### Can I still take advantage of all the new language and compiler features if I only have the standard version?

Yes, the core compiler is the same throughout the different versions of Delphi being offered (e.g. Standard, Professional, Enterprise, etc.)

### Is there a Translation Suite for Delphi?

Yes, Delphi Enterprise now ships with Borland Translation Suite.

### **Can I develop Windows CE applications with Delphi?**

No.

### **Can I take advantage of the new data types MS SQL Server 7 offers?**

No, not with the SQL Links driver. Microsoft no longer supports DB-LIB with the release of MS SQL Server 7 which means that DB-LIB doesn't have support for the 4 new data types that SQL 7 offers - namely NTEXT, NCHAR, NVARCHAR and GUID. In order to successfully use new types offered by SQL Server 7 and above you'll need to use CT-LIB, or use dbGo.

### **What vendors/versions of ODBC drivers have Delphi and the BDE been tested with?**

Please see the list in the BDE readme.txt or online at <http://www.borland.com/devsupport/bde/odbccertinfo.html>

Last Modified: 16-APR-03

## Article #27406: What do I do if I am getting missing or corrupted file messages?

### Question:

What do I do if I am getting missing or corrupted file messages?

### Answer:

You will often find "default" versions of these files on the CD for your Borland product.

First, search your system for the files listed in the error message by going to Start | Find | Files or Folders...

Type the name of the file, Look in: your local hard drive and click Find now.

If the file(s) are not on your system then copy them from the Borland CD to your hard drive. If the file(s) are on your hard drive then try checking the path to make sure the files are in the correct directories. If you still get the error then try copying the "default" file(s) from the Borland CD over the file(s) on your system, replacing them. Be sure to remove the Read-Only attributes.

Last Modified: 13-JUN-01

## Article #27407: How do I determine if I have a bad CD?

### Question:

How do I determine if I have a bad CD?

### Answer:

It is extremely unusual to have received a CD that is corrupt. In many cases, the CD-ROM itself is not reading the CD properly. One of the following actions may correct the problem, or allow the installation to proceed:

- Try a hard drive installation.
- If the CD-ROM is external, try turning the CD-ROM drive on it's side. As strange as this may sound, in many cases it will change the behavior.
- If you are using Windows drivers, switch to the manufacturer's CD-ROM drivers (try the reverse if you are using the manufacturer's drivers). Also, check with your manufacturer to obtain a more recent copy of their driver.
- Compare the file size of any files that you suspect are corrupt to the file size of those on your CD. If you can copy the installation directory from the CD to the hard drive, and the file sizes match, then the CD is most likely fine -- the problem is elsewhere.
- If the CD-ROM drive simply will not read from the CD at all (and works on other CDs), then replacing the CD with an identical CD will probably not work either. This is usually due to the fact that there are different CD-ROM formats and not all drives can read all formats. Be sure to check for firmware updates for your CD drive. Alternately, you could try using another CD-ROM drive (or copy the files over the network from another machine).

## Article #27411: Borland Delphi Install Frequently Asked Questions

### My system freezes when I start Delphi - I don't even see the splash screen.

Check display colors - Delphi cannot run in Windows 98 with 16 colors. If that does not fix the issue then add the following line to the system.ini file under the [display] section: BusThrottle=1 (reboot afterwards). This tells the Video card that it cannot dominate the Bus and must give some time to the OS. It looks as if the problem is the video driver is not releasing the Bus back to the OS after it switches to main memory.

### When I start Delphi I see the splash screen, then my system freezes.

The problem is most likely a compatibility conflict with the video driver. Borland tests its products against generic S3 drivers provided by Microsoft or S3 Inc. Any drivers compliant with this standard should not cause this problem with Delphi. Video drivers that do not fully comply with this standard may or may not function correctly with Delphi.

Possible fixes:

- Turn Hardware acceleration off (Win 95) or down to none (Win 98).
- NT - turn off bitmap caching.
- Delphi 4 - Download Update Patch 3 (contains a work-around).
- Try starting in Safe Mode (Win 95) or VGA mode (NT).
- Contact your specific video card vendor about getting a compatible generic S3-compliant video driver.
- Try variations of color depth and resolution.

### There were no errors during installation, but when I run Delphi there are no components on the component palette.

#### Windows 2000:

If you are running Delphi 6 this most commonly occurs if you install 3rd party components before running Delphi at least once after installation. Registry settings are made for Delphi the first time it is run (and subsequently the first time any additional user runs it). If components are installed before those settings are in place things can get messed up [technical term]. There is a utility that comes with Delphi 6 to fix this. Located in the bin directory or on the CD, it is called **D6RegClean.exe**. Running this (ignore warning messages) and then running Delphi will restore your component palette. You will then need to re-register and reinstall any additional components.

*Note: This utility is designed specifically for issues with Windows 2000. If you are using a different OS please see other suggestions below.*

#### Windows NT:

Delphi 5 or earlier: Most likely Delphi was installed by an administrator or a user with administrator rights and the user currently logged on does not have administrator rights. The component library is failing to load because we don't have the registry keys that tell us where the packages are located.

Install first as Admin, then do a 'Registry Keys Only' install for each user to get all the necessary DLL's and registry key entries to run Delphi under a specific user profile.

Delphi 6: This shouldn't happen :) Try uninstalling and reinstalling.

### **Windows 95/98:**

It is possible for an older version of this file to be installed (overwriting the current version) by another product. If this happens then run the comctl32.dll update on the Delphi CD. It is in the Info/updates directory and is called 40comupd.exe for Delphi 4. This file is also updated with Delphi 4 Update Pack 3. For Delphi 5, the file is in the install directory on the CD. For Delphi 6 the file is called:50comupd.exe, and is located in InfoExtrasComctl on the CD.

**Delphi starts fine, but the component palette display is corrupted. Part of one icon appears on part of the next, images are drifting off the buttons, the wrong images on buttons, etc. Restarting the computer does not help.**

The problem is most likely a compatibility conflict with the video driver. Borland tests its products against generic S3 drivers provided by Microsoft or S3 Inc. Any drivers compliant with this standard should not cause this problem with Delphi 4 or 5. Video drivers that do not fully comply with this standard may or may not function correctly with Delphi.

Possible fixes:

- Try running with video hardware acceleration turned down to none. This will identify it as a video driver conflict if it eliminates the problem.
- Try running Delphi with Computer in safe mode (Win95) or VGA mode (NT).
- Try running the update 40comupd.exe found in the infoupdates folder of the Delphi 4 CD. For Delphi 5 run the Dcom95.exe in the MDAC directory or the 40comupd.exe from the install directory on the CD. This updates the file comctl32.dll. (Note: installing Internet Explorer 5.x or newer will also update this file).
- Contact your specific video card vendor about getting a compatible generic S3-compliant video driver.
- Try variations of color depth and resolution.

**I installed Update Pack 3 for Delphi 4, and now my toolbar icons are corrupted.**

This is a video driver problem. This update changes the way the Image List is handled in order to correct the problem with the component palette (see Component Palette FAQ). This is a rare problem and may require reinstalling Delphi without the service pack if the video driver issues cannot be handled another way.

**What is installation error 113?**

This error occurs when there are problems reading files from the CD. Delphi requires a 32-bit CD-ROM driver in order to read long file names. If you have a 16-bit CD-ROM driver you will need to update to 32-bit. The reason this happens with Delphi (and usually not with other programs) is because Delphi installs by copying the Runimage directory, which contains long file names, from the CD to the hard drive. Typically, other installation programs unpack a compressed file. Contact the manufacturer's web site for an update.

To verify that you have a 16-bit driver:

- Check device manager in Control Panel - if no CD-ROM then it's 16-bit.
- Go to Explorer and view the Runimage directory on the CD. If there is a tilde (~) in any of the file names then the name is long and is being truncated.

Possible fix:

- Autoexec.bat and Config.sys - remove any reference to the 16-bit CD-ROM and restart. Windows might load new drivers. If not, manually add the new drivers.

Other Issues:

- This error can happen when someone is installing off of a network and has not actually mapped a drive to the correct location (they simply share the folder). Setup needs to see the Install and Runimage folders in the ROOT directory of a drive. Right click My Computer->Map Network Drive...
- This can also happen if you are trying to do a hard drive install, but have not put the files in the ROOT of the drive.

### **What is installation error 117?**

A certain batch of CD's produced by Borland contained a glue-like substance on them that causes this error because a track on the CD cannot be read. The solution is to clean the CD using a glass cleaner like Windex. The other possible cause of this error is a damaged or scratched CD. If cleaning the CD does not make the error go away then customer should call the order desk (1-800-932-9994) to order a replacement CD.

### **I get installation Error \_ins5176 at the end of my installation.**

This is an Install Shield error. If the install continues and everything seems to work fine, then it can be ignored (the error happens during installation cleanup). Otherwise, it's much more serious and there's no easy solution. Try uninstalling the product, including registry entries, and doing a hard-drive installation in SAFE mode. This usually happens on a machine that already has another version of Delphi on it and has to do with the failure to register an OCX that is already registered.

### **What does the error Can't find PVCS when installing Delphi 4 Pro mean?**

This is an error in the install program and can be ignored. PVCS comes with Delphi 4 C/S but not Delphi 4 Pro, but can be installed with Delphi 4 Pro if customer already has PVCS.

### **What does BORDBK60.DLL or (BORDBK50.DLL for Delphi 5),(BORDBK40.DLL for Delphi 4) is missing or not registered error mean during installation or startup of Delphi?**

If the installation does not complete the cause of the problem is likely due to a software conflict. Some anti-virus software and certain NT Internet Services have been known to prevent bordbk60.dll and/or html.ocx from being registered with the operating system. In this case the best solution is to try eliminating the software in question and then try reinstalling Delphi 6. If that is not a viable solution, try step 1 below to manually register the bordbk60.dll (BORDBK50.DLL for Delphi 5),or (borbdbk40.dll for Delphi 4) or html.ocx. If the install does complete:

1. Run TREGSVR manually to register the dll. TREGSVR can be found in the Delphi 6, 5 and 4 / bin directory. To register the DLL you would type:

```
tregsvr bordbk60.dll
```

in the directory where the DLL resides (assuming you have the Delphi 6, 5 or 4 /bin directory on your path, otherwise you would include the path to bordbk60.dll).

Delphi 4: If TREGSVR says the dll has been successfully registered, but Delphi 4 doesn't work, then you have probably uninstalled Delphi 4 AFTER applying Update 2, and then reinstalled without applying Update 2. Hence, the DLL is installed correctly but Delphi 4.00 does not know how to use the Delphi 4.01 version of the DLL. To correct this problem install update pack 2 and then your version of Delphi 4 will correspond to the version of the DLL on your system.

### **How do I know which version of Delphi I have?**

#### **Delphi 6, 5, 4:**

The menu option Help/About tells you what build version you have and what service packs are installed.

#### **Delphi 3:**

Delphi 3 did not update the about box. Look at the time stamp for Delphi 32.exe if it is 3:00 am it's unpatched, 3:01 you have 3.01 and 3:02 you have 3.02. There is also a Delphi/BDE version utility available on the Borland web page under DOWNLOADS.

### **How do I completely uninstall and reinstall Delphi?**

1. Back up all project files which are located under the Delphi directory.
2. Optional: back up aliases by backing up idapi32.cfg, using it to replace the newly installed idapi32.cfg after reinstallation; It is recommended that all third party and custom components be reinstalled after the complete reinstallation of Delphi.
3. Use the Windows add/remove programs utility to remove Delphi, answering yes to remove all files
4. Manually remove the Delphi directory from your system.
5. If you are using Delphi 6 on Windows 2000, run the utility D6RegClean.exe off of the CD.
6. Install Delphi using the following steps: Insert the Delphi CD into CD-ROM Drive. If auto-play is enabled, the Delphi Setup Launcher will automatically run. If the Delphi Setup Launcher does not run automatically, run install.exe in the root directory of your Delphi CD. Follow the on-screen instructions.
7. If you backed up your aliases, copy the backed up version of idapi32.cfg over the newly installed idapi32.cfg
8. Install all third party and custom components.

### **How do I install Delphi from a local hard drive?**

You will need approximately 184 MB of hard drive space to temporarily store the installation files, 160 MB for the complete installation and free space to hold temporary files, on the drive that has windows while the installation program is running.

1. Put the Delphi CD in the drive and choose Browse the CD.
2. Copy the Install folder to the root directory (i.e. not inside any subfolders) of the local drive you will be installing from.
3. Copy the Runimage folder to the root directory of the same drive. This may take a very long time. Verify that the entire folder was copied correctly. Right-click on the folder and choose properties. This folder should contain the same number of files that the one on the CD-ROM contained.
4. Copy all of the remaining files (autorun.inf, delphi.ico, deploy.txt, etc.) to the root directory of the same drive.
5. Reboot into Safe Mode or VGA mode and double click on the install.exe that you now have on your hard drive and install Delphi as you normally would.
6. Reboot in normal mode and verify that Delphi runs correctly. Once you have done this you can delete all the files that you copied over from the CD-ROM.

### **What is Safe Mode or VGA Mode?**

Safe mode is the method for booting into a simple system configuration under Windows 95\*. VGA mode is the diagnostic mode under Windows NT. When Windows boots into Safe mode or VGA mode, it uses basic default settings that will run the operating system with minimal functionality, meaning it loads a bare bones operating system. Hardware, like your CD-ROM drive, may not function in Safe mode or VGA mode because the drivers are not loaded. Because of this it may be necessary to copy the Delphi installation files to the hard drive before restarting in safe mode (See Hard Drive Install FAQ).

\*Windows 98 has a safe mode but it has a different functionality and may not be helpful in resolving install issues. Specifically, it loads the current video driver instead of the default VGA driver provided by Microsoft, so starting in safe mode in Windows 98 will not resolve issues related to the video driver. You will need to manually change the driver.

## **How do I start my computer in Safe mode (Windows 95) or VGA mode (Windows NT)?**

Safe Mode: There are two ways:

1. Hold down the SHIFT key as you reboot until the Windows screen comes up.
2. When you restart, watch the screen for the text Starting Windows 95. When you see this hit F8 and choose Safe Mode from the option menu which comes up.

VGA Mode: Windows NT should offer a menu at start up where you can select VGA mode.

## **Why does the splash screen keep popping up?**

Either you have a bad CD-ROM driver, or a slightly damaged CD that one computer may read fine but this particular computer is not as forgiving. Try a hard drive installation or update the CD-ROM driver. You will need to contact customer service in the case of a damaged CD.

## **Why is Delphi 4 running slower than Delphi 3?**

Make sure Service Pack 2 and 3 have been installed. The debugger hooks were slow starting and finishing which caused slowness.

## **What does the ICON IMAGE IS NOT VALID error mean?**

Chances are good that you are using a Micron (or other factory assembled system) computer which has a proprietary version of the OS (95, NT, 98). You may be able to successfully install Delphi by uninstalling and re-installing the OS, or in the worst case scenario you might need to install a non-Micron-proprietary OS. Also, check to see if there is more than one copy of bordbk60.dll for Delphi 6, bordbk50.dll for Delphi 5 or bordbk40.dll for Delphi 4 on the machine.

## **Delphi used to work fine but now I get random access violations in the IDE.**

You most likely installed a bad component or package that was not written or compiled for Delphi 6, 5 or 4. Try uninstalling custom components one by one (or package by package) until the problem goes away, then get in touch with the component vendor regarding this issue.

**Whenever I save, even a blank project, I get '<garbage>' is not a valid identifier. If I try and save again I get '<garbage>' is not a valid identifier.**

Uninstall Delphi. Make sure no other software is running, especially antivirus software, and reinstall Delphi. Alternately, a customer reported that ImageFox from ACDSYSTEMS was the source of his problems, but this has not been confirmed or disproved.

**I just installed Delphi and when I access the Environment Options or open up one of my projects, I get an error message: 'Delphi32 caused a GPF in module MACXW4.DRV at...' and then Delphi shuts down.**

More than likely this is a video driver related problem. Downloading the latest video drivers for your video card should solve the problem. You can also try turning hardware acceleration off.

**What does BDE Error 8712 - Object not found mean?**

Be sure there is only one version of BDE installed on machine. To verify this, search for idapi\*.dll. Also, try renaming idapi.cfg or turning off virtual alias to see if its a ODBC problem.

**Why am I having preview and paper size problems in QuickReports? (Delphi 4 only)**

The latest version of QuickReports, version 3.0.5, has several bug fixes including some related to custom paper size and print preview. This version comes with Delphi 5. An upgrade is available for Delphi 4 users from the QuSoft web page at:

<http://www.qusoft.com/scripts/download.dll>

The file is called QR305SD4.EXE

**I am getting runtime error 255 when using Delphi 3.**

This error is reported if there is a hardware or other exception that isn't caught (this error is caught in Delphi 4). Error 255 in Delphi 3 appears to be caused by certain video drivers, or by workstations using the AMD NexGen x586 CPU. If your PC is not using the AMD NexGen x586, then the problem is probably the video driver. Try changing driver configuration, getting a newer video driver, or using the generic S3 drivers provided by Microsoft or S3 Inc.

**Article #27428: Error "database unavailable" when connecting to Interbase via IIS.**

**Question:**

Why am I getting the error "database unavailable" when connecting to Interbase via IIS?

**Answer:**

Go into the services window on the machine your apps are running on and make sure that all services such as Interbase server, IIS Admin and web Publishing and Interbase Server have the "Allow service to interact with desktop" option checked. This is accessed by right clicking the service and going to properties | Log On.

Note: This may not be the same as "Unavailable Database" which is generally caused by not having your Interbase server running.

**Article #27442: SIGSEGV error when running MySQL on Kylix.**

**Question:**

Why am I getting the error SIGSEGV when attempting to run a dbExpress demo in Kylix?

**Answer:**

DBExpress may not currently work with MySQL v3.32. It should work fine with v3.22.32.

Last Modified: 09-NOV-01

## Article #27459: What is the message "Generating font matrix" when starting Kylix?

### Question:

Why am I getting a message that says "Generating font matrix. Please wait" when I start Kylix?

### Answer:

This should only happen the first time you start Kylix using the startkyix script. The font matrix is used by the Wine implementation of the Win32 API and you should wait until it finishes. There have been reports of this appearing to take forever in some Linux versions. If it seems to take too long you can try canceling it and Kylix should still run okay.

Last Modified: 09-NOV-01

## Article #27463: My console application generates a Runtime Error when it starts for no apparent reason.

### QUESTION:

My Console Application compiles fine, but when I run it I get a Runtime Error 6. What is this error and how do I fix it?

### ANSWER:

Runtime error 6 is defined in the online help as:

```
106      Invalid numeric format  Reported by Read or Readln if a numeric value
read from a text file does not conform to the proper numeric format.
```

The most probable cause of this error is that the compiler directive for APPTYPE has not been set to console. Your console application you should set the APPTYPE to CONSOLE at the beginning of you application. If you are using dcc32 to compile you program you could also pass the /CC command line option. Your console application should look something like this:

```
program OneCoolDelphiProgram1;

{$APPTYPE CONSOLE} //This tells the compiler that the program is a console type

uses
  SysUtils;

begin
  //Insert super cool Delphi Code here
end.
```

**Article #27478: What version of TeeChart is supplied with Delphi 6?**

**QUESTION:**

**What version of TeeChart is supplied with Delphi 6?**

**ANSWER:**

The version supplied with Delphi 6 is TeeChart Standard 4.04.

Last Modified: 09-JUL-01

## Article #27486: Where can I obtain the help file for the VtChart component?

### QUESTION:

I can't bring up help for the VtChart component found under the ActiveX tab. It says contact your application vendor for the updated help file. Where can I obtain the help file for the VtChart component?

### ANSWER:

The Windows Help engine on Windows 95, 98, and Millennium uses a 16-bit list box in the Help Topics dialog's Index tab, and can display no more than 32,767 keywords. If this limitation is exceeded, the Index is blank. Rather than adding this help file to the main Delphi help system, simply open up the help file when you need to use it. The help file can be found in the following directory (for default installs):

C:\Program Files\Borland\Delphi5\OcxVciImpressVcfi.hlp

Simply navigate out to the directory where this file is located and double click on it (using Windows Explorer) and it should open right up.

**Article #27506: How to change file attributes programmatically.**

**ANSWER:**

It might be convenient to change file attributes during the run time of your application. For example you might want to create a temporary file to take advantage of Windows' ability to manage the file in memory for quicker access. To change a file's attributes at runtime you can use the function **SetFileAttributes()**. To see exactly what attributes you can set see the help for the Windows SDK ( From the Start menu go to the Delphi menu and choose Help | Windows SDK ).

**Article #27511: Insufficient disk space on C: drive while installing Delphi to D: drive.**

**Question:**

Why am I getting an error that there is not enough space on C: when I'm installing to D:?

**Answer:**

Delphi needs to copy many files to the Windows System32 directory and requires around 28 MB of space on the drive where this directory is located - even if it is not the directory where you are installing Delphi.

Last Modified: 13-JUL-01

## Article #27522: Why is there no "Save" button in the save dialog box?

### Question:

Why is there no 'Save' button in the save dialog box?

### Answer:

In the Save dialog box if you click on one of the directories listed then the Save button caption will change to 'Open'. If you then click the open button it will open the directory you have selected. If you have selected the '.' (Linux only), clicking on open will bring you up to the parent directory of the directory you are currently in. In order to get the button to say 'Save' again just click somewhere else, such as in the File name edit box.

Last Modified: 17-JUL-01

## **Article #27541: Problem generating font matrix in Kylix.**

### **Question:**

My install of Kylix was successful but after startup with "startkylix" I see the message "generating font matrix" forever. What should I do about this?

### **Answer:**

If you installed as root the font matrix will be created for each user the first time they start Kylix. How long it takes depends on the number of fonts that you have installed and the speed of your machine. If it seems to freeze or last a long time you should still be able to run Kylix even if you terminate the font matrix generation.

### **Possible workarounds**

This problem could be caused by a bad truetype font. If you have any Windows tt-fonts installed try removing them. Another thing to try is to change the order of the font search path in XF86Config or in your tt-fontserver. Try to put the tt-fonts at the end of the list.

Here is another suggestion from our newsgroups:

Rename the file "transdlg" located in your Kylix bin directory to "transdlg.renamed" and then run Kylix.

This is an issue we are currently looking into. This document will be updated when more information is available.

## Article #27543: How do I set a custom CVS PServer port?

### Question:

How do I configure the CVS PServer to use a different port value than the default?

### Answer:

You may do this from the commandline in the following way:

Windows:

```
set CVS_PSERVER_PORT=<custom port value>
```

Linux:

```
export CVS_PSERVER_PORT=<custom port value>
```

Last Modified: 30-JUL-01

**Article #27544: Some links and/or executables are missing after running Kylix install.**

**Question:**

I installed Kylix but now I can't find certain files or links on my machine. Why were they not installed?

**Answer:**

When you install Kylix you are prompted for two destination directories - one for files and one for links. If you installed as a user but specified a directory for your links that the user does not have write access to, such as `/usr/local/bin`, then the file will not be written because only root can write to this directory. The solution is to install everything in directories that the installing user has full access to such as `/home/username/kylix` and `/home/username/bin`.

Last Modified: 01-NOV-01

## **Article #27545: Error "permission denied" when trying to run Kylix**

### **Question:**

Why am I getting the error "permission denied" when I try to run Kylix?

### **Answer:**

If you installed as root and accepted the defaults then Kylix was installed under the /root directory. By default the permissions for this directory are 700 so only the root user can access this directory tree for read, write or execute. If users besides root are to use Kylix it must be installed in a directory all will have access to. See the file INSTALL that comes with Kylix for more information.

**Article #27547: The Buttons are missing or grayed out in Database Desktop.**

**PROBLEM:**

**Database desktop is not loading correctly, all the buttons are missing.**

**SOLUTION:**

This problem is due to a compatibility issue with Windows 2000 and Paradox.

In Order to resolve this issue you must use the "Application Compatibility Tool". It is located in the resource kit on the Windows 2000 CD. You can also download the Application Compatibility Tool directly from Microsoft's website:

<http://msdn.microsoft.com>

Once the resource kit is installed then select

Start

Programs

Windows 2000 Support Tools

Tools

Application Compatibility Tool

Where it says "Start the following program" browse to the location of the executable for DataBase Desktop and select it (dbd32.exe) or you can simply type in the full path and file name.

For Operating System select "Windows NT4 SP5".

Select "Make the above check box settings permanent".

## Article #27549: How do I create an executable file using the command line directive in Linux with Kylix?

### QUESTION:

How do I create an executable file, i.e. foo.exe, using dcc in Kylix?

### ANSWER:

Create the project file, i.e. foo.dpr, using VI, Pico or some other text writing tool. Next, at the command line type: dcc foo. You can pass in flags like -BE: dcc -BE foo, the will build and execute the file. There are a number of different flags you can pass in, look at the help for dcc for a full listing and description.

```
program foo
```

```
uses
```

```
    SysUtils;
```

```
begin
```

```
    writeln('Hello World');
```

```
    readln;
```

```
end.
```

**Article #27550: Error message "Failed to create process" when trying to use the Corba Server and Client Application wizards.**

**QUESTION:**

**I am getting an error message "Failed to create process" when trying to use the Corba Server and Client Application wizards in Delphi 6. What is causing this?**

**ANSWER:**

This problem derives from a user not having enough rights. In order to use the Corba Client and Server Wizards, you must have full administrative rights. Without administrative privileges, you will get the "Failed to create process error" or some error relating to this. Once the user is given administrative rights, the wizards will work correctly.

Last Modified: 03-AUG-01

**Article #27551: Getting Fatal Error "File not found: 'OrbPas.dcu'" when using a Corba Object or Corba Data Module in Delphi 6.**

**QUESTION:**

**Getting Fatal Error "File not found: 'OrbPas.dcu'" when using a Corba Object or Corba Data Module in Delphi 6. Why won't this work?**

**ANSWER:**

If you look at the Corba Compatibility notes in the Delphi 6 readme, you will see the following:  
The TypeLib interface and CorbaConnection component are only compatible with the VisiBroker 3.3 ORB.  
If you installed Visibroker 4.1 when you installed Delphi 6, this means you cannot use the Corba wizards found under the File | New | Other | Multitier tab. If you need these components, you will have to uninstall Visibroker 4.1 and install Visibroker 3.3.

Last Modified: 03-AUG-01

## Article #27553: What can I use in Kylix, as a possible replacement for ShellExecute in Windows?

### QUESTION:

How do I launch a Linux application from Kylix?

### ANSWER:

There is a method you can use to execute a shell command that will launch the application: `system()`. This executes the command you specify in the string parameter, you will need to include **libc** in your uses clause. There is a return code of -1 if the call was not successful. You could do something like this:

```
TForm.ButtonClick(Sender: TObject);
var
    idError: integer;

begin
    idError:= libc.system('emacs');
    if idError = -1 then
        ShowMessage('Error: Program did not start');
end;
```

Last Modified: 05-FEB-02

## **Article #27554: How to create a console application in Kylix.**

### **QUESTION:**

How do I create a console application in Kylix?

### **ANSWER:**

To create a console application in Kylix, you need to make sure you check the "Use Launcher Application" check box. The check box is located on the Run Parameters dialog page, in the Local tab. To get to that dialog go to: Run | Parameter. Now, if you run your application, you will notice that a console window appears, if you are in Xwindow.

**Article #27555: How to change the shape of your forms.**

**QUESTION:**

How can I change the shape of my form?

**ANSWER:**

There are a number of Windows API calls you can make to do this. You can use these calls on any component that is descendant of TWinControl, like TForm. Here is a list of the different API calls:

```
CreateEllipticRgn  
CreateEllipticRgnIndirect  
CreatePolygonRgn  
CreatePolyPolygonRgn  
CreateRectRgn  
CreateRectRgnIndirect  
CreateRoundRectRgn
```

The example I use is CreateEllipticRgn, here is one way of using it. You could put this call with in a button click.

```
SetWindowRgn(Form1.handle,CreateEllipticRGN(0,0,Width,Height),True);
```

Last Modified: 03-AUG-01

## Article #27561: How to capture the current cursor icon and draw it.

### QUESTION:

How do I get the handle of the current cursor and draw on my form?

### ANSWER:

There is a Windows API call to do this: DrawIconEx(). This function draws an icon or cursor in the area specified by the X and Y coordinates, that are parameters to this function. You can pass it a given handle and it will draw that icon. Here is an example that sets the cursor handle and draws the icon.

```
procedure TForm1.Button1Click(Sender: TObject);
var
    HCursor : THandle;
begin
    HCursor:= Screen.Cursors[Ord(Screen.Cursor)];//Gets the cursor handle.
    //
    //          X    Y          Size
    DrawIconEx(Form1.Canvas.Handle, 150, 150, HCursor, 32, 32,
                0, 0, DI_NORMAL);//Draws to canvas
end;
```

## Article #27572: How to stop IIS when you are writing web applications as ISAPI dll's

**Question:** How to I completely restart Internet Information Services (IIS) in order to unload my ISAPI DLL so I can rebuild it?

**Answer:** On Windows 2000 with IIS5, use the command iisreset from a command prompt. On Windows NT4 with IIS4, use the commands:

```
mtxstop  
net stop iisadmin /y  
net start w3svc
```

You can place these commands in a .bat file to easily restart your server at will.

## Article #27578: Oracle Stored Procedures Generate Access Violations in ORA805.dll

### QUESTION:

Oracle stored procedure worked fine with BDE 5.0.1 but later versions generate Access Violations. Is this an incompatibility with older versions of Delphi?

### ANSWER:

The problem isn't a bug in SQL links, nor is it a backwards compatibility problem with the BDE. The D4 shipping of SQLORA8.DLL didn't use the OCI 8 calls to get the stored procedure schema info, instead we were using OCI 7 calls. It is the attempt to get the stored procedure schema with OCI 8 calls that is causing the access violation.

The current work around is to use the BDE 5.0.1.

Last Modified: 04-AUG-01

**Article #27579: How to use TADOTable Seek procedure.**

**QUESTION:**

When I use TADOTable.Seek I get an access violation, "Object or provider is not capable of performing requested operation." In the help it is documented that all I need is Access 2000 and the Jet 4 Provider. How do I get Seek to work?

**ANSWER:**

The online help is slightly miss documented for this procedure. There are two other properties that need to be set in order to successfully execute the seek procedure. You can download a demo project from Code Central [here](#).

To avoid the access violation you have to set two properties for TADOTable. The first is to set CursorLocation := clUseServer. The second step is to set the TableDirect property to True. You can also specify the IndexName property to be the primary key of the table, but this seems to be optional.

Last Modified: 04-AUG-01

**Article #27588: Lost trial key.**

**Question:**

How can I get a key for the trial version sent to me if I lost or never received one?

**Answer:**

Go back to the community page where you completed the survey. Login and click the link to complete the survey and it will bring you to the screen where you can order the serial number and have it sent again. Be sure to verify that your email address is correct.

Last Modified: 06-AUG-01

**Article #27593: Error "Unsupported calling convention: REGISTER" in SOAP Application.**

**QUESTION:**

**Why am I getting the following Debugger Exception Notification: "Project Client.exe raised exception class Exception with message 'Unsupported calling convention: REGISTER'. Process stopped. Use step or run to continue." after creating a SOAP application and attempting to run the client?**

**ANSWER:**

This problem occurs because the stdcall calling convention was not used in the function declaration in the server. Include stdcall at the end of the function definition and the problem will be resolved. In the Server Interface file and in the Server Implementation file the function definition should look similar to this:

```
function Foo: String; stdcall;
```

The reason stdcall must be used is that the default calling convention is Register which passes parameters from left to right; that is, the leftmost parameter is evaluated and passed first and the rightmost parameter is evaluated and passed last. In Windows, the operating system API's use stdcall which pass parameters from right to left.

## Article #27600: What is DBGo?

### Question:

What is DBGo?

### Answer:

DBGo is another name used for the ADO add on components for the Professional version of Delphi - also known as ADOExpress.

Last Modified: 06-AUG-01

**Article #27602: Do the ADO components come with the professional version of Delphi 6?**

**Question:**

Do the ADO components (DBGo) come with the Professional version of Delphi 6? It states in the documentation that they do not.

**Answer:**

The documentation is wrong. These components did not come with the Professional version of Delphi 5, they were an optional add-on, but they do come with the Professional version of Delphi 6.

Last Modified: 06-AUG-01

**Article #27613: I can't find ADO Express for Delphi on shop.borland.com. Where can I buy ADO Express for Delphi 5?**

**QUESTION:**

**Where can I obtain ADO Express for Delphi 5?**

**ANSWER:**

ADO Express is now included in Delphi 6 Professional and Enterprise Editions. It is no longer available for Delphi 5.

Last Modified: 16-APR-02

**Article #27647: What features come with the Delphi 6 free trial?**

**Question:**

What features and extras come with the Delphi 6 free trial?

**Answer:**

The trial version includes Delphi 6 Enterprise, Visibroker, and Interbase. InstallShield is not included.

**Article #27656: Not enough disk space to install Delphi 6 on Windows 98.**

**Question:**

On Windows 98 I am told that I don't have enough space to install the product, even though I have plenty of Disk space?

**Answer:**

This is a problem with the MSI. Usually, you can proceed to exit the installer and then try install over again. The second time you try to install there shouldn't be any problems.

Last Modified: 14-AUG-01

## Article #27699: Heterogeneous queries with MSSQL 7

### Question:

Why am I getting blank data or the error "Could not find object" when trying to do a heterogeneous query in Delphi?

### Answer:

The BDE does not support the new unicode data types introduced in MSSQL7 ([more info](#)). This will prevent you from doing the heterogeneous query if the columns you are linking are one of these data types. One workaround is to do the heterogeneous join using MS SQL 7 server and then access the data from Delphi using ADO. See the following for more: <http://msdn.microsoft.com/msdnmag/issues/0800/cutting/cutting0800.asp>

**Article #27702: Why reusing or inheriting from a Remote Data Module is not a good idea.**

**QUESTION:**

Why can't I reuse or Inherit from my newly created Remote Data Module(RDM), that I just placed into the Object Repository?

**ANSWER:**

The reason is, each Remote Data Module(RDM) needs to have a unique GUID and class ID associated with it. The GUIDs and class IDs are added to the registry, where the system references them to see which object they represent. You can copy your RDM from the Repository, however you will need to change the class ID and the GUID to a unique number. Though, I suggest leaving this chore to the system.

Last Modified: 28-AUG-01

**Article #27703: How to find what the user path is for their Environment Variables.**

**QUESTION:**

How can I get the path of the different Environment Variables in Windows2000?

**ANSWER:**

There is a function call that returns a string. You can use it in a button click and see that it returns the path of the variable you choose.

```
procedure TForm1.Button3Click(Sender: TObject);  
begin  
    ShowMessage(GetEnvironmentVariable('Temp'));  
end;
```

Last Modified: 31-AUG-01

## Article #27704: How to download a file from the Internet.

### QUESTION:

How do I download a file from a URL location?

### ANSWER:

There are a number of ways to do this, below is a simple code snippet that will give you an idea of how to do this. Make sure to add ShellApi, and UrlMon to your uses clause.

```
function DownloadInternetFile(Source, Dest : String): Boolean;
begin
  try
    Result := URLDownloadToFile(nil, PChar(Source), PChar(Dest), 0, nil) = 0
  except
    Result := False;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  SourceString, DestinationString: string;
begin
  //File location on the Internet.
  SourceString := 'http://www.borland.com/images/homepage/del6homemural.gif';
  //File destination.
  DestinationString := 'C:Tempdel6homemural.gif';

  if DownloadInternetFile(SourceString, DestinationString) then
  //This will display the file from your browser.
    ShellExecute(Application.Handle, PChar('Open'), PChar(DestinationString), PChar
(''), nil, SW_NORMAL)
  else
    ShowMessage('Error during Download ' + SourceString);
end;
```

## Article #27706: How to invoke the Windows ShortCut Dialog wizard.

### QUESTION:

How do I invoke the Create Shortcut dialog wizard for my application?

### ANSWER:

You will need to add ShellApi and Registry to your uses clause. Next, pass in the directory were you want your shortcut, you may want a variable here to get input from the user. For this example I use Temp:InvokeShortcutDialog('c:Temp');. However, to save it to the DeskTop you would instead do this: LaunchShortcutDialog('C:Documents and Settings"User Name"Desktop'); or use a string variable: PathShortcut : string, so the function call looks like this: LaunchShortcutDialog(PathShortcut);.

```
function InvokeShortcutDialog(Directory : string) : boolean;
var
  Reg : TRegistry;
  CmdLine : string;
begin
  Result := false;
  Reg := TRegistry.Create;
  try
    Reg.Rootkey := HKEY_CLASSES_ROOT;
    if Reg.OpenKeyReadOnly('.LNKShellNew') then
      begin
        CmdLine := Reg.ReadString('Command');
        CmdLine := StringReplace(CmdLine, '%1', Directory, []);
        Result := True;
        WinExec(PChar(CmdLine), SW_SHOWNORMAL );
      end
    finally
      Reg.free;
    end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  InvokeShortcutDialog('c:Temp');
end;
```

## Article #27707: How to close your application using the Escape key.

### QUESTION:

How can I make my application close when the "Escape" key is pressed?

### ANSWER:

Make sure that you set the KeyView property of the Form to True. This will make keyboard events occur on the form, before the active control. You should set this in the create event of the form. Below, you will find a code sample that demonstrates how to do this.

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Form1.KeyPreview := True;
end;
```

```
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  //The Escape key is #27.
  if key = #27 then
    Close;
end;
```

## Article #27708: Error 10 while installing Kylix

### Question:

What is causing Error -10 while installing Kylix?

### Answer:

It's possible that a previous version of Kylix was not uninstalled completely or that there is a problem with the RPM. [[more info](#)]. There are a couple ways to work around this. The first is to install as a user other than root. If you would rather not do this you can use the "-m" option on the setup script. So you would enter: `./setup.sh -m` from a vterm. This tells the script to not use the RPM.

## Article #27718: How can I make the background color different for alternating lines of text in a TListBox in Delphi?

### QUESTION:

How can I make the background color different for alternating lines of text in a TListBox in Delphi?

### ANSWER:

Here is one way of accomplishing this. After dropping a TListBox on your form, you must change the Style property of the TListBox to lbOwnerDrawFixed. If you fail to change the Style property, the OnDrawItem event will never be called. Put the following code in the OnDrawItem event of your TListBox:

```
procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index:
Integer;
  Rect: TRect; State: TOwnerDrawState);
var
  myColor: TColor;
  myBrush: TBrush;
begin
  myBrush := TBrush.Create;
  with (Control as TListBox).Canvas do // draw on control canvas, not
on the form
  begin
    if not Odd(Index) then
      myColor := clSilver
    else
      myColor := clYellow;

    myBrush.Style := bsSolid;
    myBrush.Color := myColor;

    Windows.FillRect(handle, Rect, myBrush.Handle);

    Brush.Style := bsClear;
    // display the text
    TextOut(Rect.Left, Rect.Top, (Control as TListBox).Items
```

```
[ Index ] ) ;  
    MyBrush.Free ;  
end ;  
end ;
```

## **Article #27719: Action Manager Component referenced in Text Editor Tutorial is Missing**

### **Problem:**

**When attempting to do the Text Editor Tutorial for Delphi 6 Personal, I can't find the Action Manager Component.**

### **Solution:**

The Text Editor Tutorial found in the Quick Start manual incorrectly states that it is for all editions of Delphi. The Action Manager Component is not included in Delphi 6 personal. This component is only included in the Professional and Enterprise version. This is a bug in our documentation and has already been addressed in the latest Help File updates. To obtain the latest help files, go to the following site <http://www.borland.com/techpubs/delphi/v6/updates/per.html>

After installing the new help files, in the IDE select Help | Delphi Help and under the contents tab you will see Tutorials. The updated Tutorial can be found there.

Last Modified: 16-JAN-03

Article #27726: WebBrowser1.GoBack and WebBrowser1.GoForward creating 'Unspecified error'.

## Problem:

Using TWebBrowser GoBack method at the beginning of the history list or using the GoForward method at the end of the history list causes 'Unspecified Error'. According to the Delphi Help *"GoBack has no effect unless the history list contains additional documents."*

## Solution:

This is a documentation error in the Delphi Help. If you look in Microsoft's Platform SDK documentation you will find the following: *"if the beginning of the history list has been reached the IWebBrowser2::GoBack method should not be used."*

If you want to have a button or similar component that will allow you to GoBack and another button that will let you GoForward using the TWebBrowser component, here is an example of the best way to proceed that will avoid the unspecified error.

In your application drop a TWebBrowser component on the form and two button components. Name the first Button btnBack and the next button btnForward. For both of these buttons, **change the enabled property to False**. In the OnClick event of btnBack the code should look like this:

```
procedure TForm1.btnBackClick(Sender: TObject);
begin
    WebBrowser1.GoBack;
end;
```

In the onClick event of btnForward the code will look like this:

```
procedure TForm1.btnForwardClick(Sender: TObject);
begin
    WebBrowser1.GoForward;
end;
```

These buttons are currently disabled and we only want them enabled when appropriate. To do this we will use the TWebBrowser's OnCommandStateChange event. The code should look like this:

```
procedure TForm1.WebBrowser1CommandStateChange(Sender: TObject;  
  Command: Integer; Enable: WordBool);  
begin  
  case Command of  
    CSC_NAVIGATEBACK: btnBack.Enabled := Enable;  
    CSC_NAVIGATEFORWARD: btnForward.Enabled := Enable;  
  end;  
end;
```

This will avoid throwing the "unspecified error".

## Article #27753: How to make sure the function DLLPROC is called when your DLL is unloaded.

### QUESTION:

Why isn't DLLPROC being called when my DLL is unloaded?

### ANSWER:

Due to RTL changes, the DLLProc was not being called appropriately. This change will fix the change that you may have noticed. Once you have completed the change, you will need to recompile the RTL and copy the new System.dcu into your project directory. Your project will use the newly created System.dcu with the fix included. In System.pas, navigate down to this method @@skipTLSproc.

```
@@skipTLSproc:
```

```
    { Call any DllProc }

    PUSH     ECX
    MOV      ECX,[ESP+8]//Changed from 4 to 8.
    TEST     ECX,ECX
    JE       @@noDllProc
    MOV      EAX,[EBP+12]
    MOV      EDX,[EBP+16]
    CALL     ECX
```

## Article #27757: How to create Interbase stored procedures that return parameters with TIBQuery.

### QUESTION:

When I try to create my stored procedure using TIBQuery I get either EIBInterbaseError 'SQL error code = -104 Token unknown ...' or EIBClientError 'XSQLDA index out of range'. How do I create a stored procedure in Delphi using IBX?

### ANSWER:

Most likely your stored procedure is returning parameters. If this is the case then you will need to do two things to your IBQuery. The first is to set ParamCheck to false. The second is to clear out the Params property. Assuming that your stored procedure is legal the code to create the stored procedure might look like this in Delphi:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    IBQuery.Params.Clear;  
    IBQuery.ParamCheck := False;  
    IBQuery.ExecSQL;  
end;
```

Last Modified: 16-SEP-01

## Article #27779: Where is proxies.dcu?

### Question:

Why am I getting the error "File not found 'Proxies.dcu'"

### Answer:

This error can occur when DesignEditors is added to the Uses clause. Do not statically link in the code in the ToolsAPI folder, it is there for reference purposes only. If this is a run time package then you should separate out the design time items and put them into a design time package. You should then add DesignIde.dcp to the requires section of your design time package.

Please see the following article for more information: <http://community.borland.com/article/0,1410,27717,00.html>

Last Modified: 05-FEB-02

## Article #27780: Missing components in Delphi 6.

### Question:

Why am I missing components after installing Delphi 6?

### Answer:

This most commonly occurs if you had a previous edition of Delphi 6 that you uninstalled. It is possible that there are registry entries left over from that installation because of the new way Delphi is creating the startup registry configuration. It can also occur if you run the stand alone register program or install third party components, which will create the D6 registry key, before actually running Delphi 6 for the first time.

The solution for any of these is to run the utility **d6RegClean.exe** that comes with Delphi 6, and then restart Delphi before installing anything else. d6RegClean.exe should be located in the bin directory or on the CD.

Also be sure you are not installing two different editions of Delphi 6 on the same machine (such as Personal and Enterprise).

## Article #27784: How can I create an identical binary executable in Delphi?

### QUESTION:

Does Delphi create binary identical executable files?

### ANSWER:

No, Delphi adds Timestamps in the executable. At this point there are not any flags you can set to get an identical binary executable. The Timestamps coincide with the file datestamp, so you could use this aspect to see if anyone has changed the application in anyway. Timestamps can also be used as a simple version control system, by comparing the executables. The compiler uses the system clock for the stamp.

## Article #27799: How to convert numbers into roman numerals.

### QUESTION:

How can I convert decimals into Roman numerals?

### ANSWER:

Drop a button, two edit boxes and two labels on the form. Add the code below. Enter numbers into the edit boxes, then press the button, to see the conversion in the labels' captions.

```
function DecToRom(Dec: LongInt): String;
const
  Nums : Array[1..13] of Integer =
    (1, 4, 5, 9, 10, 40, 50, 90, 100,
     400, 500, 900, 1000);
  RomanNums: Array[1..13] of string =
    ('I', 'IV', 'V', 'IX', 'X', 'XL',
     'L', 'XC', 'C', 'CD', 'D', 'CM', 'M');
var
  i: Integer;
begin
  Result := '';
  for i := 13 downto 1 do
    while (Dec >= Nums[i]) do
      begin
        Dec := Dec - Nums[i];
        Result := Result + RomanNums[i];
      end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := DecToRom(StrToInt(Edit1.Text));
  Label2.Caption := DecToRom(StrToInt(Edit2.Text));
end;
```

## Article #27805: How to get the date of the last day in the current month.

### QUESTION:

How do can I find out the date, of the last day in the current month?

### ANSWER:

Drop a button on a form and add the code snippit below. The show message dialog will reveal the date.

```
function LastDayCurrMon: TDate;
var
  y, m, d: word;
begin
  decodedate(now, y, m, d);
  m := m + 1;
  if m > 12 then
  begin
    y := y + 1;
    m := 1;
  end;
  result := encodedate(y, m, 1) - 1;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(DateToStr(LastDayCurrMon));
end;
```

**Article #27827: Making changes to my dBase tables causes McAfee to scan tables.**

**Question:**

How can I prevent McAfee from scanning my tables when I insert/update my table?

**Answer:**

There are no programmatic work arounds, nor are there any settings that can be changed in the BDE to prevent McAfee from scanning your dbf files. Any files that are modified by the BDE can cause McAfee to scan these files. This is due to the configuration of McAfee, which can be changed if so desired. Check your McAfee user manuals for further instructions on how to do this.

Last Modified: 09-OCT-01

## Article #27845: How to debug an Apache Shared Module

### Question:

I am running Apache on Windows and want to know how to debug Apache Shared Modules?

### Answer:

It is a straight forward task to debug Shared Modules in Delphi. The only thing that needs to be done is to set the Host Application and Parameters for the Shared Module's Project. From the Delphi menu bar go to Run | Parameters. Set the Host Application to point to Apache.exe, and specify the following parameters: -X -w -f "c:\path to\httpd.conf".

When you run the project be sure that IIS is not running. If you need IIS to run while Apache is running then change the Port value stored in httpd.conf.

Last Modified: 09-MAY-02

## Article #27846: Problems installing Delphi 6 Professional or Enterprise editions after uninstalling the free personal edition.

### Question:

Why am I getting the error "Can't load package c:borlanddelphi6Binproide60.bpl" when I run Delphi 6?

### Answer:

If you had the free personal edition installed previously on the same machine, and you registered the Professional or Enterprise edition with the same ID numbers, it is possible that the registry settings from the Personal edition are not being overwritten. This may be a problem with the registration system. The easiest way to resolve it is to register with a different name/email address than the one you used for the downloaded personal edition. This may require uninstalling everything and starting over.

When removing Delphi from your machine be sure to use Add/Remove programs from the Control Panel.

If you are using Windows 2000 you can try running the utility D6RegClean.exe located in the Delphi bin directory (or on the CD in the InfoExtras folder) after you unistall the Personal edition and before installing the Professional edition.

Note: You can not have two different *editions*, such as Delphi 6 Personal and Delphi 6 Professional, installed simultaneously. You can have different *versions* though, such as Delphi 5 and Delphi 6.

## Article #27890: Working around time zone issues with Web Broker

### Question:

Why are my short term cookies not working in WebBroker?

### Answer:

When using Cookies in webbroker, it assumes all times are in GMT for cookies so setting a cookie to expire in 2 minutes will not work unless if your timezone is GMT.

Here is a workaround.

```
uses
  {$IFDEF MSWINDOWS}Windows, {$ENDIF}
  {$IFDEF LINUX}Libc, {$ENDIF}
  DateUtils;

resourcestring
  RSFailedTimeZoneInfo = 'Failed attempting to retrieve time zone
information.';

function OffsetFromUTC: TDateTime;
{$IFDEF LINUX}
var
  T: TTime_T;
  TV: TTimeVal;
  UT: TUnixTime;
begin
  gettimeofday(TV, nil);
  T := TV.tv_sec;
  localtime_r(@T, UT);
  // __tm_gmtoff is the bias in seconds from the UTC to the current
time.
  // so I multiply by -1 to compensate for this.
  Result := -1*(UT.__tm_gmtoff / 60 / 60 / 24);
end;
{$ENDIF}
{$IFDEF MSWINDOWS}
var
  iBias: Integer;
  tmez: TTimeZoneInformation;
begin
```

```

// Copied from IdGlobal.pas
case GetTimeZoneInformation(tmez) of
  TIME_ZONE_ID_INVALID:
    raise EFailedToRetrieveTimeZoneInfo.Create
(RSFailedTimeZoneInfo);
  TIME_ZONE_ID_UNKNOWN   :
    iBias := tmez.Bias;
  TIME_ZONE_ID_DAYLIGHT :
    iBias := tmez.Bias + tmez.DaylightBias;
  TIME_ZONE_ID_STANDARD :
    iBias := tmez.Bias + tmez.StandardBias;
else
  raise EFailedToRetrieveTimeZoneInfo.Create
(RSFailedTimeZoneInfo);
end;
{We use ABS because EncodeTime will only accept positive values}
Result := EncodeTime(Abs(iBias) div 60, Abs(iBias) mod 60, 0, 0);
end;
{$ENDIF}

```

Use it as: Expires := Now + (however long in TDateTimeFormat)+OffsetFromUTC;

such as: Expires := IncMinute(Now, DefaultTimeout) + OffsetFromUTC;

Last Modified: 16-OCT-01

## Article #27908: Where is TReport in Delphi 6?

### Question:

Where is the ReportSmith component TReport in Delphi 6?

### Answer:

ReportSmith was removed from Delphi after Delphi 2. It was replaced by QuickReports. Since that time the TReport component still shipped with Delphi in order for developers to maintain backward compatibility, but the component was hidden. In Delphi 6 the component has been completely removed from Delphi. However it is still possible to compile a project developed with TReport because the file Report.dcu is still included on the Delphi 6 CD, in the directory

D:\Install\program files\Borland\Delphi6\Lib\Delphi2

In order to compile the project that contains TReport copy the two files Report.dcu and RSCONSTS.dcu to your Delphi6\Lib directory.

Last Modified: 27-FEB-03

## Article #27914: Borland license information is either invalid or missing

### Problem:

Able to successfully register Delphi with Borland. A dialog box pops up stating the registration was successful. The only button on the dialog box is Exit, and once you click exit an error message pops up: Borland license information is either invalid or missing.

### Solution:

Navigate to the bin directory of Delphi 6. If you installed to the default directory it is located at:

C:\Program Files\Borland\Delphi6\bin

Run the file: "**D6RegClean.exe**". Now, insert the Delphi 6 CD and run the installer. Select the option to repair Delphi 6. Once the repair has completed, start Delphi and complete the registration process. This time it will complete successfully.

## **Article #27924: Internal Error 2381, "Directory Does not Exist"**

### **QUESTION:**

When I am installing Delphi 6 I get an Internal Error that the directory doesn't exist and then the installation fails. How can I install Delphi 6?

### **ANSWER:**

This error is thrown by MSI when it can't find a directory. Typically this is due to permission problem that the user doesn't have. To ensure that you have the necessary permissions on your drive(s), please try the following:

- 1) In Windows Explorer, select the folder.
- 2) Right-click the folder and click Properties on the shortcut menu.
- 3) On the Security tab, click Permissions.
- 4) Select the Everyone group and click Full Control in the Type of Access list.
- 5) Check the Replace Permissions on Subdirectories check box.
- 6) Click OK.
- 7) Click Yes to the prompt confirming whether you want to replace permissions on all subdirectories.
- 8) Run Delphi Installer.

## Article #27949: Unofficial WebSnap updates and bug fixes

### Unofficial WebSnap Bug Fixes

By Corbin Dunn [cdunn@nospam.borland.com](mailto:cdunn@nospam.borland.com)

Remove the nospam. from my email address when mailing me

#### Unofficial fixes - page 2 (these are post service pack 2 issues)

In general, applying these fixes require you to rebuild some of the VCL. The easiest way to do this, is to go to **Tools | Environment Options** and from the **Library** tab add **\$(DELPHI)\Source\Internet** to your Library Path.

These fixes are unofficial, are not supported by Borland, and are to be used at your own risk.

Quick Jumps:

[Crashes or hangs in your Web Application when it shuts down \(ie: ISAPI dll is unloaded, CGI exits, or Apache is stopped\).](#)

[Cannot perform this operation on a closed dataset](#)

[Transparent tags in any TPageProducer will have spaces "eaten"...](#)

[WebAppDebugger: Exception EOleException in module ModuleName.exe. Catastrophic failure](#)

[The OnPrepareStrings event of TCustomStringsValuesList never gets called.](#)

["Runtime Error 217" when unloading an ISAPI dll/CGI \(or crash of webserver on unloading of the app\)](#)

[WebSnap apps leak memory if any of the events in the SessionsService are used](#)

[When assigning things in script, you get an access violation at address xxx in module 'oleaut32.dll'.](#)

[Read of address 00000000](#)

[The application called an interface that was marshalled for a different thread](#)

[If you use the AdapterPageProducer to generate script, the SelOptions JScript will not show a value of 0...](#)

[An error occurred while attempting to initialize the Borland Database Engine \(error \\$2B05\)](#)

[If you are using the TDatasetAdapter, and the keyfield is a string which contains a single or double quote in it, it will not be properly encoded in actions.](#)

[Calculated fields in a dataset cause the TDatasetAdapter to always raise the exception "Field %s changed by another user".](#)

[Where are some good articles and updated documentation on WebSnap?](#)

[More additional information](#)

[On XP: Cannot create script engine: "SignedJavaScript". Error: 80040154](#)

[Memory leak fixes in WebSnap](#)

AV's when using the TDataSetAdapter and an exception is raised...

AV's when using MIDAS and TSocketConnection with WebSnap

AV's when using MIDAS and TSocketConnection with WebSnap (upon shutdown of the application).

This is fixed in Delphi 6 update pack 2.

When using the TDataSetAdapter, AV's will happen if an exception is raised in the opening/closing/next/prior of a dataset.

This is fixed in Delphi 6 update pack 2.

Memory leak fixes. TAutoObjectFactory objects that are created in WebAuto. TAbstractScriptComServerObject.RegisterScriptClass are never freed. Another 84 bytes are lost on each request with another bug.

This is fixed in Delphi 6 update pack 2.

The error: "Cannot perform this operation on a closed dataset" will happen if you click the Prior button in a WebSnap application, and you don't have any keyfields set.

This is fixed in Delphi 6 update pack 2.

Transparent tags in any TPageProducer will have spaces "eaten" in the tags if the ScriptEngine property is anything but blank. For instance, <#TagName ParamName="Value"> will become <#TagNameParamName="Value">.

This is fixed in Delphi 6 update pack 2.

After applying the Delphi 6 update pack 1 attempting to recompile and use the Web App Debugger always gives: "Exception EOleException in module ModuleName.exe. Catastrophic failure".

This is fixed in Delphi 6 update pack 2.

The OnPrepareStrings event of TCustomStringsValuesList never gets called.

This is fixed in Delphi 6 update pack 2.

"Runtime Error 217" when unloading an ISAPI dll or the termination of a CGI application happens. Or, your web server simply crashes when trying to unload a WebSnap ISAPI dll.

This is fixed in Delphi 6 update pack 2.

WebSnap apps leak memory if any of the events in the SessionsService are used (OnEndSession or OnStartSession).

This is fixed in Delphi 6 update pack 2.

If you try to assign something to an Adapter field's value in script, you get an:  
[Error] Unit2.htm(1): Access violation at address 779DB637 in module 'oleaut32.dll'. Read of address 00000000

Or, you try to assign something to the adapter itself, such as: <% Modules.  
PageProducerPage2.Adapter1 = 'alksjfkljsadf' %>

This is fixed in Delphi 6 update pack 2.

When running your WebSnap app you sometimes get: "The application called an interface that was marshalled for a different thread"

Or:

The error: -2147417842 (0x8001010e) is returned from any WebSnap application compiled as an ISAPI dll and run under IIS5 (Windows 2000) with the Application Protection on that directory is set to "Medium (Pooled)".

Note: This is fixed in Delphi 6 update pack 2, by having the Wizard generate this code for you. If you have existing apps, you will still have to apply this fix

The reason this happens is because the CoInitFlags are not being set to COINIT\_MULTITHREADED for an ISAPI dll (but, it is required!).

Add the following to the uses list of the main .dpr file:  
ActiveX, ComObj

and have the following in the begin..end:

begin

```
CoInitFlags := COINIT_MULTITHREADED;  
Application.Initialize;  
...
```

CoInitFlags MUST be set before Application.Initialize.

If you use the AdapterPageProducer to generate script, the SelOptions JScript will not show a value of 0 for a given name/value pair with a TDatasetValuesAdapter. For example, if you have a Value of 0 in the database, you will see:

```
<select size="0" name="A">  
<option>Bug</option>  
//          ^^^^^^ MUST BE <option value= "0">Bug</option>      !!!!!  
<option value="1">A</option>  
<option selected value="2">B</option>  
</select>
```

This is fixed in Delphi 6 update pack 2.

When using the BDE, I get the following error when starting my web application: "An error occurred while attempting to initialize the Borland Database Engine (error \$2B05)"

**Note:** This is a setup issue, not a Delphi programming problem. **Cause:** This error happens because the anonymous user that IIS starts your process as does not have permission to write to some temp directories (Typically, for security reasons, it can't write to the directory where inetinfo.exe is located in your System32\inetsrv directory.)

**Solution:** The Paradox tables were not designed for multiple users hitting the database at the same time. The best solution is to use a SQL based database, such as Interbase, Oracle, or MS SQL Server.

If you must use Paradox and the BDE, then be sure to have a TSession on your WebDataModule. Set AutoSessionName to true. The key thing is to set the NetFileDir and PrivateDir to something that the anonymous IIS account can access. A good solution would be to set the NetFileDir to: C:\Temp\Net and the PrivateDir to: C:\Temp. The two cannot point to the same directory. In addition, it is best to uniquely set the PrivateDir for each webmodule, in the OnCreate event (typically, you will create a directory based on the current thread id, and set the PrivateDir to this). Otherwise, you may see each other's data from different threads.

However, the NetDir MUST be shared across all processes and threads.

Next, you must give the IUSR\_MACHINE\_NAME and IWAM\_MACHINE\_NAME accounts full read and write permissions to the following directories:

1. The BDE directory
2. The base directory for your NetDir and PrivateDir
3. Your actual temp directory, probably C:\WINNT\Temp
4. Your directory that contains the database files
5. If all else fails, give read permissions to C:\WINNT, and then write permissions to C:\WINNT.

If you are using the TDataSetAdapter, and the keyfield is a string which contains a single or double quote in it, it will not be properly encoded in actions. This causes javascript errors on the client side browser, and the inability to do a locate on given records with quotes in the keyfield name.

This is fixed in Delphi 6 update pack 2.

Calculated fields in a dataset cause the TDataSetAdapter to always raise the exception "Field %s changed by another user". It is not possible to update a webpage using the TDataSetAdapter if the dataset contains calculated fields.

This is fixed in Delphi 6 update pack 2.

On XP, WebSnap apps give: Cannot create script engine: "SignedJavaScript". Error: 80040154

This is fixed in Delphi 6 update pack 2.

In any WebBroker application compiled with Delphi 6 update pack 1, the following symptoms may happen when unloading an ISAPI dll, exiting a CGI, closing down a WebAppDebugger project, or stopping Apache that contains a DSO:  
access violations, runtime errors, strange exceptions being raised.

This is fixed in Delphi 6 update pack 2.

Where are some good articles and updated documentation on WebSnap?

## More additional information

**The WebSnap Pack** by Jimmy Tharpe provides the following free (postcard-ware) components to enhance WebSnap (see his website for more information):

- TDBWebUserList - A replacement for TWebUserList that validates users through a database.
- TudEndUserSessionAdapter - A replacement for TEndUserSessionAdapter that adds EndUser.DisplayName.
- TudLoginFormAdapter - A replacement for TLoginFormAdapter.
- TudStringsValuesList - A replacement for TStringValuesList.

## Article #27958: Uninstalling Delphi 6 prompts for the CD even after saving the installation information to the hard drive

### Problem

During the installation of Delphi 6 the option to save the installation information to the hard drive was selected. When uninstalling Delphi 6, the following message is displayed: **"The feature you are trying to use is on a CD-ROM or other removable disk that is not available. Insert the 'Borland Delphi 6' disk and click OK."**

### Solution

The windows installer doesn't always seem to know where to look for the "Borland Delphi 6.msi" file that you saved to your hard drive when you selected the option to store the installation information. Instead of inserting your Delphi 6 CD when presented with the message described above, select Browse and navigate to the directory where you installed Delphi 6 and select the "Borland Delphi 6.msi" file. The uninstall will now proceed normally.

Last Modified: 01-NOV-01

## Article #27966: Steps to uninstall and reinstall Delphi 6

### Problem

Delphi 6 isn't working correctly and has been messed up from the initial installation. Running the Delphi 6 Repair from the installation CD didn't fix the problems so now a full reinstall seems to be necessary.

### Solution

1. Go into the control panel and select **Add/Remove Programs**.
2. Select Remove Delphi 6. Proceed with the Uninstall.
3. Open up Windows Explorer. Navigate to the directory where Delphi 6 was installed. If you have projects that are saved in the **Delphi6\Projects** directory, move them to a different location outside of the Delphi6 folder. Delete the Delphi6 folder and all its sub-directories.
4. In Windows, click on Start and select Run. Type in:  
**regedit**
5. Navigate to **HKEY\_LOCAL\_MACHINE\Software\Borland\Delphi**  
If you see a **6.0** folder, select it and hit Delete.
6. Navigate to **HKEY\_CURRENT\_USER\Software\Borland\Delphi**  
If you see a **6.0** folder, select it and hit Delete.
7. Close regedit and reboot the machine. Ensure the user account that Delphi 6 will be installed on has administrative rights, as this is necessary to install Delphi.
8. Stop all background process that are running on the machine. This also means **stop/disable any anti virus program that is running**.
9. Place the Delphi 6 CD in the CD-ROM drive and install Delphi 6. Before installing the Delphi 6 Update or any third party components, start Delphi 6 and ensure it is working correctly.

## Article #27980: Problems registering Kylix

### Question:

Why are my codes not being accepted? Why am I being asked to register again after I've already installed and registered Kylix?

### Answer:

This most often occurs when Kylix (any edition) has previously been installed on the same machine. Here are some suggestions:

- Don't paste codes - type them in.
- If you installed Kylix as root, and are running as root or a user:
  - Rename your `$HOME/.borland` directory to `$HOME/.borland.bak` (or just delete it).
  - Start Kylix.
  - Register the Software again (you should still have your serial number, authorization key and registration code).
- If you installed Kylix as a user:
  - Remove 'registry.bin' file from `$HOME/.borland` directory.
  - Start Kylix.
  - Register the Software again.

If the previous suggestions fail then run the 'locale' command on your console window. If you have the default locale setting:

```
LANG=POSIX
LC_XXX=POSIX
LC_ALL=POSIX, C or blank
```

then, could you try to set 'en\_US' to your locale settings (or whatever you locale may be). To do this enter the following in a console window:

```
export LANG=en_US
export LC_ALL=en_US
```

then, use 'locale' command again to verify that the settings are correct.

### Other notes:

Different installation locations won't help since the registration information are always stored in the same place `/home//.borland` or `/root/.borland`.

You will have to register the Software for every machine you install Kylix on, and for every user who runs Kylix on a machine.

Last Modified: 28-OCT-02

## Article #27987: Error "InstallShield for Windows is unable to start..." when installing Delphi.

### Question:

What can I do about the message "InstallShield for Windows is unable to start. Ensure that the Windows Installer engine has been installed properly" while attempting to install Delphi?

### Answer

There is a utility called **instmsiw.exe** that comes on the Delphi CD. Run this (by double clicking it) and this will reinstall the Microsoft Installer on your machine.

Last Modified: 06-NOV-01

## Article #28032: Missing components in Kylix.

### Question:

Why am I missing components in Kylix after I just installed it?

### Answer:

**When you launch Kylix, did you get any errors indicating that a package could not be loaded? If so there may be other issues and you may need to reinstall. If you downloaded the open edition please be advised that it does not include all of the components so you will only see 4 tabs of components. If you are seeing one or no tabs then try the following:**

**If you install as root and launch kylix as regular user, then as the regular user execute the following commands:**

```
cd $HOME/.borland
rm delphi60*
cd
startkylix
```

**Last Modified: 16-NOV-01**

## Article #28034: Manually unistalling Kylix.

### Question

I am trying to reinstall Kylix after deleting a previous installation and I'm getting an error stating that an installation already exists. How can I remove it?

### Answer:

Kylix should be removed by running the uninstall. If this was not done or did not remove everything properly you can manually remove Kylix.

- \* Delete all files in your .borland and Kylix directories:
- \* Check your installed packages with the rpm command:

```
rpm -qa | grep kylix
```

Uninstall these packages with rpm command (or other utility to add/remove/modify rpm packages). You can use '-e' option for the rpm command to uninstall rpm packages. After you uninstall all of the kylix packages from your system you should be able to reinstall kylix.

Last Modified: 16-NOV-01

## Article #28057: How to run executables created in Kylix

### Question:

How do I run an executable created in Kylix?

### Answer:

Kylix produces ELF binaries so in order to run them outside the IDE you need to first run 'source kylixpath' in the kylix2/bin directory. This sets up the necessary environment variables. Then, in a command window, go the directory where your compiled binary is and enter **./Project1** if your executable is called Project1.

Last Modified: 29-NOV-01

## Article #28061: Getting error -145 when trying to apply the Delphi 6 Update

### Problem

Getting error -145 when trying to apply the Delphi 6 Update

### Solution

This problem usually occurs because the data in the RootDir key in the Windows Registry is blank. Use regedit, navigate to **HKEY\_LOCAL\_MACHINE\Software\Borland\Delphi\ 6.0** Look at the Data in the RootDir key. It should point to the location where you installed Delphi 6. In most cases where I have seen error -145 this value was blank. If yours is blank, modify the RootDir key and set the Value Data to the path where your Delphi 6 is installed. If you installed to the default location it would be:

**c:\Program Files\Borland\Delphi6**

Once you do this, retry the Delphi 6 Update.

Last Modified: 24-SEP-02

## Article #28063: Is Visibroker for C++ 4.5 supported with Delphi 6?

### Question

Is Visibroker for C++ 4.5 supported with Delphi 6 Enterprise?

### Answer

No, when you install Delphi 6 Enterprise and choose to install VisiBroker, the two versions of VisiBroker that you can choose from are VisiBroker 3.3 or VisiBroker 4.1 for C++. The .dll's that ship with Delphi that support VisiBroker were built and tested against the VisiBroker for C++ 4.1 ORB, so using VisiBroker for C++ 4.5 is currently not supported with Delphi 6 Enterprise Version 6.190.

## **Article #28084: Installing the EasySoft ODBC driver from InterBase 6 from Delphi 6**

Q. How do I install the EasySoft ODBC driver for InterBase 6 from Delphi 6.

A. Run SETUP.EXE from the ib6\ODBC directory.

Note that this install only installs a driver with a 7 day license. To get an unlimited driver you must either purchase the [media kit](#) or contact [EasySoft](#).

Last Modified: 06-DEC-01

## Article #28118: How to change Kylix directory permissions for all users when installed as root.

### Question:

How do I change the directory permissions for Kylix so all users can run it?

### Answer:

Even if you installed into the /usr directory you may need to change the permissions for that directory so other users can run Kylix. To do this open a terminal window. If you are not currently logged in as root you can temporarily log in as root within the terminal window by entering **su** and then entering your password. Then, as root, enter the following:

```
cd /usr  
chmod -R 755 kylix/
```

As an alternative to using `chmod` you may be able to change directory permissions from within a graphical directory browser on your machine, by right clicking on the **kylix** directory.

## Article #28176: Cannot access deployed EJB in BES 5.0 with a Delphi Client

### Problem

I installed Borland Enterprise Server 5.0 and deployed the EuroConverter EJB found in the EJB Demo that ships with Delphi 6. I cannot access the deployed EJB with the Delphi Client. When I try running the Delphi Client I keep getting Object Not Exist error.

### Solution

First off, ensure that the osagent port inside Borland Enterprise Server is set to the same port number as the osagent that is running on the client machine.

In order for a Delphi Client to talk to an EJB deployed on BES 5.0, you must configure the Borland Enterprise Server so that SIDL is enabled. With Borland Application Server, this was always enabled as a default, however with BES 5.0 the default setting has SIDL disabled. The easiest way to enable SIDL is using the BES console. Do the following after starting up the BES server:

- Start the Console
- Expand your server
- Expand the Partition where you deployed the Enterprise Java Bean.
- Under the Partition, you will see Deployed Modules and Partition Services. Expand Partition Services.
- Select the EJB Container, right click on it and select Configure.
- Click the check box next to Enable SIDL. Click Okay.
- You will be presented with the message: "The partition needs to be restarted in order for this change to take effect. Do you want to restart the partition now?". Click Yes.

Now when you start your Delphi client it will be able to access the deployed EJB.

## Article #28178: Possible solutions for IDE Internal Error in Kylix 2.

### Question:

Why am I getting the an IDE Internal Error when loading Kylix?

### Answer: Here are some suggestions

If it is a conflict with the QT library paths you can try entering the following in a terminal window (command prompt):

```
$export LD_LIBRARY_PATH=  
$export LTDL_LIBRARY_PATH=  
$startkylix
```

If it is not a QT conflict, then another possibility for Redhat 7.1 is to try running XConfigurator as root from a term window. For other distributions this may or may not work. It is possible that this is a problem with XFree86 V4.0.3 so you can try upgrading to XFree86 V4.1 or downgrading to V3.3.6, or just comment the pex5 line in your /etc/X11/XF86Config (or XF86Config-4) and restart X:

```
Section "Module"  
    Load      "xtt"  
    Load      "ddc"  
    Load      "GLcore"  
    Load      "dbe"  
    Load      "dri"  
    Load      "extmod"  
    Load      "glx"  
#    Load     "pex5"  
    Load      "record"  
    Load      "xie"
```

Last Modified: 31-DEC-01

## Article #28182: Timeout problems with SOAP services in Delphi 6.

### Question:

I'm writing SOAP servers in Delphi 6 with service pack 1 and IndyApp. How can I set the timeout of SOAP requests, to adapt it to the type of the requests?

### Answer:

IF the client is Delphi 6, SP1 then the problem is that Borland uses WinInet which has problems with TimeOuts. There's the InternetSetOption API to configure timeouts but it has been broken for a very long time now:

<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q176420>

It used to be that only the SEND\_TIMEOUT and CONNECT\_TIMEOUT were failing but it seems that as of IE5, RECEIVE\_TIMEOUT also timed out.

There's a workaround involving another thread that Borland did not implement. It is documented at:

<http://support.microsoft.com/default.aspx?scid=kb;en-us;Q224318>

## Article #28185: How to keep seconds from being included in the display when using TDateTimePicker

### QUESTION:

How can you keep seconds from being included in the display when using TDateTimePicker?

### ANSWER:

- Note: This only applies when you have the TDateTimePicker Kind property set to dtkTime.

Drop a TDateTimePicker component on your Form. Now **add CommCtrl to the uses** clause of your unit. Place the following code in the FormCreate event:

```
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    DateTime_SetFormat(DateTimePicker1.Handle,  
        'hh:mm tt');  
end;
```

For more formatting options, look up DateTime\_SetFormat from the Microsoft Platform SDK.

Last Modified: 02-JAN-02

## Article #28186: How can one prevent a TForm from being moved or resized?

### QUESTION:

How can one disable a TForm from being moved or resized?

### ANSWER:

Place the following code in the FormCreate event:

```
procedure TForm1.FormCreate(Sender: TObject);  
var  
    hMenuHandle : HMENU;  
begin  
    hMenuHandle := GetSystemMenu(Form1.Handle, FALSE); //Get the handle  
of the Form  
    if (hMenuHandle <> 0) then  
        DeleteMenu(hMenuHandle, SC_MOVE, MF_BYCOMMAND); //disable moving  
        DeleteMenu(hMenuHandle, SC_SIZE, MF_BYCOMMAND); //disable resizing  
end;
```

If you also want to prevent the user from minimizing and maximizing the form, in the Object Inspector, select the form you are concerned with and under the BorderIcons, set the biMinimize and biMaximize properties to False.

Last Modified: 02-JAN-02

## Article #28187: Delphi 6 on Windows XP

### Question:

Can I use Delphi 6 with Windows XP?

### Answer:

Delphi 6 was not fully certified to be used on Windows XP because it came out before Windows XP. However the second update pack is certified for XP so be sure to install this.

Last Modified: 23-APR-02

## **Article #28192: Klyix 2 Not Registered**

You may have successfully register Kylix 2, but when you try to start Kylix you get an error that it isn't registered.

In the ./borland directory is a file "registry.bin". Remove registry.bin and try registering the product again. This should resolve the problem.

Last Modified: 30-OCT-02

## Article #28214: How to make the TDateTimePicker display blank.

### Question:

How do I make the TDateTimePicker display blank?

### Answer:

A little trick is to use the letters **gg** in the format property. This format pattern displays the period or era. This pattern is ignored if the date to be formatted does not have an associated period or era string - which TDateTimePicker does not - thus the display is blank. When a date is subsequently selected you can then set the format to "" in the OnChange or OnClick event handler in order to get it to display again.

The format property was added in Delphi 6. In earlier versions add CommCtrl to the uses clause of your unit and use the following code:

```
DateTime_SetFormat(DateTimePicker1.Handle, 'gg');
```

Last Modified: 09-JAN-02

## Article #28236: Component properties do not appear in the Translation Manager

### Problem:

Certain component properties, such as DBGrid column titles, do not appear in the Translation Manager, causing them to be stuck in the native language the application was developed in.

### Solution:

Try changing the default value of the property. For example, change the `DBGrid.Columns.Column1.Title.Caption` in the IDE to something other than the default. Then click Project, Languages, Update Resource DLLs. The properties should then appear in the Translation Manager.

### Explanation:

The different languages in your project are governed by resource DLLs. When you generate a resource DLL, the wizard examines the project forms' DFM files, looking for strings and values you may want to change between languages. If you examine an example form's DFM file, you'll find that the DFM contains no data for the column title. This is the reason the TM does not contain these properties.

But then, how can the column titles appear at design time and run-time? The titles are defaulting to the corresponding field name on the table it's representing. The IDE saves space in the DFM by omitting properties that can fall back on their default values, but that doesn't help the Translation Manager do it's job.

When we explicitly assign a value to these properties, we force the IDE to write these property values to the DFM which, in turn, makes the Translation Manager aware of them.

Last Modified: 13-MAR-02

## Article #28270: ISAPI DLL used to work with Delphi 5 but doesn't work in Delphi 6

My Delphi5 Isapi Dlls run fine from Netscape, but when I create an Isapi DLL in Delphi6 it fails to work in a Netscape FastTrack WebServer.

Delphi6 adds a Unit to the project that didn't exist in Delphi5. This new unit will keep the ISAPI DLL from loading into Netscape Server. To correct this problem comment out the "ISAPIThreadPool" unit from your Delphi6 source and recompile.

Your new DPR for an ISAPI dll might look something like this:

```
library ISAPI_Prog;  
  
uses  
    WebBroker,  
    // ISAPIThreadPool, comment this out for Netscape  
    ISAPIApp,  
    Unit1 in 'Unit1.pas' {WebModule1: TWebModule};  
  
{ $R *.RES }  
  
exports  
    GetExtensionVersion,  
    HttpExtensionProc,  
    TerminateExtension;  
  
begin  
    Application.Initialize;  
    Application.CreateForm(TWebModule1, WebModule1);  
    Application.Run;  
end.
```

**Article #28276: Access violation in dcc60.dll and Internal Error LA33 in Delphi 6.**

**Question:**

What is causing an access violation in dcc60.dll and then internal error LA33 in Delphi 6?

**Answer:**

If you are using the Delphi 6 trial edition or you are running a project in Delphi 6 that was created with the Delphi 6 trial edition then the problem is with the .dcu files. The DCU format for the trial version is not compatible with that for the regular version. This is intentional.

In order to resolve this you will need to rebuild everything in the edition you are currently using. If rebuilding doesn't work for some reason, you can delete the .dcu files, which will force them to be recreated.

Last Modified: 24-JAN-02

## Article #28277: ItemIndex property of TStaticActionList and TVirtualActionList does not represent which item is selected.

### Question:

Why is the ItemIndex property of TStaticActionList and TVirtualActionList not indicating which item is selected?

### Answer:

This is the designed behavior. In the help for TCustomListAction.OnItemSelected it states "Before this event is called, the list action first updates the ItemIndex property of any client controls that descend from TCustomListControl."

And in the help for TCustomListAction.ItemIndex "Note: List actions do not supply ItemIndex to all clients. The ItemIndex property controls only the ItemIndex property of clients that descend from TCustomListControl."

TStaticListAction does not descend from TCustomListControl.

If you want to get the selected text for these components you can do it like this:

```
ShowMessage( (Control as TCustomActionCombo).SelText );
```

Last Modified: 24-JAN-02

## Article #28298: Loading a TListView component that contains SubItems.

### QUESTION:

How do I load the SubItems of a TListView component?

### ANSWER:

Add a TListView to a form. Next, right click the ListView components to invoke the sub-menu, and select Columns Editor. Add two columns and set the Width property to 300. In the TListView properties set the ViewStyle to vsReport. Drop a TButton on the form and add the code sample below to the button's OnClick event.

```
procedure TfrmMain.Button1Click(Sender: TObject);
var
    NewItem: TListItem;
begin
    NewItem := ListView1.Items.Add;
    NewItem.Caption := 'FirstItem'; //some string.
    NewItem.SubItems.Add('SecondItem'); // next string.
end;
```

Last Modified: 05-FEB-02

## Article #28301: How to make your main form fill up the Desk Top space.

### QUESTION:

How do I make sure my main form occupies all of the desktop space when my application is run?

### ANSWER:

Below is a code sample that demonstrates the process.

```
procedure TForm1.FormCreate(Sender: TObject);
var
    DeskTopForm: TRect;
begin

(* You'll find more options in the Win32.hlp file under SystemParametersInfo *)
    SystemParametersInfo(SPI_GETWORKAREA, 0, Pointer(@DeskTopForm), 0);

    Top := DeskTopForm.Top;
    Left := DeskTopForm.Left;
    Height := DeskTopForm.Bottom - DeskTopForm.Top + 1;
    Width := DeskTopForm.Right - DeskTopForm.Left + 1;
end;
```

## Article #28321: How to create an example of your problem for Borland Developer Support

### Question:

The engineer working on my case wants a small example that demonstrates the issue. What should I provide?

### Answer:

Many developer support cases deal with problems that simply do not occur in code generated by the IDE. In these situations, it is very helpful to the engineer working on your case to have a small example that demonstrates the problem so they can do testing on their end. Having the engineer work out their own example of the problem takes more time which means a delayed solution. Also, not knowing exactly what to send to your engineer can lead to a lot of back-and-forth exchanges which can further delay the resolution. What follows is a list of suggestions to help you provide a good example of the issue to your engineer.

1. **Make sure your example is complete in itself:** An incomplete example will only make the case take longer. For instance, an example of your run-time database connectivity failure which doesn't compile due to missing auxilliary files. Be sure to either include the necessary files to get the example to run or remove the references to unnecessary files before sending it to the engineer. Test it before you send it to make sure it functions in illustrating the errant behavior.
2. **Make the example atomic:** That is to say, make it so that it cannot be reduced to something simpler. The example should only include source code and libraries related to the issue. This may require you to rework your code before sending it but your case will go faster this way.
3. **Try to make it generic:** Examples that are dependant on specific third-party software are much harder to deal with. Borland Developer Support does not have every permutation of database, application server, utility component set and operating system available to them for testing. Everywhere you can, remove third-party components and use the database or app server that came bundled with the IDE. It is understandable that sometimes this is not possible, but doing this when you can will speed up the resolution of your issue considerably.
4. **Make the example a complete project:** An example that can be opened as a normal IDE project is always preferable to an unmanaged heap of source code. Most of our products use a "project" abstraction as a way of managing not only source code, but also auxilliary libraries and build options. Sending a complete project is like sending a road map of your application.

5. **Send it in the structure it appears in on your drive:** Meaning once you have created an example that demonstrates the problem, the whole problem and nothing but the problem, zip it up right there and send the whole thing, folders and all. This will help eliminate time spent recreating your machine's directory structure and time spent hunting down missing files.

Following these guidelines will give your engineer the tools needed to solve the case quickly.

Last Modified: 30-AUG-02

## Article #28322: How to generate steps to reproduce your issue for Borland Developer Support

### Question:

My engineer asked me for a sequence of steps that causes my issue to occur. What should I provide?

### Answer:

A sequence of steps to reproduce an issue is the best thing you can give to the engineer working on your problem. Reproducible problems are easier to solve which means quicker resolution for you.

The more detailed the steps are, the better. Making one step per action (like filling in a field or selecting a radio button) is great but can be a little lengthy. In general, one step per dialog or equivalent action is acceptable. Below are two examples of steps given to create an EJB example, one lacking and one satisfactory:

1. Create an EJB.
2. Put it in your module.
3. Build the project.

This lacks many important details that the engineer would need to track down the problem. Don't provide steps like this. Instead, use the following as a model:

1. Create a new Project: File -> New Project...
2. Accept the defaults and hit Finish
3. Create a new EJB Module: File -> New... -> Enterprise -> EJB Module
4. Accept the defaults and hit OK.
5. Add a bean: File -> New... -> Enterprise -> Enterprise JavaBean 1.x
6. Select the EJB Module you just created. Click Next.
7. Accept defaults. Make sure Stateless Session Bean is selected. Click Next.
8. Accept defaults and click Finish.
9. Build the project: Project -> Rebuild Project...

You can see in this example that steps, values, and selections are distinct. There are many ways to do the same thing in JBuilder so the more detail you provide, the quicker the case will go.

## Article #28323: What to have ready before you call Borland Developer Support

### Question:

What resources should I have in front of me when I call Developer Support?

### Answer:

You will definitely want all of the following information before calling Borland Developer Support:

1. Your product name, version number, and SKU (Professional, Enterprise, etc.)
2. Your operating system type and version number.

Generally, this information is also helpful:

1. Sample code or project that illustrates the issue ready to email.
2. Steps to reproduce the problem.

You should be at the computer exhibiting the issue. Not having the machine at hand makes it nearly impossible to solve the case. If you are not the developer/user who encountered the issue, please try to have them on hand to answer questions. Providing all of these things will let the engineer working on your problem operate at maximum efficiency.

## Article #28327: How to detect the CPU type of the computer the application is running on.

### QUESTION:

How can I find out what type of CPU the computer has that my application is running on?

### ANSWER:

Below is a code sample that demonstrates the process. Make sure you add Registry to your uses clause.

```
function CPUType: string;
var
  Reg: TRegistry;
begin
  CPUType := '';
  Reg := TRegistry.Create;
  try
    Reg.RootKey := HKEY_LOCAL_MACHINE;
    if Reg.OpenKey('\Hardware\Description\System\CentralProcessor\0', False) then
      CPUType := Reg.ReadString('Identifier');
  finally
    Reg.Free;
  end;
end;
```

Last Modified: 05-FEB-02

## Article #28328: Getting the date of a file using Delphi.

### QUESTION:

How can one get the date of a file programmatically?

### ANSWER:

Place a TOpenDialog component on a form along with a TButton and a TLabel. Place the following code in Button1.OnClick event:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    OpenDialog1.Execute; //Use the TOpenDialog component to select the  
file we are interested in  
    Label1.Caption := DateToStr(FileDateToDateTime(FileAge(OpenDialog1.  
FileName)));  
end;
```

**Article #28329: How does one change the default directory that Delphi uses to save projects?**

**QUESTION:**

**How does one change the default directory that Delphi uses to save projects?**

**ANSWER:**

Select the Shortcut Icon that you use to start up Delphi. Right click on the icon and select **Properties**. Where it says **Start in:** replace the string in that field with the directory you would like Delphi to default to when you save projects. For example, the string I entered is:  
**C:\MyDocs\Delphi\Projects\**

**Article #28330: How to clear the document listing found in the Windows Start Menu.**

**QUESTION:**

**How can one clear the document listing found in the Windows Start Menu?**

**ANSWER:**

Add ShlObj to the uses of your application. Place a TButton on a form. In the Button1.OnClick event place the following code:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    SHAddToRecentDocs(SHARD_PATH, nil);  
end;
```

## Article #28366: Unofficial WebSnap Fixes Page 2

### Unofficial WebSnap Bug Fixes Page 2

By Corbin Dunn [cdunn@nospam.borland.com](mailto:cdunn@nospam.borland.com)

Remove the nospam. from my email address when mailing me

In general, applying these fixes require you to rebuild some of the VCL. The easiest way to do this, is to go to **Tools | Environment Options** and from the **Library** tab add **\$(DELPHI)\Source\Internet** to your Library Path. Or, you can copy the patches files to your current project directory and do a build all. These will only fix applications that are built without runtime packages.

These fixes are unofficial, are not supported by Borland, and are to be used at your own risk.

#### Quick Jumps:

The OnValidate events of an Adapter and AdapterField don't get called on a regular adapter when an Action for that Adapter is executed.

Required property of AdapterField not working when the user inputs nothing into the field

Using the TDataSetAdapterImageField with Bitmaps in a database BLOB field will always give an "Invalid bitmap" error when trying to view the image.

#### Required property of AdapterField not working when the user inputs nothing into the field.

The fix for this problem is to modify the following function in WebAdapt.pas as follows:

```
function TAdapterUpdateField.ImplCheckValueChange(
  AActionRequest: IActionRequest; AFieldIndex: Integer): Boolean;
var
  FieldValue: IActionFieldValue;
  I: Integer;
  Value: Variant;
begin
  // Test single value
  with GetActionFieldValues(AActionRequest) do
    FieldValue := Values[AFieldIndex];
  if GetValueCount = ConvertValueCount(FieldValue) then
    begin
      Result := False;
      if IsMultiValueField then
        for I := 0 to FieldValue.ValueCount do
          begin
            try
              if ConvertValues(FieldValue, I) <> GetValues(I) then
                Result := True;
            except
              Result := True;
            end;
            if Result then break;
          end
        else
          // Corbin - Add the Required check as a fix.
```

```

Value := GetValue;
if VarIsEmpty(Value) then
begin // I added the "or Required" on the line below
  if (ConvertValue(FieldValue) <> '') or Required then
    Result := True
end
else
  try
    if ConvertValue(FieldValue) <> Value then
      Result := True;
    except
      Result := True;
    end;
end
else
  Result := False;
end;

```

**The OnValidate events of an Adapter and AdapterField don't get called on a regular adapter when an Action for that Adapter is executed.**

The fix for this problem is to modify the following function in WebAdapt.pas as follows:

```

procedure TCustomAdapterAction.ImplExecuteActionRequest(AActionRequest:
IActionRequest;
  AActionResponse: IActionResponse);
var
  S: TStrings;
begin
  // corbin - make sure the adapter updates its records before calling the OnExecute
event
  Adapter.UpdateRecords; // Add this line before the rest
  // ....

```

Or, you can call (YourAdapterName).UpdateRecords as the first thing in your OnExecute event of the AdapterAction.

**Using the TDataSetAdapterImageField with Bitmaps in a database BLOB field will always give an "Invalid bitmap" error when trying to view the image.**

The fix for this problem is to modify the following function in DBAdaptImg.pas as follows. Goto line 238 (in RenderAdapterImage):

```

    else if (Bytes[0] = Ord('B')) and { Do not localize}
      (Bytes[1] = Ord('M')) then // Windows bitmap { Do not localize}
    {$IFDEF MSWINDOWS}
    begin // added begin
      ContentStream.Seek(0, soFromBeginning); // Missing in update pack 2 -
corbin - go back over the start of the bytes before converting
      ConvertBitmapToJpeg
    end // added end
    {$ENDIF MSWINDOWS}

```

I missed adding the seek back over BM before converting the bitmap to a jpeg.

## **Article #28400: Problems using ADO in a WebSnap application.**

### **Question:**

Why am I getting an internal server error (IIS) or an error that CoInitialize has not been called (Apache) in my WebSnap application?

### **Answer:**

In any multi-threaded application you must manually call CoInitialize at the correct times if you use COM. Using ADO is using COM. In ISAPI, CGI or DSO applications each request is in a different thread, so you must call CoInitialize for each thread. Try calling it in the OnActivate, and call CoUninitialize in the OnDeactivate (requires you to use the ActiveX unit). Make sure your tables and connections are not open at design time.

It works in the web app debugger because CoInitialize has been called in the client web app (since, it is a com server).

## Article #28411: Why can't I run my Kylix application outside of the IDE?

### Question:

What do I need to do to run a Kylix application outside of the IDE?

### Answer:

You need to have your `LD_LIBRARY_PATH` variable set to your bin directory. Your bin directory is located under your Kylix directory. You can set this by sourcing the `kylxpath` script. From an xterm window go to the Kylix bin directory and enter

```
source kylxpath
```

See the README file for more details.

Last Modified: 19-FEB-02

## Article #28413: Where is the browser pane in the web page editor in Kylix?

### Question:

Where is the browser tab in the web page editor?

### Answer:

Kylix 2 does not have a browser pane in the web page editor. This feature exists in Delphi 6 but was not implemented in Kylix 2. It is erroneously mentioned in the on-line help.

The web page editor is invoked when you double click on an AdapterPageProducer component, or by going to the WebPageItems property in the Object Inspector.

*Note: The preview tab in code explorer should still be present. [\[If not, click here\]](#)*

Last Modified: 19-FEB-02

## Article #28414: Where is the web page preview pane in the code editor?

### Question:

Where is the HTML preview pane in the code editor?

### Answer:

The tab for the preview pane may simply be out of sight if your window is too narrow. Try making the code explorer window wider. The Preview tab is always the farthest to the right.

If you are using Kylix and you still can't see the preview tab you should see the *Browser Preview feature issues* section of the README file, in your Kylix directory regarding the Mozilla Preview Widget. This is an installation option for Kylix that you may have left out.

Last Modified: 19-FEB-02

## Article #28417: Why can't I get breakpoints to work when debugging a COM+ or MTS app in Delphi?

### Question:

Why can't I get breakpoints to work when debugging a COM+ or MTS app in Delphi?

### Answer:

Here are some possibilities:

You may need to set the *Include remote debug symbols* option under Project | Options | Linker.

Make sure to shutdown the COM+ application that contains the DLL first. This can be done from the Component Services Admin utility.

Check that the Shutdown Timeout value is not set to some small amount (see Delphi help for more).

Last Modified: 19-FEB-02

## Article #28419: Web App Debugger incorrectly formats dates based on the current regional settings

The Web App Debugger in Delphi 6 (or 6.01 or 6.02) has a bug in it where it incorrectly formats dates based on the current regional settings. This can hide other bugs which may only appear when you deploy your application to a real web server such as IIS or Apache.

Luckily, the source for the Web App Debugger is included with Delphi 6. Open up the project WebAppDbg.dpr in \$(DELPHI)\source\internet. Then, open the file SvrHTTP.pas. On line 678, you will see the start of the procedure TWebServerRequest.SetDateVariable. Modify it as follows:

```
procedure TWebServerRequest.SetDateVariable(Index: Integer;
  Value: TDateTime);
begin
  // This previously encoded the date based on the current locale,
  // which would hide other bugs if you didn't use the web app
  debugger.
  StringVariable[Index] :=
    Format(FormatDateTime('%s', dd '%s' yyyy hh:mm:ss 'GMT',
Value), { do not localize }
  [DayOfWeekStr(Value), MonthStr(Value)]);
  // StringVariable[Index] := DateTimeToStr(Value) // Old encoding
end;
```

Compile the application and copy the executable to your \$(DELPHI)\bin directory. That should be it! You will now have a patched version of the Web App Debugger.

## Article #28431: Problems with IBExpress when installing the Delphi 6 Update Pack 2

### PROBLEM:

After installing the Delphi 6 Update Pack 2, when starting up Delphi the following error is displayed: *The procedure entry point @Ibxmlheader@initialization\$qqrv could not be located in the dynamic link library ibxpress60.bpl*

### RESOLUTION:

IBX update 6.03 for Delphi 6 must be installed after installing Update Pack 2 for Delphi 6. This can be obtained at:

<http://codecentral.borland.com>

Once at the codecentral website, click on Find and do a search by ID number. The ID number to enter is 17555

The following description explains how to resolve the problem after downloading the updated IBX:

If you apply update pack 2 to D6, the ibx 6.03 update should be run afterwards. If you have ibx 6.02 installed and install the update pack 2 for D6, you will get a function not found when loading D6 the next time. 6.03 will solve this. Alternatively you can delete the ibxpress60.bpl from the directory and reinstall 6.02. The update pack 2 does not have the 6.5 XMLHeader code in its bpl, but does not update dclib60.bpl which as of IBX 6.02 will look for these functions.

IBX 6.02's version is less than D6's update pack 2 so the installer will not just overwrite which is why you need to remove the update pack 2 version. IBX 6.03 does have a higher version number so will overwrite just fine.

## Article #28445: Endless Registration Loop when Trying to Register Delphi 6

Delphi reports that I have registered the product successfully, however when Delphi launches it reports a message that Delphi 6 isn't registered.

### **Answer:**

The problem seems to happen mainly on Windows 2000, XP and there are three easy steps to get Delphi back on the "up and up." The process will require that you have you CD handy, so make sure it is available before you begin.

1. Locate the utility D6RegClean in the Delphi6\Bin directory. Run this utility. \*Note\* That any third party components will need to be reinstalled once this process has been completed.
2. Next put your CD into the CDROM and run the repair install.
3. The final thing to do is to register again. You can either run D6Reg, which is located in the Delphi6\Bin directory, or you can start Delphi.

**Article #28447: How to disable mouse clicking in a TWebBrowser**

**QUESTION:**

**How does one disable the mouse from being used inside a TWebBrowser?**

**ANSWER:**

Place a TPanel on your form and drop the TWebBrowser on top of the TPanel. Then, change the TPanel's Enabled property to false. This will disable the use of the mouse inside the WebBrowser.

Last Modified: 28-FEB-02

**Article #28451: How can I use a dialog window to have a user select a folder without a file name?**

**QUESTION:**

**How can I use a dialog window to have a user select a folder without a file name?**

**ANSWER:**

You can accomplish this without using a TOpenDialog component. First, add FileCtrl to the Uses. Now the SelectDirectory function can be used. Drop a TButton component on your Form. Place the following code in the button's onClick event to get a demonstration of how this function works:

```
procedure TForm1.Button1Click(Sender: TObject);  
const  
    SELDIRHELP = 1000;  
var  
    dir: String;  
begin  
    dir := 'C:';  
    if SelectDirectory(dir, [sdAllowCreate, sdPerformCreate, sdPrompt],  
SELDIRHELP) then  
        Button1.Caption := dir;  
end;
```

For an explanation of the parameters that SelectDirectory takes, look up the function inside Delphi Help.

Last Modified: 28-FEB-02

## Article #28457: How to disable a Menu item with out greying it out.

### QUESTION:

How can I disable a Menu item, with out greying it out?

### ANSWER:

There are times when you find that you want to disable an option while not greying it out completely. Drop a TMainMenu component on a Form and add atleast two menu items. Next drop a TButton on the Form and in the OnClick event, add the code show below. The code sample below demonstrates how to disable a Menu item without greying it out.

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    Menu: TMenu;  
begin  
    Menu := Application.MainForm.Menu;  
    // The first Menu item will be disabled, but not greyed out.  
    EnableMenuItem(Menu.Handle, Menu.Items[0].Command, MF_DISABLED);  
end;
```

## Article #28473: How can I log off the current user from within my application?

### QUESTION:

How can I log off the current user from within my application?

### ANSWER:

You can accomplish this using the WindowsAPI call `ExitWindows`. To see how this works, drop a `TButton` component on a form and type in the following code:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    ExitWindows(0, 0); //both parameters for this call are reserved and  
    you must pass in zero's  
end;
```

Last Modified: 28-FEB-02

**Article #28475: How to ensure that a path name ends with a trailing path delimiter ('\').**

**QUESTION:**

How can I make sure that a backslash is added to the end of a path

**ANSWER:**

Delphi has a function called: `IncludeTrailingPathDelimiter`. This will return a string with a backslash '/' added to the end, if it does not already have one. Below is one example of how this function works. There is another function called: `IncludeTrailingBackslash`, this is only included for backwards compatibility (this function should not be used).

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    DirPath : string;  
begin  
    DirPath := Edit1.Text;  
    ShowMessage(IncludeTrailingPathDelimiter(DirPath));  
end;
```

Last Modified: 28-FEB-02

## Article #28478: How to remove the backslash from the end of a path.

### QUESTION:

How can I make sure there is no backslash at the end of a path?

### ANSWER:

Delphi has a function called: `ExcludeTrailingPathDelimiter`. This will return a string with one backslash '/' removed from the end if it has one (or more). Below is one example of how this function works. There is another function called: `ExcludeTrailingBackslash`, this is only included for backwards compatibility (this function should not be used).

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    DirPath : string;  
begin  
    DirPath := Edit1.Text;  
    ShowMessage(ExcludeTrailingPathDelimiter(DirPath));  
end;
```

Last Modified: 28-FEB-02

## Article #28494: *Operation Not Supported* error when calling TSQLQuery.RecordCount

### Question:

Why am I getting the error 'Operation Not Supported' when calling TSQLQuery.RecordCount?  
This error may also be preceded by the exception 'ORA-00942: table or view does not exist' in the IDE.

### Answer:

You should note from the Delphi help that reading RecordCount will generate an exception if the dataset can not determine the number of records. Do not read RecordCount if:

- The dataset represents stored procedure.
- The dataset represents a query that contains parameters.
- The dataset represents a multi-table join.

If you are not doing any of these and you are still getting the error you should note that the SQL in TSQLQuery can be case sensitive. For example, if your table name shows up in SQL Explorer or in the TableName property of TSQLTable as **CUST2** and your query is:

```
Select * from cust2
```

then you may get the error, but if your query is:

```
Select * from CUST2
```

then it should work.

## Article #28514: Unofficial SOAP Bug Fixes

### Unofficial SOAP Bug Fixes

By Bruneau Babet [bbabet@nospam.borland.com](mailto:bbabet@nospam.borland.com)

Remove the nospam. from email address when mailing me

In general, applying these fixes require you to rebuild some of the VCL. The easiest way to do this, is to go to **Tools | Environment Options** and from the **Library** tab add **\$(DELPHI)\Source\Internet;\$(DELPHI)\Source\SOAP** to your Library Path.

These fixes are unofficial, are not supported by Borland, and are to be used at your own risk.

#### Quick Jumps:

- [The case of serialized Boolean members of a complex type is incorrect \(i.e. 'True'/'False' instead of 'true'/'false'\)](#)
- [Memory leak in Servers that expose WideString parameters](#)
- [Error publishing Webservice's WSDL when MSXML4 is installed](#)
- [HTTPRIO component reloads a Service's WSDL for each Webservice call](#)
- [\(Ole\)Variant array of one element are incorrectly deserialized](#)
- [Bad XML Namespaces for 'dateTime' and other XSBuiltIn types when members of Complex Type](#)

#### The case of serialized Boolean members of a complex type is incorrect (i.e. 'True'/'False' instead of 'true'/'false')

##### **Description:**

When serializing Boolean members of a TRemotable-descendant class, the value of the latter are sent as 'True' or 'False'. Some SOAP implementations, including Delphi's, will accept these values. However, many will complain, and for good reason, since the legal literal representations of a boolean are '1', '0', 'true' or 'false'.

##### **Fix:**

The fix for this problem is to modify the following function in OPToSOAPDomConv.pas as follows:

```
function TSOAPDomConv.GetObjectPropAsText(Instance: TObject;
  PropInfo: PPropInfo): WideString;
var
  I: LongInt;
  E: Extended;
  I64: Int64;
begin
  case (PropInfo.PropType)^.Kind of
    tkInteger:
      begin
        I := GetOrdProp(Instance, PropInfo);
        Result := IntToStr(I);
      end;
    tkFloat:
      begin
        E := GetFloatProp(Instance, PropInfo);
        Result := FloatToStrEx(E);
      end;
    tkWString:
```

```

    Result := GetWideStrProp(Instance, PropInfo);
tkString,
tkLString:
    Result := GetStrProp(Instance, PropInfo);
tkInt64:
    begin
        I64 := GetInt64Prop(Instance, PropInfo);
        Result := IntToStr(I64);
    end;
tkEnumeration:
    Result := GetEnumProp(Instance, PropInfo);
    begin
        Result := GetEnumProp(Instance, PropInfo);
        if PropInfo.PropType^ = TypeInfo(System.Boolean) then
            Result := Lowercase(Result);
        end;
tkChar:
    begin
        I := GetOrdProp(Instance, PropInfo);
        Result := InvString(Char(I));
    end;
tkWChar:
    begin
        I := GetOrdProp(Instance, PropInfo);
        Result := InvString(WideChar(I));
    end;
tkClass:
    ;
tkSet,
tkMethod,

tkArray,
tkRecord,
tkInterface,

tkDynArray,
tkVariant:
    raise ESOAPDomConvertError.CreateFmt(SUnexpectedDataType, [KindNameArray
[(PropInfo.PropType)^.Kind]]);

end;

end;

```

## Memory leak in Servers that expose WideString parameters

### **Description:**

Delphi SOAP fails to delete WideStrings allocated by the framework on behalf of Servers that expose WideString parameters.

### **Fix:**

The fix for this problem is to modify InvokeRegistry.pas as follows:

## type

```
{...}
```

```
TDataContext = class
```

```
protected
```

```
  FObjsToDestroy: array of TObject;
```

```
  DataOffset: Integer;
```

```
  Data: array of Byte;
```

```
  DataP: array of Pointer;
```

```
  VarToClear: array of Pointer;
```

```
  DynArrayToClear: array of TDynToClear;
```

```
  StrToClear: array of Pointer;
```

```
  WStrToClear: array of Pointer;
```

```
public
```

```
  constructor Create;
```

```
  destructor Destroy; override;
```

```
  function AllocData(Size: Integer): Pointer;
```

```
  procedure SetDataPointer(Index: Integer; P: Pointer);
```

```
  function GetDataPointer(Index: Integer): Pointer;
```

```
  procedure AddObjectToDestroy(Obj: TObject);
```

```
  procedure RemoveObjectToDestroy(Obj: TObject);
```

```
  procedure AddDynArrayToClear(P: Pointer; Info: PTypeInfo);
```

```
  procedure AddVariantToClear(P: PVarData);
```

```
  procedure AddStrToClear(P: Pointer);
```

```
  procedure AddWStrToClear(P: Pointer);
```

```
end;
```

## implementation

```
{...}
```

```
procedure TDataContext.AddStrToClear(P: Pointer);
```

```
var
```

```
  I: Integer;
```

```
begin
```

```
  { If this string is in the list already, we're set }
```

```
  for I := 0 to Length(StrToClear) - 1 do
```

```
    if StrToClear[I] = P then
```

```
      Exit;
```

```
  I := Length(StrToClear);
```

```
  SetLength(StrToClear, I + 1);
```

```
  StrToClear[I] := P;
```

```
end;
```

```
procedure TDataContext.AddWStrToClear(P: Pointer);
```

```
var
```

```
  I: Integer;
```

```

## Error publishing WebService's WSDL when MSXML4 is installed

### **Description:**

As of SP#2, Delphi's msxmldom unit will attempt to use MSXMLDOM v4.0 if the latter is present. However, this may cause the creation and Publishing of a WSDL document by a Delphi WebService to fail. The typical symptom of this failure is that the client requesting the WSDL gets back an HTML document instead; and the document contains the following error message:

*Error: This name may not contain the ':' character*

### **Fix:**

The fix to this problem is to modify XMLDoc.pas as follows: (Note that this file is in the Source/Internet directory)

```

function TXMLNode.FindNamespaceDecl(const NamespaceURI: DOMString): IXMLNode;
var
  I: Integer;
  Attr: IXMLNode;
begin
  Result := nil;
  for I := 0 to AttributeNodes.Count - 1 do
    if SameNamespace(VarToStr(AttributeNodes[I].NodeValue), NamespaceURI) and
    (AttributeNodes[I].Prefix = SXMLNS) then
    begin
      Attr := AttributeNodes[I];
      if SameNamespace(VarToStr(Attr.NodeValue), NamespaceURI) and
        ((Attr.Prefix = SXMLNS) or (Attr.NodeName = SXMLNS)) then
        begin
          Result := AttributeNodes[I];
          Break;
        end;
    end;
  end;
end;

```

```

    if (Result = nil) and Assigned(FParentNode) then
        Result := FParentNode.FindNamespaceDecl(NamespaceURI);
    end;

procedure TXMLNode.DeclareNamespace(const Prefix, URI: DOMString);
begin
    if Prefix <> '' then
        SetAttributeNS(SXMLNS+NSDelim+Prefix, SXMLNamespaceURI, URI) else
        SetAttributeNS(SXMLNS, SXMLNamespaceURI, URI);
    end;

function TXMLNode.GetPrefixedName(const Name, NamespaceURI: DOMString): DOMString;
var
    NSDecl: IXMLNode;
begin
    { The method adds a prefix to a localname based on the specified URI.
      If there is no corresponding namespace already declared or if
      the name is already prefixed, then nothing is done. }
    if (doAutoPrefix in OwnerDocument.Options) and not IsPrefixed(Name) then
        begin
            NSDecl := FindNamespaceDecl(NamespaceURI);
            if Assigned(NSDecl) and (NSDecl.LocalName <> '') then
                if Assigned(NSDecl) and (NSDecl.NodeName <> SXMLNS) then
                    Result := MakeNodeName(NSDecl.LocalName, Name)
                else
                    Result := Name;
            end else
                Result := Name;
        end;
    end;
end;

```

## HTTPRIO component reloads a Service's WSDL for each WebService call

### **Description:**

When using the WSDLLocation property of a THTTPRIO to invoke a Web Service, each invocation results in a 'GET' of the WSDL document. NOTE: This bug was introduced when proxy support was added for the retrieval of the WSDL.

### **Fix:**

The fix to this problem is to modify WSDLNode.pas as follows:

```

{ ActivateWSDL }
function ActivateWSDL(WSDL: TWSDLItems; const Name: string; const Password: string;
const Proxy: string): Boolean;
begin
    Result := True;
    try
        { if not WSDL.Active then begin }
        if not WSDL.Active then
            begin
                WSDL.StreamLoader.UserName := Name;
                WSDL.StreamLoader.Password := Password;
                WSDL.StreamLoader.Proxy := Proxy;
            end;
    end;
end;

```

```

WSDL.Load(WSDL.FileName);
{ end }
end;

except
  on E: EDOMParseError
  begin
    Result := False;
    raise EWSDLLoadException.CreateFmt(SWSDLLError, [WSDL.FileName, E.Message]);
  end;
  on Ex: Exception do
  begin
    Result := False;
    raise Ex;
  end;
end;
end;

```

### (Ole)Variant array of one element are incorrectly deserialized

#### **Description:**

When a WebService Server or Client receives data that's deserialized into an OleVariant or Variant type, if the XML data sent is an array of a single element, the deserialization logic fails to see the data as an array; This causes a problem if the consumer of the (Ole)Variant expects an array. This problem may cause a MIDAS FetchParams of one parameter to fail, for example (while the call with two or more parameters succeed).

#### **Fix:**

The fix to this problem is to modify OPToSOAPDomConv.pas as follows:

```

procedure TSOAPDomConv.WriteVarArray(RootNode, Node: IXMLNode; Name: InvString; V:
Variant);
var
  I, DimCount: Integer;
  LoDim, HiDim, Indices: array of integer;
  V1: Variant;
  ElemNode: IXMLNode;
  VAPropSet: Boolean;
begin
  if not VarIsArray(V) then
  begin
    WriteVariant(RootNode, Node, Name, V);
  end
  else
  begin
    ElemNode := Node.AddChild(Name);
    DimCount := VarArrayDimCount(V);
    SetLength(LoDim, DimCount);
    SetLength(HiDim, DimCount);
    for I := 1 to DimCount do
    begin
      LoDim[I - 1] := VarArrayLowBound(V, I);

```

```

    HiDim[I - 1] := VarArrayHighBound(V, I);
end;
SetLength(Indices, DimCount);
for I := 0 to DimCount - 1 do
    Indices[I] := LoDim[I];
VAPropSet := False;
while True do
begin
    V1 := VarArrayGet(V, Indices);
    if VarIsArray(V1) and not VarIsType(V1, varArray or varByte) then
        WriteVarArray(RootNode, ElemNode, SDefVariantElemName, V1);
    else
begin
        WriteVarArray(RootNode, ElemNode, SDefVariantElemName, V1);
        ElemNode.SetAttributeNS(SVarArrayType, SBorlandTypeNamespace, VarType(V));
    end else
begin
        WriteVariant(RootNode, ElemNode, SDefVariantElemName, V1);
        if not VAPropSet then
            begin
                SetAttributeNS(RootNode, ElemNode, SVarArrayType, SBorlandTypeNamespace,
IntToStr(VarType(V)));
                ElemNode.SetAttributeNS(SVarArrayType, SBorlandTypeNamespace, VarType(V));
                VAPropSet := True;
            end;
        end;
    end;
    Inc(Indices[DimCount - 1]);
    if Indices[DimCount - 1] > HiDim[DimCount - 1] then
        for i := DimCount - 1 downto 0 do
            if Indices[i] > HiDim[i] then
                begin
                    if i = 0 then Exit;
                    Inc(Indices[i - 1]);
                    Indices[i] := LoDim[i];
                end;
            end;
        end;
    end;
end;
end;
end;

```

## Bad XML Namespaces for 'dateTime' and other XSBuiltIn types when members of Complex Type

### **Description:**

dateTime, decimal and other types implemented as a TXSxxxx class (in XSBuiltIn.pas) have incorrect namespaces when they are members of a complex (i.e. TRemotable-descendant) type.

### **Fix:**

The fix to this problem is to modify OPToSOAPDomConv.pas as follows:

```

function TSOAPDomConv.CreateObjectNode(Instance: TObject; RootNode, Node: IXMLNode;
                                       Name, URI: InvString; UsePrefix: Boolean):
InvString;

var

    {...}

    end
    else
    begin
        ClsType := GetTypeData((PropList[I].PropType)^).ClassType;
        RemClassRegistry.ClassToURI(ClsType, ElemURI, TypeName, IsScalar);
        MultiRef := MultiRefObject(ClsType);

        if IsScalar then
        begin
            ElemNode := InstNode.AddChild(ExtPropName);
            if not RemTypeRegistry.TypeInfoToXSD((PropList[I].PropType)^, ElemURI,
TypeName) then
                raise ESOAPDomConvertError.CreateFmt(SRemTypeNotRegistered,
[GetTypeData((PropList[I].PropType)^).ClassType.ClassName]);
                if not GetTypeData((PropList[I].PropType)^).ClassType.InheritsFrom
(TRemotable) then
                    raise ESOAPDomConvertError.CreateFmt(SScalarFromTRemotables,
[GetTypeData((PropList[I].PropType)^).ClassType.ClassName]);
                    {$IFDEF OPENDOM}
                        ElemNode.SetAttributeNS(SSoapType, XMLSchemaInstNameSpace, TypeName);
                    {$ELSE}
                        AttrNodePre := FindPrefixForURI(RootNode, Node,
XMLSchemaInstNameSpace);
                        ElemNode.Attributes[MakeNodeName(AttrNodePre, SSoapType)] := TypeName;
                    {$ENDIF}

                        ElemNode.Text := TRemotableXS(Obj).NativeToXS;
                        { Create node }
                        ElemNode := CreateScalarNodeXS(RootNode, InstNode, ExtPropName,
                                                        ElemURI, TypeName,
                                                        TRemotableXS(Obj).NativeToXS, True);
            end
        else
        begin
            if not MultiRef then
            begin
                if IsObjectWriting(Obj) then
                    raise ESOAPDomConvertError.Create(SNoSerializeGraphs);

                {...}

            finally
                FreeMem(PropList, Count * SizeOf(Pointer));
            end;
        end;
    end;
end;

```

## Article #28520: How do I search backwards in the C++Builder/Delphi editor?

### Question:

The standard editor key mapping sets F3 as the "Find Next", but there doesn't appear to be a hot-key for "Find Previous". How can I search backward?

### Answer:

There is no hot key for "Find Previous". Most of the time, people only need to "Find Previous" when they've gone too far in their "Find Next". In this situation, you can use Ctrl-Z. Technically, this will "Select previously selected text", but will effectively "Find Previous" on items already "Found".

## Article #28603: Unable to locate PDOXUSRS.NET when using Novell client 4.83

### Question:

I am receiving an error message from the BDE reporting it cannot connect to PDOXUSRS.NET located on my network server.

### Answer:

There is a file locking problem with Novell Client version 4.83 and this BDE error message is a direct result. The problem has been addressed with a patch released by Novell, located here: <http://support.novell.com/servlet/tidfinder/2961866>

## Article #28605: Project options window and other IDE windows appear too small.

### Question:

IDE windows such as the Project Options window appear too small to work with. How can I fix this problem?

### Answer:

If you are using a Matrox Dual-Head video card, the problem may be caused by their driver software. Try right clicking on the dual-head setup icon in the Taskbar (beside the time) or enter your display options, and disable the "Save/Restore Window positions" option.

Last Modified: 17-JUL-02

## Article #28615: What causes internal error T2261?

### Question:

What causes the internal compiler error t2261?

### Answer:

This is usually caused by using a **break** or **continue** statement outside of a loop construct. Breaks are designed exclusively for use inside of a loop.

Last Modified: 12-APR-02

## Article #28616: Getting a result set from an Oracle stored procedure in Delphi or C++Builder.

### Question:

How do I get a result set from an Oracle Stored Procedure?

### Answer:

A REF CURSOR is required to return a result set from a stored procedure. You will need to put the procedure in a package. To create a package use the following SQL command:

```
CREATE PACKAGE MYPKG
IS
    TYPE CursorType IS REF CURSOR;
END MyPkg;
```

Then when you create the procedure:

```
CREATE PROCEDURE RETURN_RESULT_SET
(oCursor IN OUT MyPkg.CursorType) AS
BEGIN
    open oCursor for select * from SomeTable;
END;
```

In Delphi or C++Builder, set the TStoredProc parameter DataType as type ftCursor. At this point you should treat the TStoredProc component like a TQuery and use the Open method instead of ExecProc.

You should also be sure you have the [latest BDE](#) installed.

Last Modified: 12-APR-02

## Article #28620: Problem with IBClientDataSet component in Delphi 6.

### Question:

Why is Delphi freezing when I close a form or application containing IBClientDataSet

### Answer:

There was an issue with IBClientDataset which sometimes caused a problem with the Delphi IDE. This was resolved in an updated version of the IBX components which are available for download from Code Central.

You may want to install Delphi 6 update 2 first.

Last Modified: 16-APR-02

## Article #28662: How to get WebSnap applications to display new lines in a MEMO.

You may have noticed your WebSnap applications display MEMO's without new lines even though there are new lines in the memo.

### Answer:

When WebSnap retrieves the memo field the script variable is replaced with the text from the memo. Since the end result is HTML the browser automatically ignores new lines in the document.

One simple way you can preserve new lines is to wrap the script variable in `<PRE>` `</PRE>` tags.

You can replace the server script with something like this:

```
<PRE><% WriteColText(vDataSetAdapter1_MEMO.DisplayText) %></PRE>
```

## Article #28666: Where is 2AllBooks.pdf?

### Question:

Where is the file 2allbooks.pdf?

### Answer:

This file is simply an index to the Interbase document set. This file and the corresponding documentation are not on the Delphi 6 CD, but they are available for download from our [web site](#). The file 2allbooks.pdf is contained in the [InterBase 6.0 Beta Documentation Set](#).

Last Modified: 10-MAY-02

## Article #28675: Sending an early response in a WebSnap application loses session values.

Sometimes you will want to send out information as it is being processed in your WebSnap Application. One way to do this is to call Response's `SendResponse` method. If you are using session components then you will also need to make a call to the Session's `UpdateResponse` method to preserve your session values.

An example of how to do this is listed below:

```
Session.Values['a'] := 'could be lost... unless';  
Response.Content := 'Response.SendResponse Sent';  
Session.UpdateResponse(Response); // add this line  
Response.SendResponse;           // now send the response
```

## Article #28692: Can't load package dclnet60.bpl

### Question:

Why am I getting the error "Can't load package dclnet60.bpl when running Delphi?"

### Answer:

There is a conflict between Delphi 6.0 or 6.1 and C++ Builder 6, with some files they share. The solution is to install the [Delphi 6 update pack 2](#) which fixes this.

Last Modified: 17-MAY-02

## **Article #28694: Missing database login prompt.**

### **Question**

Why am I not getting a login prompt when I open a TDatabase connection?

### **Answer**

A change between Delphi 5 and Delphi 6 requires that you now add the unit DBLogDlg to the uses clause if you want the default login dialog to appear. This dialog appears when TDatabase.LoginPrompt is set to true.

Last Modified: 17-MAY-02

**Article #28699: Oracle 9i BDE certification.**

**Question**

Does the BDE 5.2 support Oracle 9i?

**Answer**

No. BDE version 5.2 is currently certified for Oracle 8.0.4, 8.1.6, and 8.1.7 but not 9i.

If you need 9i support you can use dbExpress.

For more up to date information check the readme which ships with your version.

**Article #28718: Keep getting error: "Maximum number of DBPROCESSES already allocated".**

**PROBLEM:**

**Getting Error "Maximum number of DBPROCESSES already allocated" using Midas/BDE.**

**SOLUTION:**

Start the BDE Administrator and in the configuration go to the driver you are using and increase the MAX DBPROCESSES number.

This property is not available for all native drivers.

Last Modified: 06-JUN-02

## **Article #28734: Setting the Just-in time debugger default in Delphi 6.**

### **Question:**

Why can't I set the Just-in-time debugger default when starting Delphi 6?

### **Answer:**

If Delphi was installed as Administrator and you are running it as a user who does not have administrator rights then you cannot set this option. However, you should not need to set it since it was set by the Administrator who installed Delphi. Simply choose "no" and check the box (so it will not ask again).

Last Modified: 06-JUN-02

**Article #28735: Missing package libpng.so.2 when installing Kylix 2 on Mandrake Linux 8.2.**

**Question:**

Why am I getting an error stating that the package libpng.so.2 is missing when I try to install Kylix 2?

**Answer:**

There is a conflict with libpng version 2 and version 3 so Mandrake linux 8.2 does not ship with version 2, as outlined in [this article](#).

Please note that Kylix 2 is not supported on this version of Mandrake Linux - it is supported on Mandrake 8.0.

See the [installation requirements](#).

**Article #28740: Trial and open editions of Kylix and Delphi do not include all files.**

**Question:**

Why can't I find the file actnres.pas in the trial edition?

**Answer:**

The source code is not included in the trial editions of Kylix and Delphi. In addition the Images directory is not included in the trial and open editions of Delphi. One of the tutorials calls for the use of these files so unfortunately you will not be able to complete the

Note: Interbase is not included with the Kylix trial but it is available in a separate download from our website.

Last Modified: 10-JUN-02

**Article #28746: Internal error 2349 while installing Delphi.**

**Question:**

What does internal error 2349 mean while installing Delphi6?

**Answer:**

This is a Windows Installer (MSI) error.

It means "Copy Resumed With Different Info".

It most commonly occurs because the CD is dirty or scratched.

If cleaning the CD does not help you may need to copy the Delphi install onto your hard drive. You can also try turning off virus protection software while running the install

If you decide to copy the install to the hard drive you only need to copy the Install directory and all the files in the root of the CD including setup.exe and install.txt.

## Article #28773: Error "No invocable class registered..." in Midas/Soap app after installing Delphi 6 update pack 2.

### Question:

Why am I getting the error **No invocable class registered that implements interface SOAPMidas.IAppSOAP** of (soap action/path) "**http://www.borland.com/namespaces/Types-IAppServerSOAP**" after installing Delphi 6 update pack 2?

### Answer:

There is a new property added to TSoapConnection called UseSOAPAdapter. This property should be True if the backend is a C++ service and false if it is a Delphi service. The default in Delphi is true. If you are getting this error you should change this property to false.

### Explanation from Borland R&D:

*Delphi SOAP remotes IAppServer 'as-is'. This interface uses the safecall calling convention that is only available in Delphi. More specifically, safecall is not available in C++. In order to have C++ and Delphi interop we needed to expose SoapDM via a different interface. That new interface is IAppServerSOAP. The latter is essentially IAppServer except that the methods utilize the stdcall instead of safecall convention. This interface is used by C++Builder SOAP DataModules.*

*We struggled with whether Delphi SOAP Modules should be moved to IAppServerSOAP too. There were several reasons for and against. Eventually, we settled on leaving Delphi SOAP DM with IAppServer (for now) - mainly for compatibility reasons.*

*This means that TSoapConnection can talk to either interface. The useSOAPAdapter should be true if the backend is a C++ service and false if it is a Delphi one.*

## Article #28798: How to catch a 'Tab Character' key stroke inside your TEdit control.

**Question:** How can I catch the tab character inside of my Edit controls?

**Answer:** This can easily be done by overriding the forms CMDialogKey procedure. To see how this works drop a Edit on the form and enter in the following code:

```
procedure TMyForm.CMDialogKey(Var Msg: TWMKEY);  
begin  
    if (ActiveControl = Edit1) and (Msg.Charcode = VK_TAB) then  
        begin  
            ShowMessage('Somebody Tabbed?');  
        end;  
    inherited;  
end;
```

Also, make sure to add the following line to your forms definition:

```
procedure CMDialogKey(Var Msg: TWMKey); message CM_DIALOGKEY;
```

**Article #28812: Kylix freezes after clicking the Register Now button.**

**Question:**

Why is Kylix freezing after I click the Register Now button?

**Answer:**

It is possible that Kylix only appears to freeze when in actuality the registration dialog has opened but cannot be seen, and is waiting for input. Check all of the icons in the system tray or try moving the registration window by hitting Alt-Tab to see if you see another window with the registration dialog.

## Article #28841: The {Program Name} is linked to the missing export OLEAUT32.DLL: VarNot

### Problem

After installing Update Pack 2 for Delphi 6, deploying even the most basic application on a machine running Windows 95 will give the following error when trying to run the app:

The {Program Name} is linked to the missing export OLEAUT32.DLL:VarNot This problem will also occur on a machine running Windows 98 without any DCOM updates applied. Windows 98SE doesn't exhibit this behavior.

### Solution

In order to resolve this issue, install the Win95 DCOM 1.2 Service Pack and on a Windows 98 Machine apply the DCOM update. This update can be obtained from <http://msdn.microsoft.com>

Last Modified: 01-JUL-02

## Article #28849: SQL Explorer Form isn't Displaying Controls Properly

### Symptoms:

Occasionally the splitter bar saves a position value when SQL Explorer exits that can't be overwritten in later runs of SQL Explorer. An example of this is sometimes experienced with the Enter SQL Tab. Once the results of a SQL statement are displayed a user could choose to make the result grid larger and totally hide the "Enter SQL" part. Every now and then the splitter won't move and appears to be stuck.

### Solution:

The settings for SQL Explorer are stored in the registry and will be updated when SQL Explorer is closed, so the first step is to close all instances of SQL Explorer. If Delphi is running be sure to close it as well. Next you should start Regedit and browse to the following location in the registry:

```
HKEY_CURRENT_USER\Software\Borland\Database Explorer\ 2.0\DbXForm
```

Here are all of the settings for SQL Explorer. For the above scenario you will see a value for Dbx.QuerySplit of 0. Changing this to any positive value should resolve the issue. If you start SQL Explorer through Delphi then the value may be stored somewhere else in the registry. You will need to change this value as well if you are still experiencing the issue.

Last Modified: 08-JUL-02

## Article #28863: Using TTable generates errors when using Filters

**Synopsis:** A "Capability not supported" error is generated when I activate a table that is using filters.

**Solution:** You will want to double check the case of the fields that you are referencing in you filter string. The field names are case sensitive, so capitalizing one letter that wasn't capitalized during the building of the table is the same as misspelling the field name.

Last Modified: 30-JUL-02

## **Article #28878: Access Violation at address ### in module vcl60.bpl or coreide60.bpl when running a project in Delphi**

### **Problem:**

Getting the error "Access violation at address ### in module vcl60.bpl" when running a project in Delphi, often followed by other AVs.

### **Solution:**

The exact cause for this is not currently known. It seems to happen sometimes with a new installation of Delphi on Windows XP.

Possible solutions:

Reset the user registry settings by running the utility D6RegClean.exe which is located in the Delphi bin directory.

Reinstall Delphi, running the utility above after uninstalling (it is also located on the CD).

It is possible that the problem is linked to setting options in Delphi, such as the desktop preferences, before first running a project for the first time.

It is important to note that the registry settings for each user are set the first time Delphi is run, so be sure to run Delphi once after installing, before installing any 3rd party components.

## Article #28882: IDE Internal Error Solutions

### Question

I receive an "IDE Internal Error" message when I attempt to do practically anything in the Kylix 2 IDE. How can I resolve this problem?

### Answer

Change the driver used by XFree86 to 'fbdev' in the X configuration tool provided by your Linux distribution.

This particular solution resolved the problem on a laptop system using Trident video chipset on Mandrake 8.0 and SUSE 8.0 distributions, but may work for other distributions and chipsets. 'fbdev' is a generic, unaccelerated video driver for framebuffer devices. Use of this driver may work-around problems with the stock video driver.

A more complete solution in this situation might be to update the XF86 drivers or possibly downgrade drivers to a more stable version.

**Article #28888: Network initialization failed. Lock violation with file pdoxusrs.net.**

**Question:**

What is causing the error "Network initialization failure" and "lock violation"?

**Answer:**

There is a known file sharing issue with Novell client version 4.83 for Windows NT/2000. The solution is to install the [fix](#) from the [Novell support web site](#).

Last Modified: 22-JUL-02

**Article #28889: Applying Delphi updates to the evaluation version**

**QUESTION:**

**How do I apply the Delphi Updates to my trial (evaluation) copy of Delphi Enterprise?**

**ANSWER:**

The trial version of Delphi is simply for evaluation, not for serious development. It is not the same build as the full Delphi Enterprise version that you can purchase, which means the updates for Delphi 6 will not work on the trial version.

Last Modified: 25-JUL-02

**Article #28890: Removed FastNet while installing the Indy components.**

**QUESTION:**

**I installed the WinShoes Indy components in Delphi 5 and it removed NetMasters Fastnet components. How can I get the Fastnet components back?**

**ANSWER:**

Start Delphi 5 and select Component | Install Packages. Click on the Add Button and navigate to the Delphi 5 Bin directory. Select dclnmf50.bpl and click Open. Now select OK. You can now select Component | Configure Palette. Select [All] under the Pages ListBox. Click the Default Pages button and you will now have the FastNet tab back in your component palette.

Last Modified: 25-JUL-02

## Article #28912: MySQL queries yeild only 10 columns.

### Question:

My DBExpress connection to MySQL yeilds query results that return only 10 columns. What is the problem?

### Answer:

This is usually caused by a mismatch in driver versions. Check your 'dbxdrivers.ini' file, typically found in the "/Program Files/Common Files/Borland Shared/DBExpress" folder, and make sure the driver for MySQL is "dbexpmysql.dll" and not "dbexpmys.dll". Also make sure the proper MySQL client driver 'libmysql.dll' is accessible in the system path.

Last Modified: 25-JUL-02

## Article #28920: Delphi Generates "Can't Create Delphi32. \$\$\$" Errors when Launching.

### Synopsis:

When Delphi starts it reports errors about creating a `..\Delphi6\bin\Delphi32. $$$` file. Also, once Delphi is finished loading, it appears to be missing various items from the IDE.

### Solution:

This may be a problem with the current user not having appropriate security rights. Even if the user is part of the *Administrators* group it is still possible that the security attributes set on `\Delphi6\bin` directory don't allow your user to modify the directory.

To Resolve this issue you can change the security settings for Delphi's Bin directory. To do this:

- Open Explorer and Browse to `..\Delphi6\Bin` directory
- Right Click on the Bin directory | **Properties**
- Click on **Security Tab**
- Select your user and Allow Full Control to Permissions

If this resolves the issue, then you should examine all the directories that were created during Delphi's installation to verify these directories have Full Control set.

Last Modified: 30-JUL-02

## Article #28927: How to Get the Filename of the Process that is Currently Executing.

**Question:** I'd like to get the filename of the process that is currently executing?

**Solution:** A call to `GetModuleName` will return the name of the file that is currently executing your code. You will need to pass it the correct handle to the module in order for it to correctly return the filename that it is associated with, specifically `hInstance`. Below is some sample code to return the filename:

```
function GetModName: String;  
var  
    fName: String;  
    nsize: cardinal;  
begin  
    nsize := 128;  
    SetLength(fName, nsize);  
    SetLength(fName, GetModuleFileName(hinstance, pchar(fName), nsize));  
    Result := fName;  
end;
```

Last Modified: 30-JUL-02

**Article #28944: Runtime error 230 when running Kylix application outside of the IDE.**

**Question:**

Why am I getting runtime error 230 when running my application outside of the Kylix IDE?

**Answer:**

This error generally means your application cannot find a needed library.

Tunning the command **source \kylix\bin\kylixpath** in Linux should fix this. See the file `deploy.txt` that comes with Kylix.

If this does not resolve your error you may want to chech the Kylix deploy [newsgroup](#) for more information.

Last Modified: 31-JUL-02

## Article #28963: How to Convert a String of Integers into an Array of Byte.

**Question:** How can I create an array of byte values that correspond to an integer string of arbitrary length?

**Suggestion:** The best solution is to dynamically create an array of byte that has length equal to that of the string. Once you have your array you can fill the array with the values from the string, however there is some offset since the ascii representation of the character '1' isn't equivalent to 1. Below is a sample of how one might return an array of byte:

```
interface
uses
    ...
type
    //dynamic array type for Array of Byte
    TByteArr = array of byte;

    ...
implementation

function ArrOfByte(AStr: String): TByteArr;
var
    i: integer;
begin
    SetLength( Result, Length(AStr));
    for i := 0 to Length(AStr) - 1 do
        Result[i] := ord(AStr[i + 1]) - 48;
end;
```

## Article #28964: Converting Double Types from Little Endian to Big Endian Using Variant Records.

**Question:** How can I convert my doubles from Little Endian to Big Endian?

**Solution:** The conversion is very simple. It requires that you swap the 8 underlying bytes of the double such that the first byte goes to the last, the second byte goes to the second of last, and so on. The following Record definition and procedure should convert you doubles from Little Endian to Big Endian and back again.

```
type
  //enumeration used in variant record
  BytePos = (EndVal, ByteVal);

  PEndianCnvRec = ^EndianCnvRec;

  EndianCnvRec = packed record
    case pos: BytePos of
      //The value we are trying to convert
      EndVal: (EndianVal: double);
      //Overlapping bytes of the double
      ByteVal: (Bytes: array[0..SizeOf(Double)-1] of byte);
    end;

  //A gets B's values swapped
procedure SwapBytes( A, B: PEndianCnvRec );
var
  i: integer;
begin
  for i := high(A.Bytes) downto low(A.Bytes) do
    A.Bytes[i] := B.Bytes[High(A.Bytes) - i];
end;
```

Below is an example of how one might use the above procedure. Start a New application and drop a button on the form. Then use the following code for the button click:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  a,b,c: EndianCnvRec;
begin
  a.EndianVal := 23344.55555;
```

```
SwapBytes(@b,@a);  
ShowMessage(FloatToStr(b.EndianVal));  
SwapBytes(@c,@b);  
ShowMessage(FloatToStr(c.EndianVal));  
end;
```

## Article #28999: Error "Can't load package dclbdbdesign.so.6.9" when starting Kylix 3 for C++.

### Question:

What is causing the error "can't load package ...dclbdbdesign.so.6.9" "Access violation at address..." when starting Kylix 3 for C++?

### Answer:

There is a problem which seems to exist only with the Professional edition of Kylix 3 when running the C++ version, and only when running on certain versions of Linux, including RedHat 7.3 and SuSE 8.0. It may also occur on RH 7.2 if you have upgraded your kernel.

Please note that this error *does not* occur on any of the Linux versions and distributions Kylix 3 has been certified for (listed on [the Borland web site](#) or on [shop.borland.com](http://shop.borland.com)).

**Possible workarounds:** Some people have reported success by removing the SOAP components, and then restarting Kylix 3. After restarting you may even be able to reinstall the SOAP components.

## Article #29033: Kylix 3 freezes when opening or saving a file.

### Question:

Why is Kylix 3 freezing when I try to open or save a file?

### Answer:

The exact cause of this problem has not yet been determined. You should be able to get out of it by using kill -2 to shut down Kylix.

There is a problem which seems to exist only with the Professional edition of Kylix 3 on Redhat 7.3. It may also occur on RH 7.2 if you have upgraded your kernel.

Please note that this error *does not* occur on any of the Linux versions and distributions Kylix 3 has been certified for (listed on [the Borland web site](#) or on [shop.borland.com](http://shop.borland.com)). If you are experiencing this issue the solution is to move to a supported Linux distribution and version - i.e. Redhat 7.2.

**Possible workarounds:** One workaround that is reported to work instead is to download the latest kernel source (2.4.19) from <http://www.kernel.org/pub/linux/kernel/v2.4/> and build it.

Last Modified: 09-SEP-02

**Article #29034: Kylix 3 trial - compiler errors state "message catalog not found".**

**Question:**

Why are compilation errors showing up as "message catalog not found" instead of the text of a real message?

**Answer:**

This is a known issue with the Kylix 3 trial edition.

There is a fix available for this problem. Please see the Kylix 3 downloads page here: [http://www.borland.com/products/downloads/download\\_kylix.html](http://www.borland.com/products/downloads/download_kylix.html). Click the "Updates" link under the "Registered Users" section.

## Article #29035: Delphi 7 and Visibroker 3.3 support

### Question:

I have an application that uses Visibroker 3.3 that I wrote with Delphi 5. Can I work with this using Delphi 7?

### Answer:

Visibroker 3.3 support was removed from Delphi 7. Delphi 7 ships with Visibroker 4.5 for C++. In order to use an application that was written with Visibroker 3.3, you will have to migrate the app to Visibroker 4.5.

Last Modified: 31-AUG-02

## Article #29037: Changing the Desktop wallpaper using Delphi

### Question

How do you change the Desktop wallpaper for Windows using Delphi?

### Solution

You will use the SystemParametersInfo function found in the Windows API to set the desktop wallpaper. Drop a button on your form and in the OnClick event for the button place the following code:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    PicPath: String;  
begin  
    PicPath := 'C:\WINNT\Prairie Wind.bmp';  
    SystemParametersInfo(SPI_SETDESKWALLPAPER, 0, pChar(PicPath),  
SPIF_SENDCHANGE)  
end;
```

Last Modified: 12-SEP-02

## Article #29045: Evaluating Corba using the Delphi 7 Trial

### Question

Installing Delphi 7 Trial didn't allow the option of installing Visibroker. Can the Delphi 7 Corba features be evaluated with the Delphi 7 Trial?

### Answer

The Corba demo's do get installed with the Delphi 7 Trial. In order to get them to work, you must install an evaluation version of Visibroker 4.5 for C++. Once you do this, you will be able to try the Corba demo's. The Corba Wizards in the Object Repository will not be installed with the Delphi 7 Trial.

Last Modified: 31-AUG-02

## Article #29048: Corrupted .pdf files in the Corba EJB demo folder

### Question

Attempting to open the .pdf files in the Delphi7\Demos\Corba\Idl2Pas\EJB directory gives the error: "There was an error opening this document. The file is damaged and could not be repaired." How can I obtain the non-corrupted pdf files? The two files that are corrupted are: Getting Started EJB.pdf  
Simplified IDL demo.pdf

### Answer

You need to obtain the working .pdf files from Borland. Create an free Install Support case from Borland's site and request the working .pdf files. The URL to create a free support case is:

[http://support.borland.com/devsupport/create\\_install\\_case.html](http://support.borland.com/devsupport/create_install_case.html)

Last Modified: 31-AUG-02

## Article #29049: Help files for Idl2Pas in Delphi 7 Enterprise

### Question

The help files for Idl2Pas in Delphi 7 Enterprise didn't get installed on the hard drive. With Delphi 6, the help files were installed in the Delphi 6\Doc\Idl2Pas directory. Where is the Help for Idl2Pas in Delphi 7?

### Answer

Due to space constraints on the Delphi 7 installation CD, the help files for Idl2Pas were left out. They can be found on the Companion Tools CD (disk 1) in the borland directory. Open up the borland directory on that CD and you will see the file:

Online+PDF Docs.zip

Copy this file to your hard drive and extract the contents to a location of your choice.

Last Modified: 31-AUG-02

**Article #29050: Mystery errors compiling Delphi project.**

**Question:**

Why am I getting errors on lines where there are no errors or on lines that do not exist?

**Answer:**

This can occur if there are hidden characters in the .pas file.

The simplest way to fix it is to open the file in a text editor such as Wordpad, add a space anywhere to be sure it resaves the file and then close the file. Then try reopening and compiling in Delphi.

## Article #29064: A Better Way to End the Endless Registration Loop when Trying to Register Delphi 6

**Synopsis:** Delphi is prompting to register the product. After registering the product the an error message is displayed to register the product again. Further attempts to register the product are unsuccessful.

**Solution:** There is an alternative method to resolving the registration loop, which doesn't require D6RegClean and a repair of Delphi. Instead you can preserve your current installation by removing three registry keys and registering once more.

The registry keys can be removed using the RegEdit tool, Start | Run | RegEdit. The Keys to remove are listed below:

```
HKEY_CURRENT_USER\Software\Borland\Delphi\ 6.0\LM  
HKEY_CURRENT_USER\Software\Borland\Delphi\ 6.0\LMLIC  
HKEY_CURRENT_USER\Software\Borland\Delphi\ 6.0\LMKEY
```

## Article #29082: Where is the Rave PDF File Documentation for Delphi 7?

### Question

Where is the Rave PDF File Documentation for Delphi 7?

### Answer

These files are located on the Companion Tools CD Disk 1 and are bundled in a zip file.

**\borland\Online+PDF Docs.zip**

Unzip that on your hard drive and you will see a Rave directory with the .pdf files.

Last Modified: 20-SEP-02

## Article #29083: Where is TCorbaConnection in Delphi 7?

### Question

Where is TCorbaConnection in Delphi 7?

### Answer

TCorbaConnection was removed from Delphi 7 since it only works with VisiBroker 3.3. Support for Visibroker 3.3 has been removed from Delphi 7. Delphi 7 ships with and supports VisiBroker 4.5. Take a look at the Midas XML demo that ships with Delphi. This demo shows you how to use Corba ANY, eliminating the need to use TCorbaConnection.

Last Modified: 12-SEP-02

## Article #29091: Problem installing Delphi: Internal Error 2735.

### Problem

When installing Delphi, Internal Error 2735 is raised before the installation completes.

### Solution

Copy the Install directory and all the files in the root directory on the CD to

C:\

It is important to make sure you copy the files to the root drive. Reboot in Safe Mode and install. Reboot again to finish.

If that fails to resolve the problem, check the file attributes for the **autoexec.bat** file found in the root of your C:\ Drive. If it is set to Read Only, this can be causing the problem so simply set the file attributes to "**Archive**" and you should be able to work around this issue.

## Article #29142: E2257 in QRvDefine.hpp when compiling TRvProject

### Question:

I am using the C++ IDE of Kylix 3 and the bundled Rave Reports 4.5 Community Edition. When I try to compile a TRvProject component, I get the following error:

```
-----  
[C++ Error] QRvDefine.hpp(147): E2257 , expected  
-----
```

The line 147 referenced in QRvDefine.hpp reads:

```
-----  
typedef TRaveUnits TRaveUnits;  
-----
```

How can this be resolved?

### Answer:

Line 147 in QRvDefine.hpp is incorrect. This issue can be resolved by correcting it to:

```
-----  
typedef double TRaveUnits;  
-----
```

Be sure to save the changes to QRvDefine.hpp, and then try compiling again.

## Article #29143: Cannot register Kylix 3 due to endless registration loop

### Question:

I have installed Kylix 3 and am having problems registering it. The registration wizard appears repeatedly and will not accept my registration information as valid, even though it is correct.

How can I register Kylix 3?

### Answer:

This could be due to a corrupt registration file. The solution is to delete the existing registration files for Kylix 3, and then re-register.

First, navigate to your `.borland` directory, which will be found in the home directory of the user under which Kylix 3 was installed. If you installed as root, this will be `/root/.borland`. If you installed as an user, this will be `/home/username/.borland`.

Inside the `.borland` directory, delete these two files: `registry.dat`, `registry.slm`. Doing so should remove the existing registration information.

Then, register Kylix 3 again, and it should work properly.

Last Modified: 30-SEP-02

**Article #29156: Kylix 3 freezes on start up.**

**Question:**

Why is Kylix freezing during startup?

**Answer:**

This is most likely a video problem. The settings on your machine may need to be adjusted. Try changing the screen size and/or color resolution. 800 X 600 and 24 bit seem to work most often. If they do not work for you then continue to experiment. If this does not work you may need to update your video driver.

If the freeze is occurring after clicking the Register Now button then you should see [this document](#) as well.

Last Modified: 30-SEP-02

## **Article #29178: Kylix 3 does not install properly on Redhat 8.0**

Kylix 3 is not installing properly on Redhat 8.0. It seems some of the files are copied to the root directory instead of the kylix3 directory, and some are not copied at all. Currently we do not workaroud for this. When we do it will be posted here.

Please note that Kylix 3 is only certified for use on RedHat 7.2.

**Article #29179: Error: "d7reg.exe has encountered a problem and needs to close."**

**Question:**

Why am I getting the error "d7reg.exe has encountered a problem and needs to close. We are sorry for the inconvenience."?

**Answer:**

You may also get the error

```
"exception EReadError in module D7Reg.exe.  
Error reading image1.picture.data: Access violation at  
address 005715D6 in module qtintf70.dll."
```

This is a video driver problem. It is more likely to occur on laptops. The solution is to upgrade your video driver. You could also try different settings for your screen resolution and/or density.

## Article #29200: During installation, Serial Number and Authorization are invalid

### Question

*When installing, I reach the point where serial number and authorization key are requested. I enter them, but the installer says they are invalid. What's wrong?*

### Answer

First of all, make sure you are entering the correct serial number. Since most Borland products packages actually contain multiple software installations, it is easy to accidentally use the serial number for one product on another. Before you start typing a serial number, check the bottom right corner of the printed serial number tag, and find the product description the serial number is made for. Make sure this matches the software you are running or installing.

Second, make sure you are typing the digits and numbers in correctly. Use the correct capitalization and punctuation when entering the serials. Most Borland software provides you with multiple edit boxes for each character group of the serial number, so you may omit the hyphen (-). Other products, such as Kylix, do require you to enter the hyphens between character groups.

If you are running Windows 98, you may need an update to your system's common windows controls (comctrl32.dll) which is most easily acquired by installing Internet Explorer 5 or later. On these systems, the edit boxes themselves have a problem taking input from the keyboard and despite having entered the proper information, will still not recognize the serial correctly.

**Article #29212: When attempting to compile, the following error comes up: 'System.pas' not found**

## **Problem**

**After installing Delphi 7, I select File | New | Application and try to compile. It fails with the error: 'System.pas' not found**

## **Resolution**

This can happen if your environment path settings inside the IDE isn't setup properly. Inside the Delphi IDE, select Tools | Environment Options and select the Library tab. In the **Library Path**, make sure you have the following: *(keep in mind that your path may vary depending on where you installed Delphi)*

c:\Program Files\Borland\Delphi7\**Lib**  
c:\Program Files\Borland\Delphi7\**Bin**  
c:\Program Files\Borland\Delphi7\**Imports**  
c:\Program Files\Borland\Delphi7\**Projects\Bpl**  
c:\Program Files\Borland\Delphi7\**Rave5\Lib**

**BPL output** directory should be:

c:\Program Files\Borland\Delphi7\Projects\**Bpl**

**DCP output** directory should be:

c:\Program Files\Borland\Delphi7\Projects\**Bpl**

The **Browsing Path** should be: *(this will vary depending on whether you have Delphi 7 Personal, Professional, or Enterprise)*

c:\Program Files\Borland\Delphi7\source\vc1;  
c:\Program Files\Borland\Delphi7\Source\Rtl;  
c:\Program Files\Borland\Delphi7\source\rtl\Corba45;  
c:\Program Files\Borland\Delphi7\source\rtl\Sys;  
c:\Program Files\Borland\Delphi7\source\rtl\Win;  
c:\Program Files\Borland\Delphi7\source\rtl\common;  
c:\Program Files\Borland\Delphi7\source\Internet;  
c:\Program Files\Borland\Delphi7\source\clx;  
c:\Program Files\Borland\Delphi7\source\websnap;  
c:\Program Files\Borland\Delphi7\Source\WebMidas;  
c:\Program Files\Borland\Delphi7\Source\Indy;

c:\Program Files\Borland\Delphi7\Source\IntraWeb;  
c:\Program Files\Borland\Delphi7\Source\Samples;  
c:\Program Files\Borland\Delphi7\Source\Soap;  
c:\Program Files\Borland\Delphi7\Source\ToolsAPI;  
c:\Program Files\Borland\Delphi7\Source\Xml

## Article #29231: Converting a Delphi VisiBroker 3.3 app to Delphi 7 VisiBroker 4.5

### Question:

**How can I migrate my Delphi VisiBroker 3.3 code to use Delphi 7 and VisiBroker 4.5?**

### Answer:

In Delphi 7 you can use the command line tool: `tlibimp` to convert your VisiBroker 3.3 tlb files to Corba IDL. Type the following at the command line:

*(Keep in mind that the path depends on where your tlb file is located and substitute `MyTLBFile.tlb` with the name of the type library file you wish to convert)*

```
C:\Program Files\Borland\Delphi7\Projects\Corba\>tlibimp -Ic+ MyTLBFile.tlb
```

The files that are generated are: `MyTLBFile_TLB.dcr`, `MyTLBFile_TLB.pas` and `MyTLBFile_TLB.idl`. You can now use the Client/Server wizards and pass in the newly created IDL file to generate the stubs and skeletons. Now all that must be done is to transfer the code from the VisiBroker 3.3. application to the new VisiBroker 4.5 application in Delphi 7.

## Article #29232: My Kylix application won't run outside the IDE.

### Question:

Why is it when I try to run my Kylix App outside the IDE I get this message:  
"error loading shared libraries: libqtintf.so: cannot open shared file: No such file or directory"?

### Answer:

This message and similar ones occur when ../kylix/bin is not included in your path when trying to use CLX components. Running /usr/kylix/bin/kylixpath is a short fix, but you can also add the line to your .bashrc file to set the paths whenever you start a shell. Be sure to change the appropriate .bashrc (ie. for user jbrown /home/jbrown/.bashrc).

Example .bashrc:

```
-----  
#.bashrc  
  
..  
source /usr/kylix/bin/kylixpath  
..  
  
-----
```

Last Modified: 30-OCT-02

**Article #29239: How to enable .NET Compiler Warnings when using dcc32 compiler**

**Question:**

**How can I enable .NET Compiler Warnings when using the dcc32 compiler?**

**Answer:**

The Delphi 7 dcc32 compiler now supports three additional compiler warnings: Unsafe\_Type, Unsafe\_Code, and Unsafe\_Cast. These warnings are disabled by default, but can be enabled with source code compiler directives {\$WARN UNSAFE\_CODE ON}, compiler command line switches (dcc32 -W +UNSAFE\_CODE), and in Project|Options (Select Compiler Messages and select Unsafe Type, Unsafe Code and Unsafe TypeCast).

***NOTE: There is no space before or after the "+" in the command line switch***

## Article #29240: "CoInitialize has not been called" when using TXMLDocument

### Question:

I have an application that uses the XML components. This application worked just fine until I decided to make it multi-threaded. Now I am getting a "CoInitialize has not been called" error when I try and use an XML component.

### Answer:

Microsoft's XML parser, which the XML components use by default, is a COM-based parser, which means that COM needs to be initialized before you can use them. Delphi calls the CoInitialize function for you when an application starts up, but that function only initializes COM on the thread it was called from. You should put a call to CoInitialize at the beginning of your TThread descendant's Execute method and a matching CoUnInitialize at the end.

### Question:

I have a TXMLDocument component on my form, and I have no problems using it. However, I tried creating a TXMLDocument at runtime, and with the same exact code that worked earlier, I am getting access violations! What is causing this?

Last Modified: 31-OCT-02

## Article #29241: Strange access violations when using TXMLDocument at runtime

### Question:

I have a TXMLDocument component on my form, and I have no problems using it. However, I tried creating a TXMLDocument at runtime, and with the same exact code that worked earlier, I am getting access violations! What is causing this?

### Answer:

Most likely, you are creating TXMLDocument like this:

```
var
  Doc: TXMLDocument;
begin
  Doc := TXMLDocument.Create(nil);
end;
```

The important thing to notice is that you are passing in **nil** as the owner. What happens then is that TXMLDocument takes on a different behavior; it acts as a reference counted object that automatically frees itself when those references reach zero. This means that the next time you do something to Doc that causes a decrease in the reference count, you run the risk of destroying the object and invalidating your reference. The problem is that so much happens to TXMLDocument behind the scenes, inside of the VCL, that it is hard to say when exactly the reference count is getting modified. The easiest way to get around this is to use an interface pointer instead of a TXMLDocument reference, like so:

```
var
  Doc: IXMLDocument;
begin
  Doc := TXMLDocument.Create(nil);
end;
```

This lets you have more complete control over the reference, allowing you to specify when exactly it gets decremented by setting the reference to **nil**.

## Article #29304: Limit reached for installs using Kylix serial number

### Question:

I am attempting to register Kylix, but cannot and get the following error:

-----  
Error registering software. The limit has been reached for installs using this serial number, please contact customer service to increase the allowed install count.  
-----

How do I get around this and register Kylix?

### Answer:

Borland has a registration server that keeps count of how many times a product has been registered. The default count is five registrations. This error indicates that your serial number has already been registered five times, and the registration currently being attempted exceeds the count.

You can get this count increased by calling Borland's registration hotline at (888) 588-2230. Explain to the representative who answers the phone what product you have, as well as the full error message, and he or she (after asking for your relevant information) will be able to increase the count to allow for additional registrations.

Last Modified: 05-DEC-02

## Article #29306: Kylix 3 encounters declaration syntax errors in TIME.H

### Question:

I am using Kylix 3, and get declaration syntax errors in TIME.H when attempting to compile any project. How can I solve this problem?

### Answer:

The TIME.H declaration syntax errors can be resolved by going into the Project Options and moving the reference to /usr/include up in the Include path. Preferably, /usr/include should be moved to the very first position in the ordered Include path.

The exact cause of this problem is not yet known, but it could be related to Kylix 3 finding a different version of TIME.H elsewhere on the system. For reference, Kylix 3 contains four instances of TIME.H, in the following locations:

- /usr/include/linux
- /usr/include/bits
- /usr/include/sys
- /usr/include

## Article #29314: Upgrading from Delphi 7 Enterprise to Delphi 7 Architect

### Question:

**Is it necessary to uninstall Delphi 7 Enterprise in order to upgrade to the Architect version?**

### Answer:

In order to upgrade from Delphi 7 Enterprise to Delphi 7 Architect version, simply get the BoldSoft CD from the box and install that to your Delphi 7 Enterprise. Doing it this way, when you go Help | About, it will still show Delphi 7 Enterprise, but you will have all the BoldSoft components installed. If you want it to read Delphi 7 Architect simply uninstall the Enterprise version and install Architect.

## Article #29385: Kylix 3 C++ IDE hangs at the splash screen under Mandrake 9.0

### Question:

I have installed Kylix 3 under Mandrake 9.0. The Delphi IDE works fine, but the C++ IDE does not load past the splash screen. How can I get around this problem?

### Answer:

Kylix 3 is not officially supported under Mandrake 9.0, and at this point, it is unclear what the precise cause of this problem is. However, it does seem to be specific to Mandrake 9.0, and appears related to the SOAP and dbExpress packages. One workaround is to remove the references to those packages, as follows.

-----  
#1.

Navigate to the `.borland` directory, which can be found in the home directory of the user under which Kylix 3 was installed. If you installed as root, this will be `/root/.borland`. If you installed as an user, this will be `/home/username/.borland`.

#2.

Inside the `.borland` directory, open up the `bc69rc` file in a text editor.

#3.

Scroll to the [Known Packages] section and look for references to the SOAP and dbExpress packages. These should be called `dclsoap.so.6.9` and `dclbdbx.so.6.9`, respectively.

#4.

Remove the two aforementioned package references and save the changes to `bc69rc`.  
-----

After having done the above, the C++ IDE should work. Of course, the SOAP and dbExpress packages will be unavailable. If you require them, then they can be manually added by selecting Component | Install Packages... However, be sure to uninstall them again before exiting the C++ IDE, otherwise, the problem will reoccur the next time you attempt to start it.

## Article #29390: Kylix 3 registration fails and indicates the Serial Number is for an upgrade version only

### Question:

I have installed Kylix 3 and am attempting to register it via the "Register by Phone or Web Page" option. I have submitted my Serial Number and Registration Key, and received a reg###.txt file in return. However, after placing the reg###.txt file in my user's home directory as instructed, I get the following error in the registration wizard:

-----  
The serial number is an upgrade version only of the product, and requires a prior version of the product to be registered. That registration entry was not found, registration failed.  
-----

How can I register Kylix 3?

### Answer:

This error message is a relatively general one, and does not necessarily actually indicate a problem with the Serial Number or product version. It primarily indicates that there is a problem with the reg###.txt (## is a number that depends on what edition of Kylix you have) file.

There is an outside chance that the problem is due to a corrupt registration file. I strongly recommend first removing the existing registration information according to the steps outlined in [this](#) document. If the steps in that document do not help, then you can also delete (or rename if you want to play it safe) the entire .borland directory, thereby causing Kylix 3 to regenerate all the information within it.

If deleting registry.dat, registry.slm, and .borland do not make any difference, then chances are the problem is not due to corrupt registration files, but rather a bad reg###.txt file.

A common problem is unwanted text in the reg###.txt file. Since reg###.txt is sent to you as an e-mail attachment, this can happen if you save it via a HTML-based e-mail client. Such clients sometimes insert bits of HTML into reg###.txt upon saving, thereby rendering it invalid. Open up reg###.txt in a text editor, and see if it contains any extra text - you only want the exact same text contained in the "Borland Product Registration" e-mail. If there is any text other than that, then it will be a problem. To avoid this problem, it is recommended that you save reg###.txt via a different e-mail client (perhaps a non HTML-based one that will not insert HTML), or manually copy and paste the contents of the "Borland Product Registration" e-mail into a text file named reg###.txt (rather than directly save it through the e-mail client). This will ensure that it contains no extra text and is intact.

You should be able to successfully register Kylix 3 once your registration information and reg##.txt file are correct.

## Article #29541: Converting a Delphi VisiBroker 3.3 app to Delphi 7 VisiBroker 4.5

### Question:

**How can I migrate my Delphi VisiBroker 3.3 code to use Delphi 7 and VisiBroker 4.5?**

### Answer:

In Delphi 7 you can use the command line tool: `tlibimp` to convert your VisiBroker 3.3 tlb files to Corba IDL. Type the following at the command line:

*(Keep in mind that the path depends on where your tlb file is located and substitute MyTLBFile.tlb with the name of the type library file you wish to convert)*

**C:\Program Files\Borland\Delphi7\Projects\Corba\>tlibimp -Ic+ MyTLBFile.tlb**

The files that are generated are: `MyTLBFile_TLB.dcr`, `MyTLBFile_TLB.pas` and `MyTLBFile_TLB.idl`. You can now use the Client/Server wizards and pass in the newly created IDL file to generate the stubs and skeletons. Now all that must be done is to transfer the code from the VisiBroker 3.3. application to the new VisiBroker 4.5 application in Delphi 7.

Last Modified: 26-MAR-03

## Article #29558: Accessing InterBase via dbExpress with Kylix produces error: Unable to load libgds.so

If you install the dbExpress InterBase client driver, you will need to have libcrypt.so installed. Some Linux distributions omit this library or do not include it in a base install. If your distribution does not include libcrypt.so, contact the package maintainer, or search online Linux resources, such as <http://rpmfind.net/>.

Some Linux distributions provide all the libraries required to run Kylix, but do not use the naming conventions that Kylix expects. The most common problem is library names with embedded version information, while Kylix expects version-independent names. If Kylix software fails to run because of missing shared libraries, check for similarly named libraries in /lib and /usr/lib. You can then create a symbolic link to help Kylix find the library. For example, if you are missing libcrypt.so but find /lib/libcrypt.so.1, you would enter the following shell commands as root:

```
cd /lib  
ln -s libcrypt.so.1 libcrypt.so
```

## Article #29573: Unable to register Delphi 7 Trial

### Problem:

**The Delphi 7 Architect Trial is installed but it won't register properly or it won't import the activation file.**

### Answer:

Here some things to check:

- 1) That the attachment is saved as a .txt file rather than some other format
- 2) That the file is saved in the Home Directory specified in the e-mail that was sent
- 3) That the file is not modified in any way. (i.e. don't delete the text of the e-mail contained in the text file)
- 4) That you don't have other reg\*.txt files present in the directory as these might interfere
- 5) That you don't have any TSR's running in the background
- 6) Additionally, you should not have a full version of Delphi 7 and the Delphi 7 Architect Trial installed at the same time
- 7) If the other 6 don't solve the problem, check if there is a .borland folder in your Home Directory. If there is, delete it and try to run the Trial again. Note: Deleting this directory will also delete registration information for JBuilder 6 and up.

**Article #29575: Checking to see if the latest RTL Update has been applied to Delphi 6**

**Question:**

**How can I verify that I have applied the latest RTL update for Delphi 6?**

**Answer:**

Open up an Explorer Window and navigate to the Windows System32 directory. Look for the file titled **rtl60.bpl**. The Date/Time stamp should read 12/5/2002 6:03 AM

## Article #29651: Following the directions in the websnap readme for compiling Apache for DSO support doesn't work

### Question:

Following the directions in the websnap readme for compiling Apache for DSO support didn't work. What went wrong?

### Answer:

The readme.txt file, found in the *kylix3\examples\delphi\websnap* directory has the following section:  
----- Apache DSO's ----- Creating an Apache DSO requires that the source from Apache be recompiled with a shared core. Get the source from [www.apache.org](http://www.apache.org) and configure it with:

```
./configure \  
"--with-layout=Apache" \  
"--enable-rule=SHARED_CORE" \  
"--enable-module=most" \  
"--enable-shared=max" \  
"--prefix=/usr/local/apache"
```

In order to get Apache compiled with DSO support, change the word **most** in the line:

```
"--enable-module=most" \  
to so. The entire section should look like:
```

```
./configure \  
"--with-layout=Apache" \  
"--enable-rule=SHARED_CORE" \  
"--enable-module=so" \  
"--enable-shared=max" \  
"--prefix=/usr/local/apache"
```

## Article #29707: Exception encountered when installing the Rave BE 5.08 update

### Problem:

### When installing the Rave BE 5.08 update you get this error message:

The exception unknown software exception (0x0eedfade) occured in the application at location 0x77eab2f0.

### Answer:

This usually happens when you attempt to install the update without starting Delphi for the first time. In general, it is a good idea to start Delphi after install one time before applying any updates or installing any third party components.

Last Modified: 27-MAR-03

**Article #29754: Procedure entry point cannot be found in Rave50VCLBE70.bpl**

**Problem:**

**When starting Delphi 7, this error occurs: "The procedure entry point @Rpcanvas@initialization\$qqrv could not be located in the dynamic link library Rave50VCLBE70.bpl"**

**Answer:**

This error occurs if you install the Rave BE 5.08 update, subsequently uninstall Delphi 7, reinstall Delphi 7, and then start Delphi without applying the update. You can fix this by applying the update. If you do not want to install the Rave BE update, you can solve this by uninstalling Delphi, searching for and deleting Rave50VCLBE70.bpl and Rave50CLXBE70.bpl, and then reinstalling Delphi.

**Article #29802: Having trouble changing the path that Delphi 6 is installed to**

**Problem:**

**I installed Delphi 6 then decided to uninstall it. Now when I install it again, I am unable to choose a different path to install Delphi to. How do I change this?**

**Answer:**

There is a setting in HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\installer\UserData\[user specific number]\Components\[some GUID] that this path is pulled from. Delete or change this setting to the directory that you want to install Delphi to.

## Article #29804: Installing Kylix 3 Open Edition on Mandrake 9

### Question:

**How can I get Kylix 3 Open Edition installed and running on Mandrake 9?**

### Answer:

Open a Super User Terminal, select "Sessions/New Root Midnight Commander" and in "/", create a directory "temp"

Download or copy the file kylix3\_open.tar.gz into the "temp" directory you just created.

Check that all necessary programs are installed on your system:

Open kmenu/configuration/packaging/Remove Software or kpackage

Check for installation of the following:

kernel => 2.2 (mdk9.0 uses 2.4)

libgtk => 1.2 (mdk 9.0 uses 1.2-1.2.10-29)

libjpeg => 6.2 (mdk 9.0 uses 6.-66-25)

XIIR6 (XFree86) (mdk uses 4.2.1-3)

XFree86-dev (mdk9.0 uses 4.2.1-3)

glibc-dev (mdk9.0 uses 2.2.5-16)

Once you have verified that you have all of the necessary programs do the following:

In a Super User Terminal do:

```
cd /temp
```

```
tar xzf kylix3_open.tar.gz
```

In user terminal (NOT as root):

```
cd /temp/kylix3_open
```

```
./setup.sh
```

In Gui select "I Agree"

Now select "install"

Logout and log back in as same user to get the Borland Kylix entry in the KDE menu

In Borland Kylix 3 menu, select "register now"

In the Gui select "next"

In the Gui select "Finish"

The Gui disappears and the registration process has completed.

The Kylix Delphi and Kylix C++ IDE's can now be run.

**Article #29805: Class not registered error in Delphi 7 when dropping any component installed with dclisp70.bpl onto a form**

**Problem:**

**After installing the dclisp70.bpl package into the Delphi 7 IDE, I try to drop any component added by that package onto a form and I get a class not registered error message. Why does this occur?**

**Answer:**

The Internet Solutions Pack contains NetManage components and is included for backward compatibility with Delphi 2. The ocxs' that are required to use these components haven't shipped with Delphi since Delphi 3. We recommend that you use Indy instead.

Last Modified: 12-MAY-03

## Article #29806: Class TReport not found

### Problem:

**I am migrating an application that was developed with Delphi 2. This application uses ReportSmith and used the TReport component. I keep getting the error Class TReport not found even though I copied the Report.dcu and RSCONSTS.dcu files into my Delphi Lib directory.**

### Explanation:

The files Report.dcu and RSCONSTS.dcu are shipped with the latest version of Delphi strictly for backward compatibility. What these files allow you to do is use the command line compiler to compile your existing project that contains the TReport component. You will not be able to open up this project inside the Delphi IDE and compile because the TReport component doesn't exist so your form will be unable to render this component. I would highly recommend rewriting any code that is dependent on TReport and use a reporting tool that is current and supported with the latest versions of Delphi. Delphi 7 ships with Rave so I would suggest looking into this.

## Article #29821: Installation incomplete: Unable to locate ModelMaker

### Problem:

**When starting ModelMaker within the Delphi IDE you receive this error: "Installation incomplete: Unable to locate ModelMaker." It works fine when logged in as a user with Administrative rights but not with other users. Why does this happen?**

### Answer:

The IDE integration expert uses HKey\_Local\_Machine\Software\ModelMaker\ModelMaker\6.0 to detect the install dir. If you do not have Administrative rights during install some OS'es do not allow writing to HKLM and as a result the IDE experts cannot locate ModelMaker. You can workaroud this by starting ModelMaker from your Start menu or creating a shortcut on the desktop and running it from there.

**Article #29826: Where are the Office '97 components in Delphi 7?**

**Problem:**

**What package contains the Office '97 components in Delphi 7**

**Answer:**

The Office '97 components can be found in Delphi7\bin\dclaxserver70.bpl

Last Modified: 27-MAR-03

## Article #29833: Intraweb Context Sensitive Help not working

### Problem:

**Pressing F1 when an Intraweb component is selected fails to bring up the help information**

### Resolution:

Start up Delphi. Select **Help | Customize**. This will start Borland OpenHelp and it should open up *D7.ohp*. Select the **Contents** tab. Select **Add Files** by clicking the add files button or right clicking in the ListView box. You must add the *Intraweb.cnt* file. In order to see this file you must change the Files of Type from \*.toc to \*.cnt. If you installed Delphi to the default location, this file can be found at:

*C:\Program Files\Borland\Delphi7\Help\IntraWeb*

You will get a message asking:

*Do you want to change the system registry path of Intraweb.cnt from C:\Program Files\Borland\Delphi7\Help\IntraWeb\Intraweb.cnt to C:\Program Files\Borland\Delphi7\Help\IntraWeb\Intraweb.cnt?*

Select **yes**.

Click on the **Index** tab. Select **Add Files**. You must add the *Intraweb.hlp* file. If you installed Delphi to the default location, this file can be found at:

*C:\Program Files\Borland\Delphi7\Help\IntraWeb*

You will get a message asking:

*Do you want to change the system registry path of INTRAWEB.HLP from C:\Program Files\Borland\Delphi7\Help\IntraWeb\INTRAWEB.HLP to C:\Program Files\Borland\Delphi7\Help\IntraWeb\INTRAWEB.HLP?*

Select **yes**.

Click on the **Link** tab. Select **Add Files**. You must add the *Intraweb.hlp* file. If you installed Delphi to the default location, this file can be found at:

*C:\Program Files\Borland\Delphi7\Help\IntraWeb*

**Save** the project inside of OpenHelp. **Close** OpenHelp. You must now go to the Delphi 7 help directory (using a utility such as Windows Explorer). If you installed to the default location go to:

***C:\Program Files\Borland\Delphi7\Help***

Erase all **.gid** files. These are hidden files so make sure you are able to view hidden files. Context Sensitive help should now work with the **Intraweb** components.

**Article #29839: Where can I download the updated Registration Wizard for Delphi 7?**

**Question:**

**I am experiencing the blank registration wizard problem when I try and register Delphi 7. I heard there is an updated wizard that fixes this problem. Where can I download the updated Wizard?**

**Answer:**

Open up a browser and go to the following site:

<http://info.borland.com/devsupport/delphi/>

Click on the link that says Delphi 7 Registration Wizard.

## Article #29840: CLX components not showing up under the System tab on the component palette

### Problem:

The following components aren't showing up under the System tab on the component palette:

- DirectoryTreeView
- FileListView
- FileIconView
- FileEdit
- FileHistoryComboBox
- FilderComboBox

### Resolution:

These components will only show up if you are developing a clx application. If you do **File | New | Clx Application** you will see these components under the **System** tab on the component palette.

Last Modified: 27-MAR-03

**Article #29853: Icon Image not valid error**

**Problem:**

**When starting Delphi, it says "Icon Image not Valid". How do I resolve this?**

**Answer:**

First, go into your display settings and disable Hardware Acceleration. Then, run Delphi. If that does not help, navigate to the directory which contains your delphi32.dro file and delete it. This file may be corrupt. The next time you run Delphi, this file will be regenerated, and the problem should be solved.

Last Modified: 27-MAR-03

**Article #29862: Error: "Projects macro in project group file is missing or incorrect"**

**Problem:**

**When starting Delphi or trying to create a new application you get the error "Projects macro in project group file is missing or incorrect"**

**Answer:**

To resolve this, go into Tools|Editor Options|Display and set the Right Margin property to a higher value. This sometimes occurs when too small a value is specified.

## Article #29865: problems using valuetype in idl file: idl2pas: fatal error

### Problem:

When running idl2pas on a idl file that has a valuetype, the following error is raised:  
*idl2pas: fatal error: internal problem; please contact Inprise Customer Support*

### Explanation:

This isn't a bug. valuetype isn't currently supported with idl2pas. Review the documentation on idl2pas for a complete reference of the idl to Delphi mapping.

Last Modified: 27-MAR-03

**Article #29866: problems with dbExpress connecting to DB2. Get error: SQL0204N "tablename" is an undefined name. SQLSTATE-42704**

**Problem:**

When using dbExpress and accessing a table on a DB2 database, if I have a select statement in the CommandText property of a TSQLDataSet in the form:

```
select * from employee
```

the following error is raised when attempting to apply updates:

```
Project TestDBX.exe raised exception class EDatabaseError with message '[IBM][CLI Driver] [DB2/NT] SQL0204N "employee" is an undefined name. SQLSTATE-42704
```

This error is raised even after verifying that employee is a valid table in the database.

**Solution:**

The way dbExpress handles the SQL statement requires the Table Name and the Schema Name to be in Upper Case letters. In the CommandText property, change the sql statement to:

```
select * from EMPLOYEE
```

and the error listed above should go away.

## **Article #29872: Cannot install Delphi because a previous version is already installed**

### **Problem:**

**You cannot install Delphi because it indicates that a previous version is already installed.**

### **Answer:**

This can occur on install if a different SKU of Delphi of the same version of Delphi was not completely uninstalled. The MSI still thinks that Delphi is installed. To resolve this, run regedit and navigate to HKEY\_CURRENT\_USER\Software\Microsoft\Installer\Products and do a search for Borland. One of the subfolders will contain a reference to the version of Delphi that you are trying to install. Export this subfolder as a safety measure and then delete it from the registry. Then, try to install Delphi and you should no longer get this error message.

Last Modified: 28-MAR-03

## Article #29900: Installing Delphi in Silent Mode

### Question:

How can I do a silent mode installation of Delphi?

### Answer:

Since Delphi has a per user license agreement, silent mode installations of the product are not supported.

Quoting directly from the license.txt file:

"You may install the Product on a reasonable number of machines provided that the Named User is the only individual permitted to use the Product"

This being stated, as long as you are adhering to the license agreement, there shouldn't be a need to automate the installation process since the product shouldn't be installed on more than a handful of machines.

**Article #29994: 'Drive C: does not exist. Please verify the correct drive was given' when trying to import slip activation file**

**Problem:**

**When trying to register Delphi on a Windows 98 or Windows ME machine you receive the 'Drive C: does not exist. Please verify the correct drive was given' error after browsing to and opening your activation file.**

**Answer:**

There is a small bug in the CLX TOpenDialog which is used in the registration wizard. This error only surfaces on Windows 98 or Windows ME machines. To get around this just type the path to the activation file in the edit box rather than clicking the ellipsis to open the TOpenDialog box.

## Article #29995: Rave 4.5 CE version for Linux doesn't print

### Problem:

After installing Rave 4.5 CE version on Linux (for Kylix) everything seems to work properly except I can't get the Rave Project to print.

### Solution:

This is a known issue with the Rave 4.5 CE version on Linux. This has been fixed in the Rave 5.0 BEX release. To purchase the 5.0 BEX version, go to Navrona's web site at:

<http://www.nevrona.com>

## Article #29996: Enabling automatic scrolling in a TTreeView

### Problem:

**How do I emulate the scrolling behavior of Windows Explorer when dragging a folder to the top or bottom of my TTreeView?**

### Answer:

Set your TTreeView's DragMode property to dmAutomatic and then place this code in your Treeview's OnDragOver event:

```
procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer; State: TDragState; var Accept: Boolean);  
var  
    HitTests : THitTests;  
begin  
    HitTests := TreeView1.GetHitTestInfoAt(X,Y);  
    if (htAbove in HitTests) then  
        TreeView1.TopItem := TreeView1.TopItem.GetPrevVisible  
    else if (htBelow in HitTests) then  
        TreeView1.TopItem := TreeView1.TopItem.GetNextVisible;  
end;
```

## Article #29997: Numerous users on one Windows 2000 / NT / XP machine

### Question:

Different developers share the same machine. Each developer has their own username on the same machine. Is there a way to register Delphi once on the machine and push that registration info to each additional user on that machine?

### Answer:

No, this isn't allowed as Delphi has a per user license agreement. This means each user that will be using Delphi will need to register.

Last Modified: 02-JUN-03

## Article #30002: Failed to create process error when trying to use the CORBA Server or Client Wizards

### Problem:

Running the Corba Wizards from the Object Repository (File | New | Other | Select the CORBA tab and choose the CORBA Client or CORBA Server wizard) fails after selecting the IDL file and clicking the Generate button. It fails with the message:

*Failed to create process. The system cannot find the file specified.*

### Solution:

This problem is caused by having the wrong JRE installed on the machine. Download and install the 1.3 (make sure it is 1.3.0 as later versions will not work) JRE or JDK from Sun's website at: <http://java.sun.com>. This should resolve this issue.

**Article #30003: When launching Delphi 7 on a Windows 95 machine you get this error: 'The COREIDE70.bpl is linked to missing export USER32.DLL: TrackMouseEvent'**

**Problem:**

**When starting Delphi 7 on Windows 95, I get 'The COREIDE70.bpl is linked to missing export USER32.DLL: TrackMouseEvent'**

**Answer:**

Delphi 7 is not certified on Windows 95 and ultimately we do not recommend that you use Delphi on this operating system. What is happening is that in Windows 98 and later editions of Windows, the TrackMouseEvent function is contained within USER32.dll. However, in Windows 95 it relies on Comctl32.dll to provide that functionality. A potential solution is to update your Comctl32.dll which can be done by installing Internet Explorer 5.5 or later.

**Article #30007: Using the Rave Reporting tool, how do I make a Header repeat on each page?**

**Problem:**

**How can I make a Header repeat on each page?**

**Answer:**

One way of doing this is to create a Global Page in the Rave Visual Designer, drop a Section component on the page and then put whatever you would like in your header into the Section component. Then, on each of your pages, drop a Section component and set it's Mirror property to the Global Page's Section component.

## **Article #30008: How do I insert today's date into my Rave Report?**

### **Problem:**

**I want to insert today's date into my Rave Report but can't figure out how to do it. How can I do this?**

### **Answer:**

In the Rave Visual Designer, drop a DataText component onto your page and then click the ellipsis next to your DataText component's DataField property. This will bring up the Data Text Editor. The Report variable combobox contains a long list of items such as the current date that you can use in your report by selecting the item and clicking the Insert Report Var button.

## Article #30023: Unable to resolve error, 'Table is read only.'

**Question:** When using an UpdateSQL component I get the following error when trying to apply updates: 'Table is read only.'

**Solution:** There are a couple of possible reasons for getting this error. First you should check that the query is indeed not set to read only. Next if you are using the **OnUpdateRecord** event then you will need to specify the result for the **UpdateAction** parameter. If the update is successful then **UpdateAction** should be set to *uaApplied*.

## Article #10531: BDE and the Year 2000

- Product: *BDE*
  - Version: *All*
  - Platform: *Windows 95, Windows NT, Windows 3.1*
- 

This document describes how the Borland Database Engine (BDE) operates in conjunction with the year 2000. It discusses all native drivers, SQL Links and ODBC.

What is Year 2000 compliance? Simply put, it is the ability to store and retrieve dates in any 4 digit century (the year 10000 will be a real problem!) and handle leap year days correctly. Given this minimum specification, the BDE clearly meets it. At this time, no further specification has been agreed upon by any standards committee. (As you read this document, you'll see that various vendors handle 2 digit years differently.) However, the March 1998 issue of Computer Magazine has proposed the following standard:

*Technology, including but not limited to, information technology, embedded systems, or any other electro-mechanical or processor based system, when used in accordance with its associated documentation, is capable of accurately processing, providing, providing, and/or receiving date data from, into, and between the twentieth and twenty-first centuries, and the years 1999 and 2000, including leap year calculations; provided that all other technology properly exchanges date data with it.*

All drivers handle leap year days correctly. Note that the year 2000 has a leap year day. This document does not discuss leap year days further because all drivers handle them correctly.

The one way you can insure that your programs that use the BDE are Year 2000 compliant is to always use 4 digit years. Given this one proviso, you can ignore the rest of this document. The rest of this document considers what happens when you enter 2 digit years for each driver.

With the exception of Paradox, dBASE, and FoxPro tables and when using QBE, the BDE passes dates as entered to the Client Software. No century is assumed. It is the responsibility of the connecting client to interpret the century. Below is how each driver type is known to respond to 2 digit years. Most information has been pulled from the associated vendors web site.

### **QBE**

If YEARBIASED in BDE Administrator is TRUE, all 2-digit date queries against all databases have 1900 added to them. If YEARBIASED in BDE Administrator is FALSE, all 2-digit date queries are assumed to be in the first century (Year 0001 to 0099). Because of this, all dates not in the 20th or 1st century must be expressed as 4-digit years.

### **Paradox, dBASE, FoxPro, Local SQL**

Dates entered into tables assume the current century of the local CPU.

For BDE versions less than 5.0, Local SQL against Paradox, dBASE and FoxPro tables assume the current century to be 1900. For Local SQL to use a century other than 1900 using BDE prior to 5.0 a 4-digit year must be used.

For BDE version 5.0 and later, local SQL against Paradox, dBASE and FoxPro tables assumes dates with 2 digit years to be in 1900 for years  $\geq 50$  and years to be in 2000 for years  $< 50$ . For Local SQL to use a century other than these defaults with BDE 5.0, a 4 digit year must be used.

## **Access 95**

Microsoft

Parsing on date entry. OLEAUT32. 2.20.4049 or greater is required in order for Access 95 to correctly recognize 2-digit date shortcuts as falling within a window between 1930 and 2029. Without that file update, Access assumes that all shortcut dates fall in the current century. See Microsoft for additional information.

## **Access 97**

2-digit shortcut handling:

Microsoft Access 97 interprets dates entered with a 2-digit shortcut to mean the 21st century in the following way.

1/1/00 through 12/31/29 are interpreted as 1/1/2000 through 12/31/2029

1/1/30 through 12/31/99 are interpreted as 1/1/1930 through 12/31/1999 See also [Microsoft](#)

## **Interbase**

From [InterBase](#)

InterBase provides a reasonable default interpretation of two-digit years. The InterBase server interprets a two-digit year as the nearest year within a 50-year range. For example, 2/28/48 is interpreted as 1948, whereas 2/28/47 is 2047.

## **Oracle**

From [Oracle](#)

If the current year is in the second half of the century (50 - 99)

- and a two-digit year between '00' and '49' is entered: This will be stored as a next century year. E.g. '02' entered in 1996 will be stored as '2002'.
- and a two-digit year between '50' and '99' is entered: This will be stored as a current century year. E.g.

'97' entered in 1996 will be stored as '1997'.

If the current year is in the first half of the century (00 - 49) and a two-digit year between '00' and '49' is entered:

- and a two-digit year between '00' and '49' is entered: This will be stored as a current century year. E.g. '02' entered in 2001 will be stored as '2002'.
- and a two-digit year between '50' and '99' is entered: This will be stored as a previous century year. E.g. '97' entered in 2001 will be stored as '1997'.

## **Sybase**

From Sybase

Implied century rule: <50 = 2000, >49 = 1900

Compliance issues description or comment relating to current product version:

## **Informix**

From Informix

Customers should be aware that Informix products often depend on data from other parts of the system, and Informix year 2000 compliance is not effective unless all of the customer's hardware, operating system, other software, and firmware correctly interpret and/or translate date data into a four digit year date and, when used in combination with the Informix products, properly exchange date data with it. It is the customer's responsibility to understand the manner in which applications are written to accept a date value and the habits of users entering dates into these applications. Generally, year 2000 issues associated with these problems must be addressed at the application level.

As described below, Informix has added a "DBCENTURY environment variable" feature to the Informix products listed in the table below which may help users provide year 2000 compliance in their existing applications without re-coding. Customers are encouraged to test their applications for the compliance described above. Customer applications, built using Informix products, which use only two-digit date storage may benefit from the DBCENTURY feature described below.

## **DBCENTURY Feature to Aid in the Year 2000 Solution**

The DBCENTURY environment variable was implemented to provide customers with an API-level year 2000 solution eliminating the requirement of the customer to modify application source code. The DBCENTURY environment variable is an indicator which controls how Informix products set the default century value for Date and Datetime datatypes when the user has not entered the full four digits for a year through a custom developed application. No changes are required to the application code whatsoever to take advantage of this feature. The only action to be taken by the application user is that DBCENTURY must be added to the login profile of each user on the client system, and is thereafter automatically applied to all Informix applications associated with that

login id.

For those versions of Informix products for which the DBCENTURY environment variable is supported (see table 2 below), if the DBCENTURY variable is not set in the user's profile, the Informix product will default the century value to the present century, which it obtains from the computer's system clock. If the DBCENTURY variable is set, it can be set to select a default date that is in the past, in the future, or closest to the computer's system clock. Informix anticipates that the latest setting will be the most generally applicable for the next several decades. For example, if Current date is "06/21/1998" and user enters two dates, "10/25/95" and "08/01/03", dates stored is shown below:

**Table 1: Example of DBCENTURY settings**

<b>DBCENTURY setting</b>	<b>Dates Stored</b>
P	10/25/1995, 08/01/1903
R	10/25/1995, 08/01/1903
C	10/25/1995, 08/01/2003
F	10/25/2095, 08/01/2003

If the DBCENTURY variable is not set in the user's login profile, the dates would default to "10/25/1995" and "08/01/1903", the present century. If the user enters the full four digits for the years into a four-digit year field in the application, the year will be accepted as entered, regardless of the DBCENTURY variable setting.

If the user enters into an application only two digits for the year, and the default century set through DBCENTURY is making an incorrect assumption on the range of dates to be entered, incorrect data will be stored and returned. For example, if a user enters '03 as shorthand for 1903, and the DBCENTURY variable is set to default to the closest date, the Informix product would store 2003. If the application is expected to manage dates which are more than 50 years in the past or in the future, in order to use DBCENTURY to best suit the needs of the application, please refer to the Informix documentation regarding the use of the various settings of DBCENTURY.

## **MSSQL**

From Microsoft

SQL Server allows users to specify only the last 2 digits of the year. However the year is still stored the same as if 4 digits were specified. The "two-digit year cutoff" configuration option defines how SQL Server 7.0 expands a 2-digit year to four digits. The option is specified as a 4-digit year, the default is 2049. If only two digits are specified for a year, and they are less than or equal to the last two digits of the 2-digit year cutoff option, the date is stored as being in the same century as the option. If the specified two digits are greater than the last two digits of the 2-digit year cutoff option, the date is stored as being in the century before the one specified in the option. For example, if the 2-digit year cutoff option is left at its default of 2049, the value 49 is stored as 2049 and 50 is

stored as 1950. If the 2-digit year cutoff option is set to 2029, the value 29 is stored as 2029 and 30 is stored as 1930.

## **DB2**

IBM offers a large amount of information on the year 2000. [http://www.s390.ibm.com/vse/vsehtmls/vn13sql.htm#Header\\_3](http://www.s390.ibm.com/vse/vsehtmls/vn13sql.htm#Header_3) indicates that two-digit dates that have a year less than 43 are assumed to be in the 21st century (20xx). Otherwise, they are assumed to be in the 20th century (19xx).

Please see the IBMs year 2000 web site at [IBM](#) for additional information.

## **ODBC**

Dates entered when connected via an ODBC driver are sent to the ODBC driver exactly as entered. If you enter a 4-digit year, a 4-digit year is sent. If you enter a 2-digit year, a 2-digit year is sent. The Server that the ODBC driver connects does interpretation of the date. If your ODBC driver connects to one the SQL Links drivers listed above, dates should be interpreted the same as the SQL Link driver. Otherwise, contact the manufacturer of the database that you connect to determine how 2-digits years are interpreted.

## Article #15005: Understanding the PARADOX.NET File

Technical Information Database

TI5B.txt Understanding the PARADOX.NET File

Product :BDE

### Description:

The net file regulates access to tables. Table access is enforced through the use of lock files, which are written out to the directories containing Paradox tables. A lock file points to a particular net file, which has exclusive control over the table. This means that any user wanting access to the table must use the net file that controls the table. In practice, this means that when your BDE program shares tables with Paradox users, you must initialize BDE with a netpath set to the Paradox net path. In the case of two Engine programs sharing tables, the net paths must be identical.

The message "Multiple Paradox net file found" indicates that these rules have not been followed. If you are certain that all current users have the same net path, this message usually indicates that an old lock file exists that points to a different net file. Old lock files can be deleted if care is taken to ensure that no one is currently using them. Deleting active lock files can produce unpredictable results and could cause loss of data.

## Article #15008: What to check when you cannot get an all users int

Technical Notes Database

TN8B.txt      What to check when you cannot get an all users int  
Category      :InterBase  
Platform      :All  
Product       :Borland SQL Lin 4.5

Description:

Keywords: IB, interface, connect

Question: I have three users trying to access data on my InterBase server via Paradox. I can get two users in just fine, but the system refuses to let me enter a third one.

Answer: There are a number of things that can cause this. First, can you get all three users into Paradox? If you are not using runtime, you need a valid license of Paradox for each user. If you cannot get all users into Paradox, first check to make sure that you have adequate licenses of Paradox for Windows. If you have adequate licenses of Paradox, make sure that all users are pointed to the same pdoxusrs.net file. If you suspect the pdoxusrs.net file may be the culprit, delete any pdoxusrs.net and the paradox.net files that you may find, when everyone is out of Paradox. (This is just in case you may have had a damaged pdoxusrs.net.) If that does not solve the problem, we will look to possible causes on the server side.

On the server side, make sure that you have valid UNIX logins for

each user who will be trying to access the data on the InterBase server. You can use the UNIX command "uname" to do this. eg. uname -x

Next, run gsec with the -display option to find out if all three users have access to the remote database. If you find that one of your users does not have access to the remote database, you will need to do an add to put that person into the remote servers list of users.

The final thing to check is the amount of RAM on the UNIX machine.

SCO UNIX requires a minimum of 8 meg of RAM. It also requires an additional .5 Meg of RAM for each user.

## Article #15017: Interrupt 3 patch

Technical Information Database

TI17D.txt - Interrupt 3 patch

Category :Turbo Pascal  
Platform :DOS  
Product :

### Description:

Turbo Pascal redefines the interrupt 3 vector to its own interrupt service routine used for handling Ctrl-C. However, the vector is permanently initialized to that interrupt routine even though the "U-" directive is specified.

This patch will permanently keep the Ctrl-C vector from being initialized, but will allow the use of DEBUG break points.

Use the DOS utility, DEBUG, to apply the following patch to a copy of your .COM file. Copy DEBUG.COM into the directory (or onto the diskette) where your working copy of .COM is located. At the DOS prompt, type the following information exactly as it

- Note:
1. DEBUG is not sensitive to upper and lower case. All addresses are listed in upper case for ease of readability.
  2. While in DEBUG, the prompt appears as a dash (-).
  3. If you do not receive the appropriate response, press "q", then , to quit. Check your version numbers and, if correct, try again.

For IBM versions of Turbo Pascal:

YOU TYPE	THIS APPEARS
DEBUG TURBO.COM	-
e0BE2	XXXX:0EB2 E8.
90	DC.

```
90          FD.
90          -
w           writing xxxx bytes
q           DOS prompt
```

For Generic versions of Turbo Pascal:

YOU TYPE	THIS APPEARS
DEBUG TURBO.COM	-
e0922	xxxx:0922 E8.
90          D1.	
90          FD.	
90          -	
w           writing xxxx bytes	
q           DOS prompt

## Article #15019: Conflicts between Delphi and Netcruiser

Technical Notes Database

TN19D.txt      Conflicts between Delphi and Netcruiser  
Category      :General Programming  
Platform       :All  
Product        :Delphi    All

### Description:

Users of Netcom's Netcruiser software have complained that, after they install Delphi, Netcruiser software exits with a GPF at startup.

It seems that Delphi installs a version of gauge.vbx which is incompatible with that used by Netcruiser. Delphi itself does not need to use gauge.vbx (it is only used by the BIGauge component), so the best solution is to remove the BIGauge component from the VBX component field, delete the offending copy of gauge.vbx, and then reinstall Netcruiser.

## Article #15026: MS-DOS interrupt 24 trap routine

Technical Information Database

TI26D.txt - MS-DOS interrupt 24 trap routine

Category :Turbo Pascal  
Platform :DOS  
Product :

### Description:

The following example routines are public domain programs that have been uploaded to our Forum on CompuServe. As a courtesy to our users that do not have immediate access to CompuServe, Technical Support distributes these routines free of charge.

However, because these routines are public domain programs, not developed by Borland International, we are unable to provide any technical support or assistance using these routines. If you need assistance using these routines, or are experiencing difficu

Thanks to Marshall Brain for the original code for this routine.

These routines provide a method for Turbo Pascal programs to trap MS-DOS interrupt 24. INT 24 is called by DOS when a "critical error" occurs, and it normally prints the familiar "Abort, Retry, Ignore?" message.

With the INT 24 handler installed, errors of this type will be passed on to Turbo Pascal as an error. If I/O checking is on, this will cause a program crash. If I/O checking is off, IOResult will return an error code. The global variable INT24Err will b

In most cases, INT24Result should be used, because INT24Err must be set back to false, and DOS sometimes restores its normal INT 24 handler after an error.

-----  
\*\*Note: Turbo's normal IOResult codes (and Turbo Access error codes)

for MS-DOS DO NOT correspond to I/O error numbers given in Appendix I of the Turbo Pascal manual, or error codes given in the I/O error nn, PC=aaaa/Program aborted message. Here is

IOResult	Turbo error	
00 (0)	00 (0)	none
01 (1)	90 (144)	record length mismatch
02 (2)	01 (1)	file does not exist
03 (3)	F1 (241)	directory is full
04 (4)	FF (255)	file disappeared
05 (5)	02 (2)	file not open for input
06 (6)	03 (3)	file not open for output
07 (7)	99 (153)	unexpected end of file
08 (8)	F0 (240)	disk write error
09 (9)	10 (16)	error in numeric format
0A (10)	99 (153)	unexpected end of file
0B (11)	F2 (242)	file size overflow
0C (12)	99 (153)	unexpected end of file
0D (13)	F0 (240)	disk write error
0E (14)	91 (145)	seek beyond end of file
0F (15)	04 (4)	file not open
10 (16)	20 (32)	operation not allowed on a logical device
11 (17)	21 (33)	not allowed in direct mode
12 (18)	22 (34)	assign to standard files is not allowed
90 (144)	90 (144)	record length mismatch

```

```

End;

Procedure INT24Off; {Disable INT 24 trapping. Should be done at the
                    end of the program, if you plan to be running
                    the program from within the Turbo compiler.}

Begin
  INT24Err:=False;
  If OldINT24[1]<>0 Then
    With RegisterSet Do
      Begin
        DS:=OldINT24[1];
        DX:=OldINT24[2];
        AX:=$2524;
        MsDos(RegisterSet);
      End;
    OldINT24[1]:=0;
    OldINT24[2]:=0;
  End;

Function INT24Result: Integer;
Var I : Integer;

Begin
  I:=IOResult;
  If INT24Err Then

  Begin
    I:=I+256*(INT24ErrCode+1);
    INT24On;
  End;

  INT24Result:=I;
End;

{ INT24Result returns all the regular Turbo IOResult codes if no
critical error has occurred. If a critical error, then the
following values are added to the error code from Turbo (each
is 256 times the INT24ErrorCode value returned by DOS):

256: Attempt to write on write protected disk
512: Unknown unit [internal dos error]
768: Drive not ready [drive door open or bad drive]
1024: Unknown command [internal dos error]

```

1280:	Data error (CRC)	[bad sector or drive]
1536:	Bad request structure length	[internal dos error]
1792:	Seek error	[bad disk or drive]
2048:	Unknown media type	[bad disk or drive]
2304:	Sector not found	[bad disk or drive]
2560:	Printer out of paper	[anything that the printer might signal]
2816:	Write fault	[character device not ready]
3072:	Read fault	[character device not ready]
3328:	General failure	[several meanings]

If you need the IOResult part, use

```
I:=INT24Result and 255; [masks out the INT 24 code]
```

For the INT 24 code, use

```
I:=INT24Result Shr8; [same as Div 256, except faster]
```

INT24Result clears both error codes, so you must assign it to a variable if you want to extract both codes:

```
J:=INT24Result;
```

```
Writeln('Turbo IOResult = ',J And 255);
```

```
Writeln('DOS INT 24 code = ',J Shr 8); }
```

```
{ Main program }
```

```
{ Run this with printer off (or no printer), and nothing in drive A }
```

```
Var F : File;
    I : Integer;
```

```
Procedure PrinterTest;
```

```
Begin
```

```
  WriteLn(LST,'test');
```

```
  I:=INT24Result;
```

```
  If I<>0 Then
```

```
    WriteLn('Printer error: ',I)
```

```
  Else
```

```
    WriteLn('Printer OK');
```

```
End;
```

```
Procedure FileTest;
```

```
Begin
```

```
  Assign(F,'A:FILE');
```

```
  {$I-}
```

```
  Reset(F);
```

```
  {$I+}
```

```
  I:=INT24Result;
```

```
If I<>0 Then
  WriteLn('Open failure on A:FILE : INT24Result=',I)
Else
begin
  WriteLn('A:FILE exists');
  Close(F);
end;
End;
```

```
Begin
  INT24On;
  PrinterTest;
  FileTest;
  PrinterTest;
  INT24Off;
  FileTest;
  PrinterTest;
End.
```

## Article #15037: Delphi End User CD-ROM can not be mounted by Novel

Technical Notes Database

TN37D.txt      Delphi End User CD-ROM can not be mounted by Novel  
Category      :General Programming  
Platform       :All  
Product       :Delphi    All

### Description:

Delphi End User can not be mounted on a Novell 3.11 server running the cdnet NLM. Novell states in their documentation that "not all CD's will be mountable." Currently there seems to be no work around for this problem.

### SOLUTION:

The only solution is to use a local CD-ROM drive and copy the files to the network hard-disk.

### POSSIBLE FIXES:

If the customer is using NOVELL 3.12 or 4.01 server, then there is a patch available from Novell for CDNET.nlm, it is not stated anywhere that this will fix the problem, but it might work. Novell is currently working with Borland on this problem.

## Article #15044: Direct Video Accessing

Technical Information Database

TI44D.txt - Direct Video Accessing

Category :Turbo Pascal  
Platform :DOS  
Product :

Description:

Using Mem and MemW you may address any location on the screen and change its value. A possible use might be creating a memory mapped text editor. The following is an example of using Mem to address the text screen one byte at a time. (Exchange \$B800 for \$B000 if you have a monochrome screen.)

```
program RAM2;
```

```
Var
```

```
  j, i : integer;  
  ch : char;
```

```
begin
```

```
  j := 0;  
  for i := 1 to 2048 do  
  begin  
    Mem[$B800:j] := $80;           {Accessing video RAM  
    Mem[$B800:j + 1] := $99       a byte at a time}  
    j := j + 2  
  end;
```

```
end.
```

When accessing RAM addressing a word at a time using MemW, you must be aware of the following:

1. In text mode, when you enter a word value, it is broken down into two bytes which are placed on the screen. Consequently, word values must equal the sum of two bytes that you want sent consecutively to the screen.
2. You must first assign the low byte, then the high byte of

the word.

3. You must increase the offset by two to access the next word in memory.

```
MemArray
program RAM1;
```

```
Var
  j, i : integer;
begin
  j := 0;
  for i := 1 to 2048 do
  begin
    MemW[$B800:j] := $9908;           { Accessing video RAM a word
                                       at a time }
    j := j + 2;
  end;
end.
```

The following program demonstrates how to write directly to screen memory and save and restore text screens. These routines may cause snow on some monitors. There are routines in the Editor Toolbox to read and write to the screen without snow, but they are much harder to use and less intuitive than these ones.

```
program ScreenTest;
type
  { Row, Column }
  ScreenType = array [1..25, 1..80] of record
    Character : Char;
    Attribute : Byte;
  end;

  AnyString = string [80];    { Generic string type }
```

{ The attribute byte of this data structure is formatted as follows:

Bits 0-3 hold the foreground color, bits 4-6 hold the background color, and bit 7 indicates whether blinking is on or off.

Bit	0	1	2	3	4	5	6	7
Color Part	FG	FG	FG	FG	BG	BG	BG	BL
Color Part Value	1	2	4	8	1	2	4	1
Bit Value (Decimal)	1	2	4	8	16	32	64	128
Bit Value (Hex)	\$01	\$02	\$04	\$08	\$10	\$20	\$40	\$80 }

```

var
  ColorScreen : ScreenType absolute $B800:0;
                { Use for color screen }
  MonoScreen : ScreenType absolute $B000:0;
                { Use for monochrome screen }
  SavedScreen : ScreenType;
                { Buffer to save the screen }

function MakeAttribute(Foreground, Background : Byte;
                      Blink : Boolean) : Byte;

{ Creates an attribute byte from a combination of foreground,
background, and blinking attributes }

begin
  MakeAttribute := Foreground + (Background shl 4) +
                    (Ord(Blink) shl 7);
end; { MakeAttribute }

procedure WriteString(S : AnyString; var Screen : ScreenType;
                    Col, Row, Attrib : Byte);

{ Writes a string into screen memory starting at a particular row and
column, using Attrib as the color attribute. }

var
  Counter : Byte;

begin
  for Counter := 1 to Length(S) do
  begin
    Screen[Row, Pred(Col + Counter)].Character := S[Counter];
    Screen[Row, Pred(Col + Counter)].Attribute := Attrib;
  end;
end; { WriteString }

begin
  SavedScreen := ColorScreen;      { Save the current screen }
  Window(25, 5, 55, 15);          { Create the new window }
  GotoXY(1, 1);                   { Move inside the new window }
  TextColor(Yellow);              { Change the current colors }
  TextBackground(Red);
  ClrScr;

```

```
        { Clear the window and fill it with color }
WriteString('  Press Return to continue...', ColorScreen, 25, 5,
MakeAttribute(Yellow, Red, False));
    { Write out prompt - note that WriteString uses the
      absolute row and column, not the row and column
      of the current window }
Read;                                { Wait for return to be pressed }
ColorScreen := SavedScreen;         { Restore old screen }
end.
```

## Article #15053: Modifying the aspect ratio in the graph unit

Technical Information Database

TI53D.txt - Modifying the aspect ratio in the graph unit

Category :Turbo Pascal  
Platform :All  
Product :

Description:

```
{*****  
The .BGI files supplied with the Graph unit declare an Aspect  
Ratio constant which is used to draw circles and arc segments.  
For some applications it is necessary to alter the aspect ratio.  
One such application results when trying to perform a screen dump  
to the printer. In quad-density graphics printing, it is useful  
to redefine the aspect ratio so the displayed results will be  
circular instead of ellipsoid.
```

The following program demonstrates how a programmer can alter the predefined Xasp element of the aspect ratio and to obtain the current value. Note that the Graph unit already has the procedure for GetAspectRatio.

```
***** }
```

```
program ChangeAspectRatio;
```

```
uses  
  Crt, Graph;
```

```
function GetAspectX : word;  
{ Return the current aspect ratio element Xasp }  
begin  
  GetAspectX := word(Ptr(Seg(GraphFreeMemPtr),  
                      Ofs(GraphFreeMemPtr)+277)^);  
end;
```

```
procedure SetAspectRatio(NewAspect : word);
```

```

{ Set the current aspect ratio element Xasp }
begin
    word(Ptr(Seg(GraphFreeMemPtr),
            Ofs(GraphFreeMemPtr)+277)^) := NewAspect;
end;

var
    GraphDriver, GraphMode : integer;
    Ch : char;
    S : String;

begin
    DirectVideo := false;
    GraphDriver := Detect;
    InitGraph(GraphDriver, GraphMode, '');
    Str(GetAspectX, S);
    S := 'The initial aspect ratio was ' + S;
    OutTextXY(1,1, S);
    Circle((GetMaxX Div 2), (GetMaxY Div 4), (GetMaxY div 4));
    SetAspectRatio(5000);
    Circle((GetMaxX Div 2), 3*(GetMaxY Div 4), (GetMaxY div 4));
    Str(GetAspectX, S);
    S := 'Now the aspect ratio is ' + S;
    OutTextXY(1,(GetMaxY - 10), S);
    Ch := ReadKey;
    CloseGraph;
end.

```

## Article #15055: 'Not initialized for accessing network files'

Technical Notes Database

TN55D.txt 'Not initialized for accessing network files'  
Category :General Programming  
Platform :All  
Product :Delphi All

### Description:

Installed Delphi, then cannot access Paradox network files from neither Paradox 5.0 for Windows nor dBASE for Windows. Gets 'Not initialized for accessing network files'. The solution is to copy the IDAPI.CFG file from the CDROM and rename the previous one. The problem is that Delphi uses a newer IDAPI that puts the NetDir in a new place. The install updates both places correctly, but when modifying the NetDir, it does not get saved to both places, only the new location.

## Article #15062: Database Toolbox suggestions/corrections

Technical Information Database

TI62D.txt - Database Toolbox suggestions/corrections

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

This handout addresses some problems which have been reported by users of the Turbo Pascal DataBase ToolBox version 4.0 for use with Turbo Pascal 4.0.

### Correction

When accessing an Index File that allows duplicate keys and has greater than 32K records, the Index Key routines, FindKey and SearchKey will be unsuccessful in finding keys for records past 32K. By making the following changes to TACCESS.PAS, this proble

1. In the TaCompKeys procedure change the old code to look as follows:

```
begin
  if TaKeyStr(K1) = TaKeyStr(K2) then
    begin
      if not Dup or (DR1 = DR2) then
        TaCompKeys := 0
      else
        if DR1 > DR2 then
          TaCompKeys := 1
        else
          TaCompKeys := -1;
    end
  else
    if TaKeyStr(K1) > TaKeyStr(K2) then
      TaCompKeys := 1
    else
      TaCompKeys := -1;
end;
```

2. Save the changes to TACCESS.PAS. Call TaBuild for each .TYP file to create a new TACCESS.TPU file. Rebuild all Index Files.

### Recommended Suggestion

Users have reported unusual errors occurring in their DataBase ToolBox programs. Many of these errors can be solved by running TaBuild with the /W+ option to display the worksheet. The worksheet will show that 1,000 records will be the expected size of

For existing Data Files, where greater than 1,000 records are expected, it is recommended that you build a new TACCESS unit using the worksheet to set the maximum number of records. This requires that all Index Files be rebuilt.

## Article #15073: LINKING .OBJ OBJECT FILES FROM OTHER ASSEMBLERS

Technical Notes Database

TN73D.txt      LINKING .OBJ OBJECT FILES FROM OTHER ASSEMBLERS  
Category      :Pascal  
Platform      :All  
Product       :Turbo Pascal 4.0+

### Description:

- Q. Will the \$L compiler directive work for compiler object files other than assembler?
- A. That depends on the language. TURBO requires all the code in the .OBJ to be in \*one\* CODE segment, and all the data to be in \*one\* DATA segment. With assembly language that's easy, but it may not work with some high-level language compilers. You can use Turbo C to generate .OBJ files for use by Turbo Pascal programs. An example, CPASDEMO.PAS is included on the distribution disks.

## Article #15082: OBJECT FILE CREATION

Technical Notes Database

TN82D.txt      OBJECT FILE CREATION  
Category      :Pascal  
Platform       :All  
Product       :Turbo Pascal 4.0+

### Description:

Q. Does Turbo Pascal create object files that can be linked into other languages?  
A. Turbo Pascal 4.0+ generates .TPU (Turbo Pascal Unit) files, not .OBJ files. We've made that decision for many reasons:

1. TP 4.0+'s .TPU files are smaller than .OBJ's, and they contain symbolic information important to the support of Pascal's strict type conventions (types, constants, etc.).
2. .TPU files allow "smart linking" - elimination of unused code and data on a procedure-by-procedure basis.
3. .TPU's allow built-in project management through version 4.0+'s Make and Build commands.
4. .TPU's allow faster compilation speeds (34,000 lines per minute on a PS/2 Model 60).

## Article #15089: Microstar critical error handler corrections

Technical Information Database

TI89D.txt - Microstar critical error handler corrections

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

This handout addresses a problem reported by users of the Turbo Pascal Editor Toolbox version 4.0 for use with Turbo Pascal 4.0.

Users have found that MicroStar cannot recover from a DOS Critical Error. DOS Critical Errors occur when attempting to write or read a disk file with the disk door open, the drive empty, or the printer out of paper, etc. MicroStar reports the Critical E

The problem lies with the Interrupt 24 Handler (the DOS Critical Error Handler) implemented within MicroStar; its source may be found in the file INT24.ASM of the MicroStar source code. The INT24.ASM correctly identifies Critical Errors but does not rese

1. Load INT24.ASM into an ASCII editor (Turbo Pascal's editor will do).

2. Find Line 68 which should read as follows:

```
MOV CS:Int24ErrCode,0 ;Reset Int24ErrCode to 0
```

3. Replace this text with the following line.

```
MOV CS:Int24Err,0 ;Reset Int24Err to 0
```

4. Use the Microsoft or a compatible assembler to assemble the code to an object format (.OBJ). This must replace the INT24.OBJ supplied with the distribution disks.
5. Set the compiler destination to disk (Compile/Destination option). Load MS.PAS into the editor and perform a build

(Compile/Build option) on the entire application. Make sure the entire MicroStar source is available for recompilation.

For those without an assembler, the following Turbo Pascal program corrects the unmodified MicroStar EXE file. From the directory containing MicroStar, enter the following lines of code into the Turbo Pascal editor and run from either memory or disk.

```
program ChMS;

var
  f : file of byte;
  b : byte;

begin

Assign(f, 'MS.EXE');
reset(f);

seek( f, 129626);   b := 30;   write( f, b);
seek( f, 154257);   b := 101;  write( f, b);
seek( f, 154305);   b := 4;    write( f, b);
seek( f, 154401);   b := 103;  write( f, b);
seek( f, 154431);   b := 115;  write( f, b);
seek( f, 154701);   b := 108;  write( f, b);
seek( f, 154827);   b := 108;  write( f, b);

close(f);

end.
```

## Article #15091: LINKING TURBO C OR ASSEMBLER .OBJ OBJECT FILES

Technical Notes Database

TN91D.txt      LINKING TURBO C OR ASSEMBLER .OBJ OBJECT FILES  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

Q. Are the .OBJ files generated by Turbo C and Turbo Assembler compatible with 4.0+?

A. Yes. You can write Turbo C or Turbo Assembler routines and link the .OBJ files into your Turbo Pascal programs by using the {\$L} compiler directive. See the CTOPAS example on the distribution diskette.

## Article #15100: DATA SEGMENT USAGE OF SYSTEM UNITS

Technical Notes Database

TN100D.txt DATA SEGMENT USAGE OF SYSTEM UNITS

Category :Pascal

Platform :All

Product :Turbo Pascal 5.0 5.5

Description:

Q. How much of the 64K in the data segment is actually available to my program?

A. The amount of data segment used by the run-time library depends on which standard units you use in your program. Here is the data segment usage (in bytes) for each unit:

UNIT	Data Size
----	-----
System	664
Overlay	10
Crt	20
Dos	6
Printer	256
Graph	1070
Turbo3	256
Graph3	0
	=====
	2282

The total size of the data segment is 65,520 bytes. If you used only the System unit, the amount of data segment space left over would be

$$65520 - 664 = 64856 \text{ bytes}$$

## Article #15109: VARIABLES IN UNITS CHANGES NOT REFLECTED

Technical Notes Database

TN109D.txt      VARIABLES IN UNITS CHANGES NOT REFLECTED  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 4.0+

### Description:

- Q. I moved some variables into a unit. When I change a variable in the program, the change is not reflected in the unit used by the program. Why?
- A. Remove the duplicated variable definitions from the main program. Variables to be used in both a unit and a main program must be declared only in the interface portion of the unit.

## Article #15116: DrawAxis option: no tick marks and number labels

Technical Information Database

TI116D.txt - DrawAxis option: no tick marks and number labels

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

The following modifications may be made to the "GSHELL.PAS" file of the Turbo Pascal Graphix Toolbox to provide the DrawAxis routine with an option to turn off the display of tick marks and number labels, as in version 1.0x.

The following routine is found in the file called "GSHELL.PAS".

Change the following lines in the DrawAxis procedure:

Line 213:

```
FROM: if YDens >= 0 then  
TO:   if YDens > 0 then
```

Line 230:

```
FROM: if (YDens >= 0) and (Ys > Y1RefGlb + 13) then  
TO:   if (YDens > 0) and (Ys > Y1RefGlb + 13) then
```

Line 240:

```
FROM: if XDens >= 0 then  
TO:   if XDens > 0 then
```

Line 260:

```
FROM: if (XDens >= 0) and (Xs > X2RefGlb shl 3 + 7 - 24) then  
TO:   if (XDens > 0) and (Xs > X2RefGlb shl 3 + 7 - 24) then
```

## Article #15118: UNITS LINKED WITH DIFFERENT COMPILER DIRECTIVES

Technical Notes Database

TN118D.txt      UNITS LINKED WITH DIFFERENT COMPILER DIRECTIVES  
Category      :Pascal  
Platform      :All  
Product      :Turbo Pascal 4.0+

### Description:

- Q. What happens if you attempt to link another unit in which the compiler directives are set differently?
- A. Compiler directives are local to the unit they are declared in. Thus, the compiler directives in one unit, or in the main program, have no effect on the directives set in another unit.

## Article #15125: Patch for include file not found by Turbo Debugger

Technical Information Database

TI125D.txt - Patch for include file not found by Turbo Debugger

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

This handout describes the patches needed in order for Turbo Pascal version 5.0 to generate the correct debug information so that a \$Include file in a user defined unit can be found by Turbo Debugger. Two patches are supplied, one for TURBO.EXE and one for TPC.EXE. Both patches should be made using the DOS utility, DEBUG on copies of the original .EXE files.

### Notes:

1. DEBUG is not case sensitive to upper and lower case. All addresses are listed in upper case for ease of readability. All addresses are in hexadecimal.
2. While in DEBUG, the prompt will appear as a dash (-).
3. If you do not receive the appropriate response, press "q" followed by to quit.

### TURBO.EXE Patch

1. Rename TURBO.EXE to TURBO.BIN (DEBUG will not allow modifications to be made to a .EXE file.)

```
Prompt>ren turbo.exe turbo.bin
```

2. Load TURBO.BIN into DEBUG with the command:

```
Prompt>debug turbo.bin
```

3. Display the registers by entering "r" at DEBUG's hyphen

prompt.

-r

The system will respond with a display of the CPU register values. The following is an example:

```
AX=0000  BX=0000  CX=0000  DX=0000  SP=FFEE  BP=0000  ...  
DS=3C23  ES=3C23  SS=3C23  CS=3C23  IP=0100  NV UP    ...
```

Note the value of the CS register. Add 1000h to this value mentally; e.g., in the above example CS=3C23, then CS + 1000h is 4C23. This value will be referenced by ????.

4. At DEBUG's hyphen prompt, type:

```
-a ????:A41E
```

5. Enter the following Assembler code when the address is displayed:

```
????:A41E cmp si,dx
```

6. Press a second time.

7. Write the modified code to disk by entering the following at the prompt:

```
-w
```

8. Quit DEBUG by entering the following:

```
-q
```

9. At the DOS prompt, rename the .BIN file back to the .EXE file with the following command:

```
Prompt>ren turbo.bin turbo.exe
```

TPC.EXE Patch

1. Rename TPC.EXE to TPC.BIN (DEBUG will not allow modifications to be made to an .EXE file.)

```
Prompt>ren tpc.exe tpc.bin
```

2. Load TPC.BIN into DEBUG with the command:

```
Prompt>debug tpc.bin
```

3. At DEBUG's hyphen prompt, type:

```
-a a5d3
```

4. Enter the following Assembler code when the address is displayed:

```
XXXX:A5D3 cmp si,dx
```

5. Press a second time.

6. Write the modified code to disk by entering the following at the prompt:

```
-w
```

7. Quit DEBUG by entering the following:

```
-q
```

8. At the DOS prompt, rename the .BIN file back to the .EXE file with the following command:

```
Prompt>ren tpc.bin tpc.exe
```

## Article #15127: Units compiled more than once

Technical Notes Database

TN127D.txt      Units compiled more than once  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 4.0+

### Description:

- Q. If two units use a third unit, does the third unit get included twice in my program?
- A. No. All your units are "linked" together when you compile your program. Only one copy of each procedure and function used is generated. There is NO duplication of run-time code. In fact, Turbo Pascal 4.0+ has "smart linking" which eliminates any unused code. Turbo Pascal 5.0+ will also "smart link" unused data from the final .EXE file.

## Article #15134: Linking error message and font files.

Technical Information Database

TI134D.txt      Linking error message and font files.

Category      :General Programming

Platform      :All

Product      :Pascal    All

### Description:

This technical information handout describes how to link in the ERROR.MSG, 4x6.FON, 8x8.FON and 14x9.FON files into your \*.EXE file so that your application no longer needs these files to be present on disk. Please make these changes to copies of your

GRAF3270.DVR	GRAFEGA.DVR	ERROR.MSG	14X9.FON
GRAFATT.DVR	GRAFHGC.DVR	4X6.FON	GDRIVER.PAS
GRAFCGA.DVR	GKERNEL.PAS	8X8.FON	

First, you must convert the ERROR.MSG, 4x6.FON, 8x8.FON, and 14x9.FON files to the OBJ format.

Use the BINOBJ.EXE utility to convert these files to the OBJ format.

For example,

```
BINOBJ ERROR.MSG ERROR.OBJ FakeErr
BINOBJ 4x6.FON 4x6.OBJ Font4x6
BINOBJ 8x8.FON 8x8.OBJ FakeFont
BINOBJ 14x9.FON 14x9.OBJ FakeFont
```

Next, delete the first 13 lines of code from the procedure EnterGraphic in each of the \*.DVR and GDRIVER.PAS files with the exception of GRAFATT.DVR file. In the GRAFATT.DVR file, delete the first 15 lines of code instead. Also, in the GRAFCGA.DVR file

s

```

{$L 14x9}           { ADD }
procedure FakeFont; external;   { ADD }

procedure EnterGraphic;
{ Enter graphics mode }
...
...
begin
  if not FontLoaded then      { ADD }
    begin                    { ADD }
      Move(Mem[Seg(FakeFont):Ofs(FakeFont)], Font, SizeOf(Font));
                              {ADD}
      FontLoaded := true;    { ADD }
    end;                      { ADD }
...
.....
.....

```

The rest of the EnterGraphic procedure remains the same.

The following changes should be made in the GKERNEL.PAS unit:

```

{$L 4x6 }           {NEW}
procedure Font4x6; external;   {NEW}

{$L Error}         {NEW}
procedure FakeErr; external;   {NEW}

procedure InitGraphic;
var
  Fil : file of CharArray;
  Tfile : text;
  Test : ^integer;
  Temp : WrkString;
  I : word;
  GTBCount : integer;           {NEW}
  GTBch : char;                 {NEW}

  Function ErrorStr : WrkString; {NEW}
begin                             {NEW}
  temp := '';                      {NEW}
  repeat                            {NEW}
    GTBch := chr(mem[Seg(FakeErr):Ofs(FakeErr) + GTBcount]);
    if not ((GTBch = #10) or (GTBch = #13)) then {NEW}
      temp := temp + GTBch;         {NEW}
    inc(GTBcount);                 {NEW}

```

```
    until(GTBch = #13);           {NEW}
    ErrorStr := temp;           {NEW}
end; { Function ErrorStr }      {NEW}
```

```
begin
  MessageGlb := true;
  BrkGlb := false;
  GrafModeGlb := false;
  GotoXY(1, 1);
  if not HardwarePresent then
  begin
    ClrScr;
    GotoXY(1, 2);
    WriteLn('Fatal Error: graphics hardware not found or not
properly activated');
    Halt;
  end;
  GetMem(ErrorProc[0], 16);
  GetMem(ErrorCode[0], 24);
  ErrorProc[0]^ := 'InitGraphic';
  ErrorCode[0]^ := 'Error.MSG missing';
  GTBcount := 0;           {NEW}
  for I := 0 to MaxProcsGlb do           {MODIFIED}
  begin
    Temp := ErrorStr;           {NEW}
    if I <> 0 then
      GetMem(ErrorProc[I], Length(Temp) + 1);
      ErrorProc[I]^ := Temp;
    end;
  for I := 0 to MaxErrsGlb do           {MODIFIED}
  begin
    Temp := ErrorStr;           {NEW}
    if I <> 0 then
      GetMem(ErrorCode[I], Length(Temp) + 1);
      ErrorCode[I]^ := Temp;
    end;
  PcGlb := ErrorStr;           {MODIFIED}
  for I := 1 to MaxWorldsGlb do
    DefineWorld(I, 0, 0, XScreenMaxGlb, YMaxGlb);
  MaxWorldGlb := 1;
  for I := 1 to MaxWindowsGlb do
  begin
    DefineWindow(I, 0, 0, XMaxGlb, YMaxGlb);
    with Stack[I] do
    begin
```

```
W.Size := 0;
Contents := nil;
end;
end;
MaxWindowGlb := 1;
Move(mem[seg(Font4x6):ofs(Font4x6)], CharSet, Sizeof(CharSet));
{NEW}
```

Delete the next 12 lines of code.

The rest of the code remains the same in the GKERNEL.PAS unit.

```
BrkGlb := True;
If RamScreenGlb Then
...
...
```

## Article #15136: TYPE MISMATCH ERROR COMPILING UNITS

Technical Notes Database

TN136D.txt      TYPE MISMATCH ERROR COMPILING UNITS  
Category      :Pascal  
Platform      :All  
Product       :Turbo Pascal 4.0+

### Description:

- Q. Why is the compiler reporting "Type Mismatch Error" when I have declared every variable?
- A. The most common error of this type is caused by duplicated type definitions. First some background on how Turbo Pascal 4.0+ works. All identifiers (procedures, functions, types, variables, constants) are handled by appending the module name to the front of them (ie., ProgramName.identifier or UnitName.Identifier). Now, if you have a type, MYTYPE, in Unit MyUnit and also in MyProgram you have the following TWO DIFFERENT Types :

MyUnit.MYTYPE and MyProgram.MyType.

Please notice that by no means does "MyUnit.MYTPYE" equal "MyProgram.MYTYPE". The actual contents of MyType does not even enter into this discussion and Turbo Pascal only looks at the Type name.

The Solution? Declare types only in the interface section of the original unit AND NOWHERE ELSE!. Alternatively, declare variables with the file type name (ie., if you want to pass a variable of MYTYPE to the unit MyUnit, declare the variable:  
var MyVar : MyUnit.MYTYPE;).

## Article #15145: CREATING .TPL FILES

Technical Notes Database

TN145D.txt      CREATING .TPL FILES

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

Description:

Q. Can I create my own .TPL file?

A. Yes. However, Turbo Pascal will only use the TURBO.TPL library file. If you want to add your own units to the TURBO.TPL file, you can use the unit mover program (TPUMOVER.EXE). For example, you might want a customized version of TURBO.TPL for each of the programs you're developing. A corresponding configuration file for Turbo Pascal would specify a different Turbo directory and thus fetch the appropriate .TPL file for each of your projects.

## Article #15150: Function mapping from the Paradox Engine to BDE

Technical Information Database

TI150B.txt      Function mapping from the Paradox Engine to BDE

Category      :General Programming

Platform      :All

Product       :BDE 2.x

Description:

### Types

Paradox Engine	BDE	Variable name in this doc
PXCODE	DBIResult	rslt
TABLEHANDLE	hDBICur	tabH
RECORDHANDLE	pBYTE	rech
FIELDNUMBER	UINT16	iFld
LOCKHANDLE	UINT32	
RECORDNUMBER	UINT32	recNum
BLOBHANDLE	INT16	

### Functions

Paradox Engine	BDE
BLANK	<code>DbiPutField(tabH, iFld, rech, NULL);</code> (Cannot compare Field Data with BLANK in IDAPI. Use the value returned from <code>DbiGetField</code> in <code>bIsBlank</code> to determine if a field is blank.)
ISBANK()	Use the blank parameter in <code>DbiGetField(tabH, iFld, rech, pDest, &amp;bIsBlank);</code> or <code>DbiVerifyField(tabH, iFld, pSrc, &amp;bIsBlank);</code>
PXBlobClone()	Not Supported. (Private BLOBs are not supported in IDAPI)

PXBlobClose()	DbiFreeBlob(tabH, rech, iFld);
accept == FALSE	Not required in IDAPI. Note that
accept == TRUE	DbiFreeBlob(tabH, rech, iFld) needs to be called <u>after</u> adding a record containing a BLOB to a table.
PXBlobDrop()	DbiGetRecord(tabH, dbiNOLOCK, rech, NULL); DbiTruncateBlob(tabH, rech, iFld, 0); DbiModifyRecord(tabH, rech, FALSE);
PXBlobGet()	DbiGetBlob(tabH, rech, iFld, iOff, iLen, pDest, &iRead);
PXBlobGetSize()	DbiGetBlobSize(tabH, rech, iFld, piSize);
PXBlobOpenRead()	DbiOpenBlob(tabH, rech, iField, dbiREADONLY);
PXBlobOpenWrite()	DbiOpenBlob(tabH, rech, iField, dbiREADWRITE);
PXBlobPut()	DbiPutBlob(tabH, rech, iFld, iOff, iLen, pSrc);
PXBlobQuickGet()	DbiGetBlobHeading(tabH, iFld, rech, &iSize); (Paradox Tables only.)
PXDateDecode()	DbiDateDecode(dated, piMon, piDay, piYear);
PXDateEncode()	DbiDateEncode(iMon, iDay, iYear, pdated);
PXErrMsg()	DbiGetErrorString(iErrorCode, szError); or DbiGetErrorInfo(&ErrInfo); (Must be called immediately after the offending function - provides more information than DbiGetErrorString.)
PXExit()	DbiCloseDatabase(&hDb); DbiExit();
PXFldBlank()	DbiGetField(tabH, iFld, rech, NULL, &bIsBlank); or

```

DbiVerifyField(tabH, iFld, pSrc, &bIsBlank);
bIsBlank = TRUE is field is blank.

PXFldHandle()      DbiGetFieldDescs(tabH, &fldDesc);
                   fldDesc.iFldNum;

PXFldName()        DbiGetFieldDescs(tabH, &fldDesc);
                   fldDesc.szName;

PXFldType()        DbiGetFieldDescs(tabH, &fldDesc);
                   fldDesc.iFldType;
                   fldDesc.iSubType;

PXGetAlpha()       DbiGetField(tabH, iFld, rech,
                               (pBYTE)szString, &bIsBlank);

PXGetDate()        DbiGetField(tabH, iFld, rech,
                               (pBYTE)&Date, &bIsBlank);

PXGetDefaults()   DbiOpenCfgInfoList(hCfg, eOpenMode,
                                       eConfigMode, pszCfgPath,
                                       &tabH);

PXGetDoub()        DbiGetField(tabH, iFld, rech,
                               (pBYTE)&Double, &bIsBlank);

PXGetLong()        DbiGetField(tabH, iFld, rech,
                               (pBYTE)&Long, &bIsBlank);

PXGetShort()       DbiGetField(tabH, iFld, rech,
                               (pBYTE)&Short, &bIsBlank);

PXInit()           Not Supported. See PXWinInit.

PXKeyAdd()         DbiAddIndex(hDb, tabH, szTblName, szTblType,
                               &IdxDesc);

PXKeyDrop()        DbiDeleteIndex(hDb, tabH, szTblName,
                               szTblType, NULL, NULL,
                               iIndexId);

PXKeyMap()         Not Supported.
                   (Key Mapping is no longer needed - all
                    pertinent information is put in the index
                    descriptor - IdxDesc)

```

PXKeyNFlds()	<pre> DbiGetIndexSeqNo(tabH, NULL, NULL, 0,                   &amp;seqNo); DbiGetIndexDesc(tabH, seqNo, &amp;idxDesc); idxDesc.iFldsInKey; (Note that Paradox is the only database which has the concept of a primary index) </pre>
PXKeyQuery()	<pre> Not Supported. (The BDE does not have any function like this. You need to call DbiGetIndexDescs() and then look for the index you want. Once found all the information about that index is available to you in the structure.) </pre>
PXNetErrUser()	<pre> DbiErrGetErrorContext(ecUSERNAME,                       szUserName); </pre>
PXNetFileLock()	<pre> DbiAcqPersistTableLock(hDb, (pCHAR)fileName,                        Driver); </pre>
PXNetFileUnlock()	<pre> DbiRelPersistTableLock(hDb, (pCHAR)fileName,                        Driver); </pre>
PXNetInit()	<pre> Not Support. See PXWinInit. </pre>
PXNetRecGotoLock()	<pre> Not Supported. (Can be simulated by setting a bookmark on the record which is locked and then switching to that bookmark: DbiSetToBookMark(tabH, pBookMark);) </pre>
PXNetRecLock()	<pre> DbiGetRecord(tabH, dbiWRITELOCK, NULL,              NULL); </pre>
PXNetRecLocked()	<pre> DbiIsRecordLocked(tabH, edbiLock, piLocks); </pre>
PXNetRecUnlock()	<pre> DbiRelRecordLock(tabH, FALSE); or durring the update of the record - DbiModifyRecord(tabH, rech, TRUE); </pre>
PXNetTblChanged()	<pre> Need to register a cbTABLECHANGED callback. (Paradox only.) </pre>
PXNetTblLock()	<pre> DbiAcqTableLock(tabH, eLockType); </pre>

(Note that only Read and Write locks are supported by this function. For a FL on a table, open the table with the dbiOPENEXCL parameter or use the DbAcqPersistTableLock function.)

PXNetTblRefresh()	DbiForceReread(tabH);
PXNetTableUnlock()	DbiRelTableLock(tabH, eLockType);
PXNetUserName()	DbiGetNetUserName(pzName);
PXPswAdd()	DbiAddPassword(szPassword); (Paradox tables only.)
PXPswDel()	DbiDropPassword(szPassword); (Paradox tables only.)
PXPutAlpha()	DbiPutField(tabH, iFld, rech, (pBYTE)szString);
PXPutBlank()	DbiPutField(tabH, iFld, rech, NULL);
PXPutDate()	DbiPutField(tabH, iFld, rech, (pBYTE)&Date);
PXPutDoub()	DbiPutField(tabH, iFld, rech, (pBYTE)&Double);
PXPutLong()	DbiPutField(tabH, iFld, rech, (BYTE)&Long);
PXPutShort()	DbiPutField(tabH, iFld, rech, (pBYTE)&Short);
PXRawGet()	DbiSetProp((hDBIObj)tabH, curXLTMODE, xltNONE) DbiGetRecord(tabH, NULL, rech, NULL);
PXRawPut()	DbiSetProp((hDBIObj)tabH, curXLTMODE, xltNONE) DbiInsertRecord(tabH, dbiNOLOCK, rech, pDest);
PXRecAppend()	DbiAppendRecord(tabH, rech);

PXRecBufClose()           The application needs to release the memory associated with the record buffer. In 'C', call: free(rech).  
(Record buffers in IDAPI are owned by the application.)

PXRecBufCopy()           The application needs to copy the memory which is used for the record buffer. In 'C', call:  
memcpy(rechDest, rechSource, size).  
(Record buffers in IDAPI are owned by the application.)

PXRecBufEmpty()          DbiInitRecord(tabH, rech);

PXRecBufOpen()           The application needs to allocate memory for record buffer. In 'C', call:  
DbiGetCursorProps(tabH, &CurProps);  
rech = (pBYTE)malloc(CurProps.iRecBufSize \* sizeof(BYTE));  
(Record buffers in IDAPI are owned by the application.)

PXRecDelete()            DbiDeleteRecord(tabH, NULL);

PXRecFirst()             DbiSetToBegin(tabH);  
DbiGetNextRecord(tabH, dbiNOLOCK, NULL, NULL);  
(IDAPI has the concept of Beginning of file, which is before the first record).

PXRecGet()                DbiGetRecord(tabH, dbiNOLOCK, rech, NULL);

PXRecGoto()              Not supported by the SQL Drivers.  
Example for use with 'C':  
DBIResult gotoRec(hDBICur tabH,  
                  UINT32 recNum)  
{  
    DBIResult     lastError;  
    CURProps     curProps;  
  
    lastError = DbiGetCursorProps(tabH,  
                                  &curProps);  
    if (lastError != DBIERR\_NONE)

```

    {
        return lastError;
    }

    if (!strcmp(curProps.szTableType,
                szPARADOX))
    {
        lastError = DbiSetToSeqNo(tabH,
                                   recNum);
    }
    else if (!strcmp(curProps.szTableType,
                     szDBASE))
    {
        lastError = DbiSetToRecordNo(tabH,
                                       recNum);
    }
    else
    {
        lastError = DBIERR_NOTSUPPORTED;
    }

    return lastError;
}

```

```

PXRecInsert()      DbiInsertRecord(tabH, dbiNOLOCK, rech);

PXRecLast()        DbiSetToEnd(tabH);
                   DbiGetPriorRecord(tabH, dbiNOLOCK, NULL,
                                       NULL);
                   (IDAPI has the concept of End of File, which
                    is after the last record).

PXRecNext()        DbiGetNextRecord(tabH, dbiNOLOCK, NULL,
                                       NULL);

PXRecNFlds()       DbiGetCursorProps(tabH, &CurProps);
                   lFlds = CurProps.iFields;

PXRecNum()         Not supported for SQL Tables.
                   Example for use with 'C':
                   DBIResult getCurRecNum(hDBICur tabH,
                                             UINT32 *recNum)
                   {
                       DBIResult    lastError;
                       CURProps     curProps;

```

```

RECProps    recProps;

lastError = DbiGetCursorProps(tabH,
                               &curProps);
if (lastError != DBIERR_NONE)
{
    return lastError;
}

if (!strcmp(curProps.szTableType,
            szPARADOX))
{
    lastError = DbiGetSeqNo(tabH,
                            (pUINT32)recNum);
}
else if (!strcmp(curProps.szTableType,
                 szDBASE))
{
    lastError = DbiGetRecord(tabH,
                              dbiNOLOCK,
                              NULL,
                              &recProps);
    *recNum = recProps.iPhyRecNum;
}
else
{
    lastError = DBIERR_NOTSUPPORTED;
}

return lastError;
}

```

```

PXRecPrev()    DbiGetPriorRecord(tabH, dbiNOLOCK, NULL,
                          NULL);

```

```

PXRecUpdate() DbiModifyRecord(tabH, rech, TRUE);

```

```

PXSave()      DbiForceReread(tabH);

```

```

PXSetDefaults() DbiOpenCfgInfoList();

```

```

PXSetHWHandler() Not Supported

```

```

PXSrchFld()    DbiSetToKey(tabH, keySEARCHEQ, FALSE, iFlds
                          iLen, pIdxBuf);

```

```

PXSrchKey( )           DbiSwitchToIndex(&tabH, NULL, NULL, 0,
                       TRUE);
DbiSetToKey(tabH, keySEARCHEQ, FALSE, iFlds
             iLen, pIdxBuf);
(can only search on the currently active
 index)

PXTblAdd( )           DbiBatchMove(NULL, hSrcCur, NULL, hDestCur,
                       batAPPEND, 0, NULL, NULL, NULL,
                       NULL, NULL, NULL, NULL, NULL,
                       NULL, NULL, NULL, TRUE, FALSE,
                       NULL, TRUE);

PXTblClose( )        DbiCloseCursor(&tabH);

PXTblCopy( )         DbiCopyTable(hDb, TRUE, szSrcName,
                                   szPARADOX, szDestName);

PXTblCreate( )       DbiCreateTable(hDb, TRUE, &TblDesc);

PXTblCreateMode( )   DbiCreateTable(hDb, TRUE, &TblDesc);
(Use the optional parameters to change the
 level of the table.)

PXTblDecrypt( )      Only Supported for Paradox Tables
Example for use with 'C':
DBIResult decryptTable(hDBIDb hDb,
                       const char *tableName)
{
    CRTblDesc    crTblDesc;
    DBIResult    lastError;

    // Clear the buffer
    memset(&crTblDesc, 0,
           sizeof(CRTblDesc));

    // name of the table
    strcpy(crTblDesc.szTblName, tableName);

    lastError = DbiDoRestructure(hDb, 1,
                                  &crTblDesc,

## Article #15152: Toggling the cursor ON/OFF

Technical Information Database

TI152D.txt - Toggling the cursor ON/OFF

Category :Turbo Pascal  
Platform :DOS  
Product :

### Description:

The following example routines are public domain programs that have been uploaded to our Forum on CompuServe. As a courtesy to our users that do not have immediate access to CompuServe, Technical Support distributes these routines free of charge.

However, because these routines are public domain programs, not developed by Borland International, we are unable to provide any technical support or assistance using these routines. If you need assistance using these routines, or are experiencing difficulties, we recommend that you log onto CompuServe and request assistance from the Forum members that developed these routines.

To turn the cursor on and off you must use BIOS interrupt \$10. For more information on this interrupt, please refer to a DOS programmer's guide. Of course, manipulating the cursor can only be done in text mode and not graphics mode.

The following procedure turns the cursor on and off in Turbo Pascal:

```
procedure SetCursor(On: Boolean);
var
  reg : Registers;
begin
  if On then { Turn cursor on }
  if Mem[$0040:$0049] = 7 then
    reg.cx := $B0C { If monochrome monitor }
  else
    reg.cx := $607 { If color monitor }
```

```
else                                { Turn cursor off }
  reg.cx := $2020;
  reg.bx := 0;
  reg.ax := $0100;    { Set the interrupt function }
  Intr($10,reg);     { Call the interrupt }
end; { procedure SetCursor }
```

This procedure was revised from the question and answer section in the Turbo Pascal Tutor and Turbo Pascal version 3.0 reference guide.

In the procedure you do not need to declare the type Registers because it is predefined for you in the DOS unit. Therefore, to use this procedure, your program must also use the DOS unit.

## Article #15154: LINKING UNITS IN THE TURBO.TPL FILE

Technical Notes Database

TN154D.txt LINKING UNITS IN THE TURBO.TPL FILE

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0 5.0

### Description:

Q. The computer runs out of memory while linking a unit that's in TURBO.TPL to my program. What do I do?

A. The entire TURBO.TPL library file is loaded into memory, not just the unit, and therefore, no memory is left. The solution is to take the unit out of the library file.

## Article #15159: Some current internal limits of BDE

Some current internal limits of BDE

Description:

Here are the maximum limits for some common BDE objects. If you find you cannot reach these limits or are getting an out of memory error, increasing your SHAREDMEMSIZE in BDE Config to 4096 or more should allow you to reach these limits.

### GENERAL LIMITS

48	Clients in system
32	Sessions per client (3.5 and earlier 16 Bit, 32 Bit)
256	Session per client (4.0 32 Bit)
32	Open databases per session (3.5 and earlier 16 Bit, 32 Bit)
2048	Open databases per session (4.0 32 Bit)
32	Loaded drivers
64	Sessions in system (3.5 and earlier 16 Bit, 32 Bit)
12288	Sessions in system (4.0 32 Bit)
4000	Cursors per session
16	Entries in error stack
8	Table types per driver
16	Field types per driver
8	Index types per driver
48K	Size of configuration (IDAPI.CFG) file
64K	Size of SQL statement (RequestLive=False)
4K	Size of SQL statement (RequestLive=True)
6K	Size of SQL statement (RequestLive=True) (4.01, 32 Bit)
16K	Record buffer size (SQL or ODBC)
31	Table and field name size in characters
64	Stored procedure name size in characters

- 16 Fields in a key
- 3 File extension size in characters
- 260 Table name length in characters
- 260 Path and file name length in characters
- 15 Significant Digits

## PARADOX LIMITS

- 127 Tables open per system (4.0 and earlier 16 Bit32 Bit)
- 254 Tables open per system (4.01 32 Bit)
- 64 Record locks on one table (16Bit) per session
- 255 Record locks on one table (32Bit) per session
- 255 Records in transactions on a table (32 Bit)
- 512 Open physical files (4.0 and earlier 16 Bit32 Bit)  
(DB, PX,MB, X??, Y??, VAL,TV)
- 1024 Open physical files (4.01 32 Bit)  
(DB, PX,MB, X??, Y??, VAL,TV)
- 300 Users in one PDOXUSRS.NET file
- 255 Number of fields per table
- 255 Size of character fields
- 2 Billion records in a table
- 2 Billion bytes in .DB (Table) file
- 10800 Bytes per record for indexed tables
- 32750 Bytes per record for non-indexed tables
- 127 Number of secondary indexes per table
- 16 Number of fields in an index
- 255 Concurrent users per table
- 256 Megabytes of data per BLOB field
- 100 Passwords per session

- 15 Password length
- 63 Passwords per table
- 159 Fields with validity checks (32 Bit)
- 63 Fields with validity checks (16 Bit)
- 53 Fields with Validity checks added at onetime
- 63 Number of Sessions with Tables open on1 System

## DBASE LIMITS

- 256 Open dBASE tables per system (16 Bit)
- 350 Open dBASE tables per system (BDE 3.0 - 4.0,32 Bit)
- 512 Open dBASE tables per system (BDE 4.01, 32 Bit)
- 100 Record locks on one dBASE table (16 and 32 Bit)
- 100 Records in transactions on a dBASE table (32 Bit)
- 1 Billion records in a table
- 2 Billion bytes in .DBF (Table) file
- 4000 Size in bytes per record (dBASE 4)
- 32767 Size in bytes per record (dBASE for Windows)
- 255 Number of fields per table (dBASE 4)
- 1024 Number of fields per table (dBASE for Windows)
- 47 Number of index tags per .MDX file
- 254 Size of character fields
- 10 Open master indexes (.MDX) per table
- 220 Key expression length in characters

## Article #15161: Extend File Handles allowing more than 15.

Technical Information Database

TI161D.txt      Extend File Handles allowing more than 15.

Category      :General Programming

Platform      :All

Product       :Pascal    All

### Description:

The following is public domain information that has been uploaded to our Forum on CompuServe. As a courtesy to our users that do not have immediate access to CompuServe, Technical Support distributes these routines free of charge.

However, because these routines are public domain programs, not developed by Borland International, we are unable to provide any technical support or assistance using these routines. If you need assistance using these routines, or are experiencing difficulties, we recommend that you log onto CompuServe and request assistance from the Forum members that developed these routines.

The following unit extends the maximum number of files that can be open simultaneously from 20 to 255. Files in DOS 2.0 or later are controlled by file handles. The number of file handles available to application programs is controlled by the FILES environment variable stored in a CONFIG.SYS file. If no FILES variable is established in a CONFIG.SYS file, then only 8 file handles are available. However, DOS requires 5 file handles for its own use (controlling devices such as CON, AUX, PRN, etc). This le

aves only 3 handles for use by application programs.

By specifying a value for the FILES environment variable, you can increase the number of possible file handles from 8 up to 20. Since DOS still requires 5, 15 are left for application programs. But you cannot normally increase the number of handles beyond 20.

With DOS version 3.0, a new DOS function was added to increase the number of file handles available. However, the function must be called from application programs that have previously reserved space for the new file handles.

The unit EXTEND, described below, resizes the amount of allocated memory for a Turbo Pascal program to allow space for new file handles. In doing so, it also resizes the heap by adjusting the value of FreePtr, the pointer used in FreeList management. Since the FreeList is being manipulated, the heap must be empty when the EXTEND unit is initialized. This can be guaranteed by including EXTEND as one of the first units in your program's USES statement. If any heap has been allocated when EXTEND initialize s, the program will halt with an error message.

Notice that the interface section of the EXTEND unit is empty. The initialization section of the unit takes care of the unit's entire function. Other than including EXTEND in a program's USES statement, no other operation need be preformed.

Before using EXTEND, you must specify a FILES variable in the CONFIG.SYS file such as the following:

```
FILES = 255
```

Refer to your DOS User's Guide for more information regarding the CONFIG.SYS file and the FILES variable.

The unit EXTEND is set up for 255 file handles. You can reduce this number by changing the HANDLES constant in the unit's source code and reducing the number specified for the FILES environment variable.

```
unit Extend;
{This extends the number of file handles from 20 to 255}
{DOS requires 5 for itself. Applications can use up to 250}

interface

implementation
uses dos;
const
    Handles =255;
```

```
{You can reduce the value passed to Handles if fewer files}
{are required.}
```

```
var
    reg:registers;
begin
    {Check the Dos Version}
    {This technique only works for DOS 3.0 or later}
    reg.ah:=$30;
    MsDos(reg);
    if reg.al<3 then
        begin
            writeln('Extend Unit Require DOS 3.0 or greater');
            halt(1);
        end;

        {Reset the FreePtr}
        {This reduces the heap space used by Turbo
Pascal}
    if ofs(FreePtr^)<>0 then
        {Checks to see if the Heap is empty}
        begin
            write('Heap must be empty before Extend unit
initializes');
            writeln;
            halt(1);
        end;
    FreePtr:=ptr(seg(FreePtr^)-(Handles div 8 +1), ofs(FreePtr^));

        {Determine how much memory is allocated to
program}
    {Reg.Bx will return how many paragraphs used by program}
    reg.ah:=$4A;
    reg.es:=PrefixSeg;
    reg.bx:=$FFFF;
    msdos(reg);

        {Set the program size to the allow for new
handles}
    reg.ah:=$4A;
    reg.es:=PrefixSeg;
    reg.bx:=reg.bx-(Handles div 8 +1);
    msdos(reg);

        {Error when a Block Size is not appropriate}
```

```

if (reg.flags and 1)=1 then
    begin
        Writeln('Runtime Error ',reg.ax);
        Writeln('In the Extend Unit');
        halt(1);
    end;

        {Allocate Space for Additional Handles}

reg.ah:=$67;
reg.bx:=Handles;
MsDos(reg);
end.

```

Write the following program to a separate file. This program tests the extend unit. This test should be done on systems equipped with a hard disk.

```

program TestEx;
uses extend;
type
    filearray=array[1..250] of text;
var
    f:^filearray;
    i:integer;
    s:string;

begin
        {Allocate Space for File Variable Table}
new(f);

        {Open 250 files simultaneously}
for i:=1 to 250 do
    begin
        str(i,s);
        Assign(f^[i],'Dum'+s+'.txt');
        rewrite(f^[i]);
        writeln('Open #',s);
    end;

        {Write some text to the files}
for i:=1 to 250 do
    write(f^[i],'This is a test file');

        {Close the files}
for i:=1 to 250 do
    begin

```

```
close(f^[i]);  
writeln('Closing #',i);  
end;
```

```
                                {Erase the files}  
for i:=1 to 250 do  
  begin  
    erase(f^[i]);  
    writeln('Erasing #',i);  
  end;
```

end.

## Article #15163: TINST - NEW SETTINGS AREN'T USED

Technical Notes Database

TN163D.txt      TINST - NEW SETTINGS AREN'T USED  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 5.0 5.5

### Description:

Q. Why aren't the new settings used after I install TURBO.EXE using the TINST.EXE program?

A. You probably have a .TP file in the current or Turbo directory being loaded and the settings in the .TP file override the settings installed by TINST. Delete the .TP file.

## Article #15170: Network File Access

Technical Information Database

TI170D.txt    Network File Access  
Category    :General Programming  
Platform    :All  
Product     :Pascal    All

Description:

### FILE AND RECORD LOCKING IN TURBO PASCAL

Turbo Pascal does not have built-in support for file and record locking. It does, however, have the ability to open files for shared access. This is accomplished by setting the value of the system variable FileMode. By default, FileMode has a value of 2 which causes files opened to have single-user, read/write access. A shared, read/write mode can be had by setting FileMode to a value of 66. Whereas, a shared, read only mode is represented by the value 64.

Record and file locking is a bit more difficult. DOS version 3.0 and later provide record locking through the use of Interrupt 21H, Service 5CH. This service may be accessed through Turbo Pascal's procedure MsDos defined in the Dos unit.

Here's a routine designed to lock and unlock portions of any untyped or type file. Note, these routines may not be used with text files.

```
procedure LockBlock(var F; Offset: Longint; Length: Longint;
Lock: Boolean);
type
  LoHiRec = record
    LoWord, HiWord: Word;
  end;
var
  RecordSize: Word;
  Handle: Integer;
  File: FileRec absolute F;
  R: Registers;
```

```
begin
  Handle := File.Handle;
  RecordSize := File.RecSize;
  Offset := Offset * RecordSize;
  R.CX := LoHiRec(Offset).LoWord;
  R.DX := LoHiRec(Offset).HiWord;
  R.SI := LoHiRec(Length).LoWord;
  R.DI := LoHiRec(Length).HiWord;
  R.AH := $5C;
  if Lock then R.AL := 0 else R.AL := 1;
  MsDos(R);
  if (R.Flags and FCarry) <> 0 then
  begin
    RunError(R.AX);
  end;
end;
```

The parameter 'offset' indicates what record is to mark the beginning of the file lock. 'Length' determines how many records will be locked from this point. The 'lock' parameter determines whether the portion of the file is to be locked or unlocked.

To lock an entire file, pass 0 for offset and the results of the FileSize function for the number of records to be locked.

This routine will function as expected when using SHARE and/or MS-DOS compatible network software.

## Article #15172: EMS SUPPORT

Technical Notes Database

TN172D.txt      EMS SUPPORT  
Category      :Pascal  
Platform       :All  
Product       :Turbo Pascal 5.0 5.5

### Description:

Q. Does Turbo Pascal 5.0+ support EMS?

A. Yes. Turbo Pascal 5.0+ will use up to 64K (if selected in TINST) of EMS for storing the edit buffer. In addition, you can instruct the Overlay unit to place your overlaid units on EMS. Finally, EMS.PAS on the distribution disk shows you how to access EMS memory.

## Article #15177: Introduction to BDE Programming

Technical Information Database

TI177B.txt Introduction to BDE Programming

Category :General Programming

Platform :All

Product :BDE All

### Description:

Introduction to BDE Programming

BDE v2.0

#### I) Project Setup

This section covers the basics of what needs to be done in order to set up a Borland Database Engine project or makefile.

#### II) Design Overview

A high level overview of the steps that are required to create a simple application which retrieves fields from a table

#### III) Design Specifics

Detailed description, with code examples, of the steps described in part II.

#### IV) Error Handler

This section contains the error handler used by this example.

#### I) Project Setup

=====

This document provides a quick introduction to programming with the Borland Database Engine. By the end of this section, you should have a simple EasyWin, BDE example which gets a record from a table and displays the first two fields.

The following steps must be followed when starting to write a

BDE application.

First, set up the project or makefile

MAIN.CPP	- File to contain your code
DBERR.CPP	- Error handling routine
IDAPI.LIB	- BDE Import Library
MAIN.DEF	- Module Definition file

Select the large memory model.

For this simple application, set the target to be an EasyWin application. This way we don't have to deal with any Windows UI issues.

It is also suggested to install the IDAPI.TOK file so as to have syntax highlighting for BDE functions and types (directions on this are included in the \BDE\DOC\IDAPITOK.TXT file).

The on-line help file, IDAPI.HLP, can also be incorporated into the BC 4.5 OpenHelp architecture, allowing context sensitive help on IDAPI types and functions.

Other required setup:

-----

The Borland Database Engine is fairly stack intensive, especially when doing batch operations and queries, so it is generally recommended that the stack be set to a minimum of 25k (for Windows C/C++ applications, the stack size is set in the module definition file)

Increase the number of file handles available to the application. By default, the BDE assumes that it has access to 48 physical file handles (set by the BDE Configuration utility, System page | MAXFILEHANDLES option, 5-255). Due to this default setting, it is usually best to set the number of file handles available to an application to a minimum of 68 using the Windows API function SetHandleCount. Seemingly random errors can occur when the BDE does not have access to enough file handles.

Use the Debug Layer when developing applications. The debug layer performs much stricter error checking than the regular DLL, resulting in fewer GP faults and less re-booting of your machine. It will also produce a trace output of which IDAPI functions were called by an application. Note that use of the debug layer

requires the use of both the Debug DLL (Set using the DLLSwap utility), as well as a call to the DbgDebugLayerOptions function.

Make certain to compile with 'Allocate enums as ints' selected (in the BC 4.x IDE, Options | Project | Compiler | Code Generation). A number of structures, such as CURProps, make use of enumerations. Within the DLL, these are allocated as two byte values. Turning off this option will result in your code passing only one byte. This error generally manifests itself with stack corruption problems, such as GP faults when calling or returning from a function.

Within a module to contain BDE code, include the following header files:

WINDOWS.H  
IDAPI.H

Note that order is important. The WINDOWS.H file must be included before IDAPI.H.

## II) Design Overview

=====

Before we start writing code, a brief overview of what needs to be done to get a record from a tables:

- Increase the number of file handles available to the application
- Initialize the Borland Database Engine
- Enable the debug layer
- Open a database object
- Set the database object to point to the directory containing the table
- Set the directory for temporary objects
- Open a table, creating a cursor object
- Get the properties of the table
- Using these properties, allocate memory for a record buffer
- Position the cursor on the desired record
- Get the desired record from the cursor (table)
- Get the desired field(s) from the record
- Free all resources

Note that throughout the following short example unfamiliar variable types may be used. These are IDAPI variable types that are defined in the IDAPI.H header file. For example, BYTE,

BOOL, CHAR, and FLOAT.

### III) Design Specifics

=====

Increase the number of file handles available to the application

-----

A call to the Windows API function SetHandleCount will increase the number of file handles available to an application in the Windows environment:

```
int    HandlesAvail;
int    HandlesWanted;

HandlesAvail = 0;
HandlesWanted = 68;

HandlesAvail = SetHandleCount(HandlesWanted);
if (HandlesAvail < HandlesWanted)
{
    // Display message re: not enough available
    // file handles
    return;
}
```

Note that in non-trivial cases it is recommended to determine the number of file handles that are specified in the BDE configuration file. This would be done using the DbOpenCfgInfoList function, which will be described in a later section on configuration management.

Initialize the Borland Database Engine

-----

The Borland Database Engine is initialized using the DbInit function:

```
CHKERR(DbInit(NULL));
```

Note that the CHKERR macro is defined in the DBERR.H file, which is a part of the Error Handling module. The call to DbInit allocates system resources for the client.

Enable the Debug layer

-----  
The following code is used to enable the debug layer,  
outputting trace information to a text file on disk.

```
DbiDebugLayerOptions(DEBUGON | OUTPUTTOFILE, "MYTRACE.INF");
```

Note that in certain situations, you may also want to use the  
FLUSHEVERYOP flag, which will force output to the trace  
file after every operation. While this is slower, it is useful  
when a GP fault occurs....

Open a database object  
-----

The next step that is needed is to open a database object. All  
table access must be performed within the context of a  
database. Local databases generally use what is referred to as  
the "STANDARD" database, which is what we will be using in this  
example. The preferred method would be to create an alias to a  
local directory and using that as the database. This allows for  
easy modification in the future if one day it is decided to move  
the application from using dBASE tables to using InterBase  
tables. The DbiOpenDatabase function is used to open a database:

```
hDBIDb   hDb;       // Handle to the Database
```

```
hDb = 0; // Initialize to zero for cleanup  
        // purposes
```

```
CHKERR_CLEANUP(  
    DbiOpenDatabase(NULL, // Database name  
                    // - NULL for standard Database  
    NULL, // Database type -  
          // NULL for standard Database  
    dbiREADWRITE, // Open mode - Read/Write or  
                  // Read only  
    dbiOPENSARED, // Share mode - Shared or  
                  // Exclusive  
    NULL, // Password - not needed for the  
          // STANDARD database  
    NULL, // Number of Optional Parameters  
    NULL, // Field Desc for Optional  
          // Parameters  
    NULL, // Values for the
```

```
        // Optional Parameters
        &hDb) // Handle to the database
    );
```

```
// At the end of the function
```

```
CleanUp:
```

```
    // Close only if open
    if (hDb != 0)
    {
        DbtCloseDatabase(&hDb);
    }
```

```
Set the database object to point to the directory containing
```

```
-----
the table
-----
```

The working directory next needs to be set to the directory containing the table. While it is possible to open a table in other directories, specifying the absolute path, it is generally recommended to open tables in the working directory, as a number of operations, such as getting a list of available tables, work off the current directory. The `DbtSetDirectory` function is used to set the working directory (using the default location of the BDE example tables):

```
CHKERR_CLEANUP(
    DbtSetDirectory(hDb, // Handle to the
                    // database which is being modified
                    "C:\\BDE\\EXAMPLES\\TABLES")
                    // The new working directory
    );
```

Note that the full, absolute path needs to be used. Relative paths are not supported.

```
Set the directory for temporary objects
-----
```

While not all BDE applications create temporary objects, but larger applications will at one time or another. For example, the result set from a query or the records which cause a key violation in a restructure will be placed in a temporary table. By default, this temporary, or private directory, as it is called, is the startup directory. This will cause a problem if

the application is run off a network or a CD-ROM., as the directory cannot be shared, and it must be writable. The DbiSetPrivateDir function is used to set the private directory for a client:

```
CHKERR_CLEANUP(  
    DbiSetPrivateDir("c:\\")  
        // Select a directory on a local drive that is not  
        // used by other applications.  
        );
```

Note that the full, absolute path needs to be used. Relative paths are not supported.

Open a table, creating a cursor object

-----

Next, open the table. Upon opening a table, a cursor object is created and returned to the calling application. A cursor object is basically an abstraction which allows queries and tables to be accessed in the same method:

```
hDBICur hCur;    // Handle to the cursor (table)  
CHAR     szTblName[DBIMAXNAMELEN]; // Table name - DBIMAXNAMELEN  
        // is defined in IDAPI.H  
CHAR     szTblType[DBIMAXNAMELEN]; // Table Type  
  
hCur = 0; // Initialize to zero for cleanup  
        // purposes  
  
strcpy(szTblName, "customer"); // Name of the table  
strcpy(szTblType, szPARADOX); // Type of the tables  
        // - szPARADOX is defined in IDAPI.H
```

```
CHKERR_CLEANUP(  
    DbiOpenTable(hDb, // Handle to the  
        // database to which this cursor will  
        // be related  
        szTblName, // Name of the table  
        szTblType, // Type of the table - only  
        // used for local tables  
        NULL, // Index Name - Optional  
        NULL, // IndexTagName - Optional.  
        // Only used by dBASE  
        0, // IndexId - 0 = Primary. Optional.
```

```

        // Paradox and SQL only
dbiREADWRITE, // Open Mode -
        // Read/Write or Read Only
dbiOPENSHARED, // Shared mode -
        // SHARED or EXCL
xltFIELD, // Translate mode
        // FIELD or NONE
        // FIELD: Convert data from table
        // format to C format
        // NONE: Leave data in it's native
        // state
FALSE, // Unidirectional -
        // False means can navigate forward
        // and back.
NULL, // Optional Parameters.
&hCur) // Handle to the cursor
);

```

CleanUp:

```

// Close only if open
if (hCur != 0)
{
    DbicloseCursor(&hCur); // Note the use of DbicloseCursor
                          // - there is no DbicloseTable.
}

```

Get the properties of the table

-----

We next need to determine the size of the record buffer for the table. This information is gotten from the cursor via the DbigetCursorProps function. The Cursor properties include information on the table name, size, type, number of fields, and record buffer size. More information can be found on cursor properties in the on-line help under CURProps.

```

CURProps    curProps; // Properties of the cursor

```

```

CHKERR_CLEANUP(
    DbigetCursorProps(hCur, // Handle to the cursor
                      &curProps) // Properties of the cursor
                      // (table)
);

```

curProps.iRecBufSize contains the size of the record buffer.

Using these properties, allocate memory for a record buffer

```
pBYTE      pRecBuf; // Pointer to the record buffer

pRecBuf = NULL; // For cleanup purposes

// Allocate memory for the record buffer
pRecBuf = (pBYTE)malloc(curProps.iRecBufSize * sizeof(BYTE));
if (pRecBuf == NULL)
{
    // Display some error message
    goto CleanUp;
}

CleanUp:
    if (pRecBuf)
    {
        free(pRecBuf);
    }
```

Position the cursor on the desired record

-----

The `DbiSetToBegin()` function is used to position the cursor to the "crack" before the first record in the table. Crack semantics basically allow for the current location of the cursor to be before the first record, between records, or after the last record. One of the reasons for having crack semantics is to allow the use of one function to access all records in a table. For example, in place of having to use `DbiGetRecord` the first time, and `DbiGetNextRecord` each subsequent time, it is now possible to use `DbiGetNextRecord` to get all records in a table.

```
CHKERR_CLEANUP(
    DbiSetToBegin(hCur) // Position the specified cursor
                        // to the crack before the first record
    );
```

Get the desired record from the cursor (table)

-----

The `DbiGetNextRecord` function is normally used to get a record from a table. Note that the current record of the cursor is set to the record returned by this function (the next record

in the table):

```
CHKERR_CLEANUP(  
    DbiGetNextRecord(hCur,          // Cursor from which to get the  
                                // record.  
        dbiNOLOCK, // Lock Type  
        pRecBuf,   // Buffer to store the record  
        NULL)     // Record properties -  
                // don't need in this case  
    );
```

Get the desired field(s) from the record

-----

The last step is to get the field values out of the record buffer and into some local variable. Note that in this case we are making assumptions about which field is at which ordinal position within the table, as well as the size of the field. In general, it is recommended to use `DbiGetFieldDescs` to get information about a field before retrieving it. Also note that a single function, `DbiGetField`, is used to get all fields, other than BLOBs, from a table.

```
FLOAT      custNum;  
BOOL       isBlank;
```

```
CHKERR_CLEANUP(  
    DbiGetField(hCur,          // Cursor which contains the record  
                1,             // Field Number of the "Customer" field.  
                pRecBuf, // Buffer containing the record  
                (pBYTE)&custNum, // Variable for the Customer  
                // Number  
                isBlank) // Is the field blank?  
    );
```

Free all resources

-----

After all desired operations have been performed, the resources allocated on behalf of the application need to be cleaned up. In addition to any memory explicitly allocated using `malloc` or `new`, all engine objects must also be cleaned up, including the cursor, database, and engine:

CleanUp:

```

if (pRecBuf)
{
    // Free the record buffer
    free(pRecBuf);
}
if (hCur !=0)
{
    // Close the cursor
    DbiCloseCursor(&hCur);
}
// Close only if open
if (hDb != 0)
{
    // Close the database
    DbiCloseDatabase(&hDb);
}

// Close the BDE.
DbiExit();

```

#### IV) Error handler

```

// DBERR.H

// This file contains macros to use around BDE functions
// which are not expected to fail, or which would
// result in a fatal error. More explicit error handling needs
// to be done in the application when a non-fatal
// error can occur, for example, getting an End of file error,
// DBIERR_EOF, from a DbiGetNextRecord
// loop.

#ifndef __DBERR_H
#define __DBERR_H

#include

// Macro to use when no cleanup is required

#define CHKERR(parm) DBIError(__FILE__, __LINE__, \
                             #parm, parm) ; \
                             if (GlobalDBIErr) { \
                                 return GlobalDBIErr ;}

// Macro to use when cleanup must be done within a function

```

```
// for example, to close open tables or to free allocated memory.
// Note: must have a CleanUp label defined in each function
// where this macro is used. The CleanUp
// label should start the section of a function which frees the
// resources allocated within a given function
```

```
#define CHKERR_CLEANUP(parm) DBIError(__FILE__, __LINE__, \
                                     #parm, parm) ; \
                                     if (GlobalDBIErr) { \
                                         goto CleanUp ;}
```

```
// Global variable to contain the result code
extern DBIResult GlobalDBIErr;
```

```
// Prototype for the error handling function
DBIResult DBIError(pCHAR, UINT16, pCHAR, DBIResult);
```

```
#endif
```

```
// DBERR.C
```

```
#include
#include "DBERR.h"
```

```
// The way to use this macro is to include the DBERR.H.
// Then pass an IDAPI function as a parameter to the
// macro:
```

```
//
// #define CHKERR(parm) DBIError(__FILE__, __LINE__, \
//                               #parm, parm) ; \
//                               if ( GlobalDBIErr ) { \
//                                   return GlobalDBIErr ;}
```

```
// You would then use it as such:
//     CHKERR(DbiCreateTable(hDb, bOverWrite,
//                          &crTblDsc)) ;
```

```
// Global variable to hold return value from BDE functions
DBIResult GlobalDBIErr;
```

```
// Global variables to contain the error messages. Defined
// globally to ensure that an error message can be displayed
// even if the system is out of memory (and to keep it off
// the stack)
```

```

// Contains just the BDE error message
static char szDBIStatus[(DBIMAXMSGLEN * 7)+1];

// Contains the entire message, including file name and line
// number of the offending function.
static char szMessage[(DBIMAXMSGLEN * 7)+1+110];

//=====

**Article #15179: editors.pas 3,4,5,6 entry patch for TP6.**

Technical Information Database

TI179D.txt - editors.pas 3,4,5,6 entry patch for TP6.

Category :Turbo Pascal  
Platform :All  
Product :

Description:

The following patch fixes the problem of not being able to enter numbers 3 through 6 into the editor of the EDITORS.PAS example shipped with Turbo Pascal 6.0.

Open EDITORS.PAS in the TURBO editor and search for the EXISTING code. Once that is found change the EXISTING code to the CHANGE TO code. Save your changes and recompile EDITORS.PAS.

EXISTING:

```
LODSW
OR      BL,BL
JE
```

2

```
CMP     BL,DL
```

CHANGE TO:

```
LODSW
CMP     BL,DL
```

EXISTING:

```
var
  Key: Word;
```

CHANGE TO:

```
var
  ShiftState: Byte absolute
    $40:$17;
  Key: Word;
```

-----  
EXISTING:

## Article #15181: OUT OF MEMORY ERROR

Technical Notes Database

TN181D.txt      OUT OF MEMORY ERROR  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 4.0+

### Description:

Q. How do I avoid an Out of Memory error?

A. This error occurs when the compiler has run out of memory.

There are a number of solutions to this problem:

1. If Compiler/Destination is set to Memory, set it to Disk in the integrated environment.
2. If Options/Compile/Link buffer in the integrated environment is set to Memory, set it to Disk. Alternatively, if you're using 4.0, place a {\$L-} directive at the beginning of your program. Use the /L option to link to disk in the command-line compiler.
3. If you are using any memory-resident utilities, such as Sidekick and Superkey, remove them from memory.
4. If you are using TURBO.EXE, try using TPC.EXE instead - it takes up less memory.
5. Turn off any compiler directives which are not necessarily needed. By simply turning off range checking {\$R-} and software emulation {\$E-}, your code size will be reduced dramatically.
6. Move all units, except PRINTER.TPU, out of the TURBO.TPL file and into the installed units directory.

If none of these suggestions help, your program or unit may simply be too large to compile in the amount of memory available, and you may have to break in into two or more smaller units. Alternatively, if you're using 5.0+, you should consider using overlays.

## Article #15188: How to Print in Windows

Technical Information Database

FAQ: TI188D - How to Print in Windows

Category: Printing

Platform: All-32Bit

Product: Delphi4.x,

Description:

Printing in Windows is achieved with a device control associated with the printing device described in the WIN.INI. Before you start printing in your program, you will need to create a device control associated with your printer.

To do this, you will call the function GetProfileString as follows.

```
GetMem(Info, 80);
GetProfileString('windows','device',',,,', Info, 80);
```

Where Info is defined to be of type PChar. The resulting ASCIIIZ string will be placed in Info. Unfortunately, CreateDC requires three parameters, one for the driver, the printer type, and the port. If GetProfileString is successful, Info contains all the information required by CreateDC but contained in one string separated by semi-colons. These items must be parsed out of the string Info before CreateDC can be called. The following function is helpful in this task.

```
function GetItem(var S:PChar): PChar;
var
  P: PChar;
  I: Integer;
begin
  i:=0;
  while (S[I]<>',' ) and (S[I]<>#0) do
    inc(I);
  S[I]:=#0;
  GetItem:=S;
```

```
    if S[0]<>#0 then S:=    ;  
end;
```

The function `GetItem` does not copy the strings but rather turns the larger string into a structure containing smaller component strings. Now separating the driver, printer type, and port information is fairly straight forward. Assuming that the `PChar` variables `Driver`, `PrinterType`, `Port` and `TInfo` have been predeclared, you would use the following assignments.

```
TInfo:=Info;  
PrinterType:=GetItem(Info);  
Driver:=GetItem(Info);  
Port:=GetItem(Info);
```

The variable `TInfo` is necessary for a subsequent `FreeMem` call to free up the memory originally allocated for `Info`.

At last, you may now call `CreateDC` with the appropriate parameters (assuming `DC` was previously declared to be of type `HDC`).

```
DC:=CreateDC(Driver, PrinterType, Port, Nil);
```

If for some reason `CreateDC` is not successful, it will return a value of zero.

Now you are ready to start using the `Escape` function. `Escape` is a very special function as it allows access to device capabilities that are not supported by the Windows GDI. The second parameter to `Escape` represents the particular escape function to be used. Two fundamental escape functions always used when printing in Windows are `STARTDOC` and `ENDDOC`. These functions do any setup and shutdown required by the printer. Another important escape function is `NEWFRAME`. `NEWFRAME` forces a buffer flush and causes either a form feed operation or a page eject operation depending upon the type of printer used.

To print some text, the following code illustrates the process involved.

```
procedure Print;  
var  
    TInfo, Info: PChar;  
    Driver, PrinterType, Port: PChar;
```

DC: HDC;

begin

GetMem(Info, 80);

GetProfileString('windows', 'device', ',,', Info, 80);

TInfo:=Info;

Driver:=GetItem(Info);

PrinterType:=GetItem(Info);

Port:=GetItem(Info);

DC:=CreateDC(PrinterType, Driver, Port, Nil);

FreeMem(TInfo, 80);

if Escape(DC, \_STARTDOC, 8,  
StrNew('Doc Name'), nil)<0then

begin

MessageBox(Window, 'Printing can not be started', nil,  
mb\_Ok or mb\_IconStop);

exit;

end;

if Escape(DC, NEWFRAME, 0, nil, nil)<0 then

begin

MessageBox(Window, 'Paper can not be advanced', nil,  
mb\_Ok or mb\_IconStop);

exit;

end;

TextOut(DC, 10, 10, 'This text is being printed', 26);

if Escape(DC, NEWFRAME, 0, nil, nil)<0 then

begin

MessageBox(Window, 'Paper can not be advanced', nil,  
mb\_Ok or mb\_IconStop);

exit;

end;

if Escape(DC, ENDDOC, 0, nil, nil)<0 then

begin

MessageBox(Window, 'Error Printing', nil,  
mb\_Ok or mb\_IconStop);

exit;

end;

end;

Notice that if `Escape` fails that it returns a value less than zero. The actual errors are governed by the spooler constants `sp_Error`, `sp_OutOfDisk`, `sp_OutOfMemory`, and `sp_UserAbort`. It is recommended that a `NEWFRAME` call precede and follow the intended output to ensure that the printer is working with a fresh piece of paper and flushes its buffer when printing ends.

The coordinates used in `TextOut` are arbitrary. Exactly lines can be calculated from the values returned by `GetTextMetrics` as you would for normal output to the screen. See Chapter 4 of the Windows Reference Guide of TPW for a complete description of the `TTextMetric` type. The `tmHeight`, `tmAveCharWidth`, and `tmMaxCharWidth` fields will prove to be the most useful when determining line lengths and the number of characters per page. Use `GetDeviceCaps` to determine the maximum horizontal and vertical resolutions of your printer when calculating these values.

Since device controls are used, printing graphics is a simple extension of what is done to display graphics on screen. Here's a procedure that copies a bitmap to the printer using the techniques that have been discussed so far.

```
procedure HardCopy(HWindow: HWnd; BitMap: HBitmap);
var
  DC, ScreenDC, MemDC: HDC;
  BM: TBitmap;
  OldBitmap: HBitmap;
  Info, TInfo: PChar;
  Driver, PrinterType, Port: PChar;
begin
  GetMem(Info, 80);
  GetProfileString('windows', 'device', ',,', Info, 80);
  TInfo:=Info;
  Driver:=GetInfo(Info);
  PrinterType:=GetItem(Info);
  Port:=GetItem(Info);

  DC:=CreateDC(PrinterType, Driver, Port, Nil);
  Escape(DC, STARTDOC, 8, StrNew('HardCopy'), nil);
  Escape(DC, NEWFRAME, 0, nil, nil);

  ScreenDC:=GetDC(HWindow);
  MemDC:=CreateCompatibleDC(DC);
  ReleaseDC(HWindow, ScreenDC);
```

```
OldBitMap:=SelectObject(MemDC, BitMap);
GetObject(BitMap, sizeof(BM), @ BM);
BitBlt(DC, 0,0, BM.bmWidth, BM.bmHeight,
      MemDC, 0, 0, SRCCOPY);
```

```
Escape(DC, NEWFRAME, 0, nil, nil);
Escape(DC, ENDDOC, 0, nil, nil);
```

```
SelectObject(MemDC, OldBitMap);
DeleteDC(MemDC);
DeleteDC(DC);
```

```
end;
```

For clarity, this routine does not perform error checking in the manner of the previous example so use it with appropriate caution.

As with BitBlt, you may use any of the other GDI functions with a DC associated with the printer. The only difficulty that you may run into in this regard is the capabilities of the printer itself. To determine if a printer can handle bitmaps, use the GetDeviceCaps function as follows.

```
Value:=GetDeviceCaps(DC, RASTERCAPS);
Value:=Value and rc_BitBlt;
```

Assuming, DC to be associate with a printer device and Value to be declared as an integer, if the resulting contents of Value is not zero then the device has the ability to display bitmaps. See Device Capabilities under Chapter 1 of TPW's Windows Reference Guide for more on what GetDeviceCaps can do.

Frequently, programs give user's the ability to change the setting of the printer. However, printers often have greatly different capabilities and it is impossible to determine what printers will be capable of in the future. Therefore, no one dialog is appropriate to change printer setting. Because of these facts, Windows requires the manufacturers of printers to supply drivers and incorporate into these drivers a dialog used to alter printer settings.

There are two functions supported by the Windows API to call up this dialog DeviceMode and ExtDeviceMode. These functions do not exist in the API but rather are loaded from the driver directly.

Before you can call on these functions you must obtain a driver handle. Here's how this would be done knowing what we know so far.

```
GetMem(FullDriver,13);
GetProfileString('windows', 'device', ',,', Info, 80);
TInfo:=Info;
PrinterType:=GetItem(Info);
Driver:=GetItem(Info);
Port:=GetItem(Info);
StrLCat(StrCopy(FullDriver,Driver),'.DRV',12);
DriverHandle:=LoadLibrary(FullDriver);
```

PrinterType, Driver, Port, Info, and TInfo you have seen above. FullDriver is declared to be PChar and DriverHandle is a THandle. FullDriver is necessary to provide the file extension to Driver as the function LoadLibrary requires a complete file name. All printer drivers have the file extension .DRV.

ExtDeviceMode is a more advanced form of DeviceMode. It not only provides the dialog to allow user's change settings but also gives the means for the program to monitor and change the device settings. DeviceMode only provides the user dialog capability. However, ExtDeviceMode was introduced in version 3.0 of Windows and not all printer drivers provide a ExtDeviceMode function. But, all printer driver provide a DeviceMode function. So if ExtDeviceMode is not present, DeviceMode will be. The following code is appropriate for displaying the printer's dialog.

```
P:=GetProcAddress(DriverHandle, 'ExtDeviceMode');
if P<>nil then
begin
  ExtDeviceMode:=TExtDeviceMode(P);
  Size:=ExtDeviceMode(Window, DriverHandle,
    OutModeRec^, PrinterType, Port,
    InModeRec^, nil, 0);
  GetMem(OutModeRec, Size);
  GetMem(InModeRec, Size);
  ExtDeviceMode(Window, DriverHandle,
    OutModeRec^, PrinterType, Port,
    InModeRec^, nil, dm_Prompt);
  FreeMem(OutModeRec, Size);
  FreeMem(InModeRec, Size);
end
else begin
```

```
P:=GetProcAddress(DriverHandle, 'DeviceMode');
DeviceMode:=TDeviceMode(P);
DeviceMode(Window, DriverHandle, PrinterType, Port);
end;
FreeLibrary(DriverHandle);
```

P is declared to be of type TFarProc; ExtDeviceMode is of type TExtDeviceMode which is supplied by the WinTypes unit (the same applies for DeviceMode and TDeviceMode). Both OutModeRec and InModeRec are declared to be of type PDevMode. These two pointers control the input and output to ExtDeviceMode where required.

Notice that if the results of GetProcAddress(DriverHandle, 'ExtDeviceHandle'); are nil then ExtDeviceHandle cannot be provided by the printer. In this case, the code proceeds to the simple DeviceMode call.

Before ExtDeviceMode can be called to prompt the user, it is a good idea to call ExtDeviceMode with its mode parameter (the 8th parameter) set to zero. The result will be the amount of space required for its input and output, TDevMode parameters. This is important as these records may not be the same size as the TDevMode type. After memory is allocated for these records, the data fields of the input record may then be initialized (see Chapter 4 of TPW's Windows Reference guide for more on TDevMode).

Now ExtDeviceMode is called with the mode parameter set to dm\_Prompt which displays and activates the printer's dialog. This constant can be combined with the other constants dm\_Copy, dm\_Modify, and dm\_Update with Turbo's bitwise OR operator. (See Chapter 1 of TPW's Windows Reference Guide for information on these dm\_ Device mode selections).

Another important feature for printing is the Abort Dialog. An Abort Dialog is a dialog displayed when printing is taking place and gives the user of the program an opportunity to halt printing before it is finished.

The first thing to do, is create a dialog suitable for the task. Something like this .DLG file would serve (in a true DLG file all data for statement would appear on a single line). Though you may prefer to use a resource toolkit of some sort to build your dialog into a resource used by your program.

ABORTBOX DIALOG DISCARDABLE LOADONCALL PURE MOVEABLE 10, 37, 187,

67

```
STYLE WS_POPUP | WS_VISIBLE | WS_CAPTION | 0x80L
CAPTION "Printing in Progress"
BEGIN
    CONTROL "Escape" 100, "BUTTON", WS_CHILD | WS_VISIBLE |
        WS_TABSTOP, 73, 37, 41, 16
    CONTROL "Press Escape to Stop Printing" 102, "STATIC", WS_CHILD
        | WS_VISIBLE, 44, 12, 99, 11
END
```

Next, using the Object Windows Library, you would define an object type to govern your Abort Dialog. Its actual definition needs to be no more than something like the following.

```
var
    Abort: Boolean;
    AbortWindow: HWindow;
type
    PAbortDialog = ^TAbortDialog;
    TAbortDialog = object(TDlgWindow)
        procedure SetUpWindow; virtual;
        procedure WMCommand(var Msg: TMessage);
            virtual wm_First + wm_Command;
    end;

procedure TAbortDialog.SetUpWindow;
begin
    Abort:=false;
    SetFocus(HWindow);
    AbortWindow:=HWindow;
end;

procedure TAbortDialog.WMCommand(var Msg: TMessage);
{Will be entered whenever a button, return key or escape key is
pressed.}
begin
    Abort:=true;
end;
```

As any button press, return key press, or escape key press will abort printing only a WMCommand method is needed. InitDialog is necessary to set the focus to this dialog and to set the field Abort.

Abort is used by the dialog to determine if printing has been

aborted. To prevent interrupting printing while the dialog is displayed, a Call Back function is required to be installed. Most such functions call PeekMessage which checks the application queue for a message. If there are no messages, it returns and gives control to Windows. Here's a simple example of such a function.

```
function AbortCallback(DC: HDC; Code: Integer): Bool; export;
var
  Msg: TMsg;
begin
  While (not Abort) and PeekMessage(Msg, 0, 0, 0, pm_Remove) do
    if not IsDialogMessage(AbortWindow, Msg) then
      begin
        TranslateMessage(Msg);
        DispatchMessage(Msg);
      end;
    if Abort then AbortCallback:=false else AbortCallback:=true;
  end;
```

PeekMessage yields control to Windows when a message is not available. If a message is received and it doesn't belong to the dialog, it is sent along using the customary TranslateMessage and DispatchMessage functions. After it checks to see if the user has aborted and if so, AbortCallback returns false. Otherwise, it simply returns true which indicates printing may continue.

Now you have all that you need to install you Abort Dialog. Before, your call to Escape for the STARTDOC, the following code should be executed (assuming that you have previously declared a variable AbortDialog of type PAbortDialog and a variable called AbortCallbackProc of type TFarProc to hold the address of the callback function).

```
AbortDialog:=New(PAbortDialog,
  Init(Application^.MainWindow, 'ABORTBOX'));
AbortDialog:=PAbortDialog(Application^.
  MakeWindow(AbortDialog));
AbortCallbackProc:=MakeProcInstance(@ AbortCallback,
  HInstance);
Escape(DC, SETABORTPROC, 0, AbortCallbackProc, nil);
```

Now you would call Escape with the appropriate STARTDOC, NEWFRAME, and ENDDOC parameters as illustrated before. However, it is vital to check for errors after a NEWFRAME escape call.

For printing actually occurs during the NEWFRAME. If an error or user abort occurs Escape will return a value less than zero. If this happens do not allow the ENDDOC escape call take place; for the GDI automatically terminates the operation before returning the error value. Also, if an error other than a user abort occurs, use AbortDialog^.CloseWindow to remove the dialog from view. If the user cancels the print operation, Windows removes the dialog automatically.

## Article #15190: SYSTEM LOCK RUNNING WITHIN IDE VS. DISK RUN

Technical Notes Database

TN190D.txt      SYSTEM LOCK RUNNING WITHIN IDE VS. DISK RUN  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

Q. Why does my program run fine at DOS but locks the machine when running from IDE?

A. In most cases, this system crash is caused by a memory overwrite. The most common causes for memory overwrites are:

1. Indexes out of range      (Turn range checking on {\$R+})
2. Uninitialized variables   (Write an initialization proc)
3. Pointers out of bounds    (Verify that pointers are not pointing outside of the heap space)
4. Improper use of FillChar (Be sure to use the SizeOf or Move function)
5. Illogical operations on strings

## Article #15198: PICK FILES - TURBO READS FROM ANOTHER DRIVE

Technical Notes Database

TN198D.txt      PICK FILES - TURBO READS FROM ANOTHER DRIVE  
Category      :Pascal  
Platform        :All  
Product        :Turbo Pascal 4.0+

### Description:

- Q. Why does Turbo Pascal sometimes try to read from another drive when I run it?
- A. When you leave Turbo Pascal, it saves the name and path of the file you were last editing in a pick list. The next time you load Turbo, it checks this pick list and tries to load the file you were last editing. If the file you were last editing was in another drive, Turbo will try to read from that drive. This also occurs if you have installed another drive as your Turbo Directory.

## Article #15203: BDE Frequently Asked Questions.

Technical Information Database

TI203B.txt BDE Frequently Asked Questions.

Category :General Programming

Platform :All

Product :BDE All

### Description:

This document contains information most often provided to users of the BDE.

### FREQUENTLY ASKED QUESTIONS AND ANSWERS

-----

- 1) General
- 2) Paradox Table Specifics
- 3) dBASE Table Specifics

### GENERAL

-----

For additional information other than what is provided in this document, see:

<http://www.borland.com/devsupport/bde/faq/>

Q: Is there any "Getting started" information on the BDE?

A: Yes - get the TI177B for information on getting started with the BDE.

Q: What basic steps can I follow to make my BDE application run smoothly?

- A:
- 1) Increase stack size to 20K. (16 bit only)
  - 2) Increase the number of file handles available to your application using the Windows API function SetHandleCount. (16 bit only)
  - 3) Check the return values of each and every BDE function

call and provide some means for handling the result of any return value other than DBIERR\_NONE. (See next question also).

- 4) Take a look at TI177B, which describes the basic steps that are required in setting up a BDE application.

Q: I'm having trouble with my program, and the debugger has traced the problem into a BDE DLL. Does this mean that there is a bug in the BDE?

A: Not necessarily. Frequently if a prior call to the BDE has failed due to being passed an invalid handle or for some other reason, this will leave the BDE in an unpredictable state which will later cause a GP fault. The solution is to check the return values of each and every function call you make. The BDE sample applications contain error handling routines.

Q: Why is my application having problems when share is loaded?

A: One possibility is that share could be running out of locks or file handles. The command line 'share /L:200 /F:4096' will increase the number of files that can be locked to 200 and the memory available for files to 4096 (the default is 20 and 2048). See your DOS or WINDOWS manual for more information on share.

This information only applies to Windows 3.1. Windows for Workgroups, Windows 95 and Windows NT load share automatically. Windows 3.1 users can get this same functionality and not have to worry about running out of locks or file handles by obtaining the Windows 3.1 version of VSHARE.DLL from Microsoft.

Q: Why am I getting the error "Cannot find NetWare.DLL"?

A: An outdated netware.driv is found in the System.ini file. A newer version of this file should be gotten from your network administrator, and/or Novell.

Q: How do I use the BDE in a DLL that is called from Paradox

for Windows or dBASE for Windows?

A: Make certain to use dynamic linking when using the BDE in a DLL called from another application. This will be done automatically when using the IDAPI.LIB that ships with the BDE, but will not be done if an import library was created using IMPLIB (the shipping IDAPI.LIB is more than a standard import library).

Q: Why am I having problems getting information from the DbiGetFieldDescs function?

A: Make certain to have 'Allocate Enums as Ints' set (Options | Compiler | Code Generation in BC 4.x, Options | Project | Compiler | Code Generation in BC 5.). The FLDDesc structure, which is used by DbiGetFieldDesc, contains an enum, which within the DLL is set to the same size as an int (two bytes).

Q: Why am I having stack corruption problems? or Why is my application crashing when calling or returning from a function?

A: First, make certain that you have 25k of stack allocated for your application. Then, make certain that you have 'Allocate enums as ints' selected. A number of structures, including CURProps, make use of enumerations. As these enumerations are allocated two bytes within the DLL, we need to make certain that the application is passing two bytes as well. This is done with the 'Allocate enums as ints' option.

Q: How can I optimize BDE performance on table operations?

A: Although there are a number of ways to improve BDE performance, some general things to try are as follows:

- 1) Keep the number of maintained secondary indexes to a minimum; sometimes it is better to delete the index and recreate it than to perform a number of table operations with the indexes in place.
- 2) If possible, increase the size of the swap buffer and the number of file handles that the BDE has available to it. This will decrease the Engine's need to swap resources. Note: make certain to increase the file handles available to your

application using SetHandleCount, as well as increasing the number of file handles available to the BDE in IDAPI.CFG.

- 3) Open the table exclusively.
- 4) Batch as many operations as possible - do not read/write records one at a time. Use DbBatchMove, DbCopyTable, DbReadBlock, and/or DbWriteBlock.
- 5) When using DbWriteBlock, try to work in multiples of the physical block size, usually 2k or 4k.
- 6) If you are opening and closing one or more tables repeatedly, consider calling DbAcqPersistTableLock on a non-existent file after you initialize the BDE. This will create the .LCK file so that it will not have to be created each time a table is opened, created, etc. (Note: you'll also want to call DbRelPersistTableLock before calling DbExit).
- 7) Used Cached Updates  
Paradox Tables Only.
- 8) Work with in-memory tables when possible (Note that in-memory tables cannot be the source table to DbBatchMove).

Q: What are the current versions of the BDE?

A: <http://www.borland.com/devsupport/bde/bdever.html>

Q: Why am I getting the error 'Invalid BLOB Handle in record Buffer' when I attempt to modify a record containing a BLOB?

A: This error can occur for two different reasons.

#### Case 1 - BDE API Application

This error is caused by not setting up the record correctly. Make certain to call DbInitRecord on the record buffer before reading the record from the table.

#### CASE 2 - Any BDE Application

This error occurs when scrolling through more than 64 blobs in the results of a dead query. The solution is to either make the results of the query a live result set, or somehow limit scrolling blobs. (Such as having your SELECT statement select fewer records.)

NOTE:A future release of the BDE is planned to be able to be configured to get past the present hard coded limit.

Q: Why does my application crash when using filters?

A: Beside the general suggestion at the top of this file, as well as errors in setting up offsets of the filter, this error can be caused by setting the iPriority parameter to DbtAddFilter to 0. Make certain to set this value to 1. (There is a misprint in some copies of the BDE Users Guide to set this to 0).

Q: What's new in the 32 bit version?

A: 1) Long filename support.  
2) UNC filename support.  
3) Transactions on Paradox and dBASE tables.  
4) Cached Updates.  
5) The method for preparing queries has changed, requiring the use of a new BDEfunction, DbtQAlloc, to obtain a statement handle.  
6) BDE Configuration Information can now optionally be stored in the registry.  
7) New SQL Engine.

Q: Why am I getting the error "Too many open files" in the 16 bit version?

A: You need to call SetHandleCount and make sure the value is larger than the MAXFILEHANDLES statement in BDECFG.

Q. Can the BDE use descending indexes?

A. Only the Paradox, dBASE and FoxPro drivers support descending indexes. Selecting a descending index for any other table type will make the data appear in ascending order.

Q. With 16 bit BDE, how come I get a GPF in DBMSSOC3.DLL when connecting or disconnecting from my MSSQL database?

A. This problem can occur when using TCP/IP as the transport. The BDE calls W3DBLIB.DLL, which in turn calls DBMSSOC3.DLL. The problem occurs most commonly when using Windows NT but can occur under Windows 3.1. It has not been reported against Windows 95.

There are a number of potential solutions to this problems.

1. If the problem occurs under Windows NT, use 32 bit BDE instead.
2. Try switching providers of the TCP/IP stack. The testing for BDE 16 bit was done against Windows 3.1 using the Microsoft TCP/IP stack.
3. Use a different protocol.
4. Users have reported that replacing DBMSSOC.DLL with WDBWSKTC.DLL from the Sybase client resolves this problem.
5. For Windows 3.1 users, it has been reported you can connect using MicroSoft's 32 bit ODBC drivers, which would then use the 32 bit TCP/IP stack and solve the problem.

#### PARADOX TABLE SPECIFICS

-----  
Q: How do I access tables in a read-only directory (such as a table on a CD-ROM)?

A: A directory lock needs to be placed within the directory containing the table to prevent the BDE from attempting to create a lock file (.LCK) in that directory. An example of this is included in the SNIPIT example application, in the file RDOLOCK.C.

Q: I got "Table locked/busy" and it's neither?

A: This error happens when the application tries to lock a table when the corresponding prevent lock already exists, or when the application tries to set a prevent lock and a conflicting lock already exists. Check for old, unused lock files. Delete any .lck files that may exist after all BDE applications have terminated. Also run the TUtility program to test for table validity.

Q: Why do I get the error "Multiple Paradox Net Files Found?"

A: In addition to the case of two application referencing different physical PARADOX.NET files, this error message can be caused by old .LCK files or when two applications using the same NET file are mapped differently. Also make certain that the BDE DLL's are not left in memory. This error can also occur if differnt mapping are used to

reference the same file. For example, if h:onetwo on one system points to the same physical location as h:three on another system, the BDE will not recognize that it is only a single .NET file. Make certain that the path matches.

Q: I am working with a Peer-to-Peer network, like Windows for Workgroups, Lantastic, or Personal Netware, and I am getting "Multiple Paradox Net Files Found", what is wrong?

A: The BDE requires that everyone use the exact same directory and drive letter. Therefore, if the tables are on c:tables on the shared drive and user maps the shared drive as f: then f:tables points to the same place as the shared drive's c:tables. However, the drive letter must also match. The way around this is to subst drive c: as drive f: This way both c: and f: point to the same drive. Now f:tables on the shared drive's computer points to the c:tables and everyone is using f:tables. For more information on the subst command look in your DOS manual. However, remember that if LASTDRIVE is set to f: in your CONFIG.SYS then the last drive you can subst is f:

Q. I am getting the error "Lock file has grown too large". What is the solution?

A. Download TI256B for a detailed answer.

Q: Why am I getting the error: "Could not initialize IDAPI - not initialized for accessing network drives" when attempting to open a table on a network?

A: 1) Make certain the network control directory (NET DIR) is set to a directory on the network (not local). This is set in the BDE Configuration utility.  
2) Make certain that you have read/write/create rights to the network control directory, as well as the directory containing the table.  
3) Make certain that the private directory is set to a local directory. For example, in the Database Desktop (DBD), the private directory is set in the WIN.INI file, in the [DBD] section, PrivDir. If it is set to a directory on the network, this error can occur.  
4) Old lock files exist in the private directory. Either the application previously crashed, resulting in

improper cleanup, or another application is using the same private directory.

- 5) Under Windows for Workgroups (WfW), search your hard drive for the NWCALLS.DLL. Rename/backup the older versions of this file and run again.

If this fails to resolve the problem, you will need to make certain to not use the NetBEUI protocol as the default network protocol in Windows Setup. Select NetWare (or some other protocol) as the networking protocol, and everything should work successfully.

## dBASE TABLE SPECIFICS

-----

Q: How do I insert a Date into a dBASE table using Local SQL?

A: 'INSERT INTO myTable (myField) value ("01/01/94")'

Q: How can I create a case-insensitive index?

A: Case insensitive indexes are not directly supported, but can be simulated using an expression index with the upper() function.

Q: Why can I insert a duplicate record into a dBASE table when I have a unique index defined?

A: dBASE does not enforce the uniqueness within the table - only within the index. When the table is opened on that index, only one record with a given key value will be present in the index, but both values exist in the table.

## Article #15209: 'BLOB has been modified.', 'Index is out of date.' errors

### Technical Information Document (TI3342)

*"Index out of Date" (\$2F02), "Blob has been modified" (\$3302) errors with Paradox Tables*

- Product: *BDE*
  - Version: *All*
  - Platform: *Windows 95, Windows NT, Windows 3.1*
- 

Index out Date (\$2F02) is an error that occurs while using Paradox tables when the data in a table and a corresponding index is not consistent. In most cases (see below for the one exception), short of malicious behavior such as renaming an index, adding some data to the table, then renaming the index back, there is no programmatic way to cause this error to occur. There is no way to determine which index is out of date. All indexes must be recreated.

Blob has been modified (\$3302) is an error that occurs when the Blob portion of the record contained in the .DB file has become inconsistent with the Blob portion in the .MB file. This could occur when the write to the .DB file was successful but the .MB file did not get updated, or visa-versa.

There are a few mechanisms to fix a table where these errors have occurred.

1. First try re-starting the application. It is possible that the BDE has become unstable and is reporting incorrect errors. Also try opening the table with a different application.
2. Use Paradox 7 or 8 to run the Table Repair utility. Please see original documentation for more information.
3. Run TUtility and rebuild the table. TUtility is an unsupported utility available for download from the Borland web site in the [Utilities, programs and updates section](#).
4. Delete all indexes and recreate them (*Index out Date (\$2F02) error only*). To do this you'll need to know the structure of all your indexes (including primary) before recreating them, which means you need to know the structure of all indexes before the error occurs.

### There are 8 known possible causes for this error.

1. Incorrectly setting the LOCAL SHARE property.

Most commonly this occurs via Peer-to-Peer networking. In this case the two different database engines are on two CPUs, even though they may be the same version. See [BDE setup for Peer-To-Peer\(Non-Dedicated\) Networks](#) for additional information on Peer-to-Peer setup.

Another condition is when two different database engines execute on the same CPU concurrently and access data locally. This would be true when any combination of following are used concurrently: The Paradox Engine, BDE 16 bit, BDE 32 bit, Paradox for DOS. In this case each engine must set LOCAL SHARE to TRUE. Note that if use two applications which both use the same database engine (for example: Delphi 3 and C++ Builder 3) concurrently are run LOCAL SHARE does not need to be set to

TRUE. In this case, all locking and cached data is in a central memory pool which all BDE applications have access to. Also, if two different database engines use data remotely, LOCAL SHARE must be set to TRUE.

Code should be used at startup to check the setting of local share. Look at the [DbiOpenCfgInfoList](#) BDE API function call for more information.

2. Error transmitting data from the workstation to the server.

Most commonly, this occurs with bad network hardware (cable, card, hub, etc.). This has been determined to be a problem even though there were no other errors are detected in data transmission. To determine if this is the cause for your error, try eliminating one CPU at a time from using the data and see if the problem continues.

3. Bad VREDIR.VXD on any client accessing tables *Windows 95 ONLY*:

Several versions (notably 4.00.1113 and 4.00.1114) of the file VREDIR.VXD may need to be updated.

Reports have shown that using the original release of VREDIR.VXD (4.00.950) and a new release (4.00.1116) do not result in the errors "Blob has been modified" and/or "Index is out of date." If any one of the clients has a "bad" version of this device driver, the error can occur on any machine, not just the machine with the bad driver.

This error most likely occurs in 16Bit versions of the Borland Database Engine, although it still can occur in 32Bit versions.

For further information on the update of VREDIR.VXD, Please check the following Microsoft Articles: [Q174371](#) and [Q165403](#)

4. For Windows 95 clients only, when using data on Windows NT: Add the following key in your registry: HKEY\_LOCAL\_MACHINESystemCurrentControlSetServicesVxDVredir

Then create the string or Binary Value (either one works) with a name of DiscardCacheonOpen and make it equal to 1.

Note that this an undocumented registry entry obtained from Microsoft. Questions on its functionality should be directed to Microsoft.

5. Problem with opportunistic locking Windows NT ONLY: Try turning off opportunistic locking in the Windows NT registry: See Microsoft Article [Q129202](#)

Note: Borland internal testing has not indicated this setting to be significant. However, some Borland customers have indicated this to solve the problem.

6. Improperly closing files such as due to loss of power or restarting a workstation or the server without

closing files first may cause this problem. Paradox tables are not designed to withstand such behavior. If this is a possibility in your environment, we recommend you use a Client Server database that can recover from such conditions.

7. Extremely large numbers of indexes, especially involving Referential Integrity can cause this problem and especially when using Windows NT as the server. Borland recommends using a Client Server database under this condition. However, if you are using Windows NT as your server, switching to Novell Netware or Windows 95 as the server may resolve the problem as well.
8. The one programmatic way you can make this error occur is if you attempt to post a duplicate value to a unique, non-primary index at the same time you attempt to open the same table. This problem only occurs if local share is set to False and only occurs on local drives.

## Unverified solutions

1. Windows 95 Only: Bring up the network properties screen on all Workstations and enter the netBEUI properties screen. On the advanced tab, make sure that "Set this protocol to be the default protocol" is checked.
2. Windows 95 Only: If the previous suggestion did not work, try removing the following protocols in order. Remove one at a time and then re-test your problem:
  1. NETBIOS support for IPX/SPX-compatible Protocol
  2. TCP/IP
  3. IPX/SPX-compatible Protocol

If the problem disappears, attempt to add back in all protocols **except** for the last one that was taken out. Again, make sure netBEUI's default protocol check box is checked.

3. Windows NT Only used as a Workstation: On the Network Bindings page of the Network Properties, set the NetBEUI Protocol to be at the top of all services. The TCP/IP stack is known for having a lot of overhead that might cause timing problems. Since NT will send requests back in the same protocol as it is sent, changing the bindings on a NT machine used as a server will have no effect.

## Other resources

1. [The Delphi Magazine](http://www.itecuk.com/Delmag/Paradox.htm) has a number of interesting articles on this subject as well. See [www.itecuk.com/Delmag/Paradox.htm](http://www.itecuk.com/Delmag/Paradox.htm) for details.

## Article #15212: Understanding the PARADOX.NET file with the BDE

Technical Information Database

TI212B.txt      Understanding the PARADOX.NET file with the BDE  
Category      :General Programming  
Platform      :All  
Product       :BDE All

### Description:

When using Paradox type table with the Borland Database Engine (BDE), a Paradox net file is used in the same way that Paradox does--to keep track of the number of users. Each Paradox and BDE user is given one count. So, for example, if three Paradox and three BDE users use the same Paradox net file, the user count would be six (one for each Paradox user, and one for each BDE user).

The net file also regulates access to tables. Table access is enforced through the use of lock files, which are written out to the directories containing Paradox tables. A lock file points to a particular net file, which has exclusive control over the table. This means that any user wanting access to the table must use the net file that controls the table.

If you are using Paradox for Windows 5.0 or greater, IDAPI is used for both Paradox and BDE. The "NET DIR" path is set in the IDAPICFG.EXE or BDECFG.EXE: BDE/IDAPI Configuration Utility. Once the configuration tool is running, hi-light PARADOX, which is in the "Driver Name" List Box on the "Drivers" page. Set the "NET DIR" path to a network drive where all users that are accessing the tables have write access to.

If you are using an older version of Paradox for Windows, Paradox for DOS, or the Paradox Engine, use the appropriate method for each of these products to set the netfile path to the identical path that is set within the IDAPI/BDE Configuration Utility. In the case of two BDE programs sharing tables, the net paths must be identical.

The message "Multiple Paradox net file found" (Error 0x2C06 or 11270: DBIERR\_NETMULTIPLE) indicates that these rules have not been followed. If you are certain that all current users have the same net path, this message usually indicates that an old lock file exists that points to a different net file. Old lock files can be deleted if care is taken to ensure that no one is currently using them. Deleting active lock files can produce unpredictable results and could cause loss of data.

## Article #15221: Setting File Handles For A Windows BDE Application

Technical Information Database

TI221B.txt     Setting File Handles For A Windows BDE Application  
Category     :General Programming  
Platform     :All  
Product      :BDE 16 bit

### Description:

"Setting the number of file handles for Borland Database Engine Applications"

Solving the Borland Database Engine (BDE) error, "Not Enough file handles" (Error 0x2502 or 9474: DBIERR\_NOFILEHANDLES), is not a difficult task, but it requires an understanding of how file handles are used by DOS, Windows, and your application.

At the lowest level, the number of file handles available to any application running on your computer is specified in the "FILES=nn" statement of CONFIG.SYS. For Windows running with Windows and DOS applications, a bare minimum value is 30-40. A value of 80-120 is a more realistic starting value, which you should increase according to your application's needs.

When your application starts in Windows, the number of files available to it is based on the following two values: (1) The number you specify in a call to the Windows API call 'SetHandleCount' (default = 20), and (2) the number of files specified in the \_NFILE\_ constant in Borland's RTL source (default = 20). These two values should be the same; if they're not, the lower one will apply.

When estimating the number you'll need, note that in addition to whatever files you need for the BDE and for files you want to open, a C/C++ application will open five file handles for stdin, stdout, etc., on startup.

The number of file handles the BDE itself can use is specified on the System Page in the MaxFileHandles parameter of the BDE Configuration utility. It is important to realize that the number specified by MaxFileHandles is the number of file

handles that the BDE will expect to receive for its own exclusive use, not for use by your application as a whole. The BDE doesn't allocate file handles on its own, it gets these from your application. Thus, if you make a call to SetHandleCount with a value of 20 and set the MaxFileHandles parameter to 20, all twenty handles may go to the BDE, leaving none for your application's other needs.

To sum up, the number of file handles your BDE application will need will be the sum of 1) five standard file handles, 2) the number needed by the BDE (MaxFileHandles), and 3) the number you need for other file manipulation routines. This sum should be the number you specify in SetHandleCount, and if this total is greater than 20, you'll need to change the RTL source as well.

## Article #15225: Real number errors

Technical Notes Database

TN225D.txt      Real number errors

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 5.5

### Description:

Q. Why don't I get the expected results when I compare & print real numbers?

A. The problem with real numbers in Turbo Pascal is a problem with how a real number is stored in binary form. A binary number has no decimal point and thus a real number cannot directly translate into a binary number easily. Calculations must be performed to break a real number down into it's binary representation. As with any calculation that involves division or multiplication, small rounding errors will occur. The problem you are experiencing is a rounding error that occurs during translation from a real number into it's binary representation and back. I suggest that you round the results of your calculation to the number of decimal points that you require to alleviate the problem.

## Article #15230: Changing the NET DIR Programmatically

Technical Information Database

TI230B.txt      Changing the NET DIR Programmatically  
Category      :General Programming  
Platform      :All  
Product      :BDE All

### Description:

#### General:

The "NET DIR" parameter for the Paradox driver is usually indicated in the BDE Configuration Utility on the drivers tab. The NET DIR indicates where the PDOXUSRS.NET file is located. If the NET DIR is pointing to a location not containing a PDOXUSRS.NET file, one will be created there.

#### Changing the NET DIR programmatically:

It is possible to change where the NET DIR is pointing programmatically by using the DbiSetProp() function, but first, a handle to the BDE session must be acquired. The session handle can be acquired through DbiGetCurrSession(). Here is how one could change the NET DIR:

```
void main(void)
{
    hDBISes hSes;

    DbiInit(NULL);
    DbiGetCurrSession(&hSes);
    DbiSetProp(hSes, sesNETFILE, (UINT32)"c:\\temp");
    Dbi...
    ...
}
```

#### Notes:

The sesNETFILE constant is an Object Property and a clearer definition can be found by searching for "Object Property" in the BDE On-Line help. Another way to change the default NET DIR is to pass DbiInit() a DBIEnv structure that specifies a different .cfg (configuration) file other than the default IDAPI.CFG (calling DbiInit(NULL) will use IDAPI.CFG). This

method is not recommended because only one configuration file can be used for all BDE applications.

## Article #15234: The location of GRAPH.TPU

Technical Notes Database

TN234D.txt     The location of GRAPH.TPU  
Category     :Pascal  
Platform     :All  
Product     :Turbo Pascal 5.5

Description:

Q. Where is the GRAPH.TPU file?

A. The GRAPH.TPU is archived in the BGI.ARC file. Use the UNPACK.COM program to dearchive GRAPH.TPU from the BGI.ARC file. For example:

```
UNPACK BGI
```

## Article #15239: Error solutions and limitations of Paradox Engine

Technical Information Database

TI239B.txt Error solutions and limitations of Paradox Engine

Category :General Programming

Platform :All

Product :Paradox Engine All

Description:

Limitations of the Paradox Engine

=====

The Paradox Engine version 3.01 was intended for use on DOS 3.1 through DOS 5.x, and/or Windows 3.x environments. It can also be used in conjunction with the following networks:

- 1) IBM Token Ring version 1.1x
- 2) Novell NetWare version 2.0 through 3.12
- 3) 3Com 3+ Share network version 1.5.x
- 4) DEC Pathworks version 1.x
- 5) Microsoft LAN Manager version 2.x
- 6) Banyan Vines networks version 2.1x
- 7) AT&T StarGROUP for DOS version 3.1 through 5.x

The Paradox Engine has NOT been certified on the following OS or environments:

- 1) Windows NT 3.x
- 2) Windows 95
- 3) Windows for Workgroups 3.x
- 4) MS / IBM DOS 6.x

The Paradox Engine has NOT been certified on the following networks:

- 1) Novell NetWare version 4.x
- 2) Windows for Workgroups 3.x peer-to-peer
- 3) Windows NT 3.x peer-to-peer
- 4) Lantastic

The Paradox Engine has NOT been certified on the following chipsets:

- 1) Intel Pentium (any speed)

- 2) Cyrex
- 3) AMD

The Paradox engine relies on timing for some operations. The speed of some CPUs can cause file lock contentions in multi-user environments.

#### Common Problems that occur using the Paradox Engine

=====

Internal errors: Numbers > 200 -

- 1) Memory corruption and table corruption are the main causes of these internal errors.
- 2) These errors can be caused by using the Paradox Engine on tables that are also used by any IDAPI / BDE application; This includes products such as: Visual dBASE, Paradox, Quattro Pro. To temporarily fix the error, use the TUTILITY.EXE that ships with Paradox 4.0 for DOS and repair, not verify, the table. TUTILITY is available in the PDOXDOS forum on CompuServe. There is no permanent solution to this problem.

Random GPFs when converting from BC3.x to BC4.x -

A file named SETJMP.OBJ in the BCx\LIB\COMPAT directory needs to be linked into the EXE. RTTI necessitates new jump offsets for the Paradox Engine: this file contains the new offsets.

If an application crashes with the Paradox Engine still initialized, you MUST remove the .NET file and .LCK files associated with the program.

#### Specific Error Numbers with causes and solutions

=====

"Error# 4: File is locked" -

One possible way around this error is to create a retry loop which performs the desired operation x amount of times. The engine will do a validity check of the lock after approximately four iterations, which may clear up the contention. If CPU speed is too great i.e. Pentium 60Mhz, a greater number might be needed. See TI1002.

"Error# 8: Primary index is out of date" -

This error messages can occur if the sort order of the Engine app is different from the sort order of the table. A common cause of this is using the International sort order with Paradox while using the Engine with its default ASCII sort order. The sort order can be changed by using the PXSetDefaults function.

"Error# 15: Multiple Paradox net files found"

One paradox.net ( or pdoxusrs.net ) file controls access to any given table. This error occurs when two application using different net files try to access the same table. A common cause of this error is using different drive mappings on different machines. The Paradox Engine uses the directory path ( minus the drive letter ) to determine the location of the PDOXUSERS.NET file. Configure all workstations to reference the network control directory using the same path.

This error is also caused by using the same directory for controlling version 3.5 and version 4.0 locking mechanism. This would result in both a paradox.net and pdoxusrs.net file existing within the same directory. Delete the .net files and change the net directory of one of the application.

This error will also occur if there are old lock files ( .lck ) from a previous application lying about ( through a crash, for example ) which reference a different Paradox net file. Delete the .lck files.

#### WINDOWS:

The location of the net file is set in win.ini. There is a Windows utility provided, pxengcfg.exe, which will modify the setting in the win.ini file. Use this to utility to change the net directory.

Also make certain that all workstations are using the same DLL. Having the Engine 2.0 DLL on the path before the Engine 3.0 DLL will link in the wrong version of the Engine. This will cause network concurrency issues among other things.

"Error# 21: Insufficient password rights" -

Trying to access a 4.0 table from Paradox 3.5 or PXEng 2.0.

Can also happen when trying to run Paradox 4.0/PXEng 3.0 on the network from a directory controlled by PX 3.5 ( contains a paradox.net file ). Trying to access Paradox 5 or 7 tables with PXEng 3.x. The Paradox Engine only works with v4.x or earlier tables.

#### WINDOWS:

This error can be caused by using the wrong DLL. Check the path for old versions of the Paradox Engine DLL ( from the root directory, 'dir px\*.dll /s' ).

"Error 33: Invalid Parameter" -

From PXTblEmpty():

The PXTblEmpty function from v3.0 of the engine can incorrectly return this message. Workaround: create a new table with the same structure as the old, delete the original table ( PXTblDelete() ), and copy the new table back to the old.

From PXSrchFld():

This error can occur when the table has been opened on a secondary Index and an attempt is made to search on a field which is not part of the index.

"Error# 40: Not enough memory to complete operation" -

Use PXSetDefaults() for a DOS application, or pxengcfg.exe for a windows application, to increase the amount of swap buffer space available to the engine application. The documentation for PXSetDefaults() gives more information about the swap buffer. If in the IDE, make certain that Options | Debugger | Program Heap Size is set to 640K.

From PXTblOpen - Besides the above, this message can also mean that the table being used has become corrupted. Try running TUtility.exe on the table to test for corruption.

"Error# 50: Another user deleted record" -

This message can occur when a table has been opened more than once ( from one application or multiple applications) and a record deleted in one opening of the table is the current record for the other opening of the table. This is standard engine behavior, so some method will need to be

used to reposition the record cursor ( pointer that the engine uses for the current record ). Please see ti-1003 for more information regarding this error.

"Error# 53: Invalid offset into BLOb" -

This error can occur when the offset into a BLOb is larger than the size of the BLOb. A common situation which causes this error is calling the PxBlobPut() function when the offset plus the size of the buffer are larger than the size of the BLOb specified in the PxBlobOpenWrite() statement.

"Error# 89: Record not found" -

This message indicated that an exact match was not found. This is expected behavior when doing a CLOSESTRECORD search when an exact match is not found. There is a known problem with PXSrchFld() returning this message when it actually found the record. There is a maintenance release to the Paradox Engine 3.0 available on our local BBS at ( 408 ) 431-5096 in the 'patch' section, and on CompuServe in the BDEVTOOLS forum, lib 11. The file pxall.zip contains the libraries for the maintenance release. Disks are also available from our Customer Service department.

"Error# 96: Secondary index is out of date" -

Besides having an out of date index, this message can occur if the sort order of the Engine app is different from the sort order of the table. A common cause of this is using the Intl sort order with Paradox and using the Engine with its default ASCII sort order. The sort order can be changed by using the PXSetDefaults function.

"Error# 98: Could not login on network" -

This error comes up when the application does not have read, write, and create access to the network directory specified in either PXNetInit for DOS applications, or in win.ini for windows applications ). Can also be caused by using the LOCALSHARE parameter to PXNetInit() when share.exe is not loaded.

DOS:

make certain that the path uses double backslashes as opposed to single backslashes. Strings in C and C++

treat a single backslash as the escape character. For example, "\n" is a carriage return, line feed. Use "f:\\pdx\\netdir\\" to specify f:\pdx\netdir\.

#### WINDOWS:

Run the pxengcfg.exe utility to specify the net path.

"Error# 101: End of table" -

This error can be generated when the table is opened on the primary index, but a PXSrchFld() is being done on a field which is part of a single field secondary index. The table will be sorted according to the secondary index, but the end of table will be determined by the primary index. Open the table on the secondary index and do the search.

"Error# 107: Engine not initialized with PXNetInit" -

The Paradox Engine has not been initialized in a shareable mode. This can occur when the PXNetInit function with the NOTONNET parameter was used to initialize the engine. The NOTONNET parameter, as well as the NOSHARE parameter, do not allow the creation of any locks on your system.

"Error# 118: Table is busy" -

This error happens when the application tries to lock a table when the corresponding prevent lock already exists, or when the application tries to set a prevent lock and a conflicting lock already exists. Check for old, unused lock files. Delete any .lck files that may exist after all engine apps have terminated. Also run the TUtility program to test for table validity. See pg. 31 of the Paradox Engine users guide for more information on locks.

"Error# 120: Table is not found" -

Besides not being able to find the table, this error can also occur when the sort order that the engine uses is different from the sort order of the table. A common cause of this is using the Intl sort order with Paradox and using the Engine with its default ASCII sort order. The sort order can be changed by using the PXSetDefaults function.

"Error# 126: General Hardware Error" -

This error can occur from any network error which the Paradox Engine does not specifically handle. This error can also be generated when accessing a corrupted table. Run tutility.exe on the table to test for table corruption.

"Error# 134: Can't share Paradox net file -- is SHARE.EXE loaded?" -

Besides not having share loaded, this message can come up if share is loaded but the application does not have access to the directory where paradox.net is located. This error also occurs if the net file has gotten corrupted. Delete the net file to resolve this problem.

"Error# nnn: Internal Error #nnn " -

The most likely cause of this message is some sort of memory corruption,. Make certain that the code is compiled with all warnings turned on and test stack overflow turned on. Then try doubling the size of the stack because test stack overflow does not work in Windows or with any of our functions ). Memory corruption also occurs when a previous engine function failed but was not detected. Make certain that the return code for all engine functions is being checked. Get TI-738 on memory corruption and TI-1001 on Internal Errors. Also run TUtility on the table to test for table corruption. There were also certain cases where internal errors would be erroneously generated by v3.0 of the engine which were resolved in the maintenance release. The libraries, and the libraries only, to the Paradox Engine 3.01 maintenance release are available on our local BBS at ( 408 ) 439-9096 in the "patch" section. Disks are also available from our Customer Service department.

"Error# 400: Invalid Engine Type ( Database Framework )" -

The database library for the Paradox Engine 3.0 is built with "treat enums as ints". This means that the BEngine constructor is expecting a full two byte value coming in on the stack. If the project is built without this switch on, the compiler will assume the size of the BEngineType is a byte, and it will pass an argument which the libraries constructor will not read properly. Effectively, the compiler will do this:

```
mov al, 1 ; if we used pxLocal
push ax
```

which leaves garbage in the high order byte. This would be OK if the library was expecting a byte on the stack, but because it uses a whole word, it will read the garbage from the high order byte. Re-compile your application with the "Treat enums as ints" switch.

"Error 404: Table not open" -

This error can come from the testrest.cpp example which ships with the Paradox Engine and Database Framework if share is not loaded.

"Floating point error: Domain" -

Most likely caused by compiling the Paradox Engine in the small memory model. The Paradox Engine must be compiled in the LARGE memory model. Stack overflow can also cause this problem.

## Article #15243: Overwriting memory accidentally

Technical Notes Database

TN243D.txt      Overwriting memory accidentally

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 5.5

Description:

Q. How can my program be over-writing memory?

A. The most common causes for memory overwrites are:

1. Indexes out of range            (Turn range checking on {\$R+})
2. Uninitialized variables        (Write an initialization proc)
3. Pointers out of bounds        (Verify that pointers are not pointing outside of the heap space)
4. Improper use of FillChar or Move (Be sure to use the SizeOf function)
5. Illogical operations on strings

## Article #15247: BDE setup for Peer-To-Peer(Non-Dedicated) Networks

Technical Information Database

TI247B.txt      BDE setup for Peer-To-Peer(Non-Dedicated) Networks

Category      :General Programming

Platform      :All

Product      :BDE 3.0

### Description:

Using a BDE32 Application on a Peer-To-Peer Network

-----

A Peer-To-Peer network (a network where each machine acts as a client and a server) can be one of the following, including other network platforms that are compatible with these:

- 1) Windows 95
- 2) Windows NT
- 3) Lantastic
- 4) Netware Lite

The BDE automatically detects when tables reside on a network drive, but it cannot detect whether the tables are on a dedicated server or a server/client. Dedicated servers notify client applications that a file has been modified or locked. This functionality is not present in Peer-To-Peer (non-dedicated) networks. To achieve this functionality with Peer-To-Peer networks set "LOCAL SHARE" to TRUE in the BDE Configuration Utility on the System page. This must be done on all BDE clients that access the tables on networks listed above. This is not necessary for Novell File Server type networks.

If the tables that are being used are Paradox, there must also be a directory used for network control. This directory must also reside on the network for all client applications to use. It is good practice to have a separate directory for the application, network, and tables. The following is an example:

(Shared Directory)

```
|  
|--- (Tables Directory)  
|--- (EXE Directory)  
|--- (Network Directory)
```

There are two different BDE environments that must also be considered:

- 1) Using only BDE 32Bit applications.
- 2) Using BDE 32Bit applications along with BDE 16Bit applications.

### Setup for 32Bit Only Applications

-----

The 32Bit BDE fully supports the UNC naming convention along with long file names. It is recommended that the UNC convention is used for all BDE network connections. UNC removes the need for mapped drives. This will allow access to the tables and network directory without the user being mapped to the drive. UNC has the following syntax:

```
\\(server name)\(share name)\(path)+(file name)
```

Here is a simple example of a standard BDE alias using UNC:

```
Alias: MyUNCAlias  
Type: STANDARD  
Path: \\FooServer\FooShare\Sharedir\Tables  
Default Driver: Paradox
```

The network directory can be setup in the same fashion:

```
Drivers: Paradox  
Net Dir: \\FooServer\FooShare\Sharedir\NetDir
```

The network directory can be set at runtime using `session.netfiledir` (Delphi) or `DbiSetProp` (C++ / Delphi)

If for some reason UNC cannot be used with the 32Bit application, follow directions for using BDE 32Bit and 16Bit applications.

## Setup for 16Bit and 32Bit BDE Applications

---

Since the 16Bit Windows API does not support UNC, neither does the 16Bit BDE. To allow applications to share the tables, all clients must be mapped to the same directory on the server. If the server is also used as a client, all other clients must be mapped to the root of the drive. Drive letters from client to client do not have to be identical. Here are some examples of what will and will not work:

Client1:

Path: X:\ShareDir\Tables

Client2:

Path: X:\ShareDir\Tables

This is OK

Client1: (Also the machine with the tables):

Path: C:\ShareDir\Tables

Client2:

Path: X:\ShareDir\Tables

This is OK

Client1: (Also the machine with the tables):

Path: C:\ShareDir\Tables

Client2:

Path: X:\ShareDir\Tables

Client3:

Path: R:\ShareDir\Tables

This is OK

Client1:

Path: X:\ShareDir\Tables

Client2:

Path: X:\Tables (Where X:\Tables is actually

X:\ShareDir\Tables, but shared on the ShareDir directory)

This will not work. The BDE must be able to make the same entry into the Network Control file.

In Summary (setup for Peer-To-Peer networks):

---

16 and / or 32Bit Applications:

1) Turn "LOCAL SHARE" to TRUE in the BDE Configuration

Utility.

- 2) Do not use the UNC naming convention.
- 3) Do not use tables with long file names.
- 4) Make sure that all clients are mapped to the same directory on the server.

32Bit Only Applications:

- 1) Turn "LOCAL SHARE" to TRUE in the BDE Configuration Utility
- 2) Use the UNC naming convention to achieve a path to the network directory and table directory.

If the above steps are not followed, users could be locked out of the tables getting error:

"Directory is controlled by other .NET file."

"File: (Path1) PDOXUSRS.LCK"

"Directory: (Path2)"

OR

"Multiple .NET files in use."

"File: (Path) PDOXUSRS.LCK"

## Article #15249: Change Foreground and Background Color

Technical Information Database

TI249D.txt Change Foreground and Background Color

Category :TVISION

Platform :All

Product :Pascal All

Description:

{

This program will place a new foreground and background color and pattern on the desktop. It will also set the character that is displayed for the pattern.

This example: the \$05 defines the 0 for black foreground and the 5 for purple background.

}

```
program ColorManipulation;
```

```
uses
```

```
    Dos, Objects, Drivers, Memory, Views,  
    Menus, Dialogs, App;
```

```
type
```

```
    PMyBack = ^TMyBack;  
    TMyBack = object(TBackground)  
        constructor Init(var Bounds: TRect);  
    end;
```

```
    PMyApp = ^TMyApp;  
    TMyApp = object(TApplication)  
        MyBack: PMyBack;  
        constructor Init;  
        function GetPalette:PPalette; virtual;  
    end;
```

```
function TMyApp.GetPalette: PPalette;
```

```
const  
    MyBackColor : TPalette = CColor; { sets palette to CColor }
```

```
{ items }
```

```
begin
  MyBackColor[1]:=#$05;    { TBackGround Color Constant's first }
                          { number is background and second is }
                          { foreground }
  GetPalette :=
MyBackColor;
end;
```

```
constructor TMyBack.Init(var Bounds: TRect);
begin
  TBackground.Init(Bounds, '?');{ places ASCII 178 char as }
                                { pattern for text on desktop }
end;
```

```
constructor TMyApp.Init;
var
  R:TRect;
begin
  TApplication.Init;
  GetExtent(R);
  MyBack:= New(PMyBack, init(R));
  Desktop^.Background:= MyBack;
  Desktop^.Insert(Desktop^.Background);
end;
```

```
var
  TheApp: TMyApp;
begin
  TheApp.Init;
  TheApp.Run;
  TheApp.Done;
end.
```

## Article #15251: Out of Memory during compilation

Technical Notes Database

TN251D.txt Out of Memory during compilation

Category :Pascal

Platform :All

Product :Turbo Pascal 5.5

Description:

Q. What do I do about running out of memory during compilation?

A. There are a number of solutions to this problem:

1. If Compiler/Destination is set to Memory, set it to Disk in the integrated environment.
2. If Options/Compile/Link buffer in the integrated environment is set to Memory, set it to Disk. Alternatively, if you're using 4.0, place a {\$L-} directive at the beginning of your program. Use the /L option to link to disk in the command-line compiler.
3. If you are using any memory-resident utilities, such as Sidekick and Superkey, remove them from memory.
4. If you are using TURBO.EXE, try using TPC.EXE instead - it takes up less memory.
5. Turn off any compiler directives which are not necessarily needed. By simply turning off range checking {\$R-} and software emulation {\$E-}, your code size will be reduced dramatically.
6. Move all units, except PRINTER.TPU, out of the TURBO.TPL file and into the installed units directory.

If none of these suggestions help, your program or unit may simply be too large to compile in the amount of memory available, and you may have to break in into two or more smaller units. Alternatively, if you're using 5.0+, you should consider using overlays.

## Article #15256: Removing "Lock file has grown too large" Error

Technical Information Database

TI256B.txt     Removing "Lock file has grown too large" Error  
Category     :General Programming  
Platform     :All  
Product      :BDE All

### Description:

Lock file has grown too large, Decimal:9495 Hex:2517  
-----

This problem is specific to Paradox tables and can be caused in any BDE (16 or 32 Bit) application that meet some or all of the following criteria:

- 1) The Executable is in the same directory as the table.
- 2) The Private Directory is not correctly set or not set at all.
- 3a) Delphi: Having a TTable open on a paradox table and then performing multiple TQuery operations.
- 3b) C / C++: Having a table open with DbOpenTable and then performing multiple queries with DbQueryExec and/or DbQueryExecDirect.
- 4) LOCAL SHARE set to true in the BDE Configuration Utility on the System page.

To solve the problem, make sure that your application has done ALL of the following:

- 1) Under the directory where the executable is, create three new directories: TABLES, PRIV, and NET. Place all the tables for the application into the TABLES directory.
- 2) Set the session's private directory to the PRIV directory. Take the following steps according to the software you are using.

DELPHI:

```
Session.PrivateDir := ExtractFilePath(ParamStr(0)) + 'PRIV';
```

```
C / C++:  
DbiSetPrivateDir(szPath);  
// szPath is the fully qualified path (not relative)  
// to the PRIV directory.
```

- 3) Set the session's network directory to the NET directory. Take the following steps according to the software you are using.

```
DELPHI:  
Session.NetFileDir := ExtractFilePath(ParamStr(0)) + 'NET';
```

```
C / C++:  
DbiSetProp(hSes, sesNETFILE, (UINT32)szPath);  
// szPath is the fully qualified path (not relative)  
// to the NET directory.
```

```
// hSes is the current session handle. This can be  
// retrieved using the DBiGetCurrSession function.
```

- 4) If LOCAL SHARE is set to true and you are not sharing tables between different applications at the same time, change LOCAL SHARE to false.

The above steps will correct the Lock File Too Large error.

## Article #15260: Exec procedure not executing subprograms

Technical Notes Database

TN260D.txt      Exec procedure not executing subprograms

Category      :Pascal

Platform       :All

Product        :Turbo Pascal 5.5

### Description:

Q. Why doesn't the Exec procedure execute my subprograms?

A. Make certain that you use the {\$M} directive to set the maximum heap size to the lowest possible value. If this is done, check the value of the variable DosError to diagnose other problems. What is DosError Returning after the call:

8) Not enough Memory: User needs to lower MAX Heap  
                          {\$M Stack, Min, Max}

2) File not found: User needs to specify the full Path and extension of the command. If you're trying to execute a DOS internal command, you need to use COMMAND.COM (see DIR example in manual).

## Article #15265: Sharing Violation Error with Paradox Tables.

Technical Information Database

TI265B.txt      Sharing Violation Error with Paradox Tables  
Category      :General Programming  
Platform      :All  
Product        :BDE All

### Description:

This error is most commonly caused by a "Lock File Contention". A lock file contention occurs in this situation:

One user, User "A", is accessing one or more Paradox tables in a directory. "A" is closing the last table in the directory. The BDE detects that "A" is the last program accessing the tables in the directory. Since "A" is the last user on the tables, the .LCK files are going to be deleted. At this time, User "B" attempts to open a table in the same directory as "A" (who is about to delete the .LCK files). "B" opens the .LCK files to write an entry to. This is when "A" tries to delete the .LCK files that "B" has now opened. This will cause a sharing violation on the .LCK files. The share violation usually occurs on the last client to close the table.

### Solutions:

One solution is to override Windows error routines and ignore the error. In all test cases, then a sharing violation occurs, the table is still opened or closed.

Another solution is to keep the .LCK files in the table's directories. If the BDE detects that more than one Application (or Session) is using the tables, it will not attempt to delete the .LCK files therefore solving the problem.

If the BDE and your Paradox table all reside on the

same CPU another solution is turn off Local share in BDE Administrator. If Local Share is off .LCK files will not be created in the first place, so a sharing violation should not occur. Note that if tables are on a different CPU than the BDE setting Local Share has no significance because .LCK files are always created on remote drives.

1) C / C++ / Delphi / Paradox:

Use the Windows API SetErrorMode passing the SEM\_FAILCRITICALERRORS constant. You would only need to do this before opening and closing a table and then check to see if the table has actually been open. Please see Routine 1a and 1b below for a basic Delphi (any version) routine or Routine 2a and 2b for C / C++ routines. Paradox users will need to call into the appropriate DLL where SetErrorMode resides.

2) C / C++ / Delphi / Paradox:

Create a "Dummy" Paradox table in each table directory that the application uses. Example: executable is in directory C:MyProg. This executable opens tables in two different directories - C:MyTables and D:TempTbl. Create a "Dummy" table with the Database Desktop, or any other Paradox table creation utility, in both the C:MyTables and D:TempTbl directories. Once the tables are created, create an application that opens each of the "Dummy" programs at startup. Leave this program running at all times. If the executable can be placed on a server machine, like Windows NT, that is optimal. In this scenario, whenever applications are accessing the data, the server also has the "Dummy" tables open.

3) C / C++ / Delphi / Paradox:

Leave at least one table during the entire application's run. Open one table during startup and close the table at exit. You could even open a "Dummy" table described above.

4) C / C++ / Delphi:

Use DbtAcqPersistTableLock BDE function to create a lock on a table that does not exist (Delphi or C++

only).

Syntax:

```
(Delphi) Check(DbAcqPersistTableLock(Database1.Handle,  
'NoTable1.DB', szPARADOX));
```

```
(C++) rslt = DbAcqPersistTableLock(hDb, 'NoTable2.DB',  
szPARADOX);
```

NOTE: Each instance of the application must have a unique, non-existent table name or an attempt to place a lock in the directory will fail. If this method is used, an algorithm must be used to guarantee a unique table name. If a user can only run one instance of the program at a time, the network user name can be used as a table name.

5) Paradox ObjectPAL:

If your application is apt to cause .LCK files to be created and deleted often, the easiest (and least resource-intensive) way to prevent this is to place a read lock on a non-existent table within the directory when your application starts up. (Paradox allows us to place semaphore locks on tables that don't exist.) Since read locks don't conflict with one another, all users can do this, and the net result will be that the .LCK file will not be deleted until the last user exits the system.

Syntax:

At program startup:

```
Table.attach("DummyTbl.db")
```

```
Table.lock(Read)
```

At program shut-down:

```
Table.unlock(Read)
```

```
Table.unAttach
```

NOTES - These are observations on the problem:

1) The problem does not seem to occur on NT workstation machines. The application can be either

16 or 32 bit. SetErrorMode seems to work with both cases.

2) The problem is more likely to occur if the network protocol is netBEUI. If possible use netBIOS or IPX/SPX.

3) Constant closing and opening of tables will cause this error more often.

4) The error most commonly occurs on the close of the table, not the open. In this situation the closing application tries to delete files that another application now has open.

Example Routines:

Routine 1a) (Delphi Table Open Routine)

```
-----  
procedure TForm1.OpenTable(MyTable: TTable);  
begin  
  { Set the error mode to ignore critical errors }  
  SetErrorMode(SEM_FAILCRITICALERRORS);  
  { Open the table and check if it was opened }  
  MyTable.Open;  
  if MyTable.Active = False then  
  begin  
    { Retry opening the table }  
    MyTable.Open;  
    { If an error happens again, raise an exception }  
    if MyTable.Active = False then  
      raise  
        EDatabaseError.Create('Error Opening table');  
  end;  
  { Set the error mode back to the default }  
  SetErrorMode(0);  
end;
```

Routine 1b) (Delphi Table Close Routine)

-----

```

procedure TForm1.CloseTable(MyTable: TTable);
begin
  { Set the error mode to ignore critical errors }
  SetErrorMode(SEM_FAILCRITICALERRORS);
  { Close the table and check if it was closed }
  MyTable.Close;
  if MyTable.Active = True then
  begin
    { Retry closing the table }
    MyTable.Close;
    { If an error happens again, raise an exception }
    if MyTable.Active = True then
      raise
        EDatabaseError.Create('Error Closing table');
  end;
  { Set the error mode back to the default }
  SetErrorMode(0);
end;

```

Routine 2a) (C / C++ Table Open Routine)

```

-----
DbiResult OpenTable(hDBIDb hTmpDb, pCHAR szTblName,
                   phDBICur phTmpCur)
{
  DBIResult  rslt;

  // Set the error mode to ignore critical errors
  SetErrorMode(SEM_FAILCRITICALERRORS);

  // Open the table and check if it was opened
  rslt = DbiOpenTable(hTmpDb, szTblName, NULL,
                     NULL, NULL, NULL, dbiREADWRITE, dbiOPENSHARED,
                     xltFIELD, FALSE, NULL, phTmpCur);
  if (rslt != DBIERR_NONE)

    // Retry opening the table
    rslt = DbiOpenTable(hTmpDb, szTblName, NULL,
                       NULL, NULL, NULL, dbiREADWRITE, dbiOPENSHARED,
                       xltFIELD, FALSE, NULL, phTmpCur);

  // Set the error mode back to the default
  SetErrorMode(0);
  return rslt;
}

```

Routine 2b) (C / C++ Table Open Routine)

```
-----  
DBIResult CloseTable(phDBICur phTmpCur)  
{  
    DBIResult    rslt;  
  
    // Set the error mode to ignore critical errors  
    SetErrorMode(SEM_FAILCRITICALERRORS);  
  
    // Close the table and check if it was closed  
    rslt = DbiCloseCursor(phTmpCur);  
    if (rslt != DBIERR_NONE)  
  
        // Retry closing the table  
        rslt = DbiCloseCursor(phTmpCur);  
  
    // Set the error mode back to the default  
    SetErrorMode(0);  
    return rslt;  
}
```

## Article #15269: Communicating with the serial port

Technical Notes Database

TN269D.txt      Communicating with the serial port

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 5.5

Description:

Q. How do you communicate with the serial port?

A. Modify the AuxInOut unit described in the Reference

Guide as follows: To read incoming data, use the Reset procedure before reading. Also, you should read from a buffer rather than directly from the serial port.

Furthermore, the AuxInOut is not an ideal example to use as input buffering is not supported; you should use the enclosed Technical Information Handout #407 routines for this purpose.

TI274B.txt Steps for FAT32 Support with the BDE

Category : General Programming

Platform : All

Product : BDE 3.5

### Description:

Windows 95 version 950B and Windows 98 have a file system called FAT32. BDE Versions prior to version 3.5 will not work with this file system. BDE Versions after version 3.5 have no problem with FAT32. This document discusses how to make BDE version 3.5 work with FAT32.

The FAT file system had problems with large cluster sizes with large hard disks making storage inefficient. FAT32 keeps the cluster size at 4k enabling efficient data storage.

### COMMON BDE ERRORS EXPERIENCED WITH FAT32 SYSTEMS

-----

"Invalid File Name"

"Invalid Table Name"

"File Not Found"

"Table Not Found"

NOTE: All Delphi and CBuilder exceptions are of type EDBEngine error. The errors above are displayed within this exception type.

-----

To determine if you have a FAT32 system:

1) Right click the mouse on the My Computer icon on the desktop. Select the Properties menu item. On the general tab, under System, it will say 4.00.950 B. NOTE: 4.00.950A or 4.00.950 does not support FAT32. At the time this was written 4.00.950B is the latest. Microsoft may decide to create newer builds with FAT32 support.

2) Double click on the My Computer icon on the desktop. Right click on each local drive and select the Properties menu item. If any of the drive Types is Local Disk (FAT32), then you have a FAT32 partition on your system. Note: Local Disk (FAT) is not FAT32.

If in the above steps you have determined that you have a FAT32 file system, you can obtain a version of BDE 3.5 which does not have this problem from <http://www.borland.com/devsupport/bde/oldver.html>

## OTHER OPTIONS/WORKAROUNDS IF UPGRADE IS NOT AN OPTION

-----

If for any reason, the new DLL or set of DLLs cannot be placed on the system, you must follow the proceeding criteria:

- 1) All sub-directories must be 8 characters or less.
- 2) If tables must be in a 9 character or greater sub-directory, you can still open the table by
  - a) (Delphi, CBuilder) specifying the full path and file name in TTable.Table name, leaving DatabaseName blank.
  - b) (BC++) Passing NULL to the pszAliasName parameter and using the full path and file name in DbOpenTable.  
NOTE: DbSetDirectory will not work.
- 3) Table names can be greater than 8 characters with spaces.

## Article #15276: Loop Processing in Windows

Technical Information Database

TI276D.txt    Loop Processing in Windows  
Category    :General Programming  
Platform    :All  
Product     :Pascal    All

### Description:

There are two basic ways of handling loop processing in Windows that would otherwise take away control (tie up processing of your code and not allow other processes to run) of other running Window's applications. The first and probably the most flexible approach is to write a processing loop and 'YIELD' to other Windows application's request. The second approach would be to override TApplication's MessageLoop method and within the MessageLoop call your process.

### 'YIELD'

If your procedure that takes a while to execute contains some sort of outer loop, make a call to a procedure that allows other apps to run. Your time consuming code might look something like:

```
...  
While MoreToDo do  
begin  
    YieldToOthers;  
    DoSomeProcessing;  
end;
```

A few notes concerning this procedure:

- \* The call to HALT may need to be modified to do any cleanup required (i.e.: close open files, etc.).
- \* You'll need to be sensitive to re-entrant issues.

The procedure "YieldToOthers" would look like:

```

Procedure YieldToOthers;
var
  Msg : TMsg;
begin
  While PeekMessage(Msg,0,0,0,PM_REMOVE) do begin
    if Msg.Message = WM_QUIT then begin
      Application^.Done;
      halt; {!!}
    end;
    TranslateMessage(Msg);
    DispatchMessage(Msg);
  end;
end;

```

'MessageLoop'

This is a replacement for the TApplication MessageLoop method. It provides for an 'idle loop' where your program can continuously process its own work, and yet still yield control to windows when windows needs to do something.

```

TMyApp = object(TApplication)
  procedure MessageLoop; virtual; { add this method to your }
end;      { * descendant of TApplication * }

```

```

{ * just paste this in to your program * }
procedure TMyApp.MessageLoop;
var
  Message: TMsg;
begin
  while true do begin
    if PeekMessage(Message, 0, 0, 0, pm_Remove) then begin
      if Message.Message = wm_Quit then Exit;
      TranslateMessage(Message);
      DispatchMessage(Message);
    end
    else begin

      { ** do your stuff here ** }

    end;
  end;
end;

Status := Message.WParam;

```

end;

## Article #15278: Dumping Graphics to the printer

Technical Notes Database

TN278D.txt      Dumping Graphics to the printer

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 5.5

Description:

Q. How do you dump graphics to a printer?

A. Please see the enclosed Technical Information

Handouts, #433 and #432, for examples of printing graphics  
on Epson compatible and HP Laser Jet printers.

## Article #15283: BDE Error listing

Technical Information Database

TI283B.txt BDE Error listing  
Category :General Programming  
Platform :WINDOWS  
Product :BDE

### Description:

This document lists all the errors that can be returned by the BDE. This information is derived from IDAPI.H (C++) or BDE.INT (C++ Builder and Delphi). You also wish to look at the following document(s) for addition information on specific errors:

15809 - Handling EDBEngineError Exceptions  
16437 - BDE and Database Desktop Locking Protocol

Note: You can use DbtGetErrorString() to retrieve the error string for any error.

### System Related (Fatal Error)

8449 : \$2101 : Cannot open a system file.  
8450 : \$2102 : I/O error on a system file.  
8451 : \$2103 : Data structure corruption.  
8452 : \$2104 : Cannot find Engine configuration file.  
8453 : \$2105 : Cannot write to Engine configuration file.  
8454 : \$2106 : Cannot initialize with different  
configuration file.  
8455 : \$2107 : System has been illegally re-entered.  
8456 : \$2108 : Cannot locate IDAPI32 .DLL.  
8457 : \$2109 : Cannot load IDAPI32 .DLL.  
8458 : \$210A : Cannot load an IDAPI service library.  
8459 : \$210B : Cannot create or open temporary file.  
8460 : \$210C : Trying to load multiple IDAPIxx.DLL  
8461 : \$210D : Shared Memory Conflict

### Object of Interest not Found

8705 : \$2201 : At beginning of table.

8706 : \$2202 : At end of table.  
8707 : \$2203 : Record moved because key value changed.  
8708 : \$2204 : Record/Key deleted.  
8709 : \$2205 : No current record.  
8710 : \$2206 : Could not find record.  
8711 : \$2207 : End of BLOB.  
8712 : \$2208 : Could not find object.  
8713 : \$2209 : Could not find family member.  
8714 : \$220A : BLOB file is missing.  
8715 : \$220B : Could not find language driver.

#### Physical Data Corruption

8961 : \$2301 : Corrupt table/index header.  
8962 : \$2302 : Corrupt file - other than header.  
8963 : \$2303 : Corrupt Memo/BLOB file.  
8965 : \$2305 : Corrupt index.  
8966 : \$2306 : Corrupt lock file.  
8967 : \$2307 : Corrupt family file.  
8968 : \$2308 : Corrupt or missing .VAL file.  
8969 : \$2309 : Foreign index file format.

#### I/O related error

9217 : \$2401 : Read failure.  
9218 : \$2402 : Write failure.  
9219 : \$2403 : Cannot access directory.  
9220 : \$2404 : File Delete operation failed.  
9221 : \$2405 : Cannot access file.  
9222 : \$2406 : Access to table disabled because of  
previous error.

#### Resource or Limit error

9473 : \$2501 : Insufficient memory for this operation.  
9474 : \$2502 : Not enough file handles.  
9475 : \$2503 : Insufficient disk space.  
9476 : \$2504 : Temporary table resource limit.  
9477 : \$2505 : Record size is too big for table.  
9478 : \$2506 : Too many open cursors.  
9479 : \$2507 : Table is full.  
9480 : \$2508 : Too many sessions from this workstation.  
9481 : \$2509 : Serial number limit (Paradox).  
9482 : \$250A : Some internal limit (see context).  
9483 : \$250B : Too many open tables.

9484 : \$250C : Too many cursors per table.  
9485 : \$250D : Too many record locks on table.  
9486 : \$250E : Too many clients.  
9487 : \$250F : Too many indexes on table.  
9488 : \$2510 : Too many sessions.  
9489 : \$2511 : Too many open databases.  
9490 : \$2512 : Too many passwords.  
9491 : \$2513 : Too many active drivers.  
9492 : \$2514 : Too many fields in Table Create.  
9493 : \$2515 : Too many table locks.  
9494 : \$2516 : Too many open BLOBs.  
9495 : \$2517 : Lock file has grown too large.  
9496 : \$2518 : Too many open queries.  
9498 : \$251A : Too many BLOBs.  
9499 : \$251B : File name is too long for a Paradox version  
5.0 table.  
9500 : \$251C : Row fetch limit exceeded.  
9501 : \$251D : Long name not allowed for this tablelevel.  
9502 : \$251E : Insufficient shared memory available.

#### Integrity Violation

9729 : \$2601 : Key violation.  
9730 : \$2602 : Minimum validity check failed.  
9731 : \$2603 : Maximum validity check failed.  
9732 : \$2604 : Field value required.  
9733 : \$2605 : Master record missing.  
9734 : \$2606 : Master has detail records. Cannot delete or  
modify.  
9735 : \$2607 : Master table level is incorrect.  
9736 : \$2608 : Field value out of lookup table range.  
9737 : \$2609 : Lookup Table Open operation failed.  
9738 : \$260A : Detail Table Open operation failed.  
9739 : \$260B : Master Table Open operation failed.  
9740 : \$260C : Field is blank.  
9741 : \$260D : Link to master table already defined.  
9742 : \$260E : Master table is open.  
9743 : \$260F : Detail table(s) exist.  
9744 : \$2610 : Master has detail records. Cannot empty it.  
9745 : \$2611 : Self referencing referential integrity must  
be entered one at a time with no other  
changes to the table  
9746 : \$2612 : Detail table is open.  
9747 : \$2613 : Cannot make this master a detail of another  
table if its details are not empty.

9748 : \$2614 : Referential integrity fields must be indexed.  
9749 : \$2615 : A table linked by referential integrity requires password to open.  
9750 : \$2616 : Field(s) linked to more than one master.  
9751 : \$2617 : Expression validity check failed.

#### Invalid Request

9985 : \$2701 : Number is out of range.  
9986 : \$2702 : Invalid parameter.  
9987 : \$2703 : Invalid file name.  
9988 : \$2704 : File does not exist.  
9989 : \$2705 : Invalid option.  
9990 : \$2706 : Invalid handle to the function.  
9991 : \$2707 : Unknown table type.  
9992 : \$2708 : Cannot open file.  
9993 : \$2709 : Cannot redefine primary key.  
9994 : \$270A : Cannot change this RINTDesc.  
9995 : \$270B : Foreign and primary key do not match.  
9996 : \$270C : Invalid modify request.  
9997 : \$270D : Index does not exist.  
9998 : \$270E : Invalid offset into the BLOB.  
9999 : \$270F : Invalid descriptor number.  
10000 : \$2710 : Invalid field type.  
10001 : \$2711 : Invalid field descriptor.  
10002 : \$2712 : Invalid field transformation.  
10003 : \$2713 : Invalid record structure.  
10004 : \$2714 : Invalid descriptor.  
10005 : \$2715 : Invalid array of index descriptors.  
10006 : \$2716 : Invalid array of validity check descriptors.  
10007 : \$2717 : Invalid array of referential integrity descriptors.  
10008 : \$2718 : Invalid ordering of tables during restructure.  
10009 : \$2719 : Name not unique in this context.  
10010 : \$271A : Index name required.  
10011 : \$271B : Invalid session handle.  
10012 : \$271C : invalid restructure operation.  
10013 : \$271D : Driver not known to system.  
10014 : \$271E : Unknown database.  
10015 : \$271F : Invalid password given.  
10016 : \$2720 : No callback function.  
10017 : \$2721 : Invalid callback buffer length.  
10018 : \$2722 : Invalid directory.  
10019 : \$2723 : Translate Error. Value out of bounds.

10020 : \$2724 : Cannot set cursor of one table to another.  
10021 : \$2725 : Bookmarks do not match table.  
10022 : \$2726 : Invalid index/tag name.  
10023 : \$2727 : Invalid index descriptor.  
10024 : \$2728 : Table does not exist.  
10025 : \$2729 : Table has too many users.  
10026 : \$272A : Cannot evaluate Key or Key does not pass  
filter condition.  
10027 : \$272B : Index already exists.  
10028 : \$272C : Index is open.  
10029 : \$272D : Invalid BLOB length.  
10030 : \$272E : Invalid BLOB handle in record buffer.  
10031 : \$272F : Table is open.  
10032 : \$2730 : Need to do (hard) restructure.  
10033 : \$2731 : Invalid mode.  
10034 : \$2732 : Cannot close index.  
10035 : \$2733 : Index is being used to order table.  
10036 : \$2734 : Unknown user name or password.  
10037 : \$2735 : Multi-level cascade is not supported.  
10038 : \$2736 : Invalid field name.  
10039 : \$2737 : Invalid table name.  
10040 : \$2738 : Invalid linked cursor expression.  
10041 : \$2739 : Name is reserved.  
10042 : \$273A : Invalid file extension.  
10043 : \$273B : Invalid language Driver.  
10044 : \$273C : Alias is not currently opened.  
10045 : \$273D : Incompatible record structures.  
10046 : \$273E : Name is reserved by DOS.  
10047 : \$273F : Destination must be indexed.  
10048 : \$2740 : Invalid index type  
10049 : \$2741 : Language Drivers of Table and Index do not  
match  
10050 : \$2742 : Filter handle is invalid  
10051 : \$2743 : Invalid Filter  
10052 : \$2744 : Invalid table create request  
10053 : \$2745 : Invalid table delete request  
10054 : \$2746 : Invalid index create request  
10055 : \$2747 : Invalid index delete request  
10056 : \$2748 : Invalid table specified  
10058 : \$274A : Invalid Time.  
10059 : \$274B : Invalid Date.  
10060 : \$274C : Invalid Datetime  
10061 : \$274D : Tables in different directories  
10062 : \$274E : Mismatch in the number of arguments  
10063 : \$274F : Function not found in service library.

10064 : \$2750 : Must use baseorder for this operation.  
10065 : \$2751 : Invalid procedure name  
10066 : \$2752 : The field map is invalid.

#### Locking/Contention related

10241 : \$2801 : Record locked by another user.  
10242 : \$2802 : Unlock failed.  
10243 : \$2803 : Table is busy.  
10244 : \$2804 : Directory is busy.  
10245 : \$2805 : File is locked.  
10246 : \$2806 : Directory is locked.  
10247 : \$2807 : Record already locked by this session.  
10248 : \$2808 : Object not locked.  
10249 : \$2809 : Lock time out.  
10250 : \$280A : Key group is locked.  
10251 : \$280B : Table lock was lost.  
10252 : \$280C : Exclusive access was lost.  
10253 : \$280D : Table cannot be opened for exclusive use.  
10254 : \$280E : Conflicting record lock in this session.  
10255 : \$280F : A deadlock was detected.  
10256 : \$2810 : A user transaction is already in progress.  
10257 : \$2811 : No user transaction is currently in progress.  
10258 : \$2812 : Record lock failed.  
10259 : \$2813 : Couldn't perform the edit because another  
user changed the record.  
10260 : \$2814 : Couldn't perform the edit because another  
user deleted or moved the record.

#### Access Violation - Security related

10497 : \$2901 : Insufficient field rights for operation.  
10498 : \$2902 : Insufficient table rights for operation.  
Password required.  
10499 : \$2903 : Insufficient family rights for operation.  
10500 : \$2904 : This directory is read only.  
10501 : \$2905 : Database is read only.  
10502 : \$2906 : Trying to modify read-only field.  
10503 : \$2907 : Encrypted dBASE tables not supported.  
10504 : \$2908 : Insufficient SQL rights for operation.

#### Invalid context

10753 : \$2A01 : Field is not a BLOB.  
10754 : \$2A02 : BLOB already opened.

10755 : \$2A03 : BLOB not opened.  
10756 : \$2A04 : Operation not applicable.  
10757 : \$2A05 : Table is not indexed.  
10758 : \$2A06 : Engine not initialized.  
10759 : \$2A07 : Attempt to re-initialize Engine.  
10760 : \$2A08 : Attempt to mix objects from different sessions.  
10761 : \$2A09 : Paradox driver not active.  
10762 : \$2A0A : Driver not loaded.  
10763 : \$2A0B : Table is read only.  
10764 : \$2A0C : No associated index.  
10765 : \$2A0D : Table(s) open. Cannot perform this operation.  
10766 : \$2A0E : Table does not support this operation.  
10767 : \$2A0F : Index is read only.  
10768 : \$2A10 : Table does not support this operation because it is not uniquely indexed.  
10769 : \$2A11 : Operation must be performed on the current session.  
10770 : \$2A12 : Invalid use of keyword.  
10771 : \$2A13 : Connection is in use by another statement.  
10772 : \$2A14 : Passthrough SQL connection must be shared

Os Error not handled by Idapi

11009 : \$2B01 : Invalid function number.  
11010 : \$2B02 : File or directory does not exist.  
11011 : \$2B03 : Path not found.  
11012 : \$2B04 : Too many open files. You may need to increase MAXFILEHANDLE limit in IDAPI configuration.  
11013 : \$2B05 : Permission denied.  
11014 : \$2B06 : Bad file number.  
11015 : \$2B07 : Memory blocks destroyed.  
11016 : \$2B08 : Not enough memory.  
11017 : \$2B09 : Invalid memory block address.  
11018 : \$2B0A : Invalid environment.  
11019 : \$2B0B : Invalid format.  
11020 : \$2B0C : Invalid access code.  
11021 : \$2B0D : Invalid data.  
11023 : \$2B0F : Device does not exist.  
11024 : \$2B10 : Attempt to remove current directory.  
11025 : \$2B11 : Not same device.  
11026 : \$2B12 : No more files.  
11027 : \$2B13 : Invalid argument.  
11028 : \$2B14 : Argument list is too long.  
11029 : \$2B15 : Execution format error.

11030 : \$2B16 : Cross-device link.  
11041 : \$2B21 : Math argument.  
11042 : \$2B22 : Result is too large.  
11043 : \$2B23 : File already exists.  
11047 : \$2B27 : Unknown internal operating system error.  
11058 : \$2B32 : Share violation.  
11059 : \$2B33 : Lock violation.  
11060 : \$2B34 : Critical DOS Error.  
11061 : \$2B35 : Drive not ready.  
11108 : \$2B64 : Not exact read/write.  
11109 : \$2B65 : Operating system network error.  
11110 : \$2B66 : Error from NOVELL file server.  
11111 : \$2B67 : NOVELL server out of memory.  
11112 : \$2B68 : Record already locked by this workstation.  
11113 : \$2B69 : Record not locked.

#### Network related

11265 : \$2C01 : Network initialization failed.  
11266 : \$2C02 : Network user limit exceeded.  
11267 : \$2C03 : Wrong .NET file version.  
11268 : \$2C04 : Cannot lock network file.  
11269 : \$2C05 : Directory is not private.  
11270 : \$2C06 : Directory is controlled by other .NET file.  
11271 : \$2C07 : Unknown network error.  
11272 : \$2C08 : Not initialized for accessing network files.  
11273 : \$2C09 : SHARE not loaded. It is required to share  
local files.  
11274 : \$2C0A : Not on a network. Not logged in or wrong  
network driver.  
11275 : \$2C0B : Lost communication with SQL server.  
11277 : \$2C0D : Cannot locate or connect to SQL server.  
11278 : \$2C0E : Cannot locate or connect to network server.

#### Optional parameter related

11521 : \$2D01 : Optional parameter is required.  
11522 : \$2D02 : Invalid optional parameter.

#### Query related

11777 : \$2E01 : obsolete  
11778 : \$2E02 : obsolete  
11779 : \$2E03 : Ambiguous use of ! (inclusion operator).  
11780 : \$2E04 : obsolete

11781 : \$2E05 : obsolete  
11782 : \$2E06 : A SET operation cannot be included in its own grouping.  
11783 : \$2E07 : Only numeric and date/time fields can be averaged.  
11784 : \$2E08 : Invalid expression.  
11785 : \$2E09 : Invalid OR expression.  
11786 : \$2E0A : obsolete

## Article #15285: Creating and Using Fonts in the Resource Workshop

Technical Information Database

TI285D.txt      Creating and Using Fonts in the Resource Workshop  
Category      :General Programming  
Platform      :All  
Product       :Pascal    All

### Description:

Detailed below is a step by step description of how a Windows font file (.FON) is created using Borland's Resource Workshop and Turbo Pascal for Windows.

1. With the Resource Workshop, create a Resource file and save it to a file in compiled .RES format.. This is best done by creating a resource script (a file with the extension .RC) and selecting the .RES option for MultiSave found in the File/Preferences menu.
2. In Turbo Pascal for Windows, create a library similar to the one described below.

```
library NewFont;  
{ $D FONTRES 100,96,96 : NewFont 12 (VGA res) }  
{ $M 1024, 0 }  
{ $R NewFont }  
begin  
end.
```

The font NewFont is used in this example. You may give your fonts any name desired. Of the compiler directives, the Description directive gives the resolution of the font and provides a description of the font. In the example, the values 100, 96, 96 represent the Aspect, LogPixelsX, LogPixelsY for the device normally used with the font (in this case VGA). Aspect is calculated from the expression  $(100 * \text{AspectY}) \div (\text{AspectX})$ . The values AspectX, AspectY, LogPixelsX, and LogPixelsY are accessible through the API function GetDeviceCaps.

If you like, you may have more than one set of Aspect, LogPixelX, and LogPixelY values. For NewFont, this could take the form of

the following. Each set of values is separated by a semi-colon and space.

```
{ $D FONTRES 100,96,96; 200,96,48; 133,96,72 :  
      NewFont 12 (VGA res) }
```

For font files, the description directive must start with the term FONTRES in order for the font to be recognized as a valid Windows font file. It is also very important not to separate values within a set of Aspect, LogPixelX, LogPixelY values with spaces. Windows may not recognize a file with values so delimited.

3. Compile the library just created to a .DLL file.

4. Rename the .DLL file to one with the extension .FON. In the case of NewFont, NEWFONT.DLL would be renamed to NEWFONT.FON.

5. Often, .FON are copied into the Windows directory \WINDOWS\SYSTEM and then added using the Control Panel program.

Note, Microsoft's Control Panel program may not function correctly with fonts that do encompass the entire alphabet.

## Article #15287: The Source of "Unit file format error"

Technical Notes Database

TN287D.txt     The Source of "Unit file format error"  
Category     :Pascal  
Platform     :All  
Product     :Turbo Pascal 5.5

### Description:

Q. Why am I getting a "Unit file format error" when I compile my program with the new Turbo Pascal compiler?

A. You are using a unit that has been compiled with a different Turbo Pascal version. From the main program, use the BUILD option to recompile all dependent units.

## Article #15295: Redirecting printer output

Technical Notes Database

TN295D.txt     Redirecting printer output

Category     :Pascal

Platform     :All

Product      :Turbo Pascal 5.5

Description:

Q. How do you send a program's output to the printer?

A. Use the LST file variable declared in the PRINTER unit. For example:

```
Program SendToPrinter;  
Uses Printer;  
Begin  
  Writeln(LST,'This will go to the printer.');
```

End.

## Article #15303: Reading and Writing Files Examples

Technical Notes Database

TN303D.txt      Reading and Writing Files Examples

Category        :Pascal

Platform        :All

Product         :Turbo Pascal    5.5

Description:

Q. How do you read and write a file inside a Turbo Pascal program?

A. The following example demonstrates how to create, write and read from a text file.

```
Program FileDemo;
Var FileVar : Text;
    InString,OutString : String;
Begin
    OutString := 'Write this to a text file';
    Assign(FileVar, 'TEST.TXT');
    Rewrite(FileVar);           {Creates a file for writing}
    Writeln(FileVar,OutString);
    Close(FileVar);
    Assign(FileVar, 'TEST.TXT');
    Reset(FileVar);           {Opens an existing file for reading}
    ReadLn(FileVar,InString);
    Close(FileVar);
End.
```

## Article #15311: DEBUGGING EXTERNAL ASSEMBLY ROUTINES

Technical Notes Database

TN311D.txt      DEBUGGING EXTERNAL ASSEMBLY ROUTINES

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 5.0

### Description:

Q. Why can't I trace through my external assembly language routines which have been linked with my TP program?

A. The Pascal linker does not pull through the symbolic debug information which is necessary to do source level debugging. Therefore, you will not be able to see your TASM source code. However, if you pull up the CPU window, you can trace through the disassembled ASM code. You will not have the benefit of variable names and labels, but you will be able to see the flow of execution.

## Article #15317: Turbo Pascal vs ANSI Pascal

Technical Information Database

TI317D.txt - Turbo Pascal vs ANSI Pascal

Category : Turbo Pascal  
Platform : All  
Product :

Description:

=====  
Comparing Turbo Pascal 6.0 with ANSI Pascal  
=====

-----  
Table of Contents  
-----

1. Exceptions to ANSI Pascal requirements
  2. Extensions to ANSI Pascal
  3. Implementation-dependent features
  4. Treatment of errors
- 

This appendix compares Turbo Pascal to ANSI Pascal as defined by ANSI/IEEE770X3.97-1983 in the book American National Standard Pascal Computer Programming Language (ISBN 0-471-88944-X, published by The Institute of Electrical and Electronics Engineers in New York).

- =====  
1. Exceptions to ANSI Pascal requirements  
=====

Turbo Pascal is unable to detect whether a program violates any of the exceptions listed here.

Turbo Pascal complies with the requirements of

ANSI/IEEE770X3.97-1983 with the following exceptions:

- o In ANSI Pascal, an identifier can be of any length and all characters are significant. In Turbo Pascal, an identifier can be of any length, but only the first 63 characters are significant.
  
- o In ANSI Pascal, the `^` symbol is an alternative for the `^` symbol. In Turbo Pascal, the `^` symbol is an operator, which is never treated identically with the `^` symbol.
  
- o In ANSI Pascal, a comment can begin with `{` and end with `*`), or begin with `(*` and end with `}`. In Turbo Pascal, comments must begin and end with the same set of symbols.
  
- o In ANSI Pascal, each possible value of the tag type in a variant part must appear once. In Turbo Pascal, this requirement is not enforced.
  
- o In ANSI Pascal, the component type of a file type cannot be a structured type having a component of a file type. In Turbo Pascal, this requirement is not enforced.
  
- o In ANSI Pascal, a file variable has an associated buffer variable, which is referenced by writing the `^` symbol after the file variable. In Turbo Pascal, a file variable does not have an associated buffer variable, and writing the `^` symbol after a file variable is an error.
  
- o In ANSI Pascal, the statement part of a function must contain at least one assignment to the function identifier. In Turbo Pascal, this requirement is not enforced.
  
- o In ANSI Pascal, a field that is the selector of a variant part cannot be an actual variable parameter. In Turbo Pascal, this requirement is not enforced.
  
- o In ANSI Pascal, a component of a variable of a packed type cannot be an actual variable parameter. In Turbo Pascal, this requirement is not enforced.
  
- o In ANSI Pascal, a procedural or functional parameter is declared by writing a procedure or function heading in the

formal parameter list. In Turbo Pascal, the declaration of a procedural or functional parameter is achieved through a procedural or functional type, and uses the same syntax as the declaration of other types of parameters.

- o In ANSI Pascal, the standard procedures Reset and Rewrite do not require pre-initialization of file variables. In Turbo Pascal, file variables must be assigned the name of an external file using the Assign procedure before they are passed to Reset or Rewrite.

- o ANSI Pascal defines the standard procedures Get and Put, which are used to read from and write to files. These procedures are not defined in Turbo Pascal.

- o In ANSI Pascal, the syntax `New(p,c1,...,cn)` creates a dynamic variable with a specific active variant. In Turbo Pascal, this syntax is not allowed.

- o In ANSI Pascal, the syntax `Dispose(q,k1,...,km)` removes a dynamic variable with a specific active variant. In Turbo Pascal, this syntax is not allowed.

- o ANSI Pascal defines the standard procedures Pack and Unpack, which are used to "pack" and "unpack" packed variables. These procedures are not defined in Turbo Pascal.

- o In ANSI Pascal, the term  $i \bmod j$  always computes a positive value, and it is an error if  $j$  is zero or negative. In Turbo Pascal,  $i \bmod j$  is computed as  $i - (i \operatorname{div} j) * j$ , and it is not an error if  $j$  is negative.

- o In ANSI Pascal, a goto statement within a block can refer to a label in an enclosing block. In Turbo Pascal, this is an error.

- o In ANSI Pascal, it is an error if the value of the selector in a case statement is not equal to any of the case constants. In Turbo Pascal, this is not an error; instead, the case statement is ignored unless it contains an else clause.

- o In ANSI Pascal, statements that threaten the control variable of a for statement are not allowed. In Turbo Pascal, this requirement is not enforced.

- o In ANSI Pascal, a Read from a text file with a Char-type variable assigns a blank to the variable if Eoln was True before the Read. In Turbo Pascal, a carriage return character (ASCII 13) is assigned to the variable in this situation.
- o In ANSI Pascal, a Read from a text file with an integer-type or real-type variable ceases as soon as the next character in the file is not part of a signed integer or a signed number. In Turbo Pascal, reading ceases when the next character in the file is a blank or a control character (including the end-of-line marker).
- o In ANSI Pascal, a Write to a text file with a packed string-type value causes the string to be truncated if the specified field width is less than the length of the string. In Turbo Pascal, the string is always written in full, even if it is longer than the specified field width.
- o ANSI Pascal defines the standard procedure Page, which causes all subsequent output to a specific text file to be written on a new page. This procedure is not defined in Turbo Pascal. However, the typical equivalent of Page(F) is Write(F,Chr(12)).

```
=====
2. Extensions to ANSI Pascal
=====
```

Turbo Pascal is unable to detect whether a program uses any of the extensions listed here.

The following Turbo Pascal features are extensions to Pascal as specified by ANSI/IEEE770X3.97-1983.

- o The following are reserved words in Turbo Pascal:

absolute	inline	shr
assembler	interface	string
constructor	interrupt	unit
destructor	object	virtual
external	private	uses
far	near	xor
implementation	shl	

- o An identifier can contain underscore characters (\_).
- o Integer constants can be written in hexadecimal notation; such constants are prefixed by a \$.
- o Identifiers can serve as labels.
- o String constants are compatible with the Turbo Pascal string types, and can contain control characters and other nonprintable characters.
- o Label, constant, type, variable, procedure, and function declarations can occur any number of times in any order in a block.
- o Wherever the syntax of ANSI Pascal requires a simple constant, Turbo Pascal allows the use of a constant expression (also known as a computed constant).
- o Turbo Pascal implements the additional integer types Shortint, Longint, Byte, and Word, and the additional real types Single, Double, Extended, and Comp.
- o Turbo Pascal implements string types, which differ from the packed string types defined by ANSI Pascal in that they include a dynamic-length attribute that can vary during execution.
- o Turbo Pascal implements procedural and functional types. In addition to procedural and functional parameters, these types make possible the declaration and use of procedural and functional variables.
- o The type compatibility rules are extended to make Char types and packed string types compatible with string types.
- o Variables can be declared at absolute memory addresses using an absolute clause.
- o A variable reference can contain a call to a pointer-type function, the result of which is then dereferenced to denote a dynamic variable.
- o String-type variables can be indexed as arrays to access

individual characters in a string.

- o The type of a variable reference can be changed to another type through a variable typecast.

- o Turbo Pascal implements typed constants, which can be used to declare initialized variables of all types except file types.

- o Turbo Pascal implements three new logical operators: xor, shl, and shr.

- o The not, and, or, and xor operators can be used with integer-type operands to perform bitwise logical operations.

- o The + operator can be used to concatenate strings.

- o The relational operators can be used to compare strings.

- o Turbo Pascal implements the `@` operator, which is used to obtain the address of a variable or a procedure or function.

- o The type of an expression can be changed to another type through a value typecast.

- o The case statement allows constant ranges in case label lists, and provides an optional else part.

- o Procedures and functions can be declared with external, inline, and interrupt directives to support assembly language subroutines, inline machine code, and interrupt procedures.

- o A variable parameter can be untyped (typeless), in which case any variable reference can serve as the actual parameter.

- o Turbo Pascal implements units to facilitate modular programming and separate compilation.

- o Turbo Pascal implements the following file-handling procedures and functions, which are not available in ANSI Pascal:

Append	FilePos	Rename
BlockRead	FileSize	Rmdir
BlockWrite	Flush	Seek
ChDir	GetDir	SeekEof
Close	Mkdir	SeekEoln
Erase		

o String-type values can be input and output with the Read, Readln, Write, and Writeln standard procedures.

o Turbo Pascal implements the following standard procedures and functions, which are not found in ANSI Pascal:

Addr	Inc	Ptr
Concat	Insert	Random
Copy	Int	Randomize
CSeg	Length	Release
DSeg	Lo	RunError
Dec	Mark	SPtr
Delete	MaxAvail	Seg
Exit	MemAvail	SizeOf
FillChar	Move	SSeg
Frac	Ofs	Str
FreeMem	ParamCount	Swap
GetMem	ParamStr	TypeOf
Halt	Pi	UpCase
Hi	Pos	Val

o Turbo Pascal implements further standard constants, types, variables, procedures, and functions through standard units.

=====  
3. Implementation-dependent features  
=====

The effect of using an implementation-dependent feature of Pascal, as defined by ANSI/IEEE770X3.97-1983, is unspecified. Programs should not depend on any specific path being taken in cases where an implementation-dependent feature is being used. Implementation-dependent features include:

o the order of evaluation of index expressions in a variable reference

- o the order of evaluation of expressions in a set constructor
- o the order of evaluation of operands of a binary operator
- o the order of evaluation of actual parameters in a function call
- o the order of evaluation of the left and right sides of an assignment
- o the order of evaluation of actual parameters in a procedure statement
- o the effect of reading a text file to which the procedure Page was applied during its creation
- o the binding of variables denoted by the program parameters to entities external to the program

=====  
 4. Treatment of errors  
 =====

This section lists those errors from Appendix D of the ANSI Pascal Standard that are not automatically detected by Turbo Pascal. The numbers referred to here are the numbers used in the ANSI Pascal Standard. Errors 6, 19-22, and 25-31 are not detected because they are not applicable to Turbo Pascal.

2. If t is a tag field in a variant part and f is a field within the active variant of that variant part, it is an error to alter the value of t while a reference to f exists. This error is not detected.
3. If p is a pointer variable, it is an error to reference p<sup>^</sup> if p is nil. This error is not detected.
4. If p is a pointer variable, it is an error to reference p<sup>^</sup> if p is undefined. This error is not detected.
5. If p is a pointer variable, it is an error to alter the value of p while a reference to p<sup>^</sup> exists. This error is not

detected.

42. The function call `Eoln(f)` is an error if `Eof(f)` is `True`. In Turbo Pascal this is not an error, and `Eoln(f)` is `True` when `Eof(f)` is `True`.

43. It is an error to reference a variable in an expression if the value of that variable is undefined. This error is not detected.

46. A term of the form `i mod j` is an error if `j` is zero or negative. In Turbo Pascal, it is not an error if `j` is negative.

48. It is an error if a function does not assign a result value to the function identifier. This error is not detected.

51. It is an error if the value of the selector in a case statement is not equal to any of the case constants. In Turbo Pascal, this is not an error; instead, the case statement is ignored unless it contains an else clause.

## Article #15325: Overview of Borland and Turbo Pascal 7.0

Technical Information Database

TI325D.txt - Overview of Borland and Turbo Pascal 7.0

Category :Turbo Pascal

Platform :All

Product :

Description:

Borland Pascal with Objects 7.0  
Turbo Pascal 7.0  
Features and Benefits

Overview

Here are the primary features and benefits of Borland Pascal with Objects 7.0 and Turbo Pascal with Objects 7.0. These are taken from the Reviewer's guide which includes more detailed product descriptions and technical information.

Borland Pascal with Objects 7.0

Borland Pascal with Objects 7.0 is the most productive programming system available for DOS and Windows. It includes the following new features:

Program for DOS, DOS Protected Mode (DPMI) and Windows  
Professional tools for all three platforms with nothing else to buy

Free DOS Extender! Create DOS Protected Mode (DPMI) applications. Break the 640K barrier and use up to 16 MB of memory, without royalties

Create DOS protected mode Dynamic Link Libraries (DLLs)  
Reuse DLLs in DOS and Windows; and link C or C++ code easily

High capacity, multi-target IDEs

Choose the DOS or Windows IDE and target any platform

DOS and Windows ObjectBrowsers

Navigate source code quickly with full cross-reference information

Improved IDEs with color syntax highlighting, unlimited undo/redo. Makes it easier to read code and experiment with changes

Enhanced application frameworks

Add data validation to DOS and Windows applications easily

New language features and optimizations

Write more flexible code with better performance

Winsight and Winspector included

For faster debugging of Windows applications

Free Runtime library source code included (\$195 value included free!). Learn the secrets of object-oriented programming from the experts

Turbo Pascal 7.0

Turbo Pascal 7.0 is the fastest way to learn object-oriented programming. It includes the following new features:

High capacity IDE

Compile large real-mode applications within the IDE

ObjectBrowser

Navigate source code quickly with full cross-reference

Improved IDE with color syntax highlighting, unlimited undo/redo Makes it easier to read code and experiment with changes

Enhanced application frameworks

Add data validation to DOS and Windows applications easily

New tutorials on Turbo Vision and pointers

Makes it easy to learn object-oriented programming

## Article #15327: NESTED FOR LOOPS- How many?

Technical Notes Database

TN327D.txt      NESTED FOR LOOPS- How many?

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 4.0+

Description:

Q. How many nested for loops are allowed?

A. The amount of code that's generated can't exceed 20K bytes.

Therefore, if you have just for loops, the depth can't exceed roughly 75 lines.

## Article #15333: Questions and Answers of Borland and Turbo Pascal

Technical Information Database

TI333D.txt - Questions and Answers of Borland and Turbo Pascal

Category : Turbo Pascal

Platform : All

Product :

Description:

### Borland Pascal with Objects 7.0 Questions & Answers

#### I. General Questions

1. What are the new features of Borland Pascal with Objects 7.0?

Borland Pascal with Objects 7.0 includes all of the features necessary for high productivity application development for DOS and Windows.

The major new features are:

- o Support for DOS, DOS Protected Mode (DPMI) and Windows programming
- o Ability to create DOS Dynamic Link Libraries (DLLs) that are binary compatible with Windows
- o High capacity DOS and Windows IDEs
- o Improved IDEs with color syntax highlighting and undo/redo
- o DOS and Windows ObjectBrowsers for navigating source code
- o New compiler optimizations and language features
- o Extended DOS and Windows application frameworks
- o Over 3,800 pages of documentation with many new tutorials
- o Over 4 megabytes of on-line help including the Windows API

## 2. What are the new features of Turbo Pascal 7.0?

Turbo Pascal 7.0 includes features that make it the best way to learn object-oriented programming. The major new features of Turbo Pascal 7.0 are:

- o High capacity DOS Integrated Development Environment (IDE)
- o Improved IDE with color syntax highlighting and undo/redo
- o ObjectBrowser for navigating source code
- o Additional Turbo Vision objects
- o 1,500 pages of documentation with several new tutorials
- o 1 megabyte of on-line help with copy-and-paste examples

## 3. What's the difference between Borland Pascal with Objects 7.0 and Turbo Pascal 7.0?

Borland Pascal with Objects 7.0 includes features aimed at professional DOS and Windows programmers including the ability to create DOS Protected Mode (DPMI) applications, DOS Dynamic Link Libraries (DLLs), as well as a more complete set of professional tools including Turbo Debugger, Turbo Profiler, Turbo Assembler.

Turbo Pascal 7.0 is a subset of Borland Pascal with Objects and includes the ability to create DOS real mode programs. It includes the high capacity IDE, ObjectBrowser and extended Turbo Vision application framework, but does not support DOS Protected Mode (DPMI) or Windows development.

## 4. Who uses Pascal?

Borland has shipped over 2,000,000 units of Pascal. The largest segment of Pascal customers is professional programmers, who make up 40% of the market. Pascal is widely used for internal corporate application development, by consultants and VARs in vertical markets such as health-care and construction and by commercial "shrink wrap" software developers. Borland Pascal with Objects 7.0 is targeted directly to professional programmers who want

high productivity development for DOS and Windows.

Pascal is also the most popular language for learning structured and object-oriented programming. Turbo Pascal 7.0 is targeted at new programmers who want the fastest way to learn object-oriented programming.

5. Are there commercial applications written in Pascal?

There are many commercial "shrink wrap" software products written in Pascal. These products include leading CAD packages such as Autodesk's Generic Cadd, Fast CAD, Turbo CAD, Claris' Filemaker Pro for Windows, leading tax preparation software such as Tax Cut, Turbo Tax, Parson's Personal Tax Edge, financial packages such as Money Counts, communications packages such as QModem, Tapcis, Ozcis and many others.

6. Does Borland use Pascal to develop any of its products?

Borland has a major commercial application under development using the new Borland Pascal with Objects 7.0. Borland has not yet announced the name of the application being developed in Pascal.

In addition, the DOS IDE for Borland Pascal with Objects 7.0 is written entirely in Pascal using the Turbo Vision application framework.

7. Why has the product name changed?

We've called the new professional Pascal programming system "Borland Pascal with Objects" to reflect the professional positioning of the product and provide greater consistency with the C++ product line. Borland continues to offer Turbo Pascal 7.0 and Turbo Pascal for Windows 1.5 for entry level programmers who do not need all of the advanced capabilities that professionals require.

8. What are the benefits of creating DPMI applications?

By using Borland Pascal with Objects 7.0 you can create DOS Protected Mode (DPMI) applications that break through the 640K barrier and access up to 16 megabytes of memory for code and data. This gives you higher capacity for dealing with larger amounts of data for more efficient processing.

9. How do you create DPMI applications?

You can simply select the Compile Target menu choice to DOS protected mode and recompile existing programs. The compiler will create an EXE with a real-mode stub that automatically loads the DPMI server and runtime manager and then switches to protected mode and runs your program.

10. What DPMI technology do you use? Is there a royalty charge?

The DOS extender is fully compatible with the DPMI specification and is based entirely on Borland technology and was used in the latest version of Borland's Paradox 4.0 database. No royalty payments or runtime charges are required to distribute protected-mode applications written with Borland Pascal with Objects 7.0.

11. What is the benefit of DOS DLLs? How do you use them?

By creating programs as Dynamic Link Libraries (DLLs) you are able to share the same source code and binary file between both DOS and Windows programs. For example, a typical business application might be constructed with a DOS Turbo Vision user interface and a Dynamic Link Library that does "back end" computation and data processing. The back end DLL can be shared with a Windows version of the program that uses an ObjectWindows user interface. The source code to the DLL does not require any changes to work in Windows and, in fact, does not even need to be recompiled to work in Windows.

In the same way, you can compile C or C++ code as a Dynamic Link Library using Borland C++ or any other compiler and link that code into Windows or DOS applications written with Borland Pascal with Objects. No other language offers

the ability to create and link to DOS and Windows DLLs.

12. What are the new optimizations in Borland Pascal with Objects 7.0?

Several new compiler optimizations have been added so that existing programs can be recompiled for faster performance. These include 32 bit LongInt math operations, redundant pointer load suppression, optimized sets, constant parameters and faster string and file I/O routines.

13. Does Borland Pascal with Objects 7.0 include visual resource editing?

Yes, Borland Pascal with Objects 7.0 includes Borland's Resource Workshop, a fast, powerful way to visually create user interface elements including menus, dialogs, bitmaps, cursors, icons and so on. There are also third party visual resource editing tools available for use with Turbo Vision, including Blaise's Turbo Vision Development Toolkit.

14. Do developers need to buy the Microsoft Windows Software Development Kit (SDK) to use Borland Pascal with Objects 7.0?

No, Borland Pascal with Objects includes everything you need to develop DOS and Windows applications. It is fully compatible with Windows 3.0 and 3.1. It includes:

- o Windows Integrated Development Environment
- o Borland Pascal with Objects command line compiler
- o Windows 3.1 interface files
- o ObjectWindows application framework
- o Resource Workshop
- o WinSight
- o WinSpector
- o Resource Compiler
- o Help Compiler
- o Turbo Help hypertext system
- o Sample programs
- o Complete Windows tutorials

15. Does Borland Pascal with Objects 7.0 include help on new Windows 3.1 API functions?

The on-line Turbo Help system has been completely expanded to provide more detailed descriptions of Windows API functions as well as new entries for all new Windows 3.1 features. There are over 4 megabytes of on-line help. In addition, we are making available a complete printed reference 3 volume set of all Windows API calls for \$39.95. This three volume set includes Pascal definitions of all API calls and data structures.

16. Is the Runtime Library Source Code included?

As a special bonus to purchasers of Borland Pascal with Objects 7.0, we will include in all upgrades a retail purchase the Application Frameworks and Runtime Library Source Code. This includes the complete source code to the Turbo Vision and ObjectWindows application frameworks and is a \$195 value.

17. Is there a CASE tool for Pascal? What is Protogen?

Since there are many professional programmers who are new to Windows development, Borland will be making available a version of the Protogen CASE tool that generates Pascal source code. Protogen allows developers to draw their user interface in Windows and then automatically generate much of the standard Windows code that is required. This makes it much easier to get started in Windows and object-oriented programming. Protogen will be made available for the special price of \$49.95 to purchasers of Borland Pascal with Objects 7.0.

18. Does Borland Pascal with Objects work with the new Paradox Engine?

Yes Borland Pascal with Objects works with the latest version of the Paradox Engine 3.0. Paradox Engine 3.0 includes support for real mode, DOS protected mode (DPMI) and Windows application development in Pascal. It also

includes a complete object-oriented database framework for Pascal programmers as well as faster and more memory efficient performance. Paradox Engine 3.0 is available separately.

19. What is the minimum hardware configurations for Borland Pascal with Objects 7.0 and Turbo Pascal 7.0?

Borland Pascal with Objects 7.0 requires an 80286 or higher processor, 2 megabytes of memory, a hard disk. For Windows development you must also have Windows 3.0 or later, graphics (EGA, Hercules, VGA or higher resolution) and a mouse.

Turbo Pascal 7.0 requires 720K of disk space and 512K of memory. A hard disk and 80286 or higher processor is required to use the high-capacity IDE.

20. How do the new products affect the existing product line?

Borland Pascal with Objects 7.0 and Turbo Pascal 7.0 replace the existing Turbo Pascal Professional 6.0 and Turbo Pascal 6.0 products. Turbo Pascal for Windows 1.5 remains on the market as an entry level object-oriented programming system for Windows.

21. What is the pricing and availability?

Borland Pascal with Objects 7.0 has a suggested retail price of \$495.00. Upgrades from any previous version of Turbo Pascal for DOS or Windows to Borland Pascal with Objects 7.0 are \$149.95. As a special bonus, Borland Pascal with Objects 7.0 includes the Application Frameworks and Runtime Library source code, a \$195 value.

Turbo Pascal 7.0 has a suggested retail price of \$149.95. Upgrades from any previous version of Turbo Pascal for DOS or Windows to Turbo Pascal 7.0 is \$89.95.

Both products will ship November 2, 1992.

## Article #15335: RESERVED WORD 'PACKED'

Technical Notes Database

TN335D.txt      RESERVED WORD 'PACKED'  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 4.0+

### Description:

Q. Does the reserved word 'packed' have any effect on an array in Turbo Pascal?

A. No. There is no packing done because on an IBM PC, and compatibles, the data in the array is stored on a byte level.

## Article #15341: Creating Protected Mode Apps with Borland Pascal

Technical Information Database

TI341D.txt - Creating Protected Mode Apps with Borland Pascal

Category :Turbo Pascal

Platform :DOS

Product :

Description:

### o Benefits of Protected Mode Programming

Borland Pascal with Objects allows you to create DOS protected mode applications.

This means that your programs no longer have to be constricted by the long-standing 640 k memory limitation. This barrier has now disappeared entirely with our protected mode target that allows you to create programs that use up to 16meg of code and data.

You only need to throw a single switch inside the IDE (integrated development environment) in order to produce a protected mode application. In most circumstances there is no need to change your code at all.

Consider the following program, which reports on the available memory:

```
program MemSize;  
  
begin  
  WriteLn(MemAvail);  
end.
```

If compiled in real mode, this program will probably report that you have between 300,000 and 600,000 bytes of memory available. If you open the Compile menu, select Target, and switch from Real Mode to Protected Mode code generation, then this program will report a figure near the total amount of RAM available on your current system.

If you use the command line compiler, called BPC.EXE, then it is only necessary to add "/cp" to the command line in order to

compile a protected mode app. For instance, to compile the program listed above in real mode, one would type:

```
bpc MemSize
```

To recompile this same application in protected mode, one would type:

```
bpc/cp MemSize
```

As an unofficial test case, these two programs were run on a system with 12 megs of memory available. In the first case MemSize reported 574,144 bytes of memory available, but when compiled in protected mode, it reported 9,118,992 bytes of memory available. This is a difference of over 8 million bytes.

#### o Differences between Real and Protected Mode programming

Although most Pascal programs written under TP60 will recompile unchanged as protected mode apps, developers should be aware of the way memory is addressed in protected mode. Real mode DOS addresses typically include a segment and offset which reference an actual location in memory. But under Intel's protected mode memory scheme, the segment portion of an address is replaced with something called a selector.

Selectors are not real memory addresses but rather indexes into a descriptor table. This table is maintained by the operating system and cannot normally be accessed directly by a programmer. This means that programs which directly reference real mode memory addresses will have to be adjusted before they will run correctly in protected mode.

Fortunately, Intel has provided programmers with a DOS Protected Mode Interface (DPMI) specification, which forms a gateway between protected mode and real mode. Borland's new protected mode DOS extender is DPMI compliant, so this interface is available to experienced programmers who want to address real mode memory directly. As a result, Borland Pascal protected mode apps have almost unlimited access to real mode.

Your protected mode applications will also run inside a Windows DOS box. This is possible because Windows itself runs in protected mode and is somewhat DPMI compliant.

There are no royalties involved in using this new DOS extender technology, but BP.EXE, the new Pascal IDE, requires at least a 286 machine with two megs of memory to run. If you can

meet these requirements then the world of protected mode programming is now available to you at the flip of a switch.

For more information as to the internals of the DOS extender technology, Borland has made available the Open Architecture Handbook which goes in to some detail about this new and exciting area of programming.

## Article #15348: Installing Turbo Pascal 7.0 on a Network

Technical Information Database

TI348D.txt - Installing Turbo Pascal 7.0 on a Network

Category :Turbo Pascal  
Platform :All  
Product :

Description:

### Configuring Turbo Pascal on Network Systems

First, it must be clear to users that network requirements are not considered in the design or development of Turbo Pascal. The intended target system is an IBM PC, AT, PS/2 or 100% compatible with at least 448K of available DOS RAM, 5 megabytes hard disk space, and at least one floppy drive.

Through years of use, it has been found that Turbo Pascal happens to work satisfactorily on a number of network systems. The following guidelines may be used if installation on a network system is required.

- o Install Turbo Pascal from the original diskettes from a node with both Read and Write capability in the target directory of the server.
- o Ensure that all nodes requiring access to Turbo Pascal have at least Read rights in the directory where Turbo Pascal has been installed.
- o Have each node run Turbo Pascal at a directory where both Read and Write actions are allowed. Preferably, the current directory would reside on a local drive or at least a directory designated for use by only a single node. It is to this private disk space that Turbo Pascal's swap files and configuration files are to be saved.
- o Allow Turbo Pascal to create source and executable code

either on a local drive or at a directory designated for use by only a single node. If programs are to be created on a network, provide both Read and Write access to the appropriate areas of the network drive.

Instructions for granting access rights for a particular network system are found in documentation provided by its manufacturer. Check with the System Administrator or the manufacturer for specific information.

Before installing any software on a network, be certain that you are licensed for each node able run the software simultaneously with other nodes. If you are uncertain about any aspect of your licensing, contact your local Borland office immediately.

## Article #15350: READLN - READING A STRING

Technical Notes Database

TN350D.txt      READLN - READING A STRING

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

Description:

- Q. If I read in a string, an integer, and a character, with one Readln, how come there's a carriage return in the character variable?
- A. When a string is read in there is no way to determine if the other values are strings or non-strings. This means that regardless of a string's length, the other values are placed into the string variable, although they may not be visible. The solution is to read the string separately with a Readln.

## Article #15355: Using the VESA16.BGI that Comes with BP 7.0

Technical Information Database

TI355D.txt - Using the VESA16.BGI that Comes with BP 7.0

Category :Turbo Pascal  
Platform :All  
Product :

Description:

VESA DRIVERS

With the release of Borland Pascal for Objects 7.0, programmers can now use BGI graphics to obtain 16 color resolutions of 800 X 600, 1024 X 768, and 1280 X 1024.

HOW TO USE THE VESA16.BGI DRIVER

The VESA unit included with this Tech Info Sheet shows you a simple way to use the new VESA driver in your own program. To get started, you need only include the word VESA in your uses clause and then call the included Initialize procedure. So the simplest possible program using the VESA driver might look like this:

```
program Simple;  
uses  
    Graph,  
    Vesa;  
begin  
    Initialize('c:\bp\bgi');  
    OutText('Hello');  
    ReadLn;  
    CloseGraph;  
end.
```

This program assumes, of course, that you have the VESA unit available on disk and that your BGI drivers are kept in the C:\BP\BGI sub directory. If the system this program is run on

does not support the VESA BIOS then the code in the VESA unit will automatically switch your computer into the highest available mode.

The next few paragraphs describe a somewhat more complex program, also included in this TI, which shows you how to use the new high resolution modes. This program is called VesaSamp.Pas. It uses the VESA unit, also listed below, to load the BGI VESA graphics driver into memory. The program then shows you the highest available resolution on your system.

In order to simplify the process of entering graphics mode, the VESA UNIT provides you with an easy to use Initialize procedure which takes the location of the BGI drivers as its sole parameter. This procedure will automatically switch you into graphics mode, and also initialize several useful variables.

As presented below, program VesaSamp.Pas hardcodes the location of the BGI drivers as being in the C:\BP\BGI sub directory. If this is not the case on your system, then you need to change this code before running the program. For instance, if you store the BGI drivers in the D:\PASCAL\DRIVERS sub directory, then you should change the call that reads:

```
Initialize('c:\bp\bgi');
```

so that it reads:

```
Initialize('d:\pascal\drivers');
```

If you have the BGI drivers available in the current sub directory, then you would initialize the graphics system with the following code:

```
Initialize('');
```

After correctly setting up the Initialize procedure, the VesaSamp program will pop into graphics mode and show you the highest available resolution.

## WHAT IS THE VESA BIOS?

The VESA BIOS represents a standard for accessing SUPER VGA resolutions. The problem it addresses is that there are many different Super VGA boards on the market, but no common API for addressing them.

To attempt to bring some sort of sanity to this madness, the Video Electronics Standards Association (VESA) defined a set of

BIOS extensions that allow programmers to ask the video adapter about its abilities. These BIOS extensions are sometimes implemented directly in ROM and sometimes loaded into memory by a special TSR. Many of these TSRs are available on the Comuserve Information Service (1-800-848-8990).

Since it is always possible that the video card on any particular system might not support the VESA extensions, you should be aware that your program might not actually run in a high resolution mode. But the Borland Graphics Interface will find the highest available mode and then switch you into it.

The rest of this TI contains the sample code which shows you how to use the VESA BGI driver. You should be aware of the fact that it is necessary for the VESA .PAS unit to automatically detect whether or not you have compiled your program as a protected mode application. In other words, if you want to copy code from the VESA unit directly into your program, make sure you are getting the DOS code for DOS apps and the DPMI code for DPMI apps.

```
program VesaSamp;
{
  A test program for unit Vesa
  which provides Super VGA Resolutions
}
uses
  Graph,
  Vesa;

{ Converts an integer to a string }
function Int2Str(L : LongInt) : string;
var
  S : string;
begin
  Str(L, S);
  Int2Str := S;
end; { Int2Str }

var
  S: String;
begin
  Initialize('c:\bp\bgi');
  Rectangle(0,0,MaxX,MaxY);
  SetColor(LightGreen);
  SetBkColor(Blue);
  SetTextStyle(TriplexFont, HorizDir, 8);
```

```

S := 'MaxX = ' + Int2Str(MaxX);
OutTextXY((MaxX Div 2) - (TextWidth(S) div 2),
          (MaxY div 2) - 220, S);
S := 'MaxY = ' + Int2Str(MaxY);
OutTextXY((MaxX Div 2) - (TextWidth(S) div 2), (MaxY div 2) -
80, S);
S := 'MemAvail = ' + Int2Str(MemAvail);
OutTextXY((MaxX Div 2) - (TextWidth(S) div 2), (MaxY div 2) +
60, S);
ReadLn;
CloseGraph;
end.

```

```

{*****}
{***** VESA UNIT *****}
{*****}

```

```

unit Vesa;
{

```

Add this unit to programs that want Vesa support for high resolutions such as 800 X 600, 1024 X 768 and 1280 X 1024. If Vesa is not supported on a system the code automatically defaults to an available driver such as EGAVGA.

To Initialize the graphics system, just call Initialize with the path to VESA.BGI as the sole parameter. Pass an empty string if the driver is in the current subdirectory.

The code will automatically detect if you are running in protected mode or real mode.

Examples:

```

Initialize('c:\bp\bin');
Initialize('');

```

```

}
Interface

```

```

uses
  Graph {$IfDef DPMS}, WinApi {$EndIf};

## Article #15357: TASM 1.0 1.01 - ORDER OF ARG DIRECTIVE OPERANDS -

Technical Notes Database

TN357D.txt      TASM 1.0 1.01 - ORDER OF ARG DIRECTIVE OPERANDS -  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 5.0 5.5

### Description:

- Q. In what order should the operands to the Arg directive appear? Should they be the same as the order in the calling procedure or in reverse?
- A. The answer depends upon the language that you're using and whether or not you're using the .model memory model, language option.

Case 1: You are using the full segment definitions or you are using the .model directive without specifying a language.

The leftmost symbol in the Arg list is always nearest the top of the stack (TOS). Thus, if your proc definition is

```
myproc proc far
arg first:word, second:word
```

first will evaluate to [BP + 06H], the size of the four byte far return address plus the size of the two byte BP register pushed onto the stack. The symbol, second, will evaluate to [BP + 08H], two bytes further from TOS.

Again, the key point to remember is that the leftmost symbol is nearest TOS.

If you are using Pascal or Basic, arguments are pushed from left to right onto the stack. This is called Pascal calling syntax or Pascal calling conventions. In this case, the last argument in the list is nearest TOS. For example:

```
{ $F+ }
procedure myproc(one:integer; two:integer); external;
```

```
{ $F- }  
...  
procedure myproc(first:integer; second:integer);  
...
```

The variable, first, is pushed onto the stack followed by second. Thus, second is nearest TOS. In this case, you would want to set up your Arg list as follows:

```
myproc proc far  
arg second:word, first:word  
push bp  
mov bp,sp
```

The symbol, second, would evaluate to [BP + 06H], the symbol nearest TOS, and first would evaluate to [BP + 08H].

To get the correct results with Basic or Pascal while using the simplified segment directives or .model without the language option, you must reverse the order of the arguments as they appear in the high level language calling routine's parameter list.

If you are calling the Assembler routine from a C module and you are NOT using Pascal calling conventions, then the arguments are pushed onto the stack from right to left. Thus, the leftmost argument is nearest TOS and there is no need to reverse the order to the symbols in the Arg list.

If you wish to use Pascal calling conventions in Turbo C, use the -p option for TCC or the Pascal keyword. Pascal calling syntax can also be enabled from within TC by setting the /Options/Compiler/Code generation/Calling convention to Pascal.

Case 2: You are using the .model memory model, language directive.

All you need to do is put the Arg list symbols in the same order as they appear in the calling routine's parameter list. This is the easiest method, by far. Remember to include the comma after the memory model in the .model directive and to specify the language. If you are using Turbo Pascal, just use .model TPascal.

## Article #15363: Using Validators in OWL Applications

Technical Information Database

TI363D.txt Using Validators in OWL Applications

Category :General Programming

Platform :All

Product :Pascal All

### Description:

Starting with version 7.0, Borland Pascal introduced Validator objects for Turbo Vision and the Object Windows Library. These objects help guide the user when they are entering data in Edit fields. The purpose of this TI is to introduce the user to the idea of using Validators in OWL applications.

Validators are very flexible objects which can play several different roles in your program. A typical validator might ensure that the user can only enter numbers within a certain range into a particular field. Another common use for Validators might be to ensure that users enter stock numbers that begin with two alphanumeric characters, then include a dash followed by four numbers. An example of this type of stock number might look like this: WD-3344. These are only two examples of the many different types of validators you can create for your programs.

Validators are extremely easy to use. In most cases you only need to add one line to your code. Suppose you want to add a validator to an edit field which will ensure that the user can only enter numbers between five and eight. First you would initialize your edit field, just as you have always done:

```
AEdit := New(PEdit, InitResource(
Self, Cm_NumEdit, 50));
```

The next step is to initialize the validator. The following line of code turns the trick:

```
AEdit^.SetValidator(New(PRangeValidator, Init(5, 8)));
```

That's all you need to do. Now the only characters the user can enter into the control will have to fall within the specified range.

When compiled, the program and resource script included in this Tech Info Sheet help demonstrate many of the primary features of the validator unit. Included in the example are two range validators, four picture validators and one custom validator. The range validators ensure that input falls inside a particular numeric range. One of the picture validators helps guide the user while he enters a date, and another ensures that the user follows a valid format while entering a social security number. The other validators guide the user while he enters a stock number and a special entry that must begin with the letters 'MIKE' followed by a single number. In order to show you how to create your own Validators, we include a descendant of TPxPictureValidator called TSamValidator which gives you an idea of how to control input on a character by character basis.

Validators usually work on a letter by letter or field by field basis. That is, they will check a user's input either as he enters each character, or later on, when he exits a field. If you want to check the data only when the user closes an entire screenful of data, then you should examine the TMyEdit object, presented below. In this object, we override the TEdit methods that would normally ensure that a user's input was checked as he leaves a field. As a result, the data is checked only when the user closes the dialog in which the edit fields reside.

## Article #15365: TASM 1.0 - RETURN FAILED FROM ASSEMBLY ROUTINE - T

Technical Notes Database

TN365D.txt     TASM 1.0 - RETURN FAILED FROM ASSEMBLY ROUTINE - T  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal 4.0+

### Description:

Q. When I call my Assembler routine from Turbo Pascal, everything works OK. However, it does not seem to return properly.

Why?

A. Any routine declared in the main program or in the implementation section of a unit, is by default a near call. Your Assembly language routine, assembled to an .OBJ file, is brought into the Pascal module as if it were declared and defined in that module. Thus, by default, any call to that Assembly language routine is a near call. If you have defined your Assembly language routine as a proc far, the Assembler will generate a corresponding RETF. Thus, a near call is made, 4 bytes are popped off of the stack when the RETF is executed, and control will be returned to the wrong code segment. If you want that call to be a far call in your Pascal module, be sure to bracket the function or procedure declaration with {\$F+} and {\$F-}. Always make sure that the distance declarations and definitions agree.

## Article #15369: Printing the Run of a Program

Technical Information Database

TI369D.txt - Printing the Run of a Program

Category :Turbo Pascal  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Educators teaching structured programming in PASCAL often require students to submit a printout of the "Run" of assigned programs. The "Run" represents the output of the program as it normally appears on screen. In mainframe environments, printing the "Run" is nothing unusual. Time and access are often very limited in academic computer rooms and such a printout can be useful when correcting code off-line.

The Integrated Development Environment of Turbo Pascal has no provision for printing the "Run" of a program. On a personal computer, output may take a variety of forms; simple text, graphics, sound etc. Printing a "run" in the fashion of an academic mainframe is only relevant to code producing simple text as output. More substantial programs involving color and graphics must use other means to print the "run". Techniques dealing with graphics and color are not addressed in this document.

### Printing the Run Using the DOS Version of Turbo Pascal

In DOS, the operating system is capable of echoing to printer characters sent to the screen. This feature only functions from the DOS prompt and only for Turbo Pascal programs not using CRT or GRAPH units. The echoing function is toggled on and off with the key sequence .

1. Set the destination of the compiler to disk via the Compile|Destination menu selection.
2. Compile the program. Doing so will generate a .EXE file.
3. Exit Turbo Pascal.

4. Ensure your printer is on and on-line.
5. At a DOS prompt, hold down the key marked `Alt` and press the letter "P". Then let up on both keys.
6. Type the name of your program. Do not include the three letter extension. For instance, the program TEST.PAS is taken as just TEST. Screen and printer output will occur simultaneously.
7. When the program is done, hold down the key marked `Alt` and press the letter "L". Then let up on both keys. Next hold down `Alt` again and press the letter "P". Let up on both keys.

## Printing the Run Using the Windows Version of Turbo Pascal

Turbo Pascal for Windows is not ideally suited for introductory Computer Science coursework. Such coursework normally relies on some terminal-type interface being involved. Windows by its very nature suspends all terminal-like devices available when running DOS alone. It is designed to function exclusively in an event-driven, graphical environment. Display functions are provided by Windows and not by Turbo Pascal. Hence, standard PASCAL statements such as `Write` and `Writeln` do not function with the screen display as they do with the DOS version. For Computer Science coursework, it is strongly recommended that the DOS version of Turbo Pascal be used.

A unit called `WinCRT` ships with Turbo Pascal for Windows. This unit causes an output window to be displayed when the statements `Write`, `Writeln`, `Read`, or `Readln` are used. It mimics the function of a terminal device and serves as a temporary aid for those learning to use Windows API functions. This unit allows some traditional programming to be done but provides nothing to "print" a run.

If printing the output of a program in Windows is absolutely required, follow these steps.

1. Run the program.
2. Enlarge the output window to fill the entire screen.
3. Press the `Alt` key. The `Alt` key will copy the contents of the Windows Desktop to the clipboard.
4. Bring up the Windows Paintbrush program.
5. Create an image large enough to hold the most of the screen. See Microsoft Windows documentation for

details.

6. Using the Edit|Paste command, copy the contents of the clipboard into the image used by PaintBrush.
7. To print, use the PaintBrush's printing commands as detailed in the Microsoft Windows documentation.

This method will only print the visible portion of the Window. If program output has scrolled from view, it may need to be scrolled back into view and the screen again copied to the clipboard, copied from there to Paintbrush and then printed. For programs with significant output, this process may need to be repeated many times.

## Article #15376: Keyboard Problems Using Borland Pascal and TPX

Technical Information Database

TI376D.txt    Keyboard Problems Using Borland Pascal and TPX  
Category    :General Programming  
Platform    :All  
Product     :Pascal    All

### Description:

At times, users of Borland Pascal or Turbo Pascal's TPX compilers find difficulty using their keyboards. Usual symptoms include the following.

1. The cursor keys persistently highlighting text.
2. The cursor keys randomly producing numeric characters instead of moving the cursor.
3. Keypresses behaving as if the shift key were stuck.
4. Keystrokes producing apparently random and unrelated characters.

The problem is usually related to timing issues. In 16-bit protected mode, the addressing mode used forces all memory accesses to be directed through a table of selectors rather than to physical memory directly. Thereby, making each memory access slightly slower than seen using real mode. On most systems, the difference in timing is insignificant and no ill effects are seen. However, some systems in certain configurations may experience the problems noted above.

To address this problem, most users are able to use the KEYB.COM program that accompanies MS-DOS. Place the following statement into your AUTOEXEC.BAT file.

```
C:\DOS\KEYB US
```

Then restart your computer system. It is important to run KEYB.COM before entering the IDE. It is not appropriate to run this program from the Dos Shell selection of the IDE's file menu.

## Article #15378: TP OVERLAYS: RECLAIMING BUFFER MEMORY

Technical Notes Database

TN378D.txt TP OVERLAYS: RECLAIMING BUFFER MEMORY

Category :Pascal

Platform :All

Product :Turbo Pascal 5.5

Description:

Q. How do I reclaim the memory used by overlay buffer in TP5.5?

A. The following example demonstrates how to do so.

```
unit Marker;
```

```
interface
```

```
procedure RestoreHeap; procedure RestoreOverlay;
```

```
implementation
```

```
var OldHeapPtr,OldHeapOrg,Temp:pointer;
```

```
var OldHeapPtr,OldHeapOrg,Temp:pointer;
```

```
procedure RestoreHeap; begin
```

```
  Release(Temp); {2. Release all dynamic variables}
```

```
  OldHeapOrg:=HeapOrg; {3. Save Current Heap state }
```

```
  OldHeapPtr:=HeapPtr;
```

```
  HeapOrg:=ptr(OvrHeapOrg,$0); {4. Set Heap to Origin of Overlay  
Buffer}
```

```
  HeapPtr:=HeapOrg;
```

```
  Mark(Temp); {5. Mark the origin of this heap }
```

```
end;
```

```
procedure RestoreOverlay; begin
```

```
  Release(Temp); {6. Release all dynamic variables }
```

```
  HeapOrg:=OldHeapOrg; {7. Restore heap pointers }
```

```
  HeapPtr:=OldHeapPtr; end;
```

```
begin
```

```
  mark(temp); {1. Mark the beginning of heap after overlay buffer}
```

end.  
end.

The unit is to be used before any unit that places items into the heap during their initialization. You would call RESTOREHEAP before using the dynamic variables requiring memory used by the overlay buffer. A call to OVRCLEARBUF must come before any call to RESTOREHEAP to ensure that the overlay buffer is empty and to force a reload of overlays when you are done. Note, that all dynamic variables residing on the heap, before a RESTOREHEAP call is made, are lost. (But, you could code around this by manipulating the free list).

RESTOREOVERLAY clears the heap again and restores the heap pointers to point above the overlay buffer. You may then start using overlaid procedures and functions again.

This is a simple example and may not be suitable for all purposes.

## Article #15383: Suggestions for Installing from Backups

Technical Information Database

TI383D.txt      Suggestions for Installing from Backups

Category      :General Programming

Platform      :All

Product       :Pascal    All

### Description:

At times, Borland software is purchased using a disk format different from that used by your computer. For instance, your computer may use 3 1/2" diskettes but the software came with 5 1/4" diskettes or vice versa. Often folks will take the software to a friend using both diskette formats and make a set of disks in the format that they need.

However, when running the install program, you will find the program asking for more diskettes than you have or failing to do everything the manual indicates it will do. These problems result from moving the software from one format to another. The install program depends upon the original diskette format.

To resolve the problem, call Borland's Disk Replacement Line at (800) 621-3132 and order a set of diskettes in the proper format. Be sure to have your serial number handy when calling this service.

If immediate installation is required and sufficient hard disk space is available, you may copy all files from all diskettes to a single temporary directory on the hard disk. Run install from this directory on the hard disk. When install is finished, delete files from the temporary directory. Then you will be able to run the software normally.

## Article #15390: Creating Groups for Borland Pascal

Technical Information Database

TI390D.txt - Creating Groups for Borland Pascal

Category :Turbo Pascal  
Platform :All-32Bit  
Product :

### Description:

The install program for Borland Pascal with Objects is able to create and configure a Borland Pascal with Objects group for the Windows Program Manager. It presumes that the Windows shell being used is the Program Manager or some other utility that is DDE compatible with the Program Manager. If another shell is being used that is not DDE compatible with the Program Manager (File Manager for instance), a DDE error will occur when the Borland Pascal with Objects group is being created. This error can be ignored; the performance of Borland Pascal with Objects will not be adversely affected.

At times, the program used to create the Borland Pascal with Objects group is not automatically executed when Windows is run. In this case, it is possible to run this program from the Program Manager directly. From the Program Manager's File|Run menu enter the following command line.

```
GROUPS.EXE GROUPS.B$$
```

## Article #15396: Patch for the STDDLG Unit

Technical Information Database

TI396D.txt Patch for the STDDLG Unit  
Category :TVISION  
Platform :All  
Product :Pascal All

### Description:

When using the TFileDialog object with Borland Pascal 7.0, users may find that errors occur when navigating through subdirectories using the "..\" symbol in the files listbox.

The problem lies in the STDDLG.PAS file which normally resides in the \BP\RTL\TV subdirectory. After opening the file, search on the word RelativePath to find the following code:

```
function RelativePath(var S: PathStr): Boolean;  
begin  
  S := LTrim(RTrim(S));  
  RelativePath := not (S <> '') and ((S[1] = '\') or (S[2] =  
    ':')));  
end;
```

To resolve the problem, change the fourth line so that it looks like this:

```
RelativePath := not ((S <> '') and ((S[1] = '\') or (S[2] =  
  ':'))));
```

When you are done, you can copy your new TPU or TPP file into the \BP\UNITS subdirectory.

This problem only appears in Borland Pascal 7.0. STDDLGS shipping with Turbo Pascal 7.0 is correct.

## Article #15403: Mouse Driver Compatibility

Technical Information Database

TI403D.txt - Mouse Driver Compatibility

Category :Turbo Pascal

Platform :All

Product :

Description:

Mouse Drivers Known To Function With Borland/Turbo Pascal

From time to time, users of Borland/Turbo Pascal find that after running a program or returning from a DOS shell the mouse cursor disappears. The function of the mouse seems to be unaffected as button presses activate the menu bar and status line. However, the mouse cursor itself is gone and the user can not easily determine where the mouse is on screen.

This anomaly is frequently seen as a deficiency in Borland/Turbo Pascal, particularly as this effect is rarely if ever seen with products by other vendors.

In fact, the mouse driver in use is outdated or incomplete. As Borland/Turbo Pascal is a program able to run and debug programs, it must save the state of the mouse each time a user program is run or debugged. It must also save the state of the mouse when a DOS shell initiated. For this and all other mouse functions, the IDE relies on the mouse driver installed in either the CONFIG.SYS or AUTOEXEC.BAT file. These problems occur when a mouse driver is being used that is unable to properly save or restore its state.

Here is a list of mouse drivers known to Borland to correctly implement the Save/Restore mouse state functions.

Microsoft 6.1 or later  
Logitech 4.0 or later  
Mouse Systems 6.22 or later  
Genius 9.06 or later

Correcting such a problem with the mouse driver involves updating the mouse driver to a version compatible with those listed here. For mouse systems not described in this list, contact the manufacturer for an updated mouse driver. If an updated mouse driver is not available for a particular mouse system, it may well be worth considering replacing the mouse system with one known to function correctly.

PRODUCT : Borland/Turbo Pascal NUMBER : 1260  
VERSION : 6.0 & Up  
OS : DOS  
DATE : June 23, 1994 PAGE : 2/2

## Article #15410: Recommended PIF Settings for Windows

Technical Information Database

TI410D.txt - Recommended PIF Settings for Windows

Category :Turbo Pascal  
Platform :DOS  
Product :

### Description:

Every DOS program that runs under Windows will have an associated PIF file. These files designate how much memory an application uses and how it uses other aspects of your computer, such as the video memory.

If you do not associate a particular PIF file with a DOS application then it will use the `_Default.PIF` file which Microsoft places automatically in the Windows subdirectory. You should also be aware that whenever you open a DOS box via the MSDOS icon, then by default Windows uses the `DOSPrmpt.PIF` file, which Windows installs during setup. This PIF file will control the settings of an application that is started from inside a DOS box.

During the default installation Turbo Pascal 7.0 and Borland Pascal 7.0 both place correctly configured PIF files in the BIN subdirectory for the protected mode IDEs and debuggers such as BP, TPX and TDX. Borland Pascal will automatically create a Program Manager group with icons which are associated by default with these PIF files. This same chore is not performed automatically during the Turbo Pascal installation, so if you own that product you should be sure to associate TPX with the correct PIF file if you want to start it from a Windows icon. There is no need to associate real mode applications such as Turbo.EXE with a PIF file since they will normally run fine under either the `_Default.PIF` or the `DOSPrmpt.PIF`.

It is extremely easy to associate a DOS executable with a particular PIF file. To do so, follow the normal procedures for setting up a Windows Icon, except instead of associating an

executable with a particular icon, you should associate it with a particular PIF file. The PIF file itself will know where your executable is and how to start it.

If you want to know more about the set up or use of PIF files you should read the lengthy and detailed description of this subject in the Microsoft Windows Users Guide which shipped with your copy of Windows.

Here are the default PIF settings for the PIF files that shipped with BP7 and TP7:

=====

BP PIF:

Program FileName: BP.EXE

Window Title: Borland Pascal 7.0

Optional Parameters: /R+

Video Memory: Text

Memory Requirements

KB Required: 128

KB Desired: 640

EMS Memory

KB Required: 0

KB Limit: 1024

XMS Memory

KB Required: 0

KB Limit: 2048

Display Usage: Full Screen

Close Window on Exit: TRUE

Advanced Options

Background Priority: 50

Foreground Priority: 100

Detect Idle Time: TRUE

Emulate Text Mode: TRUE

Allow Fast Paste: TRUE

Application Shortcut Key: None

=====

TDX PIF:

Program FileName: TDX.EXE

Window Title: TDX

Video Memory: Text  
Memory Requirements  
  KB Required: 128

## Article #15416: Booting clean -- tips for installing Turbo Pascal

Technical Information Database

TI416D.txt - Booting clean -- tips for installing Turbo Pascal

Category :Turbo Pascal

Platform :All

Product :

Description:

This TI explains how to boot clean. Booting clean involves bypassing both your CONFIG.SYS and AUTOEXEC.BAT files. This is often desirable if you have reason to believe that some of the calls in these files might be conflicting with the normal operation of Turbo Pascal. For instance, trouble installing Turbo Pascal is often the result of conflicts with other programs loaded by CONFIG.SYS or AUTOEXEC.BAT files. On other occasions, conflicts with drivers or TSRs loaded in a CONFIG.SYS or AUTOEXEC.BAT file may cause problems with protected mode technology.

If you are using DOS 6, you can boot clean simply by rebooting your system and waiting till you see the words "Starting MS-DOS". While that text is on your screen, press and release the F5 key or press and hold down the SHIFT key.

Here is a second method:

Format a bootable floppy disk that can be used in Drive A. You should refer to your DOS manuals for instructions on creating such a disk. However, on many systems, all you will need to do is place an unused disk and drive and then type:

```
FORMAT A: /S
```

Be sure that there are no important files on this disk, as it will be completely reformatted and all information on it will be lost.

Create on that disk a CONFIG.SYS file having only the statement

```
FILES=20
```

and an autoexec.bat file having only the statements

```
PROMPT $p$g  
PATH=C:\BP\BIN;C:\;C:\DOS
```

The path statement listed above assumes that you are installing Borland Pascal on to the C drive of your system and using the default subdirectories. Your path may be different than this. For instance, if you are installing Turbo Pascal, you should substitute the letters TP where BP is shown here.

Some systems may be using a hard drive that requires a special driver such as DMDRVR.SYS or Stacker. If you absolutely must, leave these entries in your configuration file. You can now 'boot clean' by inserting that disk into Drive A and rebooting your computer.

If you are having difficulties running any part of the product under Microsoft Windows, you will need a modified clean boot to run Windows. Add to your CONFIG.SYS file the statement the following line:

```
DEVICE=C:\DOS\HIMEM.SYS
```

and change the path statement in your autoexec.bat file to

```
PATH=C:\BP\BIN;C:\;C:\DOS;C:\WINDOWS
```

Also, ensure the statements in the WIN.INI and SYSTEM.INI files in your Windows directories match these:

```
WIN.INI  
    load=  
    run=  
SYSTEM.INI  
    shell=progman.exe
```

## Article #15422: Does a Turbo Vision control have the input focus?

Technical Information Database

TI422D.txt Does a Turbo Vision control have the input focus?  
Category :TVISION  
Platform :All  
Product :Pascal All

### Description:

The following program demonstrates how to detect if a control in a Turbo Vision dialog has received the focus. The key is the `cmReceivedFocus` message, which gets sent to the owner of a control whenever that control is about to receive the focus. Here is sample code showing how to respond to the message:

```
procedure TTrainDialog.HandleEvent(var Event: TEvent);
begin
  if (Event.What = EvBroadCast)
  and (Event.InfoPtr = MyInputLine)
  and (Event.Command = cmReceivedFocus) then begin
    MessageBox('Got cmReceivedFocus Message, nil, mfOkCancel);
  end;
  TDialog.HandleEvent(Event);
end;
```

The above code sample assumes that an inputline has been inserted into a dialog. Whenever the user TABs to the input line, then the `cmReceivedFocus` message is sent to the control's owner. Note that its not sent to the control itself, but to the control's owner! Note also that this is a broadcast message. Of course its not enough just to pick up on broadcast `cmReceivedFocus` messages. You also have to detect which control has just received the focus. To do this, you can use the `InfoPtr` field of the incoming `TEVENT` record. This field will contain a pointer to the control that is about to receive the focus. The example code here literally compares the pointer to a second copy of a pointer to that control. If they are equal, then you know that you have the right control. Of course, the above code assumes that you have explicitly saved and declared a pointer to the inputline, as shown in the included example

program.

Now that you understand how `cmReceivedFocus` messages work, you might be interested in seeing another way of handling the same problem. This is to override the `SetState` function which actually generates `cmReceivedFocus` messages. In the program shown below, the following code fragment will enable and disable the state of a command on the statusline, depending on whether or not the control has the focus.

```
procedure TMyButton.SetState(AState: Word; Enable: Boolean);
begin
  inherited SetState(AState, Enable);
  if (AState = sfFocused) and (Enable = False) then
    DisableCommands([cmFoo]);
  if (AState = sfFocused) and (Enable = True) then
    EnableCommands([cmFoo]);
end;
```

The key to the above code is that it checks for `sfFocused` messages to find out whether the control is receiving or losing the focus.

When running the following program, watch the status line to see which control has the focus.

```
}
program DlgFocus;
uses
  App, Dialogs, Drivers, Menus, MsgBox, Validate, Views, Objects;

const
  cmDialogBox = 101;
  cmTest      = 102;
  cmButton    = 103;
  cmInput     = 104;
  InputLength = 128;
  TheMessage = 'The Input line just received focus.' + #13#10 +
               'Chose OK to set Ok in the Inputline' + #13#10 +
               'Chose Cancel to set Cancel in the InputLine';

type
  PMyButton = ^TMyButton;
  TMyButton = Object(TButton)
    procedure SetState(AState: Word; Enable: Boolean); virtual;
end;
```

```

PTrainDialog = ^TTrainDialog;
TTrainDialog = Object(TDialog)
    MyInputLine: PInputLine;
    constructor Init(Bounds: TRect; ATitle: String);
    procedure HandleEvent(var Event: TEvent); virtual;
end;

```

```

TMyApp = Object(TApplication)
    constructor Init;
    procedure InitStatusLine; virtual;
    procedure HandleEvent(var Event: TEvent); virtual;
    procedure DialogBox;
end;

```

```

procedure TMyButton.SetState(AState: Word; Enable: Boolean);
begin
    inherited SetState(AState, Enable);
    if (AState = sfFocused) and (Enable = False) then
        DisableCommands([cmButton]);
    if (AState = sfFocused) and (Enable = True) then
        EnableCommands([cmButton]);
end;

```

```

constructor TTrainDialog.Init(Bounds: TRect; ATitle: String);
var
    R: TRect;
    Control: PView;

## Article #15424: CALLING ANCESTORS CONSTRUCTOR

Technical Notes Database

TN424D.txt      CALLING ANCESTORS CONSTRUCTOR

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 5.5

Description:

Q. How do you call a constructor from an ancestor's object?

A. You can call an ancestor's constructor directly from within the constructor of the current object. For example:

Type

```
    Type1 = Object
           Constructor Init;
```

```
End;
```

```
    Type2 = Object ( Type1 )
           Constructor Init;
```

```
End;
```

```
Constructor Type1.Init;
```

```
Begin
```

```
End;
```

```
Constructor Type2.Init;
```

```
Begin
```

```
    Type1.Init;
```

```
End;
```

```
...
```

## Article #15428: Declaring an array on the heap

Technical Information Database

TI428D.txt - Declaring an array on the heap

Category :Object Pascal  
Platform :All-32Bit  
Product :

### Description:

The following program, HEAPARY.PAS, demonstrates how to place an array on the heap. Programmers need to do this when they get errors saying that there are "too many variables" or that they are out of data space.

The solution to the above errors is simply to move an array up on the heap by creating a pointer to the array. Notice that the actual definition of the array is in the TYPE section, not the VAR section. If you write a statement like:

```
var MyArray: array[0..100] of Char
```

then you are allocating memory in the data segment, which is what you want to avoid. The solution is to define the array in the TYPE section, and then declare it in the VAR section:

```
var MyArray: PMyArray;
```

where PMyArray is a pointer to an array. To see the complete code for this type of example, refer to the HEAPARY program shown below.

The \$X is just so HEAPARY.PAS can use ReadKey without returning a result, the FlushKeyBuffer and Pause methods are thrown in case you are interested. The body of the program and the Type declaration are the parts you want to look at. Always remember to dispose memory

allocated with New!

Program HeapAry;

{ \$X+ }

Uses

Dos,  
Crt;

Type

PMMyArray = ^TMyArray;  
TMyArray = array[0..999] of LongInt;

procedure FlushKeyBuffer;

var Recpack : registers;

begin

with recpack do begin  
Ax := (\$0c shl 8) or 6;  
Dx := \$00ff;

end;

Intr(\$21, recpack);

end;

procedure Pause;

begin

FlushKeyBuffer; { Make sure key buffer is empty! }  
ReadKey; { Pause }

end;

var

MyAry: PMMyArray;  
i: Integer;

begin

ClrScr;

New(MyAry); { Allocate the memory on the heap }

for i := 0 to 999 do { Fill out array }

MyAry<sup>[i]</sup> := i;

for i := 500 to 510 do { Write the array to the screen }

WriteLn(MyAry<sup>[i]</sup>);

Pause;

Dispose(MyAry); { Dispose memory! }

end.

## Article #15434: Making a help group for Borland Pascal

Technical Information Database

TI434D.txt - Making a help group for Borland Pascal

Category :Turbo Pascal

Platform :All

Product :

Description:

Introduction

-----

Borland Pascal has many text files in the \BP\DOC directory that can be very helpful, but not quickly accessible from within Windows. This document will show you how you can create a program group that contains the additional help icons by using the GROUPS.EXE program provided with Borland Pascal, and creating a text file to tell it where the files are.

Instructions

-----

The steps to create the help group are the following:

- 1) You need to load up an editor program with a copy of the GROUPS.HLP text file. To do this:

Load up an editor, the DOS command EDIT for example, and either type in the example file below, or load this instruction file and strip off all the text except for the example code. DO NOT include the --TOP-OF-FILE-- and --END-OF-FILE-- in your text file.

Use the SAVE AS command to save the text file as:

C:\WINDOWS\GROUPS.HLP

This will make sure the file is saved under the Windows directory.

- 2) Change the directories in the example file to match the directories on your system.

In the included example file, the location of the Pascal root directory is C:\BP. If your Pascal files are in the directory D:\BP, use a Global Search and Replace to search for 'C:\BP' and replace it with 'D:\BP'. This will let the GROUPS program know where your Pascal help and icon files are.

If your Windows files are not located in the C:\WINDOWS directory, you will have to do another Global Search and Replace and replace 'C:\WINDOWS' with whatever the path is to your Windows files, D:\WINDOWS for example.

- 3) Under Windows, you will need to run the GROUPS.EXE file along with the text file you've just edited as its parameter. To do this, go to the FILE menu and select RUN. In the field for Command Line, type

```
GROUPS GROUPS.HLP
```

This should run the GROUPS program, and it should ask you if you'd like to create a Windows program group. Click on Yes.

If an error box pops up, you can try typing

```
C:\WINDOWS\GROUPS C:\WINDOWS\GROUPS.HLP
```

assuming that your Windows files are located in the C:\WINDOWS directory.

- 4) Look at the icons, they should all be yellow question marks with titles underneath. Also double click on some of the icons and make sure that an editor screen comes up with a copy of the help file in it.

If there are problems:

If either the icon is wrong, or the editor shows an empty screen, the directory setting for the Pascal files is

wrong. Make sure that the Pascal directory entry is of the form C:\BP, or D:\BORLANDP, or something similar that has a valid path to your Pascal directory.

If the editor doesn't come up, there is an error with the Windows directory path entry. It should be something like C:\WINDOWS.

If the icons don't appear but the Group Box does appear, there is a format error in the GROUPS.HLP file. Make sure the file follows the example shown here.

If the Group Box doesn't appear at all, GROUPS.EXE couldn't load the text file GROUPS.HLP. Make sure the path to the file is valid, and that the file exists where the path is pointing to.

#### Example File

-----

#### IMPORTANT:

In this example file, the lines after '[icons1]' have been split before the '='. The actual text file must be implemented with each help icon command on it's own line. You must combine the lines that start with an '=' with the line above it. For example, you could position the cursor on the '=' and press BACKSPACE to bring the line up and append it to the line above it.

Each line should have the form:

```
ExecuteFile=WorkingDir,Icon Caption,IconFile
```

When this example text file is finished, it should contain 28 lines only and will create 24 help icons.

#### NOTE:

Since \BP\DOC\utils.td is too large to fit into the NOTEBOOK.EXE editor, WRITE.EXE has been substituted.

FILENAME: C:\WINDOWS\GROUPS.HLP

[group1]

-----END-OF-FILE-----

## Additional Information

### How it works:

The GROUPS.EXE program takes a text file as input and creates a Windows group according to the data in the file. The text file is of the form:

```
ExecuteFile=WorkingDir,Icon Caption,IconFile
```

The help files will be displayed with NOTEPAD.EXE in the Windows directory. You can use any Windows editor to display the files by changing the first field from 'notepad.exe' to whatever editor you'd like to use.

The WinHelp help files will also be included in the help group and are preceded by 'WINHELP.EXE'. The help icon is the same as the original help files, and can be changed by naming a different .ICO file in the last field.

The GROUPS.EXE program is also the same one used by the install program to create the Pascal program group. To recreate the original program group, execute the command

```
GROUPS GROUPS.B$$
```

The GROUPS.B\$\$ is created by the installation process, and is located in the Windows directory.

## Article #15436: CONSTRUCTOR CALL WITHIN METHOD

Technical Notes Database

TN436D.txt      CONSTRUCTOR CALL WITHIN METHOD

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 5.5

Description:

Q. I am calling my constructor from within a method, why am I having problems?

A. The problem will arise when the constructor loads the new VMT pointer. It loads the pointer to the VMT for the constructor's table, not the instances. Therefore if a descendant calls an ancestor's constructor, the descendant's VMT will now point to the ancestors VMT. The problem now occurs when the descendant tries to call a method that was defined after the ancestor. The VMT entry for this method is unknown. Look at the following example:

Type

  L1 = Object

    Constructor Init;

    Procedure First; Virtual;

End;

  L2 = Object ( L1 );

    Constructor Init;

    Procedure Second; Virtual;

End;

Constructor L1.Init;

Begin

End;

Constructor L2.Init;

Begin

End;

Procedure L1.First;

Begin

  Init;

```
End;
```

```
Procedure L2.Second;
```

```
Begin
```

```
  Init;
```

```
End;
```

```
Var
```

```
  L : L2;
```

```
Begin
```

```
  L.Init;  { This calls L2.Init and loads a pointer to }  
           { the L2 VMT into L. }  
           }
```

```
  L.First; { This will call L1.First, which in turn calls }  
           { L1.Init because as far as the procedure is }  
           { concerned, the Self pointer is a pointer }  
           { to an object of type L1. }  
           }
```

```
  L.Second; { This is undefined. Since the VMT now }  
            { pointed to by L is L1's, the pointer to }  
            { method Second is undefined. Therefore, the }  
            { call to this method is undefined. }  
            }
```

```
  ...
```

\*\*\*Note: This also applies to polymorphic procedures.

## Article #15440: Turbo Vision local menu using right mouse button

Technical Information Database

TI440D.txt Turbo Vision local menu using right mouse button  
Category :TVISION  
Platform :All  
Product :Pascal All

### Description:

This is an example Turbo Vision program that demonstrates using local menus that are activated with the right mouse button and are positioned on screen by the mouse position.

```
program Localmenu;
uses
  Drivers, Objects, Views, App, Menus;

const
  cmNothing = 101;
type

  TMyApp = object(TApplication)
    LocalMenu: PMenu;
    LocalMenuOpen: boolean;
    constructor Init;
    procedure GetEvent(var Event: TEvent); virtual;
  end;

constructor TMyApp.Init;
begin
  inherited Init;
  LocalMenu := NewMenu(
    NewItem('Item~1~', '', 0, cmNothing, hcNOContext,
    NewItem('Item~2~', '', 0, cmNothing, hcNoContext,
    nil)));
  LocalMenuOpen := false;
  EventMask := EventMask or evBroadcast;
end;

procedure TMyApp.GetEvent(var Event: TEvent);
```

```

var
  MousePt: TPoint;
  R: TRect;
  Box: PMenuBox;
  NewEvent: TEvent;
  Code: Word;
begin
  inherited GetEvent(Event);
  if ((Event.What = evMouseDown) AND (Event.Buttons =
      mbRightButton) AND NOT LocalMenuOpen)
  then
  begin
    LocalMenuOpen := true;
    MousePt := Event.Where;
    if (MousePt.X > 70) then MousePt.X := 70;
    if (MousePt.Y > 20) then MousePt.Y := 20;
    ClearEvent(Event);
    R.Assign(MousePt.X, MousePt.Y, MousePt.X+11, MousePt.Y+2);
    Box := new(PMenuBox, Init(R, LocalMenu, nil));
    Code := ExecView(Box);
    Dispose(Box);
    LocalMenuOpen := false;
    NewEvent.What := evBroadcast;
    NewEvent.Command := code;
    PutEvent(NewEvent);
  end;
end;
var
  MyApp: TMyApp;
begin
  MyApp.Init;
  MyApp.Run;
  MyApp.Done;
end.

```

## Article #15442: OVERRIDE VIRTUAL METHOD CALLING ANCESTOR

Technical Notes Database

TN442D.txt      OVERRIDE VIRTUAL METHOD CALLING ANCESTOR  
Category       :Pascal  
Platform        :All  
Product         :Turbo Pascal 5.5

### Description:

- Q. Can I override a virtual method and force a call to the ancestor objects method?
- A. No. Late binding will always call the current method and it defeats the purpose of object oriented programming to go around this feature.

### Reference:

7/16/98 4:35:32 PM

## Article #15447: Using procedural variables in Pascal

Technical Information Database

TI447D.txt - Using procedural variables in Pascal

Category :Object Pascal  
Platform :All-32Bit  
Product :

### Description:

The included program, FUNC1.PAS shows how to use procedural variables.

It creates both a pointer to a function and a pointer to a procedure and shows how to use them.

Func1 creates a pointer to a function called MyFunc, calls it once and then passes it to a procedure which then proceeds to call it. Therefore this examples shows how to assign and call a procedural variable, and also how to pass it to another procedure which can then call it.

The following lines demonstrate how to create types that can point at a procedure or function:

```
type
  TMyFunc = function(i: Integer): Integer;
  TMyProc = procedure;
```

Notice that the actual name of the function or procedure is left out, but that it is necessary to declare any variables passed to function or procedure, and to specify any return types from a function.

Its important to understand that TMyFunc and TMyProc are really pointers to functions, even though there is no need to call new and dispose, and no need to dereference the pointer with the caret symbol ("^").

Notice also that both MyProcedure and MyFunc are declared "Far". This is absolutely necessary when working with procedural variables, though of course functions declared in the header to a unit will automatically be far when called from another module.

```
program Funcl;  
  
type  
  TMyFunc = function(i: Integer): Integer;  
  TMyProc = procedure;  
  
procedure MyProcedure; far;  
begin  
  WriteLn('Hi');  
end;  
  
function MyFunc(I: Integer): Integer; far;  
begin  
  WriteLn(i);  
end;  
  
procedure Foo(F: TMyFunc);  
begin  
  F(5);  
end;  
  
var  
  F: TMyFunc;  
  P: TMyProc;  
begin  
  F := MyFunc;  
  F(10);  
  Foo(F);  
  P := MyProcedure;  
  P;  
end.
```

## Article #15449: CONSTRUCTOR CALL TO ANCESTOR WITH VIRTUALS

Technical Notes Database

TN449D.txt      CONSTRUCTOR CALL TO ANCESTOR WITH VIRTUALS

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 5.5

Description:

Q. If a descendant of a virtual object defines no virtual methods of its own, does it need to call the ancestor's constructor?

A. If an object is a descendant of a virtual object, it must call that ancestor's constructor or it's own constructor. Even if the new object does not define any virtuals of its own. For example:

Type

```
A = Object
```

```
    Constructor Init;
```

```
    Procedure AA; Virtual;
```

```
End;
```

```
B = Object ( A )
```

```
End;
```

For each instance of A and of B, Init must be called or the Virtual Method Table pointer will not be loaded correctly.

## Article #15454: Using editor toolbox with newer versions of Pascal.

Technical Information Database

TI454D.txt - Using editor toolbox with newer versions of Pascal.

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

This file is for owners of Turbo Pascal 6 or 7 who want to use the editor from the editor toolbox that shipped with Turbo Pascal Version 4.0. To begin, find the file called BINED.PAS that shipped with Toolbox. You should make the following change to BINED.PAS:

```
Procedure ResetBinaryEditor(var EDData: EdCB);  
  
var X: Integer; { <<--- ADD THIS LINE; ITS THE FIX! }  
  
begin  
    EditNew(EdData);  
end;
```

The addition of the above line sets up a stack frame for this proc.

Here's some additional text taken from the TP6 HELPM!.DOC:

With the exception of the Turbo Editor Toolbox, the 4.0 toolboxes will compile with Turbo Pascal 6.0. The Turbo Editor Toolbox needs the minor source code changes described below in order to work with the new heap manager:

MicroStar

-----

In MSVARS.PAS:

- 1) On line 219 after "var"  
    Add "FreePtr: Pointer;"
- 2) On line 295 after "begin"  
    Add "FreePtr := Ptr(Seg(HeapEnd^) - \$1000, 0);"

In INVOKE.PAS:

- 1) On line 18 after "Dos"  
Add ", MsVars"

FirstEd

-----

In EDVARS.PAS:

- 1) On line 139  
Add "FreePtr: Pointer;"  
On line 207  
Add "FreePtr := Ptr(Seg(HeapEnd^) - \$1000, 0);"

The TP6 notes then go on to talk about a new copy of BINED.OBJ. This is a fictitious copy and does not exist. Don't try to find it. Instead, add "THE FIX!" shown above.

## Article #15456: LINKER STRIPS UNUSED STATIC METHODS

Technical Notes Database

TN456D.txt LINKER STRIPS UNUSED STATIC METHODS

Category :Pascal

Platform :All

Product :Turbo Pascal 5.5

### Description:

Q. It appears that my static methods are getting stripped from my program by the smart linker when they are unused. Yet, my virtual methods are not. How come?

A. Static methods can be stripped because it can be determined at link time what methods will be called. Virtual methods can not be stripped because the program will not know what methods will be used, and what will not, until run time. This is because of late binding.

## Article #15461: Having two dialogs on your screen at once.

Technical Information Database

TI461D.txt Having two dialogs on your screen at once.

Category :TVISION

Platform :All

Product :Pascal All

Description:

```
{
  The following program demonstrates one technique for placing
  two dialogs on the screen at the same time in a Turbo Vision
  application. The key to this process is to make the first
  dialog a modeless dialog, and then the second can be either
  modal or modeless, depending on your needs. In this case,
  the second dialog is modal.
```

```
When a modal dialog is on the screen, the user must close it
before getting access to the other features in an application.
For instance, a user cannot use the main programs menu while
modal dialog is on the screen. This is not true of modeless
dialogs. Modal dialogs are started with ExecView or ExecDialog.
Modeless dialogs are "Inserted" into the desktop.
```

```
}

## Article #15468: Printing in the TP/BP IDE

Technical Information Database

TI468D.txt - Printing in the TP/BP IDE

Category :Printing  
Platform :All  
Product :

### Description:

How to print from the Pascal Integrated Development Environment  
=====

All printing is handled from the printer filter (prnfltr.exe) executable that is located in the bin directory. The source code for the prnfltr was included in both the Turbo Pascal 7.0 and the Borland Pascal 7.0 packages, although in different places. PRNFLTR.PAS is found in either the TPBIN directory or in the BPEXAMPLESUTILS directory. (Also look at the file LISTER.PAS in the BPEXAMPLESDOS or TPEXAMPLES. It is an excellent alternative to the standard printing options available in Borland Pascal.) From this file we can see the various printing options for PRNFLTR. The options can be changed from under File | Printer Setup | Command Line. The \$NOSWAP does not change.

For example, if changing from /EPSON support to /HP support, the command line should change from this:

```
$NOSWAP /EPSON
```

To this :

```
$NOSWAP /HP
```

Once the changes have been made to the command line for the PRNFLTR, be sure to save the current configuration (this will keep you from having to change the configuration every time you wish to print). The current configuration can be saved by choosing Option | Save menu option.

## OPTIONS FOR PRNFLTR

=====

```
{*****}
{
{ Printer output filter example }
{ Copyright (c) 1992 by Borland International }
{
{*****}
```

The following printers are supported:

EPSON and compatibles

HP LaserJet II, III, IIP, IID, IIID, IIISi and compatibles  
(Italics are available on IIIx, IIP)

ADOBE(R) PostScript(R)

ASCII (simply strips the highlight codes  
before sending to Lst)

Command line options:

```
/EPSON - Output EPSON printer codes
/HP - Output HP LaserJet codes
/PS - Output PostScript
/ASCII - Strip highlight codes (Default)

/Lxx - Lines per page (Default 55)
/Txx - Tabsize (Default 8)
/O[file] - Output to file or device (Default LPT1)
```

## DEFAULT LPT1

=====

The default port for printing is lpt1. If you do not have your printer set up on lpt1 the way to change the default is by using the /O[file] option, replacing [file] with whatever port the printer is on (such as lpt2).

Example (printing to an HP from lpt2):

```
$NOSWAP /HP /Olpt2
```

PRINTING PROGRAM OUTPUT

=====

If you want to print the output of your program (i.e. what happens when the program is run) the document TI1255 will describe the process.

"CANNOT FIND PRNFLTTR"

=====

If you are getting the error prnfltr cannot be found, it can be solved by placing the BIN directory in the path statement of the AUTOEXEC.BAT.

For example, if your AUTOEXEC.BAT's path statement says this:

```
path=c;;c:dos;c:windows;
```

The path statement should be changed to reflect the full path to the bin directory.

Example:

```
path=c;;c:dos;c:windows;c:bpbin;
```

Then restart your machine and try again to print.

\*\*\*

PRINTING FROM A LASER (OR A LASERJET) PRINTER

=====

If the file that you would like to print is less than a page long, sometimes it will be unable to print. The two possible solutions to this are as follows.

- 1) Put carriage returns into the document until it is more than a page long.
- 2) Also, placing a page feed character at the end of the document can sometimes solve the problem.

To create a page feed character, press the control key

and while holding it down press the P key. Keeping the control key pressed (still), then press the L key. (Recap: control P L ). A symbol should appear on the screen where the cursor was. That is the page feed character.

## TROUBLE SHOOTING

=====

If you have selected the option for the type of printer (or compatible printer) that you have and it is still not correctly printing, there are several possible things that could solve the error.

The first thing that could solve the error is to run a "clean boot".

Try a different option for the printer. From /HP and /Epson, switch to /ASCII. Also, disable the option "Send highlighting escape codes" (which appears just above the command line under File | Printer Setup) as well as using the /ASCII option could solve the problem.

If you are still not able to print after trying several combinations of options, it is possible that your printer is not correctly set up to work from DOS. (If you are on a network it is also possible that your machine is not correctly configured to print to the network printer. Check with your network administrator to see if you are correctly connected.) To test for your printer setup, try printing straight from DOS. Printing from a word processor or from Windows is not comparable because those products provide their own drivers for printing. It is possible to print from DOS using copy or print.

```
copy test.c lpt1 {if the printer is set up for lpt1}
print test.c     {if the printer is set up for lpt1}
```

If neither of those commands works then it may be necessary to reconfigure your printer for printing from DOS before you will be able to print from the Pascal Integrated Development Environment.

## Article #15470: FILES OF OBJECT TYPE

Technical Notes Database

TN470D.txt      FILES OF OBJECT TYPE  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 5.5

### Description:

Q. Why can't I make a file of ObjectType?

A. Because by the rules of polymorphism, any descendant of ObjectType would be type compatible and be able to be written to disk as well. The problem with this is that the descendants may be (and usually are) of a larger size than the ObjectType itself. Pascal's file structure require all records to be the same size, otherwise, how do you know which size object do you read in? For an example on how to do Object disk I/O, please see the STREAMS example on the distribution diskettes.

## Article #15475: Getting and setting a disks serial number

Technical Information Database

TI475D.txt     Getting and setting a disks serial number  
Category     :General Programming  
Platform     :All  
Product      :Pascal    All

Description:

The following program shows how to read and write the serial number on a disk drive. It uses interrupt \$21 function \$69 and reads the information back and forth into a record with the following declaration:

```
TSerPacket = record
  Info:Word;
  SerNo: Longint;
  Vol: Array[1..11] of char;
  FileType: Array[1..8] of char;
end;
```

The first word of the above record should always contain zero, the second contains the serial number, the third the volume label and the fourth the FileType, which is usually either FAT 16 or FAT 12.

When setting a new serial number, the programs first reads the current information, and then sets the new serial number and writes it to disk.

The code shown below provides the user with three functions:

```
GetSerialInfo: Get the current serial number
SetSerialInfo: Set a new serial number
DisplaySerialInfo: Display the information in the current
                   variable of type TPacket.
```

Notice that DisplaySerialInfo does not write information to a disk drive, but only displays that information to

the user via the screen. All of these routines depend on a global variable of type TSerPacket, which is called SPacket. It makes no sense to call DisplaySerialInfo before calling GetSerialInfo.

The drive specification is passed as a number, where the default drive is zero, drive A is one, drive B is two, etc.

```
program SetDiskSer;
```

```
{ $A+, B-, D+, E+, F-, G+, I+, L+, N-, O-, P-, Q-, R-, S-, T-, V+, X+, Y+ }  
{ $M 16384, 0, 655360 }
```

```
type
```

```
  TSerPacket = record  
    Info: Word;           { Info level always zero }  
    SerNo: Longint;      { Disk }  
    Vol: Array[1..11] of char;  
    FileType: Array[1..8] of char;  
  end;
```

```
var
```

```
  SPacket: TSerPacket;
```

```
function GetSerialInfo(Drive: Byte): Byte; assembler;
```

```
asm
```

```
  mov ah, 69h  
  mov al, 0 { This is where you 1 set serial, 0 to get serial  
            number }  
  mov bl, 1 { drive number 0 = default, 1 = A, 2 = B , 3 = C }  
  mov dx, offset [SPacket]  
  int 21h
```

```
end;
```

```
function SetSerialInfo(Drive: Byte; SerNo: LongInt): Boolean;
```

```
var
```

```
  S: String;
```

```
begin
```

```
  GetSerialInfo(Drive);  
  SPacket.SerNo := SerNo;
```

```
asm
```

```
  mov ah, 69h
```

```

mov al, 1 { This is where you 1 set serial, 0 to get serial
          number }
mov bl, Drive { drive number 0 = default, 1 = A, 2 = B ,
              3 = C }
mov dx, offset [SPacket]
int 21h
end;
end;

```

```

procedure DisplaySerialInfo;

```

```

var
  S: String;
begin
  WriteLn('Info level: ', SPacket.Info);
  WriteLn('Serial Num: ', SPacket.SerNo);
  FillChar(S, SizeOf(S), #0);
  Move(SPacket.Vol[1], S[1], 11);
  S[0] := #11;
  WriteLn('Vol: ', S);
  FillChar(S, SizeOf(S), #0);
  Move(SPacket.FileType, S[1], 8);
  S[0] := #8;
  WriteLn('Type: ', S);
end;

```

```

begin
  SetSerialInfo(1, 12); { One means Drive A, 16 is the serial
                        number }
  GetSerialInfo(1);
  DisplaySerialInfo;
  ReadLn;
end.

```

## Article #15481: Creating a temporary stack.

Technical Information Database

TI481D.txt - Creating a temporary stack.

Category :Object Pascal  
Platform :All-32Bit  
Product :

Description:

{  
The following code shows how to create a temporary stack for use during ISRs and in other situations where the default stack might not be big enough.

The following program intentionally creates a very small default stack by using the \$M compiler directive. It then calls a function which pushes \$2000 bytes onto the stack, thereby setting up a situation which should cause a 202 error.

To avoid the error, the program creates a temporary stack by allocating \$4000 bytes on the heap and moving this value into SS. It then sets SP to point at the end of this new stack and proceeds to call the function, which does not fail because of the new temporary stack.

This code has been tested in both real and protected mode.  
}

```
{ $M $800, 0, $12000 }
```

```
procedure BreakDefaultStack;  
var  
  a:array[0..$2000] of char;  
begin  
  Writeln('Hello');  
end;
```

```
var
```

```
aSS, aSP: Word;  
Stck: pointer;
```

```
begin  
  getmem(Stck, $4000);  
  Word (Stck^) := 1;  
  
  asm  
    mov aSP, sp  
    mov ax, ss  
    mov aSS, ax  
    mov ax, word ptr [Stck]  
    mov bx, word ptr [stck+2]  
    add ax, $4000-2  
    cli  
    mov ss, bx  
    mov sp, ax  
    sti  
  end;
```

```
BreakDefaultStack;
```

```
asm  
  mov ax, aSS  
  mov ss, ax  
  mov sp, aSP  
end;
```

```
  freemem(Stck, $4000);  
end.
```

## Article #15488: How to read an enhanced keyboard

Technical Information Database

TI488D.txt      How to read an enhanced keyboard

Category        :General Programming

Platform        :All

Product         :Pascal    All

### Description:

{

The code included in this example shows how to read an enhanced keyboard using Turbo Pascal. That is, it detects if the F11, F12, etc keys are pressed. It provides a substitute for the ReadKey and KeyPressed functions.

This TI includes two source files, the first a unit called ENHKEY.PAS and the second a test program called TEST.PAS. ENHKEY.PAS contains three routines:

KeyEPressed: Works just like the CRT routine called KeyPressed, except it detects keypresses on enhanced keys.

NewReadKey: Works very much like ReadKey, except it detects enhanced keys.

ReadEKey:      This is the raw readkey function. It returns a word.

The high order word contains the scan code and the low word contains the regular key. Some users might not want to call this function directly, but instead might want to access it through the NewReadKey function, which acts much more like the original ReadKey function from the CRT unit.

The code in the EnhKey unit depends on interrupt 16h, functions 10 and 11, both of which assume the presence of AT or better computer. In this day and age, that's a fairly safe bet, but you should be aware

that this code will not run on an old XT.

Notice that if NewReadKey returns zero the first time it is called, you can grab the scan code in the global variable ScanCode, or you can call NewReadKey a second time to return the ScanCode.

```
unit EnhKey;
```

```
interface
```

```
var
```

```
    ScanCode: Byte;
```

```
function KeyEPressed: Boolean;
```

```
function ReadEKey: Word;
```

```
function NewReadKey: Char;
```

```
implementation
```

```
function KeyEPressed: Boolean; assembler;
```

```
asm
```

```
    mov ah, $11
```

```
    int 16h
```

```
    mov ax, 1
```

```
    jnz
```

```
True
```

```
    xor ax, ax
```

```
True:
```

```
end;
```

```
function ReadEKey: Word; assembler;
```

```
asm
```

```
    mov ah, 10h
```

```
    int 16h
```

```
end;
```

```
function NewReadKey: Char;
```

```
var
```

```
    Ch: Word;
```

```
begin
```

```
    if ScanCode <> 0 then begin
```

```

    NewReadKey := Char(ScanCode);
    ScanCode := 0;
    exit;
end;
Ch := ReadEKey;
if Lo(Ch) = 0 then begin
    ScanCode := Hi(Ch);
    NewReadKey := #0;
    exit;
end;
NewReadKey := Char(Lo(Ch));
end;

begin
    ScanCode := 0;
end.
begin
    ScanCode := 0;
end.

{ ===== The Test Program ===== }

program Test;

## Article #15501: Configuring the Borland Pascal icon in OS/2

Technical Information Database

TI501D.txt - Configuring the Borland Pascal icon in OS/2

Category :Turbo Pascal  
Platform :All  
Product :

### Description:

The BORLAND PASCAL DOS Protected Mode Integrated Development Environment (IDE) is a DOS application that is invoked by executing BP.EXE. When OS/2 migrates BP.EXE, it migrates it as a WINDOWS application rather than as a DOS application. Therefore, when double-clicking on the BORLAND PASCAL (BP.EXE) icon, the program will fail to load properly.

This document explains how to configure the BORLAND PASCAL (BP.EXE) icon to run successfully as a DOS application.

Boot up OS/2 and follow these steps:

1. Highlight the BORLAND PASCAL (BP.EXE) icon that was created during migration.
2. With the mouse pointing at the highlighted BORLAND PASCAL icon, right mouse click and a menu will appear.
3. Left mouse click on the ARROW in the upper right hand corner of the OPEN line.
4. Left mouse click on SETTINGS.
5. If you are not at the PROGRAM tab, left mouse click on the PROGRAM tab.
6. Delete everything in the PATH & FILE NAME box. When the PATH & FILE NAME box is empty, insert an asterisk (\*) into the PATH & FILE NAME box.

7. Insert the following into the PARAMETERS box:

```
/c c:\bp\bin\bp.exe
```

Be sure to substitute the correct path to BP.EXE if you deviated from the suggested defaults.

The statement, `/c c:\bp\bin\bp.exe`, specifies that the command interpreter is to execute `c:\bp\bin\bp.exe` and then return to the command interpreter when finished.

8. Left mouse click on the SESSION tab.

9. Left mouse click on the DOS FULL-SCREEN button.

10. Left mouse click on DOS SETTINGS.

11. Scroll down to DPMI\_DOS\_API in the SETTING box, highlight DPMI\_DOS\_API.

12. In the VALUE box, choose ENABLED.

13. SAVE and EXIT.

The BORLAND PASCAL icon is now configured to run as a DOS Protected Mode application. You can now double-click on the BORLAND PASCAL icon and the IDE will load successfully.

## Article #15506: Unknown runtime errors. What's error 163?

Technical Information Database

TI506D.txt Unknown runtime errors. What's error 163?

Category :General Programming

Platform :All

Product :Pascal All

### Description:

Pascal sometimes returns runtime errors that aren't listed in the manuals. If you ever get an IORESULT code in the range 150-199, just subtract 131 from it and then look in your DOS reference manual (or in the list presented below) for the relevant critical errors.

One error that users see quite often is number 163, which is a sharing violation. It occurs when two users try to access the same file at the same time.

Here's a list of critical errors. The first column has the error number in decimal format, the second has the number in hex, and the third provides an explanation of the error:

DEC	HEX	EXPLANATION
01	-- 01	Invalid function number
02	-- 02	File not found
03	-- 03	Path not found
04	-- 04	Too many open files (no handles left)
05	-- 05	Access denied
06	-- 06	Invalid handle
07	-- 07	Memory control blocks destroyed
08	-- 08	Insufficient memory
09	-- 09	Invalid memory block address
10	-- 0A	Invalid environment
11	-- 0B	Invalid format
12	-- 0C	Invalid access mode (open mode is invalid)
13	-- 0D	Invalid data
14	-- 0E	Reserved
15	-- 0F	Invalid drive specified
16	-- 10	Attempt to remove current directory
17	-- 11	Not same device

18 -- 12 No more files  
19 -- 13 Attempt to write on a write-protected diskette  
20 -- 14 Unknown unit  
21 -- 15 Drive not ready  
22 -- 16 Unknown command  
23 -- 17 CRC error  
24 -- 18 Bad request structure length  
25 -- 19 Seek error  
26 -- 1A Unknown media type  
27 -- 1B Sector not found  
28 -- 1C Printer out of paper

## Article #15511: Creating an OWL app withoug a border and caption

Technical Information Database

TI511D.txt      Creating an OWL app withoug a border and caption

Category      :OWL

Platform      :All

Product      :Pascal    All

Description:

Sometimes programmers of OWL applications want to open a main window that has no border, no caption, and which fills the entire screen. The following example shows how to do this.

To get started, override the Init Constructor. Then set the Windows style to WS\_VISIBLE and WS\_POPUP:

```
Attr.Style := ws_Visible or ws_PopUp;
```

After doing this, the program will appear with no border and no caption. However, the window will not be visible unless you define its size. To give the program a shape, assign it a width and height:

```
Attr.X := 100;
```

```
Attr.Y := 100;
```

```
Attr.H := 200;
```

```
Attr.W := 200;
```

Of course, if you want to show the window in a maximized state, then you can simply send it a WM\_SYSCOMMAND message from the programs SETUPWINDOW procedure:

```
procedure TStepWindow.SetupWindow;
```

```
begin
```

```
  inherited SetupWindow;
```

```
  PostMessage(HWindow, WM_SYSCOMMAND, SC_MAXIMIZE, 0);
```

```
end;
```

To sum up, the shortest way from point A to point B is to

first give the window the WS\_POPUP style, and then maximize it with the WM\_SYSCOMMAND message. If you want to create a window that is not maximized, then be sure to set the window's width and height. The example below shows a maximized window:

```
program NoCaption;

uses WinTypes, WinProcs, OWindows, Strings;

type
  PStepWindow = ^TStepWindow;
  TStepWindow = object(TWindow)
    constructor Init(P: PWindowsObject; AName: PChar);
    procedure SetUpWindow; virtual;
    procedure Paint(PaintDC: HDC; var PaintInfo: TPaintStruct);
      virtual;
    procedure WMLButtonDown(var Msg: TMessage);
      virtual wm_First + wm_LButtonDown;
  end;

  TMyApplication = object(TApplication)
    procedure InitMainWindow; virtual;
  end;

constructor TStepWindow.Init(P: PWindowsObject; AName: PChar);
begin
  inherited Init(P, AName);
  Attr.Style := ws_Visible or WS_PopUp;
  { Attr.H := 200;
    Attr.W := 200; }
end;

procedure TStepWindow.SetUpWindow;
begin
  inherited SetUpWindow;
  PostMessage(HWindow, WM_SYSCOMMAND, SC_MAXIMIZE, 0);
end;

procedure TStepWindow.WMLButtonDown(var Msg: TMessage);
begin
  CloseWindow;
end;
```

```
procedure TStepWindow.Paint(PaintDC: HDC;
                           var PaintInfo: TPaintStruct);
var
  S: array[0..100] of Char;
begin
  StrCopy(S, 'Click on Window to close it');
  TextOut(PaintDC, 10, 10, S, StrLen(S));
end;

procedure TMyApplication.InitMainWindow;
begin
  MainWindow := New(PStepWindow, Init(nil, 'Steps'));
end;

var
  MyApp: TMyApplication;

begin
  MyApp.Init('Steps');
  MyApp.Run;
  MyApp.Done;
end.
```

## Article #15516: Uninstalling Delphi

Technical Information Database

TI516D.txt - Uninstalling Delphi

Category :Delphi 1.x  
Platform :All Windows  
Product :

Description:

Uninstalling Delphi (16 bit)

Contents

Introduction

- A) Deleting Directories
- B) Deleting the Program Group
- C) Removing .INI files
- D) Editing WIN.INI
- E) Editing WINHELP.INI
- F) Editing your AUTOEXEC.BAT
- G) Removing files placed in WINDOWS and WINDOWS\SYSTEM directories

Introduction

This document describes the process of "uninstalling" Delphi from your system. It is a good idea to have a back up of your system files, due to the fact that you will need to use the 'delete' command.

This document assumes the product was installed to C: drive, with default directories and full (default) installation settings. Any deviations from the default settings may require adjustments/changes to the instructions below.

A) Deleting Directories

If you have any program that uses IDAPI, please disregard any mention of deleting it or its directory below.

If you wish to delete directories using DOS commands, see section 1 below. To use Windows, see section 2.

- 1) To erase directories from your hard drive on a system with DOS 6.0 or greater, you need to be in the root directory (i.e. C:\> ) and type DELTREE

and

hit return(Example: C:\>deltree delphi). Answer Yes when it prompts to delete all subdirectories (see below for the list of directories to delete). For versions of DOS lower than 6.0, you need to go into each directory and type DEL \*.\* until all directories are empty. Then DOS will allow you to delete the directory names with the command RD

- 2) From Windows, go to File Manager. Using File Manager,

select the

folder. Then hit the Delete key.

Answer Yes to All when prompted to delete subdirectories.

The directories you need to delete are:

C:\Delphi	C:\Rptsmith
C:\Rs_run	C:\Dbd
C:\Iblocal	C:\Idapi
* C:\Informix	

\* - Client/ Server version only

## B) Deleting the Program Group

To delete the program group 'Delphi' in Windows 3.1 and Windows NT, highlight the group without opening it, and press the Delete key. Under Windows 95, the folders will have been removed by deleting the directories in the previous section.

### C) Removing .INI files

Delete the following .INI files from your \WINDOWS directory  
(CAUTION: if you have any other Borland products or any programs that use ODBC, back up the .INI files listed below before deleting them. Then test all other programs to insure they run normally!):

```
DELPHI.INI
BORHELP.INI
DBD.INI
INTERBAS.INI
* ODBC.INI
* ODBCINST.INI
* ODBCISAM.INI
RPTSMITH.INI
RS_RUN.INI
RS_SQLIF.INI
VSL.INI
MULTIHELP.INI
```

\* - files used by ODBC applications

### D) Editing WIN.INI

Make a backup of your WIN.INI file. Then, in your \WINDOWS directory, remove the following sections from your WIN.INI file (CAUTION: If any other program uses Paradox Engine, IDAPI, or Database Desktop, use discretion in deleting these lines!):

```
[DDE Servers]
DBD=C:\DBD\DBD
```

```
[DBD]
WORKDIR=C:\DBD
PRIVDIR=C:\DBD\DBDPRIV
```

```
[Interbase]
RootDirectory=C:\IBLOCAL
```

```
* [IDAPI]
DLLPATH=C:\IDAPI
CONFIGFILE01=C:\IDAPI\IDAPI.CFG
```

```
* [Borland Language Drivers]
LDPath=C:\IDAPI\LANGDRV
```

\* - DO NOT delete these if other programs  
use IDAPI

Remember to save your new WIN.INI.

#### E) Editing WINHELP.INI

Remove the following lines from WINHELP.INI located in  
your  
WINDOWS directory:

```
BDECFG.HLP=C:\IDAPI
DBD.HLP=C:\DBD
DELPHI.HLP=C:\DELPHI\BIN
WINAPI.HLP=C:\DELPHI\BIN
CWG.HLP=C:\DELPHI\BIN
CWH.HLP=C:\DELPHI\BIN
LOCALSQL.HLP=C:\DELPHI\BIN
VQB.HLP=C:\DELPHI\BIN
SQLREF.HLP=C:\IBLOCAL\BIN
WISQL.HLP=C:\IBLOCAL\BIN
RPTSMITH.HLP=C:\rptsmith
RS_DD.HLP=C:\rptsmith
SBL.HLP=C:\rptsmith
RS_RUN.HLP=C:\rptsmith
RCEXPRT.HLP=C:\DELPHI\RCEXPRT
DRVDBASE.HLP=C:\WINDOWS\SYSTEM
DRVPARDX.HLP=C:\WINDOWS\SYSTEM
ODBCINST.HLP=C:\WINDOWS\SYSTEM
```

## F) Editing your AUTOEXEC.BAT

First, make a backup of your AUTOEXEC.BAT file. Then edit your AUTOEXEC.BAT and remove C:\IBLOCAL\BIN; and C:\IDAPI; from your PATH statement if they are present.

(Example:

```
(OLD)  PATH = C:\;C:\WINDOWS;C:\DOS;C:\IDAPI;C:\IBLOCAL\BIN;
```

```
(NEW)  PATH = C:\;C:\WINDOWS;C:\DOS;)
```

Remember to save your new AUTOEXEC.BAT.

## G) Removing files from your WINDOWS and WINDOWS\SYSTEM directories

Please note: These files are listed for reference ONLY. It IS NOT recommended that you delete these files. Deletion of certain files used by other programs WILL cause your system to crash.

CAUTION!!!!CAUTION!!!!CAUTION!!!!CAUTION!!!!CAUTION!!!!  
CAUTION!!!!

Many files shown in this section are shared by other programs. Deleting them may cause other programs not to work INCLUDING WINDOWS. If you wish to remove files from these directories, please do so ONLY at your own discretion. One possible method would be to delete a file, and run ALL other programs on your system to make sure they work. Copies of all files listed below are located on the Delphi CD in the runimage directory. You may copy files from the CD if one that is required is inadvertently deleted. Please be careful.

CAUTION!!!!CAUTION!!!!CAUTION!!!!CAUTION!!!!CAUTION!!!!  
CAUTION!!!!

Files placed or updated in your \WINDOWS directory by  
Delphi:

DELPHI.CBT	M3OPEN.DLL
M3OPEN.EXE	MBW.EXE
MFTP.EXE	MHPARPA.DLL
MNETONE.EXE	MNOVLWP.DLL
MPATHWAY.DLL	MPCNFS.EXE
MPCNFS2.EXE	MPCNFS4.DLL
MSOCKLIB.DLL	MVWASYNC.EXE
MWINTCP.EXE	WINSOCK.DLL

Files placed or updated in your \WINDOWS\SYSTEM  
directory by  
Delphi:

BIBAS04.DLL	BIFLT04.DLL
BIMDS04.DLL	BIPDX04.DLL
BIPDX04.HLP	BIUTL04.DLL
BIVBX11.DLL	BLBAS04.DLL
BLINT04.DLL	BLINT04.HLP
BLMDS04.DLL	BLODBC.LIC
BLUTL04.DLL	BOLE16D.DLL
BTRV110.DLL	BWCC.DLL
CHART2FX.VBX	COMPOBJ.DLL
* COREWIN.DLL	CTL3D.DLL
CTL3DV2.DLL	* DBNMP3.DLL
DRVACCSS.HLP	DRVBTRV.HLP
DRVDBASE.HLP	DRVEXCEL.HLP
DRVFOX.HLP	DRVTEXT.HLP
GAUGE.VBX	* LDLLSQLW.DLL
MSJETDSP.DLL	MULTIHLP.DLL
NWCALLS.DLL	NWIPXSPX.DLL
* NWNETAPI.DLL	ODBC.DLL
ODBCADM.EXE	ODBCCURS.DLL
ODBCINST.DLL	ODBCINST.HLP
OLE2.DLL	OLE2.REG
OLE2CONV.DLL	OLE2DISP.DLL
OLE2NLS.DLL	OLE2PROX.DLL
* ORA6WIN.DLL	* ORA7WIN.DLL
PICT.VBX	PXENGCFG.EXE

PXENGWIN.DLL	QEBI.LIC
RED110.DLL	SIMADMIN.DLL
SIMBA.DLL	STDOLE.TLB
STORAGE.DLL	STRESS.DLL
SWITCH.VBX	TXTISAM.DLL
TYPELIB.DLL	* W3DBLIB.DLL
XBS110.DLL	XLSISAM.DLL

\* - Client/ Server version only

All .BOR files are backup files that Delphi renamed and replaced with updated or modified files, you may use these files in comparison to the files you have changed. If you have installed any software after the .BOR file was created or the .BOR file is the same as the file it replaced, the .BOR file can be deleted.

## Article #15521: Getting / Setting diskette serial # under Windows.

Technical Information Database

TI521D.txt Getting / Setting diskette serial # under Windows.

Category :General Programming

Platform :All

Product :Pascal All

### Description:

(\*

This example demonstrates how to get/set the volume serial number of a diskette under Windows or DOS Protected Mode. This sample demonstrates two important interrupts: Int \$21, service \$69 (Get/Set media info) and Int \$31 (simulate real mode interrupt from DPMI).

NOTE: To use the following code under DPMI instead of Windows, replace all of the occurrences of "WinProcs" with "WinAPI" in the USES clauses.

\*)

```
unit MediaID;  
{ Use this unit in your program }
```

### Interface

### Type

```
PMediaID = ^TMediaID;  
TMediaID = Record  
  InfoLvl:   Word;  
  SerialNum: Longint;  
  VolLabel:  Array[0..10] of Char;  
  FileSys:   Array [0..7] of Char;  
end;
```

```
TRMCS = record      { Real mode call structure }  
  DI, SI, BP, Reserved, BX, DX, CX, AX : Longint;  
  Flags, ES, DS, FS, GS, IP, SP, SS: Word;  
end;
```

```
FUNCTION GetMediaInfo( Drive: WORD; MID: PMediaID ): Boolean;
```

```

FUNCTION SetMediaInfo( Drive: WORD; MID: PMediaID ): Boolean;
  { MID should be a real mode pointer, that is, segment:offset }
  { Allocate memory for MID pointer using GlobalDOSAlloc }
  { Drive: 0=default, 1=A, 2=B, etc. }

```

## Implementation

```

uses WinAPI;

```

```

var

```

```

    R: TRMCS;

```

```

function GetMediaInfo( Drive: WORD; MID: PMediaID ): Boolean;

```

```

var

```

```

    ErrorFlag : byte;

```

```

begin

```

```

    GetMediaInfo := True;

```

```

    R.BX := Drive;    { 0 = Default, 1 = A, 2 = B, etc }

```

```

    R.DS := HiWord(Longint(MID)); { Segment (not selector) of MID }

```

```

    R.DX := LoWord(Longint(MID)); { Offset of MID }

```

```

    R.AX := $6900;    { Real mode service $69, subfunc 0 }

```

```

asm

```

```

    mov bx, 0021h { set flags to $00, Real mode interrupt $21 }

```

```

    mov cx, 0     { copy 0 words from protected mode stack }

```

```

    mov ax, seg R

```

```

    mov es, ax    { selector of real mode call structure }

```

```

    mov di, offset R { offset of real mode call structure }

```

```

    mov ax, 0300h { DPMI simulate real mode interrupt }

```

```

    int 31h

```

```

    pushf        { push flags onto stack }

```

```

    pop  bx      { pop flags into bx }

```

```

    test bx, 0   { error check: is CF flag 0? }

```

```

    je

```

```

done      { if so, then there was no error }

```

```

error:

```

```

    mov  ErrorFlag, 1 { set error flag }

```

```

done:

```

```

end;

```

```

if ErrorFlag = 1 then

```

```

    GetMediaInfo := False; { return False on error }

```

```

end;

function SetMediaInfo( Drive: WORD; MID: PMediaID ): Boolean;
var
  ErrorFlag : byte;
begin
  SetMediaInfo := True;
  R.BX := Drive;    { 0 = Default, 1 = A, 2 = B, etc }
  R.DS := HiWord(Longint(MID)); { Segment of MID }
  R.DX := LoWord(Longint(MID)); { Offset of MID }
  R.AX := $6901;    { Real mode service $69, subfunc 1 }
  asm
    mov bx, 0021h { Real mode interrupt $21 }
    mov cx, 0
    mov ax, seg R
    mov es, ax    { real mode selector call structure }
    mov di, offset R { offset of real mode call structure }
    mov ax, 0300h { DPMI simulate real mode interrupt }
    int 31h
    pushf        { push flags onto stack }
    pop  bx      { pop flags into bx }
    test bx, 0   { error check: is CF flag 0? }
    je
  done          { if so, then there was no error }

  error:
    mov  ErrorFlag, 1 { set error flag }

done:
  end;
  if ErrorFlag = 1 then
    SetMediaInfo := False; { return False on error }
  end;

begin
end.  {*** End of MediaID unit ***}

```

Here is a small sample program that demonstrates how to use the MediaID unit:

```

program DiskInfo;

```

```
uses MediaID, WinProcs, WinCRT;

var
  SReal, SProt : PMediaId;
  LongHandle : Longint;
begin
  { allocate some lower memory }
  LongHandle := GlobalDOSAlloc(SizeOf(TMediaID));
  { real mode pointer }
  SReal := PMediaID(Ptr(HiWord(LongHandle), 0));
  { protected mode pointer }
  SProt := PMediaID(Ptr(LoWord(LongHandle), 0));
  GetMediaInfo(3, SReal);      { call function }
  writeln(SProt^.SerialNum);  { write serial # }
  GlobalDOSFree(LoWord(LongHandle)); { free allocated memory }
end. {*** End of DiskInfo program ***}
```

## Article #15526: Installing Delphi on a Network

Technical Information Database

TI526D.txt - Installing Delphi on a Network

Category :Delphi 1.x  
Platform :All Windows  
Product :

Description:

----Installing Delphi to a network drive----

Note:

Delphi was never intended to be run from a network, and Borland makes no claims in it's ability to do so. This information is provided solely as a starting point and is NOT intended to be a cookbook.

This TI is assuming a basic Windows 3.1 or 3.11 installation. if you are using another operating system, appropriate adjustments will, of course, need to be made.

\*\*\*\*\*

1. Install Delphi to the Network from any Workstation, but be sure to check the "Windows Lan" option if Windows is installed on a server and it's directories are read only.
2. Edit DELPHI.INI in the windows directory.  
-enter:  
    [Globals]  
    PrivateDir = your local directory  
-add:  
    [Library]  
    SearchPath = Netdrive:\DELPHI\LIB  
    ComponentLibrary= your local directory\COMPLIB.DCL

This will allow each user to have his own private options, private DFM file, as well as a private Component Library. If a public component library is desired, the ComponentLibray line

may be left out.

3. Copy COMPLIB.DCL and DELPHI.DMT from the DELPHI\BIN directory to the local private directories.
4. Copy DELPHI.INI to all machines to be running Delphi.

If Windows is on the network, everyone will need to set up their local directories identically, since it will only have that one INI file to work from.

5. If the WINSYS option was selected at install time, there was a DELPHI\WINSYS directory created. There is a bug in the install engine, and not all of the needed files get included. Copy the files from: CDROM:\RUNIMAGE\WINDOWS and CDROM:\RUNIMAGE\WINDOWS\SYSTEM into the WINSYS directory. Then this directory will need to be included in the path. If you wish to copy these files into the WINDOWS\SYSTEM directory, be sure to back up those directories first, in case of file collisions. Care should be taken to not overwrite newer versions of these files. You may find the DOS program REPLACE.EXE useful in accomplishing this.
6. If there was no WINSYS directory created (Step 5), Copy CD:RUNIMAGE\WINDOWS and CD:\RUNIMAGE\WINODWS\SYSTEM directories to all Workstations. Put these files in a separate directory and include it in the path.(This will make uninstalling much easier.)
7. Copy the group file created in the windows directory to all other stations to be using Delphi.
8. Use Program Manager to create the group on these machines.
9. Modify the path on all workstations that will run Delphi as follows:

```
PATH=C:\IBLOCAL\BIN;C:\DELPHI\BIN
```

All users must load the DOS command SHARE(Assuming windows 3.1) before using Delphi.

10. The following line should be added to each user's AUTOEXEC.BAT:  
  
SHARE /F:4096 /L:40

11. Modify the WIN.INI on all machines (assuming a local windows installation,) adding the following:

```
[IDAPI]
DLLPATH=X:\IDAPI;C:\IDAPI
CONFIGFILE01=X:\IDAPI\IDAPI.CFG
```

```
[Borland Language Drivers]
LDPath=X\IDAPI\LANGDRV
```

```
[BWCC]
BitmapLibrary=BWCC.DLL
```

```
[Interbase]
RootDirectory=X:\IBLOCAL
```

```
[Paradox Engine]
UserName=PxEEngine
NetNamePath=X:\
MaxTables=64
RecBufs=64
MaxLocks=64
MaxFiles=64
SwapSize=64
NetNameFDSM=
```

```
[DDE Servers]
DBD=X:\DBD\DBD
```

```
[DBD]
WORKDIR=X:\DBD
PRIVDIR=C:\DBD\DBDPRIV
```

Where X is the Network Drive and path installed to.  
Note that PRIVDIR is set locally.

Note, Delphi will install numerous INI files to the Windows directory. These files can be copied over to other workstations only if the corresponding INI files do not already reside there. (They shouldn't) If this is the case you will have to manually attach these files to the ends of the existing ones.

The INI files that Delphi installs are:

RS\_SQLIF INI  
WINHELP INI  
MULTIHELP INI  
DELPHI INI  
ODBCINST INI  
ODBC INI  
RPTSMITH INI  
RS\_RUN INI  
ODBCISAM INI

The configuration described above should allow for the installed location to be set read only after it is installed, but this was only tested with a local installation of Windows.

## Article #15531: Enabling a horizontal scroll bar for a list box.

Technical Information Database

TI531D.txt - Enabling a horizontal scroll bar for a list box.

Category :General Programming  
Platform :All Windows  
Product :All32Bit,

### Description:

To enable horizontal scroll bars in list boxes you have send the listbox a LB\_SETHORIZONTALTEXT message. The sample code illustrates how to do this in the OnCreate of a form. The form simply has one listbox on it and a button. Clicking on the button removes the horizontal scroll bar.

-- Source code

```

## Article #15536: Making a form selectable without the main form.

Technical Information Database

TI536D.txt Making a form selectable without the main form.

Category :VCL

Platform :All

Product :Delphi All

Description:

Q: How do I make it so that only the form I select comes to the top? (i.e. without the main form)

A: Try this in any secondary window that you DON'T want dragging the program along:

```
...
private {This goes in the form's type declaration.}
  { Private declarations }
  procedure CreateParams(VAR Params: TCreateParams); override;
...

procedure TForm2.CreateParams(VAR Params: TCreateParams);
begin
  Inherited CreateParams(Params);
  Params.WndParent := GetDesktopWindow;
end;
```

By setting the form's parent window handle to the desktop, you remove the link that would normally force the whole application to come to the top when this form comes to the top.

## Article #15556: How to associate a string with a component.

Technical Information Database

TI556D.txt     How to associate a string with a component.

Category     :VCL

Platform     :All

Product      :Delphi   All

Description:

Q: Is there a way to associate a string with each component?

A: Since the Tag property is a longint, you can type cast it as a Pointer or PChar. So, you can basically store a pointer to a record by using the Tag property.

Note: You're not going to be able to store the string, or pointer rather, at design time. This is something you'll have to do at run time. Take a look at this example:

```
var
  i: integer;
begin
  for i := 0 to ComponentCount - 1 do

    if Components[i] is TEdit then
      Components[i].Tag := LongInt(NewStr('Hello '+IntToStr(i)));
end;
```

Here, I loop through the components on the form. If the component is a TEdit, I assign a pointer to a string to its Tag property. The NewStr function returns a PString (pointer to a string). A pointer is basically the same as a longint or better, occupies the same number of bytes in memory. Therefore, you can type cast the return value of NewStr as a LongInt and store it in the Tag property of the TEdit component. Keep in mind that this could have been a pointer to an entire record. Now I'll use that value:

```
var
  i: integer;
begin
```

```

for i := 0 to ComponentCount - 1 do
  if Components[i] is TEdit then begin
    TEdit(Components[i]).Text := PString(Components[i].Tag)^;
    DisposeStr(PString(Components[i].Tag));
  end;
end;

```

Here, again I loop through the components and work on only the TEdits. This time, I extract the value of the component's Tag property by typecasting it as a PString (Pointer to a string) and assigning that value to the TEdit's Text property. Of course, I must dereference it with the caret (^) symbol. Once I do that, I dispose of the string stored in the edit component. Important note: if you store anything in the TEdit's Tag property as a pointer, you are responsible for disposing of it also.

FYI, Since Delphi objects are really pointers to class instances, you can also store objects in the Tag property. As long as you remember to Free them.

Three methods spring to mind to use Tags to access strings that persist from app to app.

1. If your strings stay the same forever, create a string resource in Resource Workshop (or equiv) and use the Tags as indexes into your string resource.
2. Use TIniFile and create a section for your strings, and give each string a name with number so that your ini file has a section like this:

```

[strings]
string1=Aristotle
string2=Plato
string3=Well this is Delphi, after all

```

Then you can fetch them back out this way:

```

var s1: string;
...
s1 := IniFile1.ReadString('strings', 'string'+IntToStr(Tag), '');

```

3. Put your strings into a file, with each followed by a carriage return. Read them into a TStringList. Then your Tags

become an index into this stringlist:

```
StringList1.LoadFromFile('slist.txt');  
...  
s1 := StringList1[Tag];
```

Given the way Delphi is set up, I think the inifile method is easiest.

## Article #15561: How close a file opened from a Delphi DLL in VB.

Technical Information Database

TI561D.txt      How close a file opened from a Delphi DLL in VB.

Category      :Application Interop

Platform      :All

Product       :Delphi 1.0

Description:

Q: How do I close a file that was opened in a DLL (Delphi made) and called from VB?

A: This is a known problem. It comes from the fact that VB closes the 5 DOS standard handles (0..4) at startup. So the open file routine will reuse one of these handles to open the first disk file. That is not a problem in using the file, but the Pascal Close routine has a build-in safety feature: it refuses to close a file that has one of the standard handles! That is a Good Thing under DOS but screws up the works in your situation since the file opened by the DLL is never closed, not even when the DLL goes down! VC++ is obviously less restricted and will close a standard handle.

You can fix this problem yourself. Instead of using the Pascal Close/CloseFile routine to close the file in the DLL, use one of these:

```
Procedure ReallyCloseFileVar(Var F); Assembler;
```

```
{ F should be a file type }
```

```
Asm
```

```
  les  bx, F                { store F in es:bx }
  mov  bx, word ptr es:[bx] { store handle in bx }
  mov  ah, $3E              { function 3Eh = close file }
  call Dos3Call             { execute int 21h }
```

```
End;
```

```
Procedure ReallyCloseFileHandle(FileHandle: word); assembler;
```

```
{ FileHandle is the DOS file handle }
```

```
asm
```

```
  mov  bx, Handle { store handle in bx }
  mov  ah, $3E    { function 3Eh = close file }
```

```
    call DOS3Call    { execute int 21h }  
end;
```

## Article #15566: Changing the border color in DOS text mode.

Technical Information Database

TI566D.txt Changing the border color in DOS text mode.

Category :General Programming

Platform :All

Product :Pascal All

### Description:

Ever wonder how to change the color of the border around your screen in DOS text mode? It's actually very simple - just call DOS interrupt \$10, function \$0B. This sample code illustrates how. You just drop the BorderColor procedure into any of your DOS text mode programs.

Program ChBorder;

```
procedure BorderColor(NewColor: byte); assembler;
{ simply call this procedure and pass it the number }
{ of the color to which you would like the text-mode }
{ border to change. }
asm
    mov ah, 0Bh
    mov bh, 00h
    mov bl, NewColor
    int 10h
end;

begin
    BorderColor(2);
end.
```

## Article #15571: How to readln longer than 255 chars.

Technical Information Database

TI571D.txt      How to readln longer than 255 chars.

Category      :General Programming

Platform      :All

Product       :Delphi 1.0

Description:

Q: How can I readln() from a file when the lines are longer than 255 bytes?

A: ReadLn will accept an array [0..something] of Char as buffer to put the read characters in and it will make a proper zero-terminated char out of them. The only limitation is this: the compiler needs to be able to figure out the size of the buffer at compile time, which makes the use of a variable declared as PChar and allocated at run-time impossible.

Workaround:

Type

```
{use longest line you may encounter here}
```

```
TLine = Array [0..1024] of Char;
```

```
PLine = ^TLine;
```

Var

```
pBuf: PLine;
```

```
...
```

```
New( pBuf );
```

```
...
```

```
ReadLn( F, pBuf^ );
```

To pass pBuf to functions that take a parameter of type PChar, use a typecast like PChar( pBuf ).

Note: you can use a variable declared as of type TLine or an equivalent array of char directly, of course, but I tend to allocate anything larger than 4 bytes on the heap...

## Article #15576: A VERY short primer on dynamic memory allocation.

Technical Information Database

TI576D.txt     A VERY short primer on dynamic memory allocation.  
Category     :General Programming  
Platform     :All  
Product     :Delphi 1.0

Description:

Q: How do I reduce the amount of memory taken from the data segment? (or How do I allocate memory dynamically?)

A:

Let's say your data structure looks like this:

```
type
  TMyStructure = record
    Name: String[40];
    Data: array[0..4095] of Integer;
  end;
```

That's too large to be allocated globally, so instead of declaring a global variable,

```
var
  MyData: TMyStructure;
```

you declare a pointer type,

```
type
  PMyStructure = ^TMyStructure;
```

and a variable of that type,

```
var
  MyDataPtr: PMyStructure;
```

Such a pointer consumes only four bytes of the data segment.

Before you can use the data structure, you have to allocate it

on the heap:

```
New(MyDataPtr);
```

and now you can access it just like you would global data. The only difference is that you have to use the caret operator to dereference the pointer:

```
MyDataPtr^.Name := 'Lloyd Linklater';  
MyDataPtr^.Data[0] := 12345;
```

Finally, after you're done using the memory, you deallocate it:

```
Dispose(MyDataPtr);
```

## Article #15578: HEAP SPACE STILL CREATED WITH HEAP MAX 0

Technical Notes Database

TN578D.txt      HEAP SPACE STILL CREATED WITH HEAP MAX 0  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 5.5

### Description:

- Q. Compiling to disk with my heap maximum set to 0 still creates heap space when running .EXE file. Why?
- A. This has to do with the way DOS allocates memory for .EXE files in chunks of 512 bytes, rather than in chunks of 16 bytes. As a result of DOS's allocation, you always get 0-496 bytes more than you request.

## Article #15582: How to use array of const.

Technical Information Database

TI582D.txt     How to use array of const.  
Category     :Object Pascal  
Platform     :All  
Product      :Delphi All

Description:

Q: How do I use "array of const"?

A: An array of const is in fact an open array of TVarRec (a predeclared Delphi type you can look up in the online help). So the following is Object Pascal psuedocode for the general battle plan:

```
procedure AddStuff( Const A: Array of Const );
Var i: Integer;
Begin
  For i:= Low(A) to High(A) Do
    With A[i] Do
      Case VType of
        vtExtended: Begin
          { add real number, all real formats are converted to
            extended automatically }
          End;
        vtInteger: Begin

          { add integer number, all integer formats are converted
            to LongInt automatically }
          End;
        vtObject: Begin
          If VObject Is DArray Then
            With DArray( VObject ) Do Begin
              { add array of doubles }
            End
          Else If VObject Is IArray Then
            With IArray( VObject ) Do Begin
              { add array of integers }
            End;
          End;
        End;
      End;
```

```
End; { Case }  
End; { AddStuff }
```

For further information see "open arrays" in the on-line help.

## Article #15587: Making your own hotkeys.

Technical Information Database

TI587D.txt Making your own hotkeys.

Category :VCL

Platform :All

Product :Delphi All

Description:

Q: How can I trap for my own hotkeys?

A: First: set the form's KeyPreview := true;

Then, you do something like this:

```
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
begin
  if (ssCtrl in Shift) and (chr(Key) in ['A', 'a']) then
    ShowMessage('Ctrl-A');
end;
```

## Article #15593: How to scroll your form with pgUP and pgDn.

Technical Information Database

TI593D.txt     How to scroll your form with pgUP and pgDn.

Category     :VCL

Platform     :All

Product     :Delphi   All

### Description:

Q.     How can you do scrolling functions in a TForm component using keyboard commands? For example, scrolling up and down when a PgUp or PgDown is pressed. Is there some simple way to do this or does it have to be programmed by capturing the keystrokes and manually responding to them?

A.     Form scrolling is accomplished by modifying the VertScrollbar or HorzScrollbar Position properties of the form. The following code demonstrates how to do this:

```
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

## Article #15601: EXEC - SETTING HEAP MEMORY

Technical Notes Database

TN601D.txt      EXEC - SETTING HEAP MEMORY  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

Q. How do I set the heap memory when executing a child process?

A. Probably the best way to do this is through trial and error.

Set the heap maximum to some large value, and run the program.

If it runs out of memory, then divide the maximum by 2, and so on, until the parent and child programs have enough memory.

The same can be done with the heap minimum. Also, if you have access to CompuServe, you can download a routine that swaps the parent program between memory and disk.

## Article #15605: Drag a form without clicking the caption bar

Technical Information Database

TI605D.txt Drag a form without clicking the caption bar

Category :VCL

Platform :All

Product :Delphi All

Description:

{  
Q: How can I make a form move by clicking and dragging in the client area

instead of on the caption bar?

A: The easiest way to do this is to "fool" Windows into thinking that you're actually clicking on the caption bar of a form. Do this by handling the `wm_NCHitTest` windows message as shown in the sample

unit  
below.

TIP: If you want a captionless borderless window similar to a floating toolbar, set the Form's Caption to an empty string, disable all of the `BorderIcons`, and set the `BorderStyle` to `bsNone`.  
}

```
unit Dragmain;
```

```
interface
```

```
uses
```

```
SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,  
Forms, Dialogs, StdCtrls;
```

```
type
```

```
TForm1 = class(TForm)
```

```
  Button1: TButton;
```

```
  procedure Button1Click(Sender: TObject);
```

```
private
```

```
  procedure WMNCHitTest(var M: TWMNCHitTest); message wm_NCHitTest;
```

```

end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMNCHitTest(var M: TWMNCHitTest);
begin
  inherited;           { call the inherited message handler }
  if M.Result = htClient then { is the click in the client area? }
    M.Result := htCaption; { if so, make Windows think it's }
                          { on the caption bar. }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Close;
end;

end.

```

{ The text representation of the .DFM file is below:

```

object Form1: TForm1
  Left = 203
  Top = 94
  BorderIcons = []
  BorderStyle = bsNone
  ClientHeight = 273
  ClientWidth = 427
  Font.Color = clWindowText
  Font.Height = -13
  Font.Name = 'System'
  Font.Style = []
  PixelsPerInch = 96
  TextHeight = 16
  object Button1: TButton
    Left = 160
    Top = 104
    Width = 89
    Height = 33
    Caption = 'Close'
  end
end

```

```

## Article #15607: TAKING ADVANTAGE OF IEEE FLOATING-POINT TYPES

Technical Notes Database

TN607D.txt      TAKING ADVANTAGE OF IEEE FLOATING-POINT TYPES  
Category      :Pascal  
Platform      :All  
Product       :Turbo Pascal    5.0 5.5

### Description:

- Q. What is the best approach to taking advantage of the new IEEE floating-point types?
- A. The new IEEE floating-point types are available when you compile your program with `{N+}` and you have a math coprocessor; they are also available if you don't have a coprocessor, but specify `{N+,E+}`. The 8087 emulator has greater precision, but is significantly slower than the fast, 6-byte, software-only reals. When developing programs that will be compiled and run on machines without the 8087 coprocessor, consider the tradeoffs of speed (built-in reals) vs. precision (8087 hardware/emulation) and make the appropriate choice.

## Article #15613: TRUNC - CONVERTING REAL NUMBERS INTO INTEGERS

Technical Notes Database

TN613D.txt TRUNC - CONVERTING REAL NUMBERS INTO INTEGERS

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

Description:

Q. How do you convert real numbers into integers?

A. Use the Round or Trunc function and assign the result to an integer:

```
var i : integer;
begin
  i := round(12.43); i := trunc(22.22);
end.
```

## Article #15617: Accessing more than 15 files from your DOS app.

Technical Information Database

TI617D.txt     Accessing more than 15 files from your DOS app.

Category     :General Programming

Platform     :All

Product      :Pascal   All

### Description:

DOS imposes a limit of 20 open files for any one program. DOS, friendly

as it is, uses 5 of these file handles internally - leaving your application with only 15 available file handles. Fortunately, the 15-file barrier is easily broken. Just add the GetMoreHandles() function to

your application, and call it in the beginning of your program, passing it

the number of handles you would like your application to have available.

The number you pass must be in the range of 20 to 255, and it must not exceed the number specified in the FILES= statement of your CONFIG.SYS.

uses DOS;

```
function GetMoreHandles(NumHandles: Word): Boolean;
```

```
\{
```

```
  NumHandles is the number of file handles you want your application
  to have available.  If an error occurs, function will return False,
  and any DOS error will be reported in the DOSError global variable.
  NOTE: NumHandles must be less than or equal to the number specified
  in the FILES= statement in your CONFIG.SYS.
```

```
\}
```

```
Var
```

```
  ReturnVal: Boolean;
```

```
begin
```

```
  ReturnVal := True;  \{ assume success \}
```

```
  \{ Check to make sure DOS version is greater than 3.3 \}
```

```
  if (((DOSVersion and $00FF) = 3) and ((DOSVersion and $FF00) < 3))
```

```
or
```

```
    ((DOSVersion and $00FF) < 3) then ReturnVal := False;
\{ Can't allocate more than 255 or less than 20 handles \}
if (NumHandles > 255) or (NumHandles < 20) then ReturnVal := False;
if ReturnVal then asm
    mov ax, 6700h           \{ function 67h \}
    mov bx, NumHandles     \{ requested handles in bx \}
    int 21h                \{ DOS call \}
    jae @@NotAnError       \{ CF set on error \}
    mov ReturnVal, 00h     \{ return false on error \}
    mov DOSError, ax       \{ ax contains the error code \}
    @@NotAnError:
end;
GetMoreHandles := ReturnVal;
end;

## Article #15619: RANDOM RANDOMIZE - RANDOM NUMBER GENERATOR FORMULA

Technical Notes Database

TN619D.txt      RANDOM RANDOMIZE - RANDOM NUMBER GENERATOR FORMULA

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

Description:

Q. What is the formula used by the random number generator in Turbo Pascal?

A. The random number generator in Turbo Pascal uses 32-bit arithmetic. It maintains a 32-bit 'seed', which is treated as an unsigned integer. Each call to Random changes the seed by the formula  $\text{seed} := \text{multiplier} * \text{seed} + 1 \text{ mod } 4294967296$ . Turbo Pascal uses the multiplier, 134775813. The modulus, 4294967296, is 2 to the power 32. The multiplier was chosen carefully for its nice randomness properties. The seed will take on every 32-bit integer before repeating.

## Article #15623: How to Circumvent the "index not found" Exception.

Technical Information Database

TI623D.txt - How to Circumvent the "index not found" Exception.

Category :Database Programming  
Platform :All-32Bit  
Product :

### Description:

Q: How do I open a dBASE table without the required MDX file?  
I keep getting an "Index not found..." exception.

A: When you create a dBASE table with a production index (MDX), a special byte is set in the header of the DBF file. When you subsequently attempt to re-open the table, the dBASE driver will read that special byte, and if it is set, it will also attempt to open the MDX file. When the MDX file cannot be opened, an exception is raised.

To work around this problem, you need to reset the byte (byte 28 decimal) in the DBF file that causes the MDX dependency to zero.

The following unit is a simple example of how to handle the exception on the table open, reset the byte in the DBF file, and re-open the table.

```
unit Fixit;

interface

uses
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,
  Controls, Forms, Dialogs, StdCtrls, DB, DBTables, Grids, DBGrids;

type
  TForm1 = class(TForm)
    Table1: TTable;
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  end;
```

```
private
  { Private declarations }
public
  { Public declarations }
end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
const
  TheTableDir = 'c:\temp\';
  TheTableName = 'animals.dbf';
```

```
procedure RemoveMDXByte(dbFile: String);
{ This procedure accepts a DBF file as a parameter. It will patch }
{ the DBF header, so that it no longer requires the MDX file }
```

```
const
  Value: Byte = 0;
```

```
var
  F: File of byte;
```

```
begin
  AssignFile(F, dbFile);
  Reset(F);
  Seek(F, 28);
  Write(F, Value);
  CloseFile(F);
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
{ This procedure is called in response to a button click. It }
{ attempts to open a table, and, if it can't find the .MDX file, }
{ it patches the DBF file and re-execute the procedure to }
{ re-open the table without the MDX }
```

```
begin
  try
    { set the directory for the table }
    Table1.DatabaseName := TheTableDir;
    { set the table name }
    Table1.TableName := TheTableName;
    { attempt to open the table }
    Table1.Open;
```

```
except
  on E:EDBEngineError do
    { The following message indicates the MDX wasn't found: }
    if Pos('Index does not exist. File', E.Message)>0 then begin
      { Tell user what's going on. }
      MessageDlg('MDX file not found. Attempting to open
                  without index.', mtWarning, [mbOk], 0);
      { remove the MDX byte from the table header }
      RemoveMDXByte(TheTableDir + TheTableName);
      { Send the button a message to make it think it was }
      { pressed again. Doing so will cause this procedure to }
      { execute again, and the table will be opened without }
      { the MDX }
      PostMessage(Button1.Handle, cn_Command, bn_Clicked, 0);
    end;
  end;
end;

end.
```

## Article #15625: ROUNDING WITH IEEE FLOATING-POINT

Technical Notes Database

TN625D.txt      ROUNDING WITH IEEE FLOATING-POINT

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

### Description:

Q. How does rounding work with IEEE floating-point numbers?

A. The 8087 math coprocessor uses a different method for rounding numbers than what you may be used to. In order to achieve a more even distribution of values, the 8087 uses a method sometimes called "Banker's Rounding." This method dictates that a number will always be rounded to the nearest EVEN number. Note that this is quite different than always rounding UP. Here are a couple of examples:

Round(0.5) = 0

Round(1.5) = 2

## Article #15630: Compiling RWPDemo.pas in Turbo Pascal for Windows.

Technical Notes Database

TN630C.txt      Compiling RWPDemo.pas in Turbo Pascal for Windows.

Category      :Pascal

Platform      :All

Product       :RW 1.0

Description:

QUESTION:

Why do I get a Type Mismatch error at line 191 when compiling RWPDemo.Pas?

ANSWER:

RWPDemo needs a compile directive to be turned on. The trick is to place then BWCC compiler directive in the Options Compiler dialog in Conditional Define field. Then the application must be compiled using BUILD. If BUILD is not used the some of the units that are used by the demo will not be compiled.

## Article #15641: College Student Guide to Reading and Writing Files

Technical Information Database

TI641D.txt College Student Guide to Reading and Writing Files  
Category :General Programming  
Platform :All  
Product :Delphi All

### Description:

College Student Crib Notes to:

- 1) Printing out your programs' output to a file.
- 2) Printing out your programs' output to the printer.
- 3) Reading from an input file.

### Printing Out Your Programs Output to a File

----- --- ---- ----- ----- -- - ----

Often times, professors will require more than your honesty and good faith to receive full credit for your program. They will want to see both your program listing and the output generated from the program. But how do you do this in Delphi and our Pascal Products ???

Simply in Delphi ....

```
program CrtApp;
uses WinCrt;
var outfile: TextFile;
begin
  AssignFile(outfile, 'c:\outfile.txt');
  Rewrite(outfile);
  writeln(outfile, 'Hello World from Delphi');
  writeln(outfile, 'My Program works, and here is ' +
            'the output to prove it...');
  CloseFile(outfile);
end.
```

Simply in Pascal .....

```
Program HelloWorld;
```

```

var
  outfile: text;
begin
  assign(outfile, 'c:\output.txt');
  rewrite(outfile);
  writeln(outfile, 'Hello World');
  writeln(outfile, 'My Program works, and here is the
                output to prove it...');
  close(outfile);
end.

```

## Printing Out Your Programs' Output to the Printer

-----

In some cases, there may be a need to print output directly to the printer. This is the way.

In Delphi ...

```

program CrtApp;
uses WinCrt;
var outfile: TextFile;
begin
  assignfile(outfile, 'LPT1');
  rewrite(outfile);
  writeln(outfile, 'Hello World from Delphi');
  writeln(outfile, 'My Program works, and here is ' +
                'the output to prove it...');
  closefile(outfile);
end.

```

In Pascal ...

```

Program HelloWorld;
var
  outfile: text;
begin
  assign(outfile, 'LPT1');
  rewrite(outfile);
  writeln(outfile, 'Hello World');
  writeln(outfile, 'My Program works, and here is the
                output to prove it...');
  close(outfile);
end.

```

## Reading From an Input File

-----

Many times, it will be necessary to read information from an input file supplied by another person. This is an example of how to implement this.

In Delphi ...

```
program CrtApp;
uses WinCrt;
var
  infile, outfile: TextFile;
  num_lines, x: integer;
  line: string;
begin
  assignfile(infile, 'C:\INFILE.TXT');
  assignfile(outfile, 'C:\OUTFILE.TXT');
  reset(infile); {reset moves the pointer to the beginning}
                  {of the file.}
  rewrite(outfile); {clears the contents of the file}
  readln(infile, num_lines);
  for x:= 1 to num_lines do
  begin
    readln(infile, line);
    writeln(outfile, line);
  end;
  closefile(infile);
  closefile(outfile);
end.
```

In Pascal ...

```
Program ReadInput;
var
  infile, outfile: text;
  num_lines, x: integer;
  line: string;
begin
  assign(infile, 'C:\INFILE.TXT');
  assign(outfile, 'C:\OUTFILE.TXT');
  reset(infile); {reset moves the pointer to the beginning}
                  {of the file.}
  rewrite(outfile); {clears the contents of the file}
  readln(infile, num_lines);
```

```
for x:= 1 to num_lines do
begin
  readln(infile, line);
  writeln(outfile, line);
end;
close(infile);
close(outfile);
end.
```

```
{START INFILE.TXT}
```

```
2
```

```
Hello World
```

```
My Program works, and here is the output to prove it.
```

```
{END INFILE.TXT}
```

-----

## Article #15643: COMP TYPE USES

Technical Notes Database

TN643D.txt      COMP TYPE USES  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

Q. What type is Comp? What is it useful for?

A. The Comp type is a cross between an integer and a real type and is available when 8087 code is generated {\$N+}. If no math coprocessor is available, specify {\$N+,E+} and the emulator will support the Comp type. The compiler treats it as a real type without an exponent. Thus Comp is useful when you need to store extremely large numbers but don't need a decimal point. For example, you might use variables of type Comp to store amounts in cents and divide the value of the variable by 100 to determine what the value in dollars and cents would be.

## Article #15647: Using FindFirst and FindNext to find directories.

Technical Information Database

TI647D.txt Using FindFirst and FindNext to find directories.

Category :General Programming

Platform :All

Product :Pascal All

Description:

```
{
  Finding directories using Pascal's FindFirst() and
  FindNext() procedure can be a bit tricky. By default,
  FindFirst() and FindNext() will find ALL files. Not
  just directories. To determine if what FindFirst()
  and FindNext() finds is really a directory, you must
  check the Attr field of the SearchRec to determine
  if the attribute indicates that the element is a
  directory.
```

The following program adds only directory names to an array of strings.

```
}

program FindIt;

uses DOS;

const
  ArrayLimit = 512;

type
  DOSFileName = String[12];

var
  SR: SearchRec;
  A: array[1..ArrayLimit] of DOSFileName;
  i: integer;

begin
  i := 1;
  { find the first directory }
```

```
FindFirst('c:\*.*', Directory, SR);
{ check for an error }
If DosError = 0 then begin
  repeat
    { is it really a directory? }
    if (SR.Attr and Directory) <> 0 then begin
      A[i] := SR.Name; { add dir to array }
      i := i + 1;      { increment index }
    end;
    FindNext(SR);      { find next directory }
  { exit loop if a DOS error occurs }
  until DosError <> 0;
end
else
  { Write error if FindFirst() fails }
  Writeln('Can''t do it. Error code: ', DOSError);
end.
```

## Article #15653: Delphi Fact Sheet

Technical Information Database

TI653D.txt - Delphi Fact Sheet

Category :Delphi 1.x  
Platform :All Windows  
Product :

Description:

Delphi Fact Sheet

Delphi is the only Windows development tool to combine the Rapid Application Development (RAD) benefits of visual component-based design with the power of an optimizing native code compiler and scalable database access.

Delphi represents the next generation in:

- Performance--with the world's fastest compiler
- Rapid Application Development--via visual Two-Way-Tools()
- Component Reuse--a true object-oriented environment
- Scalable Database Access--the fast track to client/server

The fastest way to the fastest applications

Delphi is the next generation Windows development tool, combining the most intuitive visual design environment with the unrivaled performance of a world-class optimizing native code compiler. It compiles Windows applications at more than 350,000 lines per minute.\* An automatic MAKE facility ensures that only code that has been changed is recompiled for maximum efficiency, and the built-in assembler allows for ultimate fine-tuned performance.

The resulting executable files (EXEs) are lean, highly efficient, and run up to 10 to 20 times faster than interpreted p-code. Delphi executables are immediately deployable, royalty-free, and require no runtime interpreter Dynamic Link Library (DLL), so maximum performance is guaranteed.

RAD, from prototype to production

The comprehensive suite of visual design and debugging tools accelerate development so you move seamlessly from prototyping to deployment. You'll create high-performance applications in record time with the gallery of reusable forms, project templates, programming experts, and context-sensitive intelligent help.

And smart computer-based tutorials guide you through your project and help explain concepts. The Object Inspector; provides complete access to properties and events of a selected component, with smart Property Editors for rapid design changes. The Project Manager provides an overview of all forms and code for a development project, while the ObjectBrowser() provides a graphical view of the overall object hierarchy.

The sophisticated GUI Debugger jumps directly to the point in the source code where problems occur, so you can find and fix problems quickly and easily. And full support for conditional breakpoints, watchpoints, call stack monitoring, single-step execution, and trace mode are included.

A suite of powerful Windows resource editors lets you create and modify menus, icons, cursors, and bitmaps for low-level debugging. The WinSight() utility allows you to monitor the Windows messaging flow, while WinSpector() instantly provides comprehensive diagnostic details.

Visual Two-Way-Tools for power programming

With Delphi, you can always get to your code, and everything you can do visually can also be done in code. Innovative Two-Way-Tools maximize your productivity by letting you move seamlessly between the visual design environment and the synchronized underlying source code.

Switching between the visual design mode and the intelligent BRIEF;-style source code editor is rapid and intuitive. It supports advanced editing features such as Color Syntax Highlighting, macro recording, column block marking, and regular expression support.

## Reuse components to maximize productivity

The comprehensive Visual Component Library (VCL), a collection of more than 75 objects such as dialogs, buttons, and list boxes, includes a host of additional reusable objects including database controls, notebook tabs, grids, multimedia controls, and much more!

The completely customizable Integrated Development Environment can be tailored to individual or corporate preferences. Custom reusable components and commercial VBXs are easily added to the fully reconfigurable Component Palette. You can create and install your own application and form templates. And the Delphi component-based architecture allows you to seamlessly integrate DLLs, VBBX controls, and OLE 2.0 servers into your applications.

## Integrated database support and reporting capabilities

Delphi incorporates the Borland Database Engine (BDE), providing direct access to data stored in dBASE, Paradox, and the Local InterBase Server, and to other data formats via ODBC. And data-aware controls allow manipulation of live data at design time, improving project turnaround time.

A comprehensive selection of Visual Data Objects helps make sophisticated database application design a breeze. And the included Database Desktop() utility lets you create or restructure tables and manage connections, insulating compiled Delphi applications from changes in database locations.

Delphi also includes the PC version of ReportSmith; Borland's award-winning database reporting and query tool that supports live data access at design time. ReportSmith supports a wide range of popular database formats, and

provides a variety of graphing, tabulating, and charting options.

## The ultimate complementary tool

If you prefer to work with a variety of programming tools, Delphi is the perfect addition to your toolset. It allows

you to create reusable DLLs that can be called from applications built with C++, Paradox, dBASE, PowerBuilder, Visual Basic, and other popular development tools. Delphi can also use standard VBX controls, OLE2.0 servers, DLLs created by other development tools, Microsoft multimedia, MAPI, and pen computing APIs. No matter what you program with today, the Delphi component-based design makes it a valuable addition that leverages your existing investment in code.

Delphi gives you the control and flexibility you demand with complete access to the Windows API, while shielding you from the complexities of Windows programming.

## Object-Oriented Programming

The underlying Object Pascal language has been enhanced to fully support exception handling. All your GPFs, disk I/O errors, and other dreaded problems are automatically trapped. And it offers all of the benefits of a structured programming language and a true object-oriented development tool, including polymorphism, inheritance, and encapsulation. So Delphi applications are incredibly robust and deliver superior solutions for all of your mission-critical projects.

Enhanced compiler features such as conditional compilation and smart linking make it even easier to rapidly design professional applications intended for a variety of target environments.

## Fast track to Windows 95

Delphi applications developed for the Windows 3.1 operating environment will also run under Windows 95 and Windows NT. Upgrading them to full 32-bit performance simply involves a single-click recompile with the forthcoming Windows 95 version of Delphi. No rewriting of code is necessary!

## Smooth scaling to client/server

Delphi provides an easy path to the fast-growing market of client/server applications development. Transparent local SQL development is possible with Delphi, using the built-in Local InterBase Server, which enables you to rapidly develop

high-performance ANSI SQL-92 compliant applications for standalone systems.

To make the transition from Delphi to professional client/server development and deployment using external database hosts, upgrade to Delphi Client/Server. It's a quick and easy process requiring no additional coding. Delphi Client/Server features high-performance native drivers for Oracle, Sybase, Informix, and InterBase, along with team development support, a Visual Query Builder tool, and much more.

Delphi, the developer's solution

- Quickly and easily customize the Component Palette.
- Delphi gives you everything you need for Rapid Application Development.
- Manage all your code and visual objects with the Object Inspector.
- Two-Way-Tools give you complete control of your code.
- The Visual Component Library lets you build complete database applications in minutes.

Delphi Specifications

## Optimizing Native Code Compiler

- Compiles at over 350,000 lines per minute\*
- Create fast standalone EXEs with no runtime interpreter  
Dynamic Link Library (DLL)
- Applications run up to 10 to 20 times faster than  
interpreted p-code
- Create DLLs that work with C++, dBASE, Paradox, Visual  
Basic, PowerBuilder, and others
- Access to all Windows API functions and messages
- Optimized case statements, sets, 32-bit math operations,  
string and file routines, and more
- Math coprocessor and emulator support
- Automatic built-in MAKE facility
- Conditional compilation
- Smart Linker removes unused objects and code
- Command-line compiler and MAKE facility
- Built-in assembler for tuning performance
- Linker optimization for smaller EXEs

## Integrated Development Environment

- Integrated visual form designer with over 75 components
- Two-Way-Tools automatically synchronize code and visual  
representations
- Object Inspector allows visual customization of  
components without writing code
- Built-in tools for alignment, scaling, sizing, and tab  
order
- ObjectBrowser displays object hierarchy, units, globals,  
and code references
- Project Manager displays all files and forms
- Customizable environment including SpeedBar, Component  
Palette, editor, and browser
- Intuitive Icon, Bitmap, and Menu editors
- Open environment for adding your own tools, experts,  
components, and Property Editors

## Visual Component Library (VCL)

- Customizable palette of over 75 reusable components
- Support for the latest Microsoft systems technologies  
including OLE 2.0, DDE, VBXs, DLLs, MAPI, and ODBC
- Standard components for menus, bitmapped buttons, masked  
edit fields, panels, graphics, notebook tabs, grids,  
outlines, list boxes, combo boxes, check boxes, labels,  
and more
- Visual Data Objects for accessing databases, tables,

queries, reports, SQL stored procedures, as well as data-aware grids, navigators, lookup lists, edit fields, list boxes, combo boxes, memos, bitmaps, and more

- "Live" design-time data access
- Extend the VCL at any time with third-party libraries or with your own objects created with Delphi
- Database Field Editor for validation rules, display format, edit mask, and field width
- Standard dialog objects for file operations, printing, font and color selection, and searching
- System objects for accessing OLE 2.0 servers, DDE, multimedia and file, and directory lists
- Support for MDI, printing, and graphics
- 2-D and 3-D charts with included ChartFX control
- Compatible with hundreds of VBX controls
- Includes sample objects with complete source code written in Delphi
- VCL source code available separately

#### Object Pascal Language

- High-performance, structured, object-oriented language
- Complete support for inheritance, polymorphism, and encapsulation
- Control over privacy with Public, Private, Protected, and Published reserved words
- Create components with properties and events
- Use inheritance to customize any object
- Automatic runtime type information and object persistence
- Automatic, extensible exception handling
- Support for open arrays, user-defined types, objects, and pointers
- Advanced language support for delegation and class references
- Separate compilation of units and DLLs
- Over 150 library routines for mathematical operations, string manipulation, text formatting, and file management
- WinCRT unit for creating standard Pascal "console" programs
- Compiles Borland Pascal 7.0 for Windows code

#### Powerful Editing

- Full-featured BRIEF-style editing
- Unlimited undo and redo
- No limit on file size

- Macro record and playback
- Column block marking
- Regular expression (GREG-style) search
- Customizable Color Syntax Highlighting
- Selectable editor keystrokes with support for BRIEF and Epsilon

#### Integrated Debugging

- Integrated GUI Debugger with single-step and trace
- Conditional breakpoints and watchpoints
- Call stack view for tracing code execution
- Evaluate and modify expressions and variables
- WinSight Windows message trace utility
- WinSpector postmortem analysis tool
- Compatible with Turbo Debugger for Windows (available separately)

#### Borland Database Engine

- High-performance engine with native drivers for dBASE, Paradox, and Local InterBase Server
- Fully scalable support for migrating applications from desktop to client/sserver
- Royalty-free deployment of database engine
- Space-efficient deployment of database applications
- Includes Database Desktop for managing database aliases as well as creating and restructuring tables
- ODBC support for Access, Btrieve, Excel, DB2, AS/400, Ingres, HP ALBASE/SQL, and gateways like IBM DDCS/2, Micro Decisionware and Sybase Net-gateway. (available separately)
- Delphi Client/Server includes SQL Link native drivers for InterBase, Oracle, Sybase, Microsoft SQL Server, and Informix. (available separately)

#### Local InterBase 4.0 Server

- High-performance ANSI SQL-92 compliant
- Ideal for "off-line" development and single-user applications
- Computed fields
- Outer joins and join expressions in the where clause
- Complex data including Binary Large Objects (BLOBs()) and multidimensional arrays
- Advanced features including stored procedures, triggers, and constraints
- Fully scalable to InterBase on NT, NetWare, and UNIX

platforms

- Local InterBase Server Deployment Kit available separately

### ReportSmith 2.5

- Award-winning database reporting and query tool
- Access ReportSmith from the Delphi Tools menu and TReport component
- Features "live" report writing
- Adaptive data access works with any size database
- Prebuilt report templates and styles
- Crosstab and mailing label reports
- Multilevel sorting
- Custom group specifications
- Onscreen Print Preview mode
- Free distribution of ReportSmith runtime module
- Fully compatible with ReportSmith SQL edition

### Documentation and Help

- Extensible gallery of application templates and experts
- Seven Interactive Tutors() with "live" interaction
- Over 5Mb of on-line help
- Five manuals with over 1,200 pages of documentation: Delphi User's Guide, Component Writer's Guide, Database Application Developer's Guide, Creating Reports, and InterBase User's Guide

### Minimum System Requirements

- Intel 386-based PC or higher
- Microsoft Windows 3.1 or later, 100%-compatible version
- 6Mb of extended memory or higher
- 30Mb hard disk space
- CD-ROM drive (3.5" disks available separately)

### Networks Supported

Any Microsoft Windows 3.1 compatible network, including OS/2 2.1, Novell NetWare, Windows for Workgroups 3.11, and Windows NT 3.11.

Description:

Borland Delphi for Windows Quick Info Guide

RADical performance Windows development

Delphi is the only Windows development tool to combine the Rapid Application Development (RAD) benefits of visual component-based design, with the power of an optimizing native code compiler and scalable database access.

Delphi represents the next generation in:

- Performance--with the world's fastest compiler
- Rapid Application Development--via visual Two-Way-Tools
- Component Reuse--a true object-oriented environment
- Scalable Database Access--the fast track to client/server

The fastest way to the fastest applications

Delphi is the next-generation Windows development tool, combining the visual design environment with the unrivaled performance of a world-class optimizing native code compiler. Delphi includes the world's fastest compiler, capable of compiling Windows applications at more than 350,000 lines per minute, resulting in executable files (EXEs) that are robust and lightning-fast.

Delphi executables are also immediately deployable and completely royalty-free, and no runtime interpreter Dynamic Link Library (DLL) is required. Delphi applications

typically execute up to 10 to 20 times faster than interpreted p-code.

Only Borland can offer this unique combination of integrated tools including its award-winning report writer, ReportSmith, the Borland Database Engine, and the Local InterBase Server.

RAD, from prototype to production

Delphi accelerates Windows development by providing a comprehensive suite of visual design and debugging tools that move you seamlessly from prototyping to deployment of finished applications. Delphi's Two-Way-Tools help you optimize your programming time by switching effortlessly between visual design and the underlying source code.

Reuse components to maximize productivity

Included with Delphi is the comprehensive Visual Component Library (VCL), a collection of more than 75 standard Windows objects such as dialogs, buttons, and list boxes, along with a host of additional reusable objects including database controls, notebook tabs, grids, multimedia controls, and much more! Delphi's Integrated Development Environment (IDE) is fully customizable. Custom reusable components, external DLLs, and commercial VBXs can be rapidly added to Delphi's Component Palette.

Delphi is a true object-oriented development tool, including polymorphism, inheritance, and encapsulation. Delphi's component-based architecture allows you to seamlessly integrate DLLs, VBX controls, and OLE 2.0 servers into your applications.

Smooth scaling to client/server

Delphi has been designed to provide an easy path to the fast-growing market of client/server applications development. Transparent local SQL development is possible with Delphi, using the built-in Local InterBase Server, which enables you to rapidly develop high-performance ANSI SQL-92 compatible applications for standalone systems.

## Delphi Product Information:

### Product

- Delphi for Windows CD-ROM only. Estimated street price \$350\*
- Special Introductory Offer of \$199.95 for first 90 days (3/1/95-5/31/95).
- \$50.00 rebate coupon inside for Pascal owners. 3.5" disks available separately from Borland for \$19.95 plus \$5.00 shipping.

### Contents

Delphi for Windows  
Local InterBase Server  
ReportSmith 2.5 PC version

#### Manuals:

Delphi User's Guide  
Delphi Database Application Developer's Guide  
Delphi Component Writer's Guide  
Creating Reports  
InterBase User's Guide

### Target Audience

Programmers, VARs, Pascal developers, C++ developers, Visual Basic Pro developers, PowerBuilder developers, Paradox and dBASE developers.

### Delphi Accessories:

#### Turbo Assembler

\$99.95  
3.5" HD disks

#### Description:

Whether you're writing time-critical systems or speeding up your Delphi applications, the Turbo Assembler ensures your applications are as robust and efficient as possible.

#### Buyers:

Windows developers who want to build fast applications or

add fast code to existing applications. Programmers using Microsoft Assembler who want a way to do faster, more flexible assembly language programming.

### Visual Solutions Pack

\$99.95

3.5" HD disks

#### Description:

With the Visual Solutions Pack you can add spreadsheets, databases, word processing, graphics, and more to your Delphi applications with virtually no coding.

#### Buyers:

Windows developers using Delphi or any other development tool that supports VBX format custom controls.

### Paradox 5.0 for Windows

\$495

CD-ROM or 3.5" HD disks

Special limited-time upgrade price of \$129.95 for suite owners of competing databases. \$30 rebate for previous Paradox owners.

#### Description:

With Paradox you get relational database power made easy. DLLs and OLE 2.0 controls built with Delphi are completely compatible with your Paradox applications.

#### Buyers:

Windows database developers who want to build fast, efficient, database applications.

### Description:

The Delphi Programmer Explorer

by J. Duntemann/J. Mischel/D. Taylor

Coriolis Group

ISBN: 1-883577-25-X \$39.99

A new type of tutorial: Theory and practice alternate in short chapters, with the emphasis on creating useful software starting on the very first page.

Delphi for Dummies

by Neil Rubenking

IDG Press

ISBN: 1-56884-200-7 \$19.99

Readers will learn about Borland's new language in the easy to understand style of the Dummies series.

Teach Yourself Delphi

by Devra Hall

MIS Press

ISBN: 1-55828-390-0 \$27.95

Here is a complete, self-guided tour to the new development environment from Borland, encompassing all the features of the language and all the tools, tricks, and advantages of Delphi.

Delphi Nuts and Bolts

by Gary Cornell and Troy Strain

Osborne-McGraw-Hill

ISBN: 0-07-882-136-3 \$24.95

If you are an experienced programmer and want a fast introduction to Delphi, this book is for you.

Software Engineering with Delphi

by Edward C. Webber, J. Neal Ford, and Christopher R. Webber  
Prentice Hall Professional, Trade & Reference  
A guide to developing client/server applications with an emphasis  
on Delphi's object-oriented tools.

Delphi by Example

by Blake Watson

Que

ISBN: 1-56529-757-1 \$29.99

Aimed at the beginning programmer who has no prior experience  
with other languages or development products, this book presents  
basic concepts of programming along with a clear explanation of  
the key development tools that are part of Delphi.

Using Delphi, Special Edition

by John Matcho and Eric Uber

Que

ISBN: 1-56529-823-3 \$29.99

This 3-part tutorial on the most important Delphi features covers  
how to install the product and develop applications using  
Delphi's visual tools, explores the Windows application  
development process, and deals with some advanced programming  
topics.

Developing Client/Server Applications with Delphi

by Vince Killen and Bill Todd

Sams Publishing

Walks the reader through the development process of creating  
real-world C/S applications, explaining in detail what the  
thought processes must be even before any code is written.

Delphi Developer's Guide

by Xavier Pacheco/Steve Teixeira

Sams Publishing

ISBN: 0-672-30704-9 \$45.00

Intermediate to advanced guide to developing applications using  
Delphi.

Master Delphi  
by Charlie Calvert  
Sams Publishing  
ISBN: 0-672-30499-6 \$45.00  
Comprehensive tutorial/reference for intermediate programming  
with Delphi.

Teach Yourself Delphi in 21 Days  
by Andrew Wozniewicz  
Sams Publishing  
ISBN: 0-672-30470-8 \$29.99  
Introduces Delphi to the beginning programmer and includes  
question-and-answer section at end of each less to test readers  
progress as they learn.

Mastering Delphi  
by Marco Cantu  
Sybex  
ISBN: 0-7821-1739-2 \$29.99  
Introduces programmers to Delphi's features and techniques,  
including secrets of the environment, the programming language,  
the custom components and Windows programming in general.

Delphi How-To  
by Gary Frerking  
Waite Group Press  
ISBN: 1-57169-019-0 \$34.95  
Presents large collection of programming problems and their  
solutions in standard, easy-to-use reference format, including  
unique solutions that use VBX controls and easy ways to build  
multimedia projects with Delphi.

Developing Windows Applications Using Delphi  
by Paul Penrod  
John Wiley  
ISBN: 0-471-11017-5 \$29.95  
This introduction for traditional C programmers who want to make  
the transition to rapid application development also provides  
detailed instructions for building sophisticated Windows  
applications and for creating graphical interfaces.

Instant Delphi  
by Dave Jewell  
Wrox Press  
ISBN: 1-874416-57-5 \$19.95

Instant Delphi is the fast-paced tutorial guide for the programmer who wants to get up to speed on the Delphi product as quickly as possible.

## Article #15667: LINKER ELIMINATES UNUSED DATA

Technical Notes Database

TN667D.txt LINKER ELIMINATES UNUSED DATA

Category :Pascal

Platform :All

Product :Turbo Pascal 5.0 5.5

### Description:

Q. Does the built-in linker eliminate unused data?

A. Yes. Unused code AND data are stripped when you compile to disk. However, if more than one variable is defined in the same VAR block and any one is used, the others will not be stripped from the .EXE. For example:

```
var  A, B: integer;
var  C: integer;
begin
  A:= 0;
end.
```

In this example, although variable B is never used, it was defined in the same block as a variable A. Therefore, B will not be linked out. Variable C will be removed from the .EXE as it is not used and is not in the same VAR block.

Description:

RUNNING DELPHI FROM THE CD-ROM

-----

Delphi can be run from a CD-ROM directly. However, it is highly recommended that at least a minimum installation be seriously considered before opting for running Delphi from CD-ROM.

For a minimum installation, 33MB of available hard disk space is required.

Running from a CD-ROM, 9MB of available hard disk space is required.

To configure the system to run Delphi from the CD-ROM,

1. Copy all files found in the CD's \RUNIMAGE\WINDOWS directory to the Windows directory of the hard disk.
2. Copy all files found in the CD's \RUNIMAGE\WINDOWS\SYSTEM directory to the Windows SYSTEM directory of the hard disk.
3. Edit DELPHI.INI in a text editor like Windows Notepad. Look for the section titled [Globals]. Make entry for the PrivateDir setting that resides on a writeable disk, preferably a local hard disk.

For instance, if a directory on the C: drive where chosen called DELPRIV, the relevant section of DELPHI.INI would look as follows.

[Globals]

PrivateDir=C:\DELPRIV\

Now, Delphi can be run from the \RUNIMAGE\DELPHI\BIN directory of the CD-ROM.

#### MODIFYING COMPONENTS

-----

To allow modification of the component library used by Delphi while running from a CD ROM an copy of the Component Library must exist on a writeable disk. Use the following steps as a guide.

1. Copy COMPLIB.DCL from the CD's \RUNIMAGE\DELPHI\BIN directory to a desired directory on the hard disk.
2. Run Delphi.
3. Bring down the Options menu and select Open Library.
4. Specify the directory and file name for the COMPLIB.DCL copied to the hard disk.

## Article #15673: STRING MANIPULATION IN AN INTERRUPT ROUTINE

Technical Notes Database

TN673D.txt      STRING MANIPULATION IN AN INTERRUPT ROUTINE  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 3.0+

### Description:

Q. Can you manipulate strings inside an interrupt routine?

A. You can manipulate strings if you treat them as arrays of characters. You must use your own manipulation routines to do so and not the one's provided. In Turbo Pascal versions 4.0+ you may process strings with routines provided.

## Article #15677: Making your Delphi apps show minimized.

Technical Information Database

TI677D.txt - Making your Delphi apps show minimized.

Category :VCL  
Platform :All-32Bit  
Product :

### Description:

Q: When I select the "Run Minimized" option in Program Manager to attempt to make my Delphi application execute in a minimized state, the Delphi application seems to ignore the setting and run normally. Why is this, and how to I fix it?

A: Delphi's Application object creates a hidden "application window," and it is that window, rather than your main form, that is being sent the command to show minimized. To fix this, make your main form's OnCreate event handler look like this:

```
procedure TForm1.FormCreate(Sender: TObject);
{$IFDEF WIN32}           { Delphi 2.0 (32 bit) }
var
  MyInfo: TStartupInfo;
{$ENDIF}
begin
{$IFDEF WIN32}           { Delphi 2.0 (32 bit) }
  GetStartupInfo(MyInfo);
  ShowWindow(Handle, MyInfo.wShowWindow);
{$ENDIF}
{$IFDEF WINDOWS}       { Delphi 1.0 (16 bit) }
  ShowWindow(Handle, cmdShow);
{$ENDIF}
end;
```

In other words, for 16 bits, just pass cmdShow to ShowWindow. For 32 bits you need to obtain the start up info by calling the GetStartupInfo procedure, which fills in a TStartupInfo record, and then pass TStartupInfo.wShowWindow to ShowWindow.

## Article #15679: NON-REENTRANT CODE

Technical Notes Database

TN679D.txt      NON-REENTRANT CODE  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 4.0+

### Description:

Q. Which procedures/functions generate non-reentrant code?

A. All disk I/O routines and dynamic memory allocations will be non-reentrant. By disk I/O routines, we mean any routine that calls DOS, so this includes a number of procedures and functions in the DOS unit. Some code in the Graph, Graph3, and Crt units will generate non-reentrant code as well. Floating-point routines used to be non-reentrant in TP 3.0x, but the 6-byte library is now fully reentrant. The emulator, however, is not. Nor is the support code for the 8087 chip, unless special coding is included.

## Conclusion

### Introduction: An Overview of Client/Server Tools

Client/server development tools remain one of the fastest-growing sectors of the software industry. Forrester Research predicts that the number of client/server developers will climb from 128,400 in 1994 to 698,000 in 1996, while META Group research suggests that over 90% of all new applications will be based on the client/server model. This is an overwhelming endorsement of the popularity of client/server computing.

Client/server computing, however, is not the panacea that many have been predicting. Complex environments, with mixed data sources and immature development tools, have made client/server development a complex undertaking. Researchers such as the Gartner Group have found that the most pressing issues facing current developers of client/server applications include performance of deployed applications, rapid application development (RAD), component reuse and database scalability. Although these concerns are not unique to client/server application development, they are perhaps even more important in this sector, because of the well-documented limitations of first-generation client/server tools.

### PCs and the Evolving Client/Server Model

PCs facilitated the downsizing era, by providing inexpensive platforms for the production of reasonably capable solutions that addressed genuine business needs. These applications brought with them the promise of freedom from host-based technologies and shortened development cycles. But as these PC- and network-based applications grew, user counts expanded and more functionality was necessary. PC database applications frequently "hit the wall."

In addition, all database applications have at their very heart business rules. These rules control processes such as creating new customers and data validation. Historically, PC application development has placed the enforcement of business rules into the

user interface, so programmers would create a screen and write code to respond to user input. This code would perform a specific action based on the presence, or value of, certain information. Such actions might include allowing or preventing the posting of changes to customer data. But the user interface is certainly not the best place to store business rules.

The advent of client/server brought with it a new model that allows for business rules to be stored with the data itself. This is accomplished through the use of triggers and stored procedures created in the actual database. These procedures would enact routines to perform much the same processing that might be performed in a PC application, except that the host handles this task for all of its clients. This approach ensured that there was only one source for the business rules, since they were stored with the data. In many ways, this approach is enticing, but in reality it is plagued with problems.

When business rules are created to be enforced at the server level, they tend to be difficult to write and debug. According to David Sarna and George Febish in the September 1994 issue of *Datamation*: "These are not the tools for creating and maintaining good code. Doing it this way is SQL-abuse; SQL as a query language was never designed to do this kind of procedural computation."

With this model, as an application grows, so do the number of rules that must be created and controlled by the database. Rather than focusing on the efficient storage and retrieval of data, server resources become tied down enforcing business rules - such as ensuring that a last name is supplied for each new customer. Again, Sarna and Febish point out that "many of your business and validation rules are needed so often that they must sit on the client, or performance will go straight to hell."

## The Next Generation

Borland's Delphi is truly a next generation client/server development tool. Although it fully supports the placement of business rules in the user interface or on the server (or even a combination of both), it also presents the possibility of another model that separates the business rules from both the user interface and the server. This approach has the potential to provide greater performance, better scalability, better code reuse and an ideal platform for RAD. Delphi makes this possible

because it employs an open architecture, whereby developers can use or create a wide variety of specialized components when creating applications.

Comparative reports of software tools typically focus on feature matrices or checklists to relate the features of one product versus those of its competitors - and in this context Delphi would certainly emerge as a winner. Checklists, however, do not necessarily help developers understand how one product could be far more effective than another. Thus, the content of this white paper is focused on the needs of client/server application developers, and how Delphi addresses those needs.

What is Delphi?

Delphi represents the next generation of client /server and general Windows application development tools. It is a product of Borland's long-standing leadership in programming languages, database development tools, and object-oriented programming (OOP) technology. Delphi is unique in providing a completely visual integrated development environment (IDE) that is built around a powerful object-oriented compiled language (Object Pascal). The IDE shields programmers from the complexity of Windows development, by encapsulating the Windows application programming interface (API) inside robust, reusable components.

The implementation of a component-based architecture enhances power and flexibility. Components range from simple items (such as buttons, text edit regions or sliders) through to powerful specialized tools (such as high-performance database components used for table access, queries and batch updates). While most client/server development tools include a limited selection of these basic components, Delphi ships with more than 75 reusable components.

Developers may modify Delphi components, create their own, or purchase third-party components (which include text processors, graphics, communications and statistical utilities, among others). Once installed on Delphi's component palette, these additional components become part of the IDE, so that Delphi can be tailored to whatever the developer (or team of developers) specifically requires.

Because of the unique way in which components are implemented in

Delphi, it offers similar open architecture benefits to those of the ISA bus, for example. A component is a self-contained block of code that includes all functionality to work within a Delphi application. Just like inserting a new PC expansion card, any new component added to the library becomes part of Delphi and is indistinguishable from those that ship with the product. This open, component-based structure means that Delphi developers are not tied to any particular development methodology, and may use whatever tools or components are necessary to accomplish a task.

### Redefining Client/Server Development

First generation visual client/server development tools (such as PowerBuilder) feature environments where all components are tightly integrated and dependent upon one another. Such an approach does not encourage modification or customization of existing components, because when a component is significantly altered, it has the potential of changing the way in which it interacts with others. This not only impedes the evolution of the base product, but it also has the potential to introduce unpredictable behavior.

Delphi, on the other hand, has as its foundation a true object-oriented language, with the result that its components are essentially autonomous objects. Component changes are therefore unlikely to affect overall product stability. Also, problems with any specific component behavior can often be corrected by the developer via subclassing, and thereby overriding the errant behavior. This also holds true for components created by a developer or purchased from third-party suppliers.

### Delphi Component Types

Delphi's Visual Component Library (VCL) includes more than 75 pre-built components, which can be used in applications and deployed freely. These include the following:

Standard - Menus, Edit, Label, Buttons, Scroll Bar;

Additional - Bitmap Button, SpeedButton, Notebook, Outline, DrawGrid, Image, Multimedia; Data Access - Database, Table, Query, Batch Move, Report;

Data Controls - DataGrid, DBNavigator, DBLabel, DBEdit, DBImage, ComboBoxes;

Dialogs - Open, Save, Font, Color, Print, Print Setup, Search/Replace, Tabbed Notebook;

System - Timer, FileListBox, Drive and Directory Combo OLE, DDE;

VBX - Chart, Picture, Gauge;

Samples - Gauge, ColorGrid, SpinButton, SpinEdit, Outline, Calendar.

Delphi developers can also create their own components, by modifying existing Delphi components or building them from scratch. The source code for Delphi's VCL is available to help developers in this task. Newly-developed components (or those purchased from third-party developers) can be added to Delphi's component palette.

## Performance

In a client/server environment, overall performance depends upon a combination of factors, including efficiency of the database server, network bandwidth, "middleware" or driver performance, data access techniques, and speed of the user interface. A well-designed architecture should leverage all of these characteristics. In almost all respects, Delphi outperforms PowerBuilder by a significant margin, due to its optimizing compiler, efficient VCL components and high-performance native SQL drivers. Some sample benchmark results are listed below:

Operation (All times in seconds)	Delphi	PowerBuilder
String parse to measure non-database performance; reading file and splitting record into substrings	2.7	22.8
Use a query to load a form from a 20,000 record table. Form supports searching and filtering.	4.6	70.9
Post a record (single order)	1.4	1.3
Apply a filter on 20,000 record table	3.0	6.2

Update record	1.5	1.1
Search for a value, 20,000 records	1.1	1.5

User Interface Performance and Compiled vs Interpreted Code  
 The user interface (UI) is the most visible portion of any application. UI performance covers obvious functionality such as screen updates, along with the underlying processing of data (including numerical calculations and string manipulations). It is the portion that users interact with every day, and it is also the first place where performance differs noticeably between PowerBuilder and Delphi.

Delphi uses an optimizing native code compiler to generate standalone executable files (.EXEs) containing machine code instructions. These executable files are self-contained and, other than the database engine and the data itself, require no external files to run. Although PowerBuilder creates an executable file, it is not truly compiled. When a PowerBuilder application is run, source code instructions are converted to machine code before the instructions may be executed. This extra level of translation introduces significant run-time overhead and seriously degrades performance.

To support its runtime interpretation, PowerBuilder requires external support files in the form of runtime interpreter Dynamic Link Libraries (DLLs). In addition to the application code, these DLLs must be loaded into memory at runtime, creating a larger memory "footprint" and leaving less memory for processing and buffering data. As a result, Delphi applications execute between 10 and 20 times faster than applications created using p-code ("pseudo-code") interpreters such as PowerBuilder, even on target systems with minimal memory.

In moving from PowerBuilder 3.0a to 4.0, PowerSoft tuned its runtime interpreter to achieve slightly better performance on systems fitted with 16M of memory. This performance boost often comes at a cost, however, as final applications can increase from 20 to 70 percent in size. Despite minor enhancements, there is no way for an interpreted p-code language to even approach the execution speed of a compiled language like that of Delphi.

## Data Access - A New Approach

The two primary methods of implementing client/server solutions

with PowerBuilder involve placing business rules on either the client or the server. Unfortunately, neither one adequately addresses the issue of overall performance. If developers choose to place the burden of enforcing business rules on the server, they risk performance bottlenecks due to server and network overload. Yet shifting this task to the comparatively slow PowerBuilder UI is not an ideal solution. As it turns out, PowerBuilder's design makes it difficult not to attach at least some of the business rules directly to the UI.

Delphi, on the other hand, fully supports either of these techniques, as well as allowing for a more flexible model. Delphi developers can create a "virtual third-tier" layer containing business rules independent of the UI and the server. Instead, these rules can be encapsulated in non-visual components (NVCs) in a layer between the UI and database engine. Physically and conceptually, this separates the data and related rules from its representation to the user.

This approach brings the distributed computing vision of client/server another step closer to reality, and also provides a practical means of enhancing performance. All data moving to and from the application passes through this central conduit. The "third-tier" NVCs may be single Delphi components such as a TTable or TQuery or sophisticated combinations of components. By having a single access point to lookup tables (such as State, Province or Product Codes that may be used by several forms), the application need only fetch this data once - when it is started. This can greatly reduce the number of server requests, alleviating network traffic and server load.

More importantly, developers can place connections to the main database tables here as well. As users move between forms, cursors to their data would remain in place. Thus, if basic customer information were displayed in one form, moving to another form displaying credit history would invoke it already pointing to the appropriate customer. PowerBuilder has limited functionality in this area through the dwShareData function, which allows sharing of data between DataWindows. This process results in duplication of large, complex components, and unless sufficient RAM is available, this can further degrade client performance. In the same situation, Delphi reduces the number of components used, since data access and display are accomplished with separate components.

## Rapid Application Development (RAD)

Rapid Application Development (RAD) is an attempt to address the issues of building applications tailored to customer requirements and completing projects with minimal re-working. Historically, serious application development involved tremendous effort from a team of analysts who quizzed potential users to determine every possible requirement of the application. From this collection of information, volumes of carefully documented specifications were produced, then the users would sign off and programming commenced. Some time later, the development team would finally emerge with an application, and users were then expected to adopt the product.

This model had several shortcomings. Often, the people who built the application were not the same as those who did the analysis, resulting in reinterpretation of the specifications. Furthermore, users are often not well equipped to diagnose and describe their technology needs. During the development process, little communication existed between the developers and eventual users of the application. In days gone by, when terminals and batch operations were the only UI, this may have been an adequate model. However, with the advent of PCs, user expectations are significantly higher in regard to the UI characteristics of modern client/server applications. These applications must now provide access to data, and present it in ways that are most meaningful to users, with tools to assist in the analysis and interpretation of the data. As a result, most large organizations are confronted with a backlog of applications, which must be tackled with limited staff, budgets and time.

RAD is a development methodology based around an iterative process of specifying, creating and enhancing an application until the final product is completed. RAD is based on the notion that it is difficult to fully predefine a problem domain as complex as today's typical business applications. As the developers step through each iteration from prototype to finished product, the requirements become more clearly defined. Although not ideal for batch-style applications, RAD is very effective for the development of applications where the UI design is a key consideration.

Minimum Coding, Maximum Flexibility

RAD development tools should allow developers to quickly build prototypes with as little code as possible, and Delphi is very powerful in this respect. Building a database application with a classic Customer -> Orders -> Details form (including database connections) can be done with no lines of code in Delphi. By comparison, PowerBuilder developers must write a dozen lines of code to simply link to a database, then they must also write code to open the form, query the tables and synchronize the tables appropriately.

Delphi's comprehensive array of data-aware components minimizes the level of customization that must be done to deliver a necessary feature or function. Where appropriate functionality does not exist in a VCL component, developers have the option of modifying the component or using a third-party component (such as a VBX control or Delphi native component). Any component may be subclassed (exploiting inheritance) and reused in other areas.

#### DataWindows vs Reusable Forms

RAD methodology assumes that application design evolves through several phases, so a true RAD tool should allow developers to easily adapt to changes (which can be significant). Because PowerBuilder combines data access and display in a single component, some design changes can prove extremely difficult. When a customer requirement suddenly dictates a new approach to either data access or display, this often requires a rewrite of the DataWindow and/or the entire form. Since Delphi separates these two concepts, the adaptation process is much simpler.

As with most first-generation visual development tools, PowerBuilder embeds application code inside objects - with the exception of the DataWindow, which represents both the conduit and the display format of the data. A DataWindow is created in a separate section (or "painter"), and cannot have event-handling code written until it is pasted into a form, whereupon the relevant application code is then permanently attached to that DataWindow. Since code is hidden inside objects scattered about the form, it becomes difficult for developers to locate, and it also may be affected by modifications to objects on the form. Furthermore, by "hard-wiring" the DataWindow to the code, it becomes difficult to reuse that DataWindow in other forms. Delphi developers address this issue by writing event handlers, which are pointers to specific procedures, or references within components that indicate what procedure will be called when a

particular event occurs (mouse click, timer interrupt, etc). Form procedures are stored in a "unit" file, with all the code visible to the developer, so there is no need to search through various objects track down specific code fragments. Once procedures are created, they may be called by any event of any component. Event handlers can also call procedures written for any other event handler, or even directly access components or procedures residing in other forms. Deleting an object (such as a button) does not delete procedures created for that object, so that code changes are easier, faster and safer.

Since Delphi uses the same property/event model for all components, whether they are visual or non-visual, it is more consistent and easier to learn than products such as PowerBuilder. The end result is that Delphi clearly provides an ideal environment for RAD.

## Component Reuse

Inheritance is the ability to create new objects (descendants) from a base object (ancestor). A descendant inherits all characteristics of the ancestor, although these can be overridden. Inheritance is an object-oriented programming (OOP) fundamental that provides a means by which programmers can reuse code, and it encourages development of base objects with characteristics that are likely to be used again. Since descendants inherit any changes made to the parent object, changes that are made will propagate throughout any objects that descend from a base object. The resulting collection of objects is often called a class hierarchy or class library.

PowerBuilder allows developers to use inheritance to create a class library based on forms or groups of controls. The problem with the PowerBuilder approach is that it emphasizes inheritance of the user interface. Because DataWindows perform the task of both data access and data display, and because of the close binding between a DataWindow and various objects (and code) on a form, UI inheritance is the only type of inheritance that makes sense in PowerBuilder. However, what developers mostly need to preserve and reuse is not the visual representation of the data, but instead the complex logic that drives the business rules. In fact, the visual representation usually changes the most. Hence, reuse through inheritance in PowerBuilder often requires the

developer to spend significant time overriding the UI in order to preserve the underlying code. As a result, PowerBuilder forms often carry around much unwanted baggage.

Delphi takes an entirely different approach. In its first release, Delphi, supports inheritance of forms in code only, compared to PowerBuilder's support of UI inheritance. With the ability to separate business rules from the UI, a Delphi developer need only write these once. Different forms can access the same data components and inherit their business rules, but are not bound to them. Hence the developer is free to create any number of forms displaying data in whatever format is appropriate, knowing that the non-visual components supplying data to the user interface have fully encapsulated these business rules.

Such an approach would be difficult with a product such as PowerBuilder, because the underlying interpreter-based architecture is not truly object-oriented. According to Steve Benfield, quoted in the June/July 1994 issue of PowerBuilder Developers Journal: "PowerBuilder's DataWindows is not truly object-oriented. I could try to not use DataWindows and code PowerBuilder in a purely object-oriented way. However, the system would be so slow that it would be useless."

## The Delphi Inheritance Model

Inheritance is fundamental to Delphi, and all VCL components ultimately descend from an object known as TObject (the "T" prefix is an accepted standard to denote an object type). TObject has a great deal of capability built into it, and knows how to handle certain types of errors, along with how to display itself in the form designer. Many other components descend from TObject, each acquiring more capability and becoming more specialized along the way.

The familiar case of copying to the Windows clipboard is an example of where Delphi's inheritance can be most powerful. This turns out to be a complex procedure requiring more than 100 lines of code in PowerBuilder, whereas the following code sample shows how the same CopyToClipboard is handled in Delphi:

```
if (( ActiveControl ) is TCustomEdit ) then  
TCustomEdit(ActiveControl).CutToClipboard
```

This examples surfaces three important issues. The first is that it highlights how some very basic functionality is missing from PowerBuilder. The second is that Delphi developers deal with functions such as this on a much higher level than with traditional programming languages. Thirdly, the inheritance benefits are obvious. TCustomEdit is an ancestor of most of the editable components in Delphi (such as TEdit, TDBEdit and so on) In this example, the is operator checks to see if the active component is a descendant of TCustomEdit, and if so, the next line casts the active control as its ancestor - TCustomEdit. Because CutToClipboard is a method of TCustomEdit, all controls inherited from it will also inherit this method.

### A DataWindows Alternative

DataWindows are an important feature of PowerBuilder. By attempting to incorporate all database capability into a single structure, the result is a component that is extremely powerful, but highly complex. The PowerBuilder 3.0a reference manual allocates almost 150 pages to explaining the properties and syntax of the dwDescribe and dwModify functions, which are just two of the more than 130 functions used within DataWindows. According to Breck Carter, quoted in the June/July issue of PowerBuilder Developers Journal: "dwModify( ) and dwDescribe is a topic that I know has been a sticking point for many developers. These functions can be daunting with their screwy syntax and difficult-to-debug commands . . . If DataWindows' bazillion functions and events don't get you, you probably won't avoid being shocked and overwhelmed by dwModify."

PowerBuilder developers place all of their code and forms in a single .PBL application file, while Delphi applications reside in three main file types. The application itself comprises .DPR and .PAS files, while .DFM files contains the binary representation of forms (buttons, grids etc). Delphi's project manager provides a high-level view of all these files, and units from other directories or projects can be easily included. By storing units in separate files, team development is simplified and the allocation of tasks is made easier. Developers need not even be in the same physical location.

During compilation, Delphi keeps track of which files have changed since the last compile and only generates those changes. Delphi's compilation speed is the fastest in the industry, at

more than 350,000 lines of code per minute on a 66MHz Pentium fitted with 8M of RAM. A reasonably complex client/server application containing over a dozen forms will compile all files in less than a minute.

PowerBuilder's interpreter-based design makes direct comparisons with Delphi's compiled performance unrealistic. PowerBuilder developers cannot exit the code painter until their code is syntactically correct, so that moving between different code areas is greatly restricted. PowerBuilder then generates p-code from its scripting language, along with a runtime executable file. This p-code generation stage takes about the same amount of time as the complete syntax checking and compilation to machine code of a Delphi application. The PowerBuilder application, however, still requires translation and decoding overhead each time it is executed.

As the complexity of applications and size of development teams grows, so does the need to maintain control of the process. Keeping track of the latest versions of source files is an important part of this process, and Delphi accomplishes this by providing a direct interface to PVCS, a leading version control utility. Delphi will directly link to the PVCS DLL and integrate it into the development environment.

PowerBuilder developers frustrated with limitations of its programming language are forced to leave the environment and must turn to languages such as C++ or Pascal. Once they leave PowerBuilder, they must abandon any of their custom class libraries, which are not supported by other products. Delphi does not present such obstacles, as it is built around a comprehensive structured, object-oriented language featuring pass-through SQL commands and inline assembler. Since Delphi can encapsulate applications into DLL format, any Windows program (including PowerBuilder) can call a Delphi-generated DLL. In the same manner, Delphi applications can also access DLLs created using other development tools.

## Exception Handling

When developing serious client/server applications, it becomes essential to write code that is able to deal with the possibility of any process failing. Again, according to Breck Carter in the

1994 Special Issue of PowerBuilder Developers Journal: "The PowerScript language is less than ideal when it comes to error handling, Most functions can diagnose errors, but with very few exceptions the default action is to ignore the error and proceed. There are no debugging switches or compiler directives to change this behavior to trap all errors and halt. With the exception of the global SystemError event, there is little language support for automatic error detection or handling."

This lack of support from the PowerScript language makes it difficult, if not impossible to create robust error-handling routines without writing enormous amounts of code. In contrast, Delphi introduces a new and more powerful error-handling methodology. To understand how important this new approach is, we must first look at how it is done.

Fundamental to Delphi is the concept of objects. Every control in Delphi descends ultimately from a base object control called TObject. As shown in the diagram above, TObject and hence, all of its descendants already knows about errors. This knowledge is passed to the programmer by means of objects. When an error occurs, Delphi instantiates an Exception object of that exception type. For example, if a divide by zero error occurs, an EDivideByZero object is created. All forms have built into them, the means of dealing with most errors. Rather than having to write code to test for every possible failure, the following construct is used:

```
try
    { statements }
except
    on ESomething do { specific exception handling code } ;
    else {default exception-handling code } ;
end;
```

Delphi also allows developers to create their own exception types as follows:

```
type
EpasswordInvalid = class(Exception) ;
```

This new user type exception is used simply as follows:

```
if Password <> CorrectPassword then  
raise EpasswordInvalid.Create( 'Incorrect password entered' ) ;
```

These examples are trivial and meant only to display concepts. Delphi exception handling actually has capabilities far beyond this. For instance, Windows General Protection Failure (GPF) errors that are impossible to deal with in PowerBuilder applications may be handled via Delphi's EGPFault exception type. This simple construct provides enormous power and flexibility, and minimizes the amount of code that needs to be written, further shrinking the development cycle.

## Scalability

As more attention is focused on client/server development, the scope of such applications is expanding. Where once it was sufficient to provide basic data entry and inquiry capabilities, users now demand that their applications have functionality far beyond what can be provided from mainframe solutions. Delphi is the ideal tool for this type of transition, being built around Object Pascal, an enhancement of a language that is already known by more than two million developers.

Delphi does not hide code within UI objects, and is thus more familiar to mainframe developers and easier to work with than PowerBuilder. It maximizes code reuse, minimizes development turnaround time and has the performance and stability necessary for large applications. It is also infinitely extensible, due to its OOP architecture, comprehensive array of components and full-featured programming language.

Many applications are also being scaled up from PC databases written in dBASE, Clipper, FoxPro and Paradox. As these applications make the transition from PC environments into the full client/server model, they must be able to address both PC and server data. PowerBuilder has extremely poor performance when accessing PC databases, and does not provide support for Paradox tables beyond the Paradox 3.5 format, nor does it fully support the Paradox file locking mechanism.

Some organizations decide that a portion of their data should reside on a server platform such as Oracle, while other portions should remain in a PC format such as dBASE. Because of Delphi's broad database support and extremely good performance against

both PC and server data, it is the ideal tool for when mixed data access is required. Developers need only one development tool regardless of whether the data source is PC-based, server-based or both. Delphi is the only development tool that can adequately address all of these models. On the other hand, PowerBuilder has opted to largely ignore the PC database side.

## Borland Database Engine

Although not component-based itself, the component-like architecture of the Borland Database Engine (BDE) fits neatly into the architecture of Delphi. As the core technology for most of Borland's database tools including dBASE and Paradox, and used by millions of database users, the BDE has evolved into an extremely stable, high-performance technology that can deal with almost any database format. It may be easily configured to access popular server formats (including Oracle, Sybase, Informix and InterBase) using high-performance SQL Links. PC database formats such as dBASE and Paradox are accessed directly via drivers built into BDE, which also includes support for the wealth of ODBC drivers.

The BDE is also sold as a separate product, as all of its functionality is accessible to developers via an API. However, Delphi developers are most likely to use the native data-aware components to interact with the BDE, although it is possible to write directly to the API or even bypass it altogether if required. This open architecture provides a level of power and flexibility not possible within PowerBuilder.

## Local InterBase Server

The Local InterBase Server is a locally-installed Windows version of Borland's powerful InterBase workgroup server. Unlike the Watcom SQL engine that ships with PowerBuilder, this product is a full-featured SQL database, including:

- Stored Procedures and triggers
- Automatic two-phase commit
- Explicit transaction management
- Declarative referential integrity
- Event alerters
- Simultaneous access to multiple databases and transactions
- Multi-generational architecture
- Updatable views

## Outer joins

## User defined functions (UDFs)

Because the Local InterBase Server supports most of the functionality of the high-end InterBase server, developers can create SQL-based applications using locally-stored data. Thorough testing of these applications can be performed locally, without concern for either the server load or the possibility of damaging live data. Once an application has been tested and debugged locally, it may then be scaled to work with an external database server. If the developer has elected to use specific features of InterBase, these will perform identically when the application is deployed against an external InterBase server.

With PowerBuilder, because the Windows version of WATCH SQL lacks many of the features on the server versions of Watcom SQL, developers cannot experience the benefits of direct scaling that Delphi provides. When PowerBuilder accesses the Windows version of Watcom SQL, it must open a separate application window. Since this is a standard window, users can task-switch to the window or close it - either from the window itself or externally. This makes the Windows version of Watcom SQL unsuitable in a production environment.

The Local InterBase Server, however, loads as a DLL in Delphi and cannot be accessed by users. This, combined with its comprehensive feature set, make the Local InterBase Server ideal for applications running on notebook PCs. When a user returns to the office, the application can be linked to the server version of the database. Applications may therefore scale from notebooks up to Windows NT or Novell NetWare NLM servers, and all the way up to the largest Unix-based systems, without developers needing to change a single line of code. By offering this capability, Delphi represents the ultimate in database scalability.

## Conclusion

This paper has examined just a few of the many differences between Delphi and PowerBuilder. Both are clearly high end client/server development tools with excellent features. When examined from the perspectives of performance, scalability, reuse and RAD, Delphi clearly leads the way into the next generation of client/server development.

## Article #15685: REENTRANT CODE

Technical Notes Database

TN685D.txt REENTRANT CODE  
Category :Pascal  
Platform :All  
Product :Turbo Pascal 4.0+

### Description:

Q. How do I write reentrant code in Turbo Pascal?

A. If a routine follows these rules, it is reentrant:

1. All data is allocated on the stack.
2. The routine doesn't use any global variables.
3. The routine can be interrupted at any time without affecting the execution of the routine.
4. The routine doesn't call any other routines that are not reentrant (e.g., DOS I/O).

Introduction

With the growing demands on Windows applications developers to create increasingly complex applications in less time, the evolution of Rapid Application Development (RAD) tools has become a crucial focus of the development community. First-generation RAD tools for Windows included application frameworks (such as OWL and MFC), DLL-based class libraries, and VBXs (Visual Basic custom controls).

The release of Borland's Delphi heralds a new generation of RAD tools that combines the power of traditional 3GL compilers with the ease of use and development speed of a 4GL environment. This white paper will contrast the approach of the new technology used by Delphi with that of Microsoft's Visual Basic.

## Windows Visual Development

The earliest methodology for Windows applications programming was to code directly using calls to the Windows API. The API provided a crude mechanism for creating such items as menus and windows, leaving the developer with an enormous coding task even when creating a rudimentary application. These early programs were typically created with C compilers that were equally crude by today's standards. As a result, the expectations for what could reasonably be achieved by professional developers was severely limited by schedule and performance constraints. Early applications were also, for the most part, independent. In other words, they were generally not reliant on each other and did not share data or invoke other applications.

Appreciating the underlying potential of the Windows environment, the development community demanded better tools, to enhance their productivity and facilitate the creation of more sophisticated applications. As Windows evolved, inter-application communications using DDE and OLE was introduced, then more powerful application frameworks products such as Borland's OWL and Microsoft's MFC appeared, as well as third-party products such as zApp from Zinc and Island Systems' object-Menu.

These libraries were used to encapsulate the most common functions of Windows applications, as well as to leave room for expansion and customization by developers. Thus, a programmer could quickly create a window with a certain border style, make it modal and add a "Close" button, then invoke it with a single call. Further, the advent of C++ compilers for Windows allowed experienced developers to exploit the power of object-oriented

technology. Developers now had the means to create complex applications within acceptable schedules.

Object-oriented languages allowed developers to create classes and override specific virtual functions, providing a direct path to building custom libraries. This generation of tools still had two major shortcomings:

1. Although productivity had been significantly increased, schedules for complex applications development were still quite lengthy. For example, the common development scenario would proceed as follows:
  - a) some sample screens would be created in a prototype environment or a resource tool;
  - b) marketing would critique the screen design and modifications would be made;
  - c) the "final" screens would be integrated with code to complete the application;
  - d) any changes that were requested often became complicated and painful, since the code and the screens were so closely linked.
2. The expertise required made Windows programming the sole domain of the experienced developer. In other words, the extensive needs of the corporate community simply could not be met due to the requirement for significant programmer expertise.

Thus evolved the next stage of Windows development, characterized by 4GL visual design environments such as Microsoft Visual Basic and high-end products such as Powersoft's PowerBuilder. These environments provided a major step forward in user-friendly development, with high-level, reusable components called controls which introduced the concept of a "building block" approach to software development. Most of the application development effort could now occur within a visual design tool where the programmer would piece together an interface from a suite of available libraries. Customization of the components can be accomplished by modifying a corresponding collection of properties sheet. Any "work" to be done within the application is triggered via events that affect the interface components (mouse clicks, keyboard entries and so on). With these first-generation visual development tools, the specification of the actions to be taken on these events is defined using a Basic-like scripting language.

As proven by their broad popularity, these tools went a long way toward solving some of the problems of corporate developers. However, there remained a serious deficit in their capabilities, due to their reliance on the visual design process for creating the application and also their underlying interpreted languages.

As the demands of Windows applications buyers continued to grow, developers were stretching the limits of the existing technologies to create projects such as mission-critical client/server applications. Team development and software quality assurance issues were becoming prominent. Applications were being designed as a series of modules that would need to interact seamlessly, and capable of communicating with and invoking other applications. For example, a user may have a need to insert a graphic in the context of an application. The graphic would be found by accessing a database created by some other application potentially residing over a network on a remote system. All of this needed to be transparent to the application at hand, so that users need not be concerned with where the graphic came from or how it was created.

Specifically, the following issues thus became crucial to professional applications developers:

- \* Performance
- \* Rapid Application Development
- \* Component Reuse
- \* Database Scalability

The next logical step in this evolution is technology that combines the significantly enhanced productivity of modern RAD tools with the power and flexible architecture of proven 3GL compiled languages. The remainder of this paper will contrast how Delphi and Visual Basic address these four key criteria for a robust Windows development system.

It is assumed that readers of this paper are familiar with RAD design concepts, but a detailed knowledge of Visual Basic or Delphi is not necessary in order to understand this paper.

## Performance

Performance of deployed applications is a key issue in today's highly competitive software market. Particularly for large,

distributed client/server applications, any shortfalls in execution speed become far more apparent, due to higher overall system demands.

Delphi is based upon Object Pascal (a significant extension of the popular Borland Pascal 7.0) whereas Visual Basic uses Microsoft Basic as its underlying language. Delphi's performance is significantly better, simply because it generates compiled executable files, while Visual Basic produces semi-interpreted code. That is, Delphi is built around an optimizing native code compiler instead of the slower interpreted p-code used by products such as Visual Basic. This results in Delphi applications executing 10 to 20 times faster than interpreted code. Delphi's intelligent linker also enables segment optimization, thereby reducing executable file size by as much as 30 percent, which enables faster loading and additional performance gains.

Delphi can compile standalone executable files (.EXEs) as well as reusable Dynamic Linked Libraries (DLLs). For the ultimate in execution speed, Delphi also allows professional programmers to go one step further by writing in-line assembler code, for direct control of the microprocessor.

Other areas in which Delphi displays considerable performance gains over Visual Basic is in database connectivity. The database layer of Visual Basic is implemented via ODBC, as opposed to the more efficient Borland Database Engine used in Delphi (and other core Borland development tools). However, Delphi also supports links to data via ODBC drivers. The high-performance native SQL Links supplied with Delphi Client/Server also outperform comparable Visual Basic SQL connectivity options.

## Benchmarks

Delphi's superior performance over Visual Basic becomes immediately apparent when running a few simple benchmarks. Consider the following examples, where a database is filled with items of text representing lastname, firstname, phone and street information. The phone number field is filled with consecutive integers, then the database is re-read and filled with a global array of integers from the phone number field. Finally, the global array is sorted to become reverse-ordered using a comparatively slow bubble sort algorithm.

Similar code can be written in both Delphi and Visual Basic, with the stages of the benchmarks summarized in the following code fragments:

VB - Fill

-----

```
Sub btnFill_Click ()
Dim k As Integer
MaxArray = EdArraySize.Text
For k = 1 To MaxArray
    Data1.Recordset.AddNew
    Data1.Recordset("LastName") = "Smith " + Str(k)
    Data1.Recordset("FirstName") = "Joe " + Str(k)
    Data1.Recordset("Phone") = Str(k)
    Data1.Recordset.Update
Next k
Data1.Recordset.MoveLast
End Sub
```

VB - Read

-----

```
Sub btnSearch_Click ()
Dim k As Integer
Dim n As Integer
Dim s As String
Data1.Recordset.MoveFirst
For k = 1 To MaxArray
    s = edPhone.Text
    n = Val(s)
    Call AppendArray(k, n)
    Data1.Recordset.MoveNext
Next k
End Sub
```

VB - Sort

-----

```
Sub btnSort_Click ()
Dim j As Integer
Dim k As Integer
Dim tmp As Integer
For j = 1 To MaxArray - 1
    For k = 1 To MaxArray - j
        If GlobArray(k) < GlobArray(k + 1) Then
```

```

    ' Swap GlobArray[k+] with GlobArray[k] ...
    tmp = GlobArray(k + 1)
    GlobArray(k + 1) = GlobArray(k)
    GlobArray(k) = tmp
  End If
Next k
Next j
End Sub

```

Delphi - Fill

-----

```

procedure TForm1.Button4Click(Sender: TObject);
var
  k,err: integer;
  s: string;
begin
  val(edDBsize.Text,maxArray,err);
  for k:=1 to maxArray do
    with Table1 do
      begin
        str(k,s);
        Append;
        FieldByName('Lastname').AsString := 'NewGuy'+s;
        FieldByName('Firstname').AsString := 'Paul'+s;
        FieldByName('Phone').AsString := s;
        Post;
      end
    end;
end;

```

Delphi - Read

-----

```

procedure TForm1.btnSearchTestClick(Sender: TObject);
var
  s: string;
  n,err,k: integer;
begin
  val(edDBsize.Text,MaxArray,err);
  Table1.First;
  for k:=1 to MaxArray do
    begin
      s := DBedPhone.EditText;
      val(s,n,err);
      AppendArray(k,n);
      Table1.Next;
    end
  end;
end;

```

```
end;  
end;
```

## Delphi - Sort

-----

```
procedure TForm1.btnSortArrayClick(Sender: TObject);  
var  
  j,k,tmp: integer;  
begin  
  for j:=1 to MaxArray-1 do  
    for k:=1 to MaxArray-j do  
      if GlobArray[k] < GlobArray[k+1] then  
        begin  
          { Swap GlobArray[k+] with GlobArray[k] ... }  
          tmp := GlobArray[k+1];  
          GlobArray[k+1] := GlobArray[k];  
          GlobArray[k] := tmp;  
        end;  
      end;  
    end;  
  end;
```

## Benchmark Results

The following table shows the results for database tables ranging in size from 100 to 4000 records. The test stages Fill, Read and Sort correspond the code sections described on the previous pages.

(All benchmark times are in seconds.)

D = Delphi  
FL = Fill  
RD = Read  
X = x Sort  
ST = Sort

# items	D	VB	D	VB	D	X	VB	D	X Total	VB
	FL	FL	RD	RD	ST		ST	Total		Total
	--	--	--	--	--		--	-----		-----
100	2	2	30	1	0	0	0	2	1.5	3
1000	16	70	6	23	1	22	22	23	5	115
2000	33	141	12	46	4	21	84	49	5.5	271
3000	50	227	17	69	8	23.6	189	76	6.4	485
4000	67	297	23	77	15	19.6	294	106	6.3	668

As can be seen from the results, the resulting Delphi-generated code outperformed the Visual Basic routines, especially in code-bound portions such as the Sort stage, by about 20 times faster. Delphi's database access functionality was also shown to be about five times more efficient than that of the Visual Basic code.

### Rapid Application Development (RAD)

The other side of the performance issue relates to the speed of application development, which is crucial for programmers intent on ensuring the fastest time to market for their products. The RAD features of an environment are the key to establishing how easy it is for programmers to progress from initial design and prototyping through to final implementation and deployment.

A modern RAD environment provides developers with several elements that significantly speed the development process over the traditional sequential coding approach. These include:

- \* A visual design environment;
- \* High-level building block components (often called "controls");
- \* Contextual access to code segments directly, via objects. In other words, homing in on the specific code relating to a particular object.

Under Windows, the structure of an application is frequently molded around its graphical user interface (GUI), with the behavior of the application triggered by various Windows messages or events. The methodology for RAD flows according to the following outline:

- 1) The developer creates an empty window or form to contain the application's interface components;
- 2) The developer selects a component from a pool of available components, which are generally displayed as an array of icons. Components are then placed and sized on the form;
- 3) Relevant properties are set or adjusted for each component, according to the application's requirements;
- 4) Code is written and "attached" to all relevant events for each component;
- 5) The application is run within the development environment;
- 6) The developer can then continue to modify the form design or underlying code until the final working application is completed.

Both Visual Basic and Delphi subscribe to this general methodology, making the products appear deceptively similar. However, there are several key enhancements that Delphi adds to this process, including:

- \* More built-in controls Enhanced icon layout, via a fully-customizable, multi-page (tabbed) component palette;
- \* Extensive gallery of extensible project templates and experts;
- \* Enhanced object placement capabilities;
- \* Enhanced modification of property lists;
- \* Two-way, synchronized code window;
- \* Shared event functions;

\* Integrated graphical debugging and object inspection

## Controls

Visual Basic custom controls are referred to as VBXs, and a limited selection is supplied with Visual Basic itself. Additional controls are sold by third-party manufacturers, although these not only cost additional money but also extend the overall learning curve, due to variations in product styles. To utilize controls for a tabbed folder, notebook, database grid or 3D list box, for example, Visual Basic owners must obtain third-party VBXs. Some of the controls supplied with Visual Basic suffer from memory and other limitations, making it necessary to purchase third-party alternatives.

Delphi's Visual Component Library (VCL) is a comprehensive suite of high-performance controls that support all standard Windows functionality, along with additional features such as tabbed folders, notebooks, database grids and 3D list boxes. Delphi also supports third-party VBXs, providing access to a wide range of third-party components.

## Control Icon Array

The Visual Basic control display is an array of icons with pictorial representations that are not always intuitive. In other words, developers can be left searching for the Image Control, for example, amongst many other icons with a similar look. Developers must then place a control into the form to be certain as to its identity. The Visual Basic control icon array can quickly become unwieldy as additional third-party custom controls are acquired. Since these icons are organized as a configurable rectangle, developers working with a large set of VBX controls are forced to give up valuable screen space or sacrifice accessibility of some controls.

Delphi solves these component layout problems with several enhancements. Firstly, Delphi's component palette is organized with several tabbed notebook pages, displaying icons in a single-row, scrollable toolbar format. This keeps the display uncluttered, yet fully accessible. More importantly, Delphi's customization options allow full configuration of the grouping, placement and display of components, so that the environment can be fine-tuned to suit the working style of an individual or development team. To address the problem of obscure or

similar-looking icons, Delphi offers "fly-by help" showing the purpose of the control associated with the icon as the cursor is dragged over it.

## Templates and Experts

Delphi includes pre-built templates that make it easy to develop standard applications or complex components such as MDI windows, database forms, multi-pages dialog and dual list boxes. The architecture is fully extensible, allowing developers to easily register their own custom templates and experts into the gallery.

## Object Placement

Delphi facilitates visual design with features such as automatic object alignment, sizing and scaling, while Visual Basic supports placement only. Delphi's automatic alignment also speeds up the creation of aesthetic forms.

## Property Lists

A subtle yet significant distinction between the two development tools can be seen in the means of accessing property lists. Visual Basic users access a pull-down selection of options for a particular property via an entry bar at the top of the list, so that changing several property items, requires selection of the item, clicking on the entry bar to make the change, then clicking on the next item, and so forth. Delphi provides pull-down lists that can be accessed directly alongside the property value, making for more efficient and intuitive modifications.

## Code Window

Delphi's code editing window synchronizes all visual design representations with the underlying source code. In other words, as the application is constructed by dropping objects into a form, the corresponding bug-free code is generated simultaneously. There are no limitations, since the code is always accessible, and developers can instantly switch between the code editor and the visual design tools, allowing them to select the most efficient mode for each part of the project.

## Debugging and Object Inspecting

Visual Basic provides program debugging capabilities such as

variable watches and a call stack monitor. However, this functionality is limited in that it cannot break on a specific condition, and the call stack is modal, so it cannot be viewed during the entire debug session.

Delphi provides a full-featured debugger with conditional breakpoints and a modeless call stack viewer. The debug window and viewers can be saved from session to session, allowing developers to create a comfortable custom environment. Delphi also includes a powerful object browser similar to that used within Borland C++, which provides a comprehensive display of code objects and classes - including the capability to trace object lineage (inheritance, children) and virtual procedures.

## Component Reuse

One of the most significant advances in applications development methodology is the concept of creating an application from high-level components. By linking predefined building blocks, developers need only define the "glue" between objects that specifies the unique qualities of an application, with the potential for substantial productivity gains. Although Delphi and Visual Basic both provide various ways to reuse and share components and code, Delphi again delivers a cleaner and simpler solution.

The issue of reuse can be viewed in three areas:

- \* shared event functions
- \* reusable functions
- \* reusable building blocks (components)

## Shared Event Functions

A common problem encountered in Windows programs is how to share a function that is executed upon the occurrence of several Windows events. Although the implementation is similar in both Delphi and Visual Basic, the Delphi solution has some obvious advantages. In Visual Basic, shared functions must be placed in the local code file or in a global .BAS file if the function is to be shared. The problem with this is that the function is now global to the entire project. In contrast, Delphi allows the function to be placed in the local file or in a DCU (Pascal unit

file) which must be explicitly referenced only by the files that use it.

## Reusable Functions and Libraries

In Visual Basic, common functions or libraries are accomplished by use of a global .BAS file, which then makes the functions accessible to every file in the project. The disadvantage to this approach is that the shared functions must be global to every file. Alternatively, Visual Basic can take advantage of functions organized in a DLL, but DLLs (like VBXs) must be created by another development tool external to Visual Basic, which requires a different level of expertise and an additional learning curve. All libraries for Delphi can be created from within the Delphi environment. Pascal code is organized as units, and shared functions are accessible through a Pascal unit by simply referencing the "library" unit that contains the desired function. Delphi can also use and create high-performance Windows DLLs. Further, Delphi's underlying programming language allows developers to reuse and customize functionality within a class via subclassing (see further details of OOP methodology below).

## Components

VBXs can be developed for Visual Basic with functionality that is usable across different projects, but a significant disadvantage of VBXs is the complexity involved in creating them. There is a detailed set of restrictions associated with creation of a VBX such that they cannot be created within Visual Basic itself. Instead, the most common method to create a VBX is to use a C/C++ compiler to create a DLL and then put a VBX "wrapper" around it. The advantage of this is the speed of computation gained by using optimized C/C++ compiled code over the Visual Basic's interpreted technology. The disadvantage is that developers are forced to "switch gears" in order to work with the compiler, and the added complexity can lead to additional troubleshooting and debugging time.

Delphi components are more easily created. Unlike Visual Basic, where VBXs must be built using an external compiler, Delphi components are built within the Delphi development environment itself. This is an important distinction, because professional developers prefer to work with a consistent set of tools. Being able to use Delphi to create reusable components

becomes a major productivity enhancement, enabling more rapid development with the added benefits of reusability.

Additionally, since Delphi components are created with Delphi's optimizing native code compiler and linker, there is improved performance over traditional VBXs. One other considerable advantage of Delphi components is that developers can subclass the functionality of a component to create their own custom versions. If a specific VBX is insufficient for a Visual Basic user, the only alternative is to build (or purchase) an alternative VBX.

## Programming Language

An obvious difference between Visual Basic and Delphi is the underlying programming language. The use of Object Pascal within Delphi has several important repercussions:

- \* Pascal is a more powerful and structured language than Basic.
- \* Object Pascal is a true object-oriented programming language, providing the benefits of inheritance, encapsulation and polymorphism;
- \* Pascal is a compiled language, ensuring high-performance executables;
- \* The organization of files as DCUs provides a cleaner mechanism for creating libraries of reusable code (see Shared Event Code);
- \* Object Pascal utilizes the world's fastest commercial compiler technology;
- \* Object Pascal support in-line assembler code for maximum performance;

One final point of differentiation is that in Visual Basic, all code files must be specifically associated with a form, except for a global .BAS file. In other words, a function must be global to the entire project unless associated with a form. In Delphi, however, code files (and therefore classes and functions) can be disassociated with any form, allowing proper scoping of functions without any loss of functionality.

## OOP Design Methodology

The power and flexibility of an object-oriented design methodology is widely accepted as the best way to solve complex, real-world programming problems. Object-oriented design provides both a solid foundation and elegant architecture for an application. Some of the benefits of OOP are:

- \* Shorter development cycles;
- \* Code that is highly maintainable;
- \* Code that is easily shared with other modules or other projects;
- \* Facilitation of team programming and version control;
- \* By exploiting object inheritance and polymorphism, the coding process can become much simpler and the code itself significantly more coherent;
- \* Applications can incorporate several functions that are mostly similar but have certain distinct "personality traits".

Object Pascal is a structured, object-oriented programming language, providing full support for class architectures, inheritance, virtual functions and polymorphism. Visual Basic is not an object-oriented language. Note that although developers need not be familiar with object-oriented concepts to create programs using Delphi, professional programmers will appreciate the benefit of these capabilities.

## Database Scalability

A good RAD environment must address the pervasive issue of creating a database application, and Visual Basic and Delphi are no exceptions. In Visual Basic, developers can place a database component onto a form which can then have a property set that allows it to bidirectionally communicate with an ODBC-compatible database. The database component can be used as a crude mechanism to navigate through the database using arrows representing first, next, previous and last records. SQL queries can also be defined in code, to form a query snapshot into the database for viewing

or computation. Crystal Reports is shipped with Visual Basic, providing a report generating capability. Setup of the database structures, the associated forms, interaction between them and most of the navigation through the database must all be done explicitly via the visual design tools or within code.

Delphi includes extensive database support including the Borland Database Engine (BDE) for Paradox and dBASE access, and middleware layers that support local and remote SQL data access. The Borland database architecture provide developers with high-performance access to a variety of data sources including ODBC drivers. Delphi includes data access components and data-aware user interface components to provide a comprehensive database solution.

Delphi ships with several controls for data entry and display, including tables and grids. The grid control (TDBGrid Component) can be used to build a spreadsheet-style of application. A unique characteristic of the database grid control is that it can be linked to multiple database sources.

Delphi also includes wizards and experts that facilitate rapid design and implementation of databases and the corresponding user interface. The DataSet designer facility included with Delphi allows developers to rapidly create table or query data for database components. It is a simple matter to specify which set of fields from the database must be incorporated into the table or query.

When designing a database grid, an application often needs an editor to allow in-place modification of field data. Delphi's DBEdit provides a consolidated component to handle this task. Grid-aware, specialized versions of the control are available for labels, lists, combo boxes, images, memo (multi-line editors), check and radio buttons, lookup lists and lookup combo lists.

Delphi also features built-in support for queries and reports. A query control (TQuery Component) provides the ability to perform SQL queries in order to form the data set corresponding to the filtered elements of a database. If this data was extracted from dBASE or Paradox, you would also have the ability to modify, insert or delete records. By placing this component into a form that also contains the database component, developers can create a filtered, printable report based on some SQL or query into the data set. Delphi includes the award-winning ReportSmith report

writer for PC and SQL databases. ReportSmith provides an intuitive interface for report creation using live data at design time, and it supports queries, crosstabs, templates, calculations and unlimited report sizes.

## Moving Up to Delphi

Visual Basic developers who may be considering migrating their applications to Delphi, you may be concerned about the effort required to migrate existing Visual Basic applications in order to continue project development and maintenance within Delphi. Project migration is actually a fairly straightforward process. A conversion utility is available from EarthTrek, Inc (617) 273-0308 that performs most of the translation including project files, form files and code translation. The utility completes all of the possible automatic translation leaving some ambiguous language elements to be identified by a simple syntax check using the Delphi compiler. Many projects can be translated with virtually no effort. Others may require a few hours of post-work to complete.

## Conclusion

When examining the various RAD products in the marketplace, both Visual Basic and Delphi stand out as leading edge products. However, Delphi has clearly emerged as a next generation tool with its higher performance, highly facilitated visual design capability, extensive support for reusable components and database readiness. Delphi achieves its goals as a powerful application development system by combining a state-of-the-art visual design environment with the power, flexibility and reusability of a fully object-oriented language, the world's fastest compiler, and leading-edge database technology. Further, through the integration of Object Pascal, Delphi empowers developers with a full-featured programming environment without sacrificing rapid visual development thus allowing construction of sophisticated client-server applications in record time.

## Article #15691: INTERRUPT HANDLER RULES

Technical Notes Database

TN691D.txt      INTERRUPT HANDLER RULES

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

Description:

Q. What rules should I follow when writing an interrupt handler?

A. The following is a list of rules to keep in mind when writing an interrupt handler:

1. Use GetIntVec and SetIntVec to install/un-install interrupt handlers.
2. Use the interrupt keyword.
3. Be careful about reentrancy. Don't use any calls to DOS or to Turbo Pascal's overlay or heap management routines in your interrupt handler.
4. Interrupt procedures and functions must use the far call model (use the {\$F+} option).
5. Be proficient with the BIOS and Assembly language before attempting to write an interrupt handler.
6. Make sure your interrupt handler is not in an overlaid unit.
7. You will want to create an exit procedure to un-install the interrupt service routine.

## Article #15695: Configuration of an ODBC Driver with BDE v3.5 and less

Technical Information Database

TI695D.txt - Configuration of an ODBC Driver with BDE v3.5 and less

Category :Delphi 1.x  
Platform :All-32Bit  
Product :

Description:

CONFIGURING AN ODBC DRIVER AND ALIAS FOR DELPHI

-----

CONTROL PANEL'S ODBC OPTION

Delphi installs an ODBC option to the Windows Control Panel program. The ODBC option indicates the available data sources (drivers) installed for use by ODBC. As you will find by selecting the ODBC option, a number of formats are installed with Delphi and are seen in the main window titled Data Sources. Additional formats may be supported by the drivers installed and can be configured by selecting the Add... button.

If a new driver is to be added or removed,

1. Select the Drivers... button from the Data Sources Window. From the drivers dialog, select the Add... button and provide the path where the ODBC driver will be found.
2. Return to the Data Sources Windows and include the possible data sources available through the new driver by selecting its Add... button.
3. To configure options available for a particular data source use the Setup... button. The function of the Setup... button will vary with each data format. Very often options like the working directory for the driver are configured in this area.

Online help is available for each dialog involved with the ODBC option.

## BDE CONFIGURATION UTILITY

After installing the ODBC driver, run the BDE Configuration utility to configure the database engine to use the new driver.

1. From the drivers page, select the New ODBC driver button.
2. A dialog titled Add ODBC driver will appear. The option for SQL link driver is what will distinguish the databases created using this ODBC driver.
3. Next select the default ODBC driver. Dropping down the list from the combobox will reveal the file types supported by ODBC drivers installed on the system.
4. Select the default data source for the ODBC driver. Having set the ODBC driver in step 3 above, the list of this combobox will have the data source names appropriate for use with the selected driver.
5. Select Ok.
6. Returning to the drivers page, select File/Save from the main menu to save this configuration.

## CREATING AN ALIAS IN THE DATABASE DESKTOP

While this can be done from the BDE Configuration utility, it is more convenient overall to create ODBC aliases from the Database Desktop.

1. From the File menu, select Aliases...
2. From the resulting Alias Manager dialog, select New.
3. Type the name for your new alias in the area labeled Database Alias.
4. Use the drop down list of the Driver Type combobox to select the driver appropriate for this alias. Paradox and dBase tables are considered STANDARD. If the ODBC driver was properly configured in the BDE Configuration utility it's name will appear in this list.

5. Additional options may appear depending upon the driver type you select.

6. When finished, select Keep New to store the new alias. Then select Ok. You will be prompted for whether or not to save the aliases to IDAPI.CFG. Select Okay.

The alias will now be usable from both the Database Desktop and Delphi.

## Article #15697: FILE HANDLES USED BY TURBO PASCAL

Technical Notes Database

TN697D.txt      FILE HANDLES USED BY TURBO PASCAL  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 5.0 5.5

### Description:

Q. What file handles are used by Turbo Pascal?

A. Pascal uses a file handle for the overlays, reading the BGI driver, the Rename and Erase procedures. The other file handles are used by DOS: Standard Input, Standard Output, Standard Error, Standard Auxiliary, and Standard Printer. All except these five standard file handles are returned immediately.

## Article #15701: Creating Database Aliases in Code

Technical Information Database

TI701D.txt      Creating Database Aliases in Code

Category      :Database Programming

Platform      :All

Product       :Delphi 1.0

### Description:

This Technical Information document will help step thru concepts regarding the creation and use of ALIASES within your Delphi Applications.

Typically, you use the BDE Configuration Utility BDECFG.EXE to create and configure aliases outside of Delphi. However, with the use of the TDatabase component, you have the ability to create and use this ALIAS within your application-- not pre-defined in the IDAPI.CFG.

The ability to create Aliases that are only available within your application is important. Aliases specify the location of database tables and connection parameters for database servers. Ultimately, you can gain the advantages of using ALIASES within your applications-- without having to worry about the existence of a configuration entry in the IDAPI.CFG when you deploy your application.

### Summary of Examples:

----- -- -----

#### Example #1:

Example #1 creates and configures an Alias to use STANDARD (.DB, .DBF) databases. The Alias is then used by a TTable component.

#### Example #2:

Example #2 creates and configures an Alias to use an INTERBASE database (.gdb). The Alias is then used by a TQuery component to join two tables of the database.

#### Example #3:

Example #3 creates and configures an Alias to use STANDARD (.DB, .DBF) databases. This example

demonstrates how user input can be used to configure the Alias during run-time.

Example #1: Use of a .DB or .DBF database (STANDARD)

1. Create a New Project.
2. Place the following components on the form:
  - TDatabase, TTable, TDataSource, TDBGrid, and TButton
3. Double-click on the TDatabase component or choose Database Editor from the TDatabase SpeedMenu to launch the Database Property editor.
4. Set the Database Name to 'MyNewAlias'. This name will serve as your ALIAS name used in the DatabaseName Property for dataset components such as TTable, TQuery, TStoredProc.
5. Select STANDARD as the Driver Name.
6. Click on the Defaults Button. This will automatically add a PATH= in the Parameter Overrides section.
7. Set the PATH= to C:\DELPHI\DEMOS\DATA (PATH=C:\DELPHI\DEMOS\DATA)
8. Click the OK button to close the Database Dialog.
9. Set the TTable DatabaseName Property to 'MyNewAlias'.
10. Set the TDataSource's DataSet Property to 'Table1'.
11. Set the DBGrid's DataSource Property to 'DataSource1'.
12. Place the following code inside of the TButton's OnClick event.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    Table1.Tablename:= 'CUSTOMER';
    Table1.Active:= True;
end;
```

13. Run the application.

\*\*\* If you want an alternative way to steps 3 - 11, place the following code inside of the TButton's OnClick event.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    Database1.DatabaseName:= 'MyNewAlias';
    Database1.DriverName:= 'STANDARD';
    Database1.Params.Clear;
```

```

Database1.Params.Add('PATH=C:\DELPHI\DEMOS\DATA');
Table1.DatabaseName:= 'MyNewAlias';
Table1.TableName:= 'CUSTOMER';
Table1.Active:= True;
DataSource1.DataSet:= Table1;
DBGrid1.DataSource:= DataSource1;
end;

```

\*\*\*\*\*

## Example #2: Use of a INTERBASE database

1. Create a New Project.
2. Place the following components on the form:
  - TDatabase, TQuery, TDataSource, TDBGrid, and TButton
3. Double-click on the TDatabase component or choose Database Editor from the TDatabase SpeedMenu to launch the Database Property editor.
4. Set the Database Name to 'MyNewAlias'. This name will serve as your ALIAS name used in the DatabaseName Property for dataset components such as TTable, TQuery, TStoredProc.
5. Select INTRBASE as the Driver Name.
6. Click on the Defaults Button. This will automatically add the following entries in the Parameter Overrides section.

```

SERVER NAME=IB_SERVER:/PATH/DATABASE.GDB
USER NAME=MYNAME
OPEN MODE=READ/WRITE
SCHEMA CACHE SIZE=8
LANGDRIVER=
SQLQRYMODE=
SQLPASSTHRU MODE=NOT SHARED
SCHEMA CACHE TIME=-1
PASSWORD=

```

7. Set the following parameters

```

SERVER NAME=C:\IBLOCAL\EXAMPLES\EMPLOYEE.GDB
USER NAME=SYSDBA
OPEN MODE=READ/WRITE
SCHEMA CACHE SIZE=8
LANGDRIVER=
SQLQRYMODE=
SQLPASSTHRU MODE=NOT SHARED
SCHEMA CACHE TIME=-1

```

PASSWORD=masterkey

8. Set the TDatabase LoginPrompt Property to 'False'. If you supply the PASSWORD in the Parameter Overrides section and set the LoginPrompt to 'False', you will not be prompted for the password when connecting to the database. WARNING: If an incorrect password is entered in the Parameter Overrides section and LoginPrompt is set to 'False', you are not prompted by the Password dialog to re-enter a valid password.
9. Click the OK button to close the Database Dialog.
10. Set the TQuery DatabaseName Property to 'MyNewAlias'.
11. Set the TDataSource's DataSet Property to 'Query1'.
12. Set the DBGrid's DataSource Property to 'DataSource1'.
13. Place the following code inside of the TButton's OnClick event.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    Query1.SQL.Clear;
    Query1.SQL.ADD(
        'SELECT DISTINCT * FROM CUSTOMER C, SALES S
        WHERE (S.CUST_NO = C.CUST_NO)
        ORDER BY C.CUST_NO, C.CUSTOMER');
    Query1.Active:= True;
end;
```

14. Run the application.

### Example #3: User-defined Alias Configuration

This example brings up a input dialog and prompts the user to enter the directory to which the ALIAS is to be configured to.

The directory, servername, path, database name, and other necessary Alias parameters can be read into the application from use of an input dialog or .INI file.

1. Follow the steps (1-11) in Example #1.
2. Place the following code inside of the TButton's OnClick event.

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  NewString: string;
  ClickedOK: Boolean;
begin
  NewString := 'C:\';
  ClickedOK := InputQuery('Database Path',
    'Path: --> C:\DELPHI\DEMOS\DATA', NewString);
  if ClickedOK then
  begin
    Database1.DatabaseName:= 'MyNewAlias';
    Database1.DriverName:= 'STANDARD';
    Database1.Params.Clear;
    Database1.Params.Add('Path=' + NewString);
    Table1.DatabaseName:= 'MyNewAlias';
    Table1.TableName:= 'CUSTOMER';
    Table1.Active:= True;
    DataSource1.DataSet:= Table1;
    DBGrid1.DataSource:= DataSource1;
  end;
end;
```

3. Run the Application.

## Article #15703: FINDFIRST - THE EXISTENCE OF FILES

Technical Notes Database

TN703D.txt      FINDFIRST - THE EXISTENCE OF FILES

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 4.0+

Description:

Q. How can I check to see if a File Exists?

A. The following function will return whether or not  
a file exists:

Uses DOS;

```
function Exist( Name: PathStr ):boolean;
```

```
Var
```

```
  Search: SearchRec;
```

```
Begin
```

```
  FindFirst( Name, AnyFile and (Not Directory), Search );
```

```
  Exist := DosError = 0;
```

```
End;
```

## Article #15707: Creating & Deleting TFields at run-time

Technical Information Database

TI707D.txt     Creating & Deleting TFields at run-time  
Category     :Database Programming  
Platform     :All  
Product      :Delphi All

### Description:

TField components (or more appropriately, descendants of the TField component of types corresponding to field types) can be created at design-time using the Fields Editor. The Fields Editor is invoked by double-clicking on the design icon for a TTable or TQuery component. But TField descendants can also be created and deleted at run-time.

Descendants of the TField component (such as TStringField, TIntegerField, etc.) are created by invoking the Create method for the type of TField descendant appropriate to the field in the data set. That is, the Create method for the TStringField descendant of TField would be called to create a TField descendant for a string-type field in the current data set. The Create method requires one parameter, that of the owner of the TField descendant, which is the containing TForm. After creating the TField descendant component, a number of key properties need to be set in order to connect it with the field in the data set. These are:

FieldName: the name of the field in the table.  
Name: a unique identifier for the TField descendant component.  
Index: the TField descendant component's position in the array of TFields (the Fields property of the TTable or TQuery with which the TField will be associated).  
DataSet: the TTable or TQuery with which the TField will be associated.

The code snippet below demonstrates creating a TStringField. The containing TForm is called Form1 (referred to here with the Self variable), the active data set is a TQuery named Query1, and the field for which the TStringField component is being created is a dBASE table field named CO\_NAME. This new TField descendant will be the second TField in the Fields array property of Query1. Note that the data set with which the new TField descendant will be associated (in this case, Query1) must be closed prior to adding the TField and then reopened afterwards.

```
procedure TForm1.Button2Click(Sender: TObject);
var
    T: TStringField;
begin
    Query1.Close;
    T := TStringField.Create(Self);
    T.FieldName := 'CO_NAME';
    T.Name := Query1.Name + T.FieldName;
    T.Index := Query1.FieldCount;
    T.DataSet := Query1;
    Query1.FieldDefs.Update;
    Query1.Open;
end;
```

The example above example creates a new TStringField named Query1CO\_NAME.

Deleting an existing TField descendant is merely a matter of invoking the Free method for that component. In the example below, the TForm's FindComponent method is used to return a pointer to the TStringField component named Query1CO\_NAME. The return value for the FindComponent will either be of type TComponent if successful or nil if unsuccessful. This return value can be used to determine whether the component actually exists prior to invoking its Free method.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  TC: TComponent;
begin
  TC := FindComponent('Query1CO_NAME');
  if not (TC = nil) then begin
    Query1.Close;
    TC.Free;
    Query1.Open;
  end;
end;
```

As with creating a TField, if the data set associated with the TField descendant is currently active, it must be closed or deactivated prior to invoking this method.

## Article #15713: How to iterate through the fields of a table

Technical Information Database

TI713D.txt     How to iterate through the fields of a table  
Category     :Database Programming  
Platform     :All  
Product     :Delphi All

### Description:

Getting a list of the fields in a table at run-time can be as simple as a call to the `GetFieldNames` method of the `TTable`, `TQuery`, or `TStoredProc` component. The `GetFieldNames` method returns a list of the fields that comprise the structure of the data set in the form of a `TStrings` list, which may be inserted into such visual components as a `TListBox` through its `Items` property:

```
ListBox1.Clear;  
Table1.GetFieldNames(ListBox1.Items);
```

Of course, the `TStrings` list returned by the `GetFieldNames` method need not be used with a visual component. It could just as well serve as an array of field names stored entirely in memory, that can be used as a list or array.

But it is also possible to retrieve much more information about the fields in a table than just the names. Other descriptive attributes include field types and sizes. Retrieving these values is slightly more involved than the use of the `GetFieldNames`. Basically, this process involves iterating through the `FieldDefs` property of the `TTable`, `TQuery`, or `TStoredProc` component. The `FieldDefs` property is essentially an array of records, one record for each field in the structure. Each field record contains information about the field, including its name, type, and size. It is a relatively straightforward process to iterate

through  
this array of field descriptions, extracting information about  
individual  
fields.

There are a number of reasons why a program might need to query the  
structure of a table used in the application. One reason is a prelude  
to  
creating TField components at run-time that represent the fields in  
the  
table. The information gleaned from the structure of the table form  
the  
basis of the TField components to be created.

The example below demonstrates how to iterate through the fields  
available  
in a TTable or TQuery. The example extracts information about the  
available  
fields and displays the information in a TListBox, but the same  
methodology  
can be used to provide information necessary for the dynamic building  
of  
TField descendants. The example uses a TTable as the data set, but a  
TQuery  
can be used in the same manner as both TTable and TQuery components  
incorp-  
orate the Field-Defs property the same way.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
  F: TFieldDef;
  D: String;
begin
  Table1.Active := True;
  ListBox1.Items.Clear;
  with Table1 do begin
    for i := 0 to FieldDefs.Count - 1 do begin
      F := FieldDefs.Items[i];
      case F.DataType of
        ftUnknown: D := 'Unknown';
        ftString: D := 'String';
        ftSmallint: D := 'SmallInt';
        ftInteger: D := 'Integer';
        ftWord: D := 'Word';
```

```
ftBoolean: D := 'Boolean';
ftFloat: D := 'Float';
ftCurrency: D := 'Currency';
ftBCD: D := 'BCD';
ftDate: D := 'Date';
ftTime: D := 'Time';
ftDateTime: D := 'DateTime';
ftBytes: D := 'Bytes';
ftVarBytes: D := '';
ftBlob: D := 'BLOB';
ftMemo: D := 'Memo';
ftGraphic: D := 'Graphic';
else
  D := '';
end;
ListBox1.Items.Add(F.Name + ', ' + D);
end;
end;
Table1.Active := False;
end;
```

## Article #15715: READ - SKIPPING OVER A READLN OR READ

Technical Notes Database

TN715D.txt      READ - SKIPPING OVER A READLN OR READ

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 2.0+

### Description:

Q. Why is my program not waiting for input on a Read or Readln?

A. The program has a Read statement. When the user enters information and hits a carriage return the information and the carriage return are stored in the keyboard buffer. The Read statement reads everything until the carriage return, but not the carriage return. When the program executes the next Read or Readln it will see the carriage return in the keyboard buffer. It will then process the return and continue with the next instruction. To the user it will appear that the program has skipped over the Read or Readln. To fix this problem never use Read to read information from the keyboard, always use Readln.

## Article #15719: How to match file date/time stamps.

Technical Information Database

TI719D.txt     How to match file date/time stamps.

Category     :General Programming

Platform     :All

Product     :Delphi   All

Description:

Q: "How can I write a function that sets the date of one file equal to the date of another file?"

A: No problem. Just use the following function, which takes two strings representing full DOS path/file names. The file who's date you wish to set is the second parameter, and the date you wish to set it to is given by the file in the first parameter.

```
procedure CopyFileDate(const Source, Dest: String);
var
  SourceHand, DestHand: word;
begin
  SourceHand := FileOpen(Source, fmOutput);      { open source file }
  DestHand := FileOpen(Dest, fmInput);           { open dest file }
  FileSetDate(DestHand, FileGetDate(SourceHand)); { get/set date }
  FileClose(SourceHand);                         { close source
file }
  FileClose(DestHand);                           { close dest file }
end;
```

7/16/98 4:33:52 PM

Last Modified: 01-SEP-99

## Article #15721: RESET - READING AND WRITING TYPED UNTYPED FILES

Technical Notes Database

TN721D.txt     RESET - READING AND WRITING TYPED UNTYPED FILES  
Category     :Pascal  
Platform     :All  
Product     :Turbo Pascal 4.0+

### Description:

Q. How can I write to a binary file without destroying the information already in it?

A. You must use the Reset procedure. It opens the file for BOTH reading and writing. Furthermore, the RecordSize\*Count cannot exceed the total size of the buffer. Therefore, you may have to use

```
Reset(FileVariable, 1) { RecordSize = 1 }.
```

Now, you may use the Seek procedure, to go to a particular position in the file, and the BlockWrite procedure to write over some data. The following example demonstrates the use of BlockRead and BlockWrite:

```
program ReadWriteFile;  
var  
  FromF : file;  
  NumRead, NumWritten: Word;  
  Buf : array[1..2] of Char;  
  Ch : Char;  
begin  
  { Open input file and create it }  
  Assign(FromF, 'MyFile.Dat');  
  { Record size = 1 }  
  Buf[1] := 'a'; Buf[2] := 'b';  
  Ch := 'c';  
  Rewrite(FromF, 1);  
  BlockWrite(FromF, Ch, SizeOf(Ch), NumWritten);  
  Close(FromF);  
  Reset(FromF, 1);  
  { Open output file and write to it and read from it }  
  BlockWrite(FromF, Buf, SizeOf(Buf), NumWritten);
```

```
BlockRead(FromF,Ch,SizeOf(Ch),NumRead);  
Close(FromF);  
end.
```

## Article #15725: Adding Graphics in Your Listboxes and Comboboxes

Technical Information Database

TI725D.txt Adding Graphics in Your Listboxes and Comboboxes

Category :VCL

Platform :All

Product :Delphi All

Description:

TI: Inserting graphics in Owner Drawn ListBoxes and ComboBoxes

The ability to place graphics inside ListBoxes and ComboBoxes can improve the look of your application and set your user interface apart from the others.

Q: How do I stick graphics in a Listbox or ComboBox???

Here is an step-by-step example.....

1. Create a form.
2. Place a ComboBox and Listbox component on your form.
3. Change the Style property of the ComboBox component to `csOwnerDrawVariable` and the Style property of the ListBox to `lbOwnerDrawVariable`.

An Owner-Draw TListBox or TComboBox allows you to display both objects (ex. graphics) and strings as the items. For this example, we are adding both a graphic object and a string.

4. Create 5 variables of type TBitmap in the Form's VAR section.
5. Create a Procedure for the Form's OnCreate event.
6. Create a Procedure for the ComboBox's OnDraw Event.
7. Create a Procedure for the ComboBox's OnMeasureItem.

8. Free the resources in the Form's OnClose Event.

```
{START OWNERDRW.PAS}
unit Ownerdrw;

interface

uses
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,
  Forms, Dialogs, StdCtrls;

type
  TForm1 = class(TForm)
    ComboBox1: TComboBox;
    ListBox1: TListBox;
    procedure FormCreate(Sender: TObject);
    procedure FormClose(Sender: TObject; var Action: TCloseAction);
    procedure ComboBox1DrawItem(Control: TWinControl; Index: Integer;
      Rect: TRect; State: TOwnerDrawState);
    procedure ComboBox1MeasureItem(Control: TWinControl; Index:
Integer;
      var Height: Integer);
    procedure ListBox1DrawItem(Control: TWinControl; Index: Integer;
      Rect: TRect; State: TOwnerDrawState);
    procedure ListBox1MeasureItem(Control: TWinControl; Index:
Integer;
      var Height: Integer);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
  TheBitmap1, TheBitmap2, TheBitmap3, TheBitmap4,
  TheBitmap5 : TBitmap;
implementation

{$R *.DFM}

procedure TForm1.FormCreate(Sender: TObject);
begin
  TheBitmap1 := TBitmap.Create;
```

```

TheBitmap1.LoadFromFile('C:\delphi\images\buttons\globe.bmp');
TheBitmap2 := TBitmap.Create;
TheBitmap2.LoadFromFile('C:\delphi\images\buttons\video.bmp');

## Article #15727: READING CHARACTERS DIRECTLY FROM SCREEN

Technical Notes Database

TN727D.txt      READING CHARACTERS DIRECTLY FROM SCREEN

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 4.0+

Description:

Q. How can I read characters directly from the screen in Turbo Pascal?

A. The operation can be done though it is not implemented directly. A useful function outlined below can be used to read characters directly from the screen. The program using this function must use the DOS unit and the CRT unit.

```
function GetChar(x,y: integer): char;
var
  r: Registers;
  tx,ty: Integer;
begin
  tx:=wherex;
  ty:=wherey;
  r.ah:=8;
  r.bh:=0;          {Current video page; 0 is default}
  GotoXy(x,y);
  intr(16,r);
  GetChar:=r.al;
  GotoXy(tx,ty);
end;
```

## Article #15731: Using OnHint Events Among Multiple Forms

Technical Information Database

TI731D.txt Using OnHint Events Among Multiple Forms

Category :VCL

Platform :All

Product :Delphi All

Description:

Using OnHint Among Multiple Forms  
-----

Delphi's Online Help and Visual Component Library Reference describe an example for processing TApplication's OnHint event. The example shows how a panel can be used to display hints associated with other components. As the example sets the Application's OnHint method in the Form's OnCreate event, a program involving more than one form will have difficulty using this technique.

Moving the assignment of OnHint from the Form's OnCreate event to its OnActivate method will allow different forms involved in the application to treat Hints in their own way.

Here is an altered form of the source code presented in the Online Help and the VCL Reference.

type

```
TForm1 = class(TForm)
  Button1: TButton;
  Panel1: TPanel;
  Edit1: TEdit;
  procedure FormActivate(Sender: TObject);
private
  { Private declarations }
public
  procedure DisplayHint(Sender: TObject);
end;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.DisplayHint(Sender: TObject);  
begin  
    Panell1.Caption := Application.Hint;  
end;
```

```
procedure TForm1.FormActivate(Sender: TObject);  
begin  
    Application.OnHint := DisplayHint;  
end;
```

## Article #15733: WRITING TO FILE 'CON'

Technical Notes Database

TN733D.txt      WRITING TO FILE 'CON'

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 4.0+

### Description:

Q. Using 4.0+, can I still write to file 'Con' without changes?

A. The 'Con' file is not longer available in 4.0+. However, you can still write to the screen with a simple Write with no file variable. The file system has been completely redesigned to allow you to write your own text file device drivers. With these, you can implement a Pascal-like text-file interface to any device, such as serial ports, windowing systems, memory, etc.

## Article #15737: Making the Enter key work like a Tab in a TDBGrid

Technical Information Database

TI737D.txt Making the Enter key work like a Tab in a TDBGrid  
Category :VCL  
Platform :All  
Product :Delphi All

### Description:

Code to make the key act as the tab key while inside a grid.

This code also includes the processing of the key for the entire application - including fields, etc. The grid part is handled in the ELSE portion of the code. The provided code does not mimic the behavior

of the key stepping down to the next record when it reaches the last column in the grid - it moves back to the first column - .

```
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
{ This is the event handler for the FORM's OnKeyPress event! }
{ You should also set the Form's KeyPreview property to True }
begin
  if Key = #13 then { if it's an enter
key }
    if not (ActiveControl is TDBGrid) then begin { if not on a
TDBGrid }
      Key := #0; { eat enter key }
      Perform(WM_NEXTDLGCTL, 0, 0); { move to next
control }
    end
    else if (ActiveControl is TDBGrid) then { if it is a
TDBGrid }
      with TDBGrid(ActiveControl) do
        if selectedindex < (fieldcount -1) then { increment the
field }
          selectedindex := selectedindex +1
        else
          selectedindex := 0;
    end;
end;
```

## Article #15743: Moving to a tab by name on a TabSet

Technical Information Database

TI743D.txt     Moving to a tab by name on a TabSet  
Category     :VCL  
Platform     :All  
Product      :Delphi All

### Description:

Moving to a page by name on a TabSet.

Place a Tabset(TabSet1) and an Edit (Edit1) on your form. Change the Tabset's Tabs Property in the String List Editor to include 4 Tabs:

```
    Hello,  
    World,  
    Of,  
    Delphi,
```

Change Edit1's onChange event to:

```
procedure TForm1.Edit1Change(Sender: TObject);  
var  
    I : Integer;  
begin  
    for I:= 0 to tabset1.tabs.count-1 do  
        if edit1.text = tabset1.tabs[I] then  
            tabset1.tabindex:=I;  
end;
```

If You type any of the Tabs names in edit1 it will focus on the appropriate tab.

## Article #15749: Calling a Delphi DLL from C

Technical Information Database

TI749D.txt      Calling a Delphi DLL from C  
Category        :General Programming  
Platform        :All  
Product         :Delphi 1.0

Description:  
Calling a DLL from your C Code.

First create a simple DLL in Delphi:

```
{ Begin DLL code }  
  
Library MinMax;  
  
Function Min(X, Y: Integer): Integer; export;  
begin  
    if X < Y then Min := X else Min := Y;  
end;  
  
Function Max(X, Y: Integer): Integer; export;  
begin  
    if X > Y then Max := X else Max := Y;  
end;  
  
Exports  
    Min index 1,  
    Max index 2;  
  
begin  
end.  
  
{ End DLL code }
```

Then to Call it from your C Code:

1. In your .DEF File add:

```
IMPORTS
```

Min =MINMAX.Min

Max =MINMAX.Max

2. In your C application, you must prototype the functions as:

```
int FAR PASCAL Min(int x, y);
```

```
int FAR PASCAL Min(int x, y);
```

3. Now you can call Min or Max anywhere in your application.

## Article #15755: Getting a query's Memo field as a string

Technical Information Database

TI755D.txt     Getting a query's Memo field as a string  
Category     :Database Programming  
Platform      :All  
Product       :Delphi 1.0

### Description:

Returning a Memo value to an Edit field without using a memo field.

Place a query object on your form (Query1)

Place a Edit object on your form (Edit1)

Place a Button object on your form (Button1)

Double-Click on the query and add the memo field.

(Biolife.db using notes field)

Set Query1's SQL property to: Select \* from Biolife

Set Query1's Active property to: True

Add the following code to Button1's OnClick event:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  bs : TBlobStream;
  p  : array [0..50] of char;
begin
  FillChar(p, SizeOf(p), #0);
  bs:= TBlobStream.Create(Query1Notes, bmRead);
  try
    bs.Read(p, 50);
  finally
    bs.Free;
  end;
  Edit1.Text:=StrPas(p);
end;
```

```
{ Begin code }
```

```
program Crypt;
```

```
uses WinCRT;
```

```
const
```

```
  C1 = 52845;
```

```
  C2 = 22719;
```

```
function Encrypt(const S: String; Key: Word): String;
```

```
var
```

```
  I: byte;
```

```
begin
```

```
  Result[0] := S[0];
```

```
  for I := 1 to Length(S) do begin
```

```
    Result[I] := char(byte(S[I]) xor (Key shr 8));
```

```
    Key := (byte(Result[I]) + Key) * C1 + C2;
```

```
  end;
```

```
end;
```

```
function Decrypt(const S: String; Key: Word): String;
```

```
var
```

```
  I: byte;
```

```
begin
```

```
  Result[0] := S[0];
```

```
for I := 1 to Length(S) do begin
    Result[I] := char(byte(S[I]) xor (Key shr 8));
    Key := (byte(S[I]) + Key) * C1 + C2;
end;
end;
```

```
var
    S: string;
begin
    Write('>');
    ReadLn(S);
    S := Encrypt(S,12345);
    WriteLn(S);
    S := Decrypt(S,12345);
    WriteLn(S);
end.
```

## Article #15763: I/O REDIRECTION \$P128 \$G128

Technical Notes Database

TN763D.txt I/O REDIRECTION \$P128 \$G128

Category :Pascal

Platform :All

Product :Turbo Pascal 3.0+

Description:

Q. How do you do I/O redirection?

How can I write to standard output?

In version 3.0, I used \$P128,G128. What do I do in Version 4.0+?

A. If you want to do DOS I/O redirection when running an .EXE file generated by Turbo Pascal 4.0+, DO NOT use the Crt unit. If you do, make sure you assign a text file variable to the standard DOS output device. For example:

```
Assign(Output, ''); { assign a text file variable }
                  { to a null file name           }
Rewrite(Output);  { do a rewrite here             }
```

Any Write statement that does not specify a file variable will be redirected to the DOS standard output file. You can also use Write(Output,...).

## Article #15767: Undo in a Memo field

Technical Information Database

TI767D.txt Undo in a Memo field  
Category :VCL  
Platform :All  
Product :Delphi All

### Description:

Doing an Undo in a Memo Field:

If you have a pop-up menu in a TMemo, and put shortcuts on it for the Cut, Copy, Paste, then you can handle those events, and call CuttoClipboard, CopytoClipboard, etc.

However, if you put an Undo option onto your pop-up menu (normally Ctrl-Z) how do you instruct the TMemo to do the Undo? If the built-in undo is sufficient, you can get it easier than a Ctrl+Z:

```
Mem1.Perform(EM_UNDO, 0, 0);
```

To check whether undo is available so as to enable/disable an undo menu item:

```
Undo1.Enabled := Mem1.Perform(EM_CANUNDO, 0, 0) <> 0;
```

## Article #15779: Loading Bitmaps Into dBASE And Paradox BLOB Fields

Technical Information Database

TI779D.txt Loading Bitmaps Into dBASE And Paradox BLOB Fields  
Category :Database Programming  
Platform :All  
Product :Delphi 1.0

### Description:

There are a number of ways to load a bitmap image into the BLOB field of a dBASE or Paradox table. Three of the easier methods involve 1) copying the data from the Windows clipboard into a TDBImage component connected to the BLOB field, 2) using the LoadFromFile method of the TBLOBField component, and 3) using the Assign method to copy an object of type TBitmap into the Picture property of a TDBImage.

The first method, copying the bitmap from the clipboard, is probably most handy when an application needs to add bitmaps to a table when the end-user is running the application. A TDBImage component is used to act as an interface between the BLOB field in the table and the image stored in the clipboard. The PasteFromClipboard method of the TDBImage component is invoked to copy the bitmap data from the clipboard into the TDBImage. When the record is posted, the image is stored into the BLOB field in the table.

Because the Windows clipboard can contain data in formats other than just bitmap, it is advisable to check the format prior to calling the CopyFromClipboard method. To do this, a TClipboard object is created and its Has-

Format method is used to determine if the data in the clipboard is indeed of bitmap format. Note that to use a TClipboard object, the Clipbrd unit must be included in the Uses section of the unit that will be creating the object.

Here is an example showing the contents of the clipboard being copied into a TDBImage component, if the contents of the clipboard are of bitmap format:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  C: TClipboard;
begin
  C := TClipboard.Create;
  try
    if Clipboard.HasFormat(CF_BITMAP) then
      DBImage1.PasteFromClipboard
    else
      ShowMessage('Clipboard does not contain a bitmap!');
  finally
    C.Free;
  end;
end;
```

The second method of filling a BLOB field with a bitmap involves loading the bitmap directly from a file on disk into the BLOB field. This method lends itself equally well to uses at run-time for the end-user as for the developer building an application's data.

This method uses the LoadFromFile method of the TBLOBField component, the Delphi representation of a dBASE for Windows Binary field or a Paradox for Windows Graphic field, either of which may be used to store bitmap data in a table.

The LoadFromFile method of the TBLOBField component requires a single parameter: the name of the bitmap file to load, which is of type String.

The value for this parameter may come from a number of sources from the end-user manually keying in a valid file name to the program providing a string to the contents of the FileName property of the TOpenDialog component.

Here is an example showing the use of the LoadFromFile method for a TBLOBField component named Table1Bitmap (a field called Bitmap in the table associated with a TTable component named Table1):

```
procedure TForm1.Button2Click(Sender: TObject);
begin
    Table1Bitmap.LoadFromFile(
        'c:\delphi\images\splash\16color\construc.bmp');
end;
```

The third method uses the Assign method to copy the contents of an object of type TBitmap into the Picture property of a TDBImage component. An object of type TBitmap might be the Bitmap property of the Picture object property of a TImage component or it may be a stand-alone TBitmap object.

As with the method copying the data from the clipboard into a TDBImage component, the bitmap data in the TDBImage component is saved into the BLOB field in the table when the record is successfully posted.

Here is an example using the Assign method. In this case, a stand-alone TBitmap object is used. To put a bitmap image into the TBitmap, the LoadFromFile method of the TBitmap component is called.

```
procedure TForm1.Button3Click(Sender: TObject);
var
    B: TBitmap;
begin
    B := TBitmap.Create;
    try
        B.LoadFromFile('c:\delphi\images\splash\16color\athena.bmp');
        DBImage1.Picture.Assign(B);
    finally
        B.Free;
    end;
```

end;

Description:

Q. How can I detect what kind of video card my computer has using Turbo Pascal?

A. The Graph unit of Turbo Pascal has an autodetection scheme built-in which will allow you to detect what kind of graphics hardware is available at runtime. See the following example:

```
Program AutoDetectGraphics;
Uses Graph;
var
  gd,gm: integer;

Procedure InitializeGraphics;
begin
  gd:=Detect;
  InitGraph(gd,gm, '');
  OutTextXY(20,20,'Graphics Test!');
  readln;
  CloseGraph;
end; { InitializeGraphics }

Procedure DetectGraphics(var driver, mode: integer);
begin
  DetectGraph(driver,mode);
end; { DetectGraphics }

begin { MAIN }
  DetectGraphics(gd,gm);
  writeln('Detected: ');
  writeln('  GraphDriver = ',gd);
  writeln('  GraphMode    = ',gm);
  readln;
  InitializeGraphics;
```

end. { End of Program }

## Article #15785: Printing the contents of a TMemo or TListbox

Technical Information Database

TI785D.txt     Printing the contents of a TMemo or TListbox

Category     :VCL

Platform     :All

Product      :Delphi   All

Description:

Q: How can I print all of the lines within a TMemo or TListbox component?

A: The function below accepts a TStrings object as a parameter and prints

out each string to the default printer. Because it uses a TStrings, the function will work with any type of component that contains a TStrings-type property, such as a TDBMemo or TOutline.

{ Begin code listing }

```
uses Printers;
```

```
procedure PrintStrings(Strings: TStrings);
```

```
var
```

```
  Prn: TextFile;
```

```
  i: word;
```

```
begin
```

```
  AssignPrn(Prn);
```

```
  try
```

```
    Rewrite(Prn);
```

```
    try
```

```
      for i := 0 to Strings.Count - 1 do
```

```
        writeln(Prn, Strings.Strings[i]);
```

```
    finally
```

```
      CloseFile(Prn);
```

```
    end;
```

```
  except
```

```
    on EInOutError do
```

```
      MessageDlg('Error Printing text.', mtError, [mbOk], 0);
```

```
  end;
```

```
end;
```

```
{ End code listing }
```

To print out the contents of a TMemo or TListbox, use the following code:

```
PrintStrings(Memo1.Lines);
```

or

```
PrintStrings(Listbox1.Items);
```

## Article #15787: REVERSE VIDEO WITH GRAPH UNIT

Technical Notes Database

TN787D.txt REVERSE VIDEO WITH GRAPH UNIT

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

Description:

Q. How do you reverse the background color with the foreground color with the Graph unit routines?

A. To create reverse video in graphics mode:

1. Set the background color: SetBkColor(6). The background color is now brown.
2. Set the palette so that the background and foreground colors won't be the same: SetPalette(6,0).
3. Set the foreground color: SetColor(6).

To restore, either:

1. Use GetPalette(P) before creating reverse video and restore with SetPalette(P), or
2. a) Set the background color: SetBkColor(0). The background color is back to black.  
b) Return the palette to its original state: SetPalette(6,20).

Note that these procedures work only in graphics mode.

## Article #15791: Extracting A Bitmap From A BLOB Field

Technical Information Database

TI791D.txt     Extracting A Bitmap From A BLOB Field

Category     :Database Programming

Platform     :All

Product     :Delphi All

### Description:

Extracting a bitmap from a dBASE or Paradox blob field -- without first saving the bitmap out to a file -- is a simple process of using the Assign method to store the contents of the BLOB field to an object of type TBitmap. A stand-alone TBitmap object or the Bitmap property of the Picture object property of a TImage component are examples of compatible destinations for this operation.

Here is an example demonstrating using the Assign method to copy a bitmap from a BLOB field into a TImage component.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    Image1.Picture.Bitmap.Assign(Table1Bitmap);
end;
```

In this example, the TBLOBField object Table1Bitmap is a BLOB field in a dBASE table. This TBLOBField object was created using the Fields Editor.

If the Fields Editor is not used to create TFields for the fields in the table, the fields must be referenced using either the FieldByName method or the Fields property, both part of the TTable and TQuery components. In cases where one of those means is used to reference the BLOB field in a table, the field reference must be type-cast as a TBLOBField object

prior  
to using the Assign method. For example:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Image1.Picture.Bitmap.Assign(TBLOBField(Table1.Fields[1]));  
end;
```

A bitmap stored in a BLOB field may also be copied directly to a stand-alone TBitmap object. Here is an example showing the creation of a TBitmap object and storing into it a bitmap from a BLOB field.

```
procedure TForm1.Button2Click(Sender: TObject);  
var  
    B: TBitmap;  
begin  
    B := TBitmap.Create;  
    try  
        B.Assign(Table1.Bitmap);  
        Image1.Picture.Bitmap.Assign(B);  
    finally  
        B.Free;  
    end;  
end;
```

## Article #15793: INVERSE VIDEO TEXT

Technical Notes Database

TN793D.txt      INVERSE VIDEO TEXT  
Category        :Pascal  
Platform        :All  
Product         :Turbo Pascal 3.0+

### Description:

Q. How do I get inverse video in text mode using Turbo Pascal 3.0 and 4.0+?

A. You can create inverse video by reversing text and background colors before displaying text. For example:

```
Program InverseIt;  
{ Uses Crt; => Add if using TP 4.0+ }  
begin  
  TextBackground(White);  
  TextColor(Black);  
  writeln('This is inverse video!');  
end.
```

## Article #15797: Bitmaps And InterBase BLOB Fields

Technical Information Database

TI797D.txt      Bitmaps And InterBase BLOB Fields

Category      :Database Programming

Platform      :All

Product       :Delphi    All

### Description:

dBASE and Paradox tables provide a BLOB field to store binary data that,

when the stored data is of bitmap-format, work as-is with the TDBImage component to display images. In Database Desktop, these field types are

listed as Binary and Graphic (for dBASE and Paradox tables, respectively).

However, the process of storing bitmap images in InterBase BLOB fields and using the stored data with TDBImage components is not as straightforward.

InterBase tables do not have just one type of BLOB field. There are three

variants, or sub-types: type 0, type 1, and user-defined sub-types.

Types

0 and 1 are pre-defined types. Type 0 BLOB fields (the default type) are

for storing general binary data. Type 1 BLOB fields are for storing text

BLOB data. Either the pre-defined type 0 or a user-defined BLOB sub-type

will allow the automated retrieval of bitmap data from the BLOB field that

is to be displayed in a TDBImage component. Type 0 BLOB fields may be used

for storing bitmap-format data or raw binary data. Here is an example of

manually extracting bitmap data stored in a type 0 BLOB field (Table1-BLOBField) and displaying the data in a (non-data-aware) TImage component:

```
procedure TForm1.ExtractBtnClick(Sender: TObject);
```

```
begin
  Image1.Picture.Bitmap.Assign(Table1BLOBField);
end;
```

This manual method may be used or, more commonly, a data-aware control would be used so that the display of a given record's bitmap (in a BLOB field) will be automatically displayed. The TDBImage serves this purpose, and by setting the DataSource property to the TDataSource component associated with the underlying table and setting the DataField to the BLOB field containing the bitmap, the TDBImage component will display the image stored in the BLOB field and automatically load each record's BLOB field contents as the record pointer is changed.

The Database Desktop utility will allow the creation only of type 0 binary BLOB fields, no provision was made for user-defined BLOB field sub-types.

If it is desired that a user-defined BLOB sub-type be used to store the bitmap data, it would need to be created with an SQL statement. Typically this would be through the WISQL utility, but an appropriate SQL statement in a TQuery would suffice. Here is an SQL statement that creates a table with a user-defined BLOB field sub-type:

```
CREATE TABLE WITHBMP
(
  FILENAME CHAR(12),
  BITMAP    BLOB SUB_TYPE -1
)
```

Once a table with a compatible BLOB field is created, storing bitmap data to the BLOB field and displaying the bitmap images in a TDBImage component uses the same methods as would be used with dBASE or Paradox tables. There are a number of ways to load a bitmap image into a BLOB field.

Three of the easier methods involve 1) copying the data from the Windows clipboard into a TDBImage component connected to the BLOB field, 2) using the LoadFromFile method of the TBLOBField component, and 3) using the Assign method to copy an object of type TBitmap into the Picture property of a TDBImage.

The first method, copying the bitmap from the clipboard, is probably most handy when an application needs to add bitmaps to a table when the end-user is running the application. A TDBImage component is used to act as an interface between the BLOB field in the table and the image stored in the clipboard. The PasteFromClipboard method of the TDBImage component is invoked to copy the bitmap data from the clipboard into the TDBImage. When the record is posted, the image is stored into the BLOB field in the table.

Because the Windows clipboard can contain data in formats other than just bitmap, it is advisable to check the format prior to calling the CopyFromClipboard method. To do this, a TClipboard object is created and its HasFormat method is used to determine if the data in the clipboard is indeed of bitmap format. Note that to use a TClipboard object, the Clipbrd unit must be included in the Uses section of the unit that will be creating the object.

Here is an example showing the contents of the clipboard being copied into a TDBImage component, if the contents of the clipboard are of bitmap format:

```
procedure TForm1.Button1Click(Sender: TObject);  
var
```

```

    C: TClipboard;
begin
    C := TClipboard.Create;
    try
        if Clipboard.HasFormat(CF_BITMAP) then
            DBImage1.PasteFromClipboard
        else
            ShowMessage('Clipboard does not contain a bitmap!');
    finally
        C.Free;
    end;
end;

```

The second method of filling a BLOB field with a bitmap involves loading the bitmap directly from a file on disk into the BLOB field. This method lends itself equally well to uses at run-time for the end-user as for the developer building an application's data. This method uses the LoadFromFile method of the TBLOBField component, the Delphi representation of an InterBase BLOB field.

The LoadFromFile method of the TBLOBField component requires a single parameter: the name of the bitmap file to load, which is of type String.

The value for this parameter may come from a number of sources from the end-user manually keying in a valid file name to the program providing a string to the contents of the FileName property of the TOpenDialog component.

Here is an example showing the use of the LoadFromFile method for a TBLOBField component named Table1Bitmap (a field called Bitmap in the table associated with a TTable component named Table1):

```

procedure TForm1.Button2Click(Sender: TObject);
begin
    Table1Bitmap.LoadFromFile(
        'c:\delphi\images\splash\16color\construc.bmp');
end;

```

The third method uses the Assign method to copy the contents of an object of type TBitmap into the Picture property of a TDBImage component. An object of type TBitmap might be the Bitmap property of the Picture object property of a TImage component or it may be a stand-alone TBitmap object. As with the method copying the data from the clipboard into a TDBImage component, the bitmap data in the TDBImage component is saved into the BLOB field in the table when the record is successfully posted.

Here is an example using the Assign method. In this case, a stand-alone TBitmap object is used as the source of the bitmap data. To put a bitmap image into the TBitmap, the LoadFromFile method of the TBitmap component is called.

```
procedure TForm1.Button3Click(Sender: TObject);
var
  B: TBitmap;
begin
  B := TBitmap.Create;
  try
    B.LoadFromFile('c:\delphi\images\splash\16color\athena.bmp');
    DBImage1.Picture.Assign(B);
  finally
    B.Free;
  end;
end;
```

Going the opposite direction -- extracting a bitmap from an InterBase BLOB field (without first saving the bitmap out to a file) is a simple process of using the Assign method of the TBLOBField object to store the contents of the BLOB field to an object of type TBitmap. A stand-alone TBitmap object or the Bitmap property of the Picture object property of a TImage component are examples of compatible destinations for this operation.

Here is an example demonstrating using the Assign method to copy a

bitmap  
from a BLOB field into a TImage component (Table1Bitmap is the  
TBLOBfield  
for the BLOB field in the table).

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Image1.Picture.Bitmap.Assign(Table1Bitmap);  
end;
```

In this example, the TBLOBField object Table1Bitmap is a BLOB field  
in an  
InterBase table. This TBLOBField object was created using the Fields  
Editor. If the Fields Editor is not used to create TFields for the  
fields  
in the table, the fields must be referenced using either the  
FieldByName  
method or the Fields property, both part of the TTable and TQuery  
comp-  
onents. In cases where one of those means is used to reference the  
BLOB  
field in a table, the field reference must be type-cast as a  
TBLOBField  
object prior to using the Assign method. For example:

```
procedure TForm1.Button1Click(Sender: TObject);  
begin  
    Image1.Picture.Bitmap.Assign(TBLOBField(Table1.Fields[1]));  
end;
```

A bitmap stored in a BLOB field may also be copied directly to a  
stand-  
alone TBitmap object. Here is an example showing the creation of a  
TBitmap object and storing into it a bitmap from a BLOB field.

```
procedure TForm1.Button2Click(Sender: TObject);  
var  
    B: TBitmap;  
begin  
    B := TBitmap.Create;  
    try  
        B.Assign(Table1Bitmap);  
        Image1.Picture.Bitmap.Assign(B);  
    finally  
        B.Free;
```

end;

## Article #15799: HIDING THE CURSOR DOS INTERRUPTS

Technical Notes Database

TN799D.txt      HIDING THE CURSOR DOS INTERRUPTS

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 3.0+

Description:

Q. How can I hide the cursor using 3.0 or 4.0+?

A. Uses DOS Interrupt \$10 to hide the text cursor. For example:

```
Procedure SetCursor(On: boolean);
var
  Reg: Registers;      { type Registers is defined within }
                       { DOS unit of TP 4.0+ }
begin
  Reg.AX:= $0100;
  Reg.BX:= 0;
  if On then
    Reg.CX:= $0B0C      { $0607 if on color monitor }
  else
    Reg.CX:= $2020;
  Intr($10,Reg);
end; { SetCursor }
```

## Article #15809: Handling EDBEngineError Exceptions

Technical Information Database

TI809D.txt Handling EDBEngineError Exceptions

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Information that describes the conditions of a database engine error can

be obtained for use by an application through the use of an EDBEngineError

exception. EDBEngineError exceptions are handled in an application through

the use of a try..except construct. When an EDBEngineError exception occurs, a EDBEngineError object would be created and various fields in that

EDBEngineError object would be used to programmatically determine what went wrong and thus what needs to be done to correct the situation.

Also,

more than one error message may be generated for a given exception.

This

requires iterating through the multiple error messages to get needed information.

The fields that are most pertinent to this context are:

**ErrorCount:** type Integer; indicates the number of errors that are in

the Errors property; counting begins at zero.

**Errors:** type TDBError; a set of record-like structures that contain information about each specific error generated; each record is accessed via an index number of type Integer.

**Errors.ErrorCode:** type DBIResult; indicating the BDE error code for the

error in the current Errors record.

Errors.Category: type Byte; category of the error referenced by the ErrorCode field.

Errors.SubCode: type Byte; subcode for the value of ErrorCode.

Errors.NativeError: type LongInt; remote error code returned from the server; if zero, the error is not a server error; SQL statement return codes appear in this field.

Errors.Message: type TMessageStr; if the error is a server error, the server message for the error in the current Errors record; if not a server error, a BDE error message.

In a try..except construct, the EDBEngineError object is created directly in the except section of the construct. Once created, fields may be accessed normally, or the object may be passed to another procedure for inspection of the errors. Passing the EDBEngineError object to a specialized procedure is preferred for an application to make the process more modular, reducing the amount of repeated code for parsing the object for error information. Alternately, a custom component could be created to serve this purpose, providing a set of functionality that is easily transported across applications. The example below only demonstrates creating the DBEngineError object, passing it to a procedure, and parsing the object to extract error information.

In a try..except construct, the DBEngineError can be created with syntax such as that below:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  if Edit1.Text > ' ' then begin
    Table1.FieldName('Number').AsInteger := StrToInt(Edit1.Text);
```

```

    try
        Table1.Post;
    except on E: EDBEngineError do
        ShowError(E);
    end;
end;
end;

```

In this procedure, an attempt is made to change the value of a field in a table and then call the Post method of the corresponding TTable component. Only the attempt to post the change is being trapped in the try..except construct. If an EDBEngineError occurs, the except section of the construct is executed, which creates the EDBEngineError object (E) and then passes it to the procedure ShowError. Note that only an EDBEngineError exception is being accounted for in this construct. In a real-world situation, this would likely be accompanied by checking for other types of exceptions.

The procedure ShowError takes the EDBEngineError, passed as a parameter, and queries the object for contained errors. In this example, information about the errors are displayed in a TMemo component. Alternately, the extracted values may never be displayed, but instead used as the basis for logic branching so the application can react to the errors. The first step in doing this is to establish the number of errors that actually occurred. This is the purpose of the ErrorCount property. This property supplies a value of type Integer that may be used to build a for loop to iterate through the errors contained in the object. Once the number of errors actually contained in the object is known, a loop can be used to visit each existing error (each represented by an Errors property record) and extract information about each error to be inserted into the TMemo component.

```
procedure TForm1.ShowError(AExc: EDBEngineError);
var
  i: Integer;
begin
  Mem1.Lines.Clear;
  Mem1.Lines.Add('Number of errors: ' + IntToStr(AExc.ErrorCount));
  Mem1.Lines.Add('');
  {Iterate through the Errors records}
  for i := 0 to AExc.ErrorCount - 1 do begin
    Mem1.Lines.Add('Message: ' + AExc.Errors[i].Message);
    Mem1.Lines.Add('  Category: ' +
      IntToStr(AExc.Errors[i].Category));
    Mem1.Lines.Add('  Error Code: ' +
      IntToStr(AExc.Errors[i].ErrorCode));
    Mem1.Lines.Add('  SubCode: ' +
      IntToStr(AExc.Errors[i].SubCode));
    Mem1.Lines.Add('  Native Error: ' +
      IntToStr(AExc.Errors[i].NativeError));
    Mem1.Lines.Add('');
  end;
end;
```

## Article #15820: Trouble running Delphi programs from Delphi

Technical Information Database

TI820D.txt - Trouble running Delphi programs from Delphi

Category :Install Issues

Platform :All Windows

Product :All32Bit,

Description:

### Delphi Integrated Debugger

-----

Delphi's integrated debugger is a feature of the IDE that allows you to execute, step, trace, and otherwise debug your Delphi applications. By default, Delphi's integrated debugger is enabled (via Options|Project|Integrated Debugging) on startup of Delphi.

The debugger handles certain interrupts and operating system debugger hooks in an effort to trap General Protection Faults and other types of exceptions. Other programs that attempt to handle exceptions in the same way will quite possibly conflict with the integrated debugger. DataSafe is one example of a program that conflicts with the integrated debugger. Classic symptoms include, Delphi not recognizing that you've stopped your program and getting kicked into DOS without warning at various stages.

To test for a debugger conflict, compiling the program from Delphi, and run it from File Manager. If it runs, then disable the integrated debugger, and run your application. If it still runs, then the problem is most likely a conflict between the exception-handling software and the integrated debugger.

There are two ways to fix this. The first is to remove the conflicting software. The other is to disable the integrated

debugger by un-selecting Options|Enviroment|Integrated Debugging.

## Article #15822: MOVING FILES ACROSS DIRECTORIES

Technical Notes Database

TN822D.txt      MOVING FILES ACROSS DIRECTORIES

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 4.0+

Description:

Q. How can I move a file from one directory to another from a Turbo Pascal program?

A. If you are on a system equipped with a hard drive, you can simply use the

RENAME procedure. Assign a file variable to the file name as it currently

appears in the directory. Use the same file name when RENAME is called but

replace the directory path specified with that of directory where the file is to be placed.

This method will not work across drives. See the Copyfile example from the

description of BLOCKREAD in the Turbo Pascal Reference Lookup Chapter in the Reference Manual.

Category     :VCL

Platform     :All

Product      :Delphi   All

### Description:

The following code demonstrates how to bring up the WinHelp "Search" dialog for your application's help file. You can use TApplication's HelpCommand method to send the Help\_PartialKey command to the WinHelp system. The parameter for this command should be a PChar (cast to a longint to circumvent typechecking) that contains the string on which you'd like to search. The example below uses an empty string, which invokes "Search" dialog and leaves the edit control in the dialog empty.

```
procedure TForm1.SearchHelp;
var
  P: PChar;
begin
  Application.HelpFile := 'c:\delphi\bin\delphi.hlp';
  P := StrNew('');
  Application.HelpCommand(Help_PartialKey, longint(P));
  StrDispose(P);
end;
```

## Article #15832: Searching Through Query Result Sets

Technical Information Database

TI832D.txt Searching Through Query Result Sets

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

The TQuery component does not offer the index-based search capabilities of the TTable component (FindKey, GotoKey, and GotoNearest). So how do you search within the result data set from a TQuery to find a row with a specific field value?

One way to search a query result set is a sequential search. This type of search starts at the first row in the data set and, in a While loop, sequentially compares the value of a field in the row with a search value.

One of two results are possible: a value will be found (success) or the end of the data set will be reached (failure). The problem with this way of searching the data set is that the further into the data set a row with a matching value is, the longer it takes to arrive at that row. And, a failed search takes longest of all because it must go all the way to the last row in the data set. If the data set being searched is a large one, this process may take a considerable amount of time.

Here is a function that will perform a sequential search of the result set from a TQuery:

```
function SeqSearch(AQuery: TQuery; AField, AValue: String): Boolean;  
begin
```

```

with AQuery do begin
    First;
    while (not Eof) and (not (FieldByName(AField).AsString =
AValue)) do
        Next;
    SeqSearch := not Eof;
end;
end;

```

This function takes three parameters:

1. AQuery: type TQuery; the TQuery component in which the search is to be executed.
2. AField: type String; the name of the field against which the search value will be compared.
3. AValue: type String; the value being searched for. If the field is of a data type other than String, this search value should be changed to the same data type.

The Boolean return value of this function indicates the success (True) or failure (False) of the search.

An alternative is using a bracketing approach. On a conceptual level, this method acts somewhat like a b-tree index. It is based on the given that for a row at a given point in the data set, the value of the field being searched compared to the search value will produce one of three possible conditions:

1. The field value will be greater than the search value, or...
2. The field value will be less than the search value, or...
3. The field value will be equal to the search value.

A bracketing search process uses this means of looking at the current row in respect to the search value and uses it to successively reduce the rows

to be search by half, until only one row remains. This search field value for this sole remaining row will either be a match to the search value (success) or it will not (failure, and no match exists in the data set).

Functionally, this process lumps the condition of the search field being less than or equal to the search value into a single condition. This leaves only two possible results for the comparison of the current search field value with the search value: less than/equal to or greater than. Initially, a range of numbers is established. The low end of the range is represented by an Integer, at the start of the search process set to 0 or one less than the first row in the data set. The far end of the range is also an Integer, with the value of the RecordCount property of the TQuery. The current row pointer is then moved to a point half way between the low and high ends of the range. The search field value at that row is then compared to the search value. If the field value is less than or equal to the search value, the row being sought must be in the lower half of the range of rows so the high end of the range is reduced to the current row position. If the field value is greater than the search value, the sought value must be in the higher half of the range and so the low end is raised to the current point. By repeating this process, the number of rows that are encompassed in the range are successively reduced by half. Eventually, only one row will remain.

Putting this into a modular, transportable function, the code would look like that below:

```
function Locate(AQuery: TQuery; AField, AValue: String): Boolean;  
var  
    Hi, Lo: Integer;  
begin
```

```

with AQuery do begin
  First;
  {Set high end of range of rows}
  Hi := RecordCount;
  {Set low end of range of rows}
  Lo := 0;
  {Move to point half way between high and low ends of range}
  MoveBy(RecordCount div 2);
  while (Hi - Lo) > 1 do begin
    {Search field greater than search value, value in first half}
    if (FieldByName(AField).AsString > AValue) then begin
      {Lower high end of range by half of total range}
      Hi := Hi - ((Hi - Lo) div 2);
      MoveBy(((Hi - Lo) div 2) * -1);
    end
    {Search field less than search value, value in far half}
    else begin
      {Raise low end of range by half of total range}
      Lo := Lo + ((Hi - Lo) div 2);
      MoveBy((Hi - Lo) div 2);
    end;
  end;
  {Fudge for odd numbered rows}
  if (FieldByName(AField).AsString > AValue) then Prior;
  Locate := (FieldByName(AField).AsString = AValue)
end;
end;

```

Because there will never be a difference of less than one between the low and high ends of the range of rows, a final fudge was added to allow the search to find the search value in odd numbered rows.

This function takes the same three three parameters as the SeqSearch function described earlier.

The return value of this function is of type Boolean, and reflects the success or failure of the search. As the search does move the row pointer, the effects of this movement on the implicit posting of changed data and on where the desired position of the row pointer should be after a failed search should be taken into account in the calling application. For

instance, a TBookmark pointer might be used to return the row pointer to where it was prior to a search if that search fails.

How is this process better than a sequential search? First, in bracketing the search value, only a fraction of the number of rows will be visited as would be the case in a sequential search. Unless the row with the value being sought is in the first 1,000 rows, this search method will be faster than a sequential search. Because this process always uses the same number of records, the search time will be consistent whether searching for the value in row 1,000 or row 90,000. This is in contrast with the sequential search that takes longer the farther into the data set the desired row is.

Can this method be used with any TQuery result set? No. Because of the way this method works in basing the direction of the search as either high or low, it depends on the row being ordered in a descending manner based on the field in which the search will be conducted. This means that it can only be used if the data set is naturally in a sequential order or an ORDER BY clause is used in the SQL statement for the TQuery. The size of the result set will also be a factor when deciding whether to perform a sequential or bracketing search. This process is most advantageous for speed when used with larger result sets. With smaller sets (1,000 or less rows), though, a sequential search will often be as fast or faster.

## Article #15834: RETURNING ERROR LEVELS TO BATCH FILES

Technical Notes Database

TN834D.txt      RETURNING ERROR LEVELS TO BATCH FILES  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

- Q. How do I set the error level within a Turbo Pascal program and test for the error level inside a batch (.BAT) file?
- A. The DOS error level can only be checked in a .BAT file and only a line immediately following the application that is returning the DOS error level. For example, suppose in the program TEST we set the error level to 5.

```
Begin
  HALT(5);
End.
```

Then in a .BAT file we could have

```
TEST
IF ERROR LEVEL
  go do something ...
```

The IF ERROR LEVEL 4 will evaluate to true because 5 is greater than 4 and the "go do something..." part will be executed. Note that you must always check the highest possible error level first. The expression IF ERROR LEVEL 0 will ALWAYS evaluate to true.

## Article #15838: dBASE .DBF File Structure

Technical Information Database

TI838D.txt dBASE .DBF File Structure

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Sometimes it is necessary to delve into a dBASE table outside the control of the Borland Database Engine (BDE). For instance, if the .DBT file (that contains memo data) for a given table is irretrievably lost, the file will not be usable because the byte in the file header indicates that there should be a corresponding memo file. This necessitates toggling this byte to indicate no such accompanying memo file. Or, you may just want to write your own data access routine.

Below are the file structures for dBASE table files. Represented are the file structures as used for various versions of dBASE: dBASE III PLUS 1.1, dBASE IV 2.0, dBASE 5.0 for DOS, and dBASE 5.0 for Windows.

\*\*\*\*\*  
The data file header structure for dBASE III PLUS table file.  
\*\*\*\*\*

The table file header:

=====

Byte	Contents	Description
0	1 byte	Valid dBASE III PLUS table file (03h without a memo (.DBT file; 83h with a memo).
1-3	3 bytes	Date of last update; in YYMMDD format.
4-7	32-bit number	Number of records in the table.
8-9	16-bit number	Number of bytes in the header.
10-11	16-bit number	Number of bytes in the record.
12-14	3 bytes	Reserved bytes.
15-27	13 bytes	Reserved for dBASE III PLUS on a LAN.
28-31	4 bytes	Reserved bytes.
32-n	32 bytes	Field descriptor array (the structure of this array is

each shown below)  
n+1 1 byte 0Dh stored as the field terminator.

n above is the last byte in the field descriptor array. The size of the array depends on the number of fields in the table file.

#### Table Field Descriptor Bytes

=====

Byte	Contents	Description
0-10	11 bytes	Field name in ASCII (zero-filled).
11	1 byte	Field type in ASCII (C, D, L, M, or N).
12-15	4 bytes	Field data address (address is set in memory; not useful on disk).
16	1 byte	Field length in binary.
17	1 byte	Field decimal count in binary.
18-19	2 bytes	Reserved for dBASE III PLUS on a LAN.
20	1 byte	Work area ID.
21-22	2 bytes	Reserved for dBASE III PLUS on a LAN.
23	1 byte	SET FIELDS flag.
24-31	1 byte	Reserved bytes.

#### Table Records

=====

The records follow the header in the table file. Data records are preceded by one byte, that is, a space (20h) if the record is not deleted, an asterisk (2Ah) if the record is deleted. Fields are packed into records without field separators or record terminators. The end of the file is marked by a single byte, with the end-of-file marker, an OEM code page character value of 26 (1Ah). You can input OEM code page data as indicated below.

#### Allowable Input for dBASE Data Types

=====

Data Type	Data Input
C (Character)	All OEM code page characters.
D (Date)	Numbers and a character to separate month, day, and year (stored internally as 8 digits in YYYYMMDD format).
N (Numeric)	- . 0 1 2 3 4 5 6 7 8 9
L (Logical)	? Y y N n T t F f (? when not initialized).
M (Memo)	All OEM code page characters (stored internally as 10 digits representing a .DBT block number).

## Binary, Memo, and OLE Fields And .DBT Files

=====

Memo fields store data in .DBT files consisting of blocks numbered sequentially (0, 1, 2, and so on). The size of these blocks are internally set to 512 bytes. The first block in the .DBT file, block 0, is the .DBT file header.

Memo field of each record in the .DBF file contains the number of the block (in OEM code page values) where the field's data actually begins. If a field contains no data, the .DBF file contains blanks (20h) rather than a number.

When data is changed in a field, the block numbers may also change and the number in the .DBF may be changed to reflect the new location.

This information is from the Using dBASE III PLUS manual, Appendix C.

\*\*\*\*\*  
The data file header structure for dBASE IV 2.0 table file.  
\*\*\*\*\*

### File Structure:

=====

Byte	Contents	Meaning
-----	-----	-----
0	1byte	Valid dBASE IV file; bits 0-2 indicate version number, bit 3 the presence of a dBASE IV memo file, bits 4-6 the presence of an SQL table, bit 7 the presence of any memo file (either dBASE III PLUS or dBASE IV).
1-3	3 bytes	Date of last update; formatted as YYMMDD.
4-7	32-bit number	Number of records in the file.
8-9	16-bit number	Number of bytes in the header.
10-11	16-bit number	Number of bytes in the record.
12-13	2 bytes	Reserved; fill with 0.
14	1 byte	Flag indicating incomplete transaction.
15	1 byte	Encryption flag.
16-27	12 bytes	Reserved for dBASE IV in a multi-user environment.
28	1 bytes	Production MDX file flag; 01H if there is an MDX, 00H if not.
29	1 byte	Language driver ID.
30-31	2 bytes	Reserved; fill with 0.
32-n*	32 bytes each	Field descriptor array (see below).
n + 1	1 byte	0DH as the field terminator.

\* n is the last byte in the field descriptor array. The size of the array depends on the number of fields in the database file.

The field descriptor array:

=====

Byte	Contents	Meaning
0-10	11 bytes	Field name in ASCII (zero-filled).
11	1 byte	Field type in ASCII (C, D, F, L, M, or N).
12-15	4 bytes	Reserved.
16	1 byte	Field length in binary.
17	1 byte	Field decimal count in binary.
18-19	2 bytes	Reserved.
20	1 byte	Work area ID.
21-30	10 bytes	Reserved.
31	1 byte	Production MDX field flag; 01H if field has an index tag in the production MDX file, 00H if not.

Database records:

=====

The records follow the header in the database file. Data records are preceded by one byte; that is, a space (20H) if the record is not deleted, an asterisk (2AH) if the record is deleted. Fields are packed into records without field separators or record terminators. The end of the file is marked by a single byte, with the end-of-file marker an ASCII 26 (1AH) character.

Allowable Input for dBASE Data Types:

=====

Data	Type	Data Input
C	(Character)	All OEM code page characters.
D	(Date)	Numbers and a character to separate month, day, and year (stored internally as 8 digits in YYYYMMDD format).
F	(Floating point binary numeric)	- . 0 1 2 3 4 5 6 7 8 9
N	(Binary coded decimal numeric)	- . 0 1 2 3 4 5 6 7 8 9
L	(Logical)	? Y y N n T t F f (? when not initialized).
M	(Memo)	All OEM code page characters (stored internally as 10 digits representing a .DBT block number).

## Memo Fields And .DBT Files

=====

Memo fields store data in .DBT files consisting of blocks numbered sequentially (0, 1, 2, and so on). SET BLOCKSIZE determines the size of each block. The first block in the .DBT file, block 0, is the .DBT file header.

Each memo field of each record in the .DBF file contains the number of the block (in OEM code page values) where the field's data actually begins. If a field contains no data, the .DBF file contains blanks (20h) rather than a number.

When data is changed in a field, the block numbers may also change and the number in the .DBF may be changed to reflect the new location.

This information is from the dBASE IV Language Reference manual, Appendix D.

\*\*\*\*\*

The data file header structure for dBASE 5.0 for DOS table file.

\*\*\*\*\*

The table file header:

=====

Byte	Contents	Description
-----	-----	-----
0	1 byte	Valid dBASE for Windows table file; bits 0-2 indicate version number; bit 3 indicates presence of a dBASE IV or dBASE for Windows memo file; bits 4-6 indicate the presence of a dBASE IV SQL table; bit 7 indicates the presence of any .DBT memo file (either a dBASE III PLUS type or a dBASE IV or dBASE for Windows memo file).
1-3	3 bytes	Date of last update; in YYMMDD format.
4-7	32-bit number	Number of records in the table.
8-9	16-bit number	Number of bytes in the header.
10-11	16-bit number	Number of bytes in the record.
12-13	2 bytes	Reserved; filled with zeros.
14	1 byte	Flag indicating incomplete dBASE transaction.
15	1 byte	Encryption flag.
16-27	12 bytes	Reserved for multi-user processing.
28	1 byte	Production MDX flag; 01h stored in this byte if a prod-

uction .MDX file exists for this table; 00h if no .MDX file exists.

29	1 byte	Language driver ID.
30-31	2 bytes	Reserved; filled with zeros.
32-n	32 bytes	Field descriptor array (the structure of this array is shown below)
	each	
n+1	1 byte	0Dh stored as the field terminator.

n above is the last byte in the field descriptor array. The size of the array depends on the number of fields in the table file.

#### Table Field Descriptor Bytes

=====

Byte	Contents	Description
0-10	11 bytes	Field name in ASCII (zero-filled).
11	1 byte	Field type in ASCII (B, C, D, F, G, L, M, or N).
12-15	4 bytes	Reserved.
16	1 byte	Field length in binary.
17	1 byte	Field decimal count in binary.
18-19	2 bytes	Reserved.
20	1 byte	Work area ID.
21-30	10 bytes	Reserved.
31	1 byte	Production .MDX field flag; 01h if field has an index tag in the production .MDX file; 00h if the field is not indexed.

#### Table Records

=====

The records follow the header in the table file. Data records are preceded by one byte, that is, a space (20h) if the record is not deleted, an asterisk (2Ah) if the record is deleted. Fields are packed into records without field separators or record terminators. The end of the file is marked by a single byte, with the end-of-file marker, an OEM code page character value of 26 (1Ah). You can input OEM code page data as indicated below.

#### Allowable Input for dBASE Data Types

=====

Data Type	Data Input
C (Character)	All OEM code page characters.
D (Date)	Numbers and a character to separate month, day, and year (stored internally as 8 digits in YYYYMMDD format).

```

F (Floating point binary numeric) - . 0 1 2 3 4 5 6 7 8 9
N (Numeric) - . 0 1 2 3 4 5 6 7 8 9
L (Logical) ? Y y N n T t F f (? when not initialized).
M (Memo) All OEM code page characters (stored internally as 10
digits representing a .DBT block number).

```

Memo Fields And .DBT Files

=====

Memo fields store data in .DBT files consisting of blocks numbered sequentially (0, 1, 2, and so on). SET BLOCKSIZE determines the size of each block. The first block in the .DBT file, block 0, is the .DBT file header.

Each memo field of each record in the .DBF file contains the number of the block (in OEM code page values) where the field's data actually begins. If a field contains no data, the .DBF file contains blanks (20h) rather than a number.

When data is changed in a field, the block numbers may also change and the number in the .DBF may be changed to reflect the new location.

Unlike dBASE III PLUS, if you delete text in a memo field, dBASE 5.0 for DOS may reuse the space from the deleted text when you input new text. dBASE III PLUS always appends new text to the end of the .DBT file. In dBASE III PLUS, the .DBT file size grows whenever new text is added, even if other text in the file is deleted.

This information is from the dBASE for DOS Language Reference manual, Appendix C.

```

*****
The data file header structure for dBASE 5.0 for Windows table file.
*****

```

The table file header:

=====

Byte	Contents	Description
0	1 byte	Valid dBASE for Windows table file; bits 0-2 indicate version number; bit 3 indicates presence of a dBASE IV or dBASE for Windows memo file; bits 4-6 indicate the presence of a dBASE IV SQL table; bit 7 indicates the presence of any .DBT memo file (either a dBASE III PLUS

type or a dBASE IV or dBASE for Windows memo file).

1-3	3 bytes	Date of last update; in YYMMDD format.
4-7	32-bit number	Number of records in the table.
8-9	16-bit number	Number of bytes in the header.
10-11	16-bit number	Number of bytes in the record.
12-13	2 bytes	Reserved; filled with zeros.
14	1 byte	Flag indicating incomplete dBASE IV transaction.
15	1 byte	dBASE IV encryption flag.
16-27	12 bytes	Reserved for multi-user processing.
28	1 byte	Production MDX flag; 01h stored in this byte if a production .MDX file exists for this table; 00h if no .MDX file exists.
29	1 byte	Language driver ID.
30-31	2 bytes	Reserved; filled with zeros.
32-n	32 bytes each	Field descriptor array (the structure of this array is shown below)
n+1	1 byte	0Dh stored as the field terminator.

n above is the last byte in the field descriptor array. The size of the array depends on the number of fields in the table file.

#### Table Field Descriptor Bytes

=====

Byte	Contents	Description
-----	-----	-----
0-10	11 bytes	Field name in ASCII (zero-filled).
11	1 byte	Field type in ASCII (B, C, D, F, G, L, M, or N).
12-15	4 bytes	Reserved.
16	1 byte	Field length in binary.
17	1 byte	Field decimal count in binary.
18-19	2 bytes	Reserved.
20	1 byte	Work area ID.
21-30	10 bytes	Reserved.
31	1 byte	Production .MDX field flag; 01h if field has an index tag in the production .MDX file; 00h if the field is not indexed.

#### Table Records

=====

The records follow the header in the table file. Data records are preceded by one byte, that is, a space (20h) if the record is not deleted, an asterisk (2Ah) if the record is deleted. Fields are packed into records

without field separators or record terminators. The end of the file is marked by a single byte, with the end-of-file marker, an OEM code page character value of 26 (1Ah). You can input OEM code page data as indicated below.

Allowable Input for dBASE Data Types

=====

Data Type	Data Input
B (Binary)	All OEM code page characters (stored internally as 10 digits representing a .DBT block number).
C (Character)	All OEM code page characters.
D (Date)	Numbers and a character to separate month, day, and year (stored internally as 8 digits in YYYYMMDD format).
G (General)	All OEM code page characters (stored internally as 10 digits or OLE) representing a .DBT block number).
N (Numeric)	- . 0 1 2 3 4 5 6 7 8 9
L (Logical)	? Y y N n T t F f (? when not initialized).
M (Memo)	All OEM code page characters (stored internally as 10 digits representing a .DBT block number).

Binary, Memo, and OLE Fields And .DBT Files

=====

Binary, memo, and OLE fields store data in .DBT files consisting of blocks numbered sequentially (0, 1, 2, and so on). SET BLOCKSIZE determines the size of each block. The first block in the .DBT file, block 0, is the .DBT file header.

Each binary, memo, or OLE field of each record in the .DBF file contains the number of the block (in OEM code page values) where the field's data actually begins. If a field contains no data, the .DBF file contains blanks (20h) rather than a number.

When data is changed in a field, the block numbers may also change and the number in the .DBF may be changed to reflect the new location.

Unlike dBASE III PLUS, if you delete text in a memo field (or binary and OLE fields), dBASE for Windows (unlike dBASE IV) may reuse the space from the deleted text when you input new text. dBASE III PLUS always appends new text to the end of the .DBT file. In dBASE III PLUS, the .DBT file size grows whenever new text is added, even if other text in the file is deleted.

This information is from the dBASE for Windows Language Reference manual, Appendix C.

## Article #15840: FILE HANDLES EXTENDING

Technical Notes Database

TN840D.txt     FILE HANDLES EXTENDING  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal 4.0+

Description:

Q. How do I open more than 15 files at one time?

A. In DOS version 3.3 and above there is a function call to allocate memory

for additional file handles. This will allow you to open more than 15

files at one time as long as your Files line in your CONFIG.SYS is 5

greater than the number of files you would like to open.

Here is an example program:

```
{ $M $8000,0,$1000 } { Important do not forget }
```

```
Program Many_Files;
```

```
Uses Dos;
```

```
Var
```

```
Files:array[1..30] of file;
```

```
I:Integer;
```

```
Procedure Allow_More_Files( Max_Files:Byte );
```

```
Var
```

```
Regs:Registers;
```

```
Begin
```

```
With Regs do
```

```
Begin
```

```
AH := $67;
```

```
BX := Max_Files;
```

```
Intr( $21,Regs );
```

```
If Flags And FCarry <> 0
```

```
Then
```

```
Writeln( 'Dos error : ',AX);
```

```
End;
```

```
End;
```

```
Begin
```

```
Allow_More_Files( 30 );
For I:=1 to 30 do
  Begin
    Assign(Files[I], 'DAT.'+ Chr(I DIV 10+48) + Chr(I Mod 10
+48));
    Rewrite(Files[I]);
  End;
For I:=1 to 100 do
  Close( Files[I] );
End.
```

## Article #15844: Passing a Variable to a ReportSmith Report

Technical Information Database

TI844D.txt - Passing a Variable to a ReportSmith Report

Category :Delphi 1.x  
Platform :All Windows  
Product :

### Description:

The following code demonstrates how to pass variables to a ReportSmith report.

Note: this technical information sheet assumes that you know how to create a report that includes report variables. For additional information see chapter four of the ReportSmith manual 'Creating Reports' that shipped with Delphi.

In this case we are assigning a value ('CA') to a string report variable named 'state'.

### ReportSmith Code:

This is the info in the ReportVariables Dialog box in ReportSmith. You can get to this dialog from the reportsmith menu by choosing Tools | Report Query and pushing the Report Variables button.

Name: state  
Type: string  
Title: state var  
Prompt: Enter your favorite state.  
Entry: type-in  
Report Variables: state ; Note this variable and the value it holds are  
  
both case sensitive when passed to  
ReportSmith.

### Delphi Code:

This code assumes that you have placed a TReport component on your form named 'Report1' and set the ReportName property to the name of the

report

that will be accepting the variable as defined above.

Place the following code in the OnClick Method of a pushbutton on your form. I use a pushbutton for simplicity, but this code could just as easily be triggered by any other event.

```
procedure TForm1.Button1Click(Sender: TObject);
var s: string;
begin
  s:='CA';
  Report1.InitialValues.Add('
state=<'+s+'>');
  Report1.run;
end;
```

## Article #15850: Extracting Index Data From A Table

Technical Information Database

TI850D.txt     Extracting Index Data From A Table  
Category     :Database Programming  
Platform     :All  
Product      :Delphi All

### Description:

Getting a list of the indexes associated with a table at run-time can be as simple as a call to the `GetIndexNames` method of the `TTable`, `TQuery`, or `TStoredProc` component. The `GetIndexNames` method returns a list of the indexes that are available for the data set in the form of a `TStrings` list, which may then be inserted into such visual components as a `TListBox` through its `Items` property:

```
ListBox1.Clear;  
Table1.GetIndexNames(ListBox1.Items);
```

Of course, the `TStrings` list returned by the `GetIndexNames` method need not be used with a visual component. It could just as well serve as an array of index names stored entirely in memory, that can be used as a list or array.

But it is also possible to retrieve much more information about the indexes for a table than just the names. Other descriptive attributes include the name of each index, the names of the fields that comprise each index, and the index options used when each index was created. Retrieving these values is slightly more involved than the use of the `GetIndexNames`. Basically, this process involves iterating through the `IndexDefs` property

of the TTable, TQuery, or TStoredProc component. The IndexDefs property is essentially an array of records, one record for each index for the table.

Each index record contains information about the index. It is a relatively straightforward process to iterate through this array of index descriptions, extracting information about individual indexes.

The IndexDefs property of the TTable component contains information about the indexes for the table used by the TTable, TQuery, or TStoredProc component in use. The IndexDefs property itself has various properties that allow for the extraction of information about specific indexes. The two properties in the IndexDefs object are:

Count: type Integer; available only at run-time and read-only; indicates the number of entries in the Items property (i.e., the number of indexes in the table).

Items: type TIndexDef; available only at run-time and read-only; an array of TIndexDef objects, one for each index in the table.

The Count property of the IndexDefs object is used as the basis for a loop program construct to iterate through the Items property entries to extract specific information about each index. Each IndexDef object contained in the Items property consists of a number of properties that provide various bits of information that describe each index. All of the properties of the IndexDef object are available only at run-time and are all read-only. These properties are:

Expression: type String; indicates the expression used for dBASE multi-field indexes.

Fields: type String; indicates the field or fields upon which the

index is based.

Name: type String; name of the index.

Options: type TIndexOptions; characteristics of the index  
(ixPrimary,  
ixUnique, etc.).

Before any index information (Count or Items) can be accessed, the Update method of the IndexDefs object must be called. This refreshes or initializes the IndexDef object's view of the set of indexes.

## Examples

=====

Here is a simple For loop based on the Count property of the IndexDefs object that extracts the name of each index (if any exist) for the table represented by the TTable component Table1:

```
procedure TForm1.ListBtnClick(Sender: TObject);
var
  i: Integer;
begin
  ListBox1.Items.Clear;
  with Table1 do begin
    if IndexDefs.Count > 0 then begin
      for i := 0 to IndexDefs.Count - 1 do
        ListBox1.Items.Add(IndexDefs.Items[i].Name)
      end;
    end;
  end;
end;
```

Below is an example showing how to extract information about indexes at run-time, plugging the extracted values into a TStringGrid (named SG1).

```
procedure TForm1.FormShow(Sender: TObject);
var
  i: Integer;
  S: String;
begin
  with Table1 do begin
    Open;
    {Refresh IndexDefs object}
```

```

IndexDefs.Update;
if IndexDefs.Count > 0 then begin
  {Set up columns and rows in grid to match IndexDefs items}
  SG1.ColCount := 4;
  SG1.RowCount := IndexDefs.Count + 1;
  {Set grid column labels to TIndexDef property names}
  SG1.Cells[0, 0] := 'Name';
  SG1.ColWidths[0] := 200;
  SG1.Cells[1, 0] := 'Fields';
  SG1.ColWidths[1] := 200;
  SG1.Cells[2, 0] := 'Expression';
  SG1.ColWidths[2] := 200;
  SG1.Cells[3, 0] := 'Options';
  SG1.ColWidths[3] := 300;
  {Loop through IndexDefs.Items}
  for i := 0 to IndexDefs.Count - 1 do begin
    {Fill grid cells for current row}
    SG1.Cells[0, i + 1] := IndexDefs.Items[i].Name;
    SG1.Cells[1, i + 1] := IndexDefs.Items[i].Fields;
    SG1.Cells[2, i + 1] := IndexDefs.Items[i].Expression;
    if ixPrimary in IndexDefs.Items[i].Options then
      S := 'ixPrimary, ';
    if ixUnique in IndexDefs.Items[i].Options then
      S := S + 'ixUnique, ';
    if ixDescending in IndexDefs.Items[i].Options then
      S := S + 'ixDescending, ';
    if ixCaseInsensitive in IndexDefs.Items[i].Options then
      S := S + 'ixCaseInsensitive, ';
    if ixExpression in IndexDefs.Items[i].Options then
      S := S + 'ixExpression, ';
    if S > ' ' then begin
      {Get rid of trailing ", "}
      System.Delete(S, Length(S) - 1, 2);
      SG1.Cells[3, i + 1] := S;
    end;
  end;
end;
end;
end;
end;

```

## Special Considerations

=====

There are idiosyncracies associated with extracting information about indexes for different table types that Delphi can access.

## dBASE Tables

-----

With dBASE indexes, which properties of Fields and Expression will be filled will depend on the type of index, simple (single-field) or complex (based on multiple fields or a dBASE expression). If the index is a simple one, the Fields property will contain the name of the field in the table on which the index is based and the Expression property will be blank. If the index is a complex one, the Expression property will show the expression on which the index is based (e.g., "Field1+Field2") and the Fields property will be blank.

## Paradox Tables

-----

With Paradox primary indexes, the Name property will be blank, the Fields property will contain the field(s) on which the index is based, and the Options property will contain ixPrimary. With secondary indexes, the Name property will contain the name of the secondary index, the Fields property will contain the field(s) on which the index is based, and the Options property may or may not have values.

The Fields property for indexes based on more than one field will show the field names separated by semi-colons. Indexes based on only a single field will show the name of only that one field in the Fields property.

## InterBase Tables

-----

For both index types, single- or multiple-field, the Expression property will be blank. For single-field indexes, the Fields property will contain the field on which the index is based. For multi-field indexes, the Fields

property will show all of the multiple fields that comprise the index, each separated by a semi-colon.

Indexes designated as PRIMARY when the CREATE TABLE command is issued will have "RDB\$PRIMARYn" in the Name property, where n is a number character uniquely identifying the primary index within the database metadata. Secondary indexes will show the actual name of the index.

Foreign key constraints also result in an index being created by the system. These indexes appear in the IndexDefs property, and will have the name "RDB\$FOREIGNn" where n is a number character that uniquely identifies the index within the database metadata.

The Fields property for indexes based on more than one field will show the field names separated by semi-colons. Indexes based on only a single field will show the name of only that one field in the Fields property.

## Article #15856: Redistributing the 16 bit Borland Database Engine

Technical Information Database

TI856D.txt - Redistributing the 16 bit Borland Database Engine

Category :Delphi 1.x  
Platform :All-32Bit  
Product :

### Description:

Follow the following steps in order to deploy the redistributable BDE engine on a target machine:

- 1) Format two diskettes in the diskette drive of the target machine. Label the diskettes "Disk 1" and "Disk 2".
- 2) From the DELPHI CD, Copy the \REDIST\BDEINST\DISK1 directory to the diskette labeled "Disk 1" and \REDIST\BDEINST\DISK2 to the diskette "Disk 2".
- 3) Insert the diskette labeled "BDE Install 1" to a floppy drive (We'll use drive A: in this example) of the target machine.
- 4) Make sure there are no other programs running in Windows. From the Windows Program Manager select File|Run, enter "A:\DISK1\SETUP" in the space labeled "Command Line" and press "OK" to begin install of the Borland Database Engine on the target machine.
- 5) A dialog labeled "Database Engine Install" will appear briefly, then a dialog labeled "preparing to install...", and finally a background screen labeled "BDE Redistributable" will appear along with a dialog allowing you to Continue or Exit. Press "Continue".
- 6) A dialog "Borland Database Engine Location Settings" will appear and allow you to change the path for BDE programs and configuration file. Leave the default settings at and press "Continue".

- 7) The "Borland Database Engine Installation" dialog will appear and allow you to display previous dialogs, or execute the install. Press "Install".
- 8) Installation progress will display while files from the "Disk 1" diskette are processed.
- 9) The "BDE Redistributable Install Request" dialog will appear. Load the diskette labeled "Disk 2". Press "continue".
- 10) On completion, the "Borland Database Engine Installation Notification" dialog will inform you that BDE is installed. Press "Exit".
- 11) Exit Windows, remove any floppy disks from your drives and reboot the target machine.

If default settings were used, changes listed below will have taken place.

Two new directories, \IDAPI, and \IDAPI\LANGDRV will exist on the target machine. Note that the BDE Configuration Utility, BDECFG.EXE is located in the \IDAPI directory. Language drivers will now be located in \IDAPI\LANGDRV as \*.LD files. AUTOEXEC.BAT, CONFIG.SYS, AND SYSTEM.INI will not be affected.

WIN.INI in the \WINDOWS\SYSTEM directory will have new entries:

```
[IDAPI]
DLLPATH=C:\IDAPI
CONFIGFILE01=C:\IDAPI\IDAPI.CFG
```

```
[Borland Language Drivers]
LDPath=C:\IDAPI\LANGDRV
```

## Article #15862: Cascading Deletes With Pdox Referential Integrity

Technical Information Database

TI862D.txt Cascading Deletes With Pdox Referential Integrity  
Category :Database Programming  
Platform :All  
Product :Delphi 1.0

### Description:

Paradox tables offer a Referential Integrity feature. This feature prevents adding records to a child table for which there is no matching record in the parent table. It will also cause the key field(s) in the child table to be changed when the corresponding key field(s) in the parent are changed (commonly referred to as a cascading update). These events occur automatically, requiring no intervention by a Delphi application using these tables. However, the Paradox Referential Integrity feature will not accommodate cascading deletes. That is, Delphi will not allow you to delete a record in the parent table while matching records exist in the child table. This would make "orphans" of the child records, losing referential integrity. Delphi raises an exception when an attempt is made to delete such a parent record.

To effect a cascading delete requires that the deletion of the matching child records be deleted programmatically -- before the parent record is deleted. In a Delphi application, this is done by interrupting the process of deleting the record in the parent table, deleting the matching records in the child table (if there are any), and then continuing with the deletion of the parent record.

A record in a table is deleted by a call to the Delete method of the

TTable component, which deletes the current record in the associated table. Interrupting the this process to first perform some other operations is a matter creating a procedure associated with the BeforeDelete event of the TTable. Any commands in a BeforeDelete event procedure are executed before the call actually goes out from the application to the Borland Database Engine (BDE) to physically remove the record from the table file.

To handle the deletion of one or more child records, in a BeforeDelete event procedure the Delete method for the TTable representing the child table is called in a loop. The loop is based on the condition of the record pointer in the table not being positioned at the end of the data set, as indicated by the Eof method of the TTable. This also accounts for there being no child records at all matching the parent record to be deleted: if there are no matching records, the record pointer will already be at the end of the data set, the loop condition will evaluate to False, and the Delete method in the loop never gets executed.

```
procedure TForm1.Table1BeforeDelete(DataSet: TDataset);
begin
  with Table2 do begin
    DisableControls;
    First;
    while not Eof do
      Delete;
    EnableControls;
  end;
end;
```

In the above example, the parent table is represented by the TTable component Table1 and the child by Table2. The DisableControls and EnableControls methods are used as a cosmetic measure to freeze any data-aware components that might be displaying data from Table2 while the records are being deleted. These two methods make the process visually appear smoother, but are only optional and not essential to this process. The

Next method need not be called within this loop. This is because the loop begins at the first record and, as each record is deleted, the record that previously followed the deleted record moves up in the data set, becoming both the first and the current record.

This example presumes that the parent and child tables are linked with a Master-Detail relationship, as is typical for tables for which such Referential Integrity is configured. Linking the tables in this manner results in only those records in the child table that match the current record in the parent table being available. All other records in the child table are made unavailable through the Master-Detail filtering. If the tables are not so linked, there are two additional considerations that must be accounted for when deleting the child records. The first is that a call to the First method may or may not put the record pointer on a record that matches the current record in the parent table. This necessitates using a search method to manually move the record pointer to a matching record. The second consideration affects the condition for the loop. Because records other than those matching the current record in the parent table will be accessible, the condition for the loop must check that each record is a matching record before attempting to delete it. This checking is in addition to querying the Eof method. Because the records will be ordered by this key field (from a primary or secondary index), all of the matching records will be contiguous. This leads to the given that, as soon as the first non-matching record is reached, it can be assumed that all matching records have been deleted. Thus, the previous example would be modified to:

```
procedure TForm1.Table1BeforeDelete(DataSet: TDataset);
begin
  with Table2 do begin
    DisableControls;
```

```
FindKey([Table1.Fields[0].AsString])
while (Fields[0].AsString = Table1.Fields[0].AsString) and
  (not Eof) do
  Delete;
  EnableControls;
end;
end;
```

In the above, it is the first field in the parent table (Table1) upon which the Referential Integrity is based, and the first field in the child table (Table2) against which matching is judged.

## Article #15868: dBASE Expression Indexes: A Primer

Technical Information Database

TI868D.txt      dBASE Expression Indexes: A Primer  
Category      :Database Programming  
Platform       :All  
Product       :Delphi All

### Description:

Indexes for dBASE tables may be based on the values from a single field, unmodified, or on an expression. Index expressions, unique to dBASE indexes, may be composed of multiple fields, modifications of field values, or combinations of these. The expression for a dBASE expression index is created by using dBASE functions and syntax to concatenate multiple fields or to perform the modifications of field values for fields included in the index expressions.

Two sections are included at the end of this technical article which describe the mechanics of creating dBASE expression indexes, one applicable to doing this in the Database Desktop utility and the other for including this capability in Delphi applications.

### Expression Indexes Based On Multiple Fields

=====

dBASE functions are available for use in Delphi or the Database Desktop for the express use in index expressions, and then only in conjunction with dBASE indexes. That is, you cannot use dBASE functions or syntax to build an index expression for a Paradox or Local InterBase Server (LIBS) table. Nor can dBASE functions be used in Delphi programming. They are only available for dBASE expression indexes. The dBASE functions and syntax that can be used for expression indexes are provided by the Borland Database Engine (BDE) Dynamic Linked Library (DLL) file IDDBAS01.DLL.

When creating a dBASE index that is to be based on the values from two or more fields in the table for which the index is being created, the two or more fields are concatenated (connected together) in a manner similar to how String type values are

concatenated in Delphi syntax: the "+" operator. For example, the expression needed to create an index that orders first on a LastName field and then on a FirstName field would be:

```
LastName + FirstName
```

Unlike in dBASE itself, such indexes that are based on multiple fields are limited to using just those fields in the one table. dBASE allows the creation of indexes based on multiple fields contained in different tables. This is possible only by having the other table open at the time the index is created or when the table containing the index is used.

With multi-field indexes for other table types (e.g., Paradox and InterBase), the multiple fields are delimited by the semi-colon (;), as in:

```
LastName;FirstName
```

In dBASE expression indexes that concatenate multiple fields, an actual expression is used:

```
LastName + FirstName
```

When creating index expressions that concatenate two or more fields, all of the fields included in the index expression must be of the same data type. Additionally, if they are to be concatenated instead of added together, the fields must all be of String type. For example, given two Integer type fields, Value1 and Value2, the index expression...

```
Value1 + Value2
```

...would not cause an error. But then, neither would it concatenate the two field values; it would add them together. Thus, if Value1 for a given record contained 4 and Value2 5, the resulting index node would be an Integer value of 9, not a String concatenation "45".

If fields to be included in an expression index are not of String type, they must be converted. Here are some dBASE functions to convert various data types to String for purposes of creating index expressions:

```
STR( [, [, ]])
```

Converts from either Float or Numeric dBASE types to Character (String)

DTOS()

Converts Date value to Character, format YYYYMMDD

MLINE(, )

Extracts a single line from a memo field as a Character value

Another consideration in creating indexes based on the concatenation of multiple field is the maximum allowable length of the index value. The value returned by an index expression may not exceed 100 characters. This is a limit on the length of the value returned by the expression, not on the length of the expression itself. For example, you cannot index on the concatenation of two fields that both have a length of 255 characters.

Expression Indexes Based On Modifications Of Field Values

=====

In addition to creating indexes based on the concatenation of two or more field values, it is also possible to construct an index that is based on a modification of a field value. Examples of this include indexing on just the first three characters of a String type field, on just the year and month from a Date field, indexing on a concatenation of a String and Date field such that the ordering of the String field is ascending but the Date descending, and even indexing on Boolean field values.

Creating indexes that are based on modifications of field values requires at least a working knowledge of dBASE functions and syntax -- because the process uses dBASE, and not Delphi, functions and syntax. The dBASE function SUBSTR() extracts a substring of a String value. The Delphi equivalent for this dBASE function is Copy. But, of these two functions that serve the same purpose, only SUBSTR() may be used in dBASE index expressions.

To use dBASE functions in dBASE index expressions, simply include the function wherever an index expression is called for, using the appropriate dBASE syntax for the function, along with a reference to the name(s) of the field(s) used in the function. For example, an index expression based on only the last three characters of a String type field called Code, that is 20 characters long, would be:

```
RIGHT(Code, 3)
```

Caution should be used in constructing dBASE index expressions that modify field values to ensure that the resulting expression would return a value of a consistent length for every record in the table. For instance, the dBASE TRIM() function removes the trailing blanks (ASCII decimal 32) from a String type value. If this were used in conjunction with concatenating two String fields where the field does not contain values of the same length for all records, the value resulting from the expression will not be the same for all records. Case in point, an index expression based on the concatenation of a LastName and a FirstName field, where the TRIM() function is applied to the LastName field:

```
TRIM(LastName) + FirstName
```

This expression would not return values of a consistent length for all records. If the LastName and FirstName fields contained the values...

```
LastName  FirstName
-----  -----
Smith     Jonas
Wesson    Nancy
```

...the result of applying the index expression above would be:

```
SmithJonas
WessonNancy
```

As can be seen, the length of the value for the first record would be 10 characters, while that for the second 11 characters. The index nodes created for this index expression would be based on the field values for the first record encountered. This would result in an index node 10 characters long being applied to the field values for all record. In this example, that would result in the truncation of the expression value for the second record to "WessonNanc". This would subsequently cause searches based on the full field value to fail.

The solution to this dilemma would be to not use the TRIM() function so that the full length of the LastName field, including padding from the trailing spaces, is used. In indexes that use the IIF() function to order by one field or another, based on the

evaluation of a logical expression in the IIF(), if the two fields are of different lengths, the shorter field would need to be padded with spaces to make it the same length as the longer field. For example, assuming an index that uses the IIF() function to index either on a Company or a Name field, based on the contents of Category field, and where the Company field is 40 characters long but the Name field is 25 characters long, the Name field would need to be padded with 15 spaces; accomplished with the dBASE function SPACE(). That index expression would then be:

```
IIF(Category = "B", Company, Name + SPACE(15))
```

#### Searches And dBASE Expression Indexes

=====

dBASE expression indexes are exceptions to the norm in how they are handled by Delphi and the BDE as opposed to how multiple field indexes for other table types are handled.

This puts such dBASE indexes into a separate class. Handling of such indexes by Delphi and the BDE is different than those for other table types. One of these differences is that not all index-based searching using Delphi syntax can be used with these dBASE expression indexes. The FindKey, FindNearest, and GotoKey methods of the TTable component cannot be used with expression indexes. If an attempt to use FindKey is made, this will result in the error message: "Field index out of range." If the GotoKey method is tried, this error message may occur or the record pointer may just not move (indicating the search value was not found). Only the GotoNearest method may be used with expression indexes. Even then, the GotoNearest method may not work with some index expressions. Experimentation will be needed to see whether the GotoNearest method will work with a given index expression.

#### Filtering With dBASE Expression Indexes

=====

As with index-based searches, dBASE expression indexes present some exceptions when using Delphi filtering.

With an expression index active, the SetRange method of the TTable component will produce the error: "Field index out of range." However, with the same expression index active, the SetRangeStart and SetRangeEnd methods will successfully filter

the data set.

For example, with an expression index concatenating a LastName and a FirstName field active, the code below using the FindKey method (intended to filter to just those records where the first character of the LastName field is "S") will fail with an error:

```
begin
  Table1.SetRange(['S'], ['Szzz'])
end;
```

Whereas, the code below, with the same expression index active and filtering on the same LastName field, will successfully filter the data and not incur an error:

```
begin
  with Table1 do begin
    SetRangeStart;
    FieldByName('LastName').AsString := 'S';
    SetRangeEnd;
    FieldByName('LastName').AsString := 'Szzz';
    ApplyRange;
  end;
end;
```

And, as is the case with index-based searches, with filtering, success of a filtering attempt will also be dependent on the index expression. The use of the SetRangeStart and SetRangeEnd methods in the preceding example worked with an index that simply concatenated two String type fields. But if the expression for the index was instead based conditionally on one or the other fields through use of the IIF() function, the same filtering routine would fail (although without an error).

### Some Handy dBASE Index Expressions

=====

Here are some handy dBASE index expressions. Some are readily apparent in the intended purpose, others are more arcane.

Character field ascending and Date field descending

-----

With a Character field called Name and a Date field OrdDate:

Name + STR(OrdDate - {12/31/3099}, 10, 0)

Character field ascending and Numeric (or Float) field descending

-----  
With a Character field called Company and a Numeric field Amount  
(the Amount field being 9 digits wide with two decimal places):

Company + STR(Amount - 999999.99, 9, 2)

Ordering by a Logical field

-----  
To have True values appear before False values for a Logical  
field called Paid:

IIF(Paid, "A", "Z")

Two Numeric (or Float) fields

-----  
Assuming two Numeric fields with widths of five and two decimal  
places, the first field named Price and the second Quantity:

STR(Price, 5, 2) + STR(Quantity, 5, 2)

Ordering by one field of two, depending on a logical condition

-----  
Assuming that if the Company field is empty, the record should be  
included in the sort order by the Name field (instead of an empty  
Company field).

IIF(Company = " ", Name, Company)

Ordering by the names of months in a Character field

-----  
Assuming a field containing the names of the months ("Jan," "Feb"  
etc.) to put the records in proper month order (field named M):

IIF(M="Jan", 1, IIF(M="Feb", 2, IIF(M="Mar", 3, IIF(M="Apr", 4,  
IIF(M="May", 5, IIF(M="Jun", 6, IIF(M="Jul", 7, IIF(M="Aug", 8,  
IIF(M="Sep", 9, IIF(M="Oct", 10, IIF(M="Nov", 11, 12))))))))))

(The above is a single expression line, broken into multiple lines here due to page width.)

Ordering by the first line of a memo field

-----

For a memo field named Notes:

```
MLINE(Notes, 1)
```

Ordering by the middle three characters in a nine character long field

-----

For a nine character long field called StockNo:

```
SUBSTR(StockNo, 4, 3)
```

Creating dBASE Expression Indexes In Database Desktop

=====

In the Database Desktop utility, indexes may be created for a table either during the process of creating a new table or by restructuring an existing table. In both cases, the Define Index dialog is used to create one or more indexes for the table used.

To get to the Create Index dialog while creating a new table, in the Create dBASE Table dialog (showing the structure), from the Table Properties listbox select "Indexes" and click the Define button.

To get to the Create Index dialog to create an index for an existing table, select Utilities|Restructure, select the table file from the Select File dialog, and in the Restructure dBASE Table dialog (showing the table structure) from the Table Properties listbox select "Indexes" and click the Define button.

Once in the Create Index dialog, expression indexes can be created by clicking the Expression Index button and entering the expression to be used in the Expression Index entry field. To assist in this process, you can double-click on a field name in the Field List listbox and that field name will be inserted into the Index Expression entry field at the current insertion point (caret position).

Once the index expression has been entered, click the OK button. Enter the name of the new index tag in the Index Tag Name entry field on the Save Index As dialog and click OK. (Remember, dBASE index tag names cannot exceed ten characters in length and must abide by the normal dBASE naming conventions.)

## Creating dBASE Expression Indexes In Delphi Applications

=====

dBASE indexes can be created programmatically in Delphi applications, either as a new table is being created (CreateTable method of the TTable component) or by adding an index to an existing table.

Another peculiarity of the dBASE expression index and the BDE is that the table must exist prior to creating an expression index. Thus, while single-field indexes may be created as the table is created by populating TIndexDef objects, this cannot be done with expression indexes. Expression indexes can only be added to a newly created table after the call is made to the CreateTable method, using the AddIndex method. The Options parameter of the AddIndex method must include the index option value ixExpression. This index option is unique to dBASE indexes, and should only be used with dBASE expression indexes. For example:

```
with Table1 do begin
  Active := False;
  DatabaseName := 'Delphi_Demos';
  TableName := 'CustInfo';
  TableType := ttdBASE;
  with FieldDefs do begin
    Clear;
    Add('LastName', ftString, 30, False);
    Add('FirstName', ftString, 20, False);
  end;
  CreateTable;
  AddIndex('FullName', 'LastName + FirstName', [ixExpression]);
end;
```

## Learning More About dBASE Functions And Syntax

=====

Only dBASE functions and syntax that apply to data manipulation can be used to construct a dBASE expression index. However, it is beyond the scope of this technical article to fully list and

describe all of these functions. To learn more about dBASE data manipulation functions, the user is advised to consult the dBASE Language Reference manual or one of the many third-party dBASE books.

## Article #15870: GETINFO - FREE MEMORY IN DOS

Technical Notes Database

TN870D.txt GETINFO - FREE MEMORY IN DOS

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

### Description:

- Q. How come the GetInfo menu shows that the amount of free memory is zero but MemAvail and MaxAvail indicate free memory?
- A. The menu refers to the memory recognized by DOS, whereas MemAvail and MaxAvail refer to the free memory internal to your program. When a program loads it may take away all of the available memory from DOS. This memory would be used inside your program for the heap, overlays, and the stack, for example.

## Article #15874: Removing the vertical scrollbar from a TDBGrid

Technical Information Database

TI874D.txt Removing the vertical scrollbar from a TDBGrid

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

In order to remove the vertical scrollbar from a TDBGrid component, you must override its Paint method. Inside the Paint method you must call the SetScrollRange API procedure to set the min and max scroll values to zero (this disables the scrollbar), and then call the inherited Paint. The code below is a unit containing a new component called TNoVertScrollDBGrid that does this. You can copy the code into a file called NEWGRID.PAS, and add it to the component library as a custom component.

```
unit Newgrid;

interface

uses
  WinTypes, WinProcs, Classes, DBGrids;

type
  TNoVertScrollDBGrid = class(TDBGrid)
  protected
    procedure Paint; override;
  end;

procedure Register;

implementation

procedure TNoVertScrollDBGrid.Paint;
begin
  SetScrollRange(Self.Handle, SB_VERT, 0, 0, False);
  inherited Paint;
end;
```

```
procedure Register;  
begin  
  RegisterComponents('Data Controls', [TNoVertScrollDBGrid]);  
end;  
  
end.
```

## Article #15886: InterBase BLOB Fields: A Primer

Technical Information Database

TI886D.txt InterBase BLOB Fields: A Primer

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

InterBase BLOB fields are not all the same. They actually consist in a variety of forms, or sub-types of the general BLOB type. Knowing which sub-type of BLOB field to use when is essential to creating database applications that incorporate InterBase BLOB fields. BLOB fields come in three varieties: sub-type 0 and sub-type 1 (the two predefined sub-types), and user-defined sub-types.

Sub-type 0 BLOB fields are the type created when a CREATE command is issued and a sub-type is not specified. For clarity in SQL syntax, though, it is possible to explicitly indicate that the BLOB field is to be of sub-type 0. This sub-type of BLOB field is for the storage of binary data. InterBase makes no analysis of the data stored, it just stores it in the BLOB field on a byte-for-byte basis. The most common intended use for BLOB fields in Windows applications is the storage of bitmap binary data, typically for display in a TDBImage component. Either the BLOB field sub-type 0 or a user-defined sub-type BLOB field will work for this purpose.

The second predefined sub-type is 1. This BLOB field sub-type is designed for the storage of text. Typically, this is the free-form memo or notes data displayed and edited with the TDBMemo component. This BLOB field sub-

type is better for storing text data than the VARCHAR field because, unlike with the VARCHAR field, there is no design-time limit placed on the storage capacity of the field.

In SQL syntax, the sub-type 1 BLOB field is created by following the BLOB field type keyword with the SUB\_TYPE keyword and the integer one:

```
CREATE TABLE WITHBLOB
(
  ID CHAR(3) NOT NULL PRIMARY KEY,
  MEMO BLOB SUB_TYPE 1,
  AMOUNT NUMERIC
)
```

Aside from the two predefined BLOB field sub-types, there are user-defined sub-types. User-defined sub-types are designated by a negative integer value in association with the SUB\_TYPE keyword. The actual integer value, as long as it is negative, is actually arbitrary and up to the discretion of the table creator. A designation of -1 is functionally the same as that of a -2. The only consideration when using user-defined sub-types is ensuring that the same type of binary data is stored for every row in the table for a BLOB field of a given user-defined sub-type. InterBase will not evaluate whether this criteria is met, and it is the responsibility of the application inserting the binary data to store the appropriate type of data. No error will occur from the InterBase side if an incorrect type of binary data is stored in a user-defined BLOB field sub-type, but an application can incur difficulties if it is expecting one type of data but encounters another.

A BLOB field of a user-defined sub-type is created with the SQL syntax such as that below:

```
CREATE TABLE IMAGE_DATA
```

```
(
  FILENAME CHAR(12) NOT NULL PRIMARY KEY,
  BITMAP BLOB SUB_TYPE -1,
  EXEs BLOB SUB_TYPE -2,
)
```

When using a table created with the above command, the field BITMAP would only be used to store one distinct type of binary data for all records. In this case, bitmap data. The field EXEs implies the storage of executable files loaded from disk. If an application using this table were to mistakenly store binary data that should have been in the EXEs field into the BITMAP field, InterBase would generate no errors, but the application would have extreme difficulties displaying a stored executable file in a TDBImage component.

#### InterBase BLOB fields and Delphi

-----

When defining TField objects for InterBase BLOB fields in Delphi, the various BLOB field sub-types are assigned TField derivative types as follows:

```
Sub-type 0:   TBlobField
Sub-type 1:   TMemofield
User-defined: TBlobField
```

Because both the predefined sub-type 0 and user-defined sub-types are recognized as TBlobField objects, care must be taken when designing an application to not mistake a field of one sub-type for that of another.

The only way to differentiate between a field of sub-type 0 from that of a user-defined type is by viewing the metadata information for the table, which cannot be done from within Delphi. The Local InterBase Server utility WISQL can be used to view table metadata.

#### InterBase BLOB fields and Database Desktop

-----

The Database Desktop utility that comes with Delphi (DBD) does not create user-defined subtypes. When using BLOB fields created in Database Desktop, use the "BLOB" field type for binary data, including bitmap data. This creates a BLOB field of the predefined sub-type 0.

The DBD also offers a BLOB field type TEXT BLOB. This is equivalent to the pre-defined subtype 1, and should be used where free-form text storage will be needed. While it is functionally equivalent to the pre-defined subtype 1 BLOB field, it will appear with a slightly different type designation if you view the metadata for the table in the WISQL utility.

## Article #15892: Using The ASCII Driver With Comma-delimited Files

Technical Information Database

TI892D.txt Using The ASCII Driver With Comma-delimited Files

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Delphi (and the BDE) has the capability to use ASCII files to a limited

degree as tables. The ASCII driver has the capability to translate the data values in an ASCII fixed-length field or a comma-delimited file into

fields and values that can be displayed through a TTable component.

How

this translation of the ASCII file takes place depends on an accompanying

schema file. The schema file for an ASCII data file defines various attri-

buties necessary for parsing the ASCII data file into individual field values. The field definitions for an ASCII fixed-length field file is relatively straightforward, the offsets of various fields in the ASCII file being consistent across all rows in the file. However, for comma-delimited files, this process is slightly more complicated due to the fact that not all data values in such a file may be the same length for

all rows in the file. This article, then, concentrates on this more difficult task of reading data from comma-delimited, or varying-length field, files.

### The Schema File

=====

The schema file for an ASCII data file contains information that defines

both the file type (comma-delimited versus fixed-length field), as well as

defining the fields that are represented by the data values in each row of

the ASCII data file. (All of the settings used in a schema file are

case insensitive, so "ascii" is just as valid as "ASCII".) In order that a schema file be recognized as such, it must have the same filename as the ASCII data file for which it provides definitions, but with the filename extension .SCH (for SCHEMA). The attributes that describe the file are:

**File name:** Enclosed in square brackets, this setting specifies the name of the ASCII data file (sans the filename extension, which must be .TXT).

**Filetype:** Specifies whether the ASCII data file is structured as a fixed-length field file (use a setting of FIXED) or a comma-delimited file (with data values of potentially varying length (use a setting of VARYING)).

**Delimiter:** Specifies the character that surrounds String type data values (typically, the double quotation mark, ASCII decimal 34).

**Separator:** Specifies the character that is used to separate individual data values (typically, a comma). This character must be a visible character, i.e., cannot be a space (ASCII decimal 32).

**CharSet:** Specifies the language driver (use a setting of ASCII).

Following the file definition settings are field definitions, one for each data value on each row of the ASCII data file. These field definitions supply the information Delphi and the BDE will need to create a virtual field in memory to hold the data value, that virtual field's data type which will affect how the value is translated after being read from the ASCII file, and size and positioning attributes. The various settings that will appear in each field definition are:

Field: Virtual field name, will always be "Field"  
followed  
ord-  
the  
Field1,  
the second Field2, and so on.

Field name: Specifies the display name for the field, which  
Naming appears as the column header in a TDBGrid.  
for convention for ASCII table fields follows that  
Paradox tables.

Field type: Specifies the data type BDE is to use in  
translating the data value for each field and tells Delphi  
what type of virtual field to create.

Use the setting For values of type

```
-----  
CHAR          Character  
FLOAT         64-bit floating point  
NUMBER        16-bit integer  
BOOL          Boolean (T or F)  
LONGINT       32-bit long integer  
DATE          Date field.  
TIME          Time field.  
TIMESTAMP     Date + Time field.
```

(The actual format for date and time data values  
will be determined by the current setting in  
the BDE  
configuration, Date tab page.)

Data value length: Maximum length of a field's corresponding data  
values value. This setting determines the length of the  
virtual field that Delphi creates to receive  
read from the ASCII file.

Number of decimals: Applicable to FLOAT type fields; specifies the number of digit positions to the right of the decimal place to include in the virtual field definition.

Offset: Offset from the left that represents the starting position for the field in relation to all of the fields that precede it.

For example, the field definition below is for the first field in the ASCII table. It defines a String type data value with a name of "Text", a maximum data value length of three characters (and the field will appear as only three characters long in Delphi data-aware components such as the TDBGrid), no decimal places (a String data value will never have any decimal places), and an offset of zero (because it is the first field and there would not be any preceding fields).

```
Field1=Text,Char,3,00,00
```

Here is an example of a schema file with three fields, the first of String type and the second and third of type date. This schema file would be contained in a file named DATES.SCH to provide file and field definitions for an ASCII data file named DATES.TXT.

```
[DATES]
Filetype=VARYING
Delimiter="
Separator=,
CharSet=ascii
Field1=Text,Char,3,00,00
Field2=First Contact,Date,10,00,03
Field3=Second,Date,10,00,13
```

This schema defines a comma-delimited field where all String type data values can be recognized as being surrounded by the double quotation mark

and where distinct data values are separated by commas (excepting any commas that may appear within the specified delimiter, inside individual String data values). The character field has a length of three characters, no decimal places, and an offset of zero. The first date field has a length of 10, no decimals, and an offset of three. And the second date field has a length of 10, no decimals, and an offset of 13.

For reading ASCII comma-delimited files, the length and offset parameters for the field definitions do not apply to data values in the ASCII files (as is the case for fixed-length field files), but to the virtual fields, defined in the application, into which the values read will be placed. The length parameter will need to reflect the maximum length of the data value for each field -- not counting the delimiting quotation marks or the comma separators. This is most difficult to estimate for String type data values as the actual length of such a data value may vary greatly from row to row in the ASCII data file. The offset parameter for each field will not be the position of the data value in the ASCII file (as is the case for fixed-length field files), but the offset as represented by the cumulative length of all preceding fields (again, the defined fields in memory, not the data values in the ASCII file).

Here is a data file that would correspond to the schema file described above, in a file named DATES.TXT:

```
"A",08/01/1995,08/11/1995
"BB",08/02/1995,08/12/1995
"CCC",08/03/1995,08/13/1995
```

The maximum length of an actual data value in the first field is three ("CCC"). because this is the first field and there are no preceding fields, the offset for this field is zero. The length of this first field

(3) is used as the offset for the second field. The length of the second field, a date value, is 10, reflecting the maximum length of a data value for that field. The accumulated length of the first and second fields are then used as the offset for the third field (3 + 10 = 13) .

It is only when the proper length for the data values in the ASCII file are used and each fields length added to any preceding fields to produce offset values for succeeding fields that this process will correctly read the data. If data is misread because of improper length settings in the schema file, most values will suffer adverse translation effects, such as truncation of character data or numeric values being interpreted as zeros. Data will usually still be displayed, but no error should occur.

However, values that must be in a specific format in order to be translated into the appropriate data type will cause errors if the value read includes characters not valid in a date value. This would include a date data value which, when incorrectly read may contain extraneous characters from other surrounding fields. Such a condition will result in a data translation exception requiring an adjustment of the field length and offset settings in the schema file.

## Article #15894: READ & READLN - DIFFERENCES BETWEEN 3.0 AND 4.0+

Technical Notes Database

TN894D.txt      READ & READLN - DIFFERENCES BETWEEN 3.0 AND 4.0+  
Category      :Pascal  
Platform      :All  
Product      :Turbo Pascal 3.0+

### Description:

Q. What are the changes between Read and Readln of 3.0 and 4.0+?

A. The problem which you have encountered is due to a modification of the READ procedure in Turbo Pascal version 4.0+. In version 4.0+, the READ procedure was altered to allow the creation of text file device drivers. Also, the Read procedure handles keyboard input in the same manner as if reading from a disk file. This change has the following effects:

- 1) The carriage return and line feed character combination generated when the Return key is pressed, is no longer cleared from the file input buffer. However, the cursor still advances to the beginning of the next line.
- 2) A Read(NumericVar) call no longer defaults the NumericVar's value. In version 3.0, a simple press of the Return key caused the program to retain the value of the NumericVar and processing continued. In version 4.0, a non white-space character input is required. Simply pressing the Return key will cause the cursor to advance to the next line and continue to wait for input.
- 3) Since the carriage return and line feed combination no longer are handled, they remain in the file input buffer until the next Read call. If the next call is of the type Read(CharacterVar), CharacterVar will return the carriage return character, ASCII 13. A subsequent Read(CharacterVar) call will return the line feed character, ASCII 10. For this reason a Read(Ch); call may appear to have no effect, if it follows Read procedure call.

4) A Read(StringVar) will have a different effect. With the ASCII 13, carriage return and 10, line feed characters as the next to be read in the keyboard buffer, the EOLN function returns true. When reading from a disk file a Read(FileVar, StringVar) returns a null string in StringVar. The same is true with keyboard input. For example the following code will create an infinite loop:

```
Read(AnyVar);  
Repeat  
  Read(StringVar);  
Until StringVar <> '';
```

I suggest that you replace all Read(from standard input) to Readln calls. Many developers have resolved this difference by implementing ReadChar, ReadString, ReadInt, and ReadReal procedures based on the ReadKey function.

## Article #15898: Determining Record Number In A dBASE Table

Technical Information Database

TI898D.txt Determining Record Number In A dBASE Table

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

dBASE tables employ a fairly static record numbering system. The record number for a given record reflects its physical position in the table file. These record number are not subject to change dependent on the filtering of data or index ordering. For instance, a record that is the first record stored in the .DBF file would be record number 1. It is possible that, through the ordering of an index, this record may be displayed as the last of 100 records. In such a case, its record would remain the same -- one -- and would not be changed to 100 to reflect its position in the index ordered data set. This is in contrast with Paradox tables, where there is a sequence number. The Paradox sequence number is like the dBASE record number except that it is much more fluid and the number for a given record will reflect its position relative to the data set. That is, a record may not always have the same sequence number given filtering of the data set to reduce the number of records or when an index is active that may change the displayed order of the record.

In database applications created with Delphi and the Borland Database Engine (BDE), there is no provision built into the stock data components for extracting or determining the record for dBASE tables. Such an operation is, however, possible by making a call from the application a BDE function.

There are a number of BDE functions that will return information about the current dBASE record, such as the record number. Basically, any function that fills a BDE pRECProps structure would suffice. Such BDE functions include DbtGetRecord, DbtGetNextRecord, and DbtGetPriorRecord. Of course, only the first of these functions really applies to retrieving information about the current record. The other two move the record pointer when invoked, similar in effect to the Next and Prior methods of the TTable or TQuery components.

The pRECProps structure consists of the fields:

iSeqNum: type LongInt; specifies the sequence number of the record (relative to the data set, including filtering and index ordering);

applicable if the table type supports sequence numbers (Paradox only).

iPhyRecNum: type LongInt; specifies the record number for the record;

applicable only when the table type supports physical record numbers (dBASE only).

bRecChanged: type Boolean; not currently used.

bSeqNumChanged: type Boolean; not currently used.

bDeleteFlag: type Boolean; indicates whether the record is deleted; applicable only for table types that support soft-deletes (dBASE only).

One of these BDE functions may be invoked in a Delphi application to fill this structure, from which the physical record number may be retrieved.

Below is an example of the DbtGetRecord function used for this purpose.

```
function RecNo(ATable: TTable): LongInt;
```

```

var
  R: RECProps;
  rslt: DbarResult;
  Error: array [0..255] of Char;
begin
  ATable.UpdateCursorPos;
  rslt := DbGetRecord(ATable.Handle, dbiNoLock, nil,
R);
  if rslt = DBIERR_NONE then
    Result := R.iPhyRecNum
  else begin
    DbGetErrorString(rslt, Error);
    ShowMessage(StrPas(Error));
    Result := -1;
  end;
end;

```

As with invoking any BDE function in a Delphi application, the BDE wrapper units DbTypes, and DbErrs, DbProcs must be included in the Uses section of the unit in which the BDE function will be invoked (the Uses section not shown here). To make this function more transportable, it does not reference the subject TTable component directly, but a reference to the TTable is passed as a parameter. If this function is used in a unit that does not reference the Delphi units DB and DBTables, they must be added so that references to the TTable component will be valid.

The UpdateCursorPos method of the TTable is called to ensure that the record number current in the TTable component is synchronized with that of the underlying table.

BDE functions do not in themselves cause an exception if they fail. Rather, they return a value of BDE type DbarResult that indicates the success or failure of the intended operation. This return value must then be retrieved and evaluated by the front-end application, and the appropriate action taken. A result other than DBIERR\_NONE indicates an

unsuccessful execution of the function. An extra step may be taken (as in the example above) to query the BDE to translate an error code into a readable message with the BDE function `DbiGetErrorString`. In this example, the return value from the invoking of `DbiGetRecord` is stored in the variable `rslt`, and then compared against `DBIERR_NONE` to determine the success of the function call.

If the call to `DbiGetRecord` succeeds, the physical record number from the `iPhyRecNum` field of the `pRECPProps` structure is stored to the variable `Result`, which is the function's return value. To indicate when the function has failed (i.e., the invoking of the `DbiGetRecord` function failed), a value of negative one is returned instead of the record number. This value is purely arbitrary, and any value of a compatible type may be used at the discretion of the programmer.

## Article #15904: Managing disk volume labels in Delphi

Technical Information Database

TI904D.txt     Managing disk volume labels in Delphi  
Category     :General Programming  
Platform     :All  
Product      :Delphi 1.0

### Description:

This document contains the source code for a unit that is useful for getting, setting, and deleting volume labels from a floppy or hard disk.

The code for getting a volume label uses the Delphi FindFirst function, and the code for setting and deleting volume labels involves calling DOS

interrupt 21h, functions 16h and 13h respectively. Since function 16h isn't supported by Windows, it must be called through DPMI interrupt 31h, function 300h.

```
{ *** BEGIN CODE FOR VOLLABEL UNIT *** }  
unit VolLabel;  
  
interface  
  
uses Classes, SysUtils, WinProcs;  
  
type

## Article #15906: UPGRADING 3.0 TO 4.0+ PROBLEMS

Technical Notes Database

TN906D.txt UPGRADING 3.0 TO 4.0+ PROBLEMS

Category :Pascal

Platform :All

Product :Turbo Pascal 3.0+

### Description:

Q. What Turbo Pascal 3.0 code will cause the most problems converting to version 4.0+?

A. With our UPGRADE program (see appropriate Appendix in your manual), it's not very difficult to port your code to 4.0+. It depends a lot on the type of programs you write. The passing of parameters on the stack is done much more efficiently now, so changes will have to be made to inline machine code and assembly language. Most of the changes are optional: using new types, breaking your program into modules to take advantage of separate compilation. (The UPGRADE program has a special option to help you "unitize" your program too. It does all the "typing" for you.) Some stricter type-checking is performed in version 4.0+. For example, the Dos unit now defines the often-seen registers record type (AX, BX...); MsDos and Intr now take this type. In this case, you can typecast or change the type identifier and recompile.

## Article #15910: How to copy files in Delphi.

Technical Information Database

TI910D.txt     How to copy files in Delphi.

Category     :General Programming

Platform     :All

Product     :Delphi 1.0

Description:

Q: How do I copy a file?

A: Here are three ways:

{This way uses a File stream.}

```
Procedure FileCopy( Const sourcefilename, targetfilename: String );
```

```
Var
```

```
  S, T: TFileStream;
```

```
Begin
```

```
  S := TFileStream.Create( sourcefilename, fmOpenRead );
```

```
  try
```

```
    T := TFileStream.Create( targetfilename,  
                              fmOpenWrite or fmCreate );
```

```
    try
```

```
      T.CopyFrom(S, S.Size ) ;
```

```
    finally
```

```
      T.Free;
```

```
    end;
```

```
  finally
```

```
    S.Free;
```

```
  end;
```

```
End;
```

{This way uses memory blocks for read/write.}

```
procedure FileCopy(const FromFile, ToFile: string);
```

```
var
```

```
  FromF, ToF: file;
```

```
  NumRead, NumWritten: Word;
```

```
  Buf: array[1..2048] of Char;
```

```
begin
```

```
  AssignFile(FromF, FromFile);
```

```
  Reset(FromF, 1);                             { Record size = 1 }
```

```

AssignFile(ToF, ToFile);      { Open output file }
Rewrite(ToF, 1);             { Record size = 1 }
repeat
  BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
  BlockWrite(ToF, Buf, NumRead, NumWritten);
until (NumRead = 0) or (NumWritten <> NumRead);
CloseFile(FromF);
CloseFile(ToF);
end;

```

{This one uses LZCopy, which USES LZExpand.}

```

procedure CopyFile(FromFile, ToFileName: string);

```

```

var

```

```

  FromFile, ToFile: File;

```

```

begin

```

```

  AssignFile(FromFile, FromFileName); { Assign FromFile to
  FromFileName }

```

```

  AssignFile(ToFile, ToFileName);    { Assign ToFile to ToFileName }

```

```

  Reset(FromFile);                  { Open file for input }

```

```

  try

```

```

    Rewrite(ToFile);                { Create file for output }

```

```

    try

```

```

      { copy the file and if a negative value is returned }

```

```

      { raise an exception }

```

```

      if LZCopy(TFileRec(FromFile).Handle, TFileRec(ToFile).Handle) <

```

```

0

```

```

        then

```

```

          raise EInOutError.Create('Error using LZCopy')

```

```

        finally

```

```

          CloseFile(ToFile); { Close ToFile }

```

```

        end;

```

```

    finally

```

```

      CloseFile(FromFile); { Close FromFile }

```

```

    end;

```

```

end;

```

## Article #15912: COMPILING VERSION 2.0 CODE WITH THE VERSION 4.0+ C

Technical Notes Database

TN912D.txt      COMPILING VERSION 2.0 CODE WITH THE VERSION 4.0+ C  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 2.0+

### Description:

- Q. Why do I get a stack overflow when compiling code with Turbo Pascal 4.0+ but not with version 2.0?
- A. Version 2.0 does not indicate a stack overflow error. Version 2.0 has a 64k stack size whereas version 4.0+ has a default stack size of 16K. Use the {\$M+} directive to increase the stack size.

## Article #15916: How to terminate all running applications

Technical Information Database

TI916D.txt     How to terminate all running applications

Category     :Windows API

Platform     :All

Product      :Delphi 1.0

Description:

Q: How do I terminate all running tasks?

A: Below is some code that will help if you want to terminate ALL tasks,  
no questions asked.

A word of caution, before you run this for the first time, make sure that you save it and anything else that may have some pending data.

```
procedure TForm1.ButtonKillAllClick(Sender: TObject);
var
  pTask      : PTaskEntry;
  Task       : Bool;
  ThisTask   : THANDLE;
begin
  GetMem (pTask, SizeOf (TTaskEntry));
  pTask^.dwSize := SizeOf (TTaskEntry);

  Task := TaskFirst (pTask);
  while Task do
  begin
    if pTask^.hInst = hInstance then
      ThisTask := pTask^.hTask
    else
      TerminateApp (pTask^.hTask, NO_UAE_BOX);
    Task := TaskNext (pTask);
  end;
  TerminateApp (ThisTask, NO_UAE_BOX);
end;
```

## Article #15921: How to check to see if a drive is ready.

Technical Information Database

TI921D.txt     How to check to see if a drive is ready.

Category     :General Programming

Platform     :All

Product     :Delphi   All

### Description:

Q: How can I check to see if there is a disk in the "A" drive without an error message box telling you that it is not ready?

A: The following function accepts a drive letter as a parameter, and it will return a boolean value that indicates whether or not there is a disk in the drive.

```
function DiskInDrive(Drive: Char): Boolean;
var
  ErrorMode: word;
begin
  { make it upper case }
  if Drive in ['a'..'z'] then Dec(Drive, $20);
  { make sure it's a letter }
  if not (Drive in ['A'..'Z']) then
    raise EConvertError.Create('Not a valid drive ID');
  { turn off critical errors }
  ErrorMode := SetErrorMode(SEM_FailCriticalErrors);
  try
    { drive 1 = a, 2 = b, 3 = c, etc. }
    if DiskSize(Ord(Drive) - $40) = -1 then
      Result := False
    else
      Result := True;
  finally
    { restore old error mode }
    SetErrorMode(ErrorMode);
  end;
end;
```

## Article #15926: How to do pointer arithmetic in Delphi.

Technical Information Database

TI926D.txt     How to do pointer arithmetic in Delphi.  
Category     :General Programming  
Platform     :All  
Product      :Delphi 1.0

### Description:

Q: How do I do pointer arithmetic in Delphi?

A: First a brief explanation of pointer arithmetic. When you are dealing with dynamic memory locations and all you have is a pointer to where it all begins, you want to have the ability to traverse that line of memory to be able to perform whatever functions you have in mind for that data. This can be accomplished by changing the place in memory where the pointer points. This is called pointer arithmetic.

The main idea that must be kept in mind when doing your pointer arithmetic is that you must increment the pointer's value by the correct amount. (The correct amount is determined by the size of the object receiving the pointer. e.g. char = 1 byte; integer = 2 bytes; double = 8 bytes; etc.) The Inc() and Dec() functions will alter the amount by the correct amount. (The compiler knows what the correct size is.)

For an example of the practical application of pointer arithmetic, download the BreakApart() TI2905.

If you are doing dynamic memory allocation, it is done like this:

```
uses WinCRT;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  MyArray: array[0..30] of char;
```

```
  b: ^char;
```

```
  i: integer;
```

```
begin
```

```
  StrCopy(MyArray, 'Lloyd is the greatest!'); {get something to point
```

```

to}
  b :=
MyArray; { assign the pointer to the memory location }
  for i := StrLen(MyArray) downto 0 do
  begin
    write(b^); { write out the char at the current pointer
location. }
    inc(b); { point to the next byte in memory }
  end;
end;

```

The following code demonstrates that the Inc() and Dec() functions will increment or decrement accordingly by size of the type the pointer points to:

```

var
  P1, P2 : ^LongInt;
  L : LongInt;
begin
  P1 :=
L; { assign both pointers to the same place }
  P2 :=
L;
  Inc(P2); { Increment one }

{ Here we get the difference between the offset values of the
two pointers. Since we originally pointed to the same place in
memory, the result will tell us how much of a change occurred
when we called Inc(). }

  L := Ofs(P2^) - Ofs(P1^); { L = 4; i.e. sizeof(longInt) }
end;

```

You can change the type to which P1 and P2 point to something other than a longint to see that the change is always the correct value (SizeOf (P1^)).

## Article #15928: DEBUGGER - DISPLAYING FUNCTIONS IN THE WATCH WINDO

Technical Notes Database

TN928D.txt      DEBUGGER - DISPLAYING FUNCTIONS IN THE WATCH WINDO  
Category      :Pascal  
Platform      :All  
Product      :Turbo Pascal 5.0 5.5

### Description:

Q. What built-in functions can you display in the watch window?

A. In the Turbo Pascal User's Guide in chapter 6 there is a table 6.3 that

lists all the built-in functions that you can place in the watch window.

They are:

Abs, Addr, Chr, Cseg, Dseg, Hi, IOResult, Length,  
Lo, Maxavail, Memavail, Odd, Ofs, Ord, Pred, Ptr,  
Round, Seg, Sizeof, Sptr, Sseg Succ, Swap, and  
Trunc.

## Article #15934: DEBUGGER - POINTERS CORRUPTING MEMORY?

Technical Notes Database

TN934D.txt      DEBUGGER - POINTERS CORRUPTING MEMORY?

Category      :Pascal

Platform      :All

Product       :Turbo Pascal    5.0 5.5

### Description:

Q. How can I tell if a pointer could be corrupting my code or data segments?

A. Normally, pointers point to areas located in Turbo Pascal's heap.

You can

determine if a pointer is pointing outside of the heap by comparing its

segment value to that of HEAPORG (a predefined pointer establishing the

beginning of normal heap space). This comparison is best done by placing a

Watch on both HEAPORG and any pointers that you suspicious of. If your

pointers have segment values less than that of HEAPORG when an assignment

is made to them then memory corruption is likely. To correct the situation,

ensure that all pointers are initialized with either the NEW or GETMEM

procedures.

## Article #15938: Basic Delphi DLL template

Technical Information Database

TI938D.txt     Basic Delphi DLL template  
Category     :General Programming  
Platform     :All  
Product      :Delphi 1.0

Description:  
DLL sample

Without units

First the DLL "framework" that you wanted, save as DLLFRAME.DPR:

```
{-----DLLFRAME.DPR-----}  
library Dllframe;  
  
uses WinTypes;  
  
function GetString : string ; export ;  
begin  
    Result := 'Hello from the DLL!' ;  
end;  
  
exports  
    GetString;  
  
begin  
end.  
{-----}
```

Now here's the calling program, save it as DLLCALL.DPR:

```
{-----DLLCALL.DPR-----}  
program Dllcall;  
  
uses  
    Dialogs;
```

```
{ $R *.RES }
```

```
function GetString : string ; far ; external 'DLLFRAME' ;
```

```
begin
```

```
  MessageDlg( GetString, mtInformation, [ mbOK ], 0 ) ;
```

```
end.
```

```
With units
```

```
Here's the calling program, save it as DLLCALL.DPR:
```

```
{-----DLLCALL.DPR-----}  
program Dllcall;
```

```
uses
```

```
  Dialogs;
```

```
{ $R *.RES }
```

```
function GetString : string ; far ; external 'MyDLL' ;
```

```
begin
```

```
  MessageDlg( GetString, mtInformation, [ mbOK ], 0 ) ;
```

```
end.
```

```
{-----}
```

```
The DLL "framework" that you wanted, save as DLLFRAME.DPR:
```

```
{-----DLLFRAME.DPR-----}  
library Dllframe;

## Article #15944: Form display with different screen resolutions.

Technical Information Database

TI944D.txt Form display with different screen resolutions.

Category :VCL

Platform :All

Product :Delphi All

### Description:

When designing forms, it is sometimes helpful to write the code so that the screen and all of its objects are displayed at the same size no matter what the screen resolution is. Here is some code to show how that is done:

### implementation

const

```
ScreenWidth: LongInt = 800; {I designed my form in 800x600 mode.}
```

```
ScreenHeight: LongInt = 600;
```

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
```

```
  scaled := true;
```

```
  if (screen.width <> ScreenWidth) then
```

```
  begin
```

```
    height := longint(height) * longint(screen.height) div
```

```
ScreenHeight;
```

```
    width := longint(width) * longint(screen.width) div ScreenWidth;
```

```
    scaleBy(screen.width, ScreenWidth);
```

```
  end;
```

```
end;
```

Then, you will want to have something that checks to see that the font sizes are OK. You can iterate over each child control's font to adjust its size as necessary. This can be done as follows:

```
type
```

```
TFooClass = class(TControl); { needed to get at protected }  
           { font property }
```

```

var
  i: integer;
begin
  for i := ControlCount - 1 downto 0 do
    TFooClass(Controls[i]).Font.Size :=
      (NewFormWidth div OldFormWidth) *
      TFooClass(Controls[i]).Font.Size;
end;

```

Note: The following are issues to bear in mind when scaling Delphi applications (forms) on different screen resolutions:

- \* Decide early on in the form design stage whether you're going to allow the form to be scaled or not. The advantage of not scaling is that nothing changes at runtime. The disadvantage of not scaling is that nothing changes at runtime (your form may be far too small or too large to read on some systems if it is not scaled).

- \* If you're NOT going to scale the form, set Scaled to False.

- \* Otherwise, set the Form's Scaled property to True.

- \* Set AutoScroll to False. AutoScroll = True means 'don't change the form's frame size at runtime' which doesn't look good when the form's contents do change size.

- \* Set the form's font to a scaleable TrueType font, like Arial. MS San Serif is an ok alternate, but remember that it is still a bitmapped font. Only Arial will give you a font within a pixel of the desired height. NOTE: If the font used in an application is not installed on the target computer, then Windows will select an alternative font within the same font family to use instead. This font may not match the same size of the original font and may cause problems.

- \* Set the form's Position property to something other than poDesigned. poDesigned leaves the form where you left it at design time, which for me always winds up way off to the left on my 1280x1024 screen - and completely off the 640x480 screen.

- \* Don't crowd controls on the form - leave at least 4 pixels

between controls, so that a one pixel change in border locations (due to scaling) won't show up as ugly overlapping controls.

- \* For single line labels that are `alLeft` or `alRight` aligned, set `AutoSize` to `True`. Otherwise, set `AutoSize` to `False`.

- \* Make sure there is enough blank space in a label component to allow for font width changes - a blank space that is 25% of the length of the current string display length is a little too much, but safe. (You'll need at least 30% expansion space for string labels if you plan to translate your app into other languages) If `AutoSize` is `False`, make sure you actually set the label width appropriately. If `AutoSize` is `True`, make sure there is enough room for the label to grow on its own.

- \* In multi-line, word-wrapped labels, leave at least one line of blank space at the bottom. You'll need this to catch the overflow when the text wraps differently when the font width changes with scaling. Don't assume that because you're using large fonts, you don't have to allow for text overflow - somebody else's large fonts may be larger than yours!

- \* Be careful about opening a project in the IDE at different resolutions. The form's `PixelsPerInch` property will be modified as soon as the form is opened, and will be saved to the DFM if you save the project. It's best to test the app by running it standalone, and edit the form at only one resolution. Editing at varying resolutions and font sizes invites component drift and sizing problems.

- \* Speaking of component drift, don't rescale a form multiple times, at design time or a runtime. Each rescaling introduces roundoff errors which accumulate very quickly since coordinates are strictly integral. As fractional amounts are truncated off control's origins and sizes with each successive rescaling, the controls will appear to creep northwest and get smaller. If you want to allow your users to rescale the form any number of times, start with a freshly loaded/created form before each scaling, so that scaling errors do not accumulate.

- \* Don't change the `PixelsPerInch` property of the form, period.

- \* In general, it is not necessary to design forms at any particular resolution, but it is crucial that you review their

appearance at 640x480 with small fonts and large, and at a high-resolution with small fonts and large before releasing your app. This should be part of your regular system compatibility testing checklist.

\* Pay close attention to any components that are essentially single-line TMemos - things like TDBLookupCombo. The Windows multi-line edit control always shows only whole lines of text - if the control is too short for its font, a TMemo will show nothing at all (a TEdit will show clipped text). For such components, it's better to make them a few pixels too large than to be one pixel too small and show not text at all.

\* Keep in mind that all scaling is proportional to the difference in the font height between runtime and design time, NOT the pixel resolution or screen size. Remember also that the origins of your controls will be changed when the form is scaled - you can't very well make components bigger without also moving them over a bit.

## Article #15946: DEBUGGER - STEPPING INTO A PROCEDURE

Technical Notes Database

TN946D.txt      DEBUGGER - STEPPING INTO A PROCEDURE

Category      :Pascal

Platform      :All

Product       :Turbo Pascal 5.0 5.5

### Description:

- Q. I am using the integrated source level debugger, and I cannot step into a procedure, using the F7 key. What is wrong?
- A. First, make sure that your program and units are compiled with debug and local symbol information, as well as integrated debugging turned on. Also, the program itself may be corrupting the debug information. You should step through the code in a smaller test program and try to narrow down the problem.

## Article #15950: How to keep the app iconized.

Technical Information Database

TI950D.txt     How to keep the app iconized.

Category     :VCL

Platform     :All

Product      :Delphi 1.0

Description:

iconized apps

Q: How do I keep the form in icon form when I run it?

A:

1. You must set WindowState to wsMinimized in the form's properties.
2. In the private section of the form object's declaration, put:

```
PROCEDURE WMQueryOpen(VAR Msg : TWMQueryOpen); message  
WM_QUERYOPEN;
```

3. In the implementation section, put this method:

```
PROCEDURE TForm1.WMQueryOpen(VAR Msg : TWMQueryOpen);  
begin  
    Msg.Result := 0;  
end;
```

That's it! The form will always remain iconic.

## Article #15952: IS THERE A DEBUGGER AVAILABLE FOR TP 5.0+?

Technical Notes Database

TN952D.txt IS THERE A DEBUGGER AVAILABLE FOR TP 5.0+?

Category :Pascal

Platform :All

Product :Turbo Pascal 5.0 5.5

Description:

Q. Is there a debugger available for use with TP 5.0+?

A. There is a built-in debugger in version 5.0+. In addition, you can use the Turbo Debugger on .EXE files generated by Turbo Pascal 5.0+. Finally, you can use any debugger that can process .MAP files (see the Options/Linker menu).

## Article #15956: How to use a custom cursor.

Technical Information Database

TI956D.txt      How to use a custom cursor.

Category        :VCL

Platform        :All

Product         :Delphi    All

Description:

Q: How do I use one of the cursor files in the c:\delphi\images\cursors?

A: Use the image editor to load the cursor into a RES file.  
The following example assumes that you saved the cursor in the RES file  
as "cursor\_1", and you save the RES file as MYFILE.RES.

```
(*** BEGIN CODE ***)
{$R c:\programs\delphi\MyFile.res}    { This is your RES file }

const PutTheCursorHere_Dude = 1;      { arbitrary positive number }

procedure stuff;
begin
  screen.cursors[PutTheCursorHere_Dude] := LoadCursor(hInstance,
                                                         PChar
('cursor_1'));
  screen.cursor := PutTheCursorHere_Dude;
end;
```

## Article #15958: ACCESSING MORE THAN 64K OF DATA

Technical Notes Database

TN958D.txt      ACCESSING MORE THAN 64K OF DATA

Category      :Pascal

Platform      :All

Product      :Turbo Pascal 4.0+

### Description:

Q. I need my program to work with more than 64K of data at a time.

How

can I use large data structures in my Turbo Pascal programs?

A. You would use heap space for your larger data structures. Instead of

declaring variables to be large arrays, records, or arrays of records,

declare these variables to be pointers to your data structures and reserve

space for them with procedures NEW or GETMEM. The space reserved for

this data will not reside in the normal data segment but rather in heap

space where each data structure may occupy up to 64K.

If you need even more memory, use typed files to store your data.

Storage is limited only by the capacity of your drive system. The SEEK procedure can be used to index into the file as though it were a large array out on disk. This technique is often the only option when memory consumption must be kept to a minimum. However,

accessing

data on disk is slower than accessing data in RAM memory.

## Article #15962: How to use a popup menu with a VBX.

Technical Information Database

TI962D.txt - How to use a popup menu with a VBX.

Category :Delphi 1.x  
Platform :All Windows  
Product :

### Description:

Q: I want to be able to right click on my VBX and have a popup menu display. When I use a popup menu for the form, it shows no matter where I right click. I want to just have it popup for right clicks on the vbx.

How do I trap for that?

A: Here it is:

```
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton;  
  Shift: TShiftState; X, Y: Integer);  
begin  
  if button = mbRight then  
    with (Sender AS TControl) do  
      with ClientToScreen(Point(X,Y)) do  
        begin  
          PopupMenu1.PopupComponent := TComponent(Sender);  
          PopupMenu1.Popup(X,Y);  
        end;  
      end;  
end;
```

Note: The form's PopupMenu property must be empty, or it will popup from everywhere. If you want the form to be the only place showing the popup, place this method on the form's OnMouseDown event. If you want the VBX to be the only place, then place it on the VBX's OnMouseDown event, etc.

## Article #15964: NORMALIZING POINTERS

Technical Notes Database

TN964D.txt      NORMALIZING POINTERS  
Category      :Pascal  
Platform       :All  
Product        :Turbo Pascal 4.0+

### Description:

Q. How do I normalize a pointer in Turbo Pascal?

A. When you allocate a pointer, it is already normalized. So, if you're SURE that you won't be making the offset greater than 64K, you can skip the normalizing step.

```
PROCEDURE Normalize(VAR P);  
VAR pt : Pointer ABSOLUTE P;  
BEGIN  
  Pt := Ptr(seg(pt^) + (ofs(pt^) DIV 16), ofs(pt^) MOD 16);  
END;
```

You CAN perform pointer arithmetic, if you're desperate to do "C things" in Pascal. Just normalize the pointer (maximize segment, minimize offset), typecast it to a LongInt, and do your math. E.g.

```
Normalize(recptr);  
Inc(LongInt(recptr), SizeOf(rec));
```

where recptr is a pointer to a record, and rec is the record variable.

## Article #15968: How to set a max and min form size.

Technical Information Database

TI968D.txt     How to set a max and min form size.

Category     :VCL

Platform     :All

Product      :Delphi   All

### Description:

When you want to control how much your users can resize your form, you can control that by setting the MinMax values. (If you use the resize method to limit the size, it will work, but it won't look quite as good.)

Note: To make it so that the user cannot change the form's size at all, make the min and max sizes the same values.

This is an example of how to declare and use the `wm_GetMinMaxInfo` windows message in your applications.

```
unit MinMax;
```

```
interface
```

```
uses
```

```
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,  
  Forms, Dialogs;
```

```
type
```

```
  TForm1 = class(TForm)
```

```
  private
```

```
    { Private declarations }
```

```
    procedure WMGetMinMaxInfo(var MSG: Tmessage); message
```

```
WM_GetMinMaxInfo;
```

```
  public
```

```
    { Public declarations }
```

```
  end;
```

```
var
```

```
  Form1: TForm1;
```

implementation

{ \$R \*.DFM }

```
procedure TForm1.WMGetMinMaxInfo(var MSG: Tmessage);
Begin
  inherited;
  with PMinMaxInfo(MSG.lparam)^ do
  begin
    with ptMinTrackSize do
    begin
      X := 300;
      Y := 150;
    end;
    with ptMaxTrackSize do
    begin
      X := 350;
      Y := 250;
    end;
  end;
end;

end;
```

## Article #15970: DATA SEGMENT TOO LARGE ERROR

Technical Notes Database

TN970D.txt DATA SEGMENT TOO LARGE ERROR

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

### Description:

Q. What should I do when I get "Data segment too large" compiler error?

A. Allocate your data on the heap by using pointers.

### Reference:

7/16/98 4:35:38 PM

Last Modified: 01-SEP-99

## Article #15974: How to get the windows and DOS versions.

Technical Information Database

TI974D.txt     How to get the windows and DOS versions.

Category     :Windows API

Platform     :All

Product     :Delphi 1.0

Description:

Q: How can I get the Windows or DOS version numbers?

A: The API call GetVersion will do it, but the information is encrypted into a longint. Here is how to get and decrypt the information:

Type

```
TGetVer = record
```

```
  WinVer,
```

```
  WinRev,
```

```
  DosRev,
```

```
  DosVer: Byte;
```

```
end;
```

const

```
  VerStr = '%d.%d';
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  AllVersions: TGetVer;
```

```
begin
```

```
  AllVersions := TGetVer(GetVersion);
```

```
  Edit1.Text := Format(VerStr, [AllVersions.WinVer, AllVersions.  
WinRev]);
```

```
  Edit2.Text := Format(VerStr, [AllVersions.DOSVer, AllVersions.  
DOSRev]);
```

```
end;
```

Note1: The values that windows displays for the versions and the values that it returns through its API call are not always the same. e.g. The

workgroup version displays as 3.10 rather than 3.11.

Note2: Win32 applications should call GetVersionEx rather than GetVersion.

## Article #15976: FILE MODE LOCKING/UNLOCKING ON A NETWORK

Technical Notes Database

TN976D.txt FILE MODE LOCKING/UNLOCKING ON A NETWORK

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

### Description:

Q. How can I access my data on a network when I have more than one user?

A. The routine in the following unit will help.

Using the fm\* constants you can set the FILEMODE byte to match the amount of sharing that you wish to take place.

```
example: FileMode := fmReadWr+fmDenyNone;
```

Using the Lock function you can lock a record or a series of records.

Lock returns True if the request to lock the record was successful. If

Lock returns False it can be assumed that the record was locked by someone

else and not available for editing at this time.

Locking Needs to take place anytime that a user will be allowed to change

the data. If your program in in a view mode you can safely leave the

record unlocked.

Unit NETio;

Interface

Const {File Open Mode Constants}

	{	I	SSS	R	AAA	I= Inheritance Flag	}		
fmRead	=	\$00;	{	_	___	0	000	S= Sharing Mode Field	}
fmWrite	=	\$01;	{	_	___	0	001	R= Reserved (must Be 0)	}
fmReadWr	=	\$02;	{	_	___	0	010	A= Access Field	}
fmCompat	=	\$00	{	_	000	0	___	}	
fmDenyReadWr	=	\$10	{	_	001	0	___	}	

```

## Article #15980: How to tell what kind of drive is used.

Technical Information Database

TI980D.txt    How to tell what kind of drive is used.  
Category    :Windows API  
Platform    :All  
Product     :Delphi All

### Description:

When dealing with multiple drives, it is helpful to know whether a drive is associated with a is attached to a letter (A, B, C, etc), and what its type is. This code uses the API GetDriveType function to do that.

```
function ShowDriveType(DriveLetter: char): string;
var
  i: word;
begin
  if DriveLetter in ['A'..'Z'] then {Make it lower case.}
    DriveLetter := chr(ord(DriveLetter) + $20);
  i := GetDriveType(ord(DriveLetter) - ord('a'));
  case i of
    DRIVE_REMOVABLE: result := 'floppy';
    DRIVE_FIXED: result := 'hard disk';
    DRIVE_REMOTE: result := 'network drive';
    else result := 'does not exist';
  end;
end;
```

## Article #15982: VARIANT RECORD LONGINT TO BYTE AND WORD

Technical Notes Database

TN982D.txt     VARIANT RECORD LONGINT TO BYTE AND WORD  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal 4.0+

### Description:

Q. How can I quickly change a Longint into two Words or four Bytes?

A. With a variant record you can map a group of variables on the same memory and be able to view the variables in different ways. Here is an example:

```
Program Variant;
  Type
    Forms = Record
      Case Integer Of
        0:(L:LongInt);
        1:(W1,W2: Word);
        2:(B1,B2,B3,B4: Byte);
      End;
  Var
    Many:Forms;
  Begin
    With Many do
      Begin
        Many.L:=123456789;
        Writeln(' LongInt Value : ',L);
        Writeln(' Word Value      : ',W1,' ',W2);
        Writeln(' Byte Value       : ',B1,' ',B2,' ',B3,' ',B4);
      End
    End.
End.
```

## Article #15986: How to determine the current record number.

Technical Information Database

TI986D.txt     How to determine the current record number.

Category     :Database Programming

Platform     :All

Product      :Delphi   All

Description:

Q: "How can I determine the current record number for a dataset?"

A: If the dataset is based upon a Paradox or dBASE table then the record number can be determined with a couple of calls to the BDE (as shown below). The BDE doesn't support record numbering for datasets based upon SQL tables, so if your server supports record numbering you will need to refer to its documentation.

The following function is given as part of a whole unit and takes as its parameter any component derived from TDataset (i.e. TTable, TQuery, TStoredProc) and returns the current record number (greater than zero) if it is a Paradox or dBASE table. Otherwise, the function returns zero.

NOTE: for dBASE tables the record number returned is always the physical record number. So, if your dataset is a TQuery or you have a range set on your dataset then the number returned won't necessarily be relative to the dataset being viewed, rather it will be based on the record's physical position in the underlying dBASE table.

```
uses
  DB, DBTables, DbiProcs, DbiTypes, DbiErrs;

function GetRecordNumber(Dataset: TDataset): Longint;
var
  CursorProps: CurProps;
  RecordProps: RECProps;
begin
```

```

{ Return 0 if dataset is not Paradox or dBASE }
Result := 0;
with Dataset do
begin
  { Is the dataset active? }
  if State = dsInactive then
    raise EDatabaseError.Create('Cannot perform this operation '+
                                'on a closed dataset');

  { We need to make this call to grab the cursor's iSeqNums }
  Check(DbiGetCursorProps(Handle, CursorProps));

  { Synchronize the BDE cursor with the Dataset's cursor }
  UpdateCursorPos;

  { Fill RecordProps with the current record's properties }
  Check(DbiGetRecord(Handle, dbiNOLOCK, nil,
RecordProps));

  { What kind of dataset are we looking at? }
  case CursorProps.iSeqNums of
    0: Result := RecordProps.iPhyRecNum; { dBASE }
    1: Result := RecordProps.iSeqNum;    { Paradox }
  end;
end;
end;
end.

```

Technical Notes Database

TN988D.txt POST-DECLARATION TYPECASTING

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

Description:

Q. How can I change the type of a variable to another type?

A. The method is called type casting. Here is the syntax:

```
Type
```

```
  RecType = Record
```

```
    W : Word;
```

```
  End;
```

```
Var
```

```
  A : Array[1..2] of Byte;
```

```
  R : RecType;
```

```
Begin
```

```
  ...
```

```
  R := RecType( A ); { Convert the array into a record
```

```
type }
```

```
  ...
```

```
End.
```

## Article #15992: How to automate logon for Paradox tables

Technical Information Database

TI992D.txt     How to automate logon for Paradox tables

Category     :Database Programming

Platform     :All

Product      :Delphi   All

Description:

Password automation

Q: I have a paradox table that uses a password. How do I make it so that the form that uses the table comes up without prompting the user for the password?

A: The table component's ACTIVE property must be set to FALSE (If it is active before you have added the password, you will be prompted). Then, put this code in the handler for the form's OnCreate event:

```
Session.AddPassword('My secret password');  
Table1.Active := True;
```

Once you close the table, you can remove the password with `RemovePassword('My secret password')`, or you can remove all current passwords with `RemoveAllPasswords`. (Note: This is for Paradox tables only.)

## Article #15994: STATIC VARIABLES LIKE C

Technical Notes Database

TN994D.txt      STATIC VARIABLES LIKE C  
Category      :Pascal  
Platform      :All  
Product       :Turbo Pascal  4.0+

### Description:

- Q. Is there anything similar to C's static variables in 4.0+?
- A. You can declare private global variables in the implementation part of a unit. Such variables are only visible within that unit. Like other global variables, they retain their values across calls. Typed constant declarations declared within a procedure or function also behave exactly like C's static variables. They are local in scope but since they are allocated in the data segment, they retain their values from call to call.

## Article #15998: packing a dBASE table

Technical Information Database

TI998D.txt     packing a dBASE table  
Category     :Database Programming  
Platform     :All  
Product      :Delphi All

### Description:

packing a dBASE table

Q: How do I pack a dBASE table?

A: To pack a dBASE table that has been opened with a TTable, use the BDE function DbiPackTable. There are two basic steps to do this:

1. Add the following units to your uses clause:

```
{ For Delphi 1.0: } DBITYPES, DBIPROCS and DBIERRS;  
{ For Delphi 2.0: } BDE;
```

2) Then call the DbiPackTable BDE function as follows:

```
Check(DbiPackTable(Table1.DbHandle, Table1.Handle, Nil, szDBASE,  
TRUE));
```

### Notes:

- \* The table must be opened in exclusive mode.
- \* Use the Check procedure when calling BDE API functions. Check will raise an exception if an error occurs on the BDE call.

## Article #16004: string manipulation routines

Technical Information Database

TI1004D.txt string manipulation routines

Category :Object Pascal

Platform :All

Product :Delphi All

Description:

Here are some standard string manipulation functions:

{To determine if the character is a digit.}

```
function IsDigit(ch: char): boolean;
```

```
begin
```

```
    Result := ch in ['0'..'9'];
```

```
end;
```

{To determine if the character is an uppercase letter.}

```
function IsUpper(ch: char): boolean;
```

```
begin
```

```
    Result := ch in ['A'..'Z'];
```

```
end;
```

{To determine if the character is an lowercase letter.}

```
function IsLower(ch: char): boolean;
```

```
begin
```

```
    Result := ch in ['a'..'z'];
```

```
end;
```

{Changes a character to an uppercase letter.}

```
function ToUpper(ch: char): char;
```

```
begin
```

```
    Result := chr(ord(ch) and $DF);
```

```
end;
```

{Changes a character to a lowercase letter.}

```
function ToLower(ch: char): char;
```

```
begin
```

```
    Result := chr(ord(ch) or $20);
```

```
end;
```

```

{ Capitalizes first letter of every word in s }
function Proper(const s: string): string;
var
  i: Integer;
  CapitalizeNextLetter: Boolean;
begin
  Result := LowerCase(s);
  CapitalizeNextLetter := True;
  for i := 1 to Length(Result) do
  begin
    if CapitalizeNextLetter and IsLower(Result[i]) then
      Result[i] := ToUpper(Result[i]);
    CapitalizeNextLetter := Result[i] = ' ';
  end;
end;

{ NOTE: The following functions are available in Delphi 2.0,
  but not in Delphi 1.0. }

{Supresses trailing blanks in a string.}
function TrimRight(const s: string): string;
var
  i: integer;
begin
  i := Length(s);
  while (I > 0) and (s[i] <= ' ') do Dec(i);
  Result := Copy(s, 1, i);
end;

{Removes the leading spaces from a string.}
function TrimLeft(const S: string): string;
var
  I, L: Integer;
begin
  L := Length(S);
  I := 1;
  while (I <= L) and (S[I] <= ' ') do Inc(I);
  Result := Copy(S, I, Maxint);
end;

{ Removes leading and trailing whitespace from s);
function Trim(const S: string): string;
var
  I, L: Integer;
begin

```

```
L := Length(S);  
I := 1;  
while (I <= L) and (S[I] <= ' ') do Inc(I);  
if I > L then Result := '' else  
begin  
    while S[L] <= ' ' do Dec(L);  
    Result := Copy(S, I, L - I + 1);  
end;  
end;
```

## Article #16010: WinExecAndWait

Technical Information Database

TI1010D.txt WinExecAndWait

Category :Windows API

Platform :All

Product :Delphi 1.0

Description:

Q: How do I execute a program and have my code wait until it is finished?

A:

```
uses Wintypes,WinProcs,Toolhelp,Classes,Forms;
```

```
Function WinExecAndWait(Path : string; Visibility : word) : word;
```

```
var
```

```
    InstanceID : THandle;
```

```
    PathLen : integer;
```

```
begin
```

```
    { inplace conversion of a String to a PChar }
```

```
    PathLen := Length(Path);
```

```
    Move(Path[1],Path[0],PathLen);
```

```
    Path[PathLen] := #0;
```

```
    { Try to run the application }
```

```
    InstanceID := WinExec(
```

```
Path,Visibility);
```

```
    if InstanceID < 32 then { a value less than 32 indicates an Exec  
error }
```

```
        WinExecAndWait := InstanceID
```

```
    else
```

```
    begin
```

```
        Repeat
```

```
            Application.ProcessMessages;
```

```
        until Application.Terminated or (GetModuleUsage(InstanceID) = 0);
```

```
        WinExecAndWait := 32;
```

```
    end;
```

```
end;
```

## Article #16015: How to check for app already running.

Technical Information Database

TI1015D.txt How to check for app already running.

Category :Windows API

Platform :All

Product :Delphi 1.0

Description:

Q: How can I write my Delphi program to detect if there is already another copy running and exit if so?

A: Create a unit called PrevInst and add it to your uses clause. Here's the code:

```
unit PrevInst;

interface

uses
  WinTypes, WinProcs, SysUtils;

type
  PHWND = ^HWND;
  function EnumFunc(Wnd:HWND; TargetWindow:PHWND): bool; export;
  procedure GotoPreviousInstance;

implementation

function EnumFunc(Wnd:HWND; TargetWindow:PHWND): bool;
var
  ClassName : array[0..30] of char;
begin
  Result := true;
  if GetWindowWord(Wnd,GWW_HINSTANCE) = hPrevInst then
  begin
    GetClassName(Wnd,ClassName,30);
    if StrIComp(ClassName,'TApplication') = 0 then
    begin
      TargetWindow^ := Wnd;
      Result := false;
    end;
  end;
end;
```

```

    end;
end;
end;

procedure GotoPreviousInstance;
var
    PrevInstWnd : HWND;
begin
    PrevInstWnd := 0;
    EnumWindows(
EnumFunc, longint(
PrevInstWnd));
    if PrevInstWnd <> 0 then
        if IsIconic(PrevInstWnd) then
            ShowWindow(PrevInstWnd, SW_RESTORE)
        else
            BringWindowToTop(PrevInstWnd);
    end;

end.

```

And then make the main block of your \*.DPR file look something like this--

```

begin
    if hPrevInst <> 0 then
        GotoPreviousInstance
    else
        begin
            Application.CreateForm(MyForm, MyForm);
            Application.Run;
        end;
    end;
end.

```

## Article #16017: Compatibility with MS-DOS GENERIC MACHINES

Technical Notes Database

TN1017D.txt      Compatibility with MS-DOS GENERIC MACHINES

Category        :Pascal

Platform        :All

Product         :Turbo Pascal 4.0+

### Description:

Q. Can Turbo Pascal run on generic MS-DOS machines?

A. TPC.EXE will run on generic machines when you use the /Q option. The System, Overlay, Dos, and Printer standard units will operate correctly on MS-DOS generic machines. Generated .EXE's are MS-DOS compatible as long as you don't use the special PC units (such as Crt, Graph, and Graph3).

## Article #16021: How to use a form several times

Technical Information Database

TI1021D.txt    How to use a form several times

Category     :General Programming

Platform     :All

Product     :Delphi   All

Description:

multiple forms

Q: I have a form that is a sort of template. I want to be able to create and show the same form several times (with different data in the fields). How do I use the same form several times?

A: You need to make modeless window by calling create and show for each form instance, like this:

```
with TMyForm.create(self) do show;
```

To demonstrate how to use and control these new forms, here is an example that changes the caption and name of each form that is created. You have access to it through the form's component array. This example uses an about box (named "box") as the other form. Also, there is a variable called "TheFormCount" that keeps track of how many times the form is instantiated.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  with TBox.create(self) do begin
    Name := 'AboutBox_' + intToStr(TheFormCount);
    caption := 'About Box # ' + intToStr(TheFormCount);
    Show;
  end;
  inc(TheFormCount);
end;
```

These forms can be found and used by their name by means of the FindComponent method used something like this:

```
with Form1.FindComponent('AboutBox_' + IntToStr(Something)) as TForm
do
    DoSomethingHere;
```

## Article #16023: SERIAL COMMUNICATION AUXINOUT UNIT

Technical Notes Database

TN1023D.txt SERIAL COMMUNICATION AUXINOUT UNIT

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

### Description:

Q. I'm using the AuxInOut unit, and the machine that sends out the data tries to read incoming data. However, the incoming data is garbage. What do I do?

A. To read incoming data, use the Reset procedure before reading. Also, you should read from a buffer rather than directly from the serial port. Furthermore, the AuxInOut is not a good example to use as input buffering is not supported; you should use the TI407.ARC routines for this purpose.

## Article #16027: Manually Installing Delphi

Technical Information Database

TI1027D.txt - Manually Installing Delphi

Category :Delphi 1.x  
Platform :All Windows  
Product :

### Description:

To manually install Delphi you should first copy the entire run-image directory off of the CD-ROM onto your hard-drive. This is one of the main directories on the delphi CD-ROM. This includes copying all the files from the run-image\windows to your local \windows directory and the \windows\system files into your \windows\system directory, UNLESS you have NT. If you have NT you will want to do as above, but do not overwrite any existing files.

It is important that if you have another Borland DataBase product that you Z-copy the \idapi directory from the run-image ONTO the existing \idapi directory on your computer.

To manually install delphi you first need to add the following lines to your win.ini (this is all dependent on which drive/directory that you copied the run-image to):

```
[IDAPI]
DLLPATH=C:\IDAPI
CONFIGFILE01=C:\IDAPI\IDAPI.CFG
```

```
[Borland Language Drivers]
LDPath=C:\IDAPI\LANGDRV
```

```
[BWCC]
BitmapLibrary=BWCC.DLL
```

```
[Interbase]
RootDirectory=C:\IBLOCAL
```

```
[Paradox Engine]
UserName=PxEEngine
NetNamePath=C:\
RecBufs=64
MaxLocks=64
MaxFiles=64
SwapSize=64
```

```
[DDE Servers]
DBD=C:\DBD\DBD
```

```
[DBD]
WORKDIR=C:\DBD
PRIVDIR=C:\DBD\DBDPRIV
```

You will also want to add the following lines to your autoexec.bat file:

```
rem add the following if it they are not already present
rem you only need share if using windows 3.1
```

```
Share /f:4096 /l:40
path=%path%;c:\iblocal\bin;
```

These are once again dependent on the exact drive/directory that you copied the run-image to.

You will now want to download the file dlpgrp.zip from our download BBS or from the web site. This file will create the Icons and the Delphi Program Group.

## Article #16029: ASYNC LOST CHARACTERS BROKEN SERIAL

Technical Notes Database

TN1029D.txt ASYNC LOST CHARACTERS BROKEN SERIAL

Category :Pascal

Platform :All

Product :Turbo Pascal 4.0+

### Description:

Q. The Async routines in the manual do not work. Why?

A. The Asynchronous communications routines in the manual do not provide buffered communication. In other words, if you are not actively reading the serial port you will only get the last character that arrives. For example, if the characters ABCD come across the line and then you read the serial port, you will get back D but not A, B, or C. TI407 provides buffered input from a serial port.

## Article #16033: Printing in the DOS IDE under Windows 95

Technical Information Database

TI1033D.txt - Printing in the DOS IDE under Windows 95

Category :Printing  
Platform :All-32Bit  
Product :

Description:

Printing from the DOS IDE in Windows 95

To print from the Borland Pascal IDE under Windows 95 can require more than just selecting print from the file menu. Follow this step by step procedure if you can print from Windows applications but cannot print from the DOS IDE.

- 1.Open the printers folder under the control panel sub-directory. You can get to the control panel by going from the start button to the settings then click control panel. Inside control panel double click the printers folder.
- 2.Click the icon for the printer you are going to print on.
- 3.On the file menu click properties.
- 4.Click on the details tab and then click on the Capture Printer Port button.
- 5.In the Device list, select the printer port that you want to capture.
- 6.Type the network path to the printer, and then click OK to save the selection.
- 7.In the Print To The Following Port dialog box, select the port you just mapped.

For a handy additional reference on the topic also see the Windows help file under "Capture".

## Article #16039: Handling " system error cannot read cdrom.bmp"

Technical Information Database

TI1039D.txt Handling " system error cannot read cdrom.bmp"

Category :General Programming

Platform :All

Product :Pascal All

### Description:

If you receive the system error " system error cannot write to device CD-ROM" while writing to the file cdrom.bmp and you receive the options to cancel or to retry do the following.

1. Back up the autoexec.bat and the config.sys file in preparation for editing them.
2. Search the autoexec.bat for the lines "mcsex\d:cdrom". Change "cdrom" to "MyCDROM". Search the config.sys for a reference to "cdrom" and then make the same substitution in this file.
3. Be sure and save the changes when exiting the editor and then reboot the system.

This problem is a conflict between MSDOS and MSWINDOWS.

## Article #16051: Returns the amount required to repay a debt.

Technical Information Database

TI1051D.txt Returns the amount required to repay a debt.

Category :General Programming

Platform :All

Product :Delphi All

Description:

PAYMENT()

Returns the periodic amount required to repay a debt.

```
function payment(princ, int, term: double): double;
var temp: double;
begin
  int := int / 100;
  temp := exp(ln(int + 1) * term);
  result := princ * ((int * temp) / (temp - 1));
end;
```

Syntax

PAYMENT( , , )

The original amount to be repaid over time.

The interest rate per period expressed as a positive decimal number. Specify the interest rate in the same time increment as the term. It is to be expressed as a percentage. The number is divided by 100 inside the function.

The number of payments. Specify the term in the same time increment as the interest.

## Description

Use PAYMENT( ) to calculate the periodic amount (payment) required to repay a loan or investment of amount in payments. PAYMENT( ) returns a numeric value based on a fixed interest rate compounding over a fixed length of time. If is positive, PAYMENT( ) returns a positive number. If is negative, PAYMENT( ) returns a negative number. Express the interest rate as a decimal. For example, if the annual interest rate is 9.5%, is 9.5 for payments made annually.

Express and in the same time increment. For example, if the payments are monthly, express the interest rate per month, and the number of payments in months. You would express an annual interest rate of 9.5%, for example, as 9.5/12, which is the 9.5% divided by 12 months. The formula used to calculate PAYMENT( ) is as follows:

$$\text{pmt} = \text{princ} * \frac{\text{int} * (1 + \text{int})^{\text{term}}}{(1 + \text{int})^{\text{term}} - 1}$$

where int = rate / 100 (as a percentage).

For the monthly payment required to repay a principal amount of \$16860.68 in five years, at 9% interest, the formula expressed as a dBASE expression looks like this:

```
MyVar := PAYMENT(16860.68, 9/12, 60)           {Returns 350.00}
```

## Article #16063: Delphi 1.02 Maintenance Release Information

Technical Information Database

TI1063D.txt - Delphi 1.02 Maintenance Release Information

Category :Delphi 1.x  
Platform :All Windows  
Product :

Description:

THE DELPHI 1.02 MAINTENANCE RELEASE

-----

BRIEF OVERVIEW OF DELPHI 1.02

-----

Thank you for your interest in Borland's new RADical application development tool, Delphi. Below you will find information regarding the product's overview as well as the problems fixed with this release, but here, we would like to give you a brief overview of Delphi 1.02.

- o The Delphi 1.02 maintenance release is not a patch; it is a complete product.
- o This release is available only through Borland. It is not available via CompuServe, Borland's Web site, Borland's FTP site, or resellers.
- o This maintenance release includes the patch release of Delphi 1.01.
- o Delphi 1.02 is not Delphi32. Delphi32 will be released as a separate product.

To order the Delphi 1.02 maintenance release, please call our Order Desk at 800-453-3375 extension 1327.

NOTE: All printed and online documentation assume that you have installed Delphi using the default directory structure.

TABLE OF CONTENTS

-----

1. Product overview
2. Problems fixed in this release

3. Delphi Supplemental Documentation Set
4. Minimum system requirements

## 1. PRODUCT OVERVIEW

-----

Delphi's visual design environment lets you create sophisticated Windows applications faster than any other development tool. Because Delphi is built around and optimizing native code compiler, Delphi applications are up to 10-20 times faster than interpreted code.

Delphi integrates the Borland Database Engine, so you have instant support for dBase, Paradox, and ODBC local databases.

Delphi includes the Local InterBase Server so you can create standalone client/server applications with a high-performance ANSI SQL-92 compatible database server.

Delphi includes Borland's award-winning ReportSmith report writing tool, which allows programmers to prepare innovative reports using live data in all popular database formats.

Delphi Client/Server includes all of Delphi plus high performance native drivers for Oracle, Sybase, Microsoft SQL Server, Informix and InterBase remote servers with unlimited application deployment. You also get team development support, ReportSmith SQL, a Visual Query Builder, source code to the Visual Component Library (VCL), and the Local InterBase Server Deployment Kit.

Delphi includes an Open Tools API capability that allows you to extend the Delphi environment to include your own tools, experts, and so on. By using this API, you can seamlessly integrate these extensions into the Delphi environment. For details, refer to the file TOOLINTF.PAS located in the \DELPHI\DOC for Delphi or in the \DELPHI\SOURCE\VCL directory for Delphi Client/Server. Source code for an example expert is also located in the \DELPHI\DEMOS\EXPERTS directory.

## 2. PROBLEMS FIXED IN THIS RELEASE

-----

The purpose of this section is to provide a general list of problems that are fixed in the 1.02 Delphi release.

## ReportSmith

-----

- o Create master/detail reports to combine multiple reports in one using heterogenous data.
- o Choose to group, sort or summarize data locally or on a database server.
- o Access data using Borland's BDE drivers.
- o Include columns in a report for query-only or value-only.
- o Utilize an updated ReportBasic macro language.
- o Place page totals to display summary values for each page in a report.
- o Create data dictionaries to use with the PC or SQL versions of ReportSmith, to simplify the view of the data.

## Delphi

-----

- o Fixed problems in the Delphi online help system.

## Local InterBase

-----

- o Improved performance of index creation and SQL request involving sort operations on data that exceeds the database cache as defined during database create.
- o Improved I/O diagnostic and error messages from the server.
- o Enhanced the Local InterBase engine to handle complex requests that reference more than 500 columns causing internal buffers to exceed 64k.
- o Improved performance of Local InterBase requests that reference more than 500 columns.
- o Removed the Local InterBase internal requirement that databases have a page size of 1024. It is now possible to create and use a Database specifying any allowable InterBase page size.
- o Numeric overflow errors are now trapped by Local InterBase and reported correctly to the client application.
- o Fixed the incompatibility with Dashboard when using Dashboard, from Starfish Inc., and viewing users in the InterBase security database (Task|User Security) with the InterBase Server Manager tool.
- o Fixed cleanup problems encountered when exiting the Windows Interactive SQL tool while executing a database validate (Task|Database Validate) in the InterBase Server Manager.

## BDE

---

This version of the Borland Database Engine is the same version that is used with the new Visual dBASE 5.5.

- o Fixed TQuery and TTable so that they support Oracle synonyms. Synonyms can now be viewed by typing its name in the name table property.
- o Editing now supported of an opened Paradox table simultaneously in Delphi with referential integrity constraints.
- o Fixed the ability to support Stored Procedures that have string parameters.
- o Fixed problems relating to accessing tables on Lantastic 6.0 network.
- o Removed the nine parameter limitation for SQL queries.
- o Fixed problems relating to opening Access 2.0 files through ODBC.
- o Fixed DBD so that it is now able to open Watcom 4.0 tables.
- o Fixed 32K memory leak associated with live-query results sets and also for local queries involving joins.
- o Fixed problem moving batch from ASCII fixed-length files.
- o Now supports the SYBASE forcedindex feature.

### 3. DELPHI SUPPLEMENTAL DOCUMENTATION SET

-----  
The Supplemental Documentation Set includes the following:

- o Object Pascal Language Reference Guide  
(objlang.pdf is 1.3M.)
- o Delphi Visual Component Library  
Reference (vclref.pdf is 5.1M.)

In the United States, you can purchase hard copy versions of the Delphi Supplemental Documentation Set by calling the Borland order desk at 1-800-331-0877.

Internationally, you can purchase hard copy versions of the Delphi Supplemental Documentation Set by contacting the nearest Borland office.

### 4. MINIMUM SYSTEM REQUIREMENTS

-----  
Delphi requires Windows 3.1 or a 100% compatible operating system, an 80386 or newer processor (486 recommended), and 6Mb of system memory (Delphi Client/Server requires 8Mb, 12Mb or more is recommended for Client/Server development). A minimum installation requires approximately 30Mb of disk space (a full installation of Delphi Client/Server requires approximately

80Mb).

DCC.EXE, the DOS command-line compiler, requires at least 1Mb of extended memory.

Delphi has been tested under Windows 3.1, Windows for Workgroups 3.11, Windows NT 3.5, OS/2 Warp, and Windows 95.

## Article #16069: Creating Dynamic Components at Runtime

Technical Information Database

TI1069D.txt     Creating Dynamic Components at Runtime

Category     :General Programming

Platform     :All

Product      :Delphi 1.0

### Description:

Using Delphi forms and components is simple. When coupled with the object inspector, controlling those objects requires little effort. Creating these types dynamically is also not difficult. This document is intended to give you some tips and hints on how to make dynamic component work for you.

(please note this term "dynamically" is subjective, behind the scenes,

Delphi creates all objects dynamically. The information presented herein

is for the programmer setting creation/properties/deletion the given type at run time)

All types (a form or a component) can be created dynamically. To do this, one needs to put a declaration in the VAR section of their code. This does not create an instance of the object, it creates a pointer. This pointer resides in the data segment (if the variable is declared globally) or the stack (if the variable is declared local to a procedure

or function). In order to instantiate this class, you must call the constructor. This will allocate memory in the computers global heap for the class instance. Trying to access the component before allocating memory will produce a general protection fault.

The Create() constructor is a class method descended from the TObject Class. Create() returns a pointer. This method may or may not take one

or more parameters. For most components (all objects which descend from

TComponent are referred to as components), the constructor takes one parameter, the "owner" of type TComponent.

When dynamically creating a component, setting the Owner to "Self" is the most common practice. If you are in one of a form's methods, "Self" refers to that form in that context. If the owner is a valid object, freeing that object will also free the "owned" component. Another common parameter is "Application". This might be used for a visual component that will not be displayed to the program's users. However, most components do not require that you set a specific owner, so it is not uncommon to set the owner to Nil. Keep in mind, though, that you will not be able to change the owner afterwards. If you do pass Nil to a component's constructor, you must remember to call that component's Free method when you are through using the component.

After creation, but before they can be displayed, windowed components (those descending from TWinControl) require the Parent property to be set.

At the time you set the Parent property, it's usually also a good time to set other properties of this components instance, including event handlers (ie, Width, Color, OnClick).

Event handlers are identical to those specified in the object inspector.

Simply set the component's property name for the event you want to handle

to name of the event handler method you want invoked. Example 1 below

would call the method called "myclick" whenever the button is clicked. Please note this method will be sent the appropriate parameters, and its incoming parameter list must be exact.

Example 1:

```
var
  b1 : TButton;
begin
  .
  .
  .
  b1 := TButton.Create(Self);
  with b1 do begin
    Left := 20;
    Top := 20;
    Width := 90;
    Height := 50;
    Caption := 'my button';
```

```

    Parent := Form1;
    OnClick := MyClick; { a procedure I defined somewhere else }
end;
.
.
.
end;

```

The next example demonstrates how to create a button at run time by clicking a predefined button. Note the different way the button has been created. Either way would work. Also note the buttons that are created are not freed in this code, they will be freed when the form is released.

```

unit Unit1;
interface

uses
    SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,
    Forms, Dialogs, StdCtrls;

type
    TForm1 = class(TForm)
        Button1: TButton;
        procedure Button1Click(Sender: TObject);
    private
        { Private declarations }
    public
        { Public declarations }
        procedure myClick(Sender: TObject);
    end;

var
    Form1: TForm1;

const
    i : integer = 0;

implementation
{$R *.DFM}

procedure TForm1.myClick(Sender: TObject);
begin
    with Sender as TButton do
        Self.Caption := ClassName + ' ' + Name;

```

```
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  with TButton.Create(self) do begin
    Left := 20;
    Top := 30 + i;
    Width := 120;
    Height := 40;
    Name := 'ThisButton' + IntToStr(i);
    Caption := 'There' + IntToStr(i);
    OnClick := MyClick; { a procedure I defined somewhere else }
    Parent := Form1;
  end; {end with}
  inc(i, 40);
end; {end button1.click}

end.
```

## Article #16075: Loading a Custom Cursor from a RES File

Technical Information Database

TI1075D.txt Loading a Custom Cursor from a RES File

Category :VCL

Platform :All

Product :Delphi All

Description:

Q: How do I use one of the cursor files in the  
c:\delphi\images\cursors?

A: Use the image editor to load the cursor into a RES file.  
The following example assumes that you saved the cursor in the  
RES file as "cursor\_1", and you save the RES file as MYFILE.RES.

```
(*** BEGIN CODE ***)
{$R c:\programs\delphi\MyFile.res}    { This is your RES file }

const PutTheCursorHere_Dude = 1;      { arbitrary positive number }

procedure stuff;
begin
    screen.cursors[PutTheCursorHere_Dude] := LoadCursor(hInstance,
                                                         PChar('cursor_1'));
    screen.cursor := PutTheCursorHere_Dude;
end;
```

## Article #16081: Loading Bitmaps and Cursors from RES Files

Technical Information Database

TI1081D.txt Loading Bitmaps and Cursors from RES Files

Category :VCL

Platform :All

Product :Delphi All

Description:

### Loading Bitmaps and Cursors from RES files

Bitmaps and cursors can be stored in a resource (RES) files and linked into your application's EXE file. RES files can be created with Delphi's Image Editor or Borland's Resource Workshop that comes with the Delphi RAD Pack. Bitmaps and cursors stored in RES files (after being bound into an EXE or DLL) can be retrieved by using the API functions LoadBitmap and LoadCursor, respectively.

#### Loading Bitmaps

-----

The LoadBitmap API call is defined as follows:

```
function LoadBitmap(Instance: THandle;  
                   BitmapName: PChar): HBitmap;
```

The first parameter is the instance handle of the module (EXE or DLL) that contains the RES file you wish to get a resource from. Delphi provides the instance handle of the EXE running in the global variable called Hinstance. For this example it is assumed that the module that you are trying to load the bitmap from is your application. However, the module could be another EXE or DLL file. The following example loads a bitmap called BITMAP\_1 from a RES file linked into the application's EXE:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    Bmp: TBitmap;  
begin
```

```

Bmp := TBitmap.Create;
Bmp.Handle := LoadBitmap(HInstance, 'BITMAP_1');
Canvas.Draw(0, 0, Bmp);
Bmp.Free;
end;

```

There is one drawback to using the LoadBitmap API call though LoadBitmap is a Windows 3.0 API call and loads in bitmaps only as DDBs (Device Dependent Bitmaps). This can cause color palette problems when retrieving DIBs (Device Independent Bitmaps) from RES files. The code listed below can be used to retrieve DIBs from RES files. This code loads the bitmap as a generic resource, puts it into a stream, and then does a LoadFromStream call which causes Delphi to realize the color palette automatically.

```

procedure TForm1.Button1Click(Sender: TObject);
const
  BM = $4D42; {Bitmap type identifier}
var
  Bmp: TBitmap;
  BMF: TBitmapFileHeader;
  HResInfo: THandle;
  MemHandle: THandle;
  Stream: TMemoryStream;
  ResPtr: PByte;
  ResSize: Longint;
begin
  BMF.bfType := BM;
  {Find, Load, and Lock the Resource containing BITMAP_1}
  HResInfo := FindResource(HInstance, 'BITMAP_1', RT_Bitmap);
  MemHandle := LoadResource(HInstance, HResInfo);
  ResPtr := LockResource(MemHandle);

  {Create a Memory stream, set its size, write out the bitmap
  header, and finally write out the Bitmap }
  Stream := TMemoryStream.Create;
  ResSize := SizeofResource(HInstance, HResInfo);
  Stream.SetSize(ResSize + SizeOf(BMF));
  Stream.Write(BMF, SizeOf(BMF));
  Stream.Write(ResPtr^, ResSize);

  {Free the resource and reset the stream to offset 0}
  FreeResource(MemHandle);
  Stream.Seek(0, 0);

```

```
{Create the TBitmap and load the image from the MemoryStream}
Bmp := TBitmap.Create;
Bmp.LoadFromStream(Stream);
Canvas.Draw(0, 0, Bmp);
Bmp.Free;
Stream.Free;
end;
```

## Loading Cursors

-----

The LoadCursor API call is defined as follows:

```
function LoadCursor(Instance: THandle;
                    CursorName: PChar): HCursor;
```

The first parameter is the Instance variable of the module that contains the RES file. As above, this example assumes that the module that you are trying to load the cursor from is your application. The second parameter is the name of the cursor.

Under the interface section declare:

```
const
  crMyCursor = 5; {Other units can use this constant}
```

Next, add the following two lines of code to the form's OnCreate event as follows:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Screen.Cursors[crMyCursor] := LoadCursor(HInstance, 'CURSOR_1');
  Cursor := crMyCursor;
end;
```

or you may want to change one of the standard Delphi cursors as follows (the Cursor constants can be found in the On-line Help under Cursors Property):

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  {This example changes the SQL Hourglass cursor}
  Screen.Cursors[crSQLWait] := LoadCursor(HInstance, 'CURSOR_1');
end;
```

Note: Normally it is necessary to delete any cursor resources with the DeleteCursor, however, in Delphi this is not necessary because Delphi will delete the all cursors in the Cursors array.

## Article #16087: SQL: Embedded Spaces in Field/Column Names

Technical Information Database

TI1087D.txt SQL: Embedded Spaces in Field/Column Names

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Implementing SQL with spaces or special characters in field/column names

Implementing SQL statements in Delphi's TQuery component (or the SQL query facilities of Database Desktop, Visual dBASE or Paradox for Windows) requires special syntax for any columns that contain spaces or special characters.

Using the Biolife.DB table of from Delphi's demo data to illustrate, and without the use of any special syntax requirements, a SQL Select statement might be formed as follows,

```
SELECT
  Species No,
  Category,
  Common_Name,
  Species Name,
  Length (cm),
  Length_In,
  Notes,
  Graphic
FROM
  BIOLIFE
```

While appearing normal, the space in the species number and name columns and the column expressing length in centimeters - as well as the parentheses present - cause syntax errors.

Two changes must be taken to correct the syntax of the above SQL statement. First, any columns containing spaces or special characters must be surrounded by single (apostrophe) or double quotes. Secondly, a table reference and a period must precede

the quoted column name. This second requirement is particularly important since a quoted string alone is interpreted as a string expression to be yielded as a column value. A properly formatted statement follows:

```
SELECT
  BIOLIFE."Species No",
  BIOLIFE."Category",
  BIOLIFE."Common_Name",
  BIOLIFE."Species Name",
  BIOLIFE."Length (cm)",
  BIOLIFE."Length_In",
  BIOLIFE."Notes",
  BIOLIFE."Graphic"
FROM
  "BIOLIFE.DB" BIOLIFE
```

The above example uses the table alias BIOLIFE as the table reference that precedes the column name. This reference may take the form of an alias name, the actual table name, or a quoted file name when using dBASE or Paradox tables. The following SQL statements would serve equally well.

Note: This SQL statement may be used provided that the necessary alias is already opened. In the case of the TQuery this means the alias is specified in the DatabaseName property.

```
SELECT
  BIOLIFE."Species No",
  BIOLIFE.Category,
  BIOLIFE.Common_Name,
  BIOLIFE."Species Name",
  BIOLIFE."Length (cm)",
  BIOLIFE.Length_In,
  BIOLIFE.Notes,
  BIOLIFE.Graphic
FROM
  BIOLIFE
```

If an alias is not available then the entire path to the table can be specified as in this example:

```
SELECT
  "C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Species No",
  "C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Category",
```

```
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Common_Name",  
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Species Name",  
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Length (cm)",  
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Length_In",  
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Notes",  
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"."Graphic"
```

```
FROM
```

```
"C:\DELPHI\DEMOS\DATA\BIOLIFE.DB"
```

Finally, two facilities that automatically handle this special formatting exist. The first is the Visual Query Builder that is a part of the Client/Server version of Delphi. The Visual Query Builder performs this formatting automatically as the query is built. The other facility is Database Desktop's Show SQL feature, available when creating or modifying a QBE-type query. After selecting Query|Show SQL from the main menu, the displayed SQL text may be cut and pasted where needed.

## Article #16093: Dynamically Allocating Arrays

Technical Information Database

TI1093D.txt - Dynamically Allocating Arrays

Category :General Programming  
Platform :All-32Bit  
Product :

Description:

{  
Dynamic Arrays

Is it possible to create a dynamically-sized array in Delphi?

Yes. First, you need to create an array type using the largest size you might possibly need. When creating a type, no memory is actually allocated. If you created a variable of that type, then the compiler will attempt to allocate the necessary memory for you. Instead, create a variable which is a pointer to that type. This causes the compiler to only allocate the four bytes needed for the pointer.

Before you can use the array, you need to allocate memory for it. By using `AllocMem`, you will be able to control exactly how many bytes are allocated. To determine the number of bytes you'll need to allocate, simply multiply the array size you want by the size of the individual array element. Keep in mind that the largest block that can be allocated at one time in a 16-bit environment is 64KB. The largest block that can be allocated at one time in a 32-bit environment is 4GB. To determine the maximum number of elements you can have in your particular array (in a 16-bit environment), divide 65,520 by the size of the individual element.

Example: `65520 div SizeOf(LongInt)`

Example of declaring an array type and pointer:

```
type  
  ElementType = LongInt;
```

```

const
  MaxArraySize = (65520 div SizeOf(ElementType));
  (* under a 16-bit environment *)

type
  MyArrayType = array[1..MaxArraySize] of ElementType;

var
  P: ^MyArrayType;

const
  ArraySizeIWant: Integer = 1500;

```

Then when you wish to allocate memory for the array, you could use the following procedure:

```

procedure AllocateArray;
begin
  if ArraySizeIWant <= MaxArraySize then
    P := AllocMem(ArraySizeIWant * SizeOf(LongInt));
end;

```

Remember to make sure that the value of ArraySizeIWant is less than or equal to MaxArraySize.

Here is a procedure that will loop through the array and set a value for each member:

```

procedure AssignValues;
var
  I: Integer;
begin
  for I := 1 to ArraySizeIWant do
    P^[I] := I;
end;

```

Keep in mind that you must do your own range checking. If you have allocated an array with five members and you try to assign a value to the sixth member of the array, you will not receive an error message. However, you will get memory corruption.

Remember that you must always free up any memory that you allocate. Here is an example of how to dispose of this array:

```

procedure DeallocateArray;

```

```
begin
  P := AllocMem(ArraySizeIWant * SizeOf(LongInt));
end;
```

Below is an example of a dynamic array:

```
}

unit Unit1;

interface

uses
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,
  Controls, Forms, Dialogs, StdCtrls;

type
  ElementType = Integer;

const
  MaxArraySize = (65520 div SizeOf(ElementType));
  { in a 16-bit environment }

type
  { Create the array type. Make sure that you set the range to
    be the largest number you would possibly need. }
  TDynamicArray = array[1..MaxArraySize] of ElementType;
  TForm1 = class(TForm)
    Button1: TButton;
    procedure FormCreate(Sender: TObject);
    procedure Button1Click(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;
  { Create a variable of type pointer to your array type. }
  P: ^TDynamicArray;

const
  { This is a typed constant. They are actually static
```

variables that are initialized at runtime to the value taken from the source code. This means that you can use a typed constant just like you would use any other variable. Plus you get the added bonus of being able to automatically initialize its value. }

```
DynamicArraySizeNeeded: Integer = 10;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
```

```
begin  
  { Allocate memory for your array. Be very careful that you  
    allocate the amount that you need. If you try to write  
    beyond the amount that you've allocated, the compiler will  
    let you do it. You'll just get data corruption. }
```

```
  DynamicArraySizeNeeded := 500;
```

```
  P := AllocMem(DynamicArraySizeNeeded * SizeOf(Integer));
```

```
  { How to assign a value to the fifth member of the array. }
```

```
  P^[5] := 68;
```

```
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin  
  { Displaying the data. }
```

```
  Button1.Caption := IntToStr(P^[5]);
```

```
end;
```

```
procedure TForm1.FormDestroy(Sender: TObject);
```

```
begin  
  { Free the memory you allocated for the array. }
```

```
  FreeMem(P, DynamicArraySizeNeeded * SizeOf(Integer));
```

```
end;
```

```
end.
```

## Article #16099: Resource Expert: What It Is and How to Install It

Technical Information Database

TI1099D.txt    Resource Expert: What It Is and How to Install It  
Category     :Product Info  
Platform     :All  
Product      :Delphi 1.0

### Description:

Resource Expert: what it is and how to install and use it.

### What is the Resource Expert

The Resource Expert is a Delphi expert add-on that is available as a part of the Delphi Rad Pack. The expert assists the programmer in porting existing projects to Delphi by converting dialog and menu resource scripts intended for use in traditional Windows applications. Dialog resources and their contents are converted to Delphi forms with the analogous controls converted to Delphi components.

### How to install the Resource Expert

The Resource Expert is installed via the Delphi Rad Pack's Resource Workshop 4.5 install procedure. Once installed, it is incorporated into the Delphi component library and is available as an option on the Delphi Help Menu or via the Experts page of the Forms Gallery dialog. Installation of the Resource Expert files may be installed from within the Windows environment or from the command line under Windows 95 or Windows NT.

To install the Resource Expert files from within Windows,

- 1) Begin the installation procedure for Borland Resource Workshop.
- 2) On the third dialog, entitled 'Resource Workshop - Resource Expert Options', ensure that the 'Install Resource Expert' check box is checked.

- 3) The 'Install to:' entry indicates the destination directory for the Resource Expert files, indicating C:\DELPHI\RCEXPRT by default. Change this entry as needed.
- 4) Proceed with the rest of the Resource Workshop installation process as normal.

To install the Resource Expert files from the command line, type the following commands,

- 1) MD C:\DELPHI\RCEXPRT
- 2) CD C:\DELPHI\RCEXPRT
- 3) E:\INSTALL\RW\UNPAQ -X E:\INSTALL\RW\RESEXP.PAK

Note: The last command above assumes that the E: drive is a CD-ROM drive containing the Rad Pack Installation CD.

Once the installation of the Resource Expert files is completed, the Delphi Component Library must be recompiled. To do this,

- 1) Load Delphi.
- 2) Select Options|Install Components.
- 3) Click the Add... button.
- 4) When the Add Module dialog appears, enter the full path name of the rcexpert.pas file or find the file via the Browse... button.
- 5) Finally, choose the OK button on the Install Components Dialog.

## How to use the Resource Expert

To convert a resource script, all source files normally required to compile the script must be present. This would include .RC, .MNU, or .DLG file(s) and any .H or .PAS include files they refer to. Resource scripts typically use WINDOWS.H and BWCC.H. These files are usually located in directories such as \BC4\INCLUDE or \BP7\UNITS. The Resource Expert supports the RC language extensions defined by Resource Workshop.

Again, the Resource Expert may be invoked via the Help|Resource Expert menu option or via the Experts page of the Forms Gallery dialog. The latter will appear if the 'Use on new form' check

box is checked on the Preferences page of the Environment Options dialog.

Once the Resource Expert has been invoked, click the 'Next' button to bypass the page that introduces the expert to the user. The second page of the expert allows the user to select the resource scripts to convert. A number of scripts may be chosen provided that they all reside in the same directory. The particular type of script to view (.RC, .DLG or .MNU) can be selected via the 'List Files of Type' combo box. After selecting the scripts to convert, click the 'Next' button again. The third page presents a single 'Include Path' edit box. Enter the list of directories containing .H, .INC, or .PAS include files used by the resource scripts, (if any). Each directory name should be separated by a semicolon. Again, click the 'Next' button to continue. On the fourth and final page of the expert, the 'Convert' button appears. Clicking it begins the actual conversion process. If the resources script contain many dialogs, the 'Show all forms' check box may be un-checked in order to speed the conversion process and to minimize impact on Windows system resources.

If a syntax error is encountered during the conversion process, the erroneous statement will be discarded and conversion will resume at the next statement or block. Errors will be noted in the log file ERRLOG.TXT and displayed in a Delphi editor window.

Once the conversion process is complete, separate forms for each dialog resource will have been created. For menu resources, a simple form containing the converted menu component will have been created. If a project was active before the conversion began, the converted forms are added to the project. Each form may now be used and modified as would any Delphi form.

## Article #16105: Delphi Configuration Files

Technical Information Database

TI1105D.txt - Delphi Configuration Files

Category :Delphi 1.x  
Platform :All  
Product :

### Description:

Delphi employs a number of files for its configuration, some global to the Delphi environment, some project specific. Chief among all the configuration files is DELPHI.INI. DELPHI.INI resides in the Windows directory and contains most of the configurable items to be found within Delphi. Being the largest Delphi configuration file, DELPHI.INI contains settings to control the Delphi speed bar, component palette, component library, gallery, installed experts, editor, printing, tools menu and all the environment options found on the Environment Options dialog. This document will explore DELPHI.INI in depth.

DELPHI.CBT is a copy of DELPHI.INI (minus the ReportSmith section) that is installed along with Delphi and may serve as a sort of backup for restoring the original Delphi setup. It resides in the Windows directory along with DELPHI.INI. Below is the ReportSmith section and its one entry that should be placed in a DELPHI.INI created from DELPHI.CBT.

```
[ReportSmith]
ExePath=C:\RPTSMITH
```

Delphi also makes use of Desktop (.DSK) files. Desktop files, like most Delphi configuration files, are formatted in the same manner as .INI files, with section headers and individual settings in each section. The purpose of desktop files is to retain the appearance and content of the Delphi desktop between sessions or between projects. Each desktop file contains information regarding the presence and appearance of the Delphi main window, the Object Inspector, the Alignment Palette, the Project Manager, and the Watch, Breakpoint, CallStack, and

component list windows. Also kept in each desktop file is the number of editor windows open as well as the names, number and order of files open in each editor window.

If the 'Desktop files' check box (on the Preferences page of the Environment Options dialog) is checked, Delphi will automatically create desktop files for each project closed and saved. Each desktop file carries the same root name as the saved project file. If no project is active when Delphi exits, a default desktop file, DELPHI.DSK, is created. The last active project determines which desktop file Delphi loads at startup. Again, if no project was active when Delphi exited last, then DELPHI.DSK is loaded. While project specific desktop files reside in the same directory with the corresponding project, DELPHI.DSK resides in the \DELPHI\BIN directory. The PrivateDir setting in the Globals section of DELPHI.INI may be used to relocate DELPHI.DSK to a different location.

Option files (.OPT) are another INI-like file in which Delphi maintains values directly corresponding to those settings on the Compiler, Linker, and Directories/Conditionals pages of the Project Options dialog. Each of these pages has a corresponding section in the option file and each setting has a individual entry in that section. Each option file also retains the last parameter string entered via the Run Parameters dialog. An option file is created for each project saved. Like .DSK files, the root name of the .OPT file is the same as its corresponding project and reside in the same directory as that project.

A default option file, DEFPROJ.OPT, is created if the Default check box of the Project Options dialog is checked. The settings in DEFPROJ.OPT serve as the default project settings each time a new project is created.

Additionally, the Delphi command line compiler, DCC.EXE, supports the use of the configuration file DCC.CFG. DCC.CFG is a text file opened when the command line compiler starts and is used in addition to options entered on the command line. Command line options may be placed in DCC.CFG, each on a separate line. When DCC starts, it looks for DCC.CFG in the current directory. If it is not found there, the directory in which DCC.EXE resides is then searched. A sample DCC.CFG follows:

```
/b
/q
/v
/eC:\DELPHI\WORK
```

The above settings instruct the command line compiler to build all units (/b), compile without displaying file names and line numbers (/q), append debug information to the .EXE (/v), and place the compiled units and executable in the C:\DELPHI\WORK directory (/eC:\DELPHI\WORK). The contents of the installed DCC.CFG are included below to serve in restoring it should it be deleted or damaged.

```
/m
/cw
/rD:\DELPHI\LIB
/uD:\DELPHI\LIB
/id:\DELPHI\LIB
```

STDVCS.CFG is a file installed with the Client/Server of Delphi, but is only used in conjunction with the Version Control manager DLL. The contents of the installed STDVCS.CFG are included here to serve in restoring it should it be deleted or damaged.

```
NODELETEWORK WRITEPROTECT
NOCASE VCSID
```

```
COMMENTPREFIX .PAS = "{ "
COMMENTPREFIX .PRJ = "{ "
```

```
NOEXPANDKEYWORDS .FRM
NOEXPANDKEYWORDS .EXE
NOEXPANDKEYWORDS .DLL
NOEXPANDKEYWORDS .DOC
NOEXPANDKEYWORDS .ICO
NOEXPANDKEYWORDS .BMP
```

Lastly, MULTIHELP.INI is a file Delphi uses to provide context-sensitive help across multiple help files. This file should not be modified; doing so may cause the Delphi Help system to behave erratically. The contents of the installed MULTIHELP.INI are included here to serve in restoring it should it be deleted or damaged.

DBD.HLP=C:\DBD

Note:

What follows below is a comprehensive dissection of the DELPHI.INI file. In order to save space, a few conventions were observed in the describing possible values for settings.

Where only one of a limited set of values is applicable, a pipe symbol is used to separate each of the possible value, e.g.:

MapFile=0|1|2|3

allows only the values 0, 1, 2, or 3

Where a single value within a range is applicable, the range of values is presented inside brackets with the minimum and maximum values separated by two periods, e.g.:

GridSizeX=[2..128]

permits any value between 2 and 128, inclusively.

=====

Section: [Globals] - The Globals section contains settings not included in other sections and that have an effect on Delphi as a whole. Items in the Globals section may be changed only by editing DELPHI.INI.

---

PrivateDir=

This item controls where Delphi both creates and locates the files DELPHI.DSK, DELPHI.DMT, DEFPROJ.OPT and STDVCS.CFG. The default location is the \DELPHI\BIN directory. If Delphi is run from a read-only directory (or from a CD-ROM) this item should be set to a writeable directory, either on a network or local drive. This item should contain a fully qualified path, including the drive letter. Example:

PrivateDir=J:\USERS\JSMITH ; Private network directory

HintColor=

This item controls the color of the fly-by hint window for the Delphi IDE. The value may be a decimal or hex constant, or one of the symbolic color constants defined in VCL (e.g. clCyan). Note that the text in the hint window is always painted using clWindowText. The default value is clYellow.

PropValueColor=

This item controls the color of the text in the right-hand (value) pane of the Object Inspector. The value may be a decimal or hex constant, or one of the symbolic color constants defined in VCL (e.g. clBlue). The default value is clWindowText.

Section: [Library] - The Library section contains entries for those settings found on the Library page of the Environment Options dialog (accessed via Options|Environment). The options in this section take effect when the Options|Rebuild Library menu option is chosen.

---

SearchPath=

Specifies search paths where the compiler can find the units

needed to build the component library. Path names should be listed consecutively, separated by a semicolon. This entry is changed via the 'Library Path' combo box. Example:

```
SearchPath=D:\DELPHI\LIB;d:\delphi\rcexpert
```

ComponentLibrary=

Specifies the name of the active component library. This item is changed via the Options|Open Library menu option. It may also be changed from the 'Library filename' edit of the Install Components dialog (accessed via Options|Install Components). Example:

```
ComponentLibrary=D:\DELPHI\BIN\REXPRT.DCL
```

SaveLibrarySource=0|1

Indicates whether Delphi saves the source code for the component library when installing new components or rebuilding it via Options|Rebuild Library. A setting of 1 causes the project source to be saved using the library file's root name with a .DPR extension. The default value is 0. This setting is changed via the 'Save library source code' check box.

MapFile=0|1|2|3

Determines the type of map file produced, if any, when the component library is rebuilt. The map file is placed in the same directory as the library, and it has a .MAP extension. The default value is 0. This setting is changed via the 'Map file' radio button group.

Option	Effect
0 - Off	Does not produce map file.
1 - Segments	Linker produces a map file that includes a list of segments, the program start address, and any warning or error messages produced during the link.
2 - Publics	Linker produces a map file that includes a list of segments, the program start address, any

warning or error messages produced during the link, and a list of alphabetically sorted public symbols.

- 3 - Detailed Linker produces a map file that includes a list of segments, the program start address, any warning or error messages produced during the link, a list of alphabetically sorted public symbols, and an additional detailed segment map. The detailed segment map includes the address, length in bytes, segment name, group, and module information.

LinkBuffer=0|1

Specifies the location of the link buffer. A setting of 1 causes Delphi to use available disk space for the link buffer; 0 causes the use of available memory. The default value is 0. This setting is changed via the 'Link Buffer' radio button group.

DebugInfo=0|1

Determines whether the component library file is compiled and linked with debug information. A setting of 1 causes the inclusion of debug information. The default setting is 0. The setting is changed via the 'Compile with debug info' check box.

Section: [Gallery] - The Gallery section controls the use and base location of the form and project galleries. It contains those settings found in the Gallery: group box on the Preferences page of the Environment Options dialog.

-----  
BaseDir=

Points to the directory where Delphi attempts to find Gallery files. To share a gallery directory with other users, set this item to point to a shared network directory. This item should contain a fully qualified path, including the drive letter. This entry may be changed only by editing DELPHI.INI.

Example:

```
BaseDir=D:\DELPHI\GALLERY
```

```
GalleryProjects=0|1
```

Indicates whether Delphi displays the Browse Gallery dialog box when the File|New Project menu option is chosen. A setting of 1 causes the Browse Gallery dialog box to display. The default setting is 0. The setting is changed via the 'Use on New Project' check box.

```
GalleryForms=0|1
```

Indicates whether Delphi displays the Browse Gallery dialog box when the File|New Form menu option is chosen. A setting of 0 prevents the Browse Gallery dialog box from displaying. The default setting is 1. The setting is changed via the 'Use on New Form' check box.

Section: [Experts] - The Experts section lists the Experts which Delphi will attempt to load and initialize upon startup. Any value may be used on the left of the equals sign, as the item name is not interpreted. Borland recommends using a combination of the vendor name and the product name. Example:

```
[Experts]
```

```
ComponentWare.CommExpert=c:\delphi\cware\commexpt.dll
```

```
CodeFast.TheExpert=c:\delphi\codefast\codefast.dll
```

Section: [ReportSmith] - The ReportSmith section contains just one entry which specifies the directory in which ReportSmith is installed.

---

```
ExePath=
```

ExePath indicates the location of RPTSMITH.EXE. This entry is

placed in DELPHI.INI at install time and may be changed only by editing DELPHI.INI. Example:

```
ExePath=D:\RPTSMITH
```

Section: [Session] - The Session section and its one entry identify the active project when Delphi was last closed.

---

Project=

Identifies the active project when Delphi was last closed. This setting is only meaningful if the DesktopFile setting in the AutoSave section is set to 1. This setting also serves to identify the project's desktop file (using a .DSK extension). This setting is updated automatically when Delphi exits.

Example:

```
Project=D:\DELPHI\WORK\MAILAPP.DPR
```

Section: [MainWindow] - The MainWindow section defines characteristics of the Delphi main window as they relate to the speedbar and component palette. The SpeedBar Layout section details the actual contents of the speedbar. Likewise, the .Palette section details the actual contents of the component palette.

---

Split=[-1..400]

Indicates the horizontal position if the vertical bar separating the speedbar and component palette. The default value is 183. This setting is changed by moving the split bar with the mouse.

SpeedHints=0|1

Determines whether hints are displayed as the mouse passes over buttons on the speedbar. A setting of 0 prevents the display

of speedbar hints. The default setting is 1. This setting is changed using the Show Hints menu option of the speedbar speedmenu.

PaletteHints=0|1

Determines whether hints are displayed as the mouse passes over buttons on the palette. A setting of 0 prevents the display of palette hints. The default setting is 1. This setting is changed using the Show Hints menu option of the palette speedmenu.

Speedbar=0|1

When set to 0, prevents the display of the speedbar. The default setting is 1. This setting is changed via the View|Speedbar menu option or via the Hide option of the speedbar speedmenu.

Palette=0|1

When set to 0, prevents the display of the component palette. The default setting is 1. This setting is changed via the View|Component Palette menu option or via the Hide option of the component palette speedmenu.

Section: [Speedbar Layout] - The Speedbar Layout details the specific contents of the speedbar. The contents of this section are changed via the Configure option of the speedbar speedmenu.

---

Count=[0..52]

Specifies the number of buttons on the speedbar. The default is 14.

Button[0..51]=n,x,y

This entry appears once for each button on the speedbar. Each button entry is uniquely numbered, the first being Button0. The number n identifies a unique pre-defined id code. The x value is a number specifying the horizontal position of the button on the speedbar. The y value is a number specifying the vertical position of the button on the speedbar. Below is a listing of the default speedbutton set and their corresponding menu options.

```

Button0=30001,4,2      ; File|Open Project...
Button1=30002,27,2    ; File|Save Project
Button2=30007,4,25    ; File|Open File...
Button3=30008,27,25   ; File|Save File
Button4=30009,50,2    ; File|Add File...
Button5=30010,50,25   ; File|Remove File...
Button6=30069,79,2    ; View|Units...
Button7=30070,102,2   ; View|Forms...
Button8=30068,79,25   ; View|Toggle Form/Unit
Button9=30004,102,25  ; File|New Form
Button10=30090,131,2  ; Run|Run
Button11=30093,154,2  ; Run|Program Pause
Button12=30092,131,25 ; Run|Trace Into
Button13=30091,154,25 ; Run|Step Over

```

Section: [Desktop] - The Desktop section contains a single entry that determines which desktop settings are saved when Delphi exits. This section and its one entry is only meaningful if the DesktopFile entry in the AutoSave section is 1.

-----  
SaveSymbols=0|1

Determines if browser symbol information is saved along with Desktop information when Delphi exits. This setting is changed via the 'Desktop contents:' radio button group box. The default setting is 1.

Option	Effect
-----	-----
0 - Desktop only	Saves directory information, open files in the editor, and open windows.
1 - Desktop and symbols	Saves desktop information and browser

symbol information from the last successful compile.

Section: [AutoSave] - The Autosave section determines which files and options are saved automatically when the current project is run or when Delphi exits. This section corresponds to the 'Autosave options:' group box of the Preferences page of the Environment Options Dialog.

---

EditorFiles=0|1

When set to 1, causes Delphi to save all modified files in the Code Editor when Run|Run, Run|Trace Into, Run|Step Over, or Run|Run To Cursor are chosen, or when Delphi exits. The default setting is 0. This setting is changed via the 'Editor files' check box on the Preferences page of the Environment Options Dialog.

DesktopFile=0|1

When set to 0, prevents Delphi from saving the arrangement of the desktop when a project is closed or when Delphi exits. The default setting is 1. This setting is changed via the 'Desktop' check box on the Preferences page of the Environment Options Dialog.

Note: Further discussion regarding desktop files are discussed below under Desktop (.DSK) files.

Section: [FormDesign] - The FormDesgin section contains those settings that control the appearance and behavior of a forms grid at design time. This section corresponds to the 'Form designer:' group box of the Preferences page of the Environment Options Dialog.

---

DisplayGrid=0|1

Determines the design time visibility of the dots that comprise

the form grid. A setting of 0 avoids grid display. The default setting is 1. This setting is changed via the 'Display grid' check box.

SnapToGrid=0|1

Indicates whether components are automatically aligned with the grid when components are moved with the mouse. A setting of 0 avoids grid alignment. The default setting is 1. This setting is changed via the 'Snap to grid' check box.

GridSizeX=[2..128]

Sets grid spacing in pixels along the x-axis. The default value is 8. This setting is changed via the 'Grid Size X' edit.

GridSizeY=[2..128]

Sets grid spacing in pixels along the y-axis. The default value is 8. This setting is changed via the 'Grid Size Y' edit.

DefaultFont=

This item controls the default font for new forms. The name of the font, the font size, and optionally the style of the font may be entered, each separated by commas. (Supported font styles are "bold" and "italic.") This setting may be changed only by editing DELPHI.INI. Example:

DefaultFont=MS Sans Serif, 8, bold, italic

Section: [Debugging] - The Debugging section contains those settings that control integrated debugging and the appearance of Delphi during project execution. This section corresponds to the 'Debugging:' group box of the Preferences page of the Environment Options Dialog.

---

IntegratedDebugging=0|1

Allows or prevents the uses of the Delphi Integrated Debugger. A setting of 0 prevents integrated debugging. The default setting is 1. This setting is changed via the 'Integrated Debugging' check box.

DebugMainBlock=0|1

When set to 1, causes the debugger to stop at the first unit initialization that contains debug information. The default setting is 0. This setting is changed via the 'Step program block' check box.

BreakOnExceptions=0|1

When set to 1, stops the application when an exception is encountered and displays the following the exception class, exception message and the location of the exception. When set to 0, exceptions do not stop the running application. The default setting is 1. This setting is changed via the 'Break on exception' check box.

MinimizeOnRun=0|1

When set to 1, minimizes Delphi when the current project is executed. The default is 0. This setting is changed via the 'Minimize on run' check box.

HideDesigners=0|1

When set to 1, hides designer windows, such as the Object Inspector and Form window, while the application is running. The default setting is 1. This setting is changed via the 'Hide designers on run' check box.

NoResetWarning=0|1

When set to 1, prevents Delphi from presenting a warning message when Program Reset is selected. The default setting is 0. This setting may be changed only by editing DELPHI.INI.

Section: [Compiling] - The compiling section contains a single entry that determines whether the user is presented with a dialog that reports compiler progress. This section corresponds to the 'Compiling:' group box of the Preferences page of the Environment Options Dialog.

---

ShowCompilerProgress=0|1

Specifies whether compilation progress is reported. A setting of 1 causes Delphi to display a window detailing compilation progress. The default setting is 0. This setting is changed via the 'Show compiler progress' check box.

Section: [Browser] - The Browser section contains settings that are found on the Browser page of the Environment Options dialog. These settings specify how ObjectBrowser functions and what symbol information is displayed.

---

Filters=

This setting determines which filters are active in the Object Browser. The value is the sum of the values listed below for each filter desired.

Value	Filter
-----	-----
2	Constants
4	Types
8	Variables
16	Functions and Procedures
32	Properties
128	Inherited
256	Virtuals only
1024	Private
2048	Protected

4096 Public  
8192 Published

The default setting is 15806, which activates all filters. Each filter corresponds to a check box in the 'Symbol filters:' group box. For example, the following setting activates the Properties, Public and Published filters:

Filters=12320 ; 8192 + 4096 + 32 = 12320

InitialView=1|2|3

InitialView determines the type of information the browser displays when first opened. The default setting is 2. This setting is changed via the 'Initial view:' radio button group box.

Value	Viewed
-----	-----
1	Units
2	Objects
3	Globals

Sort=0|1

When set to 1, causes Delphi to display symbols in alphabetical order by symbol name. When set to 0, symbols display in order of declaration. The default setting is 0. This setting is changed via the 'Sort always' check box.

QualifiedSymbols=0|1

When set to 1, causes Delphi to display the qualified identifier for a symbol. When set to 0, only the symbol name is displayed. The default setting is 0. This setting is changed via the 'Qualified symbols' check box.

CollapsedNodes=

Specifies which branches of the object tree hierarchy are collapsed when the ObjectBrowser is started. This entry is a

list of class names, separated by separated by semicolons.  
This setting is changed via the 'Collapse Nodes:' combo box.  
Example:

```
CollapsedNodes=Exception;TComponent
```

```
ShowHints=0|1
```

Determines whether hints are displayed as the mouse passes over filter buttons. A setting of 0 prevents the display of filter hints. The default setting is 1. This setting is changed using the Show Hints menu option of the ObjectBrowser speedmenu.

Section: [Custom Colors] - The Custom colors section lists up to sixteen user defined colors. Each color is specified as a six-digit hexadecimal RGB value. An unused color entry is indicated by the hexadecimal value FFFFFFFF. Entries in this section are created and updated via the Color dialog of any components Color property (accessed by double-clicking the entry area of the Color property).

---

```
Color[A..P]=
```

Specifies an individual RGB value for a user defined color.

Section: [Print Selection] - The Print Selection section contains those options that appear when the File|Print menu option is chosen. These settings correspond to the options displayed in the 'Options:' group box.

---

```
HeaderPage=0|1
```

When set to 1, Delphi includes the name of the file, current date, and page number at the top of each page. The default setting is 0. This setting is changed via the 'Header/page number' check box.

LineNumbers=0|1

When set to 1, Delphi places line numbers in the left margin of the printed output. The default setting is 0. This setting is changed via the 'Line numbers' check box.

SyntaxPrinting=0|1

When set to 1, Delphi uses bold, italic, and underline characters to indicate elements with syntax highlighting. When set to 0, Delphi uses no special formatting when printing. The default value is 1. This setting is changed via the 'Syntax print' check box.

UseColor=0|1

When set to 1, causes Delphi to print colors that match colors on screen. This option requires that the current printer support color. The default value is 0. This setting is changed via the 'Use Color' check box.

WrapLines=0|1

When set to 1, causes Delphi to use multiple lines to print characters beyond the page width. When set to 0, code lines are truncated and characters beyond the page width do not print. The default value is 0. This setting is changed via the 'wrap lines' check box.

LeftMargin=[0..79]

Specifies the number of character spaces used as a margin between the left edge of the page and the beginning of each line. The default value is 0. This setting is changed via the 'Left margin' edit.

Section: [Highlight] - The Highlight section contain those

settings that determine the syntax and context specific colors used in the Code Editor. The settings in this section are changed via the Editor Colors page of the Environment Options dialog.

---

ColorSpeedSetting=0|1|2|3

Determines which color scheme was last selected. Changing this setting directly does not affect the actual colors used for individual elements. The Color SpeedSetting combo box does not save color schemes; it only serves as a quick means of setting all color elements at once. The default setting is 0. The table below shows each value's corresponding speedsetting.

Value	SpeedSetting
0	Defaults
1	Classic
2	Twilight
3	Ocean

=

All the color entries correspond to a single color element. Each color element entry uses the following format:

=fRGB,bRGB,attr,deffore,defback,fcell,bcell

Value code	Meaning
fRGB	Foreground RGB value
bRGB	Background RGB value
attr	Text attribute; zero or more of B, I and U
deffore	Use default foreground color (1=yes, 0=no)
defback	Use default background color (1=yes, 0=no)
fcell	Foreground color grid cell number
bcell	Background color grid cell number

Section: [Editor] - This section describes the appearance and behavior of the Delphi Code Editor. Settings from both the Editor options and Editor display pages are detailed

here.

---

DefaultWidth=  
DefaultHeight=

These two items, if present, control the initial width and height of the Delphi Code Editor window. Delphi does not update these values, but it does read them each time a Code Editor is created. The default width is 406; the default height is 234. These settings may be changed only by editing DELPHI.INI.

FontName=  
FontSize=

These settings specify the name and size, respectively, of a mono-spaced font that the Code Editor uses to display text. Courier New is the default font, 10 the default size. These entries may be changed via the 'Editor font:' and 'Size:' combo boxes on the Editor display page.

BlockIndent=[1..16]

Specifies the number of spaces to indent a marked block. The default value is 1. This setting may be changed via the 'Block indent' combo box on the Editor display page.

UndoLimit=[0..]

Specifies the number of keystrokes that can be undone, which is limited by available memory. The default value is 32,767. This setting may be changed via the 'Undo limit:' combo box on the Editor Options page.

TabRack=

Determines the columns at which the cursor will move to each time the Tab key is pressed. Each successive tab stop must be separated by a space and must be larger than its predecessor. If only one number is specified, tab stops are spaced apart

evenly, using that number. If two numbers are specified then tab stops occur at the specified positions and at positions that mark the difference between the two values. The default tab stops are 9 and 17. This setting may be changed via the 'Tab stops:' combo box on the Editor Options page. Note: this option has no effect if the smart tabs setting is enabled.

`RightMargin=[0..1024]`

Specifies the right margin of the Code Editor. The default value is 80. The valid range is 0 to 1024. This setting may be changed via the 'Right margin:' combo box on the Editor display page.

`Extensions=`

#### Combo Box

Specifies file masks of those files that will display with syntax highlighting. Typically, only specific extensions are included. The default setting is '\*.PAS;\*.DPR;\*.DFM;\*.INC;\*.INT'. This setting may be changed via the 'Syntax extensions:' combo box on the Editor Options page. Example:

```
Extensions=*.PAS;*.DPR;*.SRC
```

`FindTextAtCursor=0|1`

When set to 1, causes Delphi to Place the text at the cursor into the 'Text To Find' combo box in the Find Text dialog box when the Search|Find menu option is chosen. When set to 0, the default setting, the search text must be typed in. This entry may be changed via the 'Find text at cursor' check box on the Editor Options page.

`BRIEFRegularExpressions=0|1`

When set to 1, permits the use of Brief-style regular expressions when searching for text. The default setting is 0. This entry may be changed via the 'BRIEF regular expressions' check box on the Editor Options page.

PreserveLineEnds=0|1

Determines whether end-of-line characters are changed to carriage return/line feed pairs or are preserved. When set to 0, Delphi converts end-of-line characters to carriage return/line feed pairs. The default value is 1. This entry may be changed via the 'Preserve Line Ends' check box on the Editor display page.

FullZoom=0|1

Determines whether the Code Editor fills the entire screen when maximized. When set to 0 (the default), the Code Editor does not cover the Delphi main window when maximized. A setting of 1 allows the Code Editor window to encompass the entire screen. This setting may be changed via the 'Zoom to full screen' check box on the Editor Display page.

DoubleClickLine=0|1

When set to 1, causes Delphi to highlight the whole line when the user double-clicks any character in the line. When set to 0 (the default), only the selected word is highlighted. This entry may be changed via the 'Double click line' check box on the Editor Options page.

BRIEFCursors=0|1

Determines whether Delphi uses BRIEF-style cursor shapes in the Code Editor. A setting of 1 causes Delphi to use Brief-style cursors. The default setting is 0. This setting may be changed via the 'BRIEF cursor shapes' check box on the Editor Display page.

ForceCutCopyEnabled=0|1

When set to 1, enables the Edit|Cut and Edit|Copy menu options, even when no text is selected. The default setting is 0. This entry may be changed via the 'Force cut and copy enabled' check

box on the Editor Options page.

KeyBindingSet=0|1|2|3

Determines which pre-defined key mapping set Delphi recognizes. The default setting is 0. This setting may be changed via the 'Keystroke mapping:' list box on the Editor Display page. The table below identifies the appropriate mapping for the desired value.

Value	Mapping
-----	-----
0	Default
1	Classic
2	Brief
3	Epsilon

Mode=

This setting determines the state of sixteen of the options available on the Editor Options page and two of the options on the Editor Display page. The value is the sum of the values listed below for each check box checked. Unless noted, all the options below correspond to a similarly named check box on the Editor Options page.

- 1 Insert mode - Inserts text at the cursor without overwriting existing text.
- 2 Auto indent mode - Positions the cursor under the first nonblank character of the preceding nonblank line when Enter is pressed.
- 4 Use tab character - Inserts tab character. If disabled, inserts space characters. This option and the Smart Tabs option are mutually exclusive. enabled, this option is off.
- 16 Backspace un-indent - Aligns the insertion point to the previous indentation level (out-dents it) when Backspace is pressed, if the cursor is on the first nonblank character of a line.
- 32 Keep trailing blanks - Saves trailing spaces and tabs present at the end of a line.
- 64 Optimal fill - Begins every auto-indented line with the minimum number of characters possible, using tabs

and spaces as necessary.

- 128 Cursor through tabs - Enables the arrow keys to move the cursor to the beginning of each tab.
- 256 Group undo - Undoes the last editing command as well as any subsequent editing commands of the same type when Alt+Backspace, Ctrl+Z is pressed or the Edit|Undo menu option is chosen.
- 512 Persistent blocks - Keeps marked blocks selected even when the cursor is moved, until a new block is selected.
- 1024 Overwrite blocks - Replaces a marked block of text with whatever is typed next. If Persistent Blocks is also selected, text entered is added to the currently selected block.
- 4096 Create backup file - Creates a backup file when source files are saved. This item is set via the 'Create backup file' check box on the Editor Display page.
- 8192 Use Syntax highlight - Enables syntax highlighting.
- 16384 Visible right margin - Enables the display of a line at the right margin of the Code Editor. This item is set via the 'Visible right margin' check box on the Editor Display page.
- 32768 Smart tabs - Tabs to the first non-whitespace character in the preceding line. This option and the Smart Tabs option are mutually exclusive.
- 131072 Cursor beyond EOF - Allows cursor positioning beyond the end-of-file.
- 262144 Undo after save - Allows retrieval of changes after a save.

EditorSpeedSetting=0|1|2|3

Determines which editor emulation scheme was last selected. Changing this setting directly does not affect the actual keystroke mapping or the editor options used. The Editor SpeedSetting combo box does not save emulation schemes; it only serves as a quick means of setting many editor options at once. The default setting is 0. The table below shows each value's corresponding speedsetting.

Value	SpeedSetting
-----	-----
0	Default keymapping

- 1 IDE classic
- 2 Brief emulation
- 3 Epsilon emulation

Section: [.Palette] - This section describes the content of the Component Palette. Each entry name in this section matches a single page name on the component palette. The value for each entry is a list of the component type names that appear on that page, each separated by a semicolon. This section appears once for each component library configured via the Palette page of the Environment Options dialog.

Section: [Transfer] - The Transfer section defines those items that appear on the Tools menu. Entries in this section are defined when using the Tool Properties dialog. The Tool Properties dialog is itself accessed via the Options|Tools menu option.

---

Count=

Specifies the number of items that should appear on the Tools menu. This item is changed by adding or removing programs from the Tools Options dialog.

Title#=

Path#=

WorkingDir#=

Params#=

These entries appear once each for every item on the Tools menu. Each item name is immediately followed by a number indicating its position in the Tools menu, zero being the first.

Title#            Specifies the text that actually appears on the Tools menu.

Path#            Specifies the full path to the program that the menu option will execute.

WorkingDir#      Determines the current directory when the program starts.

Params#            Specifies the parameters to pass to the program at startup.

Section: [Closed Files] - The Closed Files section lists the full path name of the last three closed project files. The files are listed in the order of most recently used first. Each entry takes the form

File\_#=.DPR,col1,row1,col2,row2

where # is either 0, 1 or 2. Col1 identifies the first visible column in the code editor, row1 the first visible row. Col2 is the cursor column, row2 the cursor row.

Section: [VBX] - The VBX section contains various settings that are available when installing a VBX into the Delphi Component Library.

---

VBXDir=

Contains the last location from which a VBX was installed. This value is saved automatically by Delphi upon installing a VBX.

UnitDir=

Specifies the last location in which Delphi placed a source unit for use with the previously installed VBX. This value is saved automatically by Delphi upon installing a VBX.

PalettePage=BVSP

This entry retains the last specified name of the component palette page onto which Delphi placed the most recently installed VBX. This value is saved automatically by Delphi upon installing a VBX.

Section: [Version Control]

---

VCSManager=

This item specifies the fully qualified path of a Version Control manager DLL. Delphi Client/Server, which includes team support, supplies a Version Control manager by the name STDVCS.DLL, located in the \BIN directory. Example:

VCSManager=d:\delphi\bin\stdvcs.dll

Section: [Resource Expert] - The Resource Expert section appears only if the Delphi Resource Expert is installed. This section has but one entry.

---

RCIncludePath=

Specifies the list of directories (separated by semicolons) that the expert should search to find any include files needed for resource file conversion. Example:

RCIncludePath=D:\DELPHI\WORK;D:\RESOURCE\INCLUDE

Section: [History\_##] - A number of history sections, each with a unique number following the underscore, reside in DELPHI.INI. Each history section corresponds directly to a particular combo box in a Delphi dialog. Each section contains at least one entry; the Count entry, indicating the number of history items in the section. Each actual history item is named by an H, followed by its order in the history list, H0 being first. The table below indicates to which combo box the particular section belongs. Only those histories saved by Delphi are listed.

Section	Combo box location
[History_0]	'Text to find', Find Text or Replace Text dialog
[History_1]	'Replace with', Replace Text dialog
[History_2]	'Output directory', Directory/conditionals page

of Project Options dialog  
[History\_3] 'Search path', Directory/conditionals page of  
Project Options dialog  
[History\_7] 'Conditionals', Directory/conditionals page of  
Project Options dialog  
[History\_8] 'Undo Limit', Editor options page of Environment  
Options dialog  
[History\_9] 'Right margin', Editor display page of  
Environment Options dialog  
[History\_10] 'Tab stops', Editor options page of Environment  
Options dialog  
[History\_11] 'Syntax extensions', Editor options page of  
Environment Options dialog  
[History\_12] 'Enter new line number', Go to Line Number dialog  
[History\_18] 'Block indent', Editor options page of  
Environment Options dialog  
[History\_20] 'File name', Open Project dialog  
[History\_23] 'File name', Install VBX file dialog  
[History\_25] 'File name', Unit file name dialog (under  
Install VBX)  
[History\_33] 'Collapse nodes', Browser page of Environment  
Options dialog  
[History\_34] 'Library path', Library page of Environment  
Options dialog  
[History\_35] 'File name', Open Library dialog  
[History\_36] 'File name', Save Project1 As dialog

## Article #16111: BDE: Writing Buffer to Disk

Technical Information Database

TI11111D.txt BDE: Writing Buffer to Disk

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Product: Delphi and the Borland Database Engine

Number: ??????

Versions: 1.x, 2.x

OS: WINDOWS 3.x, WINDOWS 95, WINDOWS NT

DATE: December 7, 1995

TITLE: Using DbUseIdleTime and DbSaveChanges.

### General:

=====

Changes made to a table are not written directly to disk until the table is closed. A power failure or system crash can result in a loss of data, and an inconvenience. To avoid this loss of data, two direct Database Engine calls can be made, both of which have the similar effects. These functions are DbUseIdleTime and DbSaveChanges.

DbSaveChanges(hDBICur):

=====

DbSaveChanges saves to disk all the updates that are in the buffer of the table associated with the cursor (hDBICur). It can be called at any point. For example, one may want to make save changes to disk every time a record is updated (add dbiProcs to uses clause):

```
procedure TForm1.Table1AfterPost(DataSet: TDataSet);
begin
  DbSaveChanges(Table1.handle);
end;
```

This way, one does not have to worry about losing data if a

power failure or system crash occurs after a record update.

DbiSaveChanges can also be used to make a temporary table (created by DbiCreateTempTable) permanent.

This function does NOT apply to SQL tables.

DbiUseIdleTime:

=====

DbiUseIdleTime can be called when the "Windows Message Queue" is empty. It allows the Database Engine to save "dirty buffers" to disk. In other words, it does what DbiSaveChanges does, but performs the operation on ALL the tables that have been updated. This operation however, will not necessarily occur after every record update, because it can only be executed when there is an idle period.

In Delphi, it can be used in this fashion (add dbiProcs to uses clause):

```
procedure TForm1.FormCreate(Sender: TObject);
begin
    Application.OnIdle := UseIdle;
end;
```

```
procedure TForm1.UseIdle(Sender: TObject; var Done: Boolean);
begin
    DbiUseIdleTime;
end;
```

USAGE NOTES:

=====

Using both DbiUseIdleTime and DbiSaveChanges (after every record modification) is redundant and will result in unnecessary function calls. If the application is one that performs a great deal of record insertions or modifications in a small period of time, it is recommended that the client either call DbiUseIdleTime during an idle period, or call DbiSaveChanges after a group of updates.

If not very many updates are being performed on the table, the client may choose to call DbiSaveChanges after every post or

set up a timer and call DbUseIdleTime when a timer even is generated.

## Article #16117: Creating and Using Parameterized Queries

Technical Information Database

TI1117D.txt Creating and Using Parameterized Queries

Category :Database Programming

Platform :All

Product :Delphi All

Description:

Q: How do I pass a variable to a query?

A: First, you must write a query that uses a variable.

```
Select Test."FName", Test."Salary Of Employee"
```

```
From Test
```

```
Where Test."Salary of Employee" > :val
```

Note: If you just write the field name as "Salary of Employee" you will get a Capability Not Supported error. It must be Test."Salary of Employee".

In this can the variable name is "val", but it can be whatever you want (of course). Then, you go to the TQuery's params property and set the "val" parameter to whatever the appropriate type is. In our example here we will call it an integer.

Next, you write the code that sets the parameter's value. We will be setting the value from a TEdit box.

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Query1 do
  begin
    Close;
    ParamByName('val').AsInteger := StrToInt(Edit1.Text);
    Open;
  end;
end;
```

Note: you may want to place this code in a try..except block as a safety precaution.

If you want to use a LIKE in your query, you can do it this way:

Note: This next section uses the customer table from the \delphi\demos\data directory. It can also be referenced by using the DBDEMOS alias.

SQL code within the TQuery.SQL property:

```
SELECT * FROM CUSTOMER
WHERE Company LIKE :CompanyName
```

Delphi code:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Query1 do
  begin
    Close;
    ParamByName('CompanyName').AsString := Edit1.Text + '%';
    Open;
  end;
end;
```

An alternate way of referencing a parameter (other than ParamByName) is params[TheParameterNumber].

The way that this line:

```
ParamByName('CompanyName').AsString := Edit1.Text + '%';
```

can be alternately written is:

```
Params[0].AsString := Edit1.Text + '%';
```

The trick to the wildcard is in the concatenating of the percentage sign at the end of the parameter.

## Article #16123: Working With Auto-increment Field Types

Technical Information Database

TI1123D.txt Working With Auto-increment Field Types

Category :Database Programming

Platform :All

Product :Delphi 1.0

### Description:

In Delphi applications, the use of tables containing fields that autoincrement, or change automatically in some manner unknown to the application, can be problematic. Paradox, InterBase, Sybase and Informix tables all provide means of inserting or updating field values automatically, without intervention from the front-end application. Not every table operation is affected by this mechanism, however. So, this document will attempt to provide a guideline for dealing with issues relating to the use of such field types in Paradox 5.0, Informix 5.x, MS/Sybase SQL Server 4.x, InterBase 4.0 and Local InterBase tables.

For each table type, a different mechanism provides this behind-the-scenes behavior. Paradox tables support an Autoincrement field type. When new records are added to such tables, the Borland Database Engine determines the highest current value in that column, adds one, and updates the new row with the new value.

For Informix tables, this behavior is provided by an Informix-specific field type called Serial. Serial columns differ from Paradox Autoincrement fields in that their values may be changed, while Autoincrement columns are read-only.

InterBase and MS/Sybase SQL Server tables do not support a special type for this kind of behavior, but may employ triggers to accomplish the same task. Triggers are specialized procedures that reside on the database server and automatically execute in response to events such as table inserts, updates and deletes. The use of tables with associated triggers can be particularly problematic, since triggers are capable of doing much more than just incrementing column values.

The three areas that are affected by these field types are simple inserts, batchmoves, and table linking.

## Handling Update and/or Append BatchMoves

---

### Paradox Tables

Since the Autoincrement field type is a read-only type, attempting to perform a batchmove operation with such a column in the destination table may cause an error. To circumvent this, the TBatchMove components Mappings property must be set to match source table fields to the target destination fields excluding the destination table's Autoincrement field.

### Informix Tables

Batch moving rows to Informix tables with Serial columns will not cause an error in and of itself. However, caution should be used since Serial columns are updateable and are often used as primary keys.

### InterBase Tables

#### MS/Sybase SQL Server Tables

Triggers on InterBase and SQL Server tables may catch any improper changes made to the table, but this depends strictly upon the checks placed in the trigger. Here again, caution should be used since trigger-updated columns are often used as primary keys.

## Linking Tables via MasterSource & MasterFields

---

### Paradox Tables

### Informix Tables

If the MasterFields and MasterSource properties are used to create linked tables in a master-detail relationship and one of the fields in the detail table is an Autoincrement or Serial field, then the matching field in the master table must be a Long Integer field or a Serial field. If the master table is not a Paradox table then the master table's key field may be any integer

type it supports.

InterBase Tables

MS/Sybase SQL Server Tables

Linking with these tables types presents no particular problems relating to trigger-modified fields. The only necessity is matching the appropriate column type between the two tables.

Simple Inserts/Updates

---

Paradox Tables

Since Paradox Autoincrement fields are read-only, they are not typically targeted for update when inserting new records. Therefore, the Required property for field components based on Autoincrement fields should always be set to False. This can be accomplished from within Delphi, using the Fields Editor to define field components at design time by double clicking on the TQuery or TTable component or at runtime with a statement similar to the following.

```
Table1.Fields[0].Required := False;
```

or

```
Table1.FieldName('Fieldname').Required := False;
```

Informix Tables

Although Informix Serial fields are updateable, if their autoincrement feature is to be used, then the Required property of field components based on them should be set to False. Do this in the same manner described for Paradox Tables.

InterBase Tables

MS/Sybase SQL Server Tables

Handling inserts on these trigger-modified table types requires a number of steps for smooth operation. These additional steps are

particularly necessary if inserts are accomplished via standard data-aware controls, such as DBEdits and DBMemos.

Inserting rows on trigger-modified InterBase and SQL Server tables may often yield the error message 'Record/Key Deleted'. This error message appears despite that the table is properly updated on the server. This will occur if:

1. The trigger updates the primary key. This is not only likely when a trigger is used, but is probably the most common reason for using a trigger.
- 2a. Other columns in the table have bound default values. This is accomplished with the DEFAULT clause at table creation in the case of InterBase. or with the sp\_bindefault stored procedure in SQL Server.

or

- 2b. Blob type fields are updated when a new row is inserted.

or

- 2b. Calculated fields are defined in an InterBase table.

The fundamental cause for this is that when the record (or identifying key) is changed at the server, the BDE no longer has means of specifically identifying the record for re-retrieval. That is, the record no longer appears as it did when it was posted, therefore the BDE assumes that the record has been deleted (or the key changed).

Firstly, the field components of trigger-modified fields must have their Required property set to False. Do this in the same manner described for Paradox Tables.

Secondly, to avoid the spurious error, order the table by an index that does not make use of fields updated by the trigger. This will also prevent the newly entered record from disappearing immediately after insertion.

Lastly, if requirement 1 above holds but neither 2a, 2b nor 2c hold, then code similar to the following should be used for the table component's AfterPost event handler.

```
procedure TForm1.Table1AfterPost(DataSet: TDataset);  
begin  
    Table1.Refresh  
end;
```

A Refresh of the table is necessary to re-retrieve the values changed by the server.

If criteria 2a, 2b or 2c cannot be avoided, then the table should be updated without using Delphi's data-aware controls. This can be accomplished using a TQuery component targeted at the same table. Once the query has posted the update, any table components using the same table should be Refreshed.

## Article #16129: How to Populate a TDBComboBox Or TDBListBox

Technical Information Database

TI1129D.txt How to Populate a TDBComboBox Or TDBListBox

Category :Database Programming

Platform :All

Product :Delphi All

Description:

Filling dblistboxs and dbcomboboxs

Most of Delphi's data aware components will populate themselves after they are wired up to a open dataset. However DbListboxs and DbComboboxs do not display this characteristic. These two components are not for displaying your datasets, but filling them. Use of these components is straight forward. When you update your table, the value of the DbListbox or DbCombobox will be posted in the appropriate field.

Filling the DbCombobox or DbListbox the same as filling normal comboboxs or listboxes. The lines of text in a listbox or combobox are really a tstring list. The "Items" property of the given component holds this list. Use the "Add" method for adding items to a tstring. If you want to use data types other than strings they must be converted at run time. If your list has a blank line at the end, consider setting the "IntegralHeight" property to True.

Filling a DbListbox with 4 lines programmatically might look similar to this:

```
DbListbox1.items.add('line one');  
DbListbox1.items.add('line two');  
DbListbox1.items.add('line three');  
DbListbox1.items.add('line four');
```

Filling a DbListbox at design time requires using the object inspector. By double clicking on the components "Items" property, you can bring up the "String List Editor" and input the desired rows.

Unfortunately, if a combobox is filled this way, there is not default value. Setting a DbComboboxs "text" property will achieve this result. (the "text" property is not available in the object inspector, so it must be set programmatically). Setting the default value to the first value in the DbCombobox's list looks like this:

```
DbCombobox1.text := DbCombobox1.items[0];
```

Often it is useful to fill a DBListBox from a dataset. This can be done using loop:

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  with table2 do begin
    open;
    while not EOF do
    begin
      DBlistbox1.items.add(FieldByName('name').AsString);
    next;
    end;
  end;
end;
```

## Article #16135: New Language Features in Delphi 2.0

Technical Information Database

TI1135D.txt - New Language Features in Delphi 2.0

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

### Description:

New Language Features in Delphi 2.0 - 32

Delphi 2.0 defines several new data types that exploit the features available by Windows 95. Delphi 2.0 has also changed a few data types to take advantage of the 32-bit environment.

New data types include:

- Character type
- String type
- Variant type
- Currency type

Changed data types:

- Integer
- Cardinal

Additional Syntax:

- Unit finalization section

New Data Types

--- ----

### Character Type

Delphi 2.0 introduces new wide character types to support Unicode. Delphi 1.0 treated characters as 8-bit values of type Char.

These are the standard types that represent characters in Delphi 2.0.

`ANSIChar` - A standard 8-bit ANSI character, equivalent to the `Char` type in previous versions of Delphi.

`WideChar` - A 16-bit character, representing a Unicode character. If the high-order byte is zero, the low-order byte contains an ANSI character.

`Char` - By default, `Char` is equivalent to `ANSIChar`. `Char` works in the same way as the implementation-dependent Integer type, which is equivalent to `SmallInt` in 16-bit versions of Delphi and to `LongInt` in 32-bit versions of Delphi. In Delphi 2.0, `Char` defaults to an 8-bit value.

Character-pointer types:

Pointer type	Character type
<code>PANSIChar</code>	<code>ANSIChar</code>
<code>PWideChar</code>	<code>WideChar</code>
<code>PChar</code>	<code>Char</code>

The semantics of all the character-pointer types are identical. The only thing that varies is the size of the character pointed to.

String Type

Delphi 2.0 supports strings of nearly unlimited length in addition to the 255-character counted strings previously supported. A new compiler directive, `$H`, controls whether the reserved word "string" represents a short string or the new, long string. The default state of `$H`, is `$H+`, using long strings by default. All Delphi 2.0 components use the new long string type.

These are the new string types.

`ShortString` - A counted string with a maximum length of 255 characters. Equivalent to `String` in Delphi 1.0. Each element is of type `ANSIChar`.

AnsiString - A new-style string of variable length, also called a "long string." Each element is of type ANSIChar.

string - Either a short string or an ANSI string, depending on the value of the \$H compiler directive.

Here are the compatibility issues.

Although most string code works interchangeably between short strings and long strings, there are certain short-string operations that either won't work on long strings at all or which operate more efficiently when done a different way. The following table summarizes these changes.

Short String operation	Long string equivalent	Explanation
PString type	string	All long strings are dynamically allocated, so PString is redundant and requires more bookkeeping.
S[0] := L	SetLength(S,L) SetString(S,P,L)	Because long strings are dynamically allocated, you must call the SetLength procedure to allocate the appropriate amount of memory.
StrPCopy (Buffer, S)	StrPCopy(Buffer, PChar(S))	You can typecast long strings into null-terminated strings. The address of the long string is the address of its first character, and the long string is followed by a null.
S := StrPas(P)	S := P	Long strings can automatically copy from null-terminated strings.

Long strings cannot be passed to OpenString-type parameters or var short-string parameters.

Variant Type

Delphi 2.0 introduces variant types to give you the flexibility

to dynamically change the type of a variable. This is useful when implementing OLE automation or certain kinds of database operations where the parameter types on the server are unknown to your Delphi-built client application.

A variant type is a 16-byte structure that has type information embedded in it along with its value, which can represent a string, integer, or floating-point value. The compiler recognizes the standard type identifier Variant as the declaration of a variant.

In cases where the type of a variant is incompatible with the type needed to complete an operation, the variant will automatically promote its value to a compatible value, if possible. For instance, if a variant contains an integer and you assign it to a string, the variant converts its value into the string representing the integer number, which is then assigned to the string.

You can also assign a variant expression to a variable of a standard type or pass the variant as a parameter to a routine that expects a standard type as a parameter. Delphi coerces the variant value into a compatible type if necessary, and raises an exception if it cannot create a compatible value.

## Currency Type

Delphi 2.0 defines a new type called Currency, which is a floating-point type specifically designed to handle large values with great precision. Currency is assignment-compatible with all other floating-point types (and variant types), but is actually stored in a 64-bit integer value much like the Comp type.

Currency-type values have a four-decimal-place precision. That is, the floating-point value is stored in the integer format with the four least significant digits implicitly representing four decimal places.

## Changed Data Types

-----

The implementation-dependent types Integer and Cardinal are 32-bit values in Delphi 2.0, where they were 16-bit values in Delphi 1.0. To explicitly declare 16-bit integer data types,

use the SmallInt and Word types.

## Additional Syntax

-----

You can include an optional finalization section in a unit. Finalization is the counterpart of initialization, and takes place when the application shuts down. You can think of the finalization section as "exit code" for a unit. The finalization section corresponds to calls to ExitProc and AddExitProc in Delphi 1.0.

The finalization begins with the reserved word finalization. The finalization section must appear after the initialization section, but before the final end. statement.

Once execution enters an initialization section of a unit, the corresponding finalization section is guaranteed to execute when the application shuts down. Finalization sections must handle partially-initialized data properly, just as class destructors must.

Finalization sections execute in the opposite order that units were initialized. For example, if your application initializes units A, B, and C, in that order, it will finalize them in the order C, B, and A.

The outline for a unit therefore looks like this:

```
unit UnitName;
interface
{ uses clause; optional }
...
implementation
{ uses clause; optional }
...
initialization { optional }
...
finalization { optional }
...
end.
```

## Article #16141: Preventing a Form from Resizing

Technical Information Database

TI1141D.txt Preventing a Form from Resizing

Category :VCL

Platform :All

Product :Delphi All

### Description:

In some cases, developers would want to create a regular window (Form) in Delphi that contains some of the characteristics of a dialog box. For example, they do not want to allow their users to resize the form at runtime due to user interface design issues. Other than creating the whole form as a dialog box, there is not a property or a method to handle this in a regular window in Delphi. But due to the solid connection between Delphi and the API layer, developers can accomplish this easily.

The following example demonstrates a way of handling the Windows message "WM\_GetMinMaxInfo" which allows the developer to restrict the size of windows (forms) at runtime to a specific value. In this case, it will be used to disable the functionality of sizing the window (form) at runtime.

Consider the following unit:

```
unit getminmax;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
Dialogs;
```

```
type
```

```
TForm1 = class(TForm)
```

```
private
```

```
{ Private declarations }
```

```
procedure WMGetMinMaxInfo(var Msg: TWMGetMinMaxInfo);
```

```
message WM_GETMINMAXINFO;
```

```
procedure WMInitMenuPopup(var Msg: TWMInitMenuPopup);
```

```

        message WM_INITMENUPOPUP;
    procedure WMNCHitTest(var Msg: TWMNCHitTest);
        message WM_NCHitTest;
public
    { Public declarations }
end;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.WMGetMinMaxInfo(var Msg: TWMGetMinMaxInfo);
begin
    inherited;
    with Msg.MinMaxInfo^ do
    begin
        ptMinTrackSize.x:= form1.width;
        ptMaxTrackSize.x:= form1.width;
        ptMinTrackSize.y:= form1.height;
        ptMaxTrackSize.y:= form1.height;
    end;
end;

procedure TForm1.WMInitMenuPopup(var Msg: TWMInitMenuPopup);
begin
    inherited;
    if Msg.SystemMenu then
        EnableMenuItem(Msg.MenuPopup, SC_SIZE, MF_BYCOMMAND or
MF_GRAYED)
    end;
end;

procedure TForm1.WMNCHitTest(var Msg: TWMNCHitTest);
begin
    inherited;
    with Msg do
        if Result in [HTLEFT, HTRIGHT, HTBOTTOM, HTBOTTOMRIGHT,
HTBOTTOMLEFT, HTTOP, HTTOPRIGHT, HTTOPLEFT] then
            Result:= HTNOWHERE
        end;
end. { End of Unit}

```

A message handler for the windows message "WM\_GetMinMaxInfo" in

the code above was used to set the minimum and maximum TrackSize of the window to equal the width and height of the form at design time. That was actually enough to disable the resizing of the window (form), but the example went on to handle another couple of messages just to make the application look professional. The first message was the "WMInitMenuPopup" and that was to gray out the size option from the System Menu so that the application does not give the impression that this functionality is available. The second message was the "WMNCHitTest" and that was used to disable the change of the cursor icon whenever the mouse goes over one of the borders of the window (form) for the same reason which is not to give the impression that the resizing functionality is available.

## Article #16147: SQL: Sorting on a Calculated Column

Technical Information Database

TI1147D.txt SQL: Sorting on a Calculated Column

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

At times, a given data schema will require that a data set will need to be ordered by the result of a calculation. In Delphi applications using SQL, this is possible, but the methodology varies slightly depending on the database type used.

For local SQL involving Paradox and dBASE tables, the calculated field would be given a name using the AS keyword. This allows the calculated field to be referenced for such purposes as setting a sort order with an ORDER BY clause in an SQL query. For example, using the sample table ITEMS.DB:

```
SELECT I."PARTNO", I."QTY", (I."QTY" * 100) AS TOTAL
FROM "ITEMS.DB" I
ORDER BY TOTAL
```

In this example, the calculated field is designated to be referred to as TOTAL, this column name then being available for the ORDER BY clause for this SQL statement.

The above method is not supported for InterBase. It is still possible, though, to sort on a calculated field in InterBase (IB) or the Local InterBase Server tables. Instead of using the name of the calculated field, an ordinal number representing the calculated field's position in field list is used in the ORDER BY clause. For example, using the sample table EMPLOYEE (in the EMPLOYEE.GDB database):

```
SELECT EMP_NO, SALARY, (SALARY / 12) AS MONTHLY
FROM EMPLOYEE
ORDER BY 3 DESCENDING
```

While IB or LIBS tables require this second method and cannot use the first method described, either of the two methods can be used with local

SQL. For example, using the SQL query for the Paradox table and adapting

it to use the relative position of the calculated field rather than the

name:

```
SELECT I."PARTNO", I."QTY", (I."QTY" * 100) AS TOTAL
FROM "ITEMS.DB" I
ORDER BY 3
```

## Article #16153: SQL: Using the SUBSTRING Function

Technical Information Database

TI1153D.txt SQL: Using the SUBSTRING Function

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

The SQL function SUBSTRING can be used in Delphi applications that include local SQL queries, but is not supported for InterBase (IB) or the Local InterBase Server (LIBS) tables. What follows is the syntax for the SUBSTRING function, examples of its use in local SQL queries, and an alternative that will return the same results for IB/LIBS tables.

The syntax for the SUBSTRING function is:

```
SUBSTRING( FROM [, FOR ])
```

Where:

is the name of the column in the table from which the sub-string is to be extracted.

is the point in the column value from which the sub-string to be extracted will start.

is the length of the sub-string to be extracted.

Using these values, the use of the SUBSTRING function below would return the second, third, and fourth characters from a column named COMPANY:

```
SUBSTRING(COMPANY FROM 2 FOR 3)
```

The SUBSTRING function can be used either in the field list for a SELECT query or in the WHERE clause of a query to allow for comparing a value with a specific sub-set of a column. The SUBSTRING function can only

be

used with String type columns (the CHAR type in SQL parlance). Here is an example of the SUBSTRING function used in a columns list in a SELECT query (using the sample Paradox table CUSTOMER.DB):

```
SELECT (SUBSTRING(C."COMPANY" FROM 1 FOR 3)) AS SS
FROM "CUSTOMER.DB" C
```

This SQL query extracts the first three characters from the COMPANY column, returning them as the calculated column named SS. Now, an example

of the SUBSTRING function used in the WHERE clause of an SQL query (using the same sample table):

```
SELECT C."COMPANY"
FROM "CUSTOMER.DB" C
WHERE SUBSTRING(C."COMPANY" FROM 2 FOR 2) = "an"
```

This query returns all rows from the table where the second and third characters in the COMPANY column are "ar".

As the SUBSTRING function is not supported at all by IB or LIBS databases, it is not possible to have a sub-string operation in the column list of a query (exception: IB can do sub-strings via User-Defined Functions). But through use of the LIKE operator and the accompanying character substitution marker, it is possible to effect a sub-string in a WHERE clause. For example, using the sample table EMPLOYEE (in the EMPLOYEE.GDB database):

```
SELECT LAST_NAME, FIRST_NAME
FROM EMPLOYEE
WHERE LAST_NAME LIKE "_an%"
```

This SQL query would return all rows in the table where the second and third characters of the LAST\_NAME column are "an", similar to the previous example for the Paradox table. While IB and LIBS databases would require this method for performing sub-string comparisons in the WHERE clause of a query and cannot use the SUBSTRING function, Paradox and dBASE tables (i.e., local SQL) can use either method.

## Article #16159: SQL: Summarizing a Calculated Column

Technical Information Database

TI1159D.txt SQL: Summarizing a Calculated Column

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

Occasionally in a Delphi application that uses SQL to access data, it becomes necessary to summarize calculated data. That is, to create a calculated column and apply the SUM function to it.

When performing this operation against SQL tables (such as those for the

Local InterBase Server), it is a simple matter of enclosing the calculation within the SUM function. For example, using the sample table

EMPLOYEE (in the EMPLOYEE.GDB database):

```
SELECT SUM(SALARY / 12)
FROM EMPLOYEE
```

This same methodology can also be used when the returned data set is to be

grouped by the value in another column with a GROUP BY clause:

```
SELECT EMP_NO, SUM(SALARY / 12)
FROM EMPLOYEE
GROUP BY EMP_NO
ORDER BY EMP_NO
```

While SQL databases support the summarization of calculated columns, local SQL will not. Other means would be needed to obtain the results, such as copying the results of a query with a calculated column to a temporary table (as with a TBatchMove component) and then using a TQuery component to summarize the data in the temporary table.

## Article #16165: Managing Data Segment Size

Technical Information Database

TI1165D.txt - Managing Data Segment Size

Category :Delphi 1.x  
Platform :All-32Bit  
Product :

Description:  
Managing Data Segment Size

The "Data Segment too large" error occurs in Delphi 16 bit applications when the size of static data, stack and local heap are larger than the 64k application limit imposed by Windows. This document discusses how to identify and measure portions of your code that consume memory in the data segment, and how to manage this limited resource.

What does the data segment consist of?

-----  
Task header: 16 bytes of various Windows system information  
Static data: Contains global variables and typed constants.  
Stack: Stores local variables allocated by procedures and functions. The default stack size is 16k and can be modified in the Options|Project|Linker page.  
Local heap: Used by Windows for temporary storage and defaults to 8k. Do not set the local heap to 0. Windows may expand this area of memory if necessary.

How do I measure total data segment size?

-----  
To get the size of a 16 bit Delphi application static data, stack and local heap for a project, compile the project and select the Delphi menu item Compile|Information. The dialog will list the following, given a new project with one form:

```
Source compile: 12 lines
Code size:      128981 bytes
Data size:     3636 bytes
Stack size:    16384 bytes
Local Heap size: 8192 bytes
```

A Delphi application starts with the overhead of static data declared in units that provide the applications initial functionality. If the only global variable is the form name, the application will still consume at least 3,636 bytes. Adding a second form increases the datasize to only 3640 -- an increase of only the size of the global variable needed to declare a second form.

```
var
  Form2: TForm2; { 4 byte pointer }
```

The total data segment size, (the sum of static data, stack and local heap) is 28,212 bytes:

```
Data size:      3,636
Stack size:     16,384
Local Heap size: 8,192
-----
                28,212
```

What portions of my project increase data size?

- ```
-----
-- Variables declared within the interface and implementation
   sections.
-- Typed constants declared anywhere within the application.
   An example of a typed constant declaration:
```

```
const
  MyConst: integer = 100;
```

Units declared in the Uses clause and components contain code that may have global variables or typed constants. For instance, a TBitBtn adds 180 bytes when added to a project, where at least 132 bytes are accounted for by typed constants and global variables within the Buttons.Pas unit. Adding 10 more TBitBtns to the project does not increase the project size beyond the initial 180 byte increase.

The following sample unit includes comments describing memory

usage:

```
unit Test;
```

```
interface
```

```
uses
```

```
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,  
  Controls, Forms, Dialogs, StdCtrls;
```

```
{ Functions used from the units may have global variables  
  and typed constants that will increase the size of the  
  data segment. }
```

```
type
```

```
  { Class objects are stored on the global heap, not the data  
    segment }
```

```
TForm1 = class(TForm)
```

```
  Label1: TLabel;
```

```
  Button1: TButton;
```

```
  procedure Button1Click(Sender: TObject);
```

```
public
```

```
  { MyInteger and MyString are stored  
    on the global heap. }
```

```
  MyInteger: Integer;
```

```
  MyString: String;
```

```
end;
```

```
const
```

```
{ MyConst is a typed constant and is stored in  
  static data portion of the data segment.
```

```
  Minimize the number of typed constants. }
```

```
MyConst: integer = 23;
```

```
var
```

```
{ Form1 is a global variable - stored in the static  
  data portion of the data segment. You should minimize  
  the number and size of global variables. Form1 is  
  pointer and uses only four bytes. }
```

```
Form1: TForm1;
```

```
{ MyGlobalString will consume 256 bytes even if the  
  string is only a few characters long. }
```

```
MyGlobalString: string;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
{ MyLocal is a local variable and is not stored
  in the data segment. }
  MyLocal: String;
begin
  MyLocal := 'Test application';
  Label1.Caption := MyLocal
end;

end.
```

What is the impact of components on the data size?

-----  
Here is a list of components from the Standard, Additional, Data Access, and Data Control (partial list) pages of the component palette. The list shows the compile size after added a single instance of the component to a new project. In descending order by data size usage:

| Component  | App<br>in<br>bytes | Bytes<br>Over<br>3,636 |
|------------|--------------------|------------------------|
| table      | 4272               | 636                    |
| batchmove  | 4272               | 636                    |
| storedproc | 4258               | 622                    |
| query      | 4250               | 614                    |
| database   | 4036               | 400                    |
| datasource | 3886               | 250                    |
| outline    | 3838               | 202                    |
| bitbtn     | 3816               | 180                    |
| stringgrid | 3794               | 158                    |
| drawgrid   | 3790               | 154                    |
| maskedit   | 3762               | 126                    |
| memo       | 3750               | 114                    |
| report     | 3722               | 86                     |
| listbox    | 3704               | 68                     |
| edit       | 3694               | 58                     |

|                |      |    |
|----------------|------|----|
| tabset         | 3692 | 56 |
| combobox       | 3674 | 38 |
| scrollbar      | 3654 | 18 |
| button         | 3652 | 16 |
| checkbox       | 3652 | 16 |
| radiobutton    | 3652 | 16 |
| radiogroup     | 3652 | 16 |
| panel          | 3650 | 14 |
| label          | 3648 | 12 |
| speedbutton    | 3646 | 10 |
| header         | 3644 | 8  |
| scrollbox      | 3644 | 8  |
| notebook       | 3638 | 2  |
| menu           | 3636 | 0  |
| groupbox       | 3636 | 0  |
| tabbednotebook | 3636 | 0  |
| image          | 3636 | 0  |
| shape          | 3636 | 0  |

How do I manage data segment size?

- 
- 1) Avoid declaring global variables or typed constants, particularly large arrays. Instead, declare a type and a pointer to that type. Then use memory management routines such as Getmem to allocate memory from the global heap.  
This reduces the resource hit on the data segment to the 4 bytes used by the pointer variable. See code sample below.
  - 2) Be aware of the impact of components. See above.
  - 3) If you have a large number of strings, or arrays of strings, allocate these dynamically. Note: strings default to 255 in length -- declare as a specific size where possible: (i.e. MyShortString: string[20]).
  - 4) A TStringList object can be used to create and manipulate large numbers of strings.
  - 5) The Pchar type, "pointer to a string", can be used to dynamically create and manipulate character strings using little data segment space. See online help under "String-handling routines (Null-terminated)".
  - 6) Information on memory issues is available in Object Pascal Language Guide, OBJLANG.ZIP and can be downloaded from Comuserve, DELPHI forum, and the World Wide Web, [www.borland.com/TechInfo/delphi/whatsnew/dwnloads.html](http://www.borland.com/TechInfo/delphi/whatsnew/dwnloads.html).

## Alternative to global declaration of a large structure

---

Here's an example that will waste 32 bytes of data segment, followed by a second example using only 4 bytes, and accomplishes essentially the same task.

1)

```
{ Declaring TMyStructure causes no change
  in the data segment size. }
TMyStructure = record
  Name: String[10];
  Data: array[0..9] of Integer;
end;

var
  Form1: TForm1;

{ MyStructure declaration causes a 32 byte
  increase:
  Mystructure pointer = 1 byte
  Name = 11 bytes (10 chars + length byte)
  Data = 20 bytes (10 * 2 bytes per integer)
}
MyStructure: TMyStructure;
```

2)

```
{ Declaring TMyStructure causes no change
  in the data segment size. }
PMyStructure = ^TMyStructure;
TMyStructure = record
  Name: String[10];
  Data: array[0..9] of Integer;
end;

var
  Form1: TForm1;
  { MyDataPtr causes 4 byte increase
    for the pointer variable. }
  MyDataPtr: PMyStructure;
```

implementation

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  { Here, resources are taken from the heap. }
  New(MyDataPtr);
  MyDataPtr.Name := 'Fred';
  MyDataPtr.array[0] := 560;
  Dispose(MyDataPtr);
end;
```

You can also put a variable declaration within a class:

```
type
  TMyBigArray = array[1..100] of string

  TForm1 = class(TForm)
  public
    { This declaration has no impact on data segment size. }
    MyBigArray: TMyBigArray;
  end;

var
  { This declaration increases data segment by 25,600 bytes. }
  MyOtherBigArray: TMyBigArray;
```

## Article #16171: Validating input in TEdit components

Technical Information Database

TI1171D.txt Validating input in TEdit components

Category :VCL

Platform :All

Product :Delphi All

### Description:

Q: How can I validate input in my TEdit components?

A: Assuming you're using regular TEdit components, during OnExit, you will see irregular behavior from controls if you attempt to change focus at that time.

The solution is to post a message to your form in the TEdit's OnExit event handler. This user-defined posted message will indicate that the coast is clear to begin validating input. Since posted messages are placed at the end of the message queue, this gives Windows the opportunity to complete the focus change before you attempt to change the focus back to another control.

Attached is a unit and text representation of a DFM (form) file which demonstrates this technique.

```
{ *** BEGIN CODE FOR UNIT5.PAS *** }
unit Unit5;

interface

uses
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics,
  Controls, Forms, Dialogs, StdCtrls, Mask;

const
  { User-defined message }
  um_ValidateInput = wm_User + 100;

type
  TForm5 = class(TForm)
```

```

    Edit1: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    Edit4: TEdit;
    Button1: TButton;
    procedure EditExit(Sender: TObject);
    procedure EditEnter(Sender: TObject);
private
    Refocusing: TObject;
    { User-defined message handler }
    procedure ValidateInput(var M: TMessage); message
um_ValidateInput;
end;

var
    Form5: TForm5;

implementation

{$R *.DFM}

procedure TForm5.ValidateInput(var M: TMessage);
var
    E : TEdit;
begin
    { The following line is my validation. I want to make sure }
    { the first character is a lower case alpha character. Note }
    { the typecast of lParam to a TEdit. }
    E := TEdit(M.lParam);
    if not (E.Text[1] in ['a'..'z']) then begin
        Refocusing := E;           { Avoid a loop      }
        ShowMessage('Bad input');  { Yell at the user }
        TEdit(E).SetFocus;        { Set focus back  }
    end;
end;

procedure TForm5.EditExit(Sender: TObject);
begin
    { Post a message to myself which indicates it's time to }
    { validate the input. Pass the TEdit instance (Self) as }
    { the message lParam. }
    if Refocusing = nil then
        PostMessage(Handle, um_ValidateInput, 0, longint(Sender));
end;

```

```
procedure TForm5.EditEnter(Sender: TObject);
begin
if Refocusing = Sender then
  Refocusing := nil;
end;

end.
{ *** END CODE FOR UNIT5.PAS *** }

## Article #16177: DDE: A simple example

Technical Information Database

TI1177D.txt - DDE: A simple example

Category :Delphi 1.x  
Platform :All Windows  
Product :

Description:

Q: How can I do DDE under Delphi using API calls ?

A: Its fairly easy to accomplish, following is an example of how to have a client program talk with a server program. Both are completely written in Delphi. In total there are 2 projects, 3 forms, and 3 units. This demo uses DDE ML API methods to handle the DDE requests.

The server must be running before the client will load. This demo program shows 3 different ways data can be moved between a client and a server.

1. The Client can 'POKE' data to the server.
2. The Server can automatically pass data to the Client and the Client will update a graph based on the results from the Server.
3. The Server's Data changes, then the Client will make a request to the Server for the new data, then update the graph.

\*\*\*\*\* How to handle the program. \*\*\*\*\*

Following are 8 files concatenated together. Each one has a { \*\*\* BEGIN CODE FOR FILENAME.EXT \*\*\* } CODE { \*\*\* END CODE FOR FILENAME.EXT \*\*\* } take each block of code BETWEEN THE { \*\*\* } lines and place in a file of the corresponding name, then compile and have fun !!!!

```

data  
as a bar graph.

You must run the server application first (in DDEMLSRV.PAS), and then run this client. If the server is not running, this application will fail trying to connect.

The interface to the server is defined by the list of names (Service, Topic, and Items) in the separate unit called DataEntry (DATAENTR.TPU).

The server makes the Items available in cf\_Text format; they are converted and stored locally as integers.

{ This sample application uses the DDEML library in the server side
of a
  cooperative application.  This server is a simple data-entry
application
  which allows an operator to enter three data items, which are made
available through DDE to interested clients.

This server makes its service available under the following names:

    Service: 'DataEntry'
    Topic   : 'SampledData'
    Items   : 'DataItem1', 'DataItem2', 'DataItem3'

Conceivably, other topics under this service could be defined.
Things
  such as historical data, information about the sampling, and so on
might make useful topics.

You must run this server BEFORE running the client (DDEMLCLI.PAS),
or
  the client will fail the connection.

The interface to this server is defined by the list of names
(Service,
  Topic, and Items) in the separate unit called DataEntry (DATAENTR.
TPU).
  The server makes the Items available in cf_Text format; they can be
converted and stored locally as integers by the client.

## Article #16183: TDBGrid and Multi-Selecting Records

Technical Information Database

TI1183D.txt - TDBGrid and Multi-Selecting Records

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

When you add [dgMultiSelect] to the Options property of a DBGrid, you give yourself the ability to select multiple records within the grid.

The records you select are represented as bookmarks and are stored in the SelectedRows property.

The SelectedRows property is an object of type TBookmarkList. The properties and methods are described below.

```
// property SelectedRows: TBookmarkList read FBookmarks;

// TBookmarkList = class
// public

{* The Count property returns the number of currently
   selected items in the DBGrid *}
// property Count: Integer read GetCount;

{* The Clear method will free all the selected records
   within the DBGrid and set the Count property to 0 *}
// procedure Clear;

{* The Delete method will delete all the selected rows
   from the dataset *}
// procedure Delete;

{* The Find method determines whether a bookmark is
   in the selected list. *}
// function Find(const Item: TBookmarkStr;
```

```

//      var Index: Integer): Boolean;

{* The IndexOf method returns the index of the
   bookmark within the Items property. *}
// function IndexOf(const Item: TBookmarkStr): Integer;

{* The Refresh method returns a boolean value to notify
   whether any orphans were dropped (deleted) during the
   time the record has been selected in the grid. The
   refresh method can be used to update the selected list
   to minimize the possibility of accessing a deleted
   record. *}
// function Refresh: Boolean; True = orphans found

{* The CurrentRowSelected property returns a boolean
   value and determines whether the current row is
   selected or not. *}
// property CurrentRowSelected: Boolean
//      read GetCurrentRowSelected
//      write SetCurrentRowSelected;

{* The Items property is a TStringList of
   TBookmarkStr *}
// property Items[Index: Integer]: TBookmarkStr
//      read GetItem; default;

// end;

unit Unit1;

## Article #16189: Listing the field structures of a table.

Technical Information Database

TI1189D.txt - Listing the field structures of a table.

Category :Database Programming  
Platform :All  
Product :

Description:

Q: How can I list the field structures of a table?

A: This project demonstrates listing the field structure from a given table, using the Fields and IndexDefs arrays, and displaying them in a listbox.

There is a demo (dbbrowsr.dpr) approaches this task differently. You may want to compare the two versions of this code.

Note: This code works with 16 bit only.

```
procedure TForm1.Button1Click(Sender: TObject); const
MyFielddefs: array[ftUnknown..ftGraphic] of string [8] =
  ('Unknown', 'String', 'Smallint', 'Integer', 'Word',
  'Boolean', 'Float', 'Currency', 'BCD', 'Date',
  'Time', 'DateTime', 'Bytes', 'VarBytes', 'Blob',
  'Memo', 'Graphic');

var
  i, Indx: integer;
  Definition: string;
begin
  for i := 0 to Table1.FieldCount - 1 do begin
    Definition := Table1.Fields[i].DisplayLabel;
    Definition := Definition + ' ' +
      MyFieldDefs[Table1.Fields[i].DataType];
    Table1.IndexDefs.Update;
    if Table1.Fields[i].IsIndexField then begin
      Indx := Table1.IndexDefs.Indexof(Table1.Fields[i].Name);
      if Indx > -1 then
```

```

        if ixPrimary in Table1.IndexDefs[Indx].Options then
            Definition := Definition + ' (Primary)';
        end;
        Listbox1.Items.Add(Definition);
    end;
end;

```

The version above does not work with the 32 bit version as there are more field types that must now be taken into account. Here is a version that works with the 32 bit version:

```

procedure TForm1.Button1Click(Sender: TObject);
const
    MyFielddefs: array[ftUnknown..ftTypedBinary] of string [11] =
        ('Unknown', 'String', 'Smallint', 'Integer',
         'Word', 'Boolean', 'Float', 'Currency', 'BCD',
         'Date', 'Time', 'DateTime', 'Bytes', 'VarBytes',
         'AutoInc', 'Blob', 'Memo', 'Graphic', 'FmtMemo',
         'ParadoxOle', 'DBaseOle', 'TypedBinary');
var
    i, Indx: integer;
    Definition: string;
begin
    for i := 0 to Table1.FieldCount - 1 do begin
        Definition := Table1.Fields[i].DisplayLabel;
        Definition := Definition + ' ' +
            MyFieldDefs[Table1.Fields[i].DataType];
        Table1.IndexDefs.Update;
        if Table1.Fields[i].IsIndexField then begin
            Indx := Table1.IndexDefs.Indexof(Table1.Fields[i].Name);
            if Indx > -1 then
                if ixPrimary in Table1.IndexDefs[Indx].Options then
                    Definition := Definition + ' (Primary)';
                end;
            Listbox1.Items.Add(Definition);
        end;
    end;
end;

```

## Article #16195: Showing deleted records in a dBASE table.

Technical Information Database

TI1195D.txt Showing deleted records in a dBASE table.

Category :Database Programming

Platform :All

Product :Delphi All

Description:

Q: How can I view dBASE records marked for deletion. That is, I want to view those records marked as "soft deletion"?

A: In a dBASE table, records are not removed from the table until the table is packed. Until that happens, records that are "deleted" are actually just marked as "to be" deleted. To show these existing but not displayed records, the following function, ShowDeleted(), makes use of a BDE API function, DbisetProp(), to show records marked for deletion. It is not necessary to close and re-open the table when using this function. ShowDeleted() takes a TTable and a boolean variable as parameters. The boolean parameter determines whether or not to show deleted records.

Example code follows:

```
-----  
  
unit Unit1;  
  
interface  
  
uses  
  Windows, Messages, SysUtils, Classes, Graphics, Controls,  
  Forms, Dialogs, StdCtrls, ExtCtrls, DBCtrls, Grids, DBGrids,  
  DB, DBTables;  
  
type  
  TForm1 = class(TForm)  
    Table1: TTable;  
    DataSource1: TDataSource;  
    DBGrid1: TDBGrid;  
    DBNavigator1: TDBNavigator;
```

```
    CheckBox1: TCheckBox;  
    procedure CheckBox1Click(Sender: TObject);  
public  
    procedure ShowDeleted(Table: TTable; ShowDeleted: Boolean);  
end;
```

```
var  
    Form1: TForm1;
```

```
implementation
```

```
uses DBTYPES, DBIERRS, DBIPROCS;
```

```
{ $R *.DFM }
```

```
procedure TForm1.ShowDeleted(Table: TTable; ShowDeleted: Boolean);
```

```
var  
    rslt: DBIResult;  
    szErrMsg: DBIMSG;  
begin  
    Table.DisableControls;  
    try  
        Check(DbiSetProp(hDBIObj(Table.Handle), curSOFTDELETEON,  
            LongInt(ShowDeleted)));  
    finally  
        Table.EnableControls;  
    end;  
    Table.Refresh;  
end;
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
```

```
begin  
    ShowDeleted(Table1, CheckBox1.Checked);  
end;
```

```
end.
```

## Article #16201: Determining a memo's number of lines showing.

Technical Information Database

TI1201D.txt Determining a memo's number of lines showing.

Category :General Programming

Platform :All

Product :Delphi All

Description:

Q: How can I tell how many lines a memo is capable of showing?

A: Here is the short and elegant way that works (most of the time):

```
function TForm1.MemoLinesShowing(memo: TMemo): integer;
var
  R: TRect;
begin
  Memo.Perform(EM_GETRECT, 0, Longint(
R));
  Result := (R.Bottom - R.Top) div Canvas.TextHeight('XXX');
end;
```

The problem with this code is that the TForm and the TMemo must both be using the same font. If the fonts are different, then the calculations are not accurate.

You have to retrieve the font height by selecting it into a device context. The reason you cannot use the font Height provided by Delphi is because Delphi caches the font information but doesn't actually select the font into the DC (canvas) until it is actually going to draw something. This occurs in the painting event of the memo.

To get around this problem, you can get the memo's device context using the Windows API and get the font information from the device context to calculate the text height.

The function below illustrates this process:

```
function TForm1.MemoLinesShowingLong(Memo: TMemo): integer;
```

```

Var
  Oldfont: HFont;    {the old font}
  DC: THandle;      {Device context handle}
  i: integer;       {loop variable}
  Tm: TTextMetric; {text metric structure}
  TheRect: TRect;

begin
  DC := GetDC(Memo.Handle); {Get the memo's device context}
  try
    {Select the memo's font}
    OldFont := SelectObject(DC, Memo.Font.Handle);
    try
      GetTextMetrics(DC, Tm); {Get the text metric info}
      Memo.Perform(EM_GETRECT, 0, longint(
TheRect));
      Result := (TheRect.Bottom - TheRect.Top) div
        (Tm.tmHeight + Tm.tmExternalLeading);
    finally
      SelectObject(DC, Oldfont); {Select the old font}
    end;
  finally
    ReleaseDC(Memo.Handle, DC); {Release the device context}
  end;
end;

```

## Article #16207: Delphi 2.0 Install Issues

Technical Information Database

TI1207D.txt - Delphi 2.0 Install Issues

Category :Delphi 2.x  
Platform :All-32Bit  
Product :Delphi2.x,

### Description:

Install Issues for Delphi 2.0

Last updated 3/13/96

- 1) Minimum System Requirements
- 2) a. Canceling the Delphi 2.0 install  
b. Canceling Delphi 2.0 Online Registration
- 3) Un-Installing
- 4) Re-installing Delphi 2.0 on Window's 95
- 5) Installing to systems with Paradox 7.0
- 6) Installing Delphi 1.0 and 2.0 on the same system
- 7) Errors During the Install

- 1) Minimum System Requirements

### Disk space:

a) OCX, DLL, and licensing files will require approx. 10 megs in your \windows\system directory.

b) Expansion of files during installation temporarily requires 10-15 megs in the drive that contains your \temp directory. For example, if you are installing Delphi 2.0 to drive D:, and your temporary directory path is C:\WINDOWS\TEMP, so that drive C will require 10 - 15 megs during file expansion.

### Minimum system requirements:

Processor

Desktop : intel 386dx based pc or higher with  
 math coprocessor  
 Developer: intel 486/25 based pc or higher  
 C/S Suite: intel 486/25 based pc or higher  
 MS windows '95 or NT 3.51  
 8 meg memory (12 recommended)  
 50 meg hard disk space  
 CD rom drive (3.5 floppy disks available seperately)  
 mouse or Windows pointing device

The chart below shows disk space used resulting from sample installs run on a Windows '95 system.

"Permanant Megs Used" represents the amount of disk used after a sample install to a stock Window's '95 system with no other applications running. These figures are approximate. Your disk cluster size may cause the file sizes to vary. Also, Window's '95 handling of swap file may vary according to your system configuration.

| Product      | Permanent<br>Megs<br>Used | \Borland | \Windows | (Swap<br>\System File) |
|--------------|---------------------------|----------|----------|------------------------|
| CSS compact  | 45                        | 39       | 6        | 9                      |
| CSS full     | 105                       | 98       | 7        | 24                     |
| Dev compact  | 43                        | 37       | 6        | 9                      |
| Dev full     | 104                       | 97       | 7        | 20                     |
| Desk compact | 32                        | 30       | 2        | 9                      |
| Desk full    | 61                        | 59       | 2        | 15                     |

- 2)
- a) Canceling the Delphi 2.0 install  
 Canceling before 10 - 15% may not clean the Window's '95 registry. This appears to be a limitation of the Install Shield engine.
- Canceling the install after 15% will cause Delphi 2.0 to be un-installed.

- b) Canceling Delphi 2.0 Online Registration  
 If you wish to register Delphi 2.0 at a later time, you may cancel the Registration Wizard. Canceling the Registration Wizard will not cause

an un-install. You may register Delphi 2.0 later from the "Delphi 2.0 Online Registration" icon located in the Borland Delphi 2.0 directory.

### 3) Un-Installing

Files created after the install of Delphi 2.0 and the directories that contain them, will not be deleted. For example, if you were to create a new project in \Borland\Delphi 2.0\Bin, the un-install would leave your project files and the \Borland\Delphi 2.0\Bin directory that contained them.

A general rule of thumb is that only files from the most recent install will be un-installed.

Files marked as shared, OCX's and DLL's for example, that have a "use" count of zero will cause a delete confirmation dialog to appear for each file. Microsoft standards for un-installing do not include a "Delete All" option at this stage.

### 4) Re-installing Delphi 2.0 on Window's 95

If an earlier installation of Delphi 2.0 already exists on your Window's 95 system, you must run the un-install program. This is necessary to cleanup the system registry. The un-install utility is located off the Start menu, Settings|Control Panel|Add/Remove Programs.

### 5) Installing to systems with Paradox 7.0

The necessary order to install both Delphi 2.0 and Paradox 7.0 is to

- a) install Paradox 7.0
- b) install Delphi 2.0.

If Delphi 2.0 already exists on the system, un-install Delphi 2.0, then do a) and b) listed above. If you un-install either Delphi 2.0 or Paradox 7.0, you will need to re-install the 32 bit IDAPI.

### 6) Installing Delphi 1.0 and 2.0 on the same

system

Although Delphi 1.0 and 2.0 will run on the same system, don't combine Delphi 1.0 and 2.0 into the same directory. Installing to the same directory will cause difficulty when the Delphi IDE attempts to locate the Help file.

## 7) Errors During the Install

Error 101

Error 112;

There is not enough room in the \Temp directory to expand files. Expansion of files during installation temporarily requires 10-15 megs in the drive that contains your \temp directory. For example, if you are installing Delphi 2.0 to drive D:, and your temporary directory path is C:\WINDOWS\TEMP, so that drive C will require 10 - 15 megs during file expansion.

"Cannot install Delphi, Local Interbase is Running"

Shut down Interbase from the system tray by right clicking the Interbase icon. The System Tray is the indentation located on right hand side of the task bar)

Registration Wizard dialog appears as a blank InstallShield could not find the install script. Cancel the dialog and run the Registration Wizard from the icon "Delphi 2.0 Online Registration".

Temporary directories remain after install to NT. On NT systems temporary directories named \ISTEMP0x may be left over. These directories will probably be empty, and may be deleted.

## Article #16209: Using the 80X87 emulator in TPW.

Technical Notes Database

TN1209D.txt Using the 80X87 emulator in TPW.

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

Description:

Question:

Must TPW a the math coprocessor?

Answer:

Windows implements its own 80x87 instruction emulator as a DLL that is loaded when an 80x87 instruction is detected. The reason that the '87 code generation is an option is speed: emulators are always slower than the real hardware, and slower than using the 6 byte reals. If you need double, or extended reals, or Comp integers, then you must turn on '87 code generation, and Windows will adjust itself to compensate if there is no '87 hardware when the program is running. You do not need a coprocessor to compile or run the program.

## Article #16213: How to Validate ISBNs

Technical Information Database

TI1213D.txt - How to Validate ISBNs

Category :Miscellaneous  
Platform :All-32Bit  
Product :All32Bit,

### Description:

ISBNs (or International Standard Book Numbers) are mystical code numbers that uniquely identify books. The purpose of this article is to remove the mystery surrounding the structure of the ISBN, allowing applications to perform data validation on entered candidate ISBNs.

ISBNs are composed of thirteen characters, limited to the number characters "0" through "9", the hyphen, and the letter "X". This thirteen-character code is divided into four parts, each separated by hyphens: group identifier, publisher identifier, book identification for the publisher, and the check digit. The first part (group identifier) is used to identify countries, geographical regions, languages, etc. The second part (publisher identifier) uniquely identifies the publisher. The third part (book identifier) uniquely identifies a given book within a publisher's collection. The fourth and final part (check digit) is used with the other digits in the code in an algorithm to derive a verifiable ISBN. The number of digits in the first three parts of an ISBN may contain a variable number of digits, but the check digit will always consist of a single character (between "0" and "9", or "X" for a value of 10) and the ISBN as a whole will always consists of thirteen characters (ten

numbers

plus the three hyphens dividing the four parts of the ISBN).

The ISBN 3-88053-002-5 breaks down into the parts:

Group: 3  
Publisher: 88053  
Book: 002  
Check Digit: 5

An ISBN can be verified to be a valid code using a simple mathematical algorithm. This algorithm takes each of the nine single digits from the

first three parts of the ISBN (sans the non-numeric hyphens), multiplies

each single digit by a number that is less than eleven the number of positions from the left each digit that is in the ISBN, adds together the

result of each multiplication plus the check digit, and then divides that

number by eleven. If that division by eleven results in no remainder (i.e., the number is modulo 11), the candidate ISBN is a valid ISBN.

For

example, using the previous sample ISBN 3-88053-002-5:

|                   |                                     |   |   |   |   |   |   |   |   |   |
|-------------------|-------------------------------------|---|---|---|---|---|---|---|---|---|
| ISBN:             | 3                                   | 8 | 8 | 0 | 5 | 3 | 0 | 0 | 2 | 5 |
| Digit Multiplier: | 10                                  | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
| Product:          | 30+72+64+00+30+15+00+00+04+05 = 220 |   |   |   |   |   |   |   |   |   |

Since 220 is evenly divisible by eleven, this candidate ISBN is a valid

ISBN code.

This verification algorithm is easily translated into Pascal/Delphi code.

String manipulation functions and procedures are used to extract the check digit and the remainder of the ISBN from the String type value passed to a validation function. The check digit is converted to

Integer

type, which forms the start value of the aggregate variable onto which the

multiplication of each digit in the remainder of the ISBN (the single digits that comprise the first three parts of the ISBN) will be added. A

For loop is used to sequentially process each digit in the remainder,

ignoring the hyphens, multiplying each digit times its position in the ISBN remainder relative to the other digits in the remainder. The final value of this aggregate variable is then checked to see whether it is evenly divisible by eleven (indicating a valid ISBN) or not (indicating an invalid candidate ISBN).

Here is an example of this methodology applied in a Delphi function:

```
function IsISBN(ISBN: String): Boolean;
var
  Number, CheckDigit: String;
  CheckValue, CheckSum, Err: Integer;
  i, Cnt: Word;
begin
  {Get check digit}
  CheckDigit := Copy(ISBN, Length(ISBN), 1);
  {Get rest of ISBN, minus check digit and its hyphen}
  Number := Copy(ISBN, 1, Length(ISBN) - 2);
  {Length of ISBN remainder must be 11 and check digit between 9 and
  9 or
  X}
  if (Length(Number) = 11) and (Pos(CheckDigit, '0123456789X') > 0)
  then
    begin
      {Get numeric value for check digit}
      if (CheckDigit = 'X') then
        CheckSum := 10
      else
        Val(CheckDigit, CheckSum, Err);
      {Iterate through ISBN remainder, applying decode algorithm}
      Cnt := 1;
      for i := 1 to 12 do begin
        {Act only if current character is between "0" and "9" to exclude
        hyphens}
        if (Pos(Number[i], '0123456789') > 0) then begin
          Val(Number[i], CheckValue, Err);
          {Algorithm for each character in ISBN remainder, Cnt is the
          nth
          character so processed}
          CheckSum := CheckSum + CheckValue * (11 - Cnt);
          Inc(Cnt);
        end;
      end;
    end;
end;
```

```
{Verify final value is evenly divisible by 11}
if (Checksum MOD 11 = 0) then
    IsISBN := True
else
    IsISBN := False;
end
else
    IsISBN := False;
end;
```

This is a simplified example, kept simple to best demonstrate the algorithm to decode ISBNs. There are a number of additional features that would be desirable to add for use in a real-world application. For instance, this example function requires the candidate ISBN be passed as a Pascal String type value, with the hyphens dividing the four parts of the ISBN. Added functionality might accommodate evaluating candidate ISBNs entered without the hyphens. Another feature that might be added is checking that ensures three hyphens are properly included, as opposed to just thirteen number characters.

## Article #16215: The \$G+ directive, 286 code generation, and Real M

Technical Notes Database

TN1215D.txt    The \$G+ directive, 286 code generation, and Real M  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal  1.0

Description:

Question:

If I use the \$G+ 286 code generation directive, how can I be sure that Windows is running in Real mode?

Answer:

The 286 code generation option allows the compiler to substitute more efficient 286 instructions in place of normal 8088 instructions for things like loops, jumps and memory operations. If you compile your program with \$G+, then you should call GetWinFlags early in the startup of your application - such as in your Application.Init. Check for the wf\_PtMode flag set. If it's not set, then you're not running in protected mode, and you should display a message box and exit your program. Setting the Application's status variable to a non-zero value should also work, although that would cause more code to be executed, implying greater risk of hitting a 286 instruction.

All the precompiled units in TPW will run in real mode and are not affected by the \$G+ directive. The \$G+ directive only affects code that you compile yourself.

## Article #16219: Delphi 2.0 for Windows 95 & Windows NT Factsheet

Technical Information Database

TI1219D.txt - Delphi 2.0 for Windows 95 & Windows NT Factsheet

Category :Delphi 2.x  
Platform :All-32Bit  
Product :Delphi2.x,

Description:

Delphi 2.0  
for Windows 95 and Windows NT  
Factsheet

Delphi 2.0 is the only Rapid Application Development tool that combines the performance of the world's fastest optimizing 32-bit native-code compiler, the productivity of visual component-based design, and the flexibility of scalable database architecture in a robust object-oriented environment.

"The most exciting new programming tool. Delphi combines the intuitive ease of a visual programming tool with the power of a true compiler." -PC Magazine, January 1996

The fastest way to the fastest 32-bit applications  
-----

Now, whether you are a beginning programmer, professional developer, or client/server developer, there is a version of Delphi that is right for you. Introducing Delphi Desktop 2.0, Delphi Developer 2.0, and Delphi Client/Server Suite 2.0. Delphi 2.0 for Windows 95 and Windows NT combines the most intuitive visual design environment and scalable database tools with the world's fastest optimizing 32-bit native-code compiler.

The NEW! high-performance, optimizing 32-bit native-code compiler creates standalone executables that are up to 300 to 400% faster than 16-bit Delphi applications, and up to 15 to 50 times faster than applications built with p-code interpreters. Create fast, standalone, royalty-free EXEs with no runtime interpreter DLLs

required.

Only Delphi 2.0 brings the power of true 32-bit development to a visual environment. The 32-bit architecture eliminates all 16-bit memory restrictions, enabling you to build strings and data structures up to two gigabytes.

Delphi 2.0 includes FREE! Delphi 1.0 for 16-bit Windows 3.1 application development, making it a complete solution no matter where your Windows-based applications reside today. A simple recompile allows rapid migration of 16-bit applications to 32 bits, preserving your existing investment in code.

Reuse: The key to productivity

-----

The NEW! 32-bit Visual Component Library (VCL) includes more than 90 customizable, reusable components and a dozen NEW! Windows 95 components, so you can drag-and-drop your way to your first 32-bit application in no time. Everything from tree views and list boxes, to notebook tabs, grids, and multimedia controls, is right at your fingertips. You can easily modify and reuse Delphi components and OCX controls, saving time and boosting productivity.

FREE! Quick Reports components allow you to easily create, preview, and print simple embedded reports.

NEW! Visual Form Inheritance maximizes reuse, simplifies the implementation of standards, and makes code maintenance easier. Visual Form Inheritance lets you visually create new forms that inherit all properties from another form.

Create reusable DLLs easily

-----

Build DLLs in Delphi and use them with C++, Paradox,(R) Visual Basic, and other tools. And gain tighter integration between all of your Borland(R) C++ and Delphi applications with NEW! support for OBJ files and COM objects.

Raising the bar in Rapid Application Development

-----

The object-oriented architecture and Two-Way-Tools(TM) in Delphi

maximize productivity. Everything you do visually is automatically reflected in code.

The NEW! centralized Object Repository stores forms, Data Module Objects, and business rules for reuse. Any new application can inherit, use, or copy an existing structure so you can pick the architecture that best fits your development needs.

NEW! Data Module Objects act as your application's information core, allowing you to define data sources, store relationships, and apply business rules to your database. You can separate your business rules from application code for easier maintenance.

A comprehensive suite of visual design and debugging tools accelerate development so you move seamlessly from prototype to production. The NEW! multi-error compile with hints and warnings helps you resolve errors faster. Programmers can jump to and fix multiple problems in a single compile. For quick and easy debugging of even your largest applications, the new compiler even catches logic errors like empty loops, uninitialized pointers, and unused variables.

Unleash the power of Windows 95 and Windows NT

-----  
Delphi 2.0 provides complete access to Windows 95 and NT APIs including multi-threading, MAPI, and Unicode, so you can leverage the power of the 32-bit operating system.

NEW! OCX support lets you drag-and-drop OCX controls directly into your applications from the Delphi Component Palette. Delphi also lets you subclass OCXs for easy customization. You can also integrate OLE-enabled applications like Visual Basic, Excel, Borland C++, and Paradox, with NEW! OLE Automation controller and server support.

Drag-and-drop database development

-----  
Create high-performance, scalable database applications with integrated database support. NEW! data-aware controls let you manipulate live data at design time. Simply select the fields, and Delphi instantly builds the connections.

Let Delphi 2.0 do the database work for you with NEW! Fast

Filters and Smart Lookups. Fast Filters make viewing a specific subset of your data as fast and easy as changing a property. Smart Lookups automatically provide a dropdown box to seamlessly display data from multiple tables.

The NEW! Database Explorer allows you to visually browse and manage tables and aliases without leaving the Delphi IDE.

NEW! 32-bit Borland(R) Database Engine (BDE) includes a new query engine and takes advantage of 32-bit flat address space for increased performance. It provides direct access to Visual dBASE(R) and Paradox tables, and forms a solid foundation for all your database applications.

Delphi Developer: The choice for professional programmers  
-----

If you are building sophisticated, multiuser LAN or corporate database applications, you need Delphi Developer 2.0. It provides all the power of Delphi Desktop 2.0, plus a comprehensive set of professional programming tools.

Powerful programming tools  
-----

The VCL Source Code lets you easily modify native Delphi components, and build your own custom components. Also included are sample OCXs for graphing, charting, spreadsheet, and spell-checking.

Easily add your favorite custom development tools directly to the Delphi environment with the NEW! Open Tools API. Interact with CASE tools or link to your favorite editor--whatever you need to be your most productive.

Build sophisticated, professional reports using live data at design time with the NEW! 32-bit ReportSmith.(R)

When you're ready to distribute your applications, the integrated install utility, InstallShield(R) Express, instantly builds a professional installation program for even your most complex database applications.

Advanced database power  
-----

Quickly establish and maintain data integrity with the NEW! scalable Data Dictionary. It stores customized information about the data in your tables, extended field attributes like min, max, default values, display preferences, and edit masks.

Easily build detailed views of your data with the NEW! Multi-Object Grid. It provides codeless support for quick searching and automatic lookups, and lets you decide whether data appears in rows or individual panels. Panel views support multiple dropdowns, check boxes, and edit fields.

Leverage the power of the NEW! 32-bit BDE with complete access to the BDE API and help files. You also get complete ODBC connectivity.

#### Complete scalability

-----

The scalable NEW! 32-bit Local InterBase(R) Server is included for economical off-line development and testing, and for building standalone ANSI SQL-92 compliant applications.

#### Delphi Client/Server Suite: Gain the competitive advantage

-----

Delphi Client/Server Suite 2.0 gives you a complete suite of tools to build scalable, high-performance client and server applications for Windows 95, Windows NT, and Windows 3.1.

Deploy royalty-free applications across corporate database servers using the NEW! 32-bit SQL Links high-performance native drivers for InterBase, Oracle, Sybase, and MS SQL Server.

Visually browse and modify server-specific meta data including stored procedures, triggers, event alerters, and domains with the NEW! SQL Database Explorer. Gain optimum performance by testing, debugging, and tuning your SQL applications with the NEW! SQL Monitor. Build and test sophisticated multiuser client/server applications with NEW! InterBase NT database server (2-user license). Use the NEW! Visual Query Builder to visually create complex database queries and automatically generate bug-free ANSI SQL-92 commands.

NEW! Cached Updates increase server responsiveness by reducing

the amount of network traffic between client and server. Scale networked applications and move data between formats and host platforms with the NEW! Data Pump Expert. Manage complex team projects with sophisticated source code check-in, check-out, and version control using the NEW! integrated PVCS Version Manager.

Delphi Client/Server Suite 2.0 shortens every stage of the development cycle, allowing you to respond to changing business needs, and gain the competitive advantage.

Delphi 2.0 Specifications and system requirements

#### -----

#### Optimizing Native-Code Compiler

- \* Compiles at more than 350,000 lines per minute
- \* Create fast standalone EXEs with no runtime interpreter
- Dynamic Link Library (DLL)
- \* Applications run up to 15 to 50 times faster than interpreted p-code
- \* Create DLLs that work with C++, Visual dBASE, Paradox, Visual Basic, PowerBuilder, and others
- \* Full access to Windows 95 and NT APIs
- \* Optimized case statements, sets, 32-bit math operations, string and file routines, and more
- \* Smart Linker removes unused objects and code
- \* Automatic form linking defines uses clauses
- \* Advanced math library for extended statistical and financial analysis

#### Visual Component Library (VCL)

- \* More than 90 reusable components
- \* Support for the latest Microsoft systems technologies including OCX, OLE Automation controller and server, MAPI, and ODBC
- \* Standard components for menus, buttons, masked edit fields, panels, graphics, notebook tabs, grids, outlines, list boxes, and more
- \* "Live" design-time data access
- \* VCL Source Code available separately

#### Object Pascal Language

- \* Structured, object-oriented language
- \* Supports inheritance, polymorphism, and encapsulation
- \* Control over privacy with Public, Private, Protected, and Published reserved words

- \* Create components with properties and events
- \* Use inheritance to customize any object
- \* Runtime type information and object persistence
- \* Automatic, extensible exception handling
- \* Support for open arrays, user-defined types, objects, and pointers
- \* Support for delegation and class references

#### Borland Database Engine

- \* High-performance engine with native drivers for Visual dBASE, Paradox, and Local InterBase Server
- \* Fully scalable support for migrating applications from desktop to client/server
- \* Royalty-free deployment of database engine
- \* ODBC support for Access, Btrieve, Excel, DB2, AS/400, Ingres, HP ALBASE/SQL, and gateways like IBM DDCS/2, Micro Decisionware, and Sybase Net-gateway (available separately)
- \* Local InterBase is a high-performance ANSI SQL-92 conformant SQL database server

#### Documentation and Help

- \* More than 5Mb of online help
- \* Manuals: Getting Started, Object Pascal Language Guide, Delphi User's Guide, Component Writer's Guide, and Database Application Developer's Guide

#### Minimum System Requirements

- \* Intel 486-based PC or higher
- \* Microsoft Windows 95 or Windows NT
- \* 8Mb of extended memory or higher
- \* 50Mb hard disk space
- \* CD-ROM drive (3.5" disks available separately)

#### Networks Supported

- \* Any Microsoft Windows 95 or NT-compatible networks

The fastest way to the fastest Windows 95/NT applications

## Article #16221: TPW 1.0 Hot Sheet.

Technical Notes Database

TN1221D.txt TPW 1.0 Hot Sheet.

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

Description:

Turbo Pascal for Windows 1.0 Hot Sheet.

Feature Highlights

-----  
NEW! state-of-the-art Windows integrated development environment (IDE).

- Runs under Windows

- Multiple editor windows

- Full Mouse Support

- Supports TP6 type hot keys

- Multi-file editor that can edit files up to 1MB  
complete save and restore of desktop

NEW! ObjectWindow library - Built in support for Windows, Menus, Dialogs, Buttons, List boxes, Edit fields, Icons and more. All for use in your applications.

NEW! Full access to all Windows API functions and messages.

NEW! Fully Supports creation of DLLs.

NEW! Turbo Debugger for Windows

- Supports Windows messages

- Advanced breakpoints

- Reverse execution

- Automatic DLL debugging

- Object browser and inspectors

- Single and dual monitor support

INCLUDED! Whitewater Resource Toolkit - Visually create Dialogs,

Menus, Icons, Bitmaps and String resources.

INCLUDED! Resource Compiler

INCLUDED! Windows Help Compiler

Full featured inline assembler (BASM)

Private fields and methods in object declarations

Extended syntax directive (\$X) that lets you treat functions like procedures (and ignore function results)

286 code generation

Address references in typed constants

Far and near procedures directives (\$F)

Link in initialized data (\$L) from object (OBJ) files

Smart linker removes unused objects and code

complete math coprocessor emulation and support -  
8087/80287/80387

NEW! Turbo Help hypertext on-line help facilities, including references to all Windows API functions and messages.

Turbo Pascal for Windows includes everything you need to create Windows applications. It does not require the Microsoft Windows SDK.

## System Requirements

-----

IBM PC or PS/2 and all 100% compatibles

Microsoft Windows 3.0 or later

2Mb of memory

EGA, Hercules or VGA graphics

Mouse or other pointing device

Hard Disk (Requires 6.5 Meg for full product)

## Benchmarks

-----

Machine

Lines/Min

Compaq DeskPro 386/33            84,000

Documentation

-----

1. User's Guide
2. Programmer's Guide
3. Windows Reference Guide
4. Windows Programming Guide
5. Whitwater Resource Toolkit Users Guide
6. Turbo Debugger for Windows Users Guide
7. Help Compiler Reference Guide

Pricing Information

-----

Turbo Pascal for Windows    \$249.95

Special Offer Information

-----

Registered user of ANY BORLAND LANGUAGE PRODUCT \$99.95 \*\*\*

\*\*\*Turbo Pascal for Windows is exclusively for Windows Development and does not replace Turbo Pascal version 6.0. TP6 is the current product for standard DOS development. The offer is not an upgrade it is a limited special offer to our current Turbo Pascal Customers.

## Article #16225: Delphi Client/Server Suite 2.0 for Windows 95 & NT

Technical Information Database

TI1225D.txt - Delphi Client/Server Suite 2.0 for Windows 95 & NT

Category :Delphi 2.x  
Platform :All Windows  
Product :

### Description:

Delphi Client/Server Suite 2.0 for Windows 95 and NT  
Quick Info Guide

Delphi Client/Server Suite 2.0 provides you with all the tools you need to build scalable client and server applications while shortening every stage of the development cycle everything you need to boost productivity and gain a competitive advantage.

### Scalable client/server architecture

- \* Create fast, standalone, royalty-free scalable applications that are up to 15 to 50 times faster than p-code interpreters.
- \* Unleash the power of Windows 95 and Windows NT with complete support for OCXs, OLE Automation, multi-threading, Unicode, MAPI, and more.
- \* Increase productivity with more than 100 reusable components.
- \* Deploy royalty-free applications using the NEW! 32-bit SQL Links native drivers for Oracle, Sybase, MS SQL Server, and InterBase.(R)
- \* Visually manage server-specific meta data like stored procedures and triggers with the NEW! SQL Database Explorer.
- \* Test, debug, and tune SQL applications with the NEW! SQL Monitor.
- \* Increase server responsiveness with NEW! Cached Updates.
- \* Build and test multiuser SQL applications with the NEW! InterBase NT (2-user license).
- \* Use the NEW! Data Module Objects to separate business rules from application code, and scalable NEW! Data Dictionary to implement and maintain data integrity.
- \* Generate bug-free ANSI SQL-92 code with the Visual Query Builder.

- \* Manage complex team projects with the NEW! integrated PVCS Version Control.

-----  
Everything you need to gain a competitive advantage!

- \* High-performance, optimizing 32-bit native-code compiler
- \* Create reusable DLLs and royalty-free, standalone EXEs
- \* Full Windows 95 support for OCX controls, and OLE Automation controllers and servers
- \* Complete access to Windows 95 APIs for multi-threading, Unicode, MAPI, and more
- \* Complete suite of Windows 95 components
- \* 32-bit SQL Links native drivers, with unlimited deployment license for Oracle, Sybase, MS SQL Server, and InterBase
- \* InterBase NT (2-user lic.) for scalable multiuser SQL development
- \* SQL Database Explorer to visually manage server-specific meta data
- \* SQL Monitor to test, debug, and tune SQL applications
- \* Integrated InterSolv PVCS Version Control for team development
- \* Visual Query Builder to generate bug-free SQL code
- \* Cached Updates to speed up server response time
- \* Data Pump Expert for rapid upsizing and application scaling
- \* Object-oriented component architecture
- \* Object Repository for storing and reusing objects, business rules, and forms
- \* Visual Form Inheritance to reduce coding and simplify maintenance
- \* Integrated Development Environment
- \* Visual Component Library (VCL) with more than 100 reusable components
- \* VCL Source Code and manual to develop or customize components
- \* Sophisticated data-aware components
- \* 32-bit Borland(R) Database Engine with low-level API support and Help files
- \* Database Explorer to visually browse and modify tables and aliases
- \* Data Module Objects to separate business rules from application code for easier maintenance
- \* Scalable Data Dictionary to implement and maintain data integrity
- \* Complete ODBC connectivity
- \* 32-bit Local InterBase Server for off-line SQL development

- \* 32-bit ReportSmith(R) for sophisticated reporting
- \* InstallShield(R) Express for building professional installs
- \* WinSight(TM) to monitor Windows messages
- \* Expanded Open Tools API to integrate your favorite tools
- \* Complete documentation including Object Pascal Language Guide
- \* Includes 16-bit Delphi 1.0 for Windows 3.1 development

-----

## Delphi Facts

|                                                    | Delphi | PowerBuilder | Visual Basic |

| SQL Monitor to test, debug, and true SQL apps      | Y      | N            | N            |

-----

## Minimum System Requirements

- \* Intel 486/25-based PC or higher
- \* Microsoft Windows 95 or Windows NT 3.51
- \* 8Mb of memory (12Mb recommended)
- \* 50Mb hard disk space
- \* CD-ROM drive

\* Mouse or other Windows pointing device

## Borland Delphi Client/Server Suite support services

- \* Fast Fax for Detailed Information: 1-800-408-0001
- \* TechFax(TM) for Technical Information: 1-800-822-4269
- \* Connections Developer Program: 1-800-353-2211
- \* Free Install Support: (408) 461-9195
- \* Credit Card Advisor Line: 1-800-330-3372
- \* 900-Advisor Lines:
  - o Delphi and Delphi Client/Server: 1-900-555-1015
  - o Local InterBase Server: 1-900-555-1013
  - o ReportSmith: 1-900-555-1011
  - o For Technical Support Service contracts and information: 1-800-523-7070

Satisfaction guaranteed!

You can buy the Delphi Client/Server Suite with complete assurance. If for any reason you are not fully satisfied with your purchase, you can return it to Borland within 90 days. No questions asked!

Authorization required to sell these products. Call 1-800-408-0001 to request a client/server authorization form. Educational pricing is available through Borland Authorized Educational Resellers. Call 1-800-847-7797. Advisor Line charges: \$2.00 per minute, first minute free.

Borland's DELPHI products and services are not associated with or sponsored by Delphi Internet, an online service and Internet access provider.

## Article #16227: Status line in a MDI Application.

Technical Notes Database

TN1227D.txt     Status line in a MDI Application.

Category     :Pascal

Platform     :All

Product      :Turbo Pascal  1.0

### Description:

To have a status line in an MDI application, override the windows MDI WMSize method like this:

```
TGDIDemoWindow.WMSize(var Message: TMessage);
begin
  TMDIWindow.WMSize(Message);
  {Calculate the new size of the client area}
  MoveWindow(ClientWnd^.HWindow, size of the new client area)
end;
```

This will keep the client window from obscuring your status line or other controls you might like to have in your window.

## Article #16231: Performing database queries in a background thread

Technical Information Database

TI1231D.txt - Performing database queries in a background thread

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This document explains how to perform queries in a background thread by using the TThread class. For information on the general usage of the TThread class, please refer to the Borland documentation and to the online help. You should be aware of how to use Delphi's database components to understand the this TI's contents.

Two requirements must be met in order to perform a threaded query. First, the query to be threaded must be contained within its own session by using a separate TSession component. Therefore, you would place a TSession component on your form and assign it's name to the SessonName property of the TQuery component to be used in the thread. You must use a separate TSession component for each TQuery component to be used in a thread. If you are also using a TDataBase component, a separate TDataBase must be used for each threaded query as well. The second requirement is that the threaded TQuery component must not be connected to a TDataSource in the context of the thread in which it will be executed. This must be done in the context of the primary thread.

The code example below illustrates this process. This unit shows a form which contains two each of the following comopnents: TSession, TDatabase, TQuery, TDataSource and TDBGrid. These components have the following property settings:

```
Session1
    Active True;
    SessionName "Ses1"
```

```

DataBase1
    AliasName      "IBLOCAL"
    DatabaseName   "DB1"
    SessionName    "Ses1"

Query1
    DatabaseName   "DB1"
    SessionName    "Ses1"
    SQL.Strings    "Select * from employee"

DataSource1
    DataSet       ""

DBGrid1
    DataSource     DataSource1

Session2
    Active        True;
    SessionName    "Ses2"

DataBase2
    AliasName      "IBLOCAL"
    DatabaseName   "DB2"
    SessionName    "Ses2"

Query2
    DatabaseName   "DB2"
    SessionName    "Ses2"
    SQL.Strings    "Select * from customer"

DataSource2
    DataSet       ""

DBGrid1
    DataSource     DataSource2

```

Notice that the DataSet property for both TDataSource components do not refer to anything initially. This will be set at run-time as illustrated in the code.

```

unit Unit1;

interface

```

```
uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls,
  Forms, Dialogs,
  StdCtrls, Grids, DBGrids, DB, DBTables;
```

```
type
```

```
TForm1 = class(TForm)
  Session1: TSession;
  Session2: TSession;
  Database1: TDatabase;
  Database2: TDatabase;
  Query1: TQuery;
  Query2: TQuery;
  DataSource1: TDataSource;
  DataSource2: TDataSource;
  DBGrid1: TDBGrid;
  DBGrid2: TDBGrid;
  GoBtn1: TButton;
  procedure GoBtn1Click(Sender: TObject);
end;
```

```
TQueryThread = class(TThread)
private
  FSession: TSession;
  FDatabase: TDatabase;
  FQuery: TQuery;
  FDataSource: TDataSource;
  FQueryException: Exception;
  procedure ConnectDataSource;
  procedure ShowQryError;
protected
  procedure Execute; override;
public
  constructor Create(Session: TSession; DataBase:
    TDatabase; Query: TQuery; DataSource: TDataSource);
    virtual;
end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```

constructor TQueryThread.Create(Session: TSession; DataBase:
  TDatabase; Query: TQuery; Datasource: TDataSource);
begin
  inherited Create(True);    // Create thread in a
suspendend state
  FSession := Session;      // connect all private fields
  FDatabase := DataBase;
  FQuery := Query;
  FDataSource := Datasource;
  FreeOnTerminate := True;  // Have thread object free
itself when terminated
  Resume;                   // Resume thread execution
end;

procedure TQueryThread.Execute;
begin
  try
    { Run the query and connect the datasource to the TQuery
      component by calling ConnectDataSource from main
      thread (Synchronize used for this purpose)}
    FQuery.Open;
    Synchronize(ConnectDataSource);
  except
    { Capture exception, if one occurs, and handle it in the
      context of the main thread (Synchronize used for this
      purpose. }
    FQueryException := ExceptObject as Exception;
    Synchronize(ShowQryError);
  end;
end;

procedure TQueryThread.ConnectDataSource;
begin
  FDataSource.DataSet := FQuery; // Connect the DataSource
to the TQuery
end;

procedure TQueryThread.ShowQryError;
begin
  Application.ShowException(FQueryException); // Handle the
exception
end;

procedure RunBackgroundQuery(Session: TSession; DataBase:

```

```

TDataBase; Query: TQuery; DataSource: TDataSource);
begin
  { Create a TThread instance with the various parameters. }
  TQueryThread.Create(Session, Database, Query, DataSource);
end;

```

```

{$R *.DFM}

```

```

procedure TForm1.GoBtn1Click(Sender: TObject);
begin
  { Run two separate queries, each in their own thread }
  RunBackgroundQuery(Session1, DataBase1, Query1,
Datasource1);
  RunBackgroundQuery(Session2, DataBase2, Query2,
Datasource2);
end;

```

```

end.

```

The TForm1.GoBtn1Click method is an event handle for a button click event. This event handler calls the RunBackgroundQuery procedure twice, each time passing a different set of database components. RunBackgroundQuery creates a separate instance of the TQueryThread class, passing the various database components to its constructor which in turn assigns them to the appropriate TQueryThread private data fields.

The TQueryThread contains two user-defined procedures: ConnectDataSource and ShowQryError. ConnectDataSource connects FDataSource.DataSet to FQuery. However, it does this in the primary thread by using the TThread.Synchronize method. ShowQryError handles the exception in the context of the primary thread, again by using the Synchronize method. The Create constructor and Execute method are explained in the code's comments.

## Article #16233: Changing Button Text

Technical Notes Database

TN1233D.txt Changing Button Text

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

Description:

Question:

How do you change the text on a button?

Answer:

To change the text on a button, send a WM\_SETTEXT message with the string for the lParam. For example:

```
SendMessage(btnWindow, WM_SETTEXT, 0, 'New Button Title');
```

Or if you are using OWL, call the SetCaption method of TButton.

Reference:

Last Modified: 01-SEP-99

## Article #16237: How to check a ComboBox without OnClick occurring.

Technical Information Database

TI1237D.txt How to check a ComboBox without OnClick occurring.

Category :VCL

Platform :All

Product :Delphi All

### Description:

When you modify the state of a TCheckBox by setting the value of its Checked property, the OnClick event of that TCheckBox is fired. For example, the following code:

```
CheckBox1.Checked := True;
```

causes CheckBox1.OnClick to execute.

Sometimes, however, you may want to check or uncheck the CheckBox in code without firing the OnClick event. You can do this by sending a BM\_SETCHECK message to the ComboBox. The WParam of this message can be 1 (meaning the box should be checked), or 0 (meaning the box should be unchecked). The LParam of this message is always 0.

With this in mind, the following procedure accepts as parameters a TCheckBox called CB and a Boolean parameter called CheckIt. When CheckIt is True, the box will be checked, and when it's False, the box will be unchecked:

```
procedure CheckNoClick(CB: TCheckBox; CheckIt: Boolean);
begin
  CB.Perform(BM_SETCHECK, Ord(CheckIt), 0);
end;
```

Using this procedure, the code for checking a TComboBox called ComboBox1 looks like this:

```
CheckNoClick(ComboBox1, True);
```

## Article #16239: TDW popping in dual mode in TPW.

Technical Notes Database

TN1239D.txt TDW popping in dual mode in TPW.

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

Description:

Question:

I want to make TDW come up in dual mode from within the TPW.

Answer:

Add the following lines to the tpw.ini file:

```
[Debugger]
Exepath=
Switches=
```

where is the path to the TDW.EXE and  
are the options you normally want to use with TDW, this will do  
it. The  
command-line option for the dual display is -do.

## Article #16243: TForm.MDIChildren[] Array and Form Creation

Technical Information Database

TI1243D.txt TForm.MDIChildren[] Array and Form Creation

Category :VCL

Platform :All

Product :Delphi All

### Description:

The documentation of TForm.MDIChildren[] states that the index of the first-created MDI child is 0. This is incorrect -- the index of the most-recently-created MDI child is always 0, and the index of the first-created MDI child is always MDIChildCount - 1.

With this in mind, you can use the following code to iterate over the MDI child array from from the first-created to the last:

```
procedure TForm1.IterateOverMDIChildren;
var
  i: integer;
begin
  for i := MDIChildCount - 1 downto 0 do begin
    { do something with MDI child here }
  end;
end;
```

## Article #16245: PChars in TPW.

Technical Notes Database

TN1245D.txt PChars in TPW.  
Category :Pascal  
Platform :All  
Product :Turbo Pascal 1.0

### Description:

PChar is a special pointer type that has been added to the Pascal Windows language definition. A PChar is a pointer to an array of characters with a maximum size of 64K and terminated by a null character (#0). This is a C string, and comes with all the memory management hassles and pointer arithmetic advantages of C. The PChars and arrays of char are type compatible, and a Strings unit is devoted to C-string manipulation functions (all start with "STR"). When passing a string literal to a procedure, the compiler will figure out whether the string literal should be stored in c-string format or in pascal string format, or both.

## Article #16251: WinCrt and Windows 3.0

Technical Notes Database

TN1251D.txt WinCrt and Windows 3.0

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

### Description:

WinCrt is an emulation of the Dos and Crt units. Basically, it provides a quick and dirty means of output to a Windows window. It's not intended to be a Dos to Windows porting service - WinCrt apps are not full Windows apps - just a Windows window with some text, key scanning loops, and scrollbars.

Note that writelns to the 'screen' will cause a runtime error in TPW unless the WinCrt unit is used. (WinCrt opens the standard Input and Output files, which are closed by default in TPW). The Readln, Keypressed, procedures, etc., are also only valid under the WinCrt umbrella. The text colors and text inverse are not supported. And since WinCrt takes control of the message loop and dispatch services of your windows app, WinCrt cannot be used in conjunction with OWL. You can call Windows API functions directly, however.

## Article #16257: Turbo Pascal for Windows New and GetMem procedures

Technical Notes Database

TN1257D.txt Turbo Pascal for Windows New and GetMem procedures

Category :Pascal

Platform :All

Product :Turbo Pascal 1.0

### Description:

The way memory allocation works for new and getmem is as follows:

There are two system variables: HeapBlock and HeapLimit.

When memory is allocated for a size less than HeapBlock (Default is 1k)

then the memory will be suballocated in a block of size HeapBlock (default is 8k).

Allocation of blocks larger than HeapLimit will have there own block. All allocations will be in global memory.

You will not be able to change the way this works.

## Article #16279: Redistributing Applications using the ISP

Technical Information Database

TI1279D.txt - Redistributing Applications using the ISP

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

### Description:

Applications built with the Internet Solutions Pack can be redistributed using most third party installation programs, including the InstallShield Express utility that ships with Delphi 2.0 Client/Server and Developer. In order to deploy your application, any OCX controls you used in building the application need to be redistributed along with your executable, as well as any other necessary files (eg. dll's) your program requires.

In addition, the Internet controls are dependent upon NetMasters support dll's, and must be included with your program. The following list contains of all the OCX files and NetMasters DLLs that ship with the Internet Solutions Pack (and that may need to be redistributed):

#### OCX files

-----

HTML.OCX  
HTTPCT.OCX  
NNTPCT.OCX  
POPCT.OCX  
SMTPCT.OCX  
WINSCK.OCX  
FTPCT.OCX

#### NetMasters DLLs

-----

NMOCOD.DLL  
NMSCKN.DLL  
NMF'TPSN.DLL  
NMW3VWN.DLL

NMORENU.DLL

For a list of which files you actually need to include with your distribution, use the following dependency matrix:

|             | Winsock | FTP | NNTP | SMTP | POP3 | HTTP | HTML |
|-------------|---------|-----|------|------|------|------|------|
| NMSCKN.DLL  | X       | X   | X    | X    | X    | X    | X    |
| NMORENU.DLL |         | X   | X    | X    | X    | X    | X    |
| NMOCOD.DLL  |         | X   | X    | X    | X    | X    | X    |
| WINSCK.OCX  | X       |     |      |      |      |      |      |
| FTPCT.OCX   |         | X   |      |      |      |      |      |
| NMFTPSN.DLL |         | X   |      |      |      |      |      |
| NNTPCT.OCX  |         |     | X    |      |      |      |      |
| SMTPCT.OCX  |         |     |      | X    |      |      |      |
| POPCT.OCX   |         |     |      |      | X    |      |      |
| HTTPCT.OCX  |         |     |      |      |      | X    |      |
| HTML.OCX    |         |     |      |      |      |      | X    |
| NMW3VWN.DLL |         |     |      |      |      |      | X    |

Patches:

The following patches are available for download from the Borland Delphi 32 CompuServe Forum (BDELPHI32) and the Borland website ([www.borland.com](http://www.borland.com)).

NMPATCH.ZIP - Unzip this file and follow the included directions. This patch was supplied by NetMasters and will actually update the controls themselves.

ISP.DCU - Place in the Delphi 2.0\lib subdirectory and recompile

your project. This will prevent the error message about not being licensed.

To deploy your program using InstallShield Express, follow these steps:

- 1) Start up ISXpress, and build your Setup project as you normally would (if you are unfamiliar with building a Setup project with InstallShield Express, refer to the InstallShield online help).
- 2) In the Components & Groups portion of the setup, add your executable file into an appropriate group (eg. the Program Files group (default)).
- 3) Create a new group for the shared files (eg. "Shared Files"), and set the Destination Directory to . Then launch the Explorer and drag the necessary files (as determined by using the above matrix) to the newly created folder. These files should be located in your Windows\System directory on your hard drive (if not, you can find them on the Delphi 2.0 CD-ROM under \RUNIMAGE\DELPHI20\WINDOWS\SYSTEM32).
- 4) Finish the rest of the Setup procedure.

You are now ready to deploy your application. InstallShield will automatically register all OCX's and DLLs that have set as their destination directory.

## Article #16285: How to Create a TDBGrid Lookup Field in 32-bit Delphi

Technical Information Database

TI1285D.txt - How to Create a TDBGrid Lookup Field in 32-bit Delphi

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

1. Drop 2-TTable's, 1-TDataSource and 1-TDBGrid on a form.
2. Connect Table1 to DataSource1 to DBGrid1
  - a. DataSource1.DataSet = Table1
  - b. DBGrid1.DataSource = DataSource1
3. Setup Table1
  - a. Table1.Database = DBDemos
  - b. Table1.TableName = Customer
  - c. Table1.Active = True
4. Setup Table2
  - a. Table2.Database = DBDemos
  - b. Table2.TableName = Orders
  - c. Table2.Active = True
5. Add all of the fields for Table1 by bringing up the Fields Editor:
  - a. Double click on Table1
  - b. Right click on Fields Editor
  - c. Add New Fields. Add all of them
6. Add a new field for Table1.
  - a. Right click on Fields Editor, and select New Field.
7. Specify the following parameters for the newly added field.
  - a. Name: Bob
  - b. Type: String
  - c. Size: 30
  - d. Select Lookup
  - e. Key Fields: CustNo - Field in Table1 to store value
  - f. DataSet: Table2 - Table lookup is being done on

g: LookUpKeys: CustNo - This Key gets copied to KeyField  
h: Result Field: OrderNo - Value to display to the user in the  
drop down box

8. Run the application

## Article #16299: TP6 IDE Memory Documentation

Technical Notes Database

TN1299D.txt TP6 IDE Memory Documentation

Category :Pascal

Platform :All

Product :Turbo Pascal 6.0

Description:

Subject: TP6 IDE memory doc

Both the IDE and Turbo Pascal's itself are very configurable and there are several steps you can take to make more workspace available for compiling and debugging your programs. Some solutions are easy to implement, while others involve altering your code or turning off debug information selectively. Always start with the options that are painless and safe and then, if necessary, take progressively more radical steps in order to increase the IDE's capacity. Once you find a system configuration that provides you with enough capacity, you might want to permanently modify the your AUTOEXEC.BAT, CONFIG.SYS, and TURBO.TP, and TURBO.EXE files.

SCAN ITEM:

Changes you make in the Options|Environment|Startup dialog box are saved directly into TURBO.EXE and are permanent. Changes you make in other dialog settings inside the IDE can be saved in a TURBO.TP configuration file. For more information, refer to the IDE Reference Chapter xxxx.

Outside the IDE

-----

- x. Remove TSRs from memory. If you have Sidekick or Superkey loaded in memory or EMS, exit the IDE, remove them, and then reload TURBO.EXE.
- x. Modify CONFIG.SYS to remove unnecessary drivers (ANSI.SYS, disk caches, etc.). You can also reduce the number of files and buffers to: FILES = 20, BUFFERS = 20. Make sure these

changes are safe for other software you are using.

## Re-configuring Turbo Pascal

- 
- x. Set Compile|Destination to Disk.
- x. On the Options|Linker dialog box, set Link Buffer to Disk.
- x. Using the Options|Environment|Startup menu, try one or more of the following:

### SCAN ITEM:

There are command-line parameters that you can pass to TURBO.EXE at startup that correspond to all of the settings on the Options|Environment|Startup menu. Refer to P-xxx.

- x. If you have expanded memory on your system (EMS), make sure the Use e(x)panded memory option is enabled and make plenty of EMS available to Turbo Pascal (by reducing the amount of EMS being used by resident programs or drivers like RAM disks, Sidekick, etc.). The IDE can use at least 400K of EMS for overlays, extra buffers, and other system resources. All these will increase the workspace for your programs. (Making more than 400K EMS available will increase the IDE's performance, although it will not make more memory available to compile and debug your programs.)

### SCAN ITEM:

If you have EMS available, disabling this option will have no effect on IDE capacity.

- x. If you're not trying to debug a graphics program, make sure the (G)raphics screen save option is disabled. Like all startup options, you can enable this option on the command-line when you do need to debug a graphics program.
- x. Reduce the default (O)verlay and (W)indow heap sizes. Every Kbyte you subtract here yields another KByte for your program. If you have EMS available, reducing these heap sizes somewhat won't have much negative impact on the IDE's performance.
- x. Disable the Load (T)URBO.TPL option. TURBO.TPL contains the commonly used standard units and is loaded into memory

at startup to optimize linker performance. By disabling this option, you'll still be able to compile and debug programs, but you'll have to extract all the units from TURBO.TPL first (using the TPUMOVER utility. Refer to TPUMOVER.DOC on your distribution disk).

SCAN NOTE: If you don't have the IDE load TURBO.TPL, you won't be able to evaluate expressions using the Evaluate/Modify box unless a debugging session is active.

As an alternative, you can leave the Load (T)URBO.TPL option enabled and still reduce the size of TURBO.TPL by about 15K. Just extract all units from TURBO.TPL with the exception of SYSTEM.TPU. Then delete all units from TURBO.TPL with the exception of SYSTEM.TPU.

SCAN ITEM:

Make sure to leave the extracted units on disk and in your unit path (Options|Directories|Unit directory) so your programs can still make use of the Dos, Crt, Overlay and the Printer units.

- x. On a unit-by-unit basis, turn off debug information in those units that are already debugged. A common technique is to build a "test harness" around your code as you develop it. Once that code is implemented, tested and debugged, turn off symbol information in that unit by disabling the (D)ebug information switch on the Options|Compiler box and recompiling. You can also embed a {\$D-} in the unit itself. If you do so, it's a good idea to use conditional directives and defines to control enabling and disabling debug information in various units (refer to chap xxxx). If you proceed as described here and end up with debug information disabled everywhere in your program--and are still having capacity problems--consider modifying your code as described below.

SCAN ITEM:

Of course, if you're not debugging, you can greatly increase IDE capacity by disabling the Integrated debugging switch in the Options|Debugger box.

Modifying your source code

-----

Some of the following measures are easy to do and yield big

capacity gains. Others are more radical and you might want to use conditional directives (see P-xxxx) to turn them on or off.

- x. Overlay units in your program. This is very safe, flexible, and can dramatically increase the IDE workspace. Refer to chapter xxx in the Programmer's Guide for more information.
- x. Using the Options|Memory sizes menu, reduce the (S)tack size and (L)ow heap limit. Make sure there's enough stack for your program, especially if you've turned off stack checking as recommended below.
- x. Using the Options|Compiler box, try one or more of the following:
  - x. Disable (R)ange checking and (S)tack checking. (S)tack checking is on by default. Turn it off once your program is stable and you've determined its stack requirements.
  - x. Disable (E)mulation during debugging. Of course, only enable emulation and (8)087/80287 code generation if you are doing IEEE floating point. If you have a numeric coprocessor on your debugging machine, disable emulation while you're debugging non-floating point code.
- x. Reduce the number of symbols in the interface sections of units. Don't declare something in the interface section of a unit unless it's used by code outside the unit. Doing this is good, safe programming practice and will make more symbol space available during the compilation of large programs.

## Turbo Debugger and the IDE

-----

Turbo Pascal itself and the IDE both offer many ways for you to gain capacity by making adjustments to default settings. If you run out memory compiling or debugging your programs and have tried most of the painless ideas offered above, consider using the IDE to edit and compile your programs, and then using Turbo Debugger to debug them. If you have Turbo Debugger and want to use it to debug programs developed in the IDE, configure the IDE as follows:

- o Set Compile|Destination to disk.

- o In the Options|Debugger box, disable Integrated and enable Standalone debugging.

You can also use the command-line compiler, TPC.EXE, or the extended memory command-line compiler, TPCX.EXE to build massive programs (several megabytes in size). Then you can use TD, TD286 or TD386 to debug them.

## Article #16303: Making your 32 bit Delphi applications "sing"

Technical Information Database

TI1303D.txt - Making your 32 bit Delphi applications "sing"

Category :Windows API  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This TI demonstrates how to make your 32 bit Delphi application "sing" by loading and playing a wave file four different ways:

- 1) Use the `sndPlaySound()` function to directly play a wave file.
- 2) Read the wave file into memory, then use the `sndPlaySound()` to play the wave file
- 3) Use `sndPlaySound` to directly play a wave file thats embedded in a resource file attached to your application.
- 4) Read a wave file thats embedded in a resource file attached to your application into memory, then use the `sndPlaySound()` to play the wave file.

To build the project you will need to:

- 1) Create a wave file called 'hello.wav' in the project's directory.
- 2) Create a text file called 'snddata.rc' in the project's directory.
- 3) Add the following line to the file 'snddata.rc':  
HELLO WAVE hello.wav
- 4) At a dos prompt, go to your project directory and compile the .rc file using the Borland Resource

compiler (brcc32.exe) by typing the path to brcc32.exe and giving 'snddata.rc' as a parameter.

Example:

```
bin\brcc32 snddata.rc
```

This will create the file 'snddata.res' that Delphi will link with your application's .exe file.

Final Note: Keep on Jamm'n!

## Article #16305: TP 6.0 Carton Text

Technical Notes Database

TN1305D.txt    TP 6.0 Carton Text  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal  6.0

Description:  
Carton Text

Turbo Pascal with Objects  
Develop sophisticated applications easily with Turbo Vision

New Turbo Pascal 6.0  
Object-oriented programming with Turbo Vision

Turbo Pascal(R) now includes Turbo Vision, the first object-oriented application framework for MS-DOS. With Turbo Vision, your applications automatically inherit a multi-window, mouse-based user interface.

Turbo Vision is a complete library of objects including windows, pull down menus, dialog boxes and scrollbars--with built-in mouse support. It also includes collection and stream objects for data management. With Turbo Vision, even the most sophisticated applications are within reach. It's easy to learn but has power to spare for major applications. In fact, we used Turbo Vision to write Turbo Pascal's new Integrated Development Environment! So not only can you build better programs, you can do it faster than ever.

\*\* Screenshot (TP1)

Zoom through source code and eliminate bugs quickly with the new Integrated Development Environment.

Powerful Sample Applications

Turbo Vision comes with a complete set of applications including desktop tools such as a calculator, a calendar, a rolodex, a disk browser and more--all with complete source code. And since

they're written using Turbo Vision they're easy to add to your own programs or customize.

## \*\*Screenshot (TP2)

Learning Turbo Pascal is a snap. Copy, paste and compile over 200 sample programs from the Turbo Help hypertext system.

## Features:

- o Turbo Vision application framework
  - o Over 50 object types and 350 methods
  - o Windows, dialogs, menus, mouse support and more
  - o Completely extensible
- o New Integrated Development Environment
  - o Multi-file editor with macros
  - o Overlapping windows and mouse support
  - o Built-in support for Expanded Memory (EMS)
  - o Integrated source code debugging
  - o Turbo Help hypertext system
  - o Conditional breakpoints and CPU window
- o New inline assembler for low-level programming
- o Turbo Pascal 6.0 has all the power and speed you need
  - o Fast! Compiles 50,000 lines per minute\*
  - o Object-oriented programming now supports private methods and data
  - o Smart linker removes unused code, objects
  - o Fast overlays for large programs
  - o 8087 emulation and coprocessor support
  - o BGI graphics for fonts, shapes, charts and more
  - o Source code compatible with Turbo Pascal 5.x

## \*\* Mouse type:

\*On IBM PS/2 Model 80

Minimum system requirements" For the IBM PS/2(R) and IBM(R) family of personal computers and all 100% compatibles. PC-DOS (MS-DOS) 2.0 or later. 512K RAM minimum (256K for command line version). Two floppy disk drives. BGI graphics supports VGA, EGA, CGA, MCGA, Hercules, ATT400 and IBM 8514 monitors.

Turbo Pascal is a registered trademark of Borland International, Inc. Copyright (C) 1990 Borland International, Inc. All rights reserved.

\*\*\*\*\*

Turbo Pascal Professional  
Develop professional applications with Turbo Vision

New Turbo Pascal Professional 6.0

Includes:

- o Turbo Pascal(R) 6.0 with Turbo Vision
- o Protected-mode command-line compiler
- o Turbo Debugger(R)
- o Turbo Profiler TM
- o Turbo Assembler(R)

Turbo Pascal now includes Turbo Vision, the first object-oriented application framework for MS-DOS. With Turbo Vision, your applications automatically inherit a multi-window, mouse-based user interface.

Turbo Vision is a complete library of objects including windows, pull down menus, dialog boxes and scrollbars--with built-in mouse support. It also includes collection and stream objects for data management. With Turbo Vision, even the most sophisticated applications are within reach. In fact, we used Turbo Vision to write Turbo Pascal's new Integrated Development Environment! So not only can you build better programs, you can do it faster than ever.

\*\* Screenshot (TP1)

Zoom through multiple source code files with the new Integrated Development Environment.

Turbo-Driven Compiler

Turbo Pascal Professional now includes a protected mode command-line compiler that allows you to take full advantage of extended memory and create programs several megabytes in size.

Turbo Debugger--The Best Gets Better

Turbo Debugger 2.0 supports object-oriented programming in Turbo Pascal 6.0. It's the only debugger to support reverse

execution, which allows you to step backwards to find bugs you may have missed.

## \*\* Screenshot (TP PRO)

Use Turbo Debuggers' object browsers and inspectors to track down the toughest bugs.

## Turbo Profiler

The world's first interactive profiler helps you tune your programs for maximum speed. Turbo profiler measures the performance of your programs by showing you where time is spent in your routines, overlays, interrupts and file I/O.

## Turbo Assembler

The world's fastest 100% MASM-compatible assembler produces optimized code for the 8086/286/386/486.

## Turbo Pascal

- o New Turbo Vision application framework
- o New protected mode compiler for large programs
- o New built-in assembler (TASM and MASM compatible)
- o New integrated development environment with multiple windows, macros and mouse support
- o Object-oriented programming now supports private data and methods
- o Fast! Compiles 50,000 lines per minute\*
- o Includes smart linker, fast overlays, 8087 support, Turbo Help system and BGI graphics

## Turbo Debugger

- o Reverse execution
- o Object browsers and inspectors

## Turbo Profiler

- o Histograms of program execution
- o Track call history

## Turbo Assembler

- o Multi-pass optimizing assembler supporting 486

\*\* Mouse type:

\*On IBM PS/2 Model 80

Minimum system requirements" For the IBM PS/2(R) and IBM(R) family of personal computers and all 100% compatibles. PC-DOS (MS-DOS) 2.0 or later. 512K RAM minimum (256K for command line version). Two floppy disk drives. BGI graphics supports VGA, EGA, CGA, MCGA, Hercules, ATT400 and IBM 8514 monitors.

## Article #16309: Obtaining the Physical Path of a Table

Technical Information Database

TI1309D.txt - Obtaining the Physical Path of a Table

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

When a Table is referenced through an alias, the physical path is not readily available. To obtain this path, use the `DbiGetDatabaseDesc` BDE function. This function takes the alias name and a pointer to a `DBDesc` structure. The `DBDesc` structure will be filled with the information pertaining to that alias. This structure is defined as:

```
pDBDesc = ^DBDesc;  
DBDesc = packed record          { A given Database Description }  
    szName          : DBINAME;   { Logical name (Or alias) }  
    szText          : DBINAME;   { Descriptive text }  
    szPhyName       : DBIPATH;   { Physical name/path }  
    szDbType        : DBINAME;   { Database type }  
end;
```

The physical name/path will be contained in the `szPhyName` field of the `DBDesc` structure.

Possible return values for the `DBIGetDatabaseDesc` function are:

|                                 |                                                                               |
|---------------------------------|-------------------------------------------------------------------------------|
| <code>DBIERR_NONE</code>        | The database description for <code>pszName</code> was retrieved successfully. |
| <code>DBIERR_OBJNOTFOUND</code> | The database named in <code>pszName</code> was not found.                     |

The code example below illustrates how to obtain the physical path name of a `TTable` component using the `DBDemos` alias:

```
var  
    vDBDesc: DBDesc;  
    DirTable: String;  
begin
```

```
    Check(DbiGetDatabaseDesc(PChar(Table1.DatabaseName),
vDBDesc));
    DirTable := Format('%s\s', [vDBDesc.szPhyName, Table1.TableName]);
    ShowMessage(DirTable);
end;
```

## Article #16311: TP6 Benchmarks

Technical Notes Database

TN1311D.txt    TP6 Benchmarks  
Category     :Pascal  
Platform     :All  
Product      :Turbo Pascal  6.0

Description:

TP6 Benchmarks  
August 23, 1990

Here are the timings for a full build of TCALC (as shipped on TP55 disks) using TPC.EXE version 6.0:

| Machine               | Mhz | Disk Type | Seconds | Lines Per Minute |
|-----------------------|-----|-----------|---------|------------------|
| -----                 | --- | ----      | -----   | -----            |
| IBM PS/2 Model 60     | 8   | RAM       | 14.7    | 34,114           |
| Toshiba 5200          | 25  | Fixed     | 11.3    | 44,378           |
| Toshiba 5200          | 25  | RAM       | 5.2     | 96,438           |
| Compaq DeskPro 386/33 | 33  | Fixed     | 5.9     | 84,996 **        |
| Compaq DeskPro 386/33 | 33  | RAM       | 2.9     | 172,924          |

Note that all components reside on the disk type indicated (compiler, sources, TPUs and EXE that are output). Here's the DOS commandline that performs the compilation:

```
tpc /q /b tcalc
```

\*\* indicates the figure we will publish (85 K LPM)

## Article #16315: Making accelerators work with a TPageControl

Technical Information Database

TI1315D.txt - Making accelerators work with a TPageControl

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

The TPageControl found on the Win95 page of the Component Palette does not currently work with accelerators. However, it is possible to create a descendant of TPageControl which includes this feature.

The component shown in the code to follow is such a control. This TPageControl descendant captures the CM\_DIALOGCHAR message. This allows you to capture key strokes that may be accelerators for a given form. The CMDialogChar message handler uses the IsAccel function to determine if the captured key code refers to an accelerator on one of the TPageControls pages. If so, the appropriate page is made active and is given focus.

```
unit tapage;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, ComCtrls;

type

  TAPageControl = class(TPageControl)
  private
    procedure CMDialogChar(var Msg: TCMDialogChar); message
      CM_DIALOGCHAR;
  end;

procedure Register;
```

implementation

```
procedure TAPageControl.CMDDialogChar(var Msg: TCMDDialogChar);
var
  i: Integer;
  S: String;
begin
  if Enabled then
    for I := 0 to PageCount - 1 do
      if IsAccel(Msg.CharCode, Pages[i].Caption) and
        Pages[I].TabVisible then begin
        Msg.Result := 1;
        ActivePage := Pages[I];
        Change;
        Exit; // exit for loop.
      end;
    inherited;
  end;

procedure Register;
begin
  RegisterComponents('Test', [TAPageControl]);
end;

end.
```

## Article #16317: TP6 Marketing QNAs

Technical Notes Database

TN1317D.txt TP6 Marketing QNAs

Category :Pascal

Platform :All

Product :Turbo Pascal 6.0

Description:

Turbo Pascal 6.0  
Questions and Answers  
Draft 3 - Oct 22, 1990

### I. General Questions

#### A. Who is the target audience for Turbo Pascal 6.0?

Turbo Pascal 6.0 is targeted to the hundreds of thousands of MS-DOS application programmers who want to create professional looking applications but don't have time to write the code from scratch. Turbo Pascal 6.0 with Turbo Vision brings sophisticated application development within reach.

#### B. What are the major new features of Turbo Pascal 6.0?

The most important features of Turbo Pascal 6.0 are the Turbo Vision object-oriented application framework and the new Integrated Development Environment (IDE). These new features will increase productivity of application programmers using Turbo Pascal. In addition, Turbo Pascal Professional now includes a Turbo Drive compiler that can compile much larger programs using extended memory.

#### C. What is new in the Integrated Development Environment (IDE)?

The new Integrated Development Environment includes multi-file, multi-window editing with full mouse support and a macro language for customization. You can also set conditional breakpoints and view a register window while debugging. The new IDE includes Turbo Help, a hyper text system with help on the entire system as well as over 200 sample programs that can be automatically cut and paste

into an editor and compiled.

D. What has changed in the compiler from version 5.5 to 6.0? In addition to Turbo Vision and the new Integrated Development Environment (IDE) several changes have been made to the Pascal compiler itself in Turbo Pascal 6.0 to give programmers a more powerful development system. We have added inline assembler so that you can mix Pascal and assembly language easily. Turbo Pascal 6.0 now also generate 80286 code to take advantage of instructions on 80286 and 80386 processors for faster performance. The compiler supports privacy in objects. This allows you to declare object methods and fields as private therefore providing better encapsulation. Also, there is an extended syntax compiler directive ( $\$X+$ ) that allows you to ignore the return value of a function call treating thereby using a function as a procedure call. Lastly, Turbo Pascal Professional includes the Turbo Drive compiler that allows you to compile very large programs by using extended memory.

E. Does Turbo Pascal 6.0 use VROOMM?

Turbo Pascal 6.0's automatic overlay manager is based on the same technology as VROOMM (Virtual Real-Time Object-Oriented Memory Manager) used in Quattro Pro, Paradox and C++. Future versions of Turbo Pascal may incorporate all of the VROOMM technology.

F. How large a program can you create with the Turbo Drive compiler?

The Turbo Drive command line compiler can use as much extended memory as is available. Therefore you can compile programs that are several megabytes in size without removing debug information. However, the programs you create still run in real mode and therefore use Turbo Pascal's automatic overlay manager to run in 640K.

G. What is Turbo Drive?

Turbo Drive is a core Borland technology used to create applications that break the 640K DOS barrier by using extended memory. Turbo Drive is used in Turbo Pascal Professional as well as Turbo Debugger 286 and 386 and Paradox 3.5.

## II. Turbo Vision Questions

### A. What is an application framework?

An application framework is the basic architecture of your program, already developed, with all the building blocks inter-linked. Because Turbo Vision is object-oriented your applications automatically inherit a powerful, extensible user interface. The application framework includes an object library with support for event handling, user interface management and data management.

Turbo Vision is a major step forward that brings sophisticated user interfaces, including mouse support, windows and context sensitive help, to DOS programmers, without requiring complex programming. The end result is that programmers can create better programs in less time. Another advantage is that the Turbo Vision architecture is much easier to extend since the framework of every application is already in place.

### B. What type of data management objects are built-in?

Turbo Pascal 6.0 includes collections objects as well as streams that allow you to create persistent objects. All of the objects included in Turbo Vision can be stored on disk automatically using streams. The supplied objects can be used as the basis for more sophisticated user-written objects. In the future, a version of the Paradox Engine will also be accessible from Turbo Pascal.

### C. How large is Turbo Vision?

Turbo Vision includes over 50 objects and 350 methods. Since Turbo Vision is written in Turbo Pascal with assembly language it compiles to about 40K for a typical application. The result is that Turbo Vision is not only productive, but extremely efficient.

### D. How will people learn to program with Turbo Vision?

We have included a tutorial as well as reference documentation on programming with Turbo Vision. The Turbo Help system includes detailed coverage of Turbo Vision. There are also many sample programs included on disk. Programmers new to object-oriented programming may wish to refer to many of the third party books that feature more detailed tutorials on Turbo Vision programming.

E. Are there any royalty fees or runtime charges with Turbo Vision?

No. Programs written using Turbo Vision can be distributed without royalty fees or runtime charges.

F. Are there other application frameworks for MS-DOS?

Turbo Vision is the first application framework designed for MS-DOS. Other systems, such as MacApp on the Macintosh, are available on graphical systems.

G. How does Turbo Vision effect third party vendors?

Turbo Vision provides a solid foundation and rich architecture for third party vendors to build on. We expect that there will be a large marketplace for high-level application objects including communications, electronic mail, databases, spreadsheets, specialized financial, scientific and engineering objects and so on. All of these can be built on top of Turbo Vision to allow programmers to concentrate on their specific application domain and not on what it takes to put it on the screen and fit it into their own application architectures. Turbo Vision is the key component that will allow this kind of extensibility.

H. Will Turbo Vision be moved to the Turbo C++ platform?

Borland is committed to providing application frameworks across a variety of languages and platforms.

I. Will Turbo Vision be available for Windows?

Although the architecture and user interface of a Turbo Vision program is similar to that of a Windows program, Turbo Vision has been optimized for creating character based applications. A similar approach could be used for Windows though it would have to be optimized for a graphical environment.

### III. Other Questions

A. Is the Paradox Engine compatible with Turbo Pascal?

We are committed to making the Paradox Engine compatible with Turbo Pascal. This will give Turbo Pascal programmers additional power for creating applications that have sophisticated data management requirements.

B. Does Turbo Pascal support Microsoft Windows or OS/2 development?

Turbo Pascal 6.0 does not currently support Windows or OS/2 development. We plan to support both platforms in future releases of the product and we have committed significant development resources toward this end. We will first deliver products for Windows and follow with products for OS/2. Both Windows and OS/2 are emerging platforms that are a key part of our Turbo language strategy. Programmer's using Turbo Vision today will be creating applications that have the same architecture as is found on Windows and Presentation Manager.

C. Are Turbo Pascal objects compatible with Turbo C++?

Currently Turbo Pascal objects are not compatible with C++. We are examining ways to improve compatibility between Turbo Pascal and Turbo C++ to allow programmers to use a common object format.

D. Does Turbo Pascal support multiple inheritance?

Turbo Pascal does not support multiple inheritance and thus an object can only inherit from one ancestor object. Although multiple inheritance adds flexibility, it also adds complexity for the programmer. Single inheritance provides the greatest amount of reusability with the least amount of additional complexity.

#### IV. Pricing and Availability Questions

A. When will Turbo Pascal 6.0 be available?

Turbo Pascal 6.0 is shipping immediately!

B. What is the retail pricing for Turbo Pascal 6.0?

Turbo Pascal \$149.95

Turbo Pascal Professional \$299.95

(includes Turbo Pascal, Turbo Drive Compiler, Turbo Debugger, Turbo Assembler, Turbo Profiler)

Educational Pricing (Scholar Program)

Turbo Pascal \$39.95

C. What is the price of the Runtime Library?

The Runtime Library, including source code to Turbo Vision, is \$199.95. Current owners of the Runtime Library can upgrade for \$99.95.

D. What is the upgrade path for current Turbo Pascal customers?

We are offering registered of any version of Turbo Pascal an upgrade price of \$69 for Turbo Pascal 6.0 and \$95 for Turbo Pascal Professional.

## Article #16321: How to dynamically create a TPageControl

Technical Information Database

TI1321D.txt - How to dynamically create a TPageControl

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This document demonstrates how to dynamically add tab sheets (TTabSheet objects) to a Windows 9x/NT Page Control (TPageControl object). Both of these objects are declared in the ComCtrls unit. So make sure that ComCtrls is listed in the 'uses' clause on your form.

### HOW TO DYNAMICALLY CREATE A PAGE CONTROL

-----

Before we get into dynamically creating tab sheets, lets first discuss how to dynamically create a PageControl (if one isn't on the form already). This is done by calling TPageControl's Create constructor with an owner parameter of Self. The Create constructor returns a object reference of the newly created Page Control object and assigns it to the 'PageControl' variable. The second step is to set PageControl's Parent property to Self. The Parent property determines where the new PageControl is to be displayed; in this case its the form itself. Here's a code snippet that demonstrates this.

```
var  
    PageControl : TPageControl;  
  
PageControl := TPageControl.Create(Self);  
PageControl.Parent := Self;
```

Note: When the form gets destroyed the Page Control and it tab sheets will be destroyed also because they are owned by the form.

## HOW TO DYNAMICALLY CREATE A TAB SHEET

---

There are two basic steps to dynamically add a new page to a PageControl. The first is to dynamically create the TTabSheet as follows:

```
var
  TabSheet : TTabSheet;

TabSheet := TTabSheet.Create(Self);
```

Then we need to give it a caption as follows:

```
TabSheet.Caption := 'Tabsheet 1';
```

And finally, the most important piece is to tell the new tab sheet which Page Control it belongs to. This is done by assigning the TTabSheet's PageControl property a TPageControl reference variable like the one created above (PageControl). Here's a code snippet that demonstrates this.

```
TabSheet.PageControl := PageControl;
```

## HOW TO DYNAMICALLY ADD A CONTROL TO A TAB SHEET

---

The key to creating and placing any control on a tab sheet is to assign it's Parent property a TTabSheet class reference variable. Here is an example.

```
var
  Button : TButton;

Button := TButton.Create(Self);
Button.Caption := 'Button 1';
Button.Parent := TabSheet;
```

For more information on the TPageControl and TTabSheet objects refer to the on-line documentation as well as look at the ComCtrls.pas file in your ..\Delphi..\SOURCE\VCL directory.

## FULL SOURCE EXAMPLE

---

```
// This code is extracted from a form with a single button on it.
```

```
unit DynamicTabSheetsUnit;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls,  
  Forms, Dialogs, StdCtrls, Buttons;
```

```
type
```

```
  TForm1 = class(TForm)  
    Button1: TButton;  
    procedure Button1Click(Sender: TObject);  
    procedure TestMethod(Sender: TObject);  
  private  
    { Private declarations }  
  public  
    { Public declarations }  
  end;
```

```
var
```

```
  Form1: TForm1;
```

```
implementation
```

```
uses ComCtrls;
```

```
{ $R *.DFM }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  PageControl : TPageControl;  
  TabSheet : TTabSheet;
```

```
begin
```

```
  // Create the PageControl  
  PageControl := TPageControl.Create(Self);  
  PageControl.Parent := Self;
```

```
  // Create 1st page and associate it with the PageControl  
  TabSheet := TTabSheet.Create(Self);  
  TabSheet.Caption := 'TabSheet 1';  
  TabSheet.PageControl := PageControl;
```

```
// Create the first page

with TButton.Create(Self) do
begin
    Caption := 'Button 1';
    OnClick := TestMethod; // Assign an event handle
    Parent := TabSheet;
end;

// Create 2nd page and associate it with the PageControl

TabSheet := TTabSheet.Create(Self);
TabSheet.Caption := ' Tabsheet 2';
TabSheet.PageControl := PageControl;
end;

procedure TForm1.TestMethod(Sender: TObject);
begin
    ShowMessage('Hello');
end;

end.
```

## Article #16323: TP6.0 Hot Sheet

Technical Notes Database

TN1323D.txt TP6.0 Hot Sheet

Category :Pascal

Platform :All

Product :Turbo Pascal 6.0

Description:

TP6.0 Hot Sheet

November 7, 1990

### Feature Highlights

- o NEW! state-of-the-art integrated development environment (IDE)

- Multiple overlapping windows

- Mouse Support

- Multi-file editor that can edit files up to 1MB

- Enhanced debugging facilities

- NEW! Conditional breakpoints

- Step over and trace into

- Watch expressions

- Evaluate/modify

- Call stack

- NEW! Register viewer

- complete save and restore of desktop

- o NEW! Object Oriented application framework, Turbo Vision, for use in your applications.

- o NEW! full featured inline assembler (BASM)

- o NEW! private fields and methods in object declarations

- o extended syntax directive (\$X) that lets you treat functions like procedures (and ignore function results)

- o NEW! 286 code generation
- o address references in typed

constants

- o far and near procedures directives (\$F)
- o link in initialized data (\$L) from object files
- o NEW! heap manager is faster and reduces fragmentation
- o Built in Overlay Manager based on VROOM (Virtual Run-time Object-Oriented Memory Manager) technology, used in Turbo C++, Paradox and Quattro Pro. Supports EMS.
- o Borland Graphics Interface (BGI)  
Smart linker removes unused objects and code
- o complete math coprocessor emulation and support - 8087/80287/80387
- o enhanced hypertext online help facilities, with complete cut and paste example code for every library procedure and function.
- o Online Tutorial (TPTOUR)

### System Requirements

IBM PC or PS/2 and all 100% compatibles  
PC/MS-DOS 2.0 or later  
Dual Floppy drive (hard disk recommended)  
(5.5MB of total free disk space for TP6.0 Professional)

### Memory/Storage Requirements

|                         | Memory | Storage  |
|-------------------------|--------|----------|
| Turbo Pascal 6.0        |        |          |

#### Benchmarks

| Machine               | MHz | DiskType | Seconds | Lines/Min |
|-----------------------|-----|----------|---------|-----------|
| IBM PS/2 Mod 60       | 8   | RAM      | 14.7    | 34,114    |
| Toshiba 5200          | 20  | Fixed    | 11.3    | 44,378    |
| Toshiba 5200          | 20  | RAM      | 5.2     | 96,438    |
| Compaq DeskPro 386/33 | 33  | Fixed    | 5.9     | 84,996    |
| Compaq DeskPro 386/33 | 33  | RAM      | 2.9     | 172,924   |

#### Documentation

Turbo Pascal 6.0 includes:

User's Guide

Programmer's Guide

Turbo Vision Guide

Library Reference

In addition Turbo Pascal Professional includes:

Turbo Debugger User's Guide

Turbo Profiler User's Guide

Turbo Assembler User's Guide

Turbo Assembler Reference Guide

# Turbo Assembler Quick Reference

## Pricing Information

- o Turbo Pascal 6.0 \$149.95
- o (Scholar Program \$39.95)
- o Turbo Pascal Professional 6.0 \$299.95

NEW! Turbo Driven Protected-mode compiler

Turbo Debugger

2.0

Turbo Assembler 2.0

Turbo Profiler 1.0

- o Turbo Pascal RTL \$199.95

Full RTL Source code

NEW! Full Turbo Vision Source Code

## Upgrade Information

- o Turbo Pascal x.x to Turbo Pascal 6.0 \$69.95
- o Turbo Pascal x.x to Turbo Pascal Professional \$99.95\*\*\*
- o Turbo Pascal RTL x.x to Turbo Pascal 6.0 RTL \$99.95
- o Turbo Pascal 6.0 to Turbo Pascal Professional (Disk Only)  
\$30.00

\*\*\*Turbo Pascal Professional is the preferred upgrade path. Includes TPCX.EXE the protected mode command line compiler that is not available

with the standard edition. This is the suggested upgrade even if you currently own the Turbo Debugger, Assembler and Profiler.

## Article #16327: BDE Callbacks to Provide Status on Operations

Technical Information Database

TI1327D.txt - BDE Callbacks to Provide Status on Operations

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This TI demonstrates using a BDE DbiParam function to drive a progress bar during a lengthy batch move operation under the 32-bit versions of Delphi.

Additional documentation on BDE function calls can be found in the file BDE32.HLP (located in the directory where the 32 bit IDAPI is installed).

When you install a callback function to the BDE, the BDE will "call back" to a function in your application, letting your application know when certain events take place, and in some cases, allow your application to return information back to the BDE.

The BDE defines several callback types that may be installed:

during large batch operations.  
requests a response from the caller.

This TI details installing a cbGENPROGRESS callback to drive a progress bar in your application.

To do this, first call the DbiParam() function to retrieve the handle to any callback that might already be installed (and it's parameters), and save this information to a data structure. Then install your callback, replacing any previous callback installed.

You will need to pass a pointer the data structure containing

the information to the previously installed callback to the BDE when you install your callback, so when your callback function is executed, you can call the original callback (if one is installed).

The BDE will call back to your application every so often, reporting either a text message containing the number of records it has processed or how far the batch move has progressed, expressed as an integer percentage. Your callback should be able to deal with either of these situations. If the percentage field of the callback structure is greater than -1, then the percentage is correct and you are free to update your progress bar. If the percentage reported is less than zero, the callback has received a text message in the szTMsg field containing a message that includes the number of records processed. In this case, you will need to parse the text message and convert the remaining string to an integer, then calculate the percentage done and update the progress bar.

Finally, when your batch move is complete, you will need to un-register your callback, and reinstall the previous callback function (if it exists).

The following code example is based on a form containing two tables, a batch move component, a progress bar, and a button.

----- Code Follows -----

```
unit Testbc1;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, StdCtrls, Grids, DBGrids, DB, DBTables, ComCtrls;

type
  TForm1 = class(TForm)
    Table1: TTable;
    BatchMove1: TBatchMove;
    Table2: TTable;
    Button1: TButton;
    ProgressBar1: TProgressBar;
    procedure Button1Click(Sender: TObject);
```

```
private
  { Private declarations }
public
  { Public declarations }
end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
uses Bde; {Dbi Types and Procs are located here}
```

```
{$R *.DFM}
```

```
{data structure type to save previous callback info}
```

```
type TDbiCbInfo = record
  ecbType      : CBType;
  iClientData  : longint;
  DataBuffLn   : word;
  DataBuff     : pCBPROGRESSDesc;
  DbiCbFn      : pointer;
```

```
end;
type PDbiCbInfo = ^TDbiCbInfo;
```

```
{Our callback function}
```

```
function DbiCbFn(ecbType      : CBType;
                 iClientData  : Longint;
                 CbInfo       : pointer): CBRTYPE stdcall;
```

```
var
  s : string;
begin
  {Check to see if the callback type is what we expect}
  if ecbType = cbGENPROGRESS then begin
    {if iPercentDone is less than zero then extract the number}
    {of records processed from szMsg parameter}
    if pCBPROGRESSDesc(CbInfo).iPercentDone < 0 then begin
      s := pCBPROGRESSDesc(CbInfo).szMsg;
      Delete(s, 1, Pos(':', s) + 1);
      {Calculate percentage done and set the progress bar}
      Form1.ProgressBar1.Position :=
        Round((StrToInt(s) / Form1.Table1.RecordCount) * 100);
    end else
      begin
```

```

DbiCbFn);

Form1.ProgressBar1.Position := 0;
BatchMove1.Execute;

{if a previous callback exists - reinstall it else}
{unregister our callback}
if OldDbiCbInfo.DbiCbFn <> nil then
    DbiRegisterCallBack(Table2.Handle,
                        cbGENPROGRESS,
                        OldDbiCbInfo.iClientData,
                        OldDbiCbInfo.DataBuffLn,
                        OldDbiCbInfo.DataBuff,
                        OldDbiCbInfo.DbiCbFn) else
    DbiRegisterCallBack(Table2.Handle,
                        cbGENPROGRESS,
                        longint(
OldDbiCbInfo),
                        SizeOf(cbDataBuff),
cbDataBuff,
                        nil);

{lets show our success!}
Table2.Open;

end;

end.

```

## Article #16329: TP6 Fact Sheet (Draft 1.0)

Technical Notes Database

TN1329D.txt TP6 Fact Sheet (Draft 1.0)

Category :Pascal

Platform :All

Product :Turbo Pascal 6.0

Description:

Fact Sheet

TURBO

PASCAL 6.0

PROFESSIONAL

TURBO PASCAL 6.0 PROFESSIONAL:

PROGRAMMING WITH VISION

New Turbo Pascal 6.0 includes Turbo Vision, the first object-oriented application framework for MS-DOS. With Turbo Vision, your applications automatically inherit a multi-window, mouse-based user interface. Turbo Pascal 6.0 also includes a new Integrated Development Environment with multiple windows and mouse support. So not only can you build better programs, you can do it faster than ever.

Turbo Pascal 6.0 Professional features Turbo Pascal 6.0 together with Turbo Debugger, the standard tool for object-oriented debugging, and Turbo Profiler and Turbo Assembler. A protected-mode Turbo Pascal compiler that frees conventional memory and lets you compile extra-large applications is included in the Professional package to complete your inventory of professional programming tools.

TURBO PASCAL 6.0 PROFESSIONAL

NEW! Turbo Vision

NEW! Integrated Development Environment

NEW! Inline assembler

NEW! Conditional breakpoints

NEW! Protected-mode compiler

Object-oriented programming extensions include:

Inheritance

Static and virtual methods

Static and dynamic objects

Constructors and destructors

NEW! Private methods and data fields

Integrated debugger with object support

Turo help hypertext system with copy and paste

High speed--compiles more than 50,000 (80,000?) lines per minute

Enhanced smart linker removes unused objects and code

Complete math coprocessor emulation and support--8087/80287/80387

State-of-the-art overlay management

#### PACKAGED APPLICATIONS WITH TURBO VISION

Turbo Vision is the first object-oriented application framework for DOS. It provides Turbo Pascal programmers with a solid architecture on which to build all their applications. Just as the same steel-girder framework can be used to build a school, an apartment house, or a hospital, so Turbo Vision provides programmers with an inheritable object hierarchy suitable for packaging applications. Programmers no longer have to reinvent features; their programs inherit them.

Turbo Vision is a professional tool. To prove it, we wrote our new IDE using Turbo Vision (and we wrote it in record time!). With the new IDE, you can write your programs, compile, run, and debug them within a single integrated environment. And you can do

it all on the leading edge of technology--with the Turbo Vision application framework.

Turbo Pascal 6.0, with Turbo Vision, OOP, units, an enhanced smart linker, and an intelligent, unit-based overlay manager give you the ability to create large and complex programs easily.

#### INTEGRATED DEBUGGING--

##### THE LEADER OF THE PACK

With Turbo Pascal, you can debug your programs without leaving the comfort of the integrated environment. Examine objects and their associated methods. Step over or single-step through each line of your program, watching your variables as they change with each statement. Set conditional breakpoints. Watch and evaluate variables, data structures, and expressions. Assign new values to your variables and data structures while debugging. With this visibility into your code, you can find and fix errors with greater ease.

#### HELP!

Turbo Pascal's indexed and cross-referenced online Turbo Help hypertext system uses hypertext to give context-sensitive help on a comprehensive range of topics. There's an example for every standard Turbo Pascal procedure and function. If you see something you'd like to use, the IDE lets you copy it from Help into your program in the editor. A separate RAM-resident program offers you the identical help from anywhere in your system (not just inside the integrated environment), and only uses 25K of memory. (Have we dropped this?)

#### EDITING MADE EASY

Automatic indenting and outdenting, search and replace, and block operations (mark, move, copy and delete) all make editing your programs faster and easier. And Turbo Pascal automatically uses expanded memory (EMS), freeing up to 400K of real memory for compilation. If you prefer to use your own editor, a command-line version of Turbo Pascal is included in your package.

#### NEW! INLINE ASSEMBLER

Sometimes you need to drop down to assembly language for extra speed or control. Turbo Pascal 6.0 makes it easy to mix Pascal and assembly language code in your programs. The ability to mix Pascal and assembler gives programmers the edge in creating fast applications in less time.

## UNITS--PERFECT YOUR PROGRAM

### PIECE BY PIECE

Units are separate source code modules, written and compiled individually, that can be called by your program or other units. Since a single unit can be used by many different programs, you can get it right once and not bother with it again. With units, you can build your own library of flawless code to use over and over again.

## OVERLAY MANAGEMENT--

### BIGGER PROGRAMS, GREATER SPEED

Feeling cramped by the 640K barrier? Turbo Pascal's improved overlay manager allows you to write programs of unlimited size. It's based on Borland's VROOMM (Virtual Realtime Object-Oriented Memory Manager) technology, used in Quattro Pro and Paradox. Using the sophisticated "least recently used" (LRU) algorithm and EMS (if available), the overlay manager runs your overlaid programs fast. And all you have to do is to call an initialization routine and specify which units may be overlaid.

## MATH COPROCESSOR SUPPORT

Turbo Pascal offers full math coprocessor emulation and support. This lets you take advantage of the high-precision, high-speed math capabilities provided by the 8087, 80287, or 80387 math coprocessor chips when present, yet your programs will work even if one isn't there.

## GRAPHICS

The Borland Graphics Interface (BGI) lets you easily use graphics and animation in your programs. Turbo Pascal's complete graphics library has more than 70 functions that you can use to draw and fill shapes, create viewports, produce multiple-font text, and handle bit-level images. BGI supports a wide variety of graphics adapters: VGA, EGA, CGA, MCGA, Hercules, ATT400, IBM 8514, and PC3270.

## CUSTOMIZABLE

Borland knows that you want to make Turbo Pascal your very own. The IDE comes with a sophisticated macro language that allows you to customize your editor command keys. The IDE's pull-down menus allow you to modify default settings, change your screen colors, and more.

## SOLID SUPPORT

When you need help, Borland's experienced Technical Support Group

is there for you. Borland's Support Group has earned a reputation in the industry as being one of the best there is. Why? Because our customers are treated with courtesy and concern, and receive sound technical knowledge from professionals well-versed in the products they support.

#### THE RUNTIME LIBRARY

Professional programmers often wish they could change standard functions and procedures slightly to better work with the application at hand. As part of our open-architecture policy, Borland offers users the Turbo Pascal 6.0 runtime library, including the source for Turbo Vision, at moderate additional cost. The runtime library source provides you with a broad range of state-of-the-art functions, including graphics, I/O, math coprocessor emulation, sorting and searching, DOS interfacing, and overlay management. You can use these routines just as they are, or you can customize them to fit your exact needs. Either way, you save valuable time by incorporating proven, professional, customizable code in your programs.

#### TURBO PASCAL 6.0 PROFESSIONAL

INCLUDES THE POWER AND PERFORMANCE OF TURBO ASSEMBLER, TURBO DEBUGGER AND TURBO PROFILER

When you have Turbo Pascal 6.0 Professional, you have the right tools to undertake your most complicated applications. Turbo Pascal, Turbo Debugger, Turbo Profiler, and Turbo Assembler work beautifully together. You don't have to do anything special to move from one to another. Write your Turbo Pascal program, debug it with Turbo Debugger, find the bottlenecks with Turbo Profiler, then link in Turbo Assembler code for optimum speed.

#### TURBO DEBUGGER 2.0

Turbo Debugger 2.0 supports object-oriented debugging in Turbo Pascal, and has the breakthrough capabilities you need to find the toughest bugs:

Undo multiple instructions with reverse execution

Debug using Turbo Drive(TM) 286 protected mode, 386 virtual mode, and remote debugging to fix programs of any size

Browse your object hierarchy; inspect classes and objects; walk through structures and records; follow linked lists

Edit with multiple overlapping windows, mouse support, icons,

dialog boxes, and scroll bars in the new user interface

Examine your program in 13 different views, including breakpoints, watch, and CPU

Catch bugs with the powerful breakpoint facility (including hardware breakpoints)

Debug TSRs and device drivers

Debug using the built-in assembler

Record and playback keystrokes

Use in 25-, 43-, or 50-line mode

#### OBJECT DEBUGGING

In addition to letting you examine and debug data structures, Turbo Debugger offers a feature unique among debuggers: You can debug objects as well. This means you can browse through your all of your data structures and objects and view their contents, follow pointers, walk down linked lists, and examine methods. You can even change the value of structure and object members. Turbo Debugger allows you to debug object instances as easily as data structures. Turbo Debugger's hierarchy browser gives you a high-level view of your object hierarchy, its easy to find the source of bugs inherited by objects.

#### YOU ARE IN CONTROL!

Turbo Debugger can directly undo the execution of CPU instructions or source lines to help you to find the most difficult bugs. In addition, Turbo Debugger provides keystroke recording and playback, so you can find bugs triggered by long and involved sequences of user input.

#### DEBUG PROGRAMS OF ANY SIZE

286 protected mode: Load Turbo Debugger itself into extended memory and use only 70K of real memory.

386 virtual machine mode: Run Turbo Debugger entirely from extended memory, giving every all of conventional RAM to the program you're debugging.

Remote debugging: Run Turbo Debugger on one computer to debug

programs on another, using only 15K on the target system.

EMS support: Take advantage of EMS memory for symbol table caching, leaving more room for your program.

Two monitors on one machine: Run Turbo Debugger on one screen, your program on the other. This method is especially useful for debugging programs that contain graphics.

#### POWERFUL BREAKPOINTS GIVE YOU GREATER CONTROL OVER YOUR DEBUGGING SESSIONS

You can define Turbo Debugger's breakpoints in three ways: where the breakpoint occurs, the condition under which the break is triggered, and what happens when the break occurs. {Shall we drop this paragraph?}

#### ASSEMBLER AND SOURCE LEVEL POWER

Debug at the source code level using the module window. If you prefer, debug at the assembler level, by opening the CPU window. Open both windows to debug your program's source and machine code side by side.

#### TURBO PROFILER 1.0 BEYOND OPTIMIZATION

Turbo Profiler takes you beyond optimization by giving you the information you need to optimize your algorithms and data structures. An optimizing compiler generates the fastest possible executable code for the program you give it. Turbo Profiler goes one step further by helping you enhance the design of the program for maximum performance.

#### PROFILE THE EXECUTION OF YOUR PROGRAMS

Turbo Profiler gives you a profile of the execution of your program, graphically displaying where your program is spending its time. It interactively measures your program, allowing you to identify bottlenecks in your code and fine-tune the design for optimal performance. Turbo Profiler brings performance analysis to the mainstream of PC programming.

Turbo Profiler measures:

Where time is spent in your program

How many times a line is executed

How many times a routine is called and from where

What files are accessed most often and for how long

When and where resources such as (CPU, disk, keyboard, printer, and interrupts) are consumed

#### EASY TO USE

With its multiple overlapping windows, icons, mouse support, and context-sensitive online help, Turbo Profiler's intuitive user interface lets you become productive immediately, whether you've used a profiler before or not. Using easy-to-read histograms, Turbo Profiler makes it clear where your program is consuming time.

#### PROFILE PROGRAMS OF ANY SIZE

Using the same advanced technology as Turbo Debugger, Turbo Profiler can profile programs of any size by using a 386 or remote profiling.

#### MULTIPLE VIEWS

Turbo Profiler provides many ways to see into your program. The Execution Profile view tells you how many times and how often your program's modules, functions, and individual lines are executed. You can tell Turbo Profiler which lines, routines, and modules you are interested in from the Module view. The File Activity view shows you how many times and for how long each file is accessed, and how many bytes are read from or written to it. You can view DOS interrupt and overlay activities from the Interrupt and Overlay views. A total of nine different windows allow you to thoroughly inspect your program's performance.

#### TURBO ASSEMBLER 2.0

Multi-pass optimizing assembler with NOP squishing

MASM compatible and two to three times faster than MASM

Generates assembler code for 8086, 80286, 80386, and 80486

Ideal mode supports extended syntax and MASM

CALL statement allows inclusion of arguments and optional languages

Generates Microsoft Windows-compatible code from your DOS program  
(no macros!)

Assembles multiple files at the same time

Allows named local labels, nested structures and unions

#### BETTER THAN MASM

Turbo Assembler offers a superior professional alternative to Microsoft Assembler (MASM). Turbo Assembler is compatible with MASM 4.0, 5.0, and 5.1--even more so than MASM itself. MASM 5.1 can't claim full compatibility with earlier versions of MASM--Turbo Assembler can.

#### QUIRKS MODE

MASM has what can best be described as "quirks." Anomalies. Things that don't work the way you might expect. Some programmers have learned to work with them; their code needs special support. So Turbo Assembler has a Quirks mode that fully duplicates the functioning of MASM quirks. Programs written to use those quirks run under Turbo Assembler.

#### IDEAL MODE

When you're first learning assembly language, you can benefit from Turbo Assembler's Ideal mode, with simplified parsing methods, improved consistency, and stricter type-checking. Ideal mode makes learning Turbo Assembler painless for the beginner since it's simpler to learn. And for the expert, programs are easier to read and write. You can use Standard MASM mode, Quirks mode, and Ideal mode all in the same program, taking advantage of Turbo Assembler's new features while maintaining compatibility with your existing MASM code.

#### TECHNICAL SPECIFICATIONS

##### SYSTEM REQUIREMENTS

##### COMPUTER AND STORAGE REQUIREMENTS

For the IBM PS/2, the IBM family of personal computers, and all 100% compatibles. A hard disk with a minimum of \_\_\_\_\_MB free storage is required.

## OPERATING SYSTEM

PC-DOS (MS-DOS) 2.0 or later

## MEMORY AND STORAGE REQUIREMENTS

## A FAST OBJECT LESSON

Object-oriented applications model the way we think, and application frameworks like Turbo Vision model the way we build. Objects and object hierarchies are easy to extend and easier to maintain. Objects contain both data and code, and Turbo Vision fulfils the potential of objects. As in a spreadsheet cell, the

value and the formula are together. Objects can inherit properties from other objects, and Turbo Vision takes maximum advantage of this feature. Your applications inherit characteristics of a prepackaged application framework. Your application can have mouse support, dialog boxes, and overlapping windows, all of which are inherited from Turbo Vision.

Objects are intelligent, too. Clicking the mouse on a radio button inside of a dialog box has a different result from mousing on a zoom box or scroll bar.

Turbo Pascal's object-oriented extensions are fast, efficient, and elegant. You get the full power of inheritance, data abstraction, and late binding. For maximum flexibility, you can allocate dynamic objects referenced through pointers. For maximum efficiency, you can declare static objects and object constants that are referenced directly. Static and virtual methods can both be used in the same program for maximum performance and extensibility. Constructors and destructors make creating, initializing, and disposing of dynamic objects simple and reliable. They also reduce errors, save programming time, and improve readability.

With Turbo Pascal Objects, your code is compact, flexible, and reusable. With Turbo Vision, your applications acquire a polished look without a lot of perspiration. What's more, your programs become easier to extend and easier to maintain. Object-oriented programming with Turbo Pascal and Turbo Vision is programming that makes sense.

## Article #16333: Accessing Paradox Tables on CD or Read-Only Drive

Technical Information Database

TI1333D.txt Accessing Paradox Tables on CD or Read-Only Drive

Category :Database Programming

Platform :All

Product :Delphi All

### Description:

This Technical Information document will step through the concepts regarding accessing Paradox tables which are located on a CD-ROM or any read-only device.

The Paradox locking scheme requires the existence of a PDOXUSRS.LCK file to handle its locking logic. This file is generally created at run-time and resides in the directory which also contains the tables. However, with a CD-ROM there is not a way to create this file at run-time on the CD-ROM. The solution is simple, we create this file and put it on the CD-ROM when the CD is pressed. The following steps will give you a very simple utility program for creating the PDOXUSRS.LCK file which you will then copy to the CD-ROM image.

1. Starting with a blank project add the following components: TEdit, TButton and TDatabase.

2. In the OnClick event for the button use the following code:

```
procedure TForm1.Button1Click(Sender: TObject);
begin
    if ChkPath then
        Check(Db1AcqPersistTableLock(Database1.Handle,
            'PARADOX.DRO', 'PARADOX'));
end;
```

3. The ChkPath function is a user defined method of the form. It will simply check the path entered in the Edit box and make sure it exists.

Here is the function:

```

function TForm1.ChkPath : Boolean;
var
  s : array[0..100] of char;
begin
  If DirectoryExists(Edit1.Text) then begin
    DataBase1.DatabaseName:= 'TempDB';
    DataBase1.DriverName:= 'Standard';
    DataBase1.LoginPrompt:= false;
    DataBase1.Connected := False;
    DataBase1.Params.Add('Path=' + Edit1.Text);
    DataBase1.Connected := TRUE;
    Result := TRUE;
  end
  else begin
    StrPCopy(s,'Directory : ' + Edit1.text + ' Does Not Exist');
    Application.MessageBox(s, 'Error!', MB_ICONSTOP);
    Result := FALSE;
  end;
end;

{ Note: Don't forget to put the function header in the public section
  of the form.}

```

4. There is one more thing you need to add before compiling, in the Uses statement at the top of the unit add the following units:

```

Delphi 1.0: FileCtrl, DbiProcs, DbiTypes, DbiErrs.
Delphi 2.0: FileCtrl , BDE

```

When you have compiled and executed the utility program, it will create two files in the directory you specified. The two files created are: PDOXUSRS.LCK and PARADOX.LCK.

Note: The PARADOX.LCK file is only necessary when accessing Paradox for DOS tables so you can delete it.

5. The only thing left for you to do is copy the remaining file (PDOXUSRS.LCK) to the CD-ROM image. Of course your tables will be Read-Only.

Note: If you want to clean up this utility for future use, you can

change the text property of the Edit box to be some default directory and change the Caption property of the Button to be something more meaningful.

Here is the final version of the code:

```
unit Unit1;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls,
  Forms, Dialogs, DB, StdCtrls, FileCtrl,

  {$IFDEF WIN32}
    BDE;
  {$ELSE}
    DbiProcs, DbiTypes, DbiErrs;
  {$ENDIF }

type
  TForm1 = class(TForm)
    Edit1: TEdit;
    Button1: TButton;
    Database1: TDatabase;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
    function ChkPath : Boolean;
  end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

function TForm1.ChkPath : Boolean;
var
  s : array[0..100] of char;
```

```

begin
  If DirectoryExists(Edit1.Text) then begin
    DataBasel.DatabaseName:= 'TempDB';
    DataBasel.DriverName:= 'Standard';
    DataBasel.LoginPrompt:= false;
    DataBasel.Connected := False;
    DataBasel.Params.Add('Path=' + Edit1.Text);
    DataBasel.Connected := TRUE;
    Result := TRUE;
  end
  else begin
    StrPCopy(s,'Directory : ' + Edit1.text + ' Does Not Exist');
    Application.MessageBox(s, 'Error!', MB_ICONSTOP);
    Result := FALSE;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  if ChkPath then
    Check(DbAcqPersistTableLock(DataBasel.Handle,
      'PARADOX.DRO', 'PARADOX'));
end;

end.

```

## Article #16339: Synchronize a DLL to an Open Dataset

Technical Information Database

TI1339D.txt Synchronize a DLL to an Open Dataset

Category :Database Programming

Platform :All

Product :Delphi 2.0

### Description:

Synchronize a DLL to an Open Dataset

This document demonstrates how to use Object Pascal to link a DLL dynamically, on-the-fly, into an active Database, thus, giving the Developer the ability to 'Modularize' features. (Whether at Run-Time or Design-Time)

The technique of linking a DLL Dynamically into an EXE is useful in many cases. Examples include, an Accounting package which offers several 'plug-in' modules (A/R, A/P, General Ledger, etc.) or a Point of Sale package with Current Stock, FIFO/LIFO Ordering, Vendor Tracking, etc., modules.

This TI will provide a solid example of how to do this with one dll, 'Editdll.dll', but will give the Developer the essentials leading to extensive modularation in projects.

### Prerequisites:

-----  
Familiarity with the TTable component, DLL usage, BDE API, and BDE hCursor knowledge. \*WIN API for Dynamical loading of any DLL's.

### SAMPLE APPLICATION

The following form, EditForm, is based on the COUNTRY table in the DBDEMO's directory. When the user presses the 'Edit' button or double-clicks a record (row), a dialog box appears, from 'EditDll.dll',

displaying record specific information. At this point, the DLL has synchronized itself not only with the dataset (& session) but also with the current record. This mean's, the user can now modify the same data EditForm is viewing! So, with no ado, let's delve into the sample code.

(For best results, simply cut and paste into appropriate files)

```
>Main Form Project<
```

```
-----
```

```
{ MAINDB.DPR }  
program maindb;
```

```
uses
```

```
    Forms,  
    mainform in 'mainform.pas' {DBMainForm};
```

```
{ $R *.RES }
```

```
begin
```

```
    Application.Initialize;  
    Application.CreateForm(TDBMainForm, DBMainForm);  
    Application.Run;
```

```
end.
```

```
>>
```

```
{ MAINFORM.PAS }  
unit mainform;
```

```
interface
```

```
uses
```

```
    SysUtils, Windows, Messages, Classes, Graphics, Controls,  
    StdCtrls, Forms, DBCtrls, DB, DBGrids, DBTables, Grids, ExtCtrls,  
    BDE;
```

```
type
```

```
TDBMainForm = class(TForm)

private
  { private declarations }
public
  { public declarations }
end;

```

```

var
  DBMainForm: TDBMainForm;

```

```

implementation

```

```

{$R *.DFM}

```

```

procedure TDBMainForm.FormCreate(Sender: TObject);
begin
  Table1.Open;
end;

```

```

// {NOTES: DBHandle is a Handle to the Database & DSHandle is a
cursor
// to the record being viewed. Also, if the purpose is to
dynamically
// load a DLL at run-time, use the LoadLibrary, GetProcAddress, and
// FreeLibrary API calls in place of the implicit load calls at
startup.
// An Example of the APICalling convention is: }
// Type
// {For GetProcAddress}
// BDEDataSync =
//   function(const DBHandle: HDBIDB; const DSHandle: HDBICur):
Boolean;
//           stdcall;
// {For the trapping of DLL load error's}
// EDLLLoadError = class(Exception);
// var h: hwnd;

```

```

//      p: BDEDataSync;
//      LastError: DWord;
// begin
// UpdateCursorPos;
// Try
//   h := loadLibrary('EDITDLL.DLL');
//   {NOTE to Delphi 1.0 users: Whereas Win32 LoadLibrary returns a
//   NULL if the DLL load was unsuccessful, thus requiring a call to
//   GetLastError to find the error, Win16 LoadLibrary returns
//   an error value (less than HINSTANCE_ERROR) which can be checked
//   in the Win16API SDK as to the reason for the failure.}
//   if h = 0 then begin
//       LastError := GetLastError;
//       Raise EDLLLoadError.create(IntToStr(LastError) +
//                                   ': Unable to load DLL');
//       end;
//   try
//       p := getProcAddress(h, 'EditData');
//       if p(DBHandle, Handle) then Resync([]);
//   finally
//       freeLibrary(h);
//   end;
// Except
//   On E: EDLLLoadError do
//       MessageDLG(E.Message, mtInformation, [mbOk],0);
// end;
// end;
// {or}

## Article #16345: Clean-Boot 32 bit Delphi Installation

Technical Information Database

TI1345D.txt - Clean-Boot 32 bit Delphi Installation

Category :Install Issues  
Platform :All-32Bit  
Product :All32Bit,

Description:

-----  
HOW TO INSTALL DELPHI IN A CLEAN-BOOT ENVIRONMENT IN WINDOWS 9x  
-----

CONTENTS

-----  
Section 1: INTRODUCTION  
Section 2: WHAT IS SAFE MODE?  
Section 3: HOW TO BOOT-UP WINDOWS 95 IN SAFE MODE

-----  
Section 1: INTRODUCTION  
-----

This document demonstrates how to do a clean-boot installation for the desktop and Client/Server versions of Delphi 1.0, and the all other versions of Delphi in Windows 95.

-----  
Section 2: WHAT IS SAFE MODE?  
-----

An important feature that comes with Windows 95 is the "Safe Mode" option. "Safe Mode" is one of the several different ways of loading Windows 95. In "Safe Mode", Windows 95 does not load and use any of your device drivers installed in your system, including your video card, sound card, modem, monitor, mouse, joysticks, etc. Instead, Windows 95 loads up and use the default standard VGA mode in 16 colors and a standard mouse and keyboard driver. One of the advantage of using "Safe Mode" is to free up more conventional memorys and remove any device driver that can cause conflicts during the installation process.

-----  
SECTION 3: HOW TO BOOT-UP WINDOWS 95 IN SAFE MODE  
-----

1. When you boot-up your system the first time, press F8 when you see STARTING WINDOWS 95 on the screen. Usually the message display on the top-left hand corner.

2. If you press F8 before Windows 95 starts loading, you will see the Boot-Up Main Option as follow:

1. Normal
2. Logged
3. Safe Mode
4. Safe Mode With Network Support
5. Step-by-step Confirmation
6. Command Prompt Only
7. Safe Mode Command Prompt Only
8. Previous Version of MS-DOS

NOTE: Some of the options listed above might not be available on your system, for example, "Safe Mode With Network Support" if your system don't have network feature installed. It depends on your system configuration.

3. Select "Safe Mode" from the Main Option menu and Windows 95 will load the operating system.

4. To install Delphi, please refer to Delphi install.txt and readme.txt.

## Article #16357: Detecting Windows Shutdown

Technical Information Database

TI1357D.txt - Detecting Windows Shutdown

Category :VCL  
Platform :All  
Product :All32Bit,

### Description:

It is possible for you to detect when windows is being shutdown and to prevent this shutdown from within a running Delphi application.

The simple solution is to add an event handler to the main form's OnCloseQuery event. This event handler occurs as a result of a WM\_QUERYENDSESSION message which is sent to all running application in Windows when Windows is about to be shut down. The boolean CanClose parameter to this event can be set to True to allow Windows to shut down or, CanClose can be set to False to prevent Windows from shutting down.

The code below illustrates using this event.

----- Code Follows -----

```
procedure TForm1.FormCloseQuery(Sender: TObject; var CanClose:
Boolean);
begin
    // Ask user if shutdown should occur.
    if MessageDlg('Are you sure?', mtConfirmation, mbYesNoCancel, 0) =
mrYes
    then CanClose := true    // Allow Windows to shut down.
    else CanClose := false; // Prevent Windows from shutting down.
end;
```

## Article #16363: Returning Default Cursor after Running Queries

Technical Information Database

TI1363D.txt Returning Default Cursor after Running Queries

Category :General Programming

Platform :All

Product :Delphi All

Description:

Q: Why does the Mouse cursor not change back to an arrow after I do a Query?

A: When performing an open on a query, Delphi will change the cursor for you, even in the middle of an event, such as a button click. The example below will cause the cursor to show as a SQL Hourglass Icon, after you close the showmessage dialog box. The Mouse will behave as if its in the arrow state.

```
// Add to a button click event, the Query used does not  
// matter I used  
// Select * from Customer (on IBLocal)
```

```
with query1 do begin  
  close;  
  open;  
  showmessage(IntToStr(RecordCount));  
end; // with
```

What appears to be happening is that when Delphi tries to change the Cursor back to the Arrow, a new form has already been shown (the showmessage dialog) and so its job is done as the cursor will automatically be set to the arrow on the showmessage dialog form.

To solve this problem, add a `Application.ProcessMessages` before showing anew form, this will clear all pending message commands from the message queue, and the Mouse Cursor will appear normal again.

```
// Add to a button click event, the Query used does
```

```
// not matter I used
// Select * from Customer (on IBLocal)

with query1 do begin
  close;
  open;
  application.ProcessMessages;          // Add This Line.
  showmessage(IntToStr(RecordCount));
end; // with
```

## Article #16369: Dynamic creation and circularly linking forms

Technical Information Database

TI1369D.txt Dynamic creation and circularly linking forms

Category :General Programming

Platform :All

Product :Delphi All

### Description:

Question: How do I make a simple method to rotate between forms?  
How do I add my own return results to a ShowModal form?  
How do I instantiate forms at runtime?

Answer: The method required is quite simple to implement. For my example I used 3 forms, the MainForm, Form1, and Form2. I placed a button on the MainForm that will bring up Form1, then from that form you could rotate through any number of forms via buttons placed on those forms. For my example, only Form1 and Form2 can be flipped between.

step 1. Places these two lines in the interface section of this Form, which will be referred to as the main form

```
const
    mrNext = 100;
    mrPrevious = 101;
```

step 2. On the main form add a button and add the following block of code into it.

```
var
    MyForm: TForm;
    R, CurForm: Integer;
begin
    R := 0;
    CurForm := 1;
    while R <> mrCancel do begin
        Case CurForm of
            1: MyForm := TForm1.Create(Application);
            2: MyForm := TForm2.Create(Application);
        end;
```

```

try
  R := MyForm.ShowModal;
finally
  MyForm.Free;
end;
case R of
  MrNext : Inc(CurForm);
  MrPrevious : Dec(CurForm);
end;
  // these 2 lines will make sure we don't go out of
bounds
  if CurForm < 1 then CurForm := 2
  else if CurForm > 2 then CurForm := 1;
end; // while
end;

```

step 3. Add forms 1 and 2 (and any others you are going to have) to the uses statement for the MainForm.

step 4. On Form1 and Form2 add the MainForm to the uses (so they can see the constants.

step 5. On Form1, Form2 and all subsequent forms add 2 TBitBtn's, labeled Next and Previous. In the OnClick Events for these buttons

add the following line of code.

If it's a Next Button add : ModalResult := mrNext;

If it's a Previous Button add : ModalResult := mrPrevious;

## Article #16375: Avoid using Resource Heap with Tabbed Notebooks

Technical Information Database

TI1375D.txt Avoid using Resource Heap with Tabbed Notebooks

Category :General Programming

Platform :All

Product :Delphi All

Description:

Intended Audience:

-----  
Anyone who wants to necessarily avoid using User Resource heap in conjunction with TTabbedNotebooks.

Prerequisites:

- 
- Familiarity with the TTabbedNotebook and TTimer components.
  - Understanding of Microsoft Windows Architecture; specifically User resources.

Purpose of the TI:

-----  
This document demonstrates how to use Object Pascal to help control the number of active handlesWindows, the User Resource heap specifically, keeps track of. Why does this matter? Simplifying things, Windows keeps track of every Focusable Control via a Handle. The issue is,Windows cannot simply maintain an inexhaustible amount of Windows Handles (4 byte pointers) and this is where this TI's sample code will help "ease" the resource load which might restrict the Delphi Developer.

The User DLL actually is the Library which allocates and maintains resources for all Windows and related data structures, including focusable object's and other unmentioned, but nonetheless important USER functions, under Windows. It is this USER DLL resource limitation\* which we are temporarily working around. An example of an added resource load is, every control we add to a form, takes up 4 bytes of the USER 64k.

With this in mind, what exactly are we doing? We will be

destroying\*\* the Handles which Windows is architecturely designed to remember. By destroying these Handles, thus freeing USER resource drain, it does not mean we need to recreate said objects again. On the contrary, currently built into the VCL is the ability to keep track of said objects, which are in fact pointers to structures. So, knowing the VCL will maintain a Handle and windows will recreate a new Handle as NEEDED, instead of maintaining one permanently, as designed, we can take control of the USER resources manually and "ease" the overall USER resource load.

This TI will demonstrate the freeing of USER Handle resources via Delphi's TTabbedNoteBook (specifically destroying Page Handles), Delphi's DestroyHandle (TWinControl procedure for removing USER handles), and the Windows API call LockWindowUpdate (Locking unwanted repaints).

The technique of freeing a TTabbedNoteBook Page Handle can be extended to anyTWinControl descendant. TWinControl is the ancestor class which introduces the creating/destroying of Windows Handles; CreateHandle & DestroyHandle.

\* 64K for Win3.1 & 64K for Win95 16-bit subsystem alone. For further information, contact Microsoft or look in the MSDN.

\*\* As a side effect of destroying said Handles, the TTabbedNotebook used in this TI will experience faster page movement.

#### SAMPLE CODE

The following attached events are direct excerpts from a Project with a TTimer, TTabbedNotebook (with multiple pages) and an assorted plethora of controls on each notebook page. (The later is to emphasize the benefits of adding the below code) The attached Event snippet's should reside in the OnTimer event of the TTimer control and the OnChange event of the TTabbedNotebook, respectively. With no further adou, let's try our new code:

```
-----  
...  
Implementation
```

```
Type TSurfaceWin = class(TWinControl);
```

```
procedure TForm1.Timer1Timer(Sender: TObject);
```

```
begin
{This code will update the Form caption with the percentages of
 free SYSTEM, GDI, &USER for Windows.}
caption := 'SYSTEM: ' +
           inttostr(getfreesystemresources(GFSR_SYSTEMRESOURCES)) +
           ' GDI: ' + inttostr(getfreesystemresources(GFSR_GDIRESOURCES)) +
           ' USER: ' + inttostr(getfreesystemresources(GFSR_USERRESOURCES));
end;
```

```
procedure TForm1.TabbedNotebook1Change(Sender: TObject; NewTab:
           Integer; var AllowChange: Boolean);
```

```
begin
```

```
{LockWindowUpdate prevents any drawing in a given window}
```

```
LockWindowUpdate(handle);
```

```
{The reason for TSurfaceWin is because the DestroyHandle call is
declared abstract in TWinControl, which means, only descendant
classes can surface this Procedure. The rest of the line is meant
to flag the current page of the TabbedNotebook and destroy its
handle as we move to another page. NOTE: Even though we destroy
the handle, Windows itself remembers the page object and will
reassign/create a new one when the tab is once more clicked to. }
```

```
TSurfaceWin(TabbedNotebook1.pages.objects[tabbedNotebook1.
           pageindex]).DestroyHandle;
```

```
{Release the Lock on the Form so any Form drawing can work}
```

```
LockWindowUpdate(0);
```

```
end;
```

## Article #16377: Installing Acrobat Reader for Windows

Technical Notes Database

TN1377D.txt Installing Acrobat Reader for Windows

Category :General Programming

Platform :All

Product :Delphi All

Description:

ADOBE FAXYI

COMPREHENSIVE OVERVIEW:

INSTALLING ADOBE ACROBAT READER FOR WINDOWS

WHAT'S COVERED

Overview of the Installation Process

Files Installed by the Acrobat Reader

Description of Installed Files

Changes Made to the WIN.INI and SYSTEM.INI Files

Installing Acrobat Reader 2.0 when an Earlier Version of Acrobat Reader is Installed

Installing Acrobat Reader when a Version of ATM Earlier than 3.01 has been Installed

Default .INI File Listings Description of .INI File Functions and Settings

Installing Acrobat Reader Manually

This document is designed to help network administrators and support staff who want to predict how installing the Acrobat Reader might affect their networks and users. By understanding how the Acrobat Reader Installer works, it is possible to decide the best way to install the Acrobat Reader.

For information on obtaining Acrobat Reader 2.0, see Related Records.

OVERVIEW OF THE INSTALLATION PROCESS

When the Acrobat Reader Installer is launched in Windows, it partially decompresses itself in

the directory listed in the "Set Temp=" line in the AUTOEXEC.BAT file. Once the installer application is decompressed in this directory, it displays the license agreement. After select-ing "Accept" in the "Electronic End User License Agreement" dialog box, "Install" in the "Acrobat Installer" dialog box, and "OK" after entering your name and company, Acrobat Reader files are installed. If the "Set Temp=" line in the AUTOEXEC.BAT file points to an invalid drive or directory or there is insufficient free disk space on the drive specified, errors will occur during the Acrobat Reader installation.

The Acrobat Reader Installer installs the Acrobat Application, supporting libraries, on-line documentation, configuration (.INI) files, fonts, and Adobe Type Manager 3.01 (ATM) into pre-designated locations. The version of ATM included with Acrobat Reader isn't a complete version of ATM; it will only run under Windows 386-enhanced mode, does not include a control panel for adding or removing fonts, and, by default, is not available to other applications.

#### FILES INSTALLED BY THE ACROBAT READER

Acrobat reader installs the following files and directories (in quotes):

#### "ACROREAD"

```
ACROGRAF.DLL 117808 10-14-94 2:12a
ACROREAD.REG 686 [date/time of install]
ACROCORE.DLL 364640 10-14-94 2:12a
ACROREAD.EXE 299040 10-14-94 2:12a
VIEWLIB.DLL 405904 10-14-94 2:12a
"HELP"
  HELP_R.PDF 61575 10-14-94 2:12a
  README_R.TXT 11033 10-14-94 2:12a
```

NOTE: ACROREAD is the default installation name of the Acrobat Reader directory and can be renamed during the installation process. If installing under a networked version of Windows, the following files are installed into each user's personal WINDOWS

directory. Otherwise, these files are installed into the shared WINDOWS directory.

#### "WINDOWS"

```
ATM .INI 917 [date/time of install]
ACROREAD.INI 136 [date/time of install]
~ACROBAT.TMP 76 [date/time of install]
ADOBEACR.GRP 1632 [date/time of install]
```

An ATMFONTS.QLC file is created in the directory indicated by the "QLCDir=" line in the ATM.INI file. By default, the ATMFONTS.QLC file is installed in the same directory in which the ATM.INI file is located. The size of the file varies depending on how many fonts are installed.

If installing onto a system with an ATM.INI file that includes a "PFB\_Dir=" pointing to a valid directory, the following files are installed to that directory. If there is no ATM.INI file present on the system, or the directory listed in the PFB\_Dir= line is invalid, the files are installed in the root of the WINDOWS directory. If the SY\_\_\_\_.PFB or ZD\_\_\_\_.PFB files are present, they are not updated.

```
SY____ PFB 31586 [date/time of install]
ZD____ PFB 40858 [date/time of install]
ZX____ PFB 74870 [date/time of install]
ZY____ PFB 95283 [date/time of install]
```

If installing onto a system with an ATM.INI file that includes a "PFM\_Dir=" line pointing to a valid directory, the following files are installed to that directory. If there is no ATM.INI file present on the system, or the directory listed in the "PFM\_Dir=" line is invalid, the files are installed in the root of the WINDOWS directory. If the SY\_\_\_\_.PFM or ZD\_\_\_\_.PFM files are present, they are not updated.

```
SY____ PFM 672 [date/time of install]
ZD____ PFM 684 [date/time of install]
ZX____ PFM 683 [date/time of install]
ZX____ MMM 7188 [date/time of install]
ZY____ PFM 684 [date/time of install]
```

If Installing Acrobat Reader under a non-networked version of Windows, the following files are installed into the WINDOWS\SYSTEM directory. If installing Acrobat Reader under a networked version of Windows, the following files are installed in the root of the shared WINDOWS directory.

ATM32.DLL 372384 10-6-94 3:01a  
ATMSYS.DRV 26336 10-6-94 3:01a

When the file ATM32.DLL is first installed, it is installed with the name "ATM32.NDL." The next time windows is restarted the ATM driver (ATMSYS.DRV) will check for .NDL files. If any are found, the current .DLL (if any) will be deleted and the .NDL file will be renamed to take its place. If the DLL cannot be deleted, an error will occur.

If you don't have write access to the shared WINDOWS directory when installing Acrobat Reader, the files will not be installed and the error message "You are attempting a network node install, but certain components which must be installed by the network administrator are missing or are out of date. Please see your administrator" will be displayed followed by the message "The Installation is complete." After the unsuccessful installation Acrobat or Windows will fail to launch. If Acrobat Reader was installed without write access to the shared WINDOWS directory, restore the ATM.INI and SYSTEM.INI files to their original state prior to installing Acrobat Reader.

#### DESCRIPTION OF INSTALLED FILES

|              |                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------|
| ACROGRAF.DLL | Acrobat viewer support file.                                                                                                  |
| ACROCORE.DLL | Acrobat viewer support file.                                                                                                  |
| ACROREAD.EXE | Acrobat Reader program file.                                                                                                  |
| VIEWLIB.DLL  | Acrobat viewer support file.                                                                                                  |
| ACROREAD.REG | OLE registration information. Acrobat Reader can accept only DDE open/close messages. Reader is not an OLE-aware application. |

HELP\_R.PDF On-line documentation.

README\_R.TXT Installation directions, upgrade information, and license agreement.

ATM.INI Configuration information for the version of ATM installed with Reader.

ACROREAD.INI Configuration information for Reader. ~ACROBAT.TMP A temporary file used by the installer. It is deleted the first time Acrobat Reader is launched.

ADOBEACR.GRP Windows group where acrobat items are displayed.

ATMFonts.QLC ATM QuickLoad file. This file contains a list of installed fonts and font metrics of recently used fonts, which reduces Windows startup time. It is updated every time you exit Windows.

SY\_\_\_\_\_ PFB Symbol outline font.

ZD\_\_\_\_\_ PFB Zaph Dingbats outline font.

ZX\_\_\_\_\_ PFB Sans serif multiple master substitution outline font.

ZY\_\_\_\_\_ PFB Serif multiple master substitution outline font.

SY\_\_\_\_\_ PFM Symbol character metrics data.

ZD\_\_\_\_\_ PFM Zaph Dingbats character metrics data.

ZX\_\_\_\_\_ PFM Sans Serif multiple master substitution font metrics data.

ZX\_\_\_\_\_ MMM Sans serif multiple master metrics file.

ZY\_\_\_\_\_ PFM Serif multiple master substitution font metrics data.

ZY\_\_\_\_\_ MMM Serif multiple master metrics file.

ATM32.DLL Adobe Type Manager 3.01 program file for 386 Enhanced mode Windows.

ATMSYS.DRV Adobe Type Manager 3.01 system driver.

CHANGES MADE TO THE WIN.INI AND SYSTEM.INI FILES During the Acrobat Reader installation, the following line is added to the [extensions] section of the WIN.INI file:

```
PDF=C:\ACROREAD\ACROREAD.EXE ^.PDF
```

This allows the user to double-click on a file with a .PDF extension to launch Acrobat Reader and open the file.

The following line is added to the [Adobe Display] section:

```
UseGDI=1
```

NOTE: If there is no [Adobe Display] section heading, the installer adds it as well as the UseGDI=1" line. The number "1" in the "UseGDI=1" setting tells Acrobat Reader to use Windows features to accelerate screen redraw. However, with some video displays, this may cause problems. The setting can be changed to "0" to disable the "UseGDI=" setting if video compatibility problems arise.

The following lines are added to the users [boot] section of their SYSTEM.INI file if they do not already exist.

```
system.driv=atmsys.driv
atm.system.driv=system.driv
```

These lines load ATM when Windows is launched.

#### INSTALLING ACROBAT READER 2.0 WHEN AN EARLIER VERSION OF ACROBAT READER IS INSTALLED

The Acrobat Reader Installer does not remove obsolete Reader 1.0 components (e.g., help files, ReadMe files, etc.). When Acrobat Reader 2.0 is installed in a different directory from the one in which Acrobat Reader 1.0 is installed, neither application's performance is affected.

#### INSTALLING ACROBAT READER WHEN A VERSION OF ATM EARLIER THAN 3.01 HAS BEEN INSTALLED

When Acrobat Reader 2.0 is installed into a system with a full version of ATM earlier than version 3.01, the alert "The current version of Adobe Type Manager (ATM) on your system is not compatible with Adobe Acrobat 2.0. You may partially upgrade your version of ATM at this time, or you may call Adobe at 1-800-83-FONTS for a full upgrade." appears. Selecting "OK" to partially upgrade ATM allows ATM and Acrobat to run only in Windows 386 Enhanced Mode. If "Cancel" is selected, Acrobat will not run.

CHANGES MADE AFTER SELECTING "OK" TO PARTIALLY UPGRADE ATM - If the version of ATM being upgraded is 2.6, references to the substitution multiple master fonts

AdobeSansXMM and AdobeSerifMM are replaced by references to the newer AdobeSanMM and AdobeSerMM multiple master fonts.

- ATM sections new to ATM 3.01 are added to the current ATM.INI.
- Sections of .INI files concerning printer drivers are not updated.
- The ATM control panel application is not removed or updated. The older control panel should continue to function with ATM 3.01, but using a mismatched driver and control panel is not supported by Adobe. If problems are encountered, upgrade to full ATM by calling 1-800-83-FONTS.
- A new ATM32.DLL and ATMSYS.DRV are added to the WINDOWS\SYSTEM directory.

#### DEFAULT .INI FILE LISTINGS

Acrobat Reader has its own .INI file, ACROREAD.INI, which is first written to contain only the following information:

[Oem]

OEM1=For product information and online help,  
OEM2=please see the file HELP\_R.PDF in  
OEM3=the Acrobat(tm) Reader Help folder.

When Acrobat Reader is first launched, the following lines are added to the ACROREAD.INI file:

```
[AdobeViewer]
User=John Smith
MaxDoc=1
MaxApp=1
ShortMenu=0
ShowToolbar=1
MaxPageCacheZoom=131072
MinPageCacheTicks=12
MaxPageCacheBytes=4194304
FullScrolling=0
DefaultSplitterPos=140
ThreadIndicator=180
DrawMissingThumbs=0
ThumbViewScale=8192
ThumbViewTimeout=120
DefaultFitType=FitR
```

```
DefaultInheritZoom=0
MaxCosDocCache=200000
DefaultOverviewType=1
CaseSensitive=0
WholeWords=0
UseDIC=0
CustomColor0=16777215
CustomColor1=16777215
CustomColor2=16777215
CustomColor3=16777215
CustomColor4=16777215
CustomColor5=16777215
CustomColor6=16777215
CustomColor7=16777215
CustomColor8=16777215
CustomColor9=16777215
CustomColor10=16777215
CustomColor11=16777215
CustomColor12=16777215
CustomColor13=16777215
CustomColor14=16777215
CustomColor15=16777215
```

The first time "OK" is selected in the "General Preferences" dialog box under the Edit menu, the following lines are added to the ACROREAD.INI file:

```
DefaultMag=100
DefaultMagType=0
GreekThreshold=6
GreekText=1
Chameleons=0
ShowLargeDIBS=1
PageUnits=1
SkipDeleteWarnings=0
DisplayAboutDialog=1
UsePageCache=1
MaxThreadZoom=200
SkipOpenDialog=0
```

The first time "OK" is selected in the "Full Screen Preferences" dialog box under the Edit menu, the following lines are added to the ACROREAD.INI file:

```
FullScreenColor=0
```

```
DefaultSlideTimer=5
UseSlideTimer=0
ForceTBHidden=0
WrapSlideShowPages=1
```

## Description of .INI File Functions and Settings

Unless stated otherwise, lines with invalid values are ignored, and the default value, as shown in the ACROREAD.INI file above, is used.

NOTE: Some of the following .INI functions are described as "Reserved" to indicate the entries relate to a feature or plug-in that has not yet been implemented. "Reserved" .INI entries should not be altered in any way.

|                   |                                                                                                                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Oem]             | These lines appear on the splash screen when Reader starts.                                                                                                                                            |
| User              | The name typed by the user into the installer dialog box during installation. Appears on the splash screen when Reader starts.                                                                         |
| MaxDoc            | Controls default size of displayed document windows. If "MaxDoc=1," documents are Maximized. If "MaxDoc=0," documents are cascaded.                                                                    |
| MaxApp            | Sets the default size for the application window. If "MaxApp=1," the application window size is Maximized (full screen). If "MaxApp=0," application window size and position is Determined by Windows. |
| ShortMenu         | Ignored by Reader.                                                                                                                                                                                     |
| ShowToolBar       | If "ShowToolBar=1," Reader displays the toolbar, if "ShowToolBar=0," the toolbar is initially hidden. The setting can be changed by selecting "Show Toolbar" or "Hide Toolbar" from the Window menu.   |
| MaxPageCacheZoom  | Sets the maximum page magnification at which caching will occur.                                                                                                                                       |
| MinPageCacheTicks | Sets the time threshold for page caching in 1/12ths of seconds. If a page draws in less than this amount of time, the                                                                                  |

page will not be cached.

MaxPageCacheBytes            Sets the size of the page cache in bytes.

FullScrolling                If "FullScrolling=1," the scrolling region on each page is made larger, so that when using the elevator thumb or page down key, it is possible to scroll past the bottom of a page before it turns to the next page. This setting does not affect documents whose pages fit completely within the display. If "FullScrolling=0," the page is set for a normal scrolling region.

DefaultSplitterPos           The value, in pixels, which sets the horizontal position of the boarder which divides the document area and the overview area when book-marks or thumbnails are being displayed. Any value smaller than the minimum value of 100 is rounded up (clamped) to 100.

ThreadIndicator              Reserved

DrawMissingThumbs           Reserved

ThumbViewScale              Sets the display size of thumbnails. The default of 8192 is roughly 12% of actual size. 65535 is 100%. 2000, or about 3%, is the minimum size. Invalid values will be clamped.

ThumbViewTimeout            Reserved

DefaultFitType               Reserved

DefaultInheritZoom          Reserved

MaxCosDocCache              Reserved

DefaultOverviewType         Default pagemode if one is not specified in the PDF file.

| value | meaning                           |
|-------|-----------------------------------|
| 0     | viewer takes no action            |
| 1     | page is displayed                 |
| 2     | page and thumbnails are displayed |
| 3     | page and bookmarks are displayed  |
| 4     | full screen mode                  |

CaseSensitive                If "CaseSensitive=0," case-sensitive searching is disabled by default.

                              If "CaseSensitive=1," case-sensitive searching is enabled. This setting can be overridden in the "Find" dialog box, but for the current session

only (i.e., the ACROREAD.INI file is not updated).

WholeWords If "WholeWords=0," "Match Whole Word Only" searching is disabled by default. If "WholeWords=1," "Match Whole Word Only" is enabled. This setting can overridden in the "Find" dialog box, but for the current session only (i.e., the ACROREAD.INI file is not updated).

UseDIC Reserved

CustomColorx (where x is a number from 0-15) Reserved.

The remaining ACROREAD.INI value settings can be set in Acrobat Reader by selecting a new value in the "General Preferences" or "Full Screen Preferences" dialog boxes.

DefaultMag If the PDF being opened does not have a default magnification specified in it, the value listed here will be used when "DefaultMagType=0." Valid values are 12 to 800. Values outside this range will be clamped.

DefaultMagType Specifies the magnification type. "DefaultMagType=0" uses the DefaultMag value, "DefaultMagType=1" displays at "Fit Page" magnification, "DefaultMagType=2" displays at "Fit Width" magnification, "DefaultMagType=4" displays at "Fit Visible" magnification. If the "DefaultMagType=" number is invalid, Acrobat Reader assumes a value of 1.

GreekThreshold Minimum height of text, in pixels, before Reader will render character shapes. Text below this size will display as a colored bar. Ignored if GreekText is set to 0.

GreekText If "GreekText=1," Acrobat Reader will greek text below GreekThreshold pixels. If "GreekText=0," text is rendered no matter what its size.

Chameleons Font(s) to use when a font required by a PDF is not available. If

"Cha-meleons= 0," Both Serif and Sans Serif are used, if "Chameleons=1," only Sans Serif is used and if "Chameleons=2," only Serif is used.

ShowLargeDIBS If "ShowLargeDIBS=1," Acrobat Reader will draw all graphics. If "ShowLargeDIBS=0," Acrobat Reader will only draw graphics that consume less than 4K of space within the PDF before decompression.

PageUnits Default measurement system. Acrobat Reader uses points if "PageUnits=0," inches if "PageUnits=1," and millimeters if "PageUnits=2."

SkipDeleteWarnings Ignored by Reader.

DisplayAboutDialog The Acrobat Reader splash screen is displayed during startup if "DisplayAboutDialog=1," and is not displayed if "DisplayAboutDialog=0."

UsePageCache Page caching is enabled if "UsePageCache=1," and is disabled if "UsePageCache=0."

MaxThreadZoom Maximum magnification to use when viewing in fit visible magnification. Valid values are between 12 to 800. Invalid values will be clamped.

SkipOpenDialog If Acrobat is launched and no PDF is specified on the command line, Reader will display an open dialog if "SkipOpenDialog=0." If "SkipOpenDialog=1," a blank workspace is displayed.

FullScreenColor Color to use as a background when displaying in full screen mode. Uses standard Windows color numbering system.

DefaultSlideTimer Time, in seconds to wait between slides. Use "SlideTimer=" setting must be set to 1 to be used.

UseSlideTimer If "UseSlideTimer=1," enabling full screen mode activates an automatic slide show, switching slides at intervals specified by the "DefaultSlideTimer" setting.

ForceTBHidden Ignored.

WrapSlideShowPages When "UseSlideTimer=1 (on)," setting

"WrapSlideShowPages=" to a number other than 0 will cause the pages of the PDF to be looped endlessly. Set "WrapSlideShowPages=0" to disable looping and allow Acrobat Reader to exit from full screen mode when all pages have been displayed.

The Acrobat Reader Installer creates an ATM.INI containing the below entries if an ATM.INI does not already exist. If an ATM.INI file already exists, lines shown below, which do not exist in the current ATM.INI, are added.

```
[Settings]
Private=On
ATMIcon=off
TmpDir=C:\DOS
TmpCount=0
QLCDDir=C:\WINDOWS
ATM=off
FontCache=256
SynonymPSBegin=9

PFB

AdobeSanMM=C:\WINDOWS\PFM\ZX\_\_\_\_\_.PFM,C:\WINDOWS\ZX\_\_\_\_\_.

PFB

AdobeSerMM=C:\WINDOWS\PFM\ZY\_\_\_\_\_.PFM,C:\WINDOWS\ZY\_\_\_\_\_.

PFB

[MMFonts]  
AdobeSanMM=C:\WINDOWS\PFM\ZX\_\_\_\_\_.MMM,C:\WINDOWS\ZX\_\_\_\_\_.

PFB

AdobeSerMM=C:\WINDOWS\PFM\ZY\_\_\_\_\_.MMM,C:\WINDOWS\ZY\_\_\_\_\_.

NOTE: For more information on the ATM.INI file, see the file TECHREF.  
WRI included with most  
copies of ATM 3.0x. A few lines specific to the Acrobat installer are  
discussed here.

ATM                    If "ATM= on" then ATM is available to all  
applications. If "ATM=off," ATM is  
                      either completely or partially disabled, depending on  
how the "Private" line  
                      is set.

Private                When "ATM=" is set to off, "Private=on" makes ATM  
available to Acrobat, but no  
                      other applications. When "Private=off," ATM not be  
available to Acrobat Reader,  
                      preventing Reader from launching. This line is used  
only by Acrobat and will not  
                      be present in the ATM.INI unless Acrobat has been  
installed.

ATMIcon                If "ATMIcon=on," ATM displays its icon at startup, If  
"ATMIcon=off," it does not.

#### MANUALLY INSTALLING ACROBAT READER

It is recommended to install Acrobat Reader using the Acrobat Reader  
installer. However, in some  
cases a custom install is required.

Manually installing Acrobat Reader:

1. The ACROGRAF.DLL, ACROCORE.DLL, ACROREAD.EXE, VIEWLIB.DLL, and README\_R.TXT must all be installed into the same directory. Item 3 of the Adobe Acrobat Reader License agreement requires the agreement be distributed with the Acrobat Reader software. The license agreement can be found in the README\_R.TXT file. The HELP\_R.PDF is not required but is strongly recommended.

2. An ATM.INI must be present in the WINDOWS directory, and have the information necessary for Acrobat to locate all the fonts normally installed with Reader. Refer to the TECHREF.WRI file included with many copies of ATM to learn what lines of the ATM.INI file are required for a particular installation.

3. An ACROREAD.INI file is recommended, but not required. Acrobat will create one if it is not present.

4. The following printer fonts and font metric files must be installed and pointed to by the ATM.

INI file: SY\_\_\_\_\_ PFB, ZD\_\_\_\_\_ PFB, ZX\_\_\_\_\_ PFB, ZY\_\_\_\_\_ PFB,  
SY\_\_\_\_\_ PFM, ZD\_\_\_\_\_ PFM,  
ZX\_\_\_\_\_ PFM, ZX\_\_\_\_\_ MMM, ZY\_\_\_\_\_ PFM, and ZY\_\_\_\_\_ MMM.

5. ATM32.DLL and ATMSYS.DRV files for ATM 3.01 or later must be installed. Lines must be added to the SYSTEM.INI file so the driver loads with Windows.

NOTE: It is recommended to always try using the Adobe Installer instead of a manual installation to Acrobat Reader. Adobe Technical Support cannot help with manual installations of Acrobat Reader because there are too many variables in performing a correct custom installation.

## Article #16381: The DocInput Object: Properties and Methods

Technical Information Database

TI1381D.txt - The DocInput Object: Properties and Methods

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

### Description:

The DocInput Object is an object from the NetMasters Internet Solutions Pack deployed with Delphi 2.01. It describes the input information for a document being transferred to the control. All of the internet controls in the suite that can receive a doc use this object as a property. The DocInput Object has the following properties:

BytesTotal, BytesTransferred, DocLink, FileName, Headers, PushStreamMode, State and Suspended.

BytesTotal is the total byte count of the item to be transmitted. The default or initial value is zero. The data type is a Long. It is a runtime and read only property. This value is obtained from the header property content-length. This value is used by the control to determine the amount of information to be transferred. It is also accessible to you to manage the buffer that you will use to re-assemble the data after transfer.

The BytesTransferred property is a property given to you inside the OnDocInput event. It is a runtime read only property that is of type long. It is set to zero when a new transfer begins. It is updated at the beginning of the OnDocInput Event. This value will reflect the value of the last transfer when no other transfer is in progress. The BytesTransferred property can be used to show progress on a progress bar or to confirm that the actual amount transferred corresponds to that which is expected.

The DocLink property tells the receiving control that the

source of the document will not be sent via data streaming or via an input file. It references a DocOutput.DocLink property which becomes the source of data in the transfer. This property is a read/write property that is runtime only. The property is of type DocLink. It is a string type and the defaultvalue is ''. When the DocLink property is set to a value other than '', the FileName property is automatically set to ''. This property is used to specify a source that is an internet control that has a DocOutput.DocLink property set to correspond with it (i.e. they are used in pairs).

The FileName property is a read/write runtime only property that is of type string. Its default value is ''. It must be a valid filename. This property can be set by passing it as an argument to a DocInput object. If this property is set to a value other than '', then the DocLink property is set to ''.

The Headers property is a runtime readonly property. The "headers" is a collection of DocHeader items that define the doc being transferred. The contents of the headers property should be modified before calling the GetDoc method. Each DocHeader represents a MultiPurpose Internet Mail Extension(MIME). Mime is the mechanism for specifying and describing the format of Internet Message Bodies. (See rfc1341 for details). The headers used depend on the protocol used but two are common to all protocols:

1. content-type

content type indicates the MIME specification of the ensuing document. "text/plain" is an example of this.

2. content-length

content length indicates the size of the documents in bytes.

The state property is a runtime read only property of the enumerated type DocStateConstants. The default value is icDocNone. The state property is updated by the control itself each time the DocInput event is activated.

The suspended property is a runtime read only property that is of type boolean. It is set by calling the suspend method. If it is set to true transfer is suspended.

The PushStream property is a read/write, runtime only property that is of the type boolean. The default value is false. If the FileName or DocLink properties are set to values other than ''

then the PushStream property is not accessible.

The DocInput object has 4 methods:  
GetData, PushStream, SetData and Suspend.

The GetData method tells the DocInput object to retrieve the current block of data when the DocOutput event is activated. This method can only be called during the OnDocInput event and only when the State property is set to icDocData(3). When using the FileName or DocLink properties this method may be used to examine data during transfer.

The PushStream method should only be called when the PushStreamMode has been set to true and when data is available. PushStream sets the State property based on the next step of the document transfer and activates the DocInput event when appropriate. It then returns to wait for the next call to PushStream. SetData should be called before calling PushStream.

The SetData method specifies the next data buffer to be transferred when the DocInput event is activated. SetData is called during a DocInput event or before calling SendDoc. If it is used before calling SendDoc then it is an alternative to sending the InputData parameters to InputData. The type should be specified as a variant.

The Suspend method takes the form suspend(true) or suspend(false). If the method has been called true twice then it must be called false twice to resume transfer.

This is some example code on how to use the DocInput Object. The full program that this code is from can be seen in the demos sub directory of the Delphi 2.01 CD-Rom. The project name is SimpMail.dpr. This example is a great example of using the headers property of the object. The DocInput event also shows proper use and testing of the State property.

```
{Clear and repopulate MIME headers, using the component's  
DocInput property. A separate DocInput OLE object could also be  
used. See RFC1521/1522 for complete information on MIME types.}  
procedure TMainForm.CreateHeaders;  
begin  
  with SMTP1 do  
  begin  
    DocInput.Headers.Clear;
```

```

DocInput.Headers.Add('To', eTo.Text);
DocInput.Headers.Add('From', eHomeAddr.Text);
DocInput.Headers.Add('CC', eCC.Text);
DocInput.Headers.Add('Subject', eSubject.Text);
DocInput.Headers.Add('Message-Id', Format('%s_%s_%s',
    [Application.Title, DateTimeToStr(Now), eHomeAddr.Text]));
DocInput.Headers.Add('Content-Type',
    'TEXT/PLAIN charset=US-ASCII');
end;
end;

```

```

{Send a simple mail message}
procedure TMainForm.SendMessage;
begin
    CreateHeaders;
    with SMTP1 do
        SendDoc(NoParam, DocInput.Headers, reMessageText.Text, '',
            '');
end;

```

```

{Send a disk file. Leave SendDoc's InputData parameter blank and
specify a filename for InputFile to send the contents of a disk
file. You can use the DocInput event and GetData methods to do
custom encoding (Base64, UUEncode, etc.) }
procedure TMainForm.SendFile(FileName: string);
begin
    CreateHeaders;
    with SMTP1 do
        begin
            DocInput.FileName := FileName;
            SendDoc(NoParam, DocInput.Headers, NoParam,
                DocInput.FileName, '');
        end;
end;

```

```

{The DocInput event is called each time the DocInput state
changes during a mail transfer. DocInput holds all the
information about the current transfer, including the headers,
the number of bytes transferred, and the message data itself.
Although not shown in this example, you may call DocInput's
SetData method if DocInput.State = icDocData to encode the data
before each block is sent.}
procedure TMainForm.SMTP1DocInput(Sender: TObject;
    const DocInput: Variant);
begin

```

```

case DocInput.State of
  icDocBegin:
    SMTPStatus.SimpleText := 'Initiating document transfer';
  icDocHeaders:
    SMTPStatus.SimpleText := 'Sending headers';
  icDocData:
    if DocInput.BytesTotal > 0 then
      SMTPStatus.SimpleText :=
        Format('Sending data: %d of %d bytes (%d%%)',
          [Trunc(DocInput.BytesTransferred),
            Trunc(DocInput.BytesTotal),
              Trunc(DocInput.BytesTransferred/DocInput.BytesTotal*100)])
    else
      SMTPStatus.SimpleText := 'Sending...';
  icDocEnd:
    if SMTPError then
      SMTPStatus.SimpleText := 'Transfer aborted'
    else
      SMTPStatus.SimpleText := Format('Mail sent to %s
        (%d bytes data)',
        [eTo.Text, Trunc(DocInput.BytesTransferred)]);
end;
SMTPStatus.Update;
end;

```

## Article #16392: Creating Class Properties

Technical Information Database

TI1392D.txt - Creating Class Properties

Category :Object Pascal  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This TI demonstrates how to add a class property to a new component like the Font property on most components.

The following example declares a class, TMyClassProp which contains several fields including an enumerated type field.

### Notes:

1. PropertyObject - must be of type TPersistent or a descendant class of TPersistent.
2. Must create an instance of this TMyClassProp in the Create of the component.

----- Unit Follows -----

```
unit SubClass;
```

```
interface
```

```
uses
```

```
Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
Dialogs;
```

```
type
```

```
{ First Create a enumerated list of elements  
then create a set of these elements }
```

```
TEnumList = (Mom, Dad, Sibling, Sister, Brother);  
TEnum = set of TEnumList;
```

```
{ Here is the Class Object we want to use as a property in our  
Component.
```

It has 4 properties, a Boolean, Word, String, and the enumerated type. }

```
TMyClassProp = class(TPersistent)
  FBool: Boolean;
  FWord: Word;
  FString: String;
  FEnum: TEnum;

published
  property HaveCar: Boolean read FBool Write FBool;
  property Age: Word read FWord write FWord;
  property Name: String read FString write FString;
  property Relation: TEnum read FEnum write FEnum;
end; // TMyClassProp

{ Now create the component which will contain a property of type
  TMyClassProp.}
TMyComponent = class(TComponent)
  FEnum: TEnum;           { Enumerated type, just for fun }
  FSubClass: TMyClassProp; { The Class Property we want }
public
  constructor Create(AOwner: TComponent); override;
  destructor Destroy; override;
published
  property Relation: TEnum read FEnum write FEnum;
  property Relative: TMyClassProp read FSubClass write FSubClass;
  { Published declarations }
end;

procedure Register;

implementation

  { Override Create, to create an instance of the Class property.
    This is required. }

constructor TMyComponent.Create(AOwner: TComponent);
begin
  inherited;
  FSubClass := TMyClassProp.Create;
end;
```

```
{ Override Destroy to perform house cleaning. }
destructor TMyComponent.Destroy;
begin
  FSubClass.Free;
  inherited;
end;

procedure Register;
begin
  RegisterComponents('Samples', [TMyComponent]);
end;

end.
```

## Article #16397: Optimizing Oracle Connections with Windows 95

Technical Information Database

TI1397D.txt - Optimizing Oracle Connections with Windows 95

Category :Database Programming  
Platform :All-32Bit  
Product :

Description:

Intended Audience:

-----

Anyone who wants to Improve Oracle IP Connection time under Windows 95.

Prerequisites:

-----

- Windows 95
- Oracle Client Software Installed & Setup to connect to a Oracle Server via TCP/IP.
- (Optional) Delphi 2.0 C/S Software to test result.

Purpose of the TI:

-----

To help speed up Connection time to Oracle under Windows 95. Under WinNT this is not an issue, therefore, this TI applies only to Windows 95. Performance times, as seen on some computer's, with & without this modification are:

Before : Win95 = 10-15 Seconds.  
          WinNT = 2-3     Seconds.

After : Win95 = 3-4     Seconds. (Big Improvement)

Problem: Windows 95 inherently searches for IPC addresses on some network nodes PRIOR to making a connection to a Oracle DNS whereas WinNT does not.

Solution: Modify the Oracle SQLNET.ORA file to disable said Windows 95 feature.

### Step-by-Step Solution:

-----  
1) Open SQLNET.ORA via Notepad or Write.  
(This file can be found in the \network\admin directory.  
Disregard any other occurrences of this file)

This files looks like this:

```
#####  
# Filename.....: sqlnet.ora  
# Node.....: local.world  
# Date.....: 24-MAY-94 13:23:20  
#####  
TRACE_LEVEL_CLIENT = OFF  
sqlnet.expire_time = 15  
names.default_domain = borland.world  
name.default_zone = borland.world
```

2) Add the following Parameter to the SQLNET.ORA file:

```
AUTOMATIC_IPC = OFF
```

Modified, the SQLNET.ORA file looks like this:

```
#####  
# Filename.....: sqlnet.ora  
# Node.....: local.world  
# Date.....: 24-MAY-94 13:23:20  
#####  
AUTOMATIC_IPC = OFF  
TRACE_LEVEL_CLIENT = OFF  
sqlnet.expire_time = 15  
names.default_domain = borland.world  
name.default_zone = borland.world
```

3) Save the file the new SQLNET.ORA file and voila! Anytime an Oracle Connection is initiated, performance with increase from 15 seconds to 3 seconds required. This improves Delphi's already blazing speed.

## Article #16402: Connecting to a 32-bit Sybase server

Technical Information Database

TI1402D.txt - Connecting to a 32-bit Sybase server

Category :Database Programming  
Platform :All-32Bit  
Product :

### Description:

Connecting To Sybase 32-bit

This TI will instruct you on how to connect to a Sybase database via Borland's native 32-bit Sybase SQL Links packaged with Delphi 2.x. The Sybase client software should take up approximately 10+ megabytes of hard drive space.

### Steps To Connect:

1. Make sure that the SQL Links package is installed on your local drive. If you installed the full package of Delphi 2.x then it should be installed already.
2. Install the Sybase client software.
3. When prompted during installation to install either the 16 or 32 bit Sybase links, choose only 32-bit by checking the check box next to the 32-bit selection and making sure that the check box next to the 16-bit selection is blank.
4. After the client software is installed on your hard drive, you will be asked if you would like the install program to automatically update your AUTOEXEC.BAT file. You should choose YES.
5. When prompted to edit your SQL.INI file, choose yes.
6. In the "Input Server Name:" section, type in the alias of the server. Click on the 'Add' button to add this name to your "Server Entry:" list. Next, make sure that the "Service Type:" (It should be 'query'), the "Platform:" (it usually defaults to either NT, dos, or Win3), and the "Net-Library Driver:" (should default to either NLWNSCK or NLNWLINK) edit boxes are correct. Fill out the "Connection Information/Network Address:" by entering the network address of the server you will be connecting to in this edit box. click on the 'Add Service' button. You should now be able to Ping your server by clicking on the 'Ping' button. Exit and save the current settings.

7. Shutdown and Restart your machine.
8. Goto the Delphi program group and execute the Database Explorer.
9. In the Database explorer, make sure that you are on the Database tab. In the pull down menus, choose Object | New... A dialog box should appear with the name STANDARD next to a down arrow. Click the down arrow and select SYBASE from the list that is displayed.
10. There should now be an Alias for your Sybase connection called SYBASE1. Make sure that this name is highlighted. Click on the definitions tab in the Database Explorer. Under the "Server Name" section, type the name of one of the servers that you entered in your SQL.INI that you were able to Ping. In the "User Name" section type the name of a user with rights to the server specified in your "Server Name" section. Make sure that you know the password of the user name that you just specified.
11. Double click on the alias name (SYBASE1) and you should be prompted for a User Name and Password. The User Name should default to the name you specified in the "User Name" section of the Sybase Alias. Type in the password that corresponds to this User. Click on the OK button. You should now see a little green box around the icon next to the Sybase Alias (SYBASE1). This means that you are connected.

Testing your Connection within Delphi 2.x:

1. Drop a TDataSource, a TTable, and a TDBGrid on a blank form.
2. In the Object Inspector for the TDataSource, Set the DataSet to 'Table1'(no quotes).
3. In the Object Inspector for the TTable, set the DataBase Name to SYBASE1. Scroll down to the TableName property and double click on the edit box next to it. You should be prompted for a user name and a password. The user name that you entered in the Database Explorer for the Sybase Alias should already be displayed. Enter the corresponding password. Click the OK button.
4. You should now see a list of table names. Choose one of these names.
5. Click on the TDBGrid. Set the DataSource Property to DataSource1.
6. Set the Active property of the TTable to TRUE.
7. You should now see the data in the TDBGrid. When you run this application, you will be prompted for the username/password. Type in your password and click OK. You should now see the data in the grid.

Error Messages:

Unable to determine net-library error: This error means that the .DLL's needed are nowhere to be found. These files should be in your

\Sybase\DLL directory:

Libblk.dll  
Libcomn.dll  
Libcs.dll  
Libct.dll  
Libintl.dll  
Libsrv.dll  
Libsybdb.dll  
Libtcl.dll  
Mscvrt10.dll  
Nldecnet.dll  
Nlmsnmp.dll  
Nlnwadv.t.exe  
Nlnwlink.dll  
Nlwnsck.dll

Disclaimer: This document does not promise a connection, it only shows the best and fastest way to connect.

## Article #16407: Hints on Overcoming Installation Problems

Technical Information Database

TI1407D.txt - Hints on Overcoming Installation Problems

Category :Delphi 2.x  
Platform :All-32Bit  
Product :Delphi2.x,

Description:

Delphi 2.0 Up and Running!

-----

This technical document is designed to assist you in reinstalling Delphi 2.0. If you require additional assistance see the borland web site for support options.

Pre-Installation Recommendations

-----

- \* Before reinstalling Delphi 2.0, run the uninstall option from the add/remove program icon in the Windows 95 control panel, or select the uninstall icon from the Delphi 2.0 program group under Windows NT.
  
- \* Do not run the uninstall from the Delphi 2.0 CD.
  
- \* Before uninstalling and reinstalling Delphi 2.0, shut down the any applications using the Borland Database Engine, and close the Local InterBase Server (if running) by selecting the Local InterBase icon (right click from the system tray in Windows 95) and choose "shutdown".

- \* Installing Delphi 2.0 on a Windows NT system requires Windows NT version 3.51 or later.
  
- \* Before installing Delphi 2.0, it is suggested that you install the latest service pack available for your Windows system. Service packs are available from the Microsoft Corporation. One good source is Microsoft's World Wide Web site on the Internet located at [www.microsoft.com](http://www.microsoft.com).
  
- \* If you already have a Delphi 1.0 installation on your system, you should install Delphi 2.0 to a different directory structure. The only directory that is recommended to be common to both versions of Delphi is the IDAPI directory.
  
- \* Be sure you have proper administration rights on the machine you are installing to.
  
- \* Installing Delphi 2.0 to a network server is not supported.
  
- \* To install Delphi 2.0 to a computer that does not have a CD-ROM drive, use a network connection or set up a direct cable connection using a parallel or serial cable, and copy the files in the install directory on the Delphi 2.0 CD to a temporary directory on the computer you wish to install to, then run the setup program from the temporary directory created on the computer without the CD-Rom. After successful installation, you may delete the files you copied to the temporary directory.
  
- \* If you are running stacker, rename VSTACKER.386 (located in your windows\system directory) to VSTACKER.\*\*\*. Restart Windows, and run the install program again.
  
- \* If you have disabled virtual memory, you need to re-enable it for the installation program allowing for at least 64MB of virtual memory.

- \* Long file names should be enabled on your operating system.
- \* If you have installed Paradox, delete all trailing lock files before installing.

## Installation Errors

-----

- \* If the online registration wizard does not complete your online registration, run the install program again, selecting cancel when you are presented with the choice of registering online. Please complete and mail the registration card included with your Delphi 2.0 product.
- \* Should you receive a blank dialog box during install, select cancel and the install should continue successfully.
- \* During the installation, should you receive one of the following error messages:

"out of disk space",  
"no temp var",  
"error 101"  
"error 102"

Add more disk space and/or make sure you have a "temp" environment variable defined and a temp directory created. There must be ample free space on the drive the temp directory is located on.

- \* During the installation, should you receive the error:

"Install Shield error filename -51"

Try the following:

- 1) Copy all the files (EXCEPT CTL3D32.DLL) from the

runimage\delphi20\windows\system32 directory on the Delphi 2.0 CD to a temporary directory on your hard disk.

- 2) Clear the read only attribute on all the files you copied to the temporary directory.
- 3) Copy the files to your windows\system directory, or windows\system32 on Windows NT systems.
- 4) Run setup again.

#### Other tips and techniques for a successful installation

-----

- \* Try running the install from your hard disk. To do this, uninstall Delphi 2.0, then simply copy the files from the install directory on the Delphi 2.0 CD to a temporary directory on any hard drive, then run the install program from that temporary directory. After successful installation, you may delete the files you copied to the temporary directory.
- \* Temporarily rename the win.ini file (located in your Windows directory) to win.in\$, reboot, and reinstall or rerun Delphi 2.0. If this helps, suspect any programs listed in the run, or load sections of win.ini, or any non standard print drivers.
- \* Boot with the standard video driver shipped with your Windows system.
- \* Check for read-only attributes on files in the Windows and windows\system directories.

#### Post Installation Issues

-----

- \* Should you receive the error message: "odbc is corrupt or not

installed correctly" or "BDECFG32.EXE Error" when you try to install a 32 bit ODBC driver to the BDE, you first need to install a 32 bit ODBC manager, available from InterSolv and Microsoft. One good source is Microsoft's World Wide Web site on the Internet located at [www.microsoft.com](http://www.microsoft.com).

- \* If you install Delphi 1.0 after installing Delphi 2.0, and Delphi 2.0 loads Delphi 1.0's help files, delete any references to the Delphi 1.0 help file in the WINHELP.INI file located in your Windows directory.

## Article #16412: A Better Way To Print a Form

Technical Information Database

TI1412D.txt - A Better Way To Print a Form

Category :Printing  
Platform :All-32Bit  
Product :All32Bit,

Description:

The following TI details a better way to print the contents of a form, by getting the device independent bits in 256 colors from the form, and using those bits to print the form to the printer.

In addition, a check is made to see if the screen or printer is a palette device, and if so, palette handling for the device is enabled. If the screen device is a palette device, an additional step is taken to fill the bitmap's palette from the system palette, overcoming some buggy video drivers who don't fill the palette in.

Note: Since this code does a screen shot of the form, the form must be the topmost window and the whole form must be viewable when the form shot is made.

```
unit Prntit;  
  
interface

## Article #16417: Creating a DataAware Control for Browsing Data

Technical Information Database

TI1417D.txt Creating a DataAware Control for Browsing Data

Category :Database Programming

Platform :All

Product :Delphi All

Description:

OVERVIEW

This document describes minimal steps necessary to create a data-aware browsing component that displays data for a single field. The example component is a panel with DataSource and DataField properties similar to the TDBText component. See the Component Writer's Guide "Making a Control Data-Aware" for further examples.

WHO SHOULD USE THIS DOCUMENT

To get the best use of this document, you should be familiar with data aware control functionality and fundamental component creation tasks, such as

- deriving components from existing components
- overriding constructor and destructors
- creating new properties
- getting and setting property values
- assigning event handlers

BASIC STEPS TO CREATE A DATA-BROWSING COMPONENT

- Create or derive a component that allows the display, but not the entry of data. For instance, you could use a

TMemo with ReadOnly set to true. In the example outlined in this document, we'll use a TCustomPanel. The TCustomPanel will allow display, but not data entry.

- Add a data-link object to your component. This object manages communication between the component and the database table.
- Add DataField and DataSource properties to the component.
- Add methods to get and set the DataField and DataSource.
- Add a DataChange method the component to handle the data-link object's OnDataChange event.
- Override the component constructor to create the datalink and hook up the DataChange method.
- Override the component destructor to cleanup the datalink.

#### CREATING THE TDBPANEL

- Create or derive a component that allows the display, but not the entry of data. We'll be using a TCustomPanel as a starting point for this example.

Choose the appropriate menu option to create a new component (this will vary between editions of Delphi), and specify TDBPanel as the class name, and TCustomPanel as the Ancestor type. You may specify any palette page.

- Add DB and DBTables to your Uses clause.
- Add a data-link object to the components private section. This example will display data for a single field, so we will use a TFieldDataLink to provide the connection between our new component and a DataSource. Name the new data-link object FDataLink.

```
{ example }
private
    FDataLink: TFieldDataLink;
```

-- Add DataField and DataSource properties to the component. We will add supporting code for the get and set methods in following steps.

Note: Our new component will have DataField and DataSource properties and FDataLink will also have its own DataField and Datasource properties.

```
{ example }
published
  property DataField: string
    read  GetDataField
    write SetDataField;
  property DataSource: TDataSource
    read  GetDataSource
    write SetDataSource;
```

-- Add private methods to get and set the DataField and DataSource property values to and from the DataField and DataSource for FDataLink.

```
{ example }
private
  FDataLink: TFieldDataLink;
  function GetDataField: String;
  function GetDataSource: TDataSource;
  procedure SetDataField(Const Value: string);
  procedure SetDataSource(Value: TDataSource);
  .
  .
implementation
  .
  .
function TDBPanel.GetDataField: String;
begin
  Result := FDataLink.FieldName;
end;

function TDBPanel.GetDataSource: TDataSource;
begin
  Result := FDataLink.DataSource;
end;

procedure TDBPanel.SetDataField(Const Value: string);
begin
```

```

    FDataLink.FieldName := Value;
end;

procedure TDBPanel.SetDataSource(Value: TDataSource);
begin
    FDataLink.DataSource := Value;
end;

-- Add a private DataChange method to be assigned to the
-- datalink's OnDataChange event.  In the DataChange method
-- add code to display actual database field data provided
-- by the data-link object.  In this example, we assign
-- FDataLink's field value to the panel's caption.

{ example }
private
    .
    .
    procedure DataChange(Sender: TObject);

implementation
    .
    .
    procedure TDBPanel.DataChange(Sender: TObject);
begin
    if FDataLink.Field = nil then
        Caption := '';
    else
        Caption := FDataLink.Field.AsString;
end;

-- Override the component constructor Create method.  In the
-- implementation of Create, create the FDataLink object, and
-- assign the private DataChange method to FDataLink's
-- OnDataChange event.

{ example }
public
    constructor Create(AOwner: TComponent); override;
    .
    .
implementation
    .
    .

```

```

constructor TMyDBPanel.Create(AOwner: TComponent);
begin
    inherited Create(AOwner);
    FDataLink := TFieldDataLink.Create;
    FDataLink.OnDataChange := DataChange;
end;

-- Override the component destructor Destroy method. In the
  implementation of Destroy, set OnDataChange to nil (avoids a
  GPF), and free FDataLink.

{ example }
public
    .
    .
    destructor Destroy; override;
    .
    .
implementation
    .
    .
destructor TDBPanel.Destroy;
begin
    FDataLink.OnDataChange := nil;
    FDataLink.Free;
    inherited Destroy;
end;

-- Save the unit and install the component (see the Users
  Guide, and the Component Writers Guide for more on
  saving units and installing components).

-- To test the functionality of the component, add a TTable,
  TDataSource, TDBNavigator and TDBPanel to a form. Set the
  TTable DatabaseName and TableName to 'DBDemos' and 'BioLife',
  and the Active property to True. Set the TDataSource
  Dataset property to Table1. Set the TDBNavigator and
  TDBPanel DataSource property to DataSource1. The TDBpanel
  DataField name should be set as 'Common_Name'. Run the
  application and use the navigator to move between records to
  demonstrate the TDBPanel's ability to detect the change in
  data and display the appropriate field value.

```

```

## Article #16422: Using InputBox, InputQuery, and ShowMessage

Technical Information Database

TI1422D.txt Using InputBox, InputQuery, and ShowMessage  
Category :General Programming  
Platform :All  
Product :Delphi 1.0

### Description:

This function will demonstrate 3 very powerful and useful procedures built into Delphi.

The InputBox and InputQuery both allow user input.

Use the InputBox function when it doesn't matter if the user chooses either the OK button or the Cancel button (or presses Esc) to exit the dialog box. When your application needs to know if the user chooses OK or Cancel (or presses Esc), use the InputQuery function.

The ShowMessage is another simple way of displaying a message to the user.

```
procedure TForm1.Button1Click(Sender: TObject);
var s, s1: string;
    b: boolean;
begin
  s := Trim(InputBox('New Password', 'Password', 'masterkey'));
  b := s <> '';
  s1 := s;

  if b then
    b := InputQuery('Confirm Password', 'Password', s1);

  if not b or (s1 <> s) then
    ShowMessage('Password Failed');
end;
```

## Article #16427: Create a new file with the .wav extension.

Technical Information Database

TI1427D.txt Create a new file with the .wav extension.

Category :General Programming

Platform :All

Product :Delphi All

### Description:

This document describes the process for creating added functionality ,that many Delphi users have requested, to the TMediaPlayer. The new functionality is the ability to create a new file with the .wav format when recording. The procedure "SaveMedia" creates a record type that is passed to the MCISend command. There is an appexception that calls close media if any error occurs while attempting to open the specified file. The application consists two buttons. Button1 calls the OpenMedia and RecordMedia procedures in that order.The CloseMedia procedure is called whenever an exception is generated in this application. Button2 calls the StopMedia,SaveMedia, and CloseMedia procedures.

## Article #16432: Using MS Internet Explorer 3.0 OCX in Delphi 2

Technical Information Database

TI1432D.txt - Using MS Internet Explorer 3.0 OCX in Delphi 2

Category :Delphi 2.x  
Platform :All-32Bit  
Product :Delphi2.x,

Description:

Topic: Access Violation when using MS Internet Explorer 3.0 WebBrowser as an OCX in Delphi.

Problem: When you create an OCX wrapper class in Delphi to host the Internet Explorer 3.0 HTML viewer control (named TExplorer or TWebBrowser depending on the age of your IE installation) and use it in a Delphi app that calls the Navigate method of that OCX control, you'll get an access violation as well as possibly ruin your whole Win95 OLE session.

Reason: IE 3.0 calls the IOleClientSite.GetContainer method of Delphi's OCX wrapper implementation. Delphi returns an error code E\_NOTIMPL, but IE 3.0 only looks for error code E\_NOINTERFACE. IE 3.0 ignores all other error codes and plows ahead with using the bogus interface pointer, thus the access violation occurs.

Solution: In Delphi 2.0's OleCtrls.pas, modify method TOleClientSite.GetContainer to return E\_NOINTERFACE instead of E\_NOTIMPL as its function result. Note that this doesn't entirely solve the IE 3.0 error checking problem, but it at least placates it.

Important Note: Delphi Developer and Delphi C/S customers can make the change and recompile without affecting any other units. Delphi Desktop customers don't have the VCL source code, so they will need an updated DCU from Borland in order to fix it.

Special Thanks: Danny Thorpe

## Article #16437: BDE and Database Desktop Locking Protocol

Technical Information Database

TI1437D.txt - BDE and Database Desktop Locking Protocol

Category :Database Programming

Platform :All Windows

Product :

Description:

Intended Audience

This information will be of benefit to anyone considering designing a database application using Delphi and the BDE.

Prerequisites

A basic knowledge or interest in Paradox locking protocols and table formats.

Purpose

To give users a better understanding of the table locking protocol.

Table and field types and features supported

Each major release of Paradox has implemented improvements to table structures since version 2.0. All Paradox table types from Paradox 1.0 through Paradox 3.5 are compatible with each other.

Paradox 4.0 adds a new data type to the table format: Binary Large Objects, commonly known as BLObs and new types of Secondary Indices. Paradox 4.0 supports two types of BLOb fields: Memo, and BLOb. Versions of Paradox prior to 4.0, or the Engine prior to 3.0, cannot read, write, or create this new table format. If you attempt to read or write a Paradox 4.0 table type in an earlier version of Paradox, it will return an error that the table is password protected.

Paradox 5.0 added several new data types to the table format: Long Integer, Time, TimeStamp, Logical, Autoincrement, BCD, Bytes. Paradox 7.0 added a descending secondary index.

Any table created or modified to include any of these newer features will default to the respective table level. The default table type created using the Database Desktop and the BDE (Borland Database Engine) is a Paradox 4.0. Although the default can be changed in the BDE configuration utility or the Database desktop configuration utility to default to Paradox 3, 4, 5 and 7 for the BDE.

Paradox 4.0 can read, write, and create Paradox table types that are compatible with Paradox 1.0 through Paradox 4.0. So a table created in Paradox 1.0 is compatible with Paradox 4.0. A table created in Engine 1.0 or 2.0 can be read by or written to by Paradox 4.0.

Paradox and the Engine do not change the table type when reading or writing. The table type is only changed when a Restructure is performed on the table.

### Paradox Locking Protocols

There are two different Paradox locking protocols: the protocol introduced with Paradox 2.0 and the protocol introduced with Paradox 4.0. These two protocols are not compatible with each other. The locking protocol has no bearing on which type of table a program can work with. There are a few programs that can support either locking protocol; however, these programs can only support one protocol at a time. We will only focus on the 4.0 locking protocol.

### Database Desktop/ Paradox 4.0 Locking Protocol

The Paradox 4.0 locking protocol is the only protocol available for Paradox 4.0 and the IDAPI Engine. The designation "Paradox 4.0 locking protocol" represents this style of locking.

### Directory Locks

Paradox 4.0 places a locking file, PDOXUSRS.LCK, in each directory where tables are being accessed. This locking file regulates concurrent access to files in the directory. The lock file references PDOXUSRS.NET, so every user must map to the data directory the same way. It also places an exclusive PARADOX.LCK file in the directory as well. It does this to prevent versions of Paradox or the Engine using the older locking system from inadvertently accessing tables.

### Working/Shareable Directories

When Paradox or Database Desktop needs to access tables in a

directory, they place a "Shareable" PDOXUSRS.LCK file in that directory and an "Exclusive" PARADOX.LCK file in that directory. This designation means that other Paradox 4.0 users can access tables in that directory. The exclusive PARADOX.LCK file is placed in this directory to keep the older, incompatible locking protocol from putting data at risk. In Paradox, this is known as a "Working" directory.

#### Private/Exclusive Directories

Paradox and Database Desktop also need a directory to store temporary files, such as the Answer table from a query. When Paradox or Paradox Runtime start, they also place an "Exclusive" PDOXUSRS.LCK file in a directory and an "Exclusive" PARADOX.LCK file in the same directory, designating that directory as the location for temporary files. This designation means that other Paradox users cannot access tables in that directory. In Paradox this is known as a "Private" directory.

#### Table Locks

Paradox 4.0 places each table lock in the directory locking file: PDOXUSRS.LCK. It no longer uses the separate table lock file of previous versions. For example, if three users are viewing the CUSTOMER.DB table and one user is restructuring the ORDERS.DB table, the PDOXUSRS.LCK file will have a shareable lock listed for each of those three users who are viewing the CUSTOMER.DB table, and an exclusive lock on ORDERS.DB for the user who is restructuring that table.

#### Paradox 4.0 Locking Protocol Concurrency

In a multi-user environment, the Paradox 4.0 locking protocol maintains concurrency, the simultaneous use of applications, through the PDOXUSRS.NET file. All users who want to share Paradox tables must map to the same PDOXUSRS.NET file in the same way using the same path, but not necessarily the same drive letter. Paradox places a PDOXUSRS.LCK and an exclusive PARADOX.LCK file in each directory where tables are being accessed preventing previous versions of Paradox from accessing files in the same directory. Each user who wants to share tables in that directory must map that directory the same way using the same drive letter and path. Paradox then places all of the locking information for that table in the PDOXUSRS.LCK file, reducing the number of files needed.

#### Network Control File

The Paradox network control file, PDOXUSRS.NET, serves as the

reference point for all lock files created by Paradox. The net file contains the users currently using the BDE and which table they're accessing. Each lock file references the network control file and contains information regarding the locks on the table and by which user, so each user must map to the same network control file in the same way, but not necessarily with the same drive letter.

For example, if you are using volume DATA on server SERVER\_1 and the network control file is in the directory \PDOXDATA each user must map \\SERVER\_1\DATA:\PDOXDATA the same way, however, each user should, but is not required to use the same drive letter. If the network you are using does not have volumes, then DATA would be a directory off the root of SERVER\_1.

If you are mapping \\SERVER\_1\DATA to the root of drive P: then each Paradox system would specify the location of PARADOX.NET as P:\PDOXDATA\. However, other users could map \\SERVER\_1\DATA to the root of drive O: and specify O:\PDOXDATA\ as the location of the network control file.

#### Configuring 16 bit Database Engine / IDAPI.CFG

The Database Engine configuration file holds the network specific information and the list of database aliases, as well as other information. You can configure IDAPI using the Database Engine configuration program, BDECFG.EXE, to set the location of the network control file. Also add, delete, modify database aliases including which driver or type of alias used and whether IDAPI will share local tables with other programs using the Paradox 4.0 locking protocol as well as some other specifics regarding the tables and how data is displayed.

#### Local Settings 16 bit

The WIN.INI file holds the locations of the IDAPI.CFG file, the Database Desktop "Working" directory, and the Database Desktop "Private" directory. You can use any text editor to change these designations in the WIN.INI file. The location of the IDAPI.CFG file is CONFIGFILE= or CONFIGFILE01= in the [IDAPI] group.

The locations of the Database Desktop "Working" and "Private" directories are in the [DBD] group as WORKDIR=, and PRIVDIR=.

#### Configuring 32 bit Database Engine / IDAPI32.CFG

The BDE configuration file holds the same information as the Database Engine configuration file. Use the BDE Configuration, BDECFG32.EXE, to configure IDAPI32.CFG. Optionally you can store the information in the registry or in both the registry and IDAPI32.CFG.

#### Local Settings 32 bit

The registry holds the locations of the IDAPI32.CFG, the "Working" directory, and the "Private" directory. The location of the IDAPI32.CFG file is stored in HKEY\_LOCAL\_MACHINE\Software\Borland\Database Engine. The value CONFIGFILE01 holds the data containing .

The location of the BDE "Working" and "Private" directories are stored in

HKEY\_CURRENT\_USER\Software\Borland\DBD\7.0\Configuration\WorkDir and HKEY\_CURRENT\_USER\Software\Borland\DBD\7.0\Configuration\PrivDir respectively. Each directory default value stores the data containing

.

#### Accessing a Paradox Table

The BDE will first try to access the PDOXUSRS.NET file. If a PDOXUSRS.NET file is not found, Paradox will create a new PDOXUSRS.NET file and continue with the startup procedure. If the PDOXUSRS.NET file is found but the owner of this net file used a different path, i.e. mapped to the server differently, an exception of "Multiple net files in use" will be raised and the BDE will shutdown. After the net is successfully opened an exclusive lock, PARADOX.LCK, is placed in the temporary, private, directory. If it fails to place the lock the BDE will shut down. This can fail if some other user has an exclusive lock in this directory or the lock files are using different net files. After it secures a directory for private use it will place a shareable PARADOX.LCK in the working directory and now Initialization is complete.

## Article #16442: Getting a record member char array into a memo.

Technical Information Database

TI1442D.txt - Getting a record member char array into a memo.

Category :Delphi 1.x  
Platform :All Windows  
Product :

### Description:

Handling large strings with the 16 bit Delphi product can be difficult. Especially when the strings are part of a record structure and you would like to flow them into a TMemo. This document shows how to create a record structure that has a 1000 character member and still write it out from a memo then read it back into a memo. The main thrust of the method is to use the GetTextBuf method of the memo. The record structure used is just a string and the array of 1000 chars, but it could be much more complex.

```
unit URcrdIO;
```

```
interface
```

```
uses
```

```
  SysUtils, WinTypes, WinProcs, Messages, Classes, Graphics, Controls,  
  Forms, Dialogs, StdCtrls,dbtables;
```

```
type
```

```
  TForm1 = class(TForm)  
    Button1: TButton;  
    Memo1: TMemo;  
    Button2: TButton;  
    procedure Button1Click(Sender: TObject);  
    procedure Button2Click(Sender: TObject);
```

```
  private
```

## Article #16447: How to Get the Most Out of DBDEMOS

Technical Information Database

TI1447D.txt - How to Get the Most Out of DBDEMOS

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

Description:

OVERVIEW:

To most Delphi Developers, DBDEMOS is just an alias, but this TI will show that DBDEMOS is more than just sample tables. Included with Delphi 2.0 is the Delphi Demo Explorer where you can easily choose to view a wide range of sample applications, based on concept or by example. Also included in this TI is a directory listing of where to find various other examples and demonstrations included with the Delphi 2.0 CD.

TARGET AUDIENCE:

This TI is aimed at all developers, from beginning to master programmers. Although beginners will be able to run though these examples in order to grasp fundamental Delphi concepts, the master programmers can use this as a reference sheet in order to gain more experience and to research further in any particular area.

DELPHI 2.0 DEMO EXPLORER

-----  
The Demo Explorer allows you to browse through a database of all Delphi demonstration programs. As outlined in `\info\Borland\Demoexpl\Readdx.Txt` on the Delphi 2.0 CD, follow the directions below to install the Delphi 2.0 Demo Explorer:

1. Close Delphi 2.0 if it is running.
2. Create a `\DemoExpl` directory off of the directory in which you installed Delphi 2.0.  
(i.e., `c:\Program Files\Borland\Delphi 2.0\DemoExpl`).

3. Copy all of the files from the \info\borland\demoexpl directory of the Delphi 2.0 CD-ROM to the directory you created in step 1.
4. Use the Run option from the Start menu to run the REGEDIT application. Find:  
  \HKEY\_CURRENT\_USER\Software\Borland\Delphi\2.0\Experts  
key by expanding the tree view in the left pane of the Registry Editor window. If you have no experts key then you must create one.
5. Highlight the Experts key in the left pane, and right click on the right pane of the Registry Editor window. From the local menu, select New|String value, enter "DemoExplorer" as the new value, and press the Enter key.
6. Right click on DemoExplorer in the right pane, and select Modify from the local menu. This will invoke the Edit String dialog. In this dialog, enter the full path from step 1 followed by "\demoexpl.dll". For example:  
  c:\Program Files\Borland\Delphi 2.0\DemoExpl\demoexpl.dll.
7. Demo Explorer is now installed. Run Delphi 2.0, and you can invoke Demo Explorer by selecting "Explore Sample Applications" from the Help menu.

#### WHERE TO FIND DB DEMOS, DATA AND RELATED FILES

-----

1. \Demos\DB contains 17 directories of demonstration database related projects.
2. \Doc
  - a) \Dataedit
  - b) \DBCAl
3. \Demos\Data contains Interbase, Paradox, dBase tables, indexes, validation, memos, bitmaps.
4. \Iblocal\Examples contains Interbase tables Employee.GDB and INTlemp.GDB for Delphi 1.0.
5. \IntrBase\Examples) contains Interbase tables Employee.GDB and INTlemp.GDB for Delphi 2.0.
6. \Source\Samples
  - a) Ibctrls.pas
  - b) IBEvents.pas
  - c) IBProc32.pas

#### DELPHI 1.0 EXAMPLES

-----

1. Animals:  
  Simplest possible example using data aware controls

and a dBase table. See also FishFact.

2. BDEDLL:  
Demonstrates use of the BDE within a DLL for Delphi 1.0. If the customer is having trouble with a DLL that uses BDE they may check the comments in these two projects. Note: If "DB" appears in the uses clause of a unit, they are using BDE. This is because DB.PAS contains an initialization section that automatically starts the Borland Database Engine. For example, if a data aware control is dropped on the form, DB will be added to the uses clause, and when the application is run, BDE will start, even if the data aware control is removed at a later time.
3. CalcFlds:  
Demonstrates assigning values to calculated fields where looking into a secondary table is necessary.
4. Datalist:  
Populates list boxes with list of available databases, tables, fields and indexes for a given session.
5. DBAware1:  
Demos the use of TDBEdit, TDBComboBox, and TDBListbox.
6. DBAware2:  
Demos the use of TDBLookupCombo and TDBLookupList. The use of TDBLookupCombo and TDBLookupList are commonly misunderstood - this project shows these controls being used for their intended use.
7. FishFact:  
Simplest possible example using data aware controls and a Paradox table. See also Animals.
8. Format:  
Though not specifically a database application, this project demonstrates the use of the Format function to manipulate the display of floating point numbers.
9. InsQuery:  
Demonstrates inserting and deleting records from a server table using SQL statements containing parameters.
10. LinkQry:  
Displays two grids of master and detail records where the relationship between the master and child tables is performed through a parameterized query.
11. MastApp:  
A complete order entry system with functionality to add, modify, browse and report on orders, customers, parts, and items. Also contains application help, and comments within the main unit on upsizing from the default Paradox to Interbase.
12. QJoin:  
An example of joining two tables using SQL statements.

- Displays customer and order records where customer numbers match.
13. Range:  
Demonstrates the use of SetRangeStart, SetRangeEnd, ApplyRange, and CancelRange.
  14. Search:  
Demonstrates a single search for customer number executed from a button click.
  15. Stocks:  
Stock charting application including Market Browser, Industry Charts, Customer Details, Customer Charts, and reporting. The projects demonstrates dynamically population of combo boxes used in turn for dynamically created SQL statements and Chart FX.
  16. Tools:  
Review the Readme.txt file in this directory for more information on setting up these projects. Here's an excerpt from the read me:
    - \* These demos show examples of:
    - \* An example database MDI application (DBBROWSE.DPR)
    - \* An example database popup application (SQLMON.DPR)
    - \* An example of how to derive new database components for the Borland Database Engine system tables (BDETABLES.PAS)
    - \* An example of how to use the database error stack available in the VCL exception class EDbEngineError. This exception is raised when a Borland Database Engine error occurs (DBEXCEPT.\*)
  17. TwoForms:  
Shows data aware controls on two forms kept in sync by accessing a common dataset control (a TTable) located on the first form.

## DELPHI 2.0 EXAMPLES

-----

1. BdQuery:  
Demonstrates how to execute a query in a background thread.
2. CachedUp:  
This example demonstrates how cached updates can be used with live data and in conjunction with the UpdateSQL component for non-live data. See About.txt in this same directory for more information.
3. CsDemos:  
Demonstrates Client/Server concepts, including triggers, stored procedures executed from both TStoredProc and TQuery, and transactions.
4. CtrlGrid:

A Stock browser showing detail data in a TDBCtrlGrid.

5. DbErrors:

This example represents a sampling of the way that you might approach trapping a number of database errors. See comments in the data module of this project.

6. Filter:

Customer/Orders browser allowing a number of query and table based filters. A second form allows building and executing filters over the customer table at runtime.

7. Find:

Demonstrates record location and incremental searches on filtered and un filtered tables. Includes examples of FindNearest, Locate, and GoToCurrent usage.

8. GdsDemo:

Order entry application for "Global Diving Supply" with grid and single record views.. This project allows you to experiment with the effects of form inheritance. The project contains two sets of both grid and single record forms which allows you to change the "GDS standard" form and watch the effects on the inherited form. The project also demonstrates techniques for calculating fields, record filtering, and locating records that match the filter, using FindFirst, FindNext, FindPrior, or FindLast.

9. IBDemo:

Demonstrates listing, registering, and generating InterBase events. The project also includes the TIbEventAlerter component from the samples component palette page.

10. Lookup:

Example of "lookup" TFields that allow for drop down combos within a TDBGrid. This feature currently available in Delphi 2.0.

11. NavMDI:

Master and detail data displayed on separate MDI forms, and navigator displayed in the MDI parent.

12. NavSDI:

Navigator, master and detail each displayed on separate forms.

13. NdxBuild:

Utility to rebuild indexes for one or all tables within a given alias. Contains code using the BDE API (the dbiRegenIndexes function ), application level exception handler, and listing of alias for a given session.

14. QBFDemo:

This example shows a way to provide users with the ability to define their own queries. If your query returns records, then a Results Viewer displays those results; otherwise,

you'll receive a message indicating that no records matched the search.

## Article #16452: Exposing the OnClick of the DBGrid control

Technical Information Database

TI1452D.txt - Exposing the OnClick of the DBGrid control

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Many people want to use the OnClick of the TDBGrid. The TDBGrid has no such event. This document tells how to surface the OnClick event for the TDBGrid. The general technique applied here can be used to surface other properties for other objects. If you know that an ancestor could do it this is how to make the descendant do it. One of the powerful things done here is the addition of the csClickEvents to the ControlStyle set property of the control. This allows the control when typecast as THack to receive and correctly process the click message from windows. The assignment of the OnClick for some other control to the OnClick of the DBGrid1 gives the ability to access and use the OnClick event of a control that has no such event.

This is a hack. There are reasons that dbgrid does not surface the click event. Use this code at your own risk.

```
unit Udbgclk;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics,
  Controls, Forms, Dialogs,
  StdCtrls, Grids, DBGrids, DBTables, DB;

type
  thack = class(tcontrol);
```

```
TForm1 = class(TForm)
  DBGrid1: TDBGrid;
  Button1: TButton;
  DataSource1: TDataSource;
  Table1: TTable;
  procedure Button1Click(Sender: TObject);
  procedure FormClick(Sender: TObject);
```

```
private
  { Private declarations }
public
  { Public declarations }
end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  THack(dbgrid1).controlstyle :=
    THack(dbgrid1).controlstyle + [csClickEvents];
  THack(dbgrid1).OnClick := Form1.OnClick;
end;
```

```
procedure TForm1.FormClick(Sender: TObject);
begin
  messagebeep(0);
  application.processmessages;
end;
```

```
end.
```

```

```

## Article #16457: Getting runtime properties at runtime

Technical Information Database

TI1457D.txt Getting runtime properties at runtime

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

Object Property Information at Runtime.

-----

You may need to know at runtime what properties are available for a particular component at runtime. The list can be obtained by a call to `GetPropList`. The types, functions and procedures, including `GetPropList`, that allow access to this property information reside in the VCL source file `TYPINFO.PAS`.

### GetPropList Parameters

-----

```
function GetPropList(TypeInfo: PTypeInfo; TypeKinds: TTypeKinds;
  PropList: PPropList): Integer;
```

The first parameter for `GetPropList` is of type `PTypeInfo`, and is part of the RTTI (Run Time Type Information) available for any object. The record structure defined:

```
PTypeInfo = ^PTypeInfo;
PTypeInfo = ^TTypeInfo;
TTypeInfo = record
  Kind: TTypeKind;
  Name: ShortString;
  {TypeData: TTypeData}
end;
```

The `TTypeInfo` record can be accessed through the objects `ClassInfo` property. For example, if you were getting the property list of a `TButton`, the call might look, so far, like this:

```
GetPropList(Button1.ClassInfo, ....
```

The second parameter, of type TTypeKinds, is a set type that acts as a filter for the kinds of properties to include in the list. There are a number of valid entries that could be included in the set (see TYPEINFO.PAS), but tkProperties covers the majority. Now our call to GetPropList would look like:

```
GetPropList(Button1.ClassInfo, tkProperties ....
```

The last parameter, PPropList is an array of PPropInfo and is defined in TYPEINFO.PAS:

```
PPropList = ^TPropList;  
TPropList = array[0..16379] of PPropInfo;
```

Now the call might read:

```
procedure TForm1.FormCreate(Sender: TObject);  
var  
  PropList: PPropList;  
begin  
  PropList := AllocMem(SizeOf(PropList^));  
  GetPropList(TButton.ClassInfo, tkProperties + [tkMethod],  
    PropList);  
  .  
  .  
  .
```

Getting Additional Information from the TTypeInfo Record

---

The example at the end of this document lists not just the property name, but it's type. The name of the property type resides in an additional set of structures. Let's take a second look at the TPropInfo record. Notice that it contains a PTypeInfo that points ultimately to a TTypeInfo record. TTypeInfo contains the class name of the property.

```
PPropInfo = ^TPropInfo;  
TPropInfo = packed record  
  PropType: PTypeInfo;  
  GetProc: Pointer;
```

```

SetProc: Pointer;
StoredProc: Pointer;
Index: Integer;
Default: Longint;
NameIndex: SmallInt;
Name: ShortString;
end;

```

```

PTypeInfo = ^PTypeInfo;
PTypeInfo = ^TTypeInfo;
TTypeInfo = record
    Kind: TTypeKind;
    Name: ShortString;
    {TypeData: TTypeData}
end;

```

#### Example code

-----

The example below shows how to set up the call to `GetPropList`, and how to access the array elements. `TForm` will be referenced in this example instead of `TButton`, but you can substitute other values in the `GetPropList` call. The visible result will be to fill the list with the property name and type of the `TForm` properties.

This project requires a `TListBox`. Enter the code below in the forms `OnCreate` event handler.

```

uses TypInfo;

procedure TForm1.FormCreate(Sender: TObject);
var
    PropList: PPropList;
    i: integer;
begin
    PropList := AllocMem(SizeOf(PropList^));
    i := 0;
    try
        GetPropList(TForm.ClassInfo, tkProperties + [tkMethod], PropList);
        while (PropList^[i] <> Nil) and (i < High(PropList^)) do
            begin
                ListBox1.Items.Add(PropList^[i].Name + ': ' +
                    PropList^[i].PropType^.Name);
            end;
    end;
end;

```

```
    Inc(i);  
    end;  
finally  
    FreeMem(PropList);  
end;  
end;
```

## Article #16462: Search and replace in strings: a task made easy

Technical Information Database

TI1462D.txt Search and replace in strings: a task made easy

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

Search and replace in strings: a task made easy.

An often overlooked, yet strong feature of Delphi is its history. This product has its roots, and shares some code with Turbo Pascal version 1 released in 1983. Since then, every version of Turbo Pascal added new features, standard functions and procedures to the language. Under its current incarnation, Delphi continues to add features and syntax.

Doing search and replace on strings has been made trivial because of these 3 functions: Pos(), Delete(), and Insert(). Pos() takes two parameters, a pattern search string, and a string to find the pattern in - it returns the location of the string, or 0 if it does not exist. Delete() takes three parameters, the string to delete from, location of where to start deleting, and how much to delete. Similarly, Insert() takes three parameters too. The string that will be inserted, the string to insert into, the location to insert.

Many class properties use strings to store values, so one can use this method on any of them. For instance, the searching and replacing of an entire TMemo component might look like this:

```
procedure TForm1.Button2Click(Sender: TObject);
var
  i : integer;
  s1 : string;
  SearchStr : string;
  NewStr : string;
```

```
    place : integer;
begin
  SearchStr := 'line';
  NewStr := 'OneEye';
  for i := 0 to Mem1.Lines.Count -1 do begin
    s1 := Mem1.Lines[i];
    Repeat
      Place := pos(SearchStr, s1);
      if place > 0 then begin
        Delete(s1, Place, Length(SearchStr));
        Insert(NewStr, s1, Place);
        Mem1.Lines[i] := s1;
      end; //if-then
    until place = 0;
  end; //for-loop
end;
```

## Article #16467: Dynamically creating a TTable & fields at runtime

Technical Information Database

TI1467D.txt - Dynamically creating a TTable & fields at runtime

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Delphi allows rapid addition and configuration of database elements to a Delphi project within the design environment, but there are situations where information needed to create and configure objects is not known at design time. For instance, you may want to add the ability to add columns of calculated values (using formulas of the users own creation) to an application at runtime. So without the benefit of the design environment, Object Inspector, and TFields editor, how do you create and configure TFields and other data related components programmatically?

The following example demonstrates dynamically creating a TTable, a database table based off the TTable, TFieldDefs, TFields, calculated fields, and attaches an event handler to the OnCalc event.

To begin, select New Application from the File menu. The entire project will be built on a blank form, with all other components created on-the-fly.

In the interface section of your forms unit, add an OnCalcFields\ event handler, and a TaxAmount field to the form declaration, as shown below.

Later we will create a TTable and hook this handler to the TTable's OnCalcFields event so that each record read fires the OnCalcFields event and in turn executes our TaxAmountCalc procedure.

type

```
 TForm1 = class(TForm)
  procedure TaxAmountCalc(DataSet: TDataset);
```

```
private
    TaxAmount: TFloatField;
end;
```

In the implementation section add the OnCalc event handler as shown below.

```
procedure TForm1.TaxAmountCalc(DataSet: TDataset);
begin
    Dataset['TaxAmount'] := Dataset['ItemsTotal'] *
        (Dataset['TaxRate'] / 100);
end;
```

Create a OnCreate event handler for the form as shown below (for more information on working with event handlers see the Delphi Users Guide, Chapter 4 "Working With Code").

```
procedure TForm1.FormCreate(Sender: TObject);
var
    MyTable: TTable;
    MyDataSource: TDataSource;
    MyGrid: TDBGrid;
begin
    { Create the TTable component -- the underlying
      database table is created later. }
    MyTable := TTable.Create(Self);
    with MyTable do
    begin
        { Specify an underlying database and table.
          Note: Test.DB doesn't exist yet. }
        DatabaseName := 'DBDemos';
        TableName := 'Test.DB';

        { Assign TaxAmountCalc as the event handler to
          use when the OnCalcFields event fires for
          MyTable. }
        OnCalcFields := TaxAmountCalc;

        { Create and add field definitions to the TTable's
          FieldDefs array, then create a TField using the
```

```

    field definition information. }
with FieldDefs do
begin
    Add('ItemsTotal', ftCurrency, 0, false);
    FieldDefs[0].CreateField(MyTable);
    Add('TaxRate', ftFloat, 0, false);
    FieldDefs[1].CreateField(MyTable);
    TFloatField(Fields[1]).DisplayFormat := '##.0%';

{ Create a calculated TField, assign properties,
and add to MyTable's field definitions array. }
TaxAmount := TFloatField.Create(MyTable);
with TaxAmount do
begin
    FieldName := 'TaxAmount';
    Calculated := True;
    Currency := True;
    DataSet := MyTable;
    Name := MyTable.Name + FieldName;
    MyTable.FieldDefs.Add(Name, ftFloat, 0, false);
end;
end;

{ Create the new database table using MyTable as
a basis. }
MyTable.CreateTable;
end;

{ Create a TDataSource component and assign
to MyTable. }
MyDataSource := TDataSource.Create(Self);
MyDataSource.DataSet := MyTable;

{ Create a data aware grid, display on the
form, and assign MyDataSource to access
MyTable's data. }
MyGrid := TDBGrid.Create(Self);
with MyGrid do
begin
    Parent := Self;
    Align := alClient;
    DataSource := MyDataSource;
end;

{ Start your engines! }

```

```
MyTable.Active := True;  
Caption := 'New table ' + MyTable.TableName;  
end;
```

The following is the full source for the project.

```
unit gridcalc;  
  
interface  
  
uses  
  Windows, Messages, SysUtils, Classes, Graphics, Controls,  
  Forms, Dialogs, Grids, DBGrids, ExtCtrls, DBCtrls, DB,  
  DBTables, StdCtrls;  
  
type  
  TForm1 = class(TForm)  
    procedure FormCreate(Sender: TObject);  
    procedure TaxAmountCalc(DataSet: TDataSet);  
  private  
    TaxAmount: TFloatField;  
  end;  
  
var  
  Form1: TForm1;  
  
implementation  
  
{ $R *.DFM }  
  
procedure TForm1.TaxAmountCalc(DataSet: TDataSet);  
begin  
  Dataset['TaxAmount'] := Dataset['ItemsTotal'] *  
    (Dataset['TaxRate'] / 100);  
end;  
  
procedure TForm1.FormCreate(Sender: TObject);  
var  
  MyTable: TTable;  
  MyDataSource: TDataSource;  
  MyGrid: TDBGrid;  
begin
```

```
MyTable := TTable.Create(Self);
```

```
with MyTable do
```

```
begin
```

```
  DatabaseName := 'DBDemos';
```

```
  TableName := 'Test.DB';
```

```
  OnCalcFields := TaxAmountCalc;
```

```
with FieldDefs do
```

```
begin
```

```
  Add('ItemsTotal', ftCurrency, 0, false);
```

```
  FieldDefs[0].CreateField(MyTable);
```

```
  Add('TaxRate', ftFloat, 0, false);
```

```
  FieldDefs[1].CreateField(MyTable);
```

```
  TFloatField(Fields[1]).DisplayFormat := '##.0%';
```

```
  TaxAmount := TFloatField.Create(MyTable);
```

```
with TaxAmount do
```

```
begin
```

```
  FieldName := 'TaxAmount';
```

```
  Calculated := True;
```

```
  Currency := True;
```

```
  DataSet := MyTable;
```

```
  Name := MyTable.Name + FieldName;
```

```
  MyTable.FieldDefs.Add(Name, ftFloat, 0, false);
```

```
end;
```

```
end;
```

```
MyTable.CreateTable;
```

```
end;
```

```
MyDataSource := TDataSource.Create(Self);
```

```
MyDataSource.DataSet := MyTable;
```

```
MyGrid := TDBGrid.Create(Self);
```

```
with MyGrid do
```

```
begin
```

```
  Parent := Self;
```

```
  Align := alClient;
```

```
  DataSource := MyDataSource;
```

```
end;
```

```
MyTable.Active := True;
```

```
Caption := 'New table ' + MyTable.TableName;
```

```
end;
```

end.

## Article #16472: Activation and Use of the CPUWindow in the IDE

Technical Information Database

TI1472D.txt - Activation and Use of the CPUWindow in the IDE

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

### Description:

Warning: The CPU window function is not fully tested and may fail in some cases. If you are having problems with the debugger or your program while using it you should disable it and this may solve your problem. Generally leave it off unless you have a specific need for it.

Delphi 2 has a built in feature, that is off by default, called the CPU window or DisassemblyView. It is easy to use and can be useful in debugging as well as in comparing code for optimization.

To activate this feature, run REGEDIT and edit the registry in the following way.

Go to HKEY\_CURRENT\_USER\Software\Borland\Delphi\2.0\Debugging. Once there add a new string key called "ENABLECPU". The value of the new key will be the string "1". That is all it takes. Now in thge Delphi IDE Select View|CPUWindow.This should bring up the new window.

Now to use this powerful feature to do comparative analysis on 2 snippets that do the same work with different source code use the following procedure.

Create 2 identical event handlers. Inside of each event handler place one of the snippets to be compared. Place a breakpoint on the first line within each handler. Run the application and activate the events. Compare the assembly code for each method. Is one shorter? If so this will execute faster.

Cases worthy of this analysis are lines of code that

will execute repeatedly, code that must be optimized for real time application, or code in applications that have to be as fast as possible for whatever reason.

A great example of code that accomplishes the same thing but produces different performance is the "with object do" construct. Many times the source code will be longer using the "with object do" construct but the unassembled code will be shorter. Many times you set properties in a series for dynamically created objects. The code:

```
with TObject.create do
begin
  property1 := ;
  property2 := ;
  property3 := ;
end;
```

executes faster than:

```
MyObj := TObject.create;
MyObj.Property1 := ;
MyObj.Property2 := ;
MyObj.Property3 := ;
```

## Article #16477: Passing Multidimensional Arrays as Parameters

Technical Information Database

TI1477D.txt - Passing Multidimensional Arrays as Parameters

Category :Object Pascal  
Platform :All-32Bit  
Product :

### Description:

Passing an array to a procedure or function is straight forward and behaves as expected. However, passing a multi-dimensional array to a function or procedure is not handled in the same way. Consider MyArray to be defined as:

```
var  
MyArray: array[1..3, 1..5] of double;
```

And you want to pass it to a procedure called DoSomething() defined as:

```
procedure DoSomething(MyArray: array of double);  
begin  
    showmessage( floattostr( MyArray[1 , 1]));  
end;
```

One might think a simple statement like `DoSomething(MyArray);` would do the trick. Unfortunately, this is not the case. The statement `DoSomething(MyArray);` will not compile. The compiler sees the two data structures involved as different types - so it will not allow the statement. The `DoSomething()` procedure is expecting an array of doubles, but the example is passing a multi-dimensional array.

Delphi handles multi-dimensional arrays as user defined type, so there is no syntax to tell a procedure that its parameter(s) are multi-dimensional arrays - without declaring a type. Creating a type, and using

this type as the parameter is the correct method to pass a multi-dimensional array. We could just pass a pointer to the array, but inside the function, we need to typecast that pointer. What type to cast it as is the next issue. You would have to have the type defined, or declared identically in 2 places. This method just doesn't make sense.

By defining a type, we can change the process to this:

```
type
  TMyArray = array[1..3, 1..5] of double;

var
  MyArray : TMyArray;

procedure DoSomething(MyArray: TMyArray);
begin
  showmessage( floattostr( MyArray[1 , 1]));
end;
```

Now the actual call looks as we expected:

```
DoSomething(MyArray);
```

If you want to use the method of passing a pointer, your function might look like this:

```
type
  PMyArray = ^TMyArray;
  TMyArray = array[1..3, 1..5] of double;

var
  MyArray : TMyArray;

procedure DoSomething(MyArray: PMyArray);
begin
  showmessage ( floattostr( (MyArray[2,3]) ));
end;
```

Note, under 32 bit version Delphi, you do not need to dereference the MyArray variable inside DoSomething(). Under older versions you might have to refer to MyArray as MyArray^.

If you want to pass just a generic pointer, you may not

be able to use it directly. You can declare a local variable, and use it. Again, you may need to cast the local variable for older versions of PASCAL. Of course this method does offer more flexibility in data usage.

```
procedure DoSomething(MyArray: pointer);  
var  
    t : ^TMyArray;  
begin  
    t := MyArray;  
    ShowMessage ( FloatToStr( t[2,3]) );  
end;
```

Regardless, both calls that use a pointer method, will look something like:

```
MyArray[2, 3] := 5.6;  
DoSomething(  
MyArray);
```

## Article #16482: Implementing Drag and Drop Functionality

Technical Information Database

TI1482D.txt     Implementing Drag and Drop Functionality

Category     :Application Interop

Platform     :All

Product     :Delphi All

### Description:

This document describes the process of creating a drag and drop functionality that could be applied to text items and graphical objects. Regular text indicates the procedural steps to execute to achieve the functionality. Text in the parentheses is explanation and background information.

1. Place the two edit boxes onto your form. {One will serve as the source for the text that you will drag and drop. The other will serve as the destination you will drop the text onto.}
2. Select the first edit box and name it SourceEdit by entering that name in the name property in the Object Inspector.
3. Select the second edit box and name it SenderEdit. {The names source and sender are not necessary. They are suggested because "source" and "sender" are default variables given to work with in the OnDragOver and OnDragDrop event procedure code blocks. The source variable is where the drag operation began, and the sender variable is the control that was dropped onto. See the help topics related to messages for further information on this and related topics.}
4. Click the SourceEdit component so it is selected and go to the Object Inspector. Set its DragMode property to dmAutomatic.
5. Select the SenderEdit and go to the events page of the Object Inspector and double click on the OnDragOver event.
6. Type exactly what is in the quotes here where the cursor is between the begin and end statements: "Accept := True;".

```
{Notice that the Accept variable is supplied for you by  
default inside of the OnDragOver event procedure code block.}
```

7. Now go to the events page of the Object Inspector and double click on the OnDragDrop event.

8. Type exactly what is in the quotes here where the cursor is between the begin and end statements:

```
" SenderEdit.Text := SourceEdit.Text ".
```

Now if you run the application you will be able to click down on the SourceEdit component and drag and drop onto the SenderEdit component. When you drop onto the SenderEdit it changes its text to whatever was in the SourceEdit.

## Article #16487: Trapping Windows Messages in Delphi

Technical Information Database

TI1487D.txt Trapping Windows Messages in Delphi

Category :General Programming

Platform :All

Product :Delphi All

### Description:

While Delphi provides many ways to trap the incoming messages to VCL controls, you may require a quick and effective method of "stealing" and replacing the windows procedure of a given window. The method presented here will effectively trap all Windows messages for any window or VCL control that has a Window handle property.

### Background:

For every window that is created, a structure is created by the system that holds information about the window. The information contained in this structure includes, among other things, the window's parent, instance information, and the address of the window's main window procedure. It is through this procedure that all Windows messages are sent for that window.

The Microsoft Windows API provides functions to both retrieve and set the values contained in this structure, making it possible to retrieve the address of a window's main procedure and reset that address to point to a user installed function.

To replace the windows procedure, we will use the API function `SetWindowsLong()`, and pass in the handle of the window we wish to work with, the constant `GWL_WNDPROC` (telling the function we wish to replace the windows procedure), and the address of our function we wish to replace it with.

When we call the `SetWindowsLong()` function, it will return the previous value we are replacing. We will want to remember that value so we can call the original procedure for all the messages we do not care to trap. We will also want to reinstall the old procedure when we are done, so that message handling returns to normal.

In our example code, we will trap the WM\_VSCROLL message of a TDBGrid component, giving us an indication that the user has scrolled the vertical scroll bar. Since all messages for the control are passed first through our procedure, we can effectively trap and do processing for any event before it is ever received by the component.

For a list of other notification messages you may be interested in trapping, you may search the Delphi's Windows help file for messages starting with WM\_.

Also note that the code has been written to compile under both sixteen and thirty-two bit versions of Delphi.

```
unit WinProcl;  
  
interface  
  
uses  
{ $IFDEF WIN32 }  
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,

## Article #16497: Direct Commands to Printer - Passthrough/Escape

Technical Information Database

TI1497D.txt - Direct Commands to Printer - Passthrough/Escape

Category :Printing  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Although Delphi's TPrinter unit makes it easy to interface to a given printer, there are times when you may need to drop down to the printers level and send device specific escape sequences. Under 16-bit versions of Windows, this was as easy as opening the printer port, but under Windows NT, directly accessing the hardware is illegal. One solution is to use the Windows "PASSTHROUGH" escape to send an escape sequence directly to the printer. In order to use the "PASSTHROUGH" escape, it must be supported by the printer driver. Be forewarned that not all printer drivers will support this feature.

It's worth noting that the "PASSTHROUGH" escape is documented as obsolete for thirty-two bit applications. It should be a number of years before this escape goes by the way, since it is used in many commercial applications.

The example code presented is not targeted to any specific printer model. You will need to know the correct escape sequences to send to the printer you are interfacing to. Note that you must still call the BeginDoc and EndDoc methods of TPrinter. During the BeginDoc call, the printer driver initializes the printer as necessary, and during the EndDoc call, the printer driver will uninitialized the printer and eject the page. When you do make your escape call, the printer may be set for the current windows mapping mode if the printer supports scaling internally. Technically, you should not do anything that would cause the printer memory to be reset, or eject a page with an escape sequence. In other words, try to leave the printer in the same state it was in when you made your escape. This is more important on intellegent

printers (Postscript printers), and not important at all on a standard TTY line printer, where you can do just about anything you like, including ejecting pages.

Code Example:

You will need to declare a structure to hold the buffer you are sending. The structure of the buffer is defined as a word containing the length of the buffer, followed by the buffer containing the data.

Before making the escape call to pass the data, we will use the escape "QUERYESCSUPPORT" to determine if the "PASSTHROUGH" escape is supported by the print driver.

Finally, be aware that your data will be inserted directly into the printers data stream. On some printer models (Postscript), you may need to add a space to the start and end of your data to separate your data from the printer drivers data.

(Postscript is a Registered Trademark of Adobe Systems Incorporated)

        { Make the escape }
        Escape(Printer.Canvas.Handle,
            PASSTHROUGH,
            0,
            @Buff,

```

```
nil);
```

```
{ End the printout }
```

```
Printer.EndDoc;
```

```
end;
```

```
end;
```

```
end.
```

## Article #16502: Creating a form based on a string

Technical Information Database

TI1502D.txt    Creating a form based on a string  
Category     :Application Interop  
Platform     :All  
Product      :Delphi All

### Description:

Creating a form based on a string.

### OVERVIEW

This document demonstrates how to instantiate a Delphi form based on a string which specifies the name of the type. Sample code is given.

### WHO SHOULD USE THIS DOCUMENT

Anyone with a basic familiarity with Delphi programming. Applies to any version of Delphi.

### INSTANTIATING A FORM BASED ON A STRING

To be able to instantiate forms based on the string representing the names of their type, you must first register the type with Delphi. This is accomplished with the function "RegisterClass".

RegisterClass is prototyped as follows:

```
procedure RegisterClass(AClass: TPersistentClass);
```

AClass is a class of TPersistent. In other words, the class you are registering must be descended at some point from TPersistent. Since all Delphi controls, including forms, fit this requirement, we have will have no problem. This could not be used, for instance, to register classes descended directly from TObject.

Once the class has been registered, you can find a pointer to the type by passing a string to FindClass. This will

return a class reference, which you can use to create the form.

An example is in order:

```
procedure TForm1.Button2Click(Sender: TObject);
var
  b : TForm;
  f : TFormClass;
begin
  f := TFormClass(findClass('Tform2'));
  b := f.create(self);
  b.show;
end;
```

This will create the TForm2 type that we registered with RegisterClass.

#### WORKING SAMPLE PROGRAM

Create a new project, and then add 4 more forms, for a total of 5. You can populate them with controls if you like, but for this example, it is not important.

On the first form, put down an edit control, and a pushbutton. Take all forms, but the main form, out of the AutoCreate List.

Finally, paste the following code over the code in unit1, this will give you the ability to type the Class NAME into the Edit, and it will create that form for you.

```
unit Unit1;

interface

uses
  Unit2, Unit3, Unit4, Unit5, Windows, Messages,
  SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, StdCtrls;

type
```

```
TForm1 = class(TForm)
  Edit1: TEdit;
  Button1: TButton;
  procedure FormCreate(Sender: TObject);
  procedure Button1Click(Sender: TObject);
private
  { Private declarations }
public
  { Public declarations }
end;
```

```
var
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  RegisterClass(Tform2);
  RegisterClass(Tform3);
  RegisterClass(Tform4);
  RegisterClass(Tform5);
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  f : TFormclass;
begin
  f := tformclass(findClass(edit1.text));
  with f.create(self) do
    show;
end;
```

## Article #16507: Finding the color depth of a canvas

Technical Information Database

TI1507D.txt Finding the color depth of a canvas

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

When programming graphics in Windows, it is often desirable to know the number of colors available for a given canvas. This information is available through the `GetDeviceCaps()` function.

The color depth of a canvas is calculated by multiplying the number of bits per pixel that is required for a given canvas by the number of planes the canvas uses.

You can find the color depth of a canvas in by using the following code:

```
TotalNumBitsPerPixel :=  
    GetDeviceCaps(Canvas.Handle, BITSPIXEL) *  
    GetDeviceCaps(Canvas.Handle, PLANES)
```

Will give you the total number of bits used to color a pixel.

Return values of:

1 = 2 colors (monochrome)

4 = 16 colors

8 = 256 colors

15 = 32,768 colors

16 = 65,536 colors

24 = 16,777,216 colors

## Article #16512: Using FindFirst and the WIN\_32\_FIND\_DATA structure

Technical Information Database

TI1512D.txt Using FindFirst and the WIN\_32\_FIND\_DATA structure  
Category :Application Interop  
Platform :All  
Product :Delphi All

### Description:

Here is how to access the WIN\_32\_FIND\_DATA structure of a TSearchRec using the FindFirst(), FindNext(), and FindClose() functions.

In this example, we will show how to display both the long and short filename for each file found. Notice in the example that the unit name is fully qualified for the FindFirst(), FindNext(), and FindClose() functions, since there is more than one implementation for these function names. The implementations that we are calling are the Delphi wrapper functions to the WinApi functions.

```
var
  sr : TSearchRec;
  R : integer;
begin
  R := Sysutils.FindFirst('C:\*.*', faAnyFile, sr);
  while R = 0 do
    begin
      Mem1.Lines.Add(sr.FindData.cFileName);
      if sr.FindData.cAlternateFileName <> '' then
        Mem1.Lines.Add(sr.FindData.cAlternateFileName) else
        Mem1.Lines.Add(sr.FindData.cFileName);
      R := Sysutils.FindNext(sr);
    end;
  Sysutils.FindClose(sr);
end;
```

## Article #16517: Setting the pixels per inch property of TPrinter

Technical Information Database

TI1517D.txt - Setting the pixels per inch property of TPrinter

Category :Printing  
Platform :All-32Bit  
Product :

### Description:

When changing printers, be aware that font sizes may not always scale properly. To ensure proper scaling, set the PixelsPerInch property of the font after changing the printer index property. Be sure not to make the change until you have started the print job.

Here are two examples:

```
*****  
uses Printers;
```

```
var  
    MyFile: TextFile;  
begin  
    Printer.PrinterIndex := 2;  
    AssignPrn(MyFile);  
    Rewrite(MyFile);  
    Printer.Canvas.Font.Name := 'Courier New';  
    Printer.Canvas.Font.Style := [fsBold];  
    Printer.Canvas.Font.PixelsPerInch:=  
        GetDeviceCaps(Printer.Canvas.Handle, LOGPIXELSY);  
    Writeln(MyFile, 'Print this text');  
    System.CloseFile(MyFile);  
end;
```

```
*****  
  
uses Printers;
```

```
begin
  Printer.PrinterIndex := 2;
  Printer.BeginDoc;
  Printer.Canvas.Font.Name := 'Courier New';
  Printer.Canvas.Font.Style := [fsBold];
  Printer.Canvas.Font.PixelsPerInch:=
    GetDeviceCaps(Printer.Canvas.Handle, LOGPIXELSY);
  Printer.Canvas.Textout(10, 10, 'Print this text');
  Printer.EndDoc;
end;
```

## Article #16522: How to use a string table resource

Technical Information Database

TI1522D.txt    How to use a string table resource

Category     :Application Interop

Platform     :All

Product      :Delphi   All

### Description:

Stringtable resources are a very useful tool when your application must store a large number of strings for use at runtime. While you may be tempted to directly embed strings into your executable, using a stringtable resource offers two advantages: 1) The strings contained in the stringtable do not consume memory until they are loaded by your application. 2) Stringtables are easily edited, providing an easy path to internationally localized versions of your application.

Stringtables are compiled into a ".res" file that is attached to your application's exe file at build time. Even after you distribute your application, the stringtable contained in your application's exe file can be edited with a resource editor. My favorite resource editor is Borland's Resource Workshop that ships with the RAD pack. It can produce and edit both 16 and 32 bit resources that are self contained, standalone, or embedded in a .exe or .dll in full WYSIWYG fashion.

It's worth noting that all versions of Delphi ship with the Borland Resource Command Line Compiler (BRCC.EXE and BRCC32.EXE), and can be found in Delphi's Bin directory.

For our example, we will build an internationalized application that displays two buttons. The buttons will have captions for "Yes" and "No" presented in English, Spanish, and Swedish.

It's worth noting that if you want to build international applications using Delphi, you should take a look at Borland's Delphi Translation Suite and Language Pack software. These packages can make porting your application to international

markets a snap!

Example:

We first must create a text file containing our string resources in the applications build directory. You may name the file anything you wish, so long as it has the file extension ".rc" and the filename without the extension is not the same as any unit or project filename. This is very important, as Delphi also will create a number of resource files for your project automatically.

Here is the contents of the .rc file for our example. It contains the words "Yes" and "No" in English, Spanish, and Swedish:

```
STRINGTABLE
{
  1, "&Yes"
  2, "&No"
  17, "&Si"
  18, "&No"
  33, "&Ja"
  34, "&Nej"
}
```

The file starts with the key word stringtable denoting that a string table resource will follow. Enclosed in the curly braces are the strings. Each string is listed by its index identifier, followed by the actual string data in quotes. Each string may contain up to 255 characters. If you need to use a non-standard character, insert the character as a backslash character followed by the octal number of the character you wish to insert. The only exception is when you want to embed a backslash character, you will need to use two backslashes. Here are two examples:

```
1, "A two\012line string"
2, "c:\\Borland\\Delphi"
```

The Index numbers that you use are not important to the resource compiler. You should keep in mind that string

tables are loaded into memory in 16 string segments.

To compile the .rc file to a .res file that can be linked with your application, simply type on the dos command line the full path to the resource compiler, and the full path to the name of the .rc file to compile. Here is an example:

```
c:\Delphi\Bin\brcc32.exe c:\Delphi\strtbl32.rc
```

When the compiler is finished, you should have a new file with the same name as the .rc file you've compiled, only with an extension of ".res".

You can link the resource file with your application simply by adding the following statement to your application's code, substituting the name of your resource file:

```
{ $R ResFileName.RES }
```

Once the .res file is linked to your program, you can load the resource from any module, even if you specified the \$R directive in the implementation section of a different unit.

Here is an example of using the Windows API function LoadString(), to load the third string contained in a string resource into a character array:

```
if LoadString(hInstance,  
             3,  
             a,  
             sizeof(a)) <> 0 then ....
```

In this example, the LoadString() function accepts the hInstance of the module containing the resource, the string index to load, the address of the character array to load the string to, and the size of the character array. The LoadString function returns the number of characters that were actually loaded not including the null terminator. Be aware that this can differ from the number of bytes loaded when using unicode.

Here is a complete example of creating an international

application with Borland's Delphi. The application is compatible with both 16 and 32 bit versions of Delphi.

To do this, you will need to create two identical .rc files, one for the 16 bit version, and the other for the 32 bit version, since the resources needed for each platform are different. In this example. we will create one file named STRTBL16.rc and another called STRTBL32.rc. Compile the STRTBL16.rc file using the BRCC.exe compiler found in Delphi 1.0's bin directory, and compile STRTBL32.rc using the BRCC32.exe compiler found in Delphi 2.0's bin directory.

We have taken into account the language that Windows is currently using at runtime. The method for getting this information differs under 16 and 32 bit Windows. To make the code more consistant, we have borrowed the language constants from the Windows.pas file used in 32 bit versions of Delphi.

```
{ $IFDEF WIN32 }
    { $R STRTBL32.RES }
{ $ELSE }
    { $R STRTBL16.RES }
    const LANG_ENGLISH = $09;
    const LANG_SPANISH = $0a;
    const LANG_SWEDISH = $1d;
{ $ENDIF }

function GetLanguage : word;
{ $IFDEF WIN32 }
{ $ELSE }
    var
        s : string;
        i : integer;
{ $ENDIF }
begin
{ $IFDEF WIN32 }
    GetLanguage := GetUserDefaultLangID and $3ff;
{ $ELSE }
    s[0] := Char(GetProfileString('intl',
                                'sLanguage',
```

```

                                'none',
s[1],
                                sizeof(s)-2));
    for i := 1 to length(s) do
        s[i] := UpCase(s[i]);
    if s = 'ENU' then GetLanguage := LANG_ENGLISH else
    if s = 'ESN' then GetLanguage := LANG_SPANISH else
    if s = 'SVE' then GetLanguage := LANG_SWEDISH else
        GetLanguage := LANG_ENGLISH;
{$ENDIF}
end;

procedure TForm1.FormCreate(Sender: TObject);
var
    a : array[0..255] of char;
    StrTblofs : integer;
begin
    {Get the current language and stringtable offset}
    case GetLanguage of
        LANG_ENGLISH : StrTblofs := 0;
        LANG_SPANISH : StrTblofs := 16;
        LANG_SWEDISH : StrTblofs := 32;
    else
        StrTblofs := 0;
    end;

    {Load language dependent "Yes" and set the button caption}
    if LoadString(hInstance,
        StrTblofs + 1,
a,
        sizeof(a)) <> 0 then
        Button1.Caption := StrPas(a);

    {Load language dependent "No" and set the button caption}
    if LoadString(hInstance,
        StrTblofs + 2,
a,
        sizeof(a)) <> 0 then
        Button2.Caption := StrPas(a);
end;

```

## Article #16532: TRichEdit Printing in Delphi 2 & Windows NT 4.0

Technical Information Database

TI1532D.txt - TRichEdit Printing in Delphi 2 & Windows NT 4.0

Category :Delphi 2.x  
Platform :All Windows  
Product :Delphi2.x,

### Description:

TRichEdit Printing Under Windows NT 4.0

This document provides a Delphi Unit that will solve the "divide by zero" error that occurs when printing from a TRichEdit control under Windows NT 4.0. To use this Unit simply include it in the USES clause of the Unit that you want to print from. Instead of calling the RichEdit.Print() method to print, call the PrintRichEdit() procedure and pass it the TRichEdit control that you want to print as a parameter.

If you own the VCL source code you can make the changes shown below to the TCustomRichEdit.Print method in the COMCTRLS.PAS file.

```
unit PrtRichU;

interface

uses
  ComCtrls;

procedure PrintRichEdit(const Caption: string;
                       const RichEdt: TRichEdit);

implementation

uses
  Windows, RichEdit, Printers;

procedure PrintRichEdit(const Caption: string;
                       const RichEdt: TRichEdit);

var
```

```

Range: TFormatRange;
LastChar, MaxLen, LogX, LogY, OldMap: Integer;
begin
  FillChar(Range, SizeOf(TFormatRange), 0);
  with Printer, Range do
  begin
    BeginDoc;
    hdc := Handle;
    hdcTarget := hdc;
    LogX := GetDeviceCaps(Handle, LOGPIXELSX);
    LogY := GetDeviceCaps(Handle, LOGPIXELSY);
    if IsRectEmpty(RichEdt.PageRect) then
    begin
      rc.right := PageWidth * 1440 div LogX;
      rc.bottom := PageHeight * 1440 div LogY;
    end
    else begin
      rc.left := RichEdt.PageRect.Left * 1440 div LogX;
      rc.top := RichEdt.PageRect.Top * 1440 div LogY;
      rc.right := RichEdt.PageRect.Right * 1440 div LogX;
      rc.bottom := RichEdt.PageRect.Bottom * 1440 div LogY;
    end;
    rcPage := rc;
    Title := Caption;
    LastChar := 0;
    MaxLen := RichEdt.GetTextLen;
    chrg.cpMax := -1;
    OldMap := SetMapMode(hdc, MM_TEXT);
    SendMessage(RichEdt.Handle, EM_FORMATRANGE, 0, 0);
    try
      repeat
        chrg.cpMin := LastChar;
        LastChar := SendMessage(RichEdt.Handle, EM_FORMATRANGE, 1,
          Longint(
Range));
        if (LastChar < MaxLen) and (LastChar <> -1) then NewPage;
      until (LastChar >= MaxLen) or (LastChar = -1);
    EndDoc;
  finally
    SendMessage(RichEdt.Handle, EM_FORMATRANGE, 0, 0);
    SetMapMode(hdc, OldMap);
  end;
end;
end;
end;

```

end.

## Article #16537: How to use a user defined resource.

Technical Information Database

TI1537D.txt How to use a user defined resource.

Category :General Programming

Platform :All

Product :Delphi All

Description:

(\*

The following demonstrates linking a user defined resource.

Resources are compiled into a ".res" file that is attached to your application's .exe file at build time. Even after you distribute your application, the resources contained in your application's .exe file can be edited with a resource editor. The resource editor in Borland's Resource Workshop, that ships with the RAD pack, can produce and edit both 16 and 32 bit resources that are self contained, standalone, or embedded in a .exe or .dll in full WYSIWYG fashion.

It's worth noting that all versions of Delphi ship with the Borland Resource Command Line Compiler (BRCC.EXE and BRCC32.EXE), and can be found in Delphi's Bin directory.

We first must create a text file containing our resource definitions in the application's build directory. You may name the file anything you wish, so long as it has the file extension ".rc" and the filename without the extension is not the same as any unit or project filename. This is very important, as Delphi also will create a number of resource files for your project automatically.

Here is the contents of the .rc file for our example:

```
MYUSERDATA MYDATATYPE TEST.TXT
```

MYUSERDATA is the resource name, MYDATATYPE is the resource type

and TEST.TXT is the name of the file continuing the user data we will link in.

We must next create the TEST.TXT file, using any ASCII editor (notepad will do fine). For our example, the file needs to contain one single line:

```
Hello!
```

To compile the .rc file to a .res file that can be linked with your application, simply type on the dos command line the full path to the resource compiler, and the full path to the name of the .rc file to compile. Here is an example:

```
c:\Delphi\Bin\brcc32.exe c:\Delphi\MYRES.RC
```

When the compiler is finished, you should have a new file with the same name as the .rc file you've compiled, only with an extension of ".res".

You can link the resource file with your application simply by adding the following statement to your application's code, substituting the name of your resource file:

```
{ $R ResFileName.RES }
```

where ResFileName.RES is the actual name of the compiled .res file.

Once the .res file is linked to your program, you can load the resource from any module, even if you specified the \$R directive in a different unit.

To actually use the resource, you must make a few Windows API calls. First you will call the FindResource() function, passing the instance handle of your application, the name of the resource to load, and the resource type. If FindResource is successful, the function will return a handle to the unloaded resource.

Next, you can call the SizeOfResource() function to find the aligned size of the resource, if you want to know the actual size of the loaded resources memory block. Be forewarned that this not the actual size of the data, but rather the size of the memory block that will be allocated when you load the resource. If you want to know the actual size of the data, you will need to embed that

information in the data itself.

To load the resource, we will call the LoadResource() function, passing the handle returned to us when we called FindResource(). This function will return a handle to the loaded resource that we can pass to the LockResource() function to retrieve a pointer to the resource that we use to actually work with the data.

In our example, we will loop through the data, adding the data to a string, until we find the embedded '!' character, signaling that the end of the data has been found.

Finally, we will free the resource by first calling UnLockResource() and then FreeResource(), passing the handle of the loaded resource.

Example Code:

\*)

implementation

```
{ $R *.DFM }
```

```
{ $R MYRES.RES }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  hRes      : THandle; {handle to the resource}  
  pRes      : pointer; {pointer to the resource}  
  ResSize   : longint; {aligned size of the resource}  
  i         : integer; {counting variable}
```

```
{ $IFDEF WIN32 }
```

```
  s         : shortstring; {a string to play with}
```

```
{ $ELSE }
```

```
  s         : string;      {a string to play with}
```

```
{ $ENDIF }
```

```
begin
```

```
  {find the resource}
```

```
  hRes := FindResource(hInstance,  
                      'MYUSERDATA',  
                      'MYDATATYPE');
```

```
  if hRes = 0 then begin
```

```
    ShowMessage('Could not find the resource');
```

```
    exit;
```

```
  end;
```

```

{get the aligned size of the resource}
ResSize := SizeOfResource(hInstance, hRes);
if ResSize = 0 then begin
    ShowMessage('Nothing to load - size = 0');
    Exit;
end;
{load the resource}
hRes := LoadResource(hInstance, hRes);
if hRes = 0 then begin
    ShowMessage('Resource Load Failure');
    Exit;
end;
{Get a pointer to the resource}
pRes := LockResource(hRes);
if pRes = nil then begin
    ShowMessage('Resource Lock Failure');
    FreeResource(hRes);
    Exit;
end;

{convert the resource pointer to a string}
s := '';
i := 0;
while pChar(pRes)[i] <> '!' do begin
    s := s + pChar(pRes)[i];
    inc(i);
end;

{prove it works}
ShowMessage(s);

{unlock and free the resource}
UnlockResource(hRes);
FreeResource(hRes);
end;

end.

```

## Article #16542: A better way to do pointer arithmetic

Technical Information Database

TI1542D.txt A better way to do pointer arithmetic

Category :Application Interop

Platform :All

Product :Delphi All

Description:

(\*

This document demonstrates a technique for incrementing pointers under Borland Pascal 7.0, Turbo Pascal for Windows, and Delphi.

Send it any pointer, and an offset of the pointer you really want (yes, huge pointers > 64 are supported) and it will return a pointer to that location. Unlike most other huge pointer code, this snippet will take into account the fact that you may be sending a pointer that does not have a zero based offset.

Be aware that you cannot access memory that crosses a 64k boundary in Win16. If you need to access a record that spans a 64K boundary, you must first grab the portion of the record that exists before the boundary, then grab the second portion that exists above the boundary, and piece them together.

Note the function is designed to be upwardly portable to Win32 where there is no need to do pointer manipulation since Win32 uses a flat (non-segmented) memory model where there are no 64k boundaries. While using the function call to get a pointer under Win32 is not exactly efficient, it will make porting legacy 16 bit code to Win32 a breeze!

\*)

type

PtrRec = record

Lo : Word;

Hi : Word;

end;

PHugeByteArray = ^THugeByteArray;

```

THugeByteArray = array[0..0] of Byte;

function GetBigPointer(lp : pointer;
                      Offset : LongInt) : Pointer;

begin
  {$IFDEF WIN32}
    GetBigPointer :=
PHugeByteArray(lp)^[Offset];
  {$ELSE}
    Offset := Offset + PTRREC(lp).Lo;
    GetBigPointer := Ptr(PtrRec(lp).Hi + PtrRec(Offset).Hi *
SelectorInc,
                          PtrRec(Offset).Lo);
  {$ENDIF}
end;

{Lets test it!}

procedure TForm1.Button1Click(Sender: TObject);
var
  h   : THandle; {handle to the memory block}
  p   : pointer; {pointer to the memory block}
  p2  : pointer; {pointer for testing}
  p3  : pointer; {pointer for testing}
begin
  {allocate two hundred thousand bytes of memory and zero out}
  h := GlobalAlloc(GHND, 200000);

  {get a pointer to the allocated memory}
  p := GlobalLock(h);

  {get a pointer to the byte at index 75000}
  p2 := GetBigPointer(p, 75000);

  {get a pointer to the byte 80000 bytes from p2}
  p3 := GetBigPointer(p2, 80000);

  {verify the byte p3 points to is zero}
  Mem1.Lines.Add(IntToStr(pByte(p3)^));

  {change the value of the byte p3 points to}
  pByte(p3)^ := 10;

```

```
{verify the change}  
    Mem1.Lines.Add(IntToStr(pByte(p3)^));
```

```
{free the memory}  
    GlobalUnlock(h);  
    GlobalFree(h);
```

```
end;
```

```
end.

## Article #16547: Assuring Proper Font Scaling When Printing

Technical Information Database

TI1547D.txt Assuring Proper Font Scaling When Printing

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

When changing printers, be aware that font sizes may not always scale properly. To ensure proper scaling, set the PixelsPerInch property of the font after changing the printer index property. Be sure not to make the change until you have started the print job.

Here are two examples:

\*\*\*\*\*

```
uses Printers;
```

```
var
```

```
    MyFile: TextFile;
```

```
begin
```

```
    Printer.PrinterIndex := 2;
```

```
    AssignPrn(MyFile);
```

```
    Rewrite(MyFile);
```

```
    Printer.Canvas.Font.Name := 'Courier New';
```

```
    Printer.Canvas.Font.Style := [fsBold];
```

```
    Printer.Canvas.Font.PixelsPerInch:=
```

```
        GetDeviceCaps(Printer.Canvas.Handle, LOGPIXELSY);
```

```
    Writeln(MyFile, 'Print this text');
```

```
    System.CloseFile(MyFile);
```

```
end;
```

\*\*\*\*\*

```
uses Printers;
```

```
begin
```

```
Printer.PrinterIndex := 2;  
Printer.BeginDoc;  
Printer.Canvas.Font.Name := 'Courier New';  
Printer.Canvas.Font.Style := [fsBold];  
Printer.Canvas.Font.PixelsPerInch:=  
    GetDeviceCaps(Printer.Canvas.Handle, LOGPIXELSY);  
Printer.Canvas.Textout(10, 10, 'Print this text');  
Printer.EndDoc;  
end;
```

## Article #16552: Delphi 3 file types with descriptions

Technical Information Database

TI1552D.txt - Delphi 3 file types with descriptions

Category :Delphi 3.x  
Platform :All-32Bit  
Product :

Description:

The .CAB File Format

This is the file format that Delphi now offers its users for web deployment. The cabinet format is an efficient way to package multiple files. The cabinet format has two key features: multiple files can be stored in a single cabinet (.cab file) and data compression is performed across file boundaries, which significantly improves the compression ratio. Cabinet file construction can be designed around the number of files to be compressed and the expected patterns for gaining access to them (sequential, random, all at once, or a few at a time). Delphi does not take advantage file compression across file boudaries.

The .LIC File Format

There really is no .lic file format per se. These files are generally just text files that contain a key string or two.

The .INF File Format

All inf files are made up of sections and items. Each named section contains its associated items. All inf files start with the header section. After the header, sections can be laid out in any order desired. Each header is as follows [HeaderName]. This is followed by the items: ItemA = ItemDetail. For detailed information on this topic please see the Device Information File Reference.

The .dpr file format.

The .dpr file is the central file to a delphi project. It serves as

the primary entry point for the executable. The dpr contains the references to the other files in the project and links forms with their associated units. This file should be edited with care as changes in it can prevent your project from loading. This file is critical for loading or moving(copying) the project.

The .pas file format.

This is a standard text file that can be edited in a text editor. Edit this file carefully as it may result in the loss of some advantages of the two way tool. For example pasting code for a button into the type declaration for a form does not result in the corresponding entry into the .dfm file. All pas files in a project are critical for rebuilding the project.

The .dfm file format.

This file contains the details of the objects contained in a form. It can be view as text by right clicking on the form and selecting view as text from the pop-up menu, or it can be converted to text and back using the convert.exe found in the bin directory. Caution should be used in altering this file as changes to it could prevent the IDE from being able to load the form. This file is critical to moving or rebuilding the project.

The .DOF File Format

This text file contains the current settings for project options, such as compiler and linker settings, directories, conditional directives, and command-line parameters. These settings can be customized on a project-by-project basis.

The .DSK File Format

This text file stores information about the state of your project, such as which windows are open and what position they are in. Like the .DOF file, this file can be customized project-by-project.

The .DPK File Format

This file contains the source code for a package (analogous to the .DPR

in a standard Delphi project) Like the .DPR file the .DPK file is a plain text file that can be edited (with caution) using a standard editor. One of the primary reasons you may need to do this would be if you were using the command line compiler.

#### The .DCP File Format

This binary image file consists of the actual compiled package. Symbol information and additional header information required by the IDE are all contained within the .DCP file. The IDE must have access to this file in order to build a project.

#### The .DPL File Format

This is the actual executable runtime package. This file is a Windows DLL with Delphi-specific features integrated into it. This file is essential for deployment of an application that uses a package.

#### The .DCI File Format

This text file contains both standard and user-defined code templates for use within the IDE. The file can be edited with a standard text editor or through the IDE. As with any text data file used by Delphi, modifying the file directly is discouraged.

#### The .DCT File Format

This proprietary binary file contains the user-defined component template information. This file is not meant to be edited by any means other than through the IDE. Since this file is proprietary the format and compatibility with future versions of Delphi may likely change.

#### The .TLB File Format

The .TLB file is a proprietary binary type library file. This file provides a way for identifying what types of objects and interfaces are available on an ActiveX server. Like a unit or a header file the .TLB serves as a repository for necessary symbol information

for an application. Since this file is proprietary the format and compatibility with future versions of Delphi may likely change.

#### The .DRO File Format

This text file contains information about the object repository. Each entry in this file contains specific information about each available item in the object repository. Even though this file is a standard text file it is not recommended that you edit it by hand. The repository should only be modified from the Tools|Repository menu in the IDE.

#### The .RES File Format

This standard binary windows-format resource file includes information about an application. By default Delphi creates a new .RES file every time a project is compiled into an application.

#### The .DB File Format

Files with this extension are standard Paradox files.

#### The .DBF File Format

Files with this extension are standard dBASE files.

#### The .GDB File Format

Files with this extension are standard Interbase files.

#### The .DMT File Format

This proprietary binary file contains the shipped and user-defined menu templates information. This file is not meant to be edited by any means other than through the IDE. Since this file is proprietary the format and compatibility with future versions of Delphi may likely change.

#### The .DBI File Format

This text file contains initialization information for

the Database Explorer. This file is not meant to be edited by any means other than through the Database Explorer.

#### The .DEM File Format

This text file contains some standard country-specific formats for a TMaskEdit component. As with any text data file used by Delphi, modifying the file directly is discouraged.

#### The .OCX File Format

An .OCX file is a specialized DLL which contains all or some associated functions of an ActiveX control. The OCX file can be thought of as a "wrapper" which contains the object and it's means of communications with other objects and servers.

## Article #16557: Moving Projects Between Machines or Directories

Technical Information Database

TI1557D.txt Moving Projects Between Machines or Directories

Category :General Programming

Platform :All

Product :Delphi All

Description:

Moving Projects Between Machines

The main files involved in a project are the DPR, DFM, PAS, and RES. These are the main files in any project. There are other files associated with any project. This document focuses on these because they are the minimum files you need to move a project.

Moving a project between machines is easy if you follow a few simple rules. First keep all the files associated with the project in the same directory. This allows for quick movement all in one operation. To move the files copy the entire directory to a new temporary directory. Now delete all the files except those with these extensions DPR, PAS, DFM, and RES. All the other files will be recreated during the first build. Having a single directory eliminates questions as to which version of a dcu or pas file is going into the build. If third party components are in the project you should install those on to the Delphi Component Palette of the target machine before attempting to open the project on that machine.

If the project files were not all in one directory you may end up editing the DPR file to provide the appropriate new path information on the target machine. The text involved is in the uses clause of the DPR or

main project file. You may also choose to preserve the DSK files or the DOF files if you have a specific need to preserve your desktop settings or your project options settings respectively. The options file can be important in cases where you have specific unit aliases, you have specified directories under project options, use packages, version info, run parameters, and version info. The dsk file is less critical and generally not moved with a project.

The res file should be moved with the project in cases where your project uses custom cursors, icons, string resources, bitmaps, etc. These are resources included by you with the compiler directive to be linked into the project and become part of the executable. The sting resources are used for internationalization or localization. Other custom resource are visual enhancement of the project user interface.

For more detailed information on the specific file types referred to in this document see the TI on file types, TI 3213.

## Article #16562: An example of drag and drop between DBGrids

Technical Information Database

TI1562D.txt - An example of drag and drop between DBGrids

Category :General Programming  
Platform :All Windows  
Product :All32Bit,

### Description:

Title: An example of drag and drop between DBGrids

This sample component and sample project demonstrates an easy way of enabling drag and drop of an arbitrary field in one data aware grid onto an arbitrary field in another data aware grid.

1. Launch Delphi x.xx (the code will work in 1 and 2 as well with some minor changes).
2. Do a File|New|Unit. Take the MyDBGrid unit (below) and paste it in the newly created unit. Do a File|Save As. Save the unit as MyDBGrid.pas.
3. Do a Component|Install Component. Switch to the Info New Package tab. Put MyDBGrid.pas in the Unit file name box. Call the package MyPackage.dpk. Hit Yes when Delphi tells you that the package will be built and installed. Hit OK when Delphi tells you that VCLxx.DPL is needed. The package will now be rebuilt and installed. You will now find the TMyDBGrid component on your Samples tab on your component palette. Close the package editor and save the package.
4. Do a File|New Application. Right click on the form (Form1) and select View As Text. Take the GridU1 form source (below) and paste it in Form1. Right click on the form and select View As Form. This may take a few moments since it's opening up the tables for you. Take the GridU1 unit (below) and paste it in the unit (Unit1).
5. Do a File|Save Project As. Save the unit as GridU1.pas. Save the project as GridProj.dpr.

6. Now, run the project and enjoy the dragging and dropping of fields inbetween or with the two grids.

```

## Article #16567: Looping Through the Controls and Components Arrays

Technical Information Database

TI1567D.txt    Looping Through the Controls and Components Arrays

Category     :General Programming

Platform     :All

Product      :Delphi   All

### Description:

There are 2 important properties in Delphi that everyone using the product should know about. The components array is a property of all components that own other components. The controls array is a property of all `TWinControls` that are parents of `TWinControls`. These properties are so important because they allow you to iterate through a group of components without knowing the names or knowing what type of controls or components they are. This could be important for example if you wanted to disable or enable all the controls on a form or within a container control (such as a panel). Proper code for this iterative process is shown below for both cases.

1. Iteration through the components array of the form:

```
begin
  for i:= 0 to componentcount - 1 do
  begin
    {enter the code to act on each member of the array here}
  end;
end;
```

2. Iteration through the controls array of the form:

```
begin
  for i:= 0 to controlcount - 1 do
  begin
```

```
    {enter the code to act on each member of the array here}  
end;  
end;
```

The variable 'i' is an integer declared for iteration one array member at a time and must be declared by the user. The variables controlcount and componentcount are additional properties of TWinControl and TComponent respectively. These properties are often used in conjunction with iteration through the corresponding array properties.

## Article #16572: Adding ODBC Drivers in Delphi with the BDE Administrator

Technical Information Database

TI1572D.txt - Adding ODBC Drivers in Delphi with the BDE Administrator

Category :General Programming  
Platform :All-32Bit  
Product :Delphi3.x, Delphi4.x,

### Description:

Adding ODBC Drivers in 32 bit Delphi with BDE Administrator

The minimum requirements necessary to install an ODBC driver in Delphi 3.0 are as follows:

- Microsoft ODBC Manger
- Windows 95 or NT
- Delphi Developer or Delphi Client/Server edition
- Vendor-provided ODBC driver (already installed on your system)

When using Delphi 3.0 there are now two common methods to add ODBC drivers to the BDE. The first step to using any of the methods is to first obtain and install the vendor-supplied ODBC driver onto your system. Once this first essential step is completed the next steps are fairly simple.

In the left panel on the screen is a list of drivers and data sources that have been previously configured for use with BDE applications.

### Method A:

1. First start the BDE Administrator from the Windows Start Menu (it will be in the Delphi 3.0 folder.)
2. Now select Object|ODBC administrator from the main menu. (this will bring up a list of currently installed drivers.)
3. Choose Add and then select the ODBC driver you would like to create a data source for, then click on OK.

4. Next fill in the appropriate information for your driver. (A minimal configuration will require the Data Source Name field. You will also need to fill in at least one other field that is a location specifier for the data. This could be a path in the case of Paradox or dBase tables or the Server field in the case of configuring an Interbase ODBC driver. Some non-exhaustive examples include; if you are using Interbase you would select a path to a .GDB file, if using Paradox or dBASE files you would specify the data directory containing your tables or if you were using Oracle you would specify the entry as it appears in your TNSNAMES.ORA file. Once this is done you have created a virtual driver and will be able to access your database files through the datasource your created.)

#### Method B:

1. First start the BDE Administrator from the Windows Start Menu (it will be in the Delphi 3.0 folder.)
2. Click on the database tab, then right click inside of the left panel.
3. Select New from the popup menu and then select the type of ODBC driver you would like to add and click OK.
4. Again right click in the database panel and select Apply from the popup menu.
5. Now you must select a valid ODBC DSN (Data Source Name) from the definition panel on the right and select apply.

Both of these methods result in the ability to hook a TDataset in Delphi to live data.

You may have noticed some new options from the Object|Options menu, these options allow you to select different configuration modes to view. It's advisable to have all check boxes in the Select Configuration Modes to View panel selected. When all the check boxes are selected you will be provided with an extensive list of all drivers and aliases available for your use. Without checking the ?virtual? setting you will not be able to ?see? the drivers that you have added through the MS ODBC manager but not explicitly through the BDE (as per method 2).

## Article #16577: Delphi/400: Activating your License Key

Technical Information Database

TI1577D.txt - Delphi/400: Activating your License Key

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Description:

This document describes the steps to obtain and apply a permanent security key for ClientObjects/400 in the Delphi/400 package. Also refer to the instructions contained in the pamphlet "Additional Information for Delphi/400 Users" that ships with Delphi/400.

Delphi/400 software is installed to both an AS/400 and a PC. When the AS/400 part of the installation is complete, a temporary automatic key of two months(60 days) will be created. After this time functionality will be unavailable, and attempting to access the AS/400 through the supplied components will generate a protection error.

To obtain a permanent key, fill in the registration card that ships with Delphi/400 and follow the mailing directions on the card. Be sure to include your AS/400 model and serial number (these numbers are used to compute a unique key). The model and serial number can be obtained by running the following AS/400 commands:

```
DSPSYSVAL(QMODEL)  
DSPSYSVAL(QSRLNBR)
```

When you receive your permanent key, activate the key by entering the following commands at an AS/400 terminal.

```
ADDLIBLE CO400  
CALL CO400INS
```

The screen that appears allows you to enter your permanent key.

## Article #16582: Displaying System Resources in Win 9x and NT 4

Technical Information Database

TI1582D.txt - Displaying System Resources in Win 9x and NT 4

Category :Application Interop  
Platform :All-32Bit  
Product :All32Bit,

Description:

### Displaying System Resources

This document describes the displaying of total system resources or the amount of available system resources for Windows 9x or Windows NT 4.0. It includes the structure of the TMemoryStatus structure, the function GlobalMemoryStatus that populates this structure as defined in Windows.pas, and the Windows API header description. It also includes a code example of populating a memo with this information in Delphi.

TMemoryStatus source can be found in Windows.PAS which is in the Source\RTL\WIN directory if you have the Client\Server Suite of Delphi.

Structure of TMemoryStatus:

```
TMemoryStatus = record
  dwLength: DWORD;
  dwMemoryLoad: DWORD;
  dwTotalPhys: DWORD;
  dwAvailPhys: DWORD;
  dwTotalPageFile: DWORD;
  dwAvailPageFile: DWORD;
  dwTotalVirtual: DWORD;
  dwAvailVirtual: DWORD;
```

Function called to populate TMemoryStatus:

```
procedure GlobalMemoryStatus(var lpBuffer: TMemoryStatus); stdcall;
```

WINAPI help for said function:

```
VOID GlobalMemoryStatus(  
    // pointer to the memory status structure  
    LPMEMORYSTATUS lpBuffer  
);
```

Code for populating a TMemo with Information about system resources:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
    Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
    Dialogs, StdCtrls;
```

```
type
```

```
    TForm1 = class(TForm)  
        Button1: TButton;  
        Mem1: TMemo;  
        procedure Button1Click(Sender: TObject);
```

```
    private
```

```
        { Private declarations }
```

```
    public
```

```
        { Public declarations }
```

```
    end;
```

```
var
```

```
    Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
    MemoryStatus: TMemoryStatus;
```

```
begin
```

```
    Mem1.Lines.Clear;
```

```
    MemoryStatus.dwLength := SizeOf(MemoryStatus);
```

```
    GlobalMemoryStatus(MemoryStatus);
```

```

with MemoryStatus do
begin
// Size of MemoryStatus record
    Mem1.Lines.Add(IntToStr(dwLength) +
        ' Size of 'MemoryStatus' record');
// Per-Cent of Memory in use by your system
    Mem1.Lines.Add(IntToStr(dwMemoryLoad) +
        '% memory in use');
// The amount of Total Physical memory allocated to your system.
    Mem1.Lines.Add(IntToStr(dwTotalPhys) +
        ' Total Physical Memory in bytes');
// The amount available of physical memory in your system.
    Mem1.Lines.Add(IntToStr(dwAvailPhys) +
        ' Available Physical Memory in bytes');
// The amount of Total Bytes allocated to your page file.
    Mem1.Lines.Add(IntToStr(dwTotalPageFile) +
        ' Total Bytes of Paging File');
// The amount of available bytes in your page file.
    Mem1.Lines.Add(IntToStr(dwAvailPageFile) +
        ' Available bytes in paging file');
// The amount of Total bytes allocated to this program
// (generally 2 gigabytes of virtual space).
    Mem1.Lines.Add(IntToStr(dwTotalVirtual) +
        ' User Bytes of Address space');
// The amount of available bytes that is left to your program to use.
    Mem1.Lines.Add(IntToStr(dwAvailVirtual) +
        ' Available User bytes of address space');
end; // with
end; // procedure

end.

```

Sample Output of what is contained in Mem1.Lines:

```

32: Size of 'MemoryStatus' record in bytes
76%: memory in use
33054720: Total Physical Memory in bytes
499712: Available Physical Memory in bytes
53608448: Total Bytes of Paging File
36372480: Available bytes in paging file
2143289344: User Bytes of Address space
2135556096: Available User bytes of address space

```

## Article #16587: Edit Controls that Align Under NT 4

Technical Information Database

TI1587D.txt - Edit Controls that Align Under NT 4

Category :VCL  
Platform :Windows NT  
Product :All32Bit,

### Description:

Creating an edit control that allows alignment under NT4.

### OVERVIEW

This document demonstrates how to create a descendant of TEdit that allows alignment of the text.

### WHO SHOULD USE THIS DOCUMENT

Anyone with a basic familiarity with Delphi programming.  
Applies to any version of Delphi.

### CREATING JUSTAEDIT

One of the features the TMemo surfaces that a TEdit does not is the ability to justify the text. This functionality exists via the Alignment property. Great! So why doesn't a TEdit have this functionality, or perhaps a more pertinent question is how do we add it?

This property, unfortunately can not be surfaced from an ancestor, because the functionality does not exist in any ancestor. So it needs to be implemented via the window style flags. ES\_LEFT, ES\_RIGHT, and ES\_CENTER specify the text alignment for edit controls. These flags do not have any bearing on single line edit controls...unless running NT 4, Service pack 3, and that is the reason the functionality does not exist in the native control. This functionality is now implemented in NT 4.0 but will have no effect in Win 3.1 and Windows 95.

WORKING CODE

unit JusEdit;

interface

uses

Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,  
Dialogs,  
StdCtrls;

type

TJustaEdit = class(TEdit)

private

## Article #16592: How do I map a network drive in Windows NT or '95?

Technical Information Database

TI1592D.txt How do I map a network drive in Windows NT or '95?

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

How do I map a network drive in Windows NT or '95?

You can use the WNetAddConnection2 API call. The prototype for the API call is in Windows.Pas.

```
function WNetAddConnection2W(var lpNetResource: TNetResourceW;  
    lpPassword, lpUserName: PWideChar;  
    dwFlags: DWORD): DWORD; stdcall;
```

To make the call you will need to fill a lpNetResource structure with a minimum set of parameters, shown in the example below. You pass this structure as the first parameter to the call, the password, user name, and a flag that indicates whether this mapping should be persistent every time the machine is logged onto. For more info on the API itself, see Window's Programmers Reference help (find the function in Windows.pas, place your text cursor over the function call, and hit F1 to bring up help).

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    NRW: TNetResource;  
begin  
    with NRW do  
    begin  
        dwType := RESOURCETYPE_ANY;  
        lpLocalName := 'X:'; // map to this driver letter  
        lpRemoteName := 'MyServerMyDirectory';  
        // Must be filled in. If an empty string is used,  
        // it will use the lpRemoteName.  
        lpProvider := '';  
    end;  
    WNetAddConnection2(NRW, 'MyPassword', 'MyUserName',
```

```
CONNECT_UPDATE_PROFILE);  
end;
```

## Article #16597: Adding shortcuts to Win95/WinNT4 Desktop/StartMenu

Technical Information Database

TI1597D.txt - Adding shortcuts to Win95/WinNT4 Desktop/StartMenu

Category :Application Interop  
Platform :All-32Bit  
Product :

Description:

Title: Adding shortcuts to the Win95/WinNT40 desktop or start menu

This sample project demonstrates an easy way to add shortcuts to your Windows 95 or Windows NT 4.0 desktop or start menu.

1. Launch Delphi.
2. In a new project, drop a TButton on the form (make sure it's called Button1). Then double click on Button1. Now you can go ahead and directly replace the code for Unit1 with the code for Unit1 below.

The program will set up a shortcut either (see the code) on the desktop or on the start menu. The shortcut will be called FooBar and it will open up your AUTOEXEC.BAT in NOTEPAD when executed.

It will read the value of the "Desktop" and "Start Menu" strings from the registry key named (under HKEY\_CURRENT\_USER):

```
Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders
```

```
-----  
The Unit1 unit  
-----
```

```
unit Unit1;  
  
interface  
  
uses  
    Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
```

```
Dialogs, StdCtrls;
```

```
type
```

```
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
```

```
var
```

```
  Form1: TForm1;
```

```
implementation
```

```
{ $R *.DFM }
```

```
uses
```

```
  ShlObj, ActiveX, ComObj, Registry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
```

```
  MyObject   : IUnknown;
  MySLink    : IShellLink;
  MyPFile    : IPersistFile;
  FileName   : String;
  Directory  : String;
  WFileName  : WideString;
  MyReg      : TRegIniFile;
```

```
begin
```

```
  MyObject := CreateComObject(CLSID_ShellLink);
  MySLink := MyObject as IShellLink;
  MyPFile := MyObject as IPersistFile;
  FileName := 'NOTEPAD.EXE';
  with MySLink do begin
    SetArguments('C:\AUTOEXEC.BAT');
    SetPath(PChar(FileName));
    SetWorkingDirectory(PChar(ExtractFilePath(FileName)));
  end;
  MyReg := TRegIniFile.Create(
    'Software\Microsoft\Windows\CurrentVersion\Explorer');
```

```
// Use the next line of code to put the shortcut on your desktop
```

```
Directory := MyReg.ReadString('Shell Folders','Desktop','');

// Use the next three lines to put the shortcut on your start menu
// Directory := MyReg.ReadString('Shell Folders','Start Menu','')+
//           '\Whoa!';
// CreateDir(Directory);

WFileName := Directory+'\FooBar.lnk';
MyPFile.Save(PWChar(WFileName),False);
MyReg.Free;
end;

end.
```

## Article #16602: Minimizing Application When a Form Minimizes

Technical Information Database

TI1602D.txt Minimizing Application When a Form Minimizes

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

How do I minimize the application when I minimize a secondary form? I want to replicate the behavior that occurs when I minimize the main form.

You can use the same logic found in `\source\vcl\forms.pas` that `TCustomForm` (in Delphi 3) uses when the form receives a system message to minimize. The form traps `WM_SYSCOMMAND` messages, checks to see if the command is to minimize the form, checks that the form is the `MainForm`, then performs the application object's `Minimize` method. If the message doesn't specify `SC_MINIMIZE` then we call `inherited` so that default processing can occur. Note: failure to include the call to `inherited` will probably cause bad things to happen.

```
.  
.br/>procedure WMSysCommand(var Message: TWMSysCommand);  
    message WM_SYSCOMMAND;  
.br/>.br/>procedure TCustomForm.WMSysCommand(var Message: TWMSysCommand);  
begin  
    if (Message.CmdType and $FFF0 = SC_MINIMIZE) and  
        (Application.MainForm = Self) then  
        Application.Minimize  
    else  
        inherited;  
end;
```

To get this same behavior you can move this code to your form's unit, and remove the logic that checks that the form is a `MainForm`.

```

unit Unit1;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, StdCtrls;

type
  TForm1 = class(TForm)
    Button2: TButton;
  private
    procedure WMSysCommand(var Message: TWMSysCommand);
      message WM_SYSCOMMAND;
  end;

var
  Form1: TForm1;

implementation

uses Unit2;

{$R *.DFM}

procedure TForm1.WMSysCommand(var Message: TWMSysCommand);
begin
  if (Message.CmdType and $FFF0 = SC_MINIMIZE) then
    Application.Minimize
  else
    inherited;
end;

end.

```

## Article #16607: Graying Out Enabled/Disabled Data Aware Controls

Technical Information Database

TI1607D.txt - Graying Out Enabled/Disabled Data Aware Controls

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Graying out enabled/disabled data aware controls

Most data aware components are capable of visually showing that they are disabled (by changing the text color to gray) or enabled (by setting the color to a user-defined windows text color). Some data aware controls such as TDBGrid, TDBRichEdit (in Delphi 3.0) and also TDBEdit (when connected to a numeric or date field) do not display this behavior.

The code below uses RTTI (Run Time Type Information) to extract property information and use that information to set the font color to gray if the control is disabled. If the control is enabled, the text color is set to the standard windows text color.

What follows is the step by step creation of a simple example which consists of a TForm with a TButton and a TDBRichEdit that demonstrates this behavior.

1. Select File|New Application from the Delphi menu bar.
2. Drop a TDataSource, a TTable, a TButton and a TDBEdit onto the form.
3. Set the DatabaseName property of the table to 'DBDEMOS'.
4. Set the TableName property of the table to 'ORDERS.DB'.
5. Set the DataSet property of the datasource to 'Table1'.
6. Set the DataSource property of the DBEdit to 'DataSource1'.
7. Set the DataField property of the DBEdit to 'CustNo'.
8. Set the Active property of the DBEdit to 'False'.

9. Add 'TypInfo' to the uses clause of the form.

Below is the actual procedure to put in the implementation section of your unit:

```
// This procedure will either set the text color of a
// dataware control to gray or the user defined color
// constant in clInfoText.

procedure SetDBControlColor(aControl: TControl);
var
  FontPropInfo: PPropInfo;
begin
  // Check to see if the control is a dataware control
  if (GetPropInfo(aControl.ClassInfo, 'DataSource') = nil) then exit
  else
    begin
  // Extract the front property
      FontPropInfo:= GetPropInfo(aControl.ClassInfo, 'Font');
  // Check if the control is enabled/disabled
      if (aControl.Enabled = false) then
  // If disabled, set the font color to gray
          TFont(GetOrdProp(aControl, FontPropInfo)).Color:=
clGrayText
        else
  // If enabled, set the font color to clInfoText
          TFont(GetOrdProp(aControl, FontPropInfo)).Color:=
clInfoText;
        end;
    end;
end;
```

The code for the buttonclick event handler should contain:

```
// This code will cycle through the Controls array and call
// SetDbControlColor for each control on your form
// making sure the font text color is set to what it
// should be.
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  i: integer;
begin
  // Loop through the control array
  for i:= 0 to ControlCount-1 do
    SetDBControlColor(Controls[i]);
```

end;

## Article #16612: Exposing a multi string object in COM

Technical Information Database

TI1612D.txt - Exposing a multi string object in COM

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All  
Product :All32Bit,

### Description:

This document is intended for those using OLE/COM and want to expose a multi string object similar to Delphi's TStrings object. The IStrings interface for COM parallels the functionality of Delphi's TStrings object. For example, in a case where you have an automation client that contains a TStrings descendant, and you would like the automation server to process the strings, the automation server can employ an implementation of an IStrings interface to store and manipulate these strings.

The example project below contains the elements and steps needed to implement an IStrings interface in a COM automation server, and to interact with the interface from a COM automation client. You'll find the complete unit source listings next, then finally a discussion of some of the design choices made in this project.

The example project contains these units:

Project1\_TLB: A Pascal wrapper for the type library containing the interface definition.

Unit1: The interface implementation containing storage for interface properties and code to implement interface methods.

Unit2: The main form for the automation server. This unit is not strictly necessary, but provides feedback to know when methods have been successfully called

AutCli: The automation client that obtains a reference to the interface and uses the interface methods.

The general steps involved are listed below. You can compare each of these steps with the unit code that follows.

1) Create a type library and add an interface called IStr, with a single property called Items of type IStrings. See Developer's Guide, chapter 42 for more information on working with type libraries and creating interfaces in the type library editor.

2) In the previous step, adding an interface using the type library editor will cause a Pascal wrapper unit to be produced (in this example, the unit is called Unit1). Unit1 will contain shell implementations of get and set methods of the Items property. In this step you add implementation code to make the get and set methods functional. Also you need to add a method to create storage for your Items property, and to clean up that storage when the interface is no longer needed. Unit1 uses Unit2. Unit2 contains a form, memo and status bar to display status of each implementation method, for diagnostic purposes.

3) Create Unit2 containing a form with TMemo and TStatusBar. The form is used to reflect activity in Unit1.pas. Though this step is not strictly necessary, it helps visualize what's happening between the automation client and server.

4) Create an automation client. In this case the unit is called AutCli and contains a memo component and two buttons that assign the Memo's TStrings data to the IStr interface's Items property.

```
{-----}
unit Project1_TLB;

{ This file contains pascal declarations imported from a type library.
  This file will be written during each import or refresh of the type
  library editor. Changes to this file will be discarded during the
  refresh process. }

end;

```

```

procedure TForm1.tbIStringsToLinesClick(Sender: TObject);
var
  TempISttrs: IStrings;
begin
  TempISttrs := MyISttr.Get_Items;
  SetOleStrings(Memol.Lines, MyISttr.Items);
end;

end.
{-----}

```

So why was Unit1, the interface implementation created? An Ole interface, such as IStrings, can be considered a contract that properties and functions will be defined in a given format and that the functions will be implemented as defined (see Developer's Guide, Chapter 36, "An Overview of COM" for more information. The fact that you define an interface does not provide implementation. For example, to make a defined IStrings interface useable you need to provide storage for the strings and mechanism to add and retrieve strings. Any additional functionality, defined in the interface, such as a Clear or IndexOf method, must also be implemented.

You may notice in Unit1 that we do not override the Create constructor as the point to create an instance of the FItems TStrings property. Instead we override the Inialize method. The reason for this can be found in the hierarchy of components starting with our TISTR object.

```

TComObject
  TTypedComObject
    TAutoObject
      TISTR

```

In this series of objects, only TComObject has a Create method, and that method IS NOT VIRTUAL. The Create method calls the TComObject.CreateFromFactory and it in turn calls the Initilize method which IS virtual. You can see more detail of the mechanics of this hierarchy in the \source\rtl\sys\comobj.pas unit.

## Article #16617: Getting Version Information From Your Program

Technical Information Database

TI1617D.txt Getting Version Information From Your Program

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

This sample project demonstrates how to get at the version info in executables.

1. Launch Delphi 3.
2. In a new project, drop a TMemo and a TButton on the form (make sure they're called Mem01 and Button1). Double click on Button1. Now you can go ahead and directly replace the code for the Button1Click procedure (see below).

-----  
The Button1Click procedure  
-----

```
procedure TForm1.Button1Click(Sender: TObject);
const
  InfoNum = 10;
  InfoStr : array [1..InfoNum] of String =
    ('CompanyName', 'FileDescription', 'FileVersion', 'InternalName',
     'LegalCopyright', 'LegalTrademarks', 'OriginalFilename',
     'ProductName', 'ProductVersion', 'Comments');
var
  S          : String;
  n, Len, i  : Integer;
  Buf        : PChar;
  Value      : PChar;
begin
  S := Application.ExeName;
  n := GetFileVersionInfoSize(PChar(S),n);
  if n > 0 then begin
    Buf := AllocMem(n);
    Mem01.Lines.Add('FileVersionInfoSize='+IntToStr(n));
```

```
GetFileVersionInfo(PChar(S),0,n,Buf);
for i:=1 to InfoNum do
  if VerQueryValue(Buf,PChar('StringFileInfo\040904E4\'+'
                        InfoStr[i]),Pointer(Value),Len) then
    Mem1.Lines.Add(InfoStr[i]+'='+Value);
  FreeMem(Buf,n);
end else
  Mem1.Lines.Add('No FileVersionInfo found');
end;
```

## Article #16627: Adding an IPersistPropertyBag to Active Controls

Technical Information Database

FAQ: TI1627D - Adding an IPersistPropertyBag to Active Controls

Category: ActiveX/OLE/COM/ActiveForm

Platform: All-32Bit

Product: All32Bit,

Description:

This document will explain how to add an IPersistPropertyBag interface to an ActiveX control. This will allow setting the properties of an ActiveX control through the use of HTML PARAM tags. Adding the IPersistPropertyBag interface to an ActiveX control will also allow it to have its properties set through the use of tools like the ActiveX Control Pad.

Adding the IPersistPropertyBag interface to an ActiveX control is a simple process. All that is necessary is to add the interface to an object's class definition and implement the interface's three methods. The following example will step you through this process using a simple ActiveX control based on TButton. In the example, for the sake of simplicity, this example will only implement this functionality for the "Caption" property. It is a simple task to extrapolate this example to provide full functionality for all properties available in a control.

Begin by using the ActiveX Control Wizard to create a ActiveX control based on TButton.

Choose File|New and select the ActiveX tab from the New Item Dialog. Then select ActiveX Control. In the next dialog box choose TButton for the VCL Class Name. The rest of the defaults in the dialog box are fine so don't change anything else. Let Delphi generate the base code for your control.

The next step is to add the IPersistPropertyBag interface to the class definition. Do this by modifying the first line of the type declaration from...

```
type
  TButtonX = class(TActiveXControl, IButtonX)
```

to...

```
type
  TButtonX = class(TActiveXControl, IButtonX, IPersistPropertyBag)
```

Now the IPersistPropertyBag interface has been added to the type declaration. Next declare the necessary methods by adding the following to the protected section.

```
function IPersistPropertyBag.InitNew = PersistPropBagInitNew;
function IPersistPropertyBag.Load = PersistPropBagLoad;
function IPersistPropertyBag.Save = PersistPropBagSave;
function PersistPropBagInitNew: HRESULT; stdcall;
function PersistPropBagLoad(const pPropBag: IPropertyBag;
  const pErrorLog: IErrorLog): HRESULT; stdcall;
function PersistPropBagSave(const pPropBag: IPropertyBag;
  fClearDirty: BOOL; fSaveAllProperties: BOOL): HRESULT;
  stdcall;
```

Then, of course, implement those functions...

```
// -- implement PersistPropBagInitNew

function TButtonX.PersistPropBagInitNew: HRESULT;
begin
  Result := S_OK;
end;

// -- implement PersistPropBagLoad

function TButtonX.PersistPropBagLoad(const pPropBag:
  IPropertyBag; const pErrorLog: IErrorLog): HRESULT; stdcall;
var
  v: OleVariant;
begin
```

```
if pPropBag.Read('Caption', v, pErrorLog) = S_OK then
    FDelphiControl.Caption := v;
Result := S_OK;
end;

// -- implement PersistPropBagSave

function TButtonX.PersistPropBagSave(const pPropBag:
    IPropertyBag; fClearDirty: BOOL; fSaveAllProperties: BOOL)
    : HRESULT; stdcall;
var
    v: OleVariant;
begin
    v:= FDelphiControl.Caption;
    pPropBag.Write('Caption', v);
    Result := S_OK;
end;
```

With that code added the Control is finished. Go ahead and build the ActiveX control and deploy it. Do this through the use of the Web Delpoy Wizard. Just set up the necessary options through Project|Web Delpoyment Options and deploy through Project|Web Deploy.

Either you or the Web Deployment Wizard will create an HTML page which will contain an OBJECT tag something like the following:

This page should work fine. However, now you have the ability to set the buttons caption through HTML by adding a PARAM tag. Your new OBJECT tag will look like the following:

The caption of the button will now say "Hello". In this example only the caption will be accessable through this method. To expose other properties, follow this example and change the name of the property you wish to use.

## Article #16632: Exposing a Font Property in an Automation Server

Technical Information Database

TI1632D.txt - Exposing a Font Property in an Automation Server

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This document is intended for those using OLE/COM and want to expose a font object similar to Delphi's TFont in their automation server. The IFontDisp interface for COM parallels the functionality of Delphi's TFont. For example, in a case where you have an automation client that contains an object with a font property and you would like the automation server method that acts on the the font's attributes (such as font name or toggling of bold or italics). The automation server can employ an implementation of an IFontDisp interface to store and manipulate the font.

The example project below contains the elements and steps needed to implement an IFontDisp interface in a COM automation server, and to interact with the interface from a COM automation client. You'll find the complete unit source listings next, then finally a discussion of some of the design choices made in this project.

The example project contains these units:

Project1\_TLB: A Pascal wrapper for the type library containing the interface definition.

Unit1: The interface implementation containing storage for interface properties and code to implement interface methods.

Unit2: The main form for the automation server. This unit is not strictly necessary, but provides feedback to know when methods have been successfully called

FontCli: The automation client that obtains a reference to the

interface and uses the interface methods.

The general steps involved are listed below. You can compare each of these steps with the unit code that follows.

1) Use File|New|ActiveX|Automation Object and within the Automation Object Wizard supply MyFontServer as the class name. Provide a single property called MyFont of type IFontDisp. See Developer's Guide, chapter 42 for more information on working with type libraries and creating interfaces in the type library editor.

2) In the previous step, adding an interface using the type library editor will cause a Pascal wrapper unit to be produced (in this example, the unit is called Unit1). Unit1 will contain shell implementations of get and set methods of the MyFont property. In this step you provide storage for the MyFont property, in the form of FFont (a TFont), and add implementation code to make the get and set methods functional.

Unit1 uses Unit2. Unit2 contains a form, memo and status bar to display status of each implementation method, for diagnostic purposes.

3) Create Unit2 containing a form with TMemo and TStatusBar. The form is used to reflect activity in Unit1.pas. Though this step is not strictly necessary, it helps visualize what's happening between the automation client and server.

4) Create an automation client. In this case the unit is called FontCli and contains a label that reflects the current font and a button to set MyFont on the server.

```
{-----}
unit Project1_TLB;

    Label1: TLabel;  
    FontDialog1: TFontDialog;  
    procedure Button1Click(Sender: TObject);  
    procedure FormCreate(Sender: TObject);  
public  
    MyFontServer: IMyFontServer;  
end;

var

Form1: TForm1;

implementation

uses ActiveX, AxCtrls;

{ \$R \*.DFM }

procedure TForm1.Button1Click(Sender: TObject);

var

Temp: IFontDisp;

begin

    if (FontDialog1.Execute) then

    begin

        Label1.Font.Assign(FontDialog1.Font);

        GetOleFont(Label1.Font, Temp);

        MyFontServer.Set\_MyFont(Temp);

    end;

```
end;  
  
procedure TForm1.FormCreate(Sender: TObject);  
begin  
    MyFontServer := CoMyFontServer.Create;  
end;  
  
end.
```

{-----}

So why was Unit1, the interface implementation created? An Ole interface, such as IFontDisp, can be considered a contract that properties and functions will be defined in a given format and that the functions will be implemented as defined (see Developer's Guide, Chapter 36, "An Overview of COM" for more information. The fact that you define an interface does not provide implementation. For example, to make a defined IFontDisp interface useable you need to provide storage for the font and mechanism to add and retrieve font information attributes such as font name, italics, size, etc.

Note:

GetOleFont and SetOleFont are defined in AxCtrls.pas.  
IFontDisp is defined in ActiveX.pas

## Article #16637: Resolving Focus to a DBGrid After Focus Transfers

Technical Information Database

TI1637D.txt - Resolving Focus to a DBGrid After Focus Transfers

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This TI shows how to resolve the inability of a DBGrid to receive focus after clicking on some other control in the parent form when the grid is on a MDI child form.

Applies to all versions of Delphi

Apparently the DBGrid has some focus control problems when on an MDI child form. This problem can be counteracted by descending from TDBGrid, and handling the mousedown messages that indicate that focus should be going back to the control. The following component fixes the problem. Note, this was written generically for all versions of Delphi. You may have problems in Delphi 2 or 3 if you do not have unit aliasing set up correctly, in which case you will want to replace "winprocs" and "wintypes" with "windows."

```
-----  
  
unit FixedDBGrid;  
  
interface  
  
uses  
    Winprocs, wintypes, Messages, SysUtils, Classes, Graphics,  
    Controls, Forms, Dialogs, Grids, DBGrids;  
  
type  
    TFixedDBGrid = class(TDBGrid)  
    private  
        { Private declarations }  
    end;  
end;
```

```
protected
  { Protected declarations }
public
  { Public declarations }
  procedure WMRButtonDown(var Message: TWMRButtonDown); message
    WM_RBUTTONDOWN;
  procedure WMLButtonDown(var Message: TWMLButtonDown); message
    WM_LBUTTONDOWN;
published
  { Published declarations }
end;
```

```
procedure Register;
```

```
implementation
```

```
procedure TFixedDBGrid.WMRButtonDown(var Message: TWMRButtonDown);
begin
  winprocs.SetFocus(handle); {remember that winprocs in Delphi 1
only!}
  inherited;
end;
procedure TFixedDBGrid.WMLButtonDown(var Message: TWMLButtonDown);
begin
  winprocs.SetFocus(handle); {remember that winprocs in Delphi 1
only!}
  inherited;
end;
procedure Register;
begin
  RegisterComponents('Samples', [TFixedDBGrid]);
end;

end.
```

## Article #16642: Importing or "Wrapping" DLL Function Calls

Technical Information Database

TI1642D.txt Importing or "Wrapping" DLL Function Calls

Category :Application Interop

Platform :All

Product :Delphi All

### Description:

Importing or "wrapping" dll function calls

Two methods exist for importing or loading functions from a Dynamic Link Library(DLL). The first method (which is discussed extensively in this document) is called "implicit" loading. Implicit loading involves loading the DLL statically at startup and accessing the functions through an Object PASCAL interface. This method should be used when an application is totally dependent upon the loading of a DLL for proper functioning. The other method available is referred to as "explicit" loading because the DLL is loaded dynamically on demand. This method requires a little more coding and should be used if the application needs to run even if the DLL fails to load properly.

What is a "wrapped" function call?

A wrapped function or set of functions consists of an entry into the interface section and an entry into the implementation section (along with associated constants or types) which corresponds to a function or set of functions to be imported from a DLL. A wrapper is simply a declaration in a PASCAL unit that provides an entry Point into a DLL. With Delphi, this wrapper is represented by a unit file containing object pascal code. The Delphi development team has already conveniently wrapped many standard Windows controls and functions for you. On occasion it may become necessary to create wrappers for dll function calls that are not already wrapped in Delphi.

The first and often the most difficult step in this process is locating information about the function(s). One of the best sources for locating documentation of the function(s) in question is the World Wide Web. An extensive search beginning with the MSDN and extending to the numerous available search engines will often reveal some pertinent information. Search C++ header files in a product like Borland C++ or MS Visual C++ to get the structure of the function calls. Type conversion and calling conventions are generally able to be resolved when converting between C++ and PASCAL. A good resource for compatibility between Delphi and C++ can be found on the Borland web site at:  
"http://www.borland.com/delphi/papers/brick.html".

After locating an example or documentation of the DLL in question the next step is to create a new unit file. The interface of the unit will contain the types and constants that are specific to the function calls of the DLL along with the function headers. These function headers are the Object PASCAL interface that is being provided for other Delphi applications to call the DLL function. Once the interface section of the unit is complete the next section is the implementation. The implementation section of the unit contains declarations of the imported external functions. These headers are not identical to those found in the interface section of the unit (these contain the actual function identifiers plus other important implementation information). For a more thorough treatment of this subject see the help topic "DLLs:accessing procedures and functions" in the Delphi 3 help file.

For example, say there exists a function called BOB in a DLL called 'BLOGGE.DLL'. (detailed below are the steps required to implicitly load the DLL)

- 1) WWW Research on the function BOB reveals that it returns a boolean and takes a word and a boolean as it's arguments.
- 2) Create a new unit file named 'UseBob.pas' via Delphi (File|New and choose unit)
- 3) The following line of code would go in the interface section of the new unit:

```
function BOB(Fire: Word; Dances: Boolean): Boolean; stdcall;
```

4) The following line of code would go in the implementation section of the new unit:

```
function BOB; external 'BLODGE';
```

5) Save the unit, name it 'UseBob.pas'.

6) It is also necessary to make sure that UseBob.pas is in the same directory of the current project or that it resides in a directory that is in the Delphi search path.

7) Add the 'UseBob' unit to a new project's uses clause. The function BOB can be called from this new project just like any other standard function.

8) At runtime BLODGE.DLL must be in the path of the current process's environment.

The steps required to explicitly load the 'BLODGE.DLL' are slightly different and involve a bit of coding. As before a knowledge of the function/procedure arguments is necessary (and a result type if it's a function).

What follows is a unit that implements the BOB function call on a button click event:

```
unit UDLLTest;
```

```
interface
```

```
uses
```

```
  Windows, Messages, SysUtils, Classes, Graphics, Controls,  
  Forms, Dialogs, StdCtrls;
```

```
type
```

```
  TForm1 = class(TForm)  
    Button1: TButton;  
    procedure Button1Click(Sender: TObject);
```

```
  private
```

```
    { Private declarations }
```

```
  public
```

```
    { Public declarations }
```

```
end;
```

```

{ Here's a type which points to our bob function }
TBOB = function(Fire: Word; Dances: Boolean): Boolean; stdcall;

var
    Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.Button1Click(Sender: TObject);
var
    BOB: TBOB;
    hDLLInst: THandle;
    IsAlive,IsDancing: Boolean;
    Years: Word;
begin
    { Load a handle to our BLODGE.DLL }
    hDLLInst:= LoadLibrary('BLODGE.DLL');
    { If the load was unsuccessful raise a custom exception }
    if (hDLLInst <= 0) then
        raise exception.create('[LoadLibrary Fail]');
    { Try to load the address of the BOB function }
    try
BOB:= GetProcAddress(hDLLInst,'BOB');
        if not assigned(BOB) then
            raise exception.Create('[GetProcAddress Fail]');
        Years:= 25;
        IsDancing:= True;
    { Now we can execute the BOB function }
        IsAlive:= BOB(Years,IsDancing);
    finally
        { Free the handle to the DLL }
        FreeLibrary(hDLLInst);
    end;
end;
end.

```

## Article #16647: Implementing TCollection

Technical Information Database

TI1647D.txt - Implementing TCollection

Category :ActiveX/OLE/COM/ActiveForm  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This document is intended for those needing to descend from a class that manages an array of lightweight persistent objects of the same type. The class that best accomplishes this is TCollection and TCollectionItem. For example, TCollection is used to manage Panels in a TStatusBar, Columns in a TDBGrid, or Constraints in a TTable.

This document begins with a discussion of the expected behavior of TCollection descendants, followed by a listing of the minimal steps necessary to implement a TCollection descendant, a listing of the component source, and finally some notes on design decisions and ideas for expansion of your TCollection descendant component.

### General Discussion

-----  
To become familiar with the default behavior of TCollection, try adding a TStatusBar component to a form, click the ellipses of the Panels property, press the Add button of the "Editing Panels". This last step adds a TStatusPanel to the editor. Click on on the TStatusPanel item in the editor and notice the change in the object inspector. Instead of seeing TStatusBar now you will see StatusBar1.Panels[0] reflected in the Object Inspector.

There are three major players involved with collections. A collection item (TCollectionItem) descendant, a TCollection that manages the list of TCollectionItems, and a component that contains the TCollection as one of it's properties. In our above example of TStatusBar, TStatusBar contains a descendant of TCollection called TPanels and TPanels manages a list of TCollectionItem descendants called TPanel. Notice that each TCollectionItem contains one or

more properties; for instance, TPanel contains Alignment, Bevel, Style, Text, and Width properties. This list changes depending on the definition of your TCollectionItem descendant.

### Creating a Minimal TCollection Implementation

-----

In a new unit you must first define three new descendant classes from TCollectionItem, TCollection and a TComponent.

```
TMyCollectionItem = class(TCollectionItem)
```

```
TMyCollection = class(TCollection)
```

```
TMyComponent = class(TComponent)
```

To make TMyCollectionItem functional, you need to define one or more properties to contain information to be tracked by the collection mechanism. The example defines a Text and a MoreStuff integer property. You will also need to override the GetDisplayName method to supply the string shown for each item in the collection property editor:

```
TMyCollectionItem = class(TCollectionItem)
private
  FText: string;
  FMoreStuff: LongInt;
  function GetDisplayName: string; override;
  procedure SetText(const Value: string);
  procedure SetMoreStuff(const Value: LongInt);
published
  property Text: string read FText write SetText;
  property MoreStuff: LongInt
    read FMoreStuff write SetMoreStuff;
end;
```

Next, define the TCollection descendant. This class will keep track of the component the collection belongs to, override the GetOwner method to accommodate streaming, and manage an array of the previously defined TCollectionItem descendants.

You will need to define a new static constructor. The parameter passed in this constructor is the reference to the component that contains the collection. Also in the constructor you need to populate the ItemClass property with the class of your TCollection item descendant. Note: ItemClass returns the class

(descended from TCollectionItem) to which the items in the collection belong.

```
TMyCollection = class(TCollection)
  private
    FMyComponent: TMyComponent;
    function GetItem(Index: Integer): TMyCollectionItem;
    procedure SetItem(Index: Integer; Value: TMyCollectionItem);
  protected
    function GetOwner: TPersistent; override;
  public
    constructor Create(MyComponent: TMyComponent);
    function Add: TMyCollectionItem;
    property Items[Index: Integer]: TMyCollectionItem
      read GetItem write SetItem; default;
end;
```

Finally, define the component that will contain the collection. The component will contain a property descended from the TCollection type defined previously. The TCollection property will need a private field, an access method to the private field, and storage allocated in the constructor and freed in the destructor.

Note: See The Developers Guide for more information on creating custom components.

```
TMyComponent = class(TComponent)
  private
    FItems: TMyCollection;
    procedure SetItems(Value: TMyCollection);
  public
    constructor Create(AOwner: TComponent); override;
    destructor Destroy; override;
  published
    property Items: TMyCollection
      read FItems write SetItems;
end;
```

Complete Unit Listing

```
-----
unit Collec1;

interface
```

```
// Note: TCollection and TCollectionItem are defined in Classes.Pas.
```

```
uses Classes;
```

```
type
```

```
  TMyComponent = class;
```

```
  TMyCollectionItem = class(TCollectionItem)
```

```
  private
```

```
    FText: string;
```

```
    FMoreStuff: LongInt;
```

```
    function GetDisplayName: string; override;
```

```
    procedure SetText(const Value: string);
```

```
    procedure SetMoreStuff(const Value: LongInt);
```

```
  public
```

```
  published
```

```
    property Text: string read FText write SetText;
```

```
    property MoreStuff: LongInt read FMoreStuff write SetMoreStuff;
```

```
  end;
```

```
  TMyCollection = class(TCollection)
```

```
  private
```

```
    FMyComponent: TMyComponent;
```

```
    function GetItem(Index: Integer): TMyCollectionItem;
```

```
    procedure SetItem(Index: Integer; Value: TMyCollectionItem);
```

```

```

```
    function GetOwner: TPersistent; override;
```

```
  public
```

```
    constructor Create(MyComponent: TMyComponent);
```

```
    function Add: TMyCollectionItem;
```

```
    property Items[Index: Integer]: TMyCollectionItem
```

```
      read GetItem write SetItem; default;
```

```
  end;
```

```
  TMyComponent = class(TComponent)
```

```
  private
```

```
    FItems: TMyCollection;
```

```
    procedure SetItems(Value: TMyCollection);
```

```
  public
```

```
    constructor Create(AOwner: TComponent); override;
```

```
    destructor Destroy; override;
```

```
  published
```

```
    property Items: TMyCollection read FItems write SetItems;
```

```

end;

procedure Register;

implementation

procedure Register;
begin
  RegisterComponents('Sample', [TMyComponent]);
end;

{ TMyCollectionItem }

// Note: Inherited default behavior of GetDisplayName is to
// return the classname.

function TMyCollectionItem.GetDisplayName: string;
begin
  Result := Text;
  if Result = '' then Result := inherited GetDisplayName;
end;

procedure TMyCollectionItem.SetText(const Value: string);
begin
  if FText <> Value then
    FText := Value;
end;

procedure TMyCollectionItem.SetMoreStuff(const Value: LongInt);
begin
  if FMoreStuff <> Value then
    FMoreStuff := Value;
end;

{ TMyCollection }

constructor TMyCollection.Create(MyComponent: TMyComponent);
begin
  inherited Create(TMyCollectionItem);
  FMyComponent := MyComponent;
end;

```

```

function TMyCollection.Add: TMyCollectionItem;
begin
    Result := TMyCollectionItem(inherited Add);
end;

function TMyCollection.GetItem(Index: Integer): TMyCollectionItem;
begin
    Result := TMyCollectionItem(inherited GetItem(Index));
end;

procedure TMyCollection.SetItem(Index: Integer;
    Value: TMyCollectionItem);
begin
    inherited SetItem(Index, Value);
end;

// Note: You must override GetOwner in Delphi 3.x to get
// correct streaming behavior.
function TMyCollection.GetOwner: TPersistent;
begin
    Result := FMyComponent;
end;

{ TMyComponent }

constructor TMyComponent.Create(AOwner: TComponent);
begin
    inherited Create(AOwner);
    FItems := TMyCollection.Create(Self);
end;

destructor TMyComponent.Destroy;
begin
    FItems.Free;
    inherited Destroy;
end;

procedure TMyComponent.SetItems(Value: TMyCollection);
begin
    FItems.Assign(Value);
end;

end.
{-----}

```

## Notes

-----

In this minimal example we didn't override the Assign method for the TCollectionItem, but this method should have further support. Here's an example of how you might implement Assign in the above project:

```
procedure TMyCollectionItem.Assign(Source: TPersistent);
begin
  if Source is TMyCollectionItem then
  begin
    Text := TMyCollectionItem(Source).Text;
    MoreStuff := TMyCollectionItem(Source).MoreStuff;
    Exit;
  end;
  inherited Assign(Source);
end;
```

Also not included in the above project is the logic needed to notify the TCollection class when one of it's contained items has changed. This could be particularly important in a visual control such as TStatusBar. TCollection supplies a virtual Update method for handling this behavior. See TStatusBar or THeaderControl in \source\vcl\commctrl.pas for further examples.

## Article #16652: Delphi Titles from Leading Book Publishers

Technical Information Database

TI1652D.txt - Delphi Titles from Leading Book Publishers

Category :Delphi 1.x  
Platform :All  
Product :

Description:

BORLAND'S DELPHI IS  
SUPPORTED BY THESE TITLES  
FROM LEADING BOOK PUBLISHERS  
April 1996

Delphi Version 2.0

-----

The following is a list of book titles for Delphi 2.0 that are currently available or will be available in the future. For more information, contact the publisher.

- \* Delphi 2 Developer's Guide; X. Pacheco/S. Teixeira; Borland Press/Sams Publishing; ISBN: 0-672-30914-9  
Phone: 800-428-5331; Fax: 800-448-3804
- \* Borland's Official No-Nonsense Guide to Delphi 2; M. Manning; Borland Press/Sams Publishing; ISBN: 0-672-30871-1;  
Phone: 800-428-5331; Fax: 800-448-3804
- \* Teach Yourself Delphi 2 in 21 Days; D. Osier; Borland Press/Sams Publishing; ISBN: 0-672-30863-0;  
Phone: 800-428-5331; Fax: 800-448-3804
- \* Database Developer's Guide with Delphi 2; K. Henderson; Borland Press/Sams Publishing; ISBN: 0-672-30862-2;  
Phone: 800-428-5331; Fax: 800-448-3804
- \* Delphi 2 Unleashed, Second Edition; C. Calvert; Borland Press/Sams Publishing; ISBN: 0-672-30858-4  
Phone: 800-428-5331; Fax: 800-448-3804

The New Delphi 2 Programming Explorer; J. Duntemann/J. Mischel/D. Taylor; Coriolis Group; ISBN: 1-883577-72-1;  
Phone: 800-410-0192; Fax: 602-483-0193

Delphi 2 Nuts and Bolts, 2nd Edition; G. Cornell;

Osborne/McGraw-Hill; ISBN: 0-07-88203-3

Phone: 800-227-0900; Fax: 510-549-6603

Special Edition Using Delphi, 2nd Edition; J. Matcho; Que;

ISBN: 0-7897-0591-5; Phone: 800-428-5331; Fax: 800-882-8583

Delphi 2 By Example, 2nd Edition; B. Watson; Que;

ISBN: 0-7897-0592-3; Phone: 800-428-5331; Fax: 800-882-8583

Building Delphi 2.0 Database Applications; P. Kimmel; Que; ISBN:

0-7897-0492-7; Phone: 800-428-5331; Fax: 800-882-8583

## Article #16657: Pascal Titles from Leading Publishers

BORLAND'S PASCAL AND TURBO PASCAL  
ARE SUPPORTED BY THESE TITLES  
FROM LEADING PUBLISHERS  
April 1996

Borland Pascal 7.0 with Objects  
-----

Borland Pascal from Square One; Jeff Duntemann; Bantam Electronic  
Publishing; ISBN 0-553-37243-2

Borland Pascal 7.0 Programming for Windows; Tom Swan;  
BantamElectronic Publishing; ISBN 0-553-37244-0

A Programmer's Guide to Turbo Vision; Ertl/Machholz/Golgath;  
Addison Wesley; ISBN 0-201-62401-X

Borland Pascal Problem Solver; Brian Long; Addison-Wesley;  
ISBN0-201-59383-1

Object-Oriented Programming in Pascal: A Graphical Approach;  
Conner/Niguidula/VanDam; Addison Wesley; ISBN 0-201-62883

Borland Pascal with Objects 7.0; Jose de Jesus/Abad Godog; M&T  
Books; ISBN 1-558-28247-5

Programming with Turbo Vision; Blake Watson; M&T Books

Borland Pascal Developer's Guide; Ed Mitchell/Namir Shammas; Que;  
ISBN 0-88022-862-8

Borland Pascal Programs for Scientists and Engineers Alan R.  
Miller; Sybex; ISBN 0-7821-1150-5

Programming in Borland Pascal; Scott Palmer; Sybex;  
ISBN 0-7821-1151-3

Borland Pascal 7 Insider; Paul Cilwa; John Wiley & Sons, Inc.  
ISBN 0-471-59894-1

Borland Pascal Step-By-Step; Keith Weiskamp; John Wiley & Sons;  
ISBN  
0-471-30429-8

Pascal and the Paradox Engine; Robert Signore/Michael  
Vernick/Michael O. Stegman; Windcrest/McGraw-Hill;  
ISBN 0-8306-4325-7

Object-Oriented Programming with Borland Pascal 7; Namir  
Shammas; Sams; ISBN: 0-672-3033-7

Turbo Pascal 7.0

-----  
Turbo Pascal 4th Edition; Elliott Koffman with Bruce Maxim;  
Addison-Wesley; ISBN 0-20-155811-4  
Turbo Pascal: An Introduction to the Art and Science of  
Programming 4th Edition; Walter Savitch; Benjamin/Cummings;  
ISBN 0-8053-0418-5  
Programming with Turbo Vision; Blake Watson; M&T Books  
Turbo Pascal 7 Complete Reference; Stephen K. O'Brien/Steve  
Nameroff; Osborne/McGraw-Hill; ISBN 0-07-881793-5  
Turbo Pascal 7 Handbook; Werner Feibel; Osborne/McGraw-Hill; ISBN  
0-07-881799-4  
Turbo Pascal Programming 101; Charles Calvert; Sams; ISBN  
0-672-30285-3  
Object Oriented Programming in Turbo Pascal 7.0; Namir Shamma;  
Sams; ISBN 0-672-30285-3  
Turbo Pascal Memory Management Techniques; Len Dorfman/Neuberger;  
Windcrest/McGraw-Hill; ISBN 0-8306-4059-2  
The Beginner's Guide to Turbo Pascal; Oleg Perminov; Wrox Press  
Ltd.; ISBN: 1-874416-30-3  
The Revolutionary Guide to Turbo Pascal; Yuri Borodich, et al;  
Wrox Press Ltd.; ISBN: 1-874416-11-7

#### Turbo Pascal for Windows

-----

Turbo Pascal for Windows 3.0 Programming; Tom Swan; Bantam  
Electronic Publishing; ISBN 0-553-35293-8  
Turbo Pascal for Windows; Gunther Faeber/Martin Pauly; Abacus  
Using Turbo Pascal for Windows; Paul Perry; Que;  
ISBN 0-88022-806-7  
Turbo Pascal for Windows Bible; Gary Entsminger; Howard W. Sams &  
Co.; ISBN 0-672-30212-8  
Programmer's Introduction to Turbo Pascal for Windows Scott D.  
Palmer; Sybex; ISBN 0-7821-1022-3  
Write TSRs Now with Borland's Turbo Assembler, Turbo C/C++ &  
Turbo Pascal; Jim Ras; Wordware Publishing, Inc.  
PC Magazine's Turbo Pascal for Windows Tips and Techniques; Neil  
Rubenking; Ziff-Davis; ISBN 1-56276-035-1

#### Turbo Pascal Version 6.0

-----

Turbo Pascal System Programming; Michael Tischer; Abacus; ISBN  
1-55755-124-3  
Turbo Vision Toolbox; Abacus

Programmer's Guide to Turbo Vision; Ertl/Machholz/Golgath;  
Addison-Wesley

Graphics Programming in Turbo Pascal 6; Ben Ezzell; Addison-  
Wesley; ISBN 0-201-58119-1

Turbo Pascal Problem Solving & Programming Design; Elliott  
Koffman; Addison-Wesley

Using Turbo Pascal 6.0; Ben Ezzell; Addison-Wesley ISBN;  
0-201-5774-7

Turbo Pascal: Introduction to Art Science of Programming; Walter  
J. Savitch; Benjamin/Cummings

Hands-On Turbo Pascal; Larry Goldstein; Brady Books;  
ISBN 0-13-629635-1

Effective Programming with Turbo Pascal 6.0; Seymour Pollock;  
Brooks-Cole Publishing

Programming Fundamentals Using Turbo Pascal; Thomas M. Boger;  
W.C. Brown

Data Structures Using Turbo Pascal; Thomas A. Boger; W.C. Brown

Turbo Pascal Third Edition; Nell Dale/Chip Weems; D.C. Heath

Problem Solving & Program Implementation Using Turbo Pascal:  
Versions 4.0-6.0; Rick Mercer; Franklin, Beedle & Associates

Turbo Pascal Theory and Practice of Good Programming; Gary W.  
Martin; HBJ (Saunders); ISBN 0-15-592375-7

Mastering Turbo Pascal 6.0 Third Edition; Tom Swan; Hayden/Howard  
W. Sams; ISBN 0-8104-6287-7

Introduction to Computer Science with Turbo Pascal; William I.  
Salmon; Irwin

A Guide to Programming in Turbo Pascal 2nd Edition (Versions 4.0  
through 6.0); Tim Corica/William Freitas/Bruce Presley;  
Lawrenceville Press

Advanced Graphics Programming in Turbo Pascal; Roger  
Stevens/Christopher Watkins; M&T Books; ISBN 1-55851-132-6

Clean Coding in Turbo Pascal 6 with Turbo Vision; Amrik Dhillon;  
M&T Books; ISBN 1-55851-228-4

Fractal Programming in Turbo Pascal; Roger T. Stevens; M&T Books;  
ISBN 1-55851-107-5

Turbo Pascal 6.0: The Nuts & Bolts of Program Construction; John  
DiElsi; McGraw-Hill; ISBN 0-07-557790-9

Oh! Pascal! Turbo Pascal 6.0; Doug Cooper; W.W. Norton & Company;  
ISBN 0-393-96077-3 (3.50"); ISBN 0-393-96249-0 (5.25")

Turbo Pascal 6 Disk Tutor 2nd Edition; Werner Feibel;  
Osborne/McGraw-Hill; ISBN 0-07-881738-2

Turbo Pascal 6: The Complete Reference; Stephen O'Brien;  
Osborne/McGraw-Hill; ISBN 0-07-881703-X

Using Turbo Pascal 4-6; Julien Hennefeld; PWS Kent

Object-Oriented Programming with Turbo Pascal and Object

Professional; Ken Knecht; Prentice Hall Professional  
Publishing; ISBN 0-13-630310-2

Turbo Pascal 6.0 By Example; Greg Perry; Que; ISBN 0-88022-908-X  
Using Turbo Pascal 6.0 2nd Edition; Michael Yester/Namir Shammass;  
Que; ISBN 0-88022-700-1

## Article #17596: Calling a Delphi DLL from your BCB Code.

Technical Information Database

TI2596C.txt Calling a Delphi DLL from your BCB Code.

Category :General

Platform :All

Product :C++Builder All

### Description:

Calling a Delphi DLL from your BCB Code.

First create a simple DLL in Delphi:

```
{ Begin DLL code }
Library MinMaxDll;
uses Windows;
Function Min(X, Y: Integer): Integer; export;
begin
    if X < Y then Min := X else Min := Y;
end;
Function Max(X, Y: Integer): Integer; export;
begin
    if X > Y then Max := X else Max := Y;
end;
procedure Del_MessageBox;export;
begin
    MessageBeep(0);
    MessageBox(0, 'Delphi Message Box', 'MinMaxDll', MB_OK or
MB_TASKMODAL);
end;
Exports
    Min name '@Min',
    Max name '@Max',
    Del_MessageBox name '@Del_MessageBox';
begin
end.
{ End DLL code }
```

Then to Call it from your BCB Code:

1. Create and insert an import library first using implib:

```
implib MinMaxDLL.lib MinMaxDLL.dll
```

Then add the import library to your BCB project, Project|Add to Project.

2. In your BCB application, you must prototype the functions as:

```
extern "C" {
    int __fastcall Min(int, int);
    void __fastcall Del_MessageBox(void);
    int __fastcall Max(int, int);
}
```

3. Now you can call Min or Max anywhere in your application.

```
Min();
Del_MessageBox();
Max();
```

Important Note:

If you are exporting other than fastcall, please read the following. Make sure you are exporting the functions in the Export Section of your

Delphi dll, and prototype the functions in the format listed in the commented fields below.

Exports {Exports section in Delphi dll}

```
Min name '@Min', { BCB prototype: extern "C"{int __fastcall Min(int, int); }
```

```
Max name '_Max', { BCB prototype: extern "C"{int __cdecl Max(int, int); }
```

```
Del_Message;      { BCB prototype: extern "C"{void __stdcall
Del_Message(); }
```

## Article #17624: Assembly linked with Pascal - can't trace through

Technical Notes Database

TN2624C.txt Assembly linked with Pascal - can't trace through

Category :OTHER

Platform :All

Product :TD 1.xx

Description:

QUESTION:

Why can't I trace through my external assembly language routines which have been linked with my TP program?

ANSWER:

The Pascal linker does not pull through the symbolic debug information which is necessary to do source level debugging. Therefore, you will not be able to see your TASM source code. However, if you pull up the CPU window, you can trace through the disassembled ASM code. You will not have the benefit of variable names and labels, but you will be able to see the flow of execution.

## Article #17795: Removing the Vertical Scroll Bar from a TDBGrid

Technical Information Database

TI2795C.txt Removing the Vertical Scroll Bar from a TDBGrid

Category :Database Issues

Platform :Win95/NT

Product : C++Builder3.x

### Description:

In order to remove the vertical scrollbar from a TDBGrid component, you must override its Paint method. Inside the Paint method you must call the SetScrollRange API procedure to set the min and max scroll values to zero (this disables the scrollbar), and then call the inherited Paint. The code below is a unit containing a new component called TNoVertScrollDBGrid that does this. You can copy the code into a file called NoScroll.cpp, and add it to the component library as a custom component.

```
-----  
// -----  
// In the header file:  
// -----  
class TNoVertScrollDBGrid : public TDBGrid  
{  
protected: void __fastcall Paint();  
};  
  
// -----  
// In the .cpp file:  
// -----  
  
//-----  
  
void __fastcall TNoVertScrollDBGrid::Paint()  
{  
    SetScrollRange(Handle, SB_VERT, 0, 0, false);  
    TDBGrid::Paint();  
}  
  
//-----  
namespace NoScroll  
{  
    void __fastcall Register(TObject *Sender)  
    {  
        TComponentClass classes[1] = {__classid(TNoVertScrollDBGrid)};  
        RegisterComponents("Data Controls", classes, 0);  
    }  
}
```

```
}  
}
```

## Article #17801: Writing a Buffer Disk

Technical Information Database

TI2801C.txt :Writing a Buffer Disk  
Category :Database Issues  
Platform :Win95/NT  
Product :

Description:

General:

=====

Changes made to a table are not written directly to disk until the table is closed. A power failure or system crash can result in a loss of data, and an inconvenience. To avoid this loss of data, two direct Database Engine calls can be made, both of which have the similar effects. These functions are `DbiUseIdleTime` and `DbiSaveChanges`.

`DbiSaveChanges(hDBICur):`

=====

`DbiSaveChanges` saves to disk all the updates that are in the buffer of the table associated with the cursor (`hDBICur`). It can be called at any point. For example, one may want to make save changes to disk every time a record is updated:

```
void __fastcall TForm1::Table1AfterPost(TDataSet *DataSet)
{
    DbiSaveChanges(Table1->Handle);
}
```

This way, one does not have to worry about losing data if a power failure or system crash occurs after a record update.

`DbiSaveChanges` can also be used to make a temporary table (created by `DbiCreateTempTable`) permanent.

This function does NOT apply to SQL tables.

DbiUseIdleTime:

=====

DbiUseIdleTime can be called when the "Windows Message Queue" is empty. It allows the Database Engine to save "dirty buffers" to disk. In other words, it does what DbiSaveChanges does, but performs the operation on ALL the tables that have been updated. This operation however, will not necessarily occur after every record update, because it can only be executed when there is an idle period.

In C++ Builder, it can be used in this fashion:

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
    Application->OnIdle = UseIdle;
}
```

```
void __fastcall TForm1::UseIdle(TObject *Sender, bool &Done)
{
    DbiUseIdleTime;
}
```

USAGE NOTES:

=====

Using both DbiUseIdleTime and DbiSaveChanges (after every record modification) is redundant and will result in unnecessary function calls. If the application is one that performs a great deal of record insertions or modifications in a small period of time, it is recommended that the client either call DbiUseIdleTime during an idle period, or call DbiSaveChanges after a group of updates.

If not very many updates are being performed on the table, the client may choose to call DbiSaveChanges after every post or set up a timer and call DbiUseIdleTime when a timer event is generated.

## Article #17805: TI2805C: Showing Deleted Records in a dBase Table

Technical Information Database

TI2805C.txt :Showing Deleted Records in a dBase Table  
Category :Database Issues  
Platform :Win95/NT  
Product :All-CBuilder,

### Description:

Q: How can I view dBASE records marked for deletion. That is, I want to view those records marked as "soft deletion"?

A: In a dBASE table, records are not removed from the table until the table is packed. Until that happens, records that are "deleted" are actually just marked as "to be" deleted. To show these existing but not displayed records, the following function, ShowDeleted(), makes use of a BDE API function, DbiSetProp(), to show records marked for deletion. It is not necessary to close and re-open the table when using this function. ShowDeleted() takes a TTable and a boolean variable as parameters. The boolean parameter determines whether or not to show deleted records.

```
//In your header file:
```

```
//-----
```

```
private://private declarations  
void ShowDeleted(TTable*, bool);
```

```
//In your .cpp file:
```

```
//-----
```

```
//-----
```

```
void TForm2::ShowDeleted(TTable *Table1, bool ShowDeleted)  
{  
    DBIResult rslt;  
    DBIMSG szErrMsg;  
  
    Table1->DisableControls();  
    try {  
        Check(DbiSetProp((hDBIObj)(Table1->Handle),  
                        curSOFTDELETEON, int(ShowDeleted)));  
    }  
    __finally {  
        Table1->EnableControls();  
    }  
}
```

```
}
Table1->Refresh();
}

void __fastcall TForm2::CheckBox1Click(TObject *Sender)
{
    ShowDeleted(Table1, CheckBox1->Checked);
}
//-----
```

## Article #18045: Searching on a secondary index in Engine 2.0

Technical Notes Database

TN3045C.txt Searching on a secondary index in Engine 2.0

Category :OTHER

Platform :All

Product :BDE 2.0

### Description:

Searching on a secondary index in Engine 2.0

When you open a table on index 0 (primary index), and you perform a search

on a field which possesses a secondary index, that secondary index WILL be

used. However, there are some tricky problems you may run into.

Although searching using SEARCHFIRST or SEARCHNEXT with PXSrchFld will search based upon the ordering of the indexed field, end of table will be

determined based upon the primary index (ie., physical ordering).

Therefore, it is safe to do a SEARCHFIRST on this field but a SEARCHNEXT may

return PXERR\_ENDOFTABLE even if all records matching the search criterion

have not been found.

What is the solution, then, if you are using SEARCHNEXT on a field search?

Open the table on the secondary index. This means that if you are doing

some of your searches on the primary index and others on an indexed field

you will want to open the same table twice - once on the primary index and

once on the secondary index.

Description:

BCPPWIN SECTION 11 - Win32 API

-----  
This document contains information that is most often provided to users

of this section. There is a listing (when available) of common Technical

Information Documents and example files that can be downloaded from the libraries. There is also a listing of the most frequently asked questions and their answers.

TECHNICAL INFORMATION DOCUMENTS AND EXAMPLE FILES

-----  
Currently no listing available.

FREQUENTLY ASKED QUESTIONS AND ANSWERS

-----  
Q:    How do I create a Win32 application in the IDE?

A:    Via the Speed Menu, go to Target Expert. Under Target Type, set Platform to Win32.

Q:    What are the command-line tools for creating Win32 applications?

A:    BCC32, TLINK32, and BRC32 are the primary Win32 tools. You can use implib, impdef, and tdump can be used for both Win32 and Win16.

Q:    Why does the IDE not work in NT?

A:    The Windows 3.1 emulation provided by NT does not fully support all the features of the IDE. The Borland development team is working vigorously to resolve this problem. The Borland command-line tools as well as TD32 work under NT.

Q:    Why do I get the error "Cannot run multiple instances of a DLL under WIN32s"?

A:    Due to stability issues, Borland dll's do not support multiple instances under Win32s. This is not an issue

under Win32, i.e. NT.

Q: My stack is not expanding past 1Mb. I have set my stack size much larger in my .def file. What is wrong?

A: It is necessary to turn on the compiler option Check Stack Overflow to enable stack expansion.

Q: Can I utilize my 16bit dll in a Win32 app?

A: Yes, if you are creating an application for Win32s. See the section under Universal Thunk in the Windows help file win32s.hlp. Windows NT does not support mixing of 16bit and 32bit code in the same process.

Q: After creating a program using stdin or stdout (i.e. printf, cout, etc. ) I try to run it under Win32s. Nothing appears. What's wrong?

A: There are two possible problems. First, if you are trying to create a console application, Win32s does not support console apps. Second, if you are creating a GUI application, Borland does not supply an EasyWin for Win32. Check the forum libraries for third-party implementations of EasyWin for Win32.

## Article #18289: Comparing connections to an AS/400 between Delphi/400 and ODBC

Technical Information Database

TI3289D.txt - Comparing connections to an AS/400 between Delphi/400 and ODBC

Category :AS400  
Platform :All-32Bit  
Product :DelphiAS400,

### Description:

This document describes how Delphi/400 compares with ODBC in regards to connections to an AS/400.

### Reference:

Reading records

For sequential access a TQuery with ODBC is faster than Delphi/400. But if you compare a TTable Delphi/400 is faster. If you want to improve performance with a TTable, TQuery or TFile400, you need to play with the "buffer count". Buffer count is the number of data base records Delphi/400 sends in only one communication record. The optimal value of "buffer count" may be determined by using the following formula:

$$\text{"Buffer count"} * \text{Record length} < 32 \text{ Kbytes}$$

It is best if this result can (or nearly) be divisible by the max frame length of your communication card; parameter MAXFRAME of the LIND of your AS/400 line description.

For Direct or Keyed access, Delphi/400 is much faster than ODBC. On large tables, executing Query1.First and then executing Query1.Last is significantly slower with ODBC. Similarly, scrolling a DBGrid to the bottom

is significantly slower with ODBC.

Below are examples how to code "buffer count" programmatically. In all cases buffercount is an integer and should be set after the Object (Database, Table, File) is opened:

Example 1

```
query1.DatabaseName := 'idco400';  
dbisetprop(hDBIObj(databasel.handle), $404000E, buffercount);
```

Example 2

```
table1.Open;  
dbisetprop(hDBIObj(table1.handle), $4050009, buffercount);
```

Example 3

```
file4001.Open;  
file4001.BufferCount := buffercount;
```

## 2. INSERTing records via a TTable

Our tests show executing the following code is approximately 6 times faster when using Delphi/400 vs. ODBC.

Var

```
  i : integer;  
  Starttime : DWORD;
```

Begin

```
  Starttime := gettickcount( );  
  databasel.connected :=true;  
  table1.active:=true;  
  for i=0 to 100 do  
  begin  
    table1.insert;  
    table1.fieldbyname('FLD1').asstring := 'my string';  
    .....  
  
    Table1.post;  
  end;  
  Table1.active:=false;  
  Databasel.connected:=false;  
  edit1.text :=floattostr( (gettickcount() - Starttime ) / 1000);
```

end;

3. Running AS/400 commands in Delphi application.

- With Delphi/400, you can run an AS/400 command and wait for return parameters. Using ODBC you must use Stored Procedures which do not have as much flexibility due to all data types not being supported.

Many thanks to Van Vinh Pham from TCIS whom is the source of technical information in this document.

## Article #19021: TP 5.0/TASM - ARG DIRECTIVE SYMBOLIC REFERENCES

Technical Notes Database

TN4021C.txt TP 5.0/TASM - ARG DIRECTIVE SYMBOLIC REFERENCES

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. I am using the Arg directive to create symbolic references to variables on the stack. I am not getting the correct values I should in the Assembler routine. What am I doing wrong?

A. It is easier if remember a few points about the Arg directive. First, the Arg directive always adjusts for a near or far call. If you have a proc definition like:

```
myproc proc far
```

the Arg directive will take into account the four (4) byte return address on the stack. If your definition looks like:

```
myproc proc near
```

the Arg directive will adjust for a two (2) byte return address on the stack. The second thing to remember is that the Arg directive always assumes that you will push BP onto the stack first and thus, will add two bytes to the size of the return address. For a far return the total will be six bytes and for a near return the total will be four bytes. The third point to remember about the Arg directive itself is that the leftmost symbol in the Arg list will be nearest the top of the stack. Finally, remember that for each subsequent symbol to the right, a number equal to the number of bytes on the stack occupied by the symbols to the left will be added to the BP register.

Consider the following examples:

```
myproc proc near
  arg first:word, second:word
  push bp
  mov  bp,sp
```

The distance is near, a two byte return address, and the BP is assumed to pushed onto the stack. Thus, any reference to first is equivalent to [BP + 04H]. Since first is a word it occupies two bytes on the stack. Thus second evaluates to [BP + 04H + 02H] or [BP + 06H].

```
myproc proc far
arg first:word, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Since first is a word, it occupies two bytes on the stack. Thus, second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:near ptr word, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus any reference to first is equivalent to [BP + 06H]. Since first is a near pointer it occupies two bytes on the stack. Thus second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:byte, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Although first is a byte value it occupies two bytes on the stack. Thus, second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:byte:1, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Although first is a byte value it occupies two bytes on the stack. To force it to use only one byte we must use the :1 after the word byte. Second evaluates to {BP + 06H + 01H} or [BP + 07H]. Note that the type of variables must match the types of those that appear in the high level language call.

## Article #19024: TASM - UNDEFINED SYMBOL WITH TURBO C

Technical Notes Database

TN4024C.txt TASM - UNDEFINED SYMBOL WITH TURBO C

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

- Q. When I try to link a Turbo C module with a TASM generated .OBJ file, the linker reports "undefined symbols".
- A. Assemble your TASM file with the /ML option. Turbo C symbols are by default, case sensitive. Turbo Assembler on the other hand, converts all symbols to uppercase by default. Therefore, make sure that the symbols case is exactly the same in the two modules, and assemble with the /ML option.

## Article #19025: TASM - LOAD AND EXECUTE OVERLAY

Technical Notes Database

TN4025C.txt TASM - LOAD AND EXECUTE OVERLAY

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

- Q. Why does Turbo Debugger not step through overlaid portions of a program?
- A. Overlays are generally accomplished through DOS interrupt 21, function 4BH. Pressing F7 while on any interrupt in Turbo Debugger causes the computer to execute everything included in the interrupt before returning control to TD. Because the overlay is executed inside of an interrupt, TD is not given control until the overlay has finished executing, and the INT 21H is returned from. The workaround is to do an instruction trace into the interrupt. You will have to trace through the DOS code which loads the overlay and transfers control to it. Also, since you are doing CPU tracing, you will not have the benefit of source level debugging.

**Article #19026: TD - AT&T 6300 clock speeds up after TD is loaded.**

Technical Notes Database

TN4026C.txt TD - AT&T 6300 clock speeds up after TD is loaded.

Category :Pascal

Platform :All

Product :TD 1.x 2.0

Description:

Q. I have an AT&T 6300 and after loading TD my clock speeds up.

A. Run TDINST and set the NMI option to NO. Make sure to save the configuration both to TD.EXE, and to a config file. Erase all other TDCONFIG.TD files in all directories before doing this.

## Article #19029: TA - FAR JUMP OR FAR CALL TO AN ADDRESS

Technical Notes Database

TN4029C.txt TA - FAR JUMP OR FAR CALL TO AN ADDRESS

Category :Pascal

Platform :All

Product :TD 1.x 2.0

Description:

Q. How can I JMP or CALL and address that is not a defined procedure or label?

A. You have to define a label as DD (double). The following code shows how.

```
.DATA
My_Struc STRUC          ; Make a structure to contain the
    OFFSETVALUE  DW      ; segment and offset values.
    SEGMENTVALUE DW      ; Remember reverse order addressing
My_Struc ENDS
SmallUnion UNION        ; Make a union - the DPTR is so that
    DPTR         DD      ; TASM will make a far call. The
    ADDR         My_Struc ; ADDR is to simplify putting your
SmallUnion ENDS        ; segment-offset address in.
JumpLocation SmallUnion ; Declare the union to be used
.CODE
...
...
MOV  JumpLocation.ADDR.OFFSETVALUE , 06000H ; Use your offset
MOV  JumpLocation.ADDR.SEGMENTVALUE , 0F000H ; Use your segment
CALL JumpLocation.DPTR
...
```

The structure within a union allows easy loading of the values. An alternative, shorter method would be to use:

```
.DATA
FarLabel DD
.CODE
...
MOV  WORD PTR [FarLabel] , 06000H
MOV  WORD PTR [FarLabel+2] , 0F000H
CALL FarLabel
```

ALSO, in IDEAL mode, you can make an absolute jump like this:  
ideal

```
codeseg
start:
    ...
    jmp     far 7c00h:5
    ...
end start
```

## Article #19030: TASM - EQU in masm mode vs. in ideal mode

Technical Notes Database

TN4030C.txt TASM - EQU in masm mode vs. in ideal mode

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. When I use EQU and the location counter \$ to get the length in bytes of a data item in ideal mode the assembler always returns a "Can't subtract dissimilar relative quantities" error message. The manual states that this error message is generated when an expression subtracts two addresses that cannot be subtracted from each other. This could happen if the

addresses

are in two different segments. It works fine in masm mode.

My code looks like this:

```
IDEAL
MODEL SMALL
DATASEG
    firstbyte      db      1
    secondbyte     db      2
    thirdbyte      db      3
    ;The following generates an error!
    totalbytes     EQU     $ - firstbyte
MASM
    ;In masm mode it works!
    thisworks      EQU     $ - firstbyte
IDEAL
CODESEG
start:
    mov ax, @data
    mov ds, ax
    ;The error is generated here!
    mov al, totalbytes
    mov al, thisworks
    mov ax, 4c00h
    int 21h
    end start
```

A. In masm mode an EQU can be treated as a string or a number. In

IDEAL mode an EQU is always treated as a text substitution. Thus, in masm mode the number \$ - firstbyte is substituted for this works when the assembler first encounters the expression. In IDEAL mode the string \$ - firstbyte is substituted when the symbol totalbytes appears in the instruction mov al, totalbytes. The variable totalbytes is in the segment defined by dataseg, but the location counter \$ refers to an offset in the segment defined by codeseg, the current segment when the text substitution takes place. This causes an error to be generated. Always remember that in ideal mode text equates with EQU take place when the constant name appears. This is referred to as late binding. If you must create a numeric equate use the = operator.

## Article #19033: TP 5.0/TD - ORDER OF ARG DIRECTIVE OPPERANDS

Technical Notes Database

TN4033C.txt TP 5.0/TD - ORDER OF ARG DIRECTIVE OPPERANDS

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. In what order should the operands to the Arg directive appear? Should they be the same as the order in the calling procedure or in reverse?

A. The answer depends upon the language that you're using and whether or not you're using the .model memorymodel, language option.

Case 1: You are using the full segment definitions or you are using the .model directive without specifying a language.

The leftmost symbol in the Arg list is always nearest the top of the stack (TOS). Thus, if your proc definition is

```
myproc proc far
    arg first:word, second:word
```

first will evaluate to [BP + 06H], the size of the four byte far return address plus the size of the two byte BP register pushed onto the stack. The symbol, second, will evaluate to [BP + 08H], two bytes further from TOS.

Again, the key point to remember is that the leftmost symbol is nearest TOS.

If you are using Pascal or Basic, arguments are pushed from left to right onto the stack. This is called Pascal calling syntax or Pascal calling conventions. In this case, the last argument in the list is nearest TOS. For example:

```
{ $F+ }
procedure myproc(one:integer; two:integer); external;
{ $F- }
.
.
.
procedure myproc(first:integer; second:integer);
.
.
```

The variable, first, is pushed onto the stack followed by second. Thus, second is nearest TOS. In this case, you would want to set up your Arg list as follows:

```
myproc proc far
  arg second:word, first:word
  push bp
  mov  bp,sp
```

The symbol, second, would evaluate to [BP + 06H], the symbol nearest TOS, and first would evaluate to [BP + 08H].

To get the correct results with Basic or Pascal while using the simplified segment directives or .model without the language option, you must reverse the order of the arguments as they appear in the high level language calling routine's parameter list.

If you are calling the Assembler routine from a C module and you are NOT using Pascal calling conventions, then the arguments are pushed onto the stack from right to left. Thus, the leftmost argument is nearest TOS and there is no need to reverse the order to the symbols in the Arg list.

If you wish to use Pascal calling conventions in Turbo C, use the -p option for TCC or the Pascal keyword. Pascal calling syntax can also be enabled from within TC by setting the /Options/Compiler/Code generation/Calling convention to Pascal.

Case 2: You are using the .model memorymodel, language directive.

All you need to do is put the Arg list symbols in the same order as they appear in the calling routine's parameter list. This is the easiest method, by far. Remember to include the comma after the memory model in the .model directive and to specify the language. If you are using Turbo Pascal, just use .model TPascal.

## Article #19035: TP 5.0/TASM - RETURN FAILED CALLING ASSEMBLY ROUT

Technical Notes Database

TN4035C.txt TP 5.0/TASM - RETURN FAILED CALLING ASSEMBLY ROUT  
Category :Pascal  
Platform :All  
Product :TD 1.x 2.0

### Description:

- Q. When I call my Assembler routine from Turbo Pascal, everything works OK. However, it does not seem to return properly. Why?
- A. Any routine declared in the main program or in the implementation section of a unit, is by default a near call. Your Assembly language routine, assembled to an .OBJ file, is brought into the Pascal module as if it were declared and defined in that module. Thus, by default, any call to that Assembly language routine is a near call. If you have defined your Assembly language routine as a proc far, the Assembler will generate a corresponding RETF. Thus, a near call is made, 4 bytes are popped off of the stack when the RETF is executed, and control will be returned to the wrong code segment. If you want that call to be a far call in your Pascal module, be sure to bracket the function or procedure declaration with {\$F+} and {\$F-}. Always make sure that the distance declarations and definitions agree.

## Article #19036: TA - SIZE OF STRUC IN IDEAL MODE

Technical Notes Database

TN4036C.txt TA - SIZE OF STRUC IN IDEAL MODE

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. In masm mode I can get the size of a struc without actually defining a variable of that type. Why do I get zero when I attempt the same thing in ideal mode?

A. In IDEAL mode, SIZE returns the total number of bytes allocated for the data item. If no variable of that type has been defined then no storage is allocated. In other words, use it on an instance of a structure, rather than on the tag name.

## Article #19037: TA 1.0 - TED.ASM; FORWARD SEGMENT REFERENCE PROBL

Technical Notes Database

TN4037C.txt    TA 1.0    - TED.ASM; FORWARD SEGMENT REFERENCE PROBL  
Category     :Pascal  
Platform     :All  
Product      :TD  1.x 2.0

### Description:

- Q.    I downloaded a file called Ted.asm that assembles with MASM but not with TASM.
- A.    The problem is with a forward segment reference.  Simply insert the following lines of code at the beginning of your program.
- ```
CSEG SEGMENT
CSEG ENDS
FILE_SEG SEGMENT
FILE_SEG ENDS
```
- Alternatively, use TASM 1.01 or later.

## Article #19039: TA - TYPE in IDEAL MODE

Technical Notes Database

TN4039C.txt TA - TYPE in IDEAL MODE

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. Why does TYPE in IDEAL mode not behave as documented in the TASM reference manual?

A. In IDEAL mode TYPE acts as a type cast and can be used in an expression with PTR to force the operand to have a specified type. For example, consider the following:

```
ideal
```

```
bvarbyte db ?
```

```
bvarword dw ?
```

```
mov al, [TYPE bvarbyte PTR bvarword]
```

```
; the above expression is the same as
```

```
mov al, [BYTE PTR bvarword]
```

## Article #19040: TA - CREATING A .COM FILE TLINK /V

Technical Notes Database

TN4040C.txt TA - CREATING A .COM FILE TLINK /V

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. How do I create a .COM file from my .ASM file? Whenever I try to create the .COM with TLINK /t I always get the message invalid entry point. I can create the .COM file with EXE2BIN.

A. In order to create a .COM file with TLINK /t you must specify an entry point at offset 100h in the file with both the ORG and END directives. The following code fragment demonstrates the required conditions. Also, a .COM file may not exceed 64K in size, may not have any segment-relative fixups, may not define a stack segment, and must have a starting address equal to 0:100h. When an extension other than .COM is used for the executable file (.BIN, for example), the starting address may be either 0:0 or 0:100h.

```
.model tiny
```

```
.code
```

```
ORG 100H
```

```
start:          ;this will be the entry point at 100H
```

```
.
```

```
.
```

```
.
```

```
END start      ;specify the entry point with END
```

```
or
```

```
mycode SEGMENT 'CODE'
```

```
    assume cs:mycode,ds:mycode,ss:mycode
```

```
    ORG 100H
```

```
    start:
```

```
    .
```

```
    .
```

```
    .
```

```
mycode ends
```

```
    end start
```

## Article #19041: TA - DEBUG .COM FILE

Technical Notes Database

TN4041C.txt TA - DEBUG .COM FILE

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. How do you debug a .COM file? I can debug my program as an exe file but not as a com file.

A. Due to the structure of a .COM file it cannot contain debug information. When you specify a file to be debugged the Turbo Debugger first looks for an exe file and then for a .COM file. The debugger will look for a symbol table in a file of the same name with a .TDS extension. You can create such a file with the utility TDSTRIP. By using the -c (create .COM file) and -s(put symbol table in .TDS file) options you can create a com file and symbol table file in one step.

The line

```
TDSTRIP -c -s exefilename
```

creates exefilename.com and exefilename.tds. Note that the -c and -s must be separated by a space.

## Article #19042: TA - NONFUNCTIONAL CONDITIONAL BREAKPOINT

Technical Notes Database

TN4042C.txt TA - NONFUNCTIONAL CONDITIONAL BREAKPOINT  
Category :Pascal  
Platform :All  
Product :TD 1.x 2.0

### Description:

- Q. How do I get my conditional breakpoint to work? I know that the condition is true but it still will not break.
- A. If when using the conditional breakpoints and expression true condition the break does not occur, check to be sure that the condition is really true by evaluating the expression in the evaluate window. For example, the following will not break correctly.

```
.data
  nptr dw ?
.code
start:
    mov ax,@data
    mov ds,ax
    mov [nptr], 0fffH
    mov dx,5           ;set a conditional break here
;break if the expression ds:[WORD PTR nptr] EQ 0fffh
;this break will fail
;if you evaluate this expression in the evaluate
;window it will evaluate to false. This particular
;expression requires parenthesis around the ds:expression
;to bind the segment override to the memory referencing
;expression
;The correct syntax is (ds:[WORD PTR nptr]) EQ 0fffh
The key here is to use the evaluate window to see how the
debugger is parsing the expression.
```

## Article #19043: TD - LOCATION POINTER SOURCE CODE

Technical Notes Database

TN4043C.txt TD - LOCATION POINTER SOURCE CODE

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

- Q. Why does the location pointer appear to be pointing to the wrong location in the source file?
- A. If your source code has been modified since the last compile the debugger may be indicating the wrong source location. Observe the status line for the module viewer. If the word modified appears you need to recompile your source code. It is a good idea to use a makefile and to periodically run make to be sure your program is up to date. See the documentation in the Turbo Assembler Reference Guide for the make utility.

## Article #19044: TD - NOT ENOUGH ENVIRONMENT SPACE

Technical Notes Database

TN4044C.txt TD - NOT ENOUGH ENVIRONMENT SPACE  
Category :Pascal  
Platform :All  
Product :TD 1.x 2.0

### Description:

- Q. Why when loading TD386 do I get a "not enough environment space" message?
- A. You need to allocate more environment space in your config.sys file with the -eXXXX option of TDH386.sys.  
device = tdh386.sys -e2000  
The above line allocates 2000 bytes of environment strings.  
The default is 1024.

## Article #19045: TD - HANGING ON NMI

Technical Notes Database

TN4045C.txt    TD - HANGING ON NMI  
Category    :Pascal  
Platform    :All  
Product     :TD 1.x 2.0

### Description:

- Q. Why does the debugger give me an initial startup message, and then hang? Sometimes I get a message concerning the NMI.
- A. By default the debugger intercepts the NMI in order to allow one to break into the debugger with a breakout switch. When the breakout switch is activated an NMI is generated and the debugger regains control. If your hardware is using the NMI then there will be a compatibility problem as the debugger does not chain on the NMI. Run Tdinst and set NMI Intercept to NO in the Options menu. Be sure to save the changes to your TD.EXE by selecting SAVE/MODIFY TD.EXE. You must then erase any tdconfig.td files as they will have the NMI Intercept set to YES and will override the setting in TD.EXE.

## Article #19046: TD - HANGING ON IBM PC

Technical Notes Database

TN4046C.txt    TD   - HANGING ON IBM PC  
Category     :Pascal  
Platform     :All  
Product      :TD  1.x 2.0

### Description:

- Q. Why does the debugger hang when loading on my old IBM PC, XT, or compatible?
- A. Check to make sure that the dipswitch that corresponds to the math coprocessor is correctly set. If it is not, the debugger will try to execute a floating point instruction and will hang while loading. Try flipping dipswitch number 1 (when numbered starting from 0) on the motherboard. If you have the setting for the coprocessor in CMOS RAM run the setup program to see if it indicates the presence of a npx. If so, change the switch setting. Alternatively, upgrade to Turbo Debugger 1.5.

## Article #19048: TASM , TLINK & use with EPROMS & intel hex files

Technical Notes Database

TN4048C.txt    TASM , TLINK & use with EPROMS & intel hex files  
Category     :Pascal  
Platform     :All  
Product      :TD 1.x 2.0

### Description:

Q. How can I download the output of the assembler to an EPROM?  
Can I get an Intel hex file from the assembler and linker?  
A. You will not be able to output an intel hex file from TASM  
and TLINK. Nor will you be able to download the .exe file  
to an eprom. The .exe file contains fixxups that must be  
resolved be the DOS loader. To download the .exe file to  
and EPROM burner you must first process the .exe file with  
a locater. Here is the address and phone number of one  
company that provides a locater.

## Article #19052: TD - CPU VIEWER

Technical Notes Database

TN4052C.txt TD - CPU VIEWER

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. Why does the debugger always come up in the CPU viewer?

A. Debugger always comes up in the CPU viewer.

This can occur in several different situations.

1)

The user may be able to open up the module viewer and view the source code but is unable to make the debugger come up viewing the source.

If the module viewer can be opened with no error message then problem is merely an incorrect path in the config file, an incorrect source directory saved to td.exe or tdconfig.td with tdinst, a /l (do not execute startup code when loading) command line option inadvertently saved to the config file when the user saved the options from within td, or the Display/Beginning Display option was set to Assembler from within tdinst and either saved to tdconfig.td or to TD.EXE.

2)

If there is an error such as

"Source file Source.ext not found. Press ESC."

when trying to open the module viewer.

In this case there are two possible causes, either the file does not exist or the Options/Path For Source is set incorrectly. Have the user set the path from within the debugger and then open the module viewer. If that works then they need to create a tdconfig.td or some other config file by either saving the current options or by running TDINST. It makes sense to have a tdconfig.td in each working directory with a correct path for those applications.

3) The user has saved the current options to a configuration file while the CPU window is open.

## Article #19054: TD - TD386 CANT LOAD VIRTUAL MODE

Technical Notes Database

TN4054C.txt TD - TD386 CANT LOAD VIRTUAL MODE

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

- Q. Why do I get a message that I can't load td386 because the processor is already in virtual mode?
- A. There cannot be a program running in either virtual or protected mode when td386 is loaded. It has to be the only program running in virtual mode. There is probably a memory manager that runs in virtual or protected mode in the system. Examples of this type of program include, but are not limited to, 386^MAX, CEMM.SYS, and any of a number of drivers that allow, among other things, extended memory to emulate expanded memory. TD386 has a built in ems simulator that will allow td use a subset of the ems calls for its symbol table. This simulator is for td only. If the application must make ems calls, the user must have an ems driver that does not run in virtual or protected mode.

## Article #19055: TD - TD and HP Vectra, unexpected interrupt 06

Technical Notes Database

TN4055C.txt    TD - TD and HP Vectra, unexpected interrupt 06  
Category     :Pascal  
Platform     :All  
Product      :TD 1.x 2.0

### Description:

- Q.    When loading TD on an HP Vectra an unexpected interrupt 06 is generated.
- A.    We have contacted HP regarding this matter and they have offered a solution. Part of the HP/HIL code uses an instruction that is illegal in virtual 8086 mode. To word around this, run the HP Setup program. At the first menu do not choose any of the selections. Instead type "YADA" . You should now receive an 8 option screen. Option 2 hp/hil defaults to on if this is set to off the unexpected interrupts 06 will go away.

### Reference:

## Article #19056: TD - TD386 unexpected interrupt 06

Technical Notes Database

TN4056C.txt TD - TD386 unexpected interrupt 06

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. After running the program for awhile, an unexpected interrupt 06 occurs.

A. Interrupt 06 is caused in virtual mode when the CPU encounters and illegal instruction. Most probably some portion of the code has been overwritten by an errant pointer, an array bounds error, or a stack overflow. If you can locate the instruction that

TD386

is trying to execute, you can set a changed memory breakpoint to find

where in your program the code is being overwritten.

## Article #19057: TD - UNEXPECTED INTERRUPT 0D

Technical Notes Database

TN4057C.txt TD - UNEXPECTED INTERRUPT 0D

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. What is unexpected interrupt 0D?

A. TD386, unexpected interrupt 0d

Interrupt 0d is the general protection exception and is generated by any protection violation that does not generate some other exception. See the above question for a more complete description of the problem. Common causes of this problem are network boards and certain hard disk controllers.

### Reference:

7/2/98 10:45:35 AM

Last Modified: 01-SEP-99

## Article #19058: TD - TD386 UNEXPECTED INTERRUPT 0A

Technical Notes Database

TN4058C.txt TD - TD386 UNEXPECTED INTERRUPT 0A

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. Why do I get unexpected interrupt 0A as soon as I call TD386?

A. This indicates that there is a hardware or device driver incompatibility. Interrupt 0A is being generated as a result of this hardware/software. In the virtual 8086 mode of the 80386,

Interrupt 0A is generated by the CPU when an invalid task state segment is encountered. TD386 is unable to determine whether the CPU generated the error, or if it was generated by the hardware. Therefore, to prevent making the situation worse, TD386

terminates

itself, and prints the "UNEXPECTED INTERRUPT" message.

If you have a Microsoft Bus Mouse make sure that you have set the jumpers correctly. The jumper should be set to number 5 for an AT type machine, including any 80386 machine with an AT bus. If the jumper is incorrectly set you will receive this error message. Try changing the jumpers until the error goes away.

## Article #19059: TD - ILLEGAL EXPRESSION HEX NUMBERS

Technical Notes Database

TN4059C.txt TD - ILLEGAL EXPRESSION HEX NUMBERS

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

- Q. Why does the debugger give me an error when I enter a hex number in one of the prompt boxes?
- A. If a user reports a message like "Illegal expression", "illegal syntax", "extra input after expression ", it could be because they are trying to enter a number that ends with a "b" or "d" like 0ff0b or 0AED. If a number ending in a "b" or "d" is entered at any prompt in the debugger, it is assumed that the user is trying to override the default radix or base. A number ending in b or d is assumed to be a binary or decimal number respectively. The user need only append a "H" to the end of the number, as in 0ff0bH or 0AEDH, if they are using assembler syntax or source language when debugging an assembler program. If a 'C' program is being debugged, it is important to prefix all hex numbers with the '0x' prefix. In general, when a message of this type is reported, one should examine the current syntax in the OPTIONS/LANGUAGE menu selection and make sure that the syntax being used corresponds to the language in the menu selection.

## Article #19060: TLINK - TLINK /V

Technical Notes Database

TN4060C.txt TLINK - TLINK /V  
Category :Pascal  
Platform :All  
Product :TD 1.x 2.0

### Description:

Q. Why does TLINK not accept the /v option?

A. TLINK and /v option

If tlink does not accept /v option it could be because an old version of tlink is in the path before the new version.

For example, the new version could be in the TD directory and the old version in the TC directory.

```
PATH=c:\TC;c:\debug\TD
```

The following command would use the old version of TLINK.

```
C:\TC\WORK>tlink /v myprog
```

## Article #19061: TD - NULL POINTER ASSIGNMENT.

Technical Notes Database

TN4061C.txt TD - NULL POINTER ASSIGNMENT.

Category :Pascal

Platform :All

Product :TD 1.x 2.0

### Description:

Q. How do I find a null pointer assignment in my Turbo C program?

A. Open a watch on

(char \* ) 0,s

(char \*) 4,s

This is the location of the Borland message. It is also the area that will be overwritten if there is a null pointer assignment. The user will be able to watch the Borland message while stepping through the code. When the null pointer assignment occurs the message in the watch window will change. The same thing can be done by opening a dump viewer and doing a CTRL-G (GOTO) to 0000.

## Article #19062: TASM 1.0 - ARG DIRECTIVE SYMBOLIC REFERENCES - THO

Technical Notes Database

TN4062C.txt    TASM 1.0 - ARG DIRECTIVE SYMBOLIC REFERENCES - THO  
Category     :Pascal  
Platform     :All  
Product      :TD 1.x 2.0

### Description:

Q. I am using the Arg directive to create symbolic references to variables on the stack. I am not getting the correct values I should in the Assembler routine. What am I doing wrong?

A. It is easier if remember a few points about the Arg directive. First, the Arg directive always adjusts for a near or far call. If you have a proc definition like:

```
myproc proc far
```

the Arg directive will take into account the four (4) byte return address on the stack. If your definition looks like:

```
myproc proc near
```

the Arg directive will adjust for a two (2) byte return address on the stack. The second thing to remember is that the Arg directive always assumes that you will push BP onto the stack first and thus, will add two bytes to the size of the return address. For a far return the total will be six bytes and for a near return the total will be four bytes. The third point to remember about the Arg directive itself is that the leftmost symbol in the Arg list will be nearest the top of the stack. Finally, remember that for each subsequent symbol to the right, a number equal to the number of bytes on the stack occupied by the symbols to the left will be added to the BP register.

Consider the following examples:

```
myproc proc near  
arg first:word, second:word  
push bp  
mov bp,sp
```

The distance is near, a two byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 04H]. Since first is a word it occupies two bytes on the stack. Thus second evaluates to [BP + 04H + 02H] or [BP + 06H].

```
myproc proc far
arg first:word, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Since first is a word, it occupies two bytes on the stack. Thus, second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:near ptr word, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus any reference to first is equivalent to [BP + 06H]. Since first is a near pointer it occupies two bytes on the stack. Thus second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:byte, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Although first is a byte value it occupies two bytes on the stack. Thus, second evaluates to [BP + 06H + 02H] or [BP + 08H].

```
myproc proc far
arg first:byte:1, second:word
push bp
mov bp,sp
```

The distance is far, a four byte return address, and the BP is assumed to be pushed onto the stack. Thus, any reference to first is equivalent to [BP + 06H]. Although first is a byte value it occupies two bytes on the stack. To force it to use only one byte we must use the :1 after the word byte. Second evaluates to {BP + 06H + 01H} or [BP + 07H]. Note that the type of variables must match the types of those that appear in the high level language call.

## Article #19063: TD386 and DOS 5.0 Compatibility

Technical Notes Database

TN4063C.txt TD386 and DOS 5.0 Compatibility

Category :Pascal

Platform :All

Product :TD 2.01

### Description:

TD386 ( & TF386 ) will hang on startup if you use DOS 5.0, and have the command:

```
DOS=HIGH
```

in the CONFIG.SYS file.

This does not happen if DOS is not loaded HIGH.

The machine is hanging inside of the DOS program loader code.

When doing the equivalent to DOS=HIGH with DR-DOS 5.0, this problem does not occur.

All of the "new" commands to load device drivers & TSR's high in DOS 5.0 are incompatible with TD386, as they use V8086 mode ( ala QEMM & 386MAX). Note that loading device drivers & TSR's high is different from DOS=HIGH , which loads the DOS kernel into the XMS high memory area, and which does not use V8086 mode.

## Article #19301: How to do a "sounds like" query in Interbase

Technical Information Database

TI4301C.txt :How to do a "sounds like" query in Interbase

Category :Database Issues

Platform :Win95/NT

Product :All-CBuilder,

### Description:

Imagine you could run a query on an Interbase table that would return a set of values that `_sound_` like your query. It is possible through the magic of UDFs (user defined functions) and an algorithm called SoundEx. Using a very simple algorithm in a DLL, you can declare a function that assigns a numeric code based on the way a word "sounds". This code can be compared against your query string to return an accurate (based on the simplicity of the algorithm) set.

----How it works----

SoundEx classifies words for how they sound by assigning a short numeric code based on a group of letters.

Take the first letter.

Then, for each of the subsequent letters, score a code for the group it belongs to. There are 6 groups :

Group	Letters
1	BFPV
2	CGJKQSXZ
3	DT
4	L
5	MN
6	R

Ignore all other letters and characters (vowels, h, punctuation, etc.) If a code has already occurred, ignore it. Continue until you have 4 characters,

if there are less, add zeroes until you have 4.

Thus

Smith becomes S5300

Smitt becomes S5300

Smythe becomes S5300

And they all sound the same or similar.

-----Implementation-----

In order to get Interbase to use the Soundex function we must do the following:

Write the function in C++ or Delphi.

Encapsulate the function in a DLL.

Declare the function and DLL to interbase as a UDF.

Create a column on our table to keep track of the SoundEx codes.

Add a trigger to update the data.

The Delphi function was originally written by John Midwinter and was implemented to

return not the SoundEx 4 character code, but a number in a Byte (SmallInt).

He did this by realising that, though the natural Soundex Code has 4 characters,

it only has  $26 * 6 * 6 * 6$  (=5,616) possible values which can be held by a small int.

And therefore chose to store it as a number rather than a character string. Below

I have provided both Delphi and C++Builder source code.

-----C++ Function-----

```
extern "C"
```

```
int __declspec(dllexport) SoundBts(char *Name)
```

```
{
```

```
    unsigned char SoundExTable[59] =
```

```
    //A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [ / ] ^ _ ' ,
```

```
    {0,1,2,3,0,1,2,0,0,2,2,4,5,5,0,1,2,6,2,3,0,1,0,2,0,2,0,0,0,0,0,0,
```

```
    //a b c d e f g h i j k l m n o p q r s t u v w x y z
```

```
    0,1,2,3,0,1,2,0,0,2,2,4,5,5,0,1,2,6,2,3,0,1,0,2,0,2};
```

```
    //This table is used to keep track of what number goes with what
```

```
letter.
```

```
    Byte i,s,SO,x;
```

```
    int Multiple, Result;
```

```
    int len;
```

```
    if (Name != "")
```

```
    {
```

```

Result = (short)UpCase(Name[0]); //initialize to first character
SO = 0; //initialize last char to 0
Multiple = 26; //26 letters in the alphabet
len = (StrLen(Name)); //length of word
for (i=0; i 64) && (s < 123)) //if it is a letter
    {
        x = SoundExTable[((int)s - 65)]; //get the SoundEx code
        if ((x > 0) && (x != SO))
            {
                Result += (x * Multiple);
                if (Multiple == (26 * 6 * 6 * 6))
                    break; //we have a sufficient code
                Multiple *= 6;
                SO = x;
            }
    }
}
else return 0;
return Result; //Finished SoundEx code
}

```

-----  
-----Delphi Function by John Midwinter-----  
library SoundBytes;

```

uses
    SysUtils;

function SoundBts(Name : PChar) : SmallInt; cdecl;
Const
{This table gives the SoundEX SCORE for all characters Upper and Lower
Case
hence no need to convert. This is faster than doing an UpCase on the
whole input string
The 5 NON Chars in middle are just given 0}

SoundExTable : Array[65..122] Of Byte
//A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [ / ] ^ _ '
=(0,1,2,3,0,1,2,0,0,2,2,4,5,5,0,1,2,6,2,3,0,1,0,2,0,2,0,0,0,0,0,0,
//a b c d e f g h i j k l m n o p q r s t u v w x y z
    0,1,2,3,0,1,2,0,0,2,2,4,5,5,0,1,2,6,2,3,0,1,0,2,0,2);

Var
    i, l, s, SO, x : Byte;
    Multiple : Word;

begin

```

```

If Name > '' //do nothing if nothing is
passed
then begin
    Result := Ord(UpCase(Name[0])); //initialise to first character
    SO := 0; //initialise last char as 0
    Multiple := 26; //initialise to 26 char of
alphabet
    l := Pred(StrLen(Name)); //get into var to save
repeating function
    For i := 1 to l do //for each char of input str
    begin
        s := Ord(name[i]); // *
        If (s > 64) and (s < 123) //see notes * below
        then begin
            x := SoundExTable[s]; //get soundex value
            If (x > 0) //it is a scoring char
            AND (x <> SO) //is different from previous
char
            then begin
                Result := Result + (x * Multiple); //avoid use of POW as it
needs maths unit
                If (Multiple = 26 * 6 * 6) //we have done enough (NB
compiles to a const
                then break; //We have done, so leave loop
                Multiple := Multiple * 6;
                SO := x; //save for next round
            end; // of if a scoring char
        end; //of if in range of SoundEx
table
    end; //of for loop
    end else result := 0;
end; //of function SoundBts

exports
    SoundBts;
begin
end.

```

-----

Putting the function into Interbase.

For this example, I have included an SQL script. The table we are updating is called People.

-----soundex.sql-----

```
CONNECT MyDatabase.gdb USER SYSDBA PASSWORD mypass ;
```

```
DECLARE EXTERNAL FUNCTION SoundBytes Char(30)
```

```

RETURNS INTEGER BY VALUE           //function declaration
ENTRY_POINT "SoundBts"             //function name (DLL entry point)
MODULE_NAME "soundex.dll" ;        //name and path of the dll

CREATE DOMAIN SoundBytesDomain      //here we create a domain for the
type                                //that the code column will hold
INTEGER                             //that the code column will hold
DEFAULT 0
NOT NULL;

ALTER TABLE PEOPLE                //add a column to hold the SoundEx
codes
ADD SOUNDBYTES INTEGER NOT NULL;

UPDATE PEOPLE                      //get the SoundEx codes into
SOUNDBYTES                          //from the NAME column
SET SOUNDBYTES = SoundBytes(NAME);

CREATE INDEX SoundByteIndex        //put an index on the table
ON PEOPLE (SOUNDBYTES);

SET TERM !! ;                      //create a trigger to update the
table with
CREATE TRIGGER SoundBytes_Update   //new soundex codes
BEFORE UPDATE AS
BEGIN
    NEW.SOUNDBYTES = SoundBytes(NEW.NAME);
END !!
SET TERM ; !!

EXIT ;

```

-----Using the function in your application-----  
There are several ways to utilize this function. You would use it in pseudo-SQL like this:

```
select * from MY_TABLE where MY_FIELD sounds like MY_QUERY
```

One of the ways is to have the server execute the SoundBts function using a select

statement:

```
select NAME from PEOPLE where
    SOUNDBYTES = SoundBytes("John")
```

There can be problems with this method, however - it can GPF because of a DLL path discrepancy.

Another way is to generate the SoundEx code within your app by importing the function from the DLL. This is quicker and you simply have to pass the number, rather than executing the UDF on the server.

The code might look like this:

```
//after importing the function, use it
SoundExCode = SoundBts("MySearchString");

//using a TQuery connected to a TDatabase attached to the Interbase
database:
//the SQL property of the query looks like this:
Select Name from People where
  soundbytes = :SXCode

//then all you need to do is this:
```

```
Query1->Prepare();
Query1->ParamByName("SXCode")->AsInteger = SoundExCode;
Query1->Open();
```

-----

This is the magic of SoundEx and Interbase UDFs. This is very simple, and the function can be fine-tuned to get closer matches (say, if your table had a whole lot of similar-sounding names).

## Article #19335: How do I create a simple MIDAS Client Server application?

Technical Information Database

TI4335C.txt - How do I create a simple MIDAS Client Server application?

Category :Database Issues  
Platform :Win95/NT  
Product :C++Builder3.x,

### Description:

How do I create a simple MIDAS Client Server application?

### Reference:

Creating the Server

1. File | New Application
2. File | New | Remote Data Module
3. Type in the name. Mine is "ExampleDataModule".
4. Put down whatever you want to send to the client as data. You can use TQuery or TTable. I'm going to use TTable exporting one of the example databases we ship with C++Builder3.  
Properties set are:  

```
Table1->DatabaseName = BCDEMOS  
Table1->TableName = animals.dbf
```
5. Right click on Table1, choose "Export Table1 from Data Module". (If you go to View | Type library, you will see that Table1 is exported as an IProvider.)
6. Now build and run the server. After running it you can close it down. It just needed to get registered. (If you put the server on a remote system then it will have to be registered with regsvr32.exe on both systems)

## Creating the Client

1. Go to Project | Project Manager and click the New button. Choose new Application.
2. Drop down a TMIDASConnection. (If you wanted to use DCOM and run the server remotely then you would have to set the computer name that the server is registered and running on.)
3. Set the property (Notice that the server has been registered.):

```
MIDASConnection->ServerName = Server.ExampleDataModule
```

4. Drop down a TClientDataSet on your form. Set the properties:

```
ClientDataSet1->RemoteServer = MIDASConnection;  
ClientDataSet1->ProviderName = Table1;
```

(Notice that Table1 has been exported) Set Active to true:

```
ClientDataSet1->Active = true;
```

5. Now do normal database stuff... I put down a TDataSource and a TDBGrid to view the data.

## Article #19523: Working with cookies

Technical Information Database

TI4523D.txt - Working with cookies

Category :Internet/WEB  
Platform :All-32Bit  
Product :All32Bit,

### Description:

The purpose of this document is not to explain what a cookie is or what it is used for. Instead this document assumes that you are familiar with the use of cookies and want to know how to work with them when developing web server applications with Delphi 3.

The TWebRequest and TWebResponse objects provided in Delphi 3 both have properties which allow for the easy use of cookies. TWebRequest has the Cookie and CookieFields properties to allow a web server application to read the cookie header sent as part of a HTTP request. The TWebResponse object has the Cookies property which allows a web server application to place a cookie on the client machine through the cookie header of the HTTP response. This is usually set through the use of the SetCookieField method.

When a server responds to a HTTP request it sends a document with a header and a content section. Delphi provides the ability to add a cookie header through the TWebResponse.Cookies property. This is best set through the use of the SetCookieField method. The following TWebActionItem demonstrates the use of the SetCookieField method to return a cookie to the requesting browser. This example uses localhost as the domain. You would use this for testing and replace this string with your domain name. The third parameter is a slash. This means that this cookie will be sent along with all requests from the browser while at this domain. For further explanations of these parameters see the aforementioned RFC 2109.

```

procedure TWebModule1.WebModule1WebActionItem1Action(Sender: TObject;
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
var
  MyCookies: TStringList;
begin
  MyCookies := TStringList.Create;
  with MyCookies do begin
    Add('Name=Frank Borland');
    Add('Address=100 Borland Way');
    Add('Product=Delphi');
  end;
  with Response do begin
    SetCookieField(MyCookies, 'localhost', '/', (Now + 1), False);
    Content := 'Cookie planted';
  end;
end;

```

When a request is made of the HTTP server the client browser issuing the request will package up all of the applicable cookie name value pairs and include them in the HTTP requests cookie header. Delphi 3 will make these available to a web server application in two ways. The first way is as a string through the Cookie property of the TWebRequest parameter of a TWebActionItem. It is also available as a TStringList property called CookieFields. CookieFields is the parsed contents of the Cookie header of an HTTP request message.

The following are TWebActionItems which extract the name value pairs and return them to the client in the form of a bare bones HTML page. The first example returns the cookie as a single string, while the second example returns each name value pair on a separate line.

```

procedure TWebModule1.WebModule1WebActionItem2Action(Sender: TObject;
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
begin
  Response.Content := '' + Request.Cookie +
  '
'; end; procedure TWebModule1.WebModule1WebActionItem3Action(Sender: TObject; Request:
TWebRequest; Response: TWebResponse; var Handled: Boolean); var i: integer; begin Response.
Content := ''; for i := 0 to (Request.CookieFields.Count - 1) do begin Response.Content := Response.
Content + '

```

' + Request.CookieFields[i] + '

'; end; Response.Content := Response.Content + "; end; //end TI Reference: None 4/1/99 11:45:44 AM

## Article #19524: Handling Winsock errors

Technical Information Database

TI4524D.txt - Handling Winsock errors

Category :Windows API  
Platform :All-32Bit  
Product :All32Bit,

### Description:

For any of the following exception handling methods to work, the VCL must in some way become aware that an error condition exists. If a call to the Winsock does not return, or does not provide information to the TCustomWinSocket descendant that called it, then there is no mechanism to handle the condition. OnError exception handler

One method for trapping exception conditions in a descendant of TCustomWinSocket is to use an OnError exception handler. This method will only handle a limited set of conditions because the mechanism provided by the Winsock for event notification only reacts to a limited list of conditions. To be notified of an exception condition within the Winsock, TCustomWinSocket registers user message CM\_SocketMessage to be sent to the component, and the CMSocketMessage message handler raises an exception. The message is registered with the Winsock by an API call to WSASyncSelect. WSASyncSelect is a request for event notification of socket read, writes, connect, close, and accept events. If the exception condition is not read, write, connect, close or accept, or if the CM\_SocketMessage is not sent by the Winsock for any reason, the error handler will not fire.

### Usage:

```
procedure TChatForm.ClientSocketError(Sender: TObject;  
    Socket: TCustomWinSocket; ErrorEvent: TErrorEvent;  
    var ErrorCode: Integer);  
const  
    ErrorEvents: array[eeGeneral..eeAccept] of string = (  
        'eeGeneral',  
        'eeSend',
```

```

    'eeReceive',
    'eeConnect',
    'eeDisconnect',
    'eeAccept'
);
begin
ListBox1.Items.Add('ClientSocketError.   TErrorEvent: ' +
    ErrorEvents[ErrorEvent] + '   ErrorCode: ' + IntToStr(ErrorCode));
    ErrorCode := 0; // don't raise an exception
end;

```

Definition:

```

procedure TCustomWinSocket.CMSocketMessage(var Message:
TCMSocketMessage);

function CheckError: Boolean;
var
    ErrorEvent: TErrorEvent;
    ErrorCode: Integer;
begin
    if Message.SelectError <> 0 then
    begin
        Result := False;
        ErrorCode := Message.SelectError;
        case Message.SelectEvent of
            FD_CONNECT: ErrorEvent := eeConnect;
            FD_CLOSE: ErrorEvent := eeDisconnect;
            FD_READ: ErrorEvent := eeReceive;
            FD_WRITE: ErrorEvent := eeSend;
            FD_ACCEPT: ErrorEvent := eeAccept;
        else
            ErrorEvent := eeGeneral;
        end;
        Error(Self, ErrorEvent, ErrorCode);
        if ErrorCode <> 0 then
            raise ESocketError.CreateFmt(sASyncSocketError, [ErrorCode]);
        end else Result := True;
    end;
end;

begin
with Message do
    if CheckError then
        case SelectEvent of

```

```

    FD_CONNECT: Connect(Socket);
    FD_CLOSE: Disconnect(Socket);
    FD_READ: Read(Socket);
    FD_WRITE: Write(Socket);
    FD_ACCEPT: Accept(Socket);
end;

```

```
end;
```

## Object Pascal Exception Handling

You can also wrap a specific call in a try..except block or setting an application level exception handler. For this to work, the component must in some way become aware of the exception condition and an exception must be raised for the exception to be trapped here.

### Example of Application Exception Handler:

```

TChatForm = class(TForm)
.
.
    public
        procedure AppException(Sender: TObject; E: Exception);
    end;
.
.
implementation
.
.
    procedure TChatForm.AppException(Sender: TObject; E: Exception);
    begin
        ListBox1.Items.Add('AppException: ' + E.Message);
    end;

    procedure TChatForm.FormCreate(Sender: TObject);
    begin
        Application.OnException := AppException;
    end;

```

### Example of Try..Except block:

```

with ClientSocket do
    try
        Active := True;

```

```

except
  on E: Exception do
    ListBox1.Items.Add('Try..except during open: ' + E.Message);
  end;
end;

```

### SocketErrorProc

For calls that use the CheckSocketResult function to check the result returned by WSAGetLastError, errors can be handled in a programmer defined function by setting the SocketErrorProc.

### Usage:

#### Interface

```

.
.
procedure MySocketError(ErrorCode: Integer);

```

#### implementation

```

.
.
procedure MySocketError(ErrorCode: Integer);
begin
  ShowMessage('MySocketError: ' + IntToStr(ErrorCode));
end;

```

```

procedure TChatForm.FormCreate(Sender: TObject);
begin
  SocketErrorProc := MySocketError;
end;

```

### Defined:

```

function CheckSocketResult(ResultCode: Integer; const Op: string):
  Integer;
begin
  if ResultCode <> 0 then
  begin
    Result := WSAGetLastError;
    if Result <> WSAEWOULDBLOCK then
      if Assigned(SocketErrorProc) then
        SocketErrorProc(Result)
      else raise ESocketError.CreateFmt(sWindowsSocketError,
        [SysErrorMessage(Result), Result, Op]);
  end;
end;

```

```
end else Result := 0;  
end;
```

Help Text for SocketErrorProc:

Unit ScktComp

SocketErrorProc handles error messages that are received from a Windows socket connection.

```
threadvar SocketErrorProc: procedure (ErrorCode: Integer);
```

Assign a value to SocketErrorProc to handle error messages from Windows socket API calls before the socket component raises an exception. Setting SocketErrorProc prevents the socket component from raising an exception. SocketErrorProc is a thread-local variable. It only handles errors that arise from the Windows socket API calls made within a single execution thread.

## Article #19528: Converting a BMP to a JPEG and vice-versa under Delphi 3

Technical Information Database

TI4528D.txt - Converting a BMP to a JPEG and vice-versa under Delphi 3

Category :Delphi 3.x  
Platform :All-32Bit  
Product :Delphi3.x,

Description:

Q: How do I convert a BMP to a JPEG and vice versa?

A: This little project demonstrates how to do it using the JPEG components that ship with Delphi 3 (in the INFO\EXTRAS\JPEG directory). Just start a brand new project in Delphi 3. Drop two TButtons on the form. Then double click on the first button. Then double click on the second button. (This hooks the event handlers up). Finally, replace the code inbetween "{\$R \*.DFM}" and "end." in Unit1 with this code:

```
uses
    JPEG;

procedure TForm1.Button1Click(Sender: TObject);
var
    MyJPEG : TJPEGImage;
    MyBMP   : TBitmap;
begin
    { Convert a BMP to a JPEG }

    MyBMP := TBitmap.Create;
    with MyBMP do
        try
            LoadFromFile('YourBmpHere.BMP');
            MyJPEG := TJPEGImage.Create;
            with MyJPEG do begin
                Assign(MyBMP);
```

```
        SaveToFile('YourJpegHere.JPEG');
        Free;
    end;
finally
    Free;
end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
    MyJPEG : TJPEGImage;
    MyBMP   : TBitmap;
begin
    { Convert a JPEG to a BMP }

    MyJPEG := TJPEGImage.Create;
    with MyJPEG do begin
        LoadFromFile('YourJpegHere.JPEG');
        MyBMP := TBitmap.Create;
        with MyBMP do begin
            Width := MyJPEG.Width;
            Height := MyJPEG.Height;
            Canvas.Draw(0,0,MyJPEG);
            SaveToFile('YourBmpHere.BMP');
            Free;
        end;
        Free;
    end;
end;
end;
```

## Article #19531: Installing JPEG Components that Ship with Delphi 3

Technical Information Database

TI4531D.txt - Installing JPEG Components that Ship with Delphi 3

Category :Delphi 3.x  
Platform :All-32Bit  
Product :All32Bit,

### Description:

#### Step 1 - Copying the JPEG files to your hard drive

Insert your Delphi 3 CD in your CD-ROM drive.

In the Explorer, browse to the INFO\EXTRAS directory.

To copy the JPEG folder, drag and drop it from the Explorer to another folder, e.g. C:\MyStuff.

All the JPEG files should now be in C:\MyStuff\JPEG.

To make thing easier for us, now copy all the files from the C:\MyStuff\JPEG\OBJ folder to the C:\MyStuff\JPEG folder.

Do this by, in the Explorer, selecting all the files in the C:\MyStuff\JPEG\OBJ. When all files are selected, right click and choose Copy. Then browse to C:\MyStuff\JPEG and choose Paste.

#### Step 2 - Installing the JPEG components

Launch Delphi 3.0

From Delphi's main menu, select Component | Install Component

You'll should now see the "Install Component" dialog.

Hit the Browse button next to the Unit file name box.

In the "Unit file name" dialog, browse to C:\MyStuff\JPEG.

Select the file named JPEG.PAS and hit Open.

The Unit file name box should now be filled in properly.

Make sure the Package file name is set to the Delphi User's Components package, which by default is in this location:

C:\Program Files\Borland\Delphi 3\Lib\dclusr30.dpk

Hit OK.

You'll now see a "Confirm" dialog, saying that the package will be installed.

Hit Yes.

You should now see an "Information" dialog, saying that the

package is installed.

Exit the package editor and make sure you save the changes to the package.

### Step 3 - Using the JPEG component

Simply drop down a TImage and load a JPEG into the Picture property. Also, make sure the JPEG unit is in the USES clause, so that the JPEG stuff is registered at run-time.

## Article #19532: Extracting a JPEG Resource from an EXE

Technical Information Database

TI4532D.txt - Extracting a JPEG Resource from an EXE

Category :VCL  
Platform :All-32Bit  
Product :Delphi3.x,

### Description:

Pick any JPEG you want to link into your project and copy it to your project directory. Now, in the same directory, create an RC file (resource script). Call it MYRES.RC and have it contain this line:

```
MYJPEG RCDATA YourJpegHere.JPEG
```

Now, compile this RC file. At the command line, say:

```
BRCC32 MYRES
```

This'll create MYRES.RES which you can link into your project.

Now, start a brand new project in Delphi 3. Drop a TButton and a TImage on the form. Then double click on the button. Then replace the code inbetween "{\$R \*.DFM}" and "end." in Unit1 with this code:

```
{ $R MyRes.RES }  
  
uses  
    JPEG;  
  
const  
    ResName = 'MYJPEG';  
  
procedure TForm1.Button1Click(Sender: TObject);  
var  
    MyRes : Integer;  
    MyResP : Pointer;  
    MyResS : Integer;  
    MyMS : TMemoryStream;  
    OldDir : String;
```

```

begin
  Caption := 'Please wait...';
  Application.ProcessMessages;
  GetDir(0,OldDir);
  ChDir(ExtractFilePath(Application.ExeName));
  MyRes := FindResource(HInstance,PChar(ResName),RT_RCDATA);
  if MyRes <> 0 then begin
    MyResS := SizeOfResource(HInstance,MyRes);
    MyRes := LoadResource(HInstance,MyRes);
    if MyRes <> 0 then begin
      MyResP := LockResource(MyRes);
      if MyResP <> nil then begin
        MyMS := TMemoryStream.Create;
        with MyMS do begin
          Write(MyResP^,MyResS);
          Seek(0,soFromBeginning);
          Imager1.Picture.Graphic := TJPEGImage.Create;
          Imager1.Picture.Graphic.LoadFromStream(MyMS);
          Free;
        end;
        UnLockResource(MyRes);
        with Imager1.Picture do
          Caption := 'Cool JPEG! ('+
            IntToStr(Width)+'x'+IntToStr(Height)+')';
        end else
          Caption := 'LockResource failed. '+
            SysErrorMessage(GetLastError);
        FreeResource(MyRes);
      end else
        Caption := 'LoadResource failed. '+
          SysErrorMessage(GetLastError);
      end else
        Caption := 'FindResource failed. '+SysErrorMessage(GetLastError);
      ChDir(OldDir);
    end;
  end;

```

## Article #19534: Creating a 32-Bit Screen Saver in 32-bit Delphi

Technical Information Database

TI4534D.txt - Creating a 32-Bit Screen Saver in 32-bit Delphi

Category :Miscellaneous  
Platform :All-32Bit  
Product :All32Bit,

### Description:

This TI shows how you can write a 32-bit screen saver in 32 bit Delphi.

The screen saver contains support for preview mode (the little monitor in Display Properties | Screen Saver), as well as password protection and a configuration dialog.

First, a brief overview of what a screen saver is. For a more complete overview, consult the MSDN (Microsoft Developers Network), books and articles on the subject. There are also web sites with screen saver information and source code.

A screen saver is just an executable that has an extension of SCR instead of EXE. In Delphi 3, you can set this using the \$E compiler directive.

A screen saver can be launched in several ways:

When the screen saver timeout happens

By going to the Screen Saver tab in Display Properties (preview)

By configuring it

By previewing it (full screen)

By changing the screen saver password (Win95)

The screen saver is launched with different parameters depending on how it's launched:

When the screen saver timeout happens, it's launched with ParamStr(1) containing either '/S', '-S', or

just 'S'.

When you go to the Screen Saver tab in Display Properties the screen saver is supposed to preview itself in the little monitor. ParamStr(1) will contain '/P', '-P', or just 'P'. At the same time, ParamStr(2) will contain the window handle for the little monitor window.

When you configure the screen saver it's launched either with no parameters at all, or ParamStr(1) will contain '/C', '-C', or just 'C'.

When previewing the screen saver in full screen mode, it's launched just as if the screen saver timeout happened. ParamStr(1) will contain either '/S', '-S', or just 'S'.

When you change the screen saver password (Win95) ParamStr(1) will contain either '/A', '-A', or just 'A'.

A screen saver has to make sure it's not launched several times. In this screen saver this is accomplished by way of a semaphore (see Simple.dpr below).

A couple of things to look out for when it comes to the little preview window:

You have to wait until the window is visible  
You have to kill the previewing when the window is made invisible  
You'll see how both of these things are handled in Simple.dpr below.

As you know a screen saver has to respond to mouse events and key presses. When you don't have a password, it should simply shut down. When you have a password set, it should ask for the password.  
You'll see this as part of the SSave unit (see SSave.pas below).

One final note before we create the screen saver:  
Debugging a screen saver can be very tricky, so make sure you save your code before you run the screen saver in any way... If it locks up, you will most likely have to reboot, or at least kill Delphi 3 using the Task Manager...

OK, now let's go ahead and create the screen saver!

1. Create a new folder, e.g. C:\Foo. Launch Delphi 3, and start a brand new application. From the Project Manager, delete Unit1 and Form1 from the project. Do a File | Save Project As, and save the project as Simple.dpr in the newly created folder.
2. Do a File | New | Form. Select Unit1 in the Code Editor. Do a File | Save As, and save the new form as SSetup.pas.
3. Do a File | New | Form. Select Unit2 in the Code Editor. Do a File | Save As, and save the new form as SSave.pas.
4. Do a File | New | Unit. Select Unit3 in the Code Editor. Do a File | Save As, and save the new unit as Globals.pas.
5. Do a File | New | Unit. Select Unit3 in the Code Editor. Do a File | Save As, and save the new unit as CodeSpot.pas.
6. Select the form SSetup. Right click on the form and select View As Text. Replace all the text in the editor with the code for SSetup.dfm below. Right click and select View As Form. Now go to the unit SSetup.pas in the editor and replace all the code with the code for SSetup.pas below.
7. Select the form SSave. Right click on the form and select View As Text. Replace all the text in the editor with the code for SSave.dfm below. Right click and select View As Form. Now go to the unit SSave.pas in the editor and replace all the code with the code for SSave.pas below.
8. Select the unit Globals.pas. Replace all the code with the code for Globals.pas below.
9. Select the unit CodeSpot.pas. Replace all the code with the code for CodeSpot.pas below.
10. Do a View | Project Source. Replace all the code with the code for Simple.dpr below.

11.Do a Project | Build All.

12.Copy the compiled screen saver Simple.Scr into your system directory (Something like C:\WinNT\System32 or C:\Win95\System). You can right click on Simple.Scr in the Explorer and select Install.

13.Have lots of fun with your new screen saver project!

## Article #19538: Surfacing an Event on an ActiveForm to a Container

Technical Information Database

TI4538D.txt - Surfacing an Event on an ActiveForm to a Container

Category :ActiveX/OLE/COM/ActiveForm

Platform :All-32Bit

Product :All32Bit,

### Description:

Let's create an ActiveForm with a button on it. Now we want to surface the OnClick event of this button to any container using our ActiveForm. What we need to do is this:

Start a brand new ActiveForm project, by selecting File | New... | ActiveX | ActiveForm. Change the ActiveX Name, Implementation Unit, and Project Name if you want. For instance, TestX, TestImpl.pas, and Test.dpr respectively.

Drop a TButton on the TestX form. Double click on the button and make the event handle say:

```
procedure TTestX.Button1Click(Sender: TObject);
var
  OldCaption : String;
begin
  with Button1 do begin
    OldCaption := Caption;
    Caption := 'Auch!';
    Sleep(1000);
    Caption := OldCaption;
  end;
end;
```

This is just to demonstrate that we can handle the button's click event in both the ActiveForm and in the container. What we just implemented was of course the ActiveForm side. Now, let's take care of the container side...

Do a View | Type Library. In ITestXEvents we need to add a new event just below OnPaint. Let's call it OnButton1Click. When you

hit Refresh you should see that the ID (dispid) of this event is set to 9.

Now go back to the OnClick event handler of Button1 on the ActiveForm. Add one line to make it look like this:

```
procedure TTestX.Button1Click(Sender: TObject);
var
  OldCaption : String;
begin
  with Button1 do begin
    OldCaption := Caption;
    Caption := 'Auch!';
    Sleep(1000);
    Caption := OldCaption;
  end;
  if FEvents <> nil then FEvents.OnButton1Click;
end;
```

This will make the container see things after you've handled the OnClick event on the ActiveForm side. If you want to let the container do its thing first, just put the line at the top instead.

Save the ActiveForm project somewhere on disk, e.g. in C:\Test.

Do a Project | Build All.

Do a Run | Register ActiveX Server.

Do a Component | Import ActiveX Control. Find Test Library in the list of registered controls. Select it, and hit Install. Put it in dclusr30.dpk (the default). After hitting OK a couple of times the control should pop up on your ActiveX tab on the component palette. Close the package editor and save the changes to the package.

Do a File | New Application. Drop down a TestX (our ActiveForm) on the form. Double click on the OnButton1Click event handler on the Events tab in the Object Inspector and make it say:

```
procedure TForm1.TestX1Button1Click(Sender: TObject);
begin
  ShowMessage('You hit me!');
end;
```

Run the application, and hit Button1 in the TestX component. You should see the Caption change for a second and then you should see your 'You hit me!' message popping up on the screen.

## Article #19540: Drag and Drop Selected Text in between Memo Components

Technical Information Database

TI4540D.txt - Drag and Drop Selected Text in between Memo Components

Category :VCL  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Without getting too deep into component creation, here's a very simple way of accomplishing drag and drop of selected text.

Create a new component (TMyMemo) descending off of TMemo.

Make the type declaration look something like this:

```
type
  TMyMemo = class(TMemo)
  private
    FLastSelStart : Integer;
    FLastSelLength : Integer;
    procedure WMLButtonDown(var Message: TWMLButtonDown);
      message WM_LBUTTONDOWN;
  published
    property LastSelStart : Integer read FLastSelStart
      write FLastSelStart;
    property LastSelLength : Integer read FLastSelLength
      write FLastSelLength;
  end;
```

Make the implementation of WMLButtonDown look like this:

```
procedure TMyMemo.WMLButtonDown(var Message: TWMLButtonDown);
var
  Ch : Integer;
begin
  if SelLength > 0 then begin
    Ch := LoWord(Perform(EM_CHARFROMPOS, 0,
      MakeLParam(Message.XPos, Message.YPos)));
    LastSelStart := SelStart;
```

```

    LastSelLength := SelLength;
    if (Ch >= SelStart) and (Ch <= SelStart+SelLength-1) then
        BeginDrag(True)
    else
        inherited;
    end
else
    inherited;
end;

```

Now, install this component into a package, start a brand new project in Delphi 3 and drop two TMyMemos down.

Make them both have an OnDragOver event handler looking like this:

```

procedure TForm1.MyMemo1DragOver(Sender, Source: TObject; X, Y:
Integer;
    State: TDragState; var Accept: Boolean);
begin
    Accept := Source is TMyMemo;
end;

```

Make them both have an OnDragDrop event handler looking like this:

```

procedure TForm1.MyMemo1DragDrop(Sender, Source: TObject;
                                X, Y: Integer);
var
    Dst, Src : TMyMemo;
    Ch       : Integer;
    Temp     : String;
begin
    Dst := Sender as TMyMemo;
    Src := Source as TMyMemo;
    Ch := LoWord(Dst.Perform(EM_CHARFROMPOS, 0, MakeLParam(X, Y)));

    if (Src = Dst) and (Ch >= Src.LastSelStart) and
        (Ch <= Src.LastSelStart+Src.LastSelLength-1) then
        Exit;

    Dst.Text := Copy(Dst.Text, 1, Ch)+Src.SelText+
                Copy(Dst.Text, Ch+1, Length(Dst.Text)-Ch);
    Temp := Src.Text;
    Delete(Temp, Src.LastSelStart+1, Src.LastSelLength);
    Src.Text := Temp;
end;

```

Launch the app and put some text into the memos, and watch what happens as you drag and drop inbetween the two memos, or even drag and drop text from one location in one memo component to another location in the same memo component.

## Article #19546: Description of Multi-Byte Character Support in Delphi, BDE

Technical Information Database

TI4546D.txt - Description of Multi-Byte Character Support in Delphi, BDE

Category :Miscellaneous  
Platform :All-32Bit  
Product :Delphi3.x, Delphi4.x,

### Description:

This TI describes the variations in the Multi-Byte Character Support (MBCS) in Borland Products that use the BDE. The BDE 4.0 and above are MBCS enabled and can handle all Asian languages i.e. Simplified Chinese(Mainland), Traditional Chinese(Tainwan), Korean, and Japanese. All Borland products that ship with the BDE 4.0 and above are enabled to handle MBCS. Paradox on the other hand is not a Borland product any more and entering MBCS into tables may give you incomplete or garbage entries.

BDE 4.0 and above do not have any localised runtime messages. For European languages many of these runtime messages are localised and can be gotten through the Borland Delphi Language Pack,(not to be confused with the Translation Suite). For Asian languages the only one that has localised for 4.0 and above is the Taiwanese(Traditional) Delphi Solution Pack sold exclusively in Taiwan.

The Japanese BDE 4.5 is actually identical to the BDE 4.5 that ships world-wide except that it contains localised Japanese runtime messages and some Japanese specific sorting and locale info. The Japanese BDE 4.51 has a special resource file(IDR2011.DLL) that contains this. It also has the BDE Administrator that is adapted to Input Method Editors for the language.

## Article #19548: Creating Lookup Fields at Runtime

Technical Information Database

TI4548D.txt - Creating Lookup Fields at Runtime

Category :Database Programming  
Platform :All-32Bit  
Product :All32Bit,

### Description:

Creating a lookup field at runtime differs in only a few ways from creating any standard TField object. (for more explicit information on this topic and other related topics see the TI entitled "Dynamically creating a TTable & fields at runtime".) Three properties of a field that must be set in order to function as a Lookup field are LookUpDataset, LookUpKeyFields and LookUpResultField. The sample code below demonstrates how to create a Lookup field at runtime using the two DBDEMOS tables 'customer.DB' and 'orders.DB'.

Start a new application (File|New Application).

Drop two TTables, a TButton, a TDBLookupComboBox and a TDataSource on a form.

Set the two TTables 'DatabaseName' property to 'DBDEMOS'.

Set Table1's 'TableName' property to 'CUSTOMER.DB' and Table2's 'TableName' property to 'ORDERS.DB'.

Right click on the TTable object for Table2 and launch the field editor. Add the 'CustNo' field object (right click on the fields editor and choose 'Add Fields', then select 'CustNo' from the list).

Copy and paste the code below into the code editor.

Example:

```
unit Unit1;
```

```
interface
```

```
uses
```

```
Forms, Classes, Controls, StdCtrls, Db, DBTables, DBCtrls;
```

```

type
  TForm1 = class(TForm)
    Table1: TTable;    // DBDemos customer table
    Table2: TTable;    // DBDemos orders table
    Button1: TButton;
    DBLookupComboBox1: TDBLookupComboBox;
    DataSource1: TDataSource;
    Table2CustNo: TFloatField; // CustNo key field object used
                                // for Lookup
    procedure Button1Click(Sender: TObject);
private
  { Private declarations }
public
  { Public declarations }
end;

var
  Form1: TForm1;

implementation

{$R *.DFM}

procedure TForm1.Button1Click(Sender: TObject);
begin
  with TStringField.Create(Table2) do begin
    FieldName := 'MyLookup';
    FieldKind:= fkLookup;
    DataSet := Table2;
    Name := DataSet.Name + FieldName;
    KeyFields:= 'CustNo';
    LookUpDataset:= Table1;
    LookUpKeyFields:= 'CustNo';
    LookUpResultField:= 'Company';
    DbLookupCombobox1.DataField:= FieldName;
    DataSource1.DataSet:= DataSet;
    Table2.FieldDefs.Add(Name, ftString, 20, false);
  end;
  DbLookupCombobox1.DataSource:= DataSource1;
  Table1.Active:= True;
  Table2.Active:= True;
end;

end.

```

## Article #19549: ShortCut Keys For Delphi

Technical Information Database

TI4549D.txt - ShortCut Keys For Delphi

Category :IDE  
Platform :All-32Bit  
Product :Delphi3.x, Delphi4.x,

Description:

Object Inspector ShortCut Keys

Ctrl+DwnArr

Makes the Object ComboBox drop Down and gives it focus.

Ctrl+Tab

Switches Between Events and Properties.

Ctrl+Enter

Executes a dialog associated with a property, makes an event handler procedure.

Alt + DwnArr

If the property is a drop down list, it will drop down this list.

### IDE ShortCutKeys

F1

Displays context-sensitive Help

F4

Run|Go to Cursor

F5

Run|Toggle Breakpoint

F7

Run|Trace Into

F8

Run|Step Over

F9

Run|Run

F11

View|Object Inspector

F12	View Toggle Form/Unit
Ctrl+F2	Run Program Reset
Ctrl+F3	View Call Stack
Ctrl+F4	Close the Focused Page in the Delphi Source Editor
Ctrl+F5	Executes the Watch List and the Watch Properties dialogs
Ctrl+F7	Executes the Evaluate Modify Dialog
Ctrl+F9	Compile application
Ctrl+F12	Executes the 'View Unit' Dialog
Ctrl+Spc	Brings up the Code Completion Window.
Ctrl+Enter	When Done in the Source Code Editor, it executes the Open Dialog Box and populates the file name with the word that the cursor was nearest to with an extension of .pas. It also opens up in the current directory.
Ctrl+Home	Top of Source File
Ctrl+End	End of Source File
Ctrl+Del or Del	Delete a component from the form
Ctrl+C	Copy Selected block to the Clipboard
Ctrl+E	Incremental Word search within a Source file. Searches one letter at a time. Also populates the word search edit box.
Ctrl+F	Full word search. this searches the Source file for a specific word.
Ctrl+J	Code Completion Window
Ctrl+K+E	Changes a word to lowercase

Ctrl+K+F	Capitalize word to the Left of cursor
Ctrl+K+N	Changes a block to uppercase
Ctrl+K+O	Changes a block to lowercase
Ctrl+K+P	Executes the Print Dialog Box
Ctrl+K+R	Reads a block from a file
Ctrl+K+T	Highlight word to the left of cursor
Ctrl+K+W	Writes a selected block to a file
Ctrl+O+G	Search Go to line number
Ctrl+O+O	Inserts compiler options and directives
Ctrl+O+U	Toggles Upper/Lower case of highlighted text
Ctrl+P	Causes next character to be interpreted as an ASCII sequence
Ctrl+R	Search and Replace a word
Ctrl+S	Save a Source file
Ctrl+T	Delete a word at a time
Ctrl+V	Paste from the Clipboard
Ctrl+X	Cut Selected block to the Clipboard
Ctrl+Y	Delete a line of UNHIGHLIGHTED Source Code
Ctrl+Z	Undo Changes
Ctrl+0	Goes to bookmark 0
Ctrl+1	Goes to bookmark 1
Ctrl+2	Goes to bookmark 2
Ctrl+3	Goes to bookmark 3

Ctrl+4  
Goes to bookmark 4

Ctrl+5  
Goes to bookmark 5

Ctrl+6  
Goes to bookmark 6

Ctrl+7  
Goes to bookmark 7

Ctrl+8  
Goes to bookmark 8

Ctrl+9  
Goes to bookmark 9

Ctrl+Shift+Spc  
Brings up the Code Parameters Window.

Ctrl+Shift+G  
Creates and displays a GUID

Ctrl+Shift+I  
Indents a highlighted block of text

Ctrl+Shift+P  
Plays back a key macro

Ctrl+Shift+R  
Records a key macro

Ctrl+Shift+U  
OutDents a Highlighted block of text

Ctrl+Shift+Y  
Deletes to the End of the Line.

Ctrl+Shift+Z  
Redo Changes

Ctrl+Shift+0  
Sets or removes bookmark 0

Ctrl+Shift+1  
Sets or removes bookmark 1

Ctrl+Shift+2  
Sets or removes bookmark 2

Ctrl+Shift+3  
Sets or removes bookmark 3

Ctrl+Shift+4  
Sets or removes bookmark 4

Ctrl+Shift+5  
Sets or removes bookmark 5

Ctrl+Shift+6  
Sets or removes bookmark 6

Ctrl+Shift+7  
Sets or removes bookmark 7

Ctrl+Shift+8

	Sets or removes bookmark 8
Ctrl+Shift+9	Sets or removes bookmark 9
Alt+F4	Closes Focused Window
Alt+F6	Switches between the last 2 objects that had focus in the IDE (i.e. the Form Designer and the Object Inspector or the Form and the Main Delphi Menu, or the Object Inspector and the Main Delphi Menu, etc..)
Alt+F10	Executes a Right Click in the Source Code Editor
Alt+F12	View Form as Text
Alt+Spc	Current Windows' System Menu
Alt+0	Executes the Window List dialog
Shift+F7	Trace to next Source Line
Shift+F12	Executes the 'View Form' Dialog
Shift+Alt+Arw	Highlights a column of text.

### Highlighting a column of text using the mouse

Hold down Alt+LeftMouseButton. Drag around to get a Highlighted Column...

### Moving Components in Design Time

Highlight the desired component:

Shift+DownArrow	Increases the Components Height property.
Shift+UpArrow	Decreases the Components Height property.
Shift+RightArrow	Increases the Components Width property.
Shift+LeftArrow	

Decreases the Components Width property.  
Ctrl+DownArrow  
Increases the Components Top property.  
Ctrl+UpArrow  
Decreases the Components Top property.  
Ctrl+RightArrow  
Increases the Components Left property.  
Ctrl+LeftArrow  
Decreases the Components Left property.  
Ctrl+Shift+DownArrow  
Increases the Components Top property by a grid snap  
space.  
Ctrl+Shift+UpArrow  
Decreases the Components Top property by a grid snap  
space.  
Ctrl+Shift+RightArrow  
Increases the Components Left property by a grid snap  
space.  
Ctrl+Shift+LeftArrow  
Decreases the Components Left property by a grid snap  
space.

### Delphi's TLB Editor

Tip: If you Create an Interface, Method, Property, etc, you can Ctrl  
+C (copy) it  
to the windows Clipboard and then when you want to create a new one,  
you can  
Ctrl+V (paste) it from the windows clipboard... The Type Library  
Editor will  
create a new object of whatever type that you copied to the clipboard.

### Delphi's Package Editor

Ctrl+S  
Save Package.  
Ctrl+B  
Compile Package.  
Ctrl+I  
Install Package.  
Ins  
Add Unit to package or add a required package to another  
packages Requires  
Page.

Del Remove Package or Unit from a package.

Enter View Required Unit/Package that is currently highlighted.

## SQL Explorer

F2 Rename an Alias.

F6 Switch between the Databases/Dictionary Tab and the Definition Tab.

Ctrl+A Apply Changes.

Ctrl+D Delete an Alias.

Ctrl+M Rename an Alias.

Ctrl+N Create a New Database Alias.

Ctrl+P Previous View.

Ctrl+R Refresh.

Ctrl+S Copy an Alias and its settings to a new alias. (Save Foo as NewName)...

Alt+F10 Executes a Right Click over the selected Item.

Alt+BckSpC Cancel.

ArrowKeys Use the Arrow Keys to navigate through the Alias List.

Pressing the Right Arrow Key while an Alias is highlighted will attempt to connect to the associated Database.

## Article #19550: Installing and Using Delphi 3 Under NT4

Technical Information Database

TI4550D.txt - Installing and Using Delphi 3 Under NT4

Category :Install Issues  
Platform :Windows NT  
Product :Delphi3.x,

### Description:

This document applies to people who wish to install Delphi 3 on an NT4 system and have multiple users use that Delphi 3 installation on that machine. For instance, you might want to install Delphi 3 as USER1, and at a later time, USER2 wants to use Delphi 3 on the same machine, and not have to log in as USER1.

It should be noted that Delphi 3 was never designed to do this, and Borland makes no claims that it will work for all users on all machines. If this document fails in your case, go with the suggestion that always applies - install Delphi 3 to the same location as both USER1 and USER2. (Of course, you'll still need all the rights mentioned in this document even in the latter case.)

There's no need to be logged in as Administrator on NT4 in order to install Delphi 3 on the system.

You will however need rights to do a lot of things, including:

- Writing shared DLLs and OCXs to NT4's System32 directory (usually C:\WinNT\System32)
- Writing registry entries to HKEY\_LOCAL\_MACHINE
- Writing registry entries to HKEY\_CURRENT\_USER
- Writing registry entries to HKEY\_CLASSES\_ROOT (part of registering OCXs)

If you're missing one of these rights, the installation will fail.

If you install as USER1, and USER2 wants to use Delphi 3, there are a few things USER2 will need:

- Access to C:\WinNT\System32
- Access to HKEY\_LOCAL\_MACHINE, specifically the Software\Borland registry keys
- Access to HKEY\_CLASSES\_ROOT
- Access to all Delphi 3 directories and subdirectories

On top of this you need to do this:

- Copy (or move) the "Borland Delphi 3" group that was put in USER1's Start Menu to the USER2's Start Menu (or to All Users).
- Export all the Borland keys from USER1's registry under HKEY\_CURRENT\_USER\Software\Borland and import them to USER2's HKEY\_CURRENT\_USER\Software\Borland.

## Article #19555: Why a Network Install of Delphi 3 Isn't Supported

Technical Information Database

TI4555D.txt - Why a Network Install of Delphi 3 Isn't Supported

Category :Install Issues  
Platform :All-32Bit  
Product :Delphi3.x,

### Description:

Delphi 3 was never designed to be installed on a network, and Borland makes no claims that a network install of Delphi 3 will work.

It may work for some users if they from all machines install Delphi 3 to the same location on the network. They will also need a lot of rights, including:

- Writing shared DLLs and OCXs to NT4's System32 directory (usually C:\WinNT\System32)
- Writing registry entries to HKEY\_LOCAL\_MACHINE
- Writing registry entries to HKEY\_CURRENT\_USER
- Writing registry entries to HKEY\_CLASSES\_ROOT (part of registering OCXs)

Delphi 3 expects all shared DLLs, packages and OCXs to be locally installed.

Furthermore, Delphi 3 expects all registry entries to be local.

As you can see, many problems may arise when trying to install Delphi 3 on a network. Possibly the most important one is the network software and hardware itself. Unforeseen problems may occur with any network configuration.

## Article #19611: How to debug ISAPI dll's on Windows 98 with Personal Web Server

Technical Information Database

FAQ: TI4611D - How to debug ISAPI dll's on Windows 98 with Personal Web Server

Category: Internet/WEB

Platform: Windows 98

Product: All32Bit,

Description:

This document describes how to debug ISAPI dll's under Win98 using Microsoft Personal Web Server (PWS). The directories referenced in this document assume a default installation of PWS. You may have to change the directories if you did not do a default installation.

1. First, create a shortcut to PWS.EXE. By default, it is located at:

```
"C:\WINDOWS\SYSTEM\inetsrv\pws.exe"
```

Right click on the new shortcut, and change the target to be:

```
"C:\WINDOWS\SYSTEM\inetsrv\pws.exe /stop"
```

This shortcut will allow you to stop PWS and unload any dll's from memory that are currently being used.

2. In your Delphi ISAPI dll project, select "Run->Parameters" and set the host application to be:

```
"C:\WINDOWS\SYSTEM\inetsrv\inetinfo.exe"
```

and the parameters to be: "-e w3svc".

3. In your Delphi ISAPI dll project, go to "Project->Options..." and on the "Directories/Conditionals" tab, set the "Output Directory" to be "c:\inetpub\scripts" (or whatever your scripts directory is).

Now to actually be able to debug your dll, you must first make sure PWS is not running. Right click on the PWS icon in the system tray, and click "Stop Service". The PWS icon should now have a red X on it. Now, double click the shortcut that was made in step one to completely unload

PWS. It may take a couple of seconds, but the PWS icon should disappear completely.

You will now be able to set breakpoints in your ISAPI dll project. Running your project will start PWS and place the PWS icon in your system tray. Right click on and select "Start Service". Access your ISAPI dll in a web browser by typing in `http://localhost/scripts/Project1.dll`. Delphi should now say "Running..." in the caption and will stop on breakpoints in your DLL code.

After you have finished debugging, to return to Delphi you must unload the dll. Right click on the PWS icon in the system tray and click "Stop Service". Then, double click on the shortcut you made in step 1. It may take a second, but Delphi will pop back up.

On a side note, I don't recommended using "Run->Program Reset (Ctrl-F2)"

while debugging ISAPI dll's under PWS. Quite often, this will cause PWS to crash, and it will require a restart of your computer to allow it to run again.

## Article #19646: How to register my program's file type with the Window's registry.

Technical Information Database

FAQ: TI4646D - How to register my program's file type with the Window's registry.

Category: Windows API

Platform: All-32Bit

Product: All32Bit,

Description:

There are several different ways to do this. One way would be to create a .reg file that contains the necessary registry keys, and then merge it with the registry. Another way is to do it with code using TRegistry. This TI describes how to do it with code but it could easily be extended to just a .reg file if need be.

```
////////////////////////////////////
```

```
uses Registry, ShlObj;
```

```
procedure TForm1.Button1Click(Sender: TObject);
```

```
const
```

```
  cMyExt = '.abc';
```

```
  cMyFileType = 'Project1.FileType';
```

```
var
```

```
  Reg: TRegistry;
```

```
begin
```

```
  Reg := TRegistry.Create;
```

```
  try
```

```
    // Set the root key to HKEY_CLASSES_ROOT
```

```
    Reg.RootKey := HKEY_CLASSES_ROOT;
```

```
    // Now open the key, with the possibility to create  
    // the key if it doesn't exist.
```

```
    Reg.OpenKey(cMyExt, True);
```

```
    // Write my file type to it.
```

```
    // This adds HKEY_CLASSES_ROOT\.abc\(\Default) = 'Project1.
```

```
FileType'
```

```
    Reg.WriteString('', cMyFileType);
```

```
    Reg.CloseKey;
```

```
    // Now create an association for that file type
```

```

Reg.OpenKey(cMyFileType, True);
// This adds HKEY_CLASSES_ROOT\Project1.FileType\Default
//   = 'Project1 File'
// This is what you see in the file type description for
// the a file's properties.
Reg.WriteString('', 'Project1 File');
Reg.CloseKey;
// Now write the default icon for my file type
// This adds HKEY_CLASSES_ROOT\Project1.FileType\DefaultIcon
//   \Default = 'Application Dir\Project1.exe,0'
Reg.OpenKey(cMyFileType + '\DefaultIcon', True);
Reg.WriteString('', Application.ExeName + ',0');
Reg.CloseKey;
// Now write the open action in explorer
Reg.OpenKey(cMyFileType + '\Shell\Open', True);
Reg.WriteString('', '&Open');
Reg.CloseKey;
// Write what application to open it with
// This adds HKEY_CLASSES_ROOT\Project1.FileType\Shell\Open
\Command
//   (Default) = '"Application Dir\Project1.exe" "%1"'
// Your application must scan the command line parameters
// to see what file was passed to it.
Reg.OpenKey(cMyFileType + '\Shell\Open\Command', True);
Reg.WriteString('', '"' + Application.ExeName + '" "%1"');
Reg.CloseKey;
// Finally, we want the Windows Explorer to realize we added
// our file type by using the SHChangeNotify API.
SHChangeNotify(SHCNE_ASSOCCHANGED, SHCNF_IDLIST, nil, nil);
finally
    Reg.Free;
end;
end;
////////////////////

```

## Article #20193: Changing BDE Driver Settings Programmatically

This document illustrates how to change BDE driver settings programmatically (settings found under “Configuration->Drivers” in the BDE Administrator only). You may need to change BDE driver settings programmatically if, for example, you want to specify the DLL32 setting for the Oracle or MSSAccess driver (to specify oracle 7 or 8, MSAccess 95 or 97), or you want to increase the value of Max DBProcesses for the MSSQL driver.

Note: If you need to change the parameters for anything that can be found on the “Database” tab in BDE administrator, then you should use Tdatabase.Params (not covered in this document).

A BDE driver can be configured at runtime using Tsession.ModifyDriver. The following code changes the Max DBProcesses driver parameter for the MSSQL driver.

Start a new application, drop a Tsession on the form, set autosessionname to true, and add the following code into the OnCreate event handler for the form:

```
procedure TForm1.FormCreate(Sender: TObject);
var
  DriverParams: TStringList;
begin
  DriverParams := TStringList.Create;
  try
    { add the parameters that you want to change only. The default for
      this param is 31. }
    DriverParams.Add('MAX DBPROCESSES=50');

    { call modify driver with name of driver and list of params }
    session1.ModifyDriver('MSSQL',DriverParams);

    { call this if you want to save the changes in the BDE for all
      applications to use, will only take affect after all BDE applications
      have been unloaded on the system. }
    session1.SaveConfigFile;
  finally
    DriverParams.Free;
  end;
end;
```

Be sure to read the documentation for Tsession.ModifyDriver in the online help files-> especially about Tsession.ConfigMode and the scope of ModifyDriver.

## Article #20245: MS SQL Server 7 Stored Procedure PRINT Statements with ADO

MS SQL Server stored procedures use a number of ways of communicating information back to the user. One of these is the PRINT statement. This statement is typically used for informational type messages. If the intention is to raise an exception in the calling application, it is preferable to use the RAISERROR statement.

Many users want to use the PRINT statement, however, and it has not been possible to access informational type messages with the BDE - only RAISERROR was supported, and then only those errors of sufficient severity to raise an exception.

With ADO it is possible to access PRINT statement messages. ADO considers these messages to be errors of severity 0 - too low to raise an exception - but nevertheless the messages are written to ADO's errors collection, which, in Delphi, is a property of the TADOConnection component.

Another fact worth pointing out is that Print statement messages are only placed in the Errors collection if the ADO command is executed with the eoExecuteNoRecords Option set to True.

How do we retrieve this message in practice?

Consider the following Stored Procedure:

```
create PROCEDURE sp_show_test (@param1 char(30)) as
begin
  If (@param1 = "Some Value")
    Select * from dbo.authors
  else
  begin
    print "Illegal value : "+@param1
    return 25
  end
end
```

This will return a result set if the input parameter is set to "Some Value", otherwise it will issue the "Illegal Value" message and return a user defined return code of 25.

How do we deal with this in Delphi? If we just use a TADODataset component, we risk getting an exception raised when a result set is not returned by the stored procedure. It is therefore better to use a TADOCommand component AND a TADODataset. The Execute method of a TADOCommand can return an ADO \_RecordSet object, which we can assign to the RecordSet property of the TADODataset. If the stored procedure does not return a result set, the \_RecordSet is still returned but in a closed state, which we can test for.

Here is a simple Delphi unit that allows us to see the Print statement's message. In addition to the three ADO components listed above this code requires a TEdit and TButton, and 'ADOInt' should be added to your uses clause:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  MyReturn : Integer;
  looper : Integer;
  MyRecordSet : _RecordSet;
begin
  ADOCommand1.Prepared := True;
```

```

ADOCCommand1.Parameters.ParamByName('@param1').Value := Edit1.Text;
MyRecordSet := ADOCCommand1.Execute;
if MyRecordSet.State = adStateOpen then
begin
    ADODataSet1.Recordset := MyRecordSet;
    ADODataSet1.Open;
end
else
begin
    ADOCCommand1.ExecuteOptions := [eoExecuteNoRecords];
    ADOCCommand1.Execute;
    MyReturn := ADOCCommand1.Parameters.ParamByName('RETURN_VALUE').Value;
    for looper := 0 to ADOCConnection1.Errors.Count - 1 do
    begin
        ShowMessage(Format('Stored Procedure %s Failed with Return Code %d and Message
"%s"',
                            [ADOCCommand1.CommandText, MyReturn,
                            TrimRight(ADOCConnection1.Errors[looper].Description)]));
    end;
end;
end;

```

As mentioned, when we execute the procedure the first time, we are expecting a result set to be returned. This will mean that the Errors collection will not be filled. If the result set has not been returned, we must execute the procedure a second time with the eoExecuteNoRecords option set.

## Article #20377: Maintaining State in Web Applications

# Advanced Web Applications

## Maintaining State in Web Applications

By Corbin Dunn

There are several ways to maintain state in a web application. Take a look at DavidI's document about maintaining state (<http://community.borland.com/article/0,1410,10265,00.html>) for some pro's and con's of each method. In this document, I will describe ways to use each method and provide an example.

### Maintaining state with cookies

**The first way**, and one of the most common ways, is to maintain state with cookies. This document was written with Delphi 5 in mind, but it should work fine in previous versions.

Cookies are stored in a file on your client machine and can be set and retrieved by a Web Application program with the help of a web browser. Cookies are sent as part of the HTML request/response header so it is transparent to the user. A cookie has a Name and Value pair, an expiration date, a domain name that the cookie is valid for, and a set of URLs that the cookie is valid for. In addition, you can set the Secure property of a cookie to only allow it to be sent and received via a secure connection (typically, HTTPS).

### Delphi Example

This best way to learn is to start up Delphi and create a new Web Application (this requires the Enterprise version of Delphi). In the new web module, add a single action and make it the default action (set Default to True). Now, add the following code in the OnAction event:

```
procedure TWebModule1.WebModule1WebActionItem1Action(Sender: TObject;
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
var
  I: Integer;
  strVisitNum: string;
begin
  // This is the main "entry" action.
  // This example will count the number of times a person
  // has been to this page using a cookie.

  strVisitNum := '1'; // Initialize the visitor number to 1

  // First check to see if there is a cookie present
```

```

if Request.CookieFields.Count > 0 then
begin
    // See if the 'Visit Number' cookie is present
    strVisitNum := Request.CookieFields.Values['Visit Number'];
    if strVisitNum <> '' then
        begin
            try
                // Try to convert it to an integer and inc it
                strVisitNum := IntToStr(StrToInt(strVisitNum) + 1);
            except // Eat exceptions (conversion exceptions)
            end;
        end
    end;

    // Set the 'Visit Number' cookie
    with Response.Cookies.Add do
        begin
            // You should set the domain to your domain to
            // get only cookies sent back to that domain (yours).
            // I'm leaving it commented out because in testing
            // you usually reference your machine by http://machinename/scripts
            // with no domain, and you can test this app by just compiling.
            // Domain := 'inprise.com';

            // Expire (quit sending the cookie) in one month from now
            Expires := IncMonth(Now, 1);
            // Limit the cookie to the path to this DLL
            Path := Request.URL; // Such as '/scripts/StateKeeper.dll'
            Secure := False;
            // The most important parts of the cookie are the Name and Value
            Name := 'Visit Number';
            Value := strVisitNum;
        end;

        Response.Content := '<html><body>Welcome!<br>You have visited ' +
            strVisitNum + ' times!</body></html>';
    end;

```

When receiving cookies, the main thing that you will be looking at is `Request.CookieFields.Values['Cookie Name'];`. If the cookie is not present, the returned string will be blank.

When setting a cookie, the most important things to set are the Name and Value properties.

## Maintaining state with Hidden Fields

In this next example, we will see how to save state with forms using the POST method and hidden fields.

Conceptually, you can send a custom form to the user based on previous selections. You can also maintain state with hidden fields. This example does both. It allows the user to select an option, and based on what option they selected, it will set it as selected in the resulting page. In addition, it keeps track of the number of times they have gone through that form by saving a counter in a hidden field.

### Delphi Example

To build this example, simply add another action in your web module and change the PathInfo to be any string (I chose '/hidden'). Then, access the page with: <http://MyMachineName/scripts/DllName.dll/hidden> (or something similar based on the names you used).

```
procedure TWebModule1.WebModule1WebActionItem2Action(Sender: TObject;
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
var
  nOptionSelected: Integer;
  strOptionString: string;
  strVisitNum: string;
begin
  // Hidden field example.

  // The first thing we do is check to see what method this
  // action was invoked by. If it was from a GET method,
  // we will return a form for the user to use and send
  // a selected option.
  // In addition, we will maintain "state" of how many visits
  // the user has made to the page with a hidden field.

  if Request.MethodType = mtGet then
  begin
    // Send a form back as the response so the user can
    // invoke this same action with it (with a POST method)
    Response.Content := '<html><body>' + #10#13 +
      '<form action="' +
      Request.URL + Request.PathInfo +
      '" method="post">' +
      'Test saving state! Select '
      +
      'something for me to remember: ' +
      '<select name="selection">' +
      '<option value="1">First Option' +
```

```
'<option value="2">Second Option' +  
'<option value="3">Third Option' +  
'<option value="4">Forth Option' +  
'</select>' +  
// Notice the hidden field below to  
// keep track of the number of "visits"  
'<input type="hidden" ' +  
'name="Visit Number" value="1">' +  
'<input type="submit">' +  
'</form></body></html>';
```

```
end  
else if Request.MethodType = mtPost then  
begin  
    // On a post, data is sent to us in the ContentFields  
    // string list.  
    try  
        nOptionSelected :=  
            StrToInt(Request.ContentFields.Values['selection']);  
    except // Catch conversion exceptions  
        nOptionSelected := -1;  
    end;  
    // Set the selected option based on which one was sent  
    // in the post data.  
    case nOptionSelected of  
        1: strOptionString := '<option value="1" selected>First Option' +  
            '<option value="2">Second Option' +  
            '<option value="3">Third Option' +  
            '<option value="4">Forth Option';  
        2: strOptionString := '<option value="1">First Option' +  
            '<option value="2" selected>Second Option' +  
            '<option value="3">Third Option' +  
            '<option value="4">Forth Option';  
        3: strOptionString := '<option value="1">First Option' +  
            '<option value="2">Second Option' +  
            '<option value="3" selected>Third Option' +  
            '<option value="4">Forth Option';  
        4: strOptionString := '<option value="1">First Option' +  
            '<option value="2">Second Option' +  
            '<option value="3">Third Option' +  
            '<option value="4" selected>Forth Option';  
    else // None selected (some error occurred if this is executed)  
        strOptionString := '<option value="1">First Option' +  
            '<option value="2">Second Option' +  
            '<option value="3">Third Option' +
```

```

                                '<option value="4">Forth Option';
end;

// Now try to inc the Visit Number
try
    // Try to convert it to an integer and inc it
    strVisitNum := Request.ContentFields.Values['Visit Number'];
    strVisitNum := IntToStr(StrToInt(strVisitNum) + 1);
except // Eat exceptions (conversion exceptions)
    strVisitNum := '1';
end;

Response.Content := '<html><body>' + #10#13 +
                    '<form action="' +
                    Request.URL + Request.PathInfo +
                    '" method="post">' +
                    'You selected option number ' +
                    Request.ContentFields.Values['selection'] +
                    ' and this is vist number ' +
                    strVisitNum + '<br>' +
                    'You can select another: ' +
                    '<select name="selection">' +
                    strOptionString +
                    '</select>' +
                    // Add the hidden field back in
                    '<input type="hidden" ' +
                    'name="Visit Number" value="' +
                    strVisitNum + '>' +
                    '<input type="submit">' +
                    '</form></body></html>';

end
else // An "Unsupported" MethodType
    Response.Content := '<html><body>Method not supported</body></html>';
end;

```

One of the key things to notice here is the line:

```
'<input type="hidden" name="Visit Number" value="' + strVisitNum + '>'
```

that adds the hidden field to keep track of the number of visits.

This example is probably one of the more elegant ways of saving state. You could easily extend it to database browsing. Instead of saving the "Visit Number" you could save the current record (or range) that the user was viewing.

The third way to maintain state is with "Fat URLs" like the following which shows how a search on HotBot can be saved: <http://hotbot.lycos.com/?MT=Corbin%27s+treehouse>

You can easily implement this in Delphi, and because of its simplicity it is one of the more common ways of saving state that is easily 'bookmarkable.'

The first thing we are going to do is take a closer look at a GET request (aka, Fat URL). Typically, they will look something like:

<http://www.mydomain.com/scripts/myIsapi.dll/PathInfo?name1=value1&name2=value2>

The first part (<http://www.mydomain.com/scripts/myIsapi.dll/PathInfo>) contains the usual information; the domain name, followed by the path to the ISAPI dll (or CGI), and then the PathInfo that specifies which action to invoke. Immediately after that is a **question mark** that signifies the start of the query data, or Fat URL. It is then followed by **Name=Value** pairs separated by ampersands.

In Delphi, the way you access these values is with the `Request.QueryFields.Values[ 'Name' ]` object which returns the value associated with a given Name.

Something to be aware of is that the web browser has to URL encode the data sent via the GET method. If you use a form to send the data with a GET method (as which is done in my example below), then you don't have to worry about anything. If you want to construct a Fat URL in code, you have to be sure to URL encode any possible Name and Value pairs. In Delphi, with the NetMaster's TNMURL component, this is a piece of cake. Here is an example:

```
function Encode(const str: string): string;
begin
    NMURL1.InputString := str;
    Result := NMURL1.Encode;
end;

var
    strFatURL: string;
begin
    strFatURL := 'http://MyMachine/scripts/MyIsapi.dll/Path?' +
        Encode('Query Name Is')
        + '=' +
        Encode('Corbin''s Tree House')
        + '&' +
        Encode('&Another Name')
        + '=' +
        Encode('Here"s The Result Value');
end;
```

Notice the small helper function "Encode" that encodes a given string with the TNMURL component and returns the encoded string. After execution, strFatURL contains: <http://MyMachine/scripts/MyIsapi.dll/Path?Query+Name+Is=Corbin%27s+Tree+House+%26Another+Name=Here%22s+The+Result+Value> which is a properly URL

encoded.

## Delphi Example

Now it is time to add some code to the Delphi example we have been working on. Add another action to your web module and give it a new PathInfo string, such as '/get' (since GET is the method which a Fat URL is invoked by).

```
procedure TWebModule1.WebModule1WebActionItem3Action(Sender: TObject;  
    Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);  
var  
    strVisitNum: string;  
begin  
    // Fat URL example (using the GET request method).  
  
    // When a web browser sends a Fat URL to the web server, you have  
    // to access the data sent via the Request.QueryFields, instead  
    // of the Request.ContentFields that are filled in with the POST  
    // method.  
  
    // First, check to see if the URL has any data sent in the Query  
    if Request.QueryFields.Count <= 0 then  
    begin  
        // Set the response to an HTML form with the GET method  
        Response.Content :=  
            '<form action="' +  
            Request.URL + Request.PathInfo +  
            '" method="get">' +  
            'Test saving state with Fat URL's!<br>' +  
            '<input type="submit" name="counter" value="1">' +  
            '</form></body></html>';  
    end  
    else  
    begin  
        // Inc the counter and send back the count number  
        try  
            strVisitNum := Request.QueryFields.Values['counter'];  
            strVisitNum := IntToStr(StrToInt(strVisitNum) + 1);  
        except // Eat exceptions (conversion exceptions)  
            strVisitNum := '1';  
        end;  
        Response.Content :=  
            '<form action="' +  
            Request.URL + Request.PathInfo +  
            '" method="get">' +  
            'Test saving state with Fat URL's!<br>' +  
            '<input type="submit" name="counter" value="' +
```

```
strVisitNum + '>' +  
'</form></body></html>';  
end;  
end;
```

You will probably notice that the URL becomes something like: <http://MyMachine/scripts/MyIsapi.dll/get?counter=23>, which means the user can very easily change the URL and the underlying request that is sent to the Web Application when a Fat URL is sent with the GET method. Of course, it is possible to do this with a POST method too, but it is more difficult because the user has to create an HTML form that sends the custom data to a Web Application.

This is just something to keep in mind. If you try to put [counter=1.123](http://MyMachine/scripts/MyIsapi.dll/get?counter=1.123) in the URL, and didn't catch the conversion exception like I do, your application would show an exception to the end user (which isn't very pretty).

You should now have a good understanding of how to save state in a Web Application.

## Advanced Web Applications

### Streaming Images from Web Applications

By Corbin Dunn

You may have had an instance when you wanted to stream a custom image out to a web page based on what the user selected. This document describes several different ways to store and send images to a web browser.

[Download this whole project.](#)

#### Sending a jpeg image from the hard drive

**This tutorial** was created with Delphi 5, but it should work fine with previous versions. You will need the Enterprise (or Client/Server) version of Delphi to create Web Applications.

#### Delphi Example

Create a new Web Application (File->New->Web Server Application, ISAPI DLL) and add a new Action. Set the PathInfo to `/motorcycle.jpg` and in the OnAction event add the following code:

```
procedure TWebModMain.WebModMainwbactnGetJpegAction(Sender: TObject;
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);

  // Helper function to get the current directory the DLL is in
function GetDllDir: string;
begin
  SetLength(Result, MAX_PATH+1); // Add 1 for the null character
  GetModuleFileName(hInstance, PChar(Result), MAX_PATH+1);
  SetLength(Result, Length(PChar(Result)));
  Result := ExtractFilePath(Result);
end;

var
  FileStream: TFileStream;
begin
  // This demonstrates returning a Jpeg file from a file on the hard drive.
  try
    FileStream := TFileStream.Create(GetDllDir + 'motorcycle.jpg', fmOpenRead);
    // Note that the file 'motorycle.jpg' must be in the same
    // directory as this DLL.
    FileStream.Position := 0; // Go to the start of the stream
    Response.ContentStream := FileStream;
    Response.ContentType := 'image/jpeg';
    Response.SendResponse;
    // Notice that the stream is not freed (it shouldn't be!)
  except // Catch all exceptions and show a custom message
    on E: Exception do
```

```

Response.Content := '<html><body>An error occurred ' +
  E.ClassName + ': ' + E.Message + '</body></html>';
end;
end;

```

---

The first thing you will see is the helper function `GetDllDir` that simply get's the current directory the DLL resides in. You will have to put the file '[motorcycle.jpg](#)' in the same directory as your ISAPI dll for this to work correctly.

Something to notice is how the whole function is wrapped in a `try..except` so that I can show a custom error message if something goes wrong. The `TFileStream.Create` can potentially raise an exception if the file passed to it doesn't exist or is locked.

Next, the `Response.ContentStream` is set to the `FileStream` we just created. Once you do this note that you **should not free the stream**. It is taken care of for you in the `TWebResponse` destructor.

Then the `Response.ContentType` is set based on what we are sending (a Jpeg in this case), and the `Response` is sent with `Response.SendResponse`.

One thing which you may want to do is send other file types. A problem you may encounter is what to set the `Response.ContentType` to. This can easily be solved in code by looking up the `ContentType` in the registry:

```

// MimeType is a string
Reg := TRegistry.Create;
try
  Reg.RootKey := HKEY_CLASSES_ROOT;
  if Reg.OpenKey(ExtractFileExt(FileName), False) then
    begin
      if Reg.ValueExists('Content Type') then
        MimeType := Reg.ReadString('Content Type');
      Reg.CloseKey;
    end;
  finally
    Reg.Free;
  end;

```

Of course, if the `ContentType` wasn't found, you will probably want to default to something such as 'text/plain' (plain text).

Another thing which you may be interested in doing is setting the "suggested file name" when a user goes to download a file by sending back a response other than an image. This can easily be done by adding a custom `Content-Disposition` header field:

```

Response.CustomHeaders.Add('Content-Disposition: ' +
  'filename="Suggested Name.ext"');

```

If you would like to know more about what you can do with the `Content-Disposition` header, take a look at the RFC: <http://www.w3.org/Protocols/rfc2616/rfc2616-sec19.html>

At one point I wanted to create an ISAPI dll that was completely self contained with its own images. All I had to output was a simple checked or unchecked image, so I decided a simple way to solve this problem was to put the GIF images in the resource portion of the DLL.

The first thing I did was to create a text file named "web\_gifs.rc". Inside it, I had the lines:

```
CHECKED GIF "checked.gif"  
UNCHECKED GIF "unchecked.gif"
```

The two gif files were in the same directory as the "web\_gifs.rc" file, and I compiled it into a resource file (.res) with a command line of:

```
brcc32 web_gifs.rc
```

For ease of use, I included a simple batch file that does this for you. I then added two new Actions to my project: one with a PathInfo of '/unchecked.gif' and another with a PathInfo of '/checked.gif'. I then created an OnAction event, and hooked them both to the same event with the following code in the event:

---

```
// Link the Gif's into the DLL resource section  
{$R web_gifs.RES}
```

```
procedure TWebModMain.WebModMainwbactnGetGifAction(Sender: TObject;  
  Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);  
var  
  ImageType: string;  
begin  
  try  
    // Two Web Actions are hooked up to this single OnAction.  
    // Based on which PathInfo is in the Action, we send the  
    // correct Gif image.  
    if (Sender as TWebActionItem).PathInfo = '/unchecked.gif' then  
      ImageType := 'UNCHECKED' // Resource name in .RES file  
    else  
      ImageType := 'CHECKED';  
    Response.ContentStream := TResourceStream.Create(hInstance, ImageType, 'GIF');  
    Response.ContentType := 'image/gif';  
    Response.SendResponse;  
  except  
    on E: Exception do  
      Response.Content := '<html><body>An error occurred ' +  
        E.ClassName + ': ' + E.Message + '</body></html>';  
  end;  
end;
```

---

Based on the previous example, this one should be very easy to understand.

The next challenge was to dynamically create a custom image at run-time and return it to the user. Conceptually, the way this will be done is to create a TBitmap, draw on that Bitmap's Canvas, and then save that Bitmap to a TJpegImage. The JpegImage can then be streamed out to the web browser as before.

---

### Delphi Example

I created another WebAction and set the PathInfo to '/custom.jpg'. The OnAction event is as follows:

```
procedure TWebModMain.WebModMainwbactnGetOnFlyAction(Sender: TObject;
Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
var
  Bitmap: TBitmap; // The unit Graphics must be in your uses clause
  JpegImage: TJpegImage; // The unit JPEG must be in your uses clause
  MemoryStream: TMemoryStream;
  I: Integer;
begin
  // This demonstrates creating a custom image on the fly,
  // converting it from a Bitmap to a Jpeg, and sending the
  // Jpeg to the browser.
  try
    Bitmap := TBitmap.Create;
    try
      // Draw some custom stuff on the bitmap
      Bitmap.Width := 300;
      Bitmap.Height := 300;
      for I := 0 to Bitmap.Height - 1 do
        begin
          // Add a little color
          Bitmap.Canvas.Pen.Color := Trunc(I/Bitmap.Height*255);
          Bitmap.Canvas.MoveTo(0, I);
          Bitmap.Canvas.LineTo(Bitmap.Width - 1, I);
        end;
      // Set the background mode to be transparent when writing text.
      SetBkMode(Bitmap.Canvas.Handle, TRANSPARENT);

      // Write a custom message based on some of the Request properties
      Bitmap.Canvas.Font.Color := clWhite;
      Bitmap.Canvas.TextOut(5, 5, 'Hello Host ' + Request.RemoteHost +
        ' (' + Request.RemoteAddr + ')');
      Bitmap.Canvas.TextOut(5, 30, 'You are using ' + Request.UserAgent);
      Bitmap.Canvas.TextOut(5, 55, 'The date/time is ' + DateTimeToStr(Now));

      JpegImage := TJPEGImage.Create;
      try
        // Assign the Bitmap to the Jpeg
        JpegImage.Assign(Bitmap);
        MemoryStream := TMemoryStream.Create;
        JpegImage.SaveToStream(MemoryStream);
        MemoryStream.Position := 0;
        Response.ContentStream := MemoryStream;
        Response.ContentType := 'image/jpeg';
        Response.SendResponse;
```

```

    finally
        JpegImage.Free;
    end;
finally
    Bitmap.Free;
end;
except
    on E: Exception do
        Response.Content := '<html><body>An error occurred ' +
            E.ClassName + ': ' + E.Message + '</body></html>';
    end;
end;

```

---

A new thing to notice in this example is the saving the Jpeg to a TMemoryStream. The Jpeg and Bitmap can safely be freed, but the MemoryStream is automatically freed for you in the TWebResponse's destructor.

## Putting it all together

When you want to display any of the images, all you have to do is type in the path to the DLL and add the right PathInfo. More commonly, you will probably embed it into an <IMG> tag, such as: 

The last thing to do in this example is to put it all together. I created one more action and set the Default property to True. In the OnAction event I added the following code:

```

procedure TWebModMain.WebModMainwbactnDefaultAction(Sender: TObject;
    Request: TWebRequest; Response: TWebResponse; var Handled: Boolean);
begin
    // Default action, display several different images
    // that were streamed out by the ISAPI dll
    Response.Content := '<html><body>' + #10#13 +
        '<h2>Below are some images sent out from this Web Application</h2>' +
        '<b>Here is a Gif that was streamed out from a resource inside ' +
        'the Dll: checked  and unchecked: ' +
        '<br><br>' +
        'Here is a Jpeg that was loaded from a file:<br>' +
        '<br><br>' +
        'Here is a custom image created on the fly:<br>' +
        '' +
        '</b></body></html>';
end;

```

## Article #20385: How can I install Delphi on a Micron computer?

### How can I install Delphi on a Micron computer?

It seems that the proprietary OS that is shipped with Micron conflicts with Delphi as well as some of the hardware drivers. Compiled here are a number of solutions that seem to resolve the issue.

1. Uninstall/Reinstall: Make sure that any directories and/or registry keys that refer to Delphi have been removed during the uninstall process. Before reinstalling, disable all software running in the background i.e. anti-virus applications. If using Win98, it is a good idea to turn down the Hardware Acceleration to none before reinstalling. If using Win95 boot into safe-mode when reinstalling, and for WinNT 4.x boot into VGA-mode.
2. Hard drive install: Copy the Runimage and Install directories from the Delphi CD to the root of your hard drive. Next, copy all the loose files at the root of the CD to the root of your hard drive. Make sure that the Runimage and Install directories are the same size as the ones on the CD. After everything is copied over, but before you install, read the above Uninstall/Reinstall section.
3. If you are using a proprietary OS from Micron, and reinstalling a non-proprietary OS is out of the question, make sure you have all the latest updates. Especially for the CD-ROM, video card drivers and system files. The Micron web-site has a number of drivers, however you should go to the video card/CD-ROM vendors sites first. You may need to go to the Microsoft site also. Once you have all the updates and drivers you may need to delete the old drivers and reboot so the OS auto-detects the latest drivers for you.
4. Network: If you have access to other non-Micron computers over a network you may need to install from one of those machines. There are a few ways of doing this. Using the non-Micron's CD-ROM, run the setup.exe from the non-micron computer and choose a directory on the Micron computer to install into. Or Map a drive to the non-micron's CD-ROM and install from there. Or use the same procedure as a hard drive install using the non-micron's hard drive. Then map a drive to where you copied over the files and install from there.
5. Reinstalling a non-proprietary version of your OS. This is a worst case last effort scenario, but it has been a solution when none of the above worked.

## Article #20450: Adding TextCompletion to a TComboBox

### Adding text completion to a TComboBox

The Netscape Communicator location box, The Windows 98 'Run' dialog, and other programs, have implemented a very user friendly feature known commonly as text completion. This document describes how to add similar functionality to a TComboBox. The most elegant and reusable way to add this functionality is by descending from TComboBox and overriding the ComboWndProc to handle the WM\_KEYUP message. By adding a new property 'TextCompletion', the functionality can be toggled to act like a regular TComboBox. Below is the component unit that implements text completion in a TComboBox. This unit can be installed as is.

```
unit CompletingComboBox;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms, Dialogs,
  StdCtrls;

type
  TCompletingComboBox = class(TComboBox)
  private
    FTextCompletion: Boolean;
    function GetTextCompletion: Boolean;
    procedure SetTextCompletion(const Value: Boolean);
  protected
    // override the WndProc() so that we can trap KeyUp events.
    procedure ComboWndProc(var Message: TMessage; ComboWnd: HWND;
      ComboProc: Pointer); override;
  public
    { Public declarations }
  published
    property TextCompletion: Boolean read GetTextCompletion write SetTextCompletion;
  end;

procedure Register;

implementation

procedure Register;
begin
  RegisterComponents('Standard', [TCompletingComboBox]);
end;

{ TCompletingComboBox }

function TCompletingComboBox.GetTextCompletion: Boolean;
begin
  Result := fTextCompletion;
end;
```

```

procedure TCompletingComboBox.SetTextCompletion(const Value: Boolean);
begin
    fTextCompletion := Value;
end;

procedure TCompletingComboBox.ComboWndProc(var Message: TMessage; ComboWnd: HWND;
    ComboProc: Pointer);
var
    rc, len: Integer;
begin
    inherited;
    case Message.Msg of
        WM_KEYUP:
            begin
                // test to see if its a character that should not be processed.
                if (Message.WParam <> 8) and (Message.WParam <> VK_DELETE) and
                    (Message.WParam <> VK_SHIFT) and (fTextCompletion = True) then
                    begin
                        // Use CB_FINDSTRING to locate the string in the Items property
                        rc := Perform(CB_FINDSTRING, -1, Integer(PChar(Caption)));
                        // if its in there then add the new string to the Text and
                        // select the portion that wasn't typed in by the user
                        if rc <> CB_ERR then
                            begin
                                // store the length of the current string
                                len := Length(Text);

                                // set the new string
                                ItemIndex := rc;

                                // highlight the rest of the text that was added.
                                SelStart := len;
                                SelLength := Length(Text) - len;

                                // return 0 to signify that the message has been handled.
                                Message.Result := 0;
                            end;
                        end;
                    end;
            end; // case
    end;
end.

```

## Advanced Web Applications

### Redirecting a request to another URL or HTML page

By Corbin Dunn

[Download the entire Delphi 5 project for this document.](#)

At some point, you may want to redirect a user request to another URL or HTML page on your server. This is quite easy to do with the following code inside your `OnAction` event:

```
Response.SendRedirect('http://www.borland.com');
```

One question that you may ask is exactly what this does. The easiest way to find out is to look at the full headers that the server returns:

```
HTTP/1.1 302 Object Moved
Location: http://www.borland.com
Server: Microsoft-IIS/5.0
Content-Type: text/html
Content-Length: 145
```

```
<head><title>Document Moved</title></head>
<body><h1>Object Moved</h1>
This document may be found
<a HREF="http://www.borland.com">here</a></body>
```

But how did I produce this output? It is easy to "spy" on the headers returned by a webserver by simulating a GET request just like a web browser would make:

### Simulating an HTTP GET request

Click on the Start button, and go to Run. Type in:

```
telnet support.microsoft.com 80
```

This will open up a connection to support.microsoft.com on the standard HTTP port (80), and you will see a blank telnet window.

Carefully type the following in the telnet window, noting the case:

```
GET / HTTP/1.0
```

Note that what you are typing will not be echoed back to you, so be sure to type carefully.

After you type in the request, press return twice to send the request.

Effectively, a break down what you are doing is this:

- **GET** - This is the request type. GET is the most common, and is used for getting standard web pages and images. POST is another common request type used for posting data to a web server.
- **/** - The next thing you type is a slash. This is the relative document that you want on the server. "/" means the default document. You could have easily typed something else, such as "/a\_directory/a\_file.html".
- **HTTP/1.0** - This is the HTTP version that your "browser" supports. 1.0 is the lowest, and will always work. 1.1 is also becoming a standard, but some servers may not support HTTP/1.1. You can look at the first line of the response to see what version they do support.
- **Two returns** - Two returns are used to send the request. Two are needed because some requests may span multiple lines, and the server waits for a blank line followed by another return before executing the request.

After you press the two returns, you should get some content back, such as the response headers and requested file.

The thing that we are interested in looking at is the response code:

```
HTTP/1.1 302 Object Moved
```

The first part tells us what version of HTTP that the server supports (1.1 in this case). The second part is the response code, and the third part is a server defined response message for that code.

To find out exactly what each response code means, and when you should give it, you can look at the HTTP RFC (Request For Comments): <http://www.w3.org/Protocols/rfc2068/rfc2068>

From that document, we can see that 302 means:

```
302 Found
```

```
The requested resource resides temporarily under a different URI.  
Since the redirection might be altered on occasion, the client SHOULD
```

continue to use the Request-URI for future requests. This response is only cacheable if indicated by a Cache-Control or Expires header field.

...

In other words, you should use a response of 302 when you want to redirect the user to another URL, but don't want them to have to change the link that they came from. All the proper headers are set up for you when you use:

```
Response.SendRedirect('http://www.borland.com');
```

If you want to inform the web browser that the URL has been permanently moved, you need to send a response code 301:

### 301 Moved Permanently

The requested resource has been assigned a new permanent URI and any future references to this resource SHOULD use one of the returned URIs. Clients with link editing capabilities ought to automatically re-link references to the Request-URI to one or more of the new references returned by the server, where possible. This response is cacheable unless indicated otherwise.

The new permanent URI SHOULD be given by the Location field in the response. ...

The reason for doing this is because some search engines will see a 301 response, and will update their database with the new link (since it was moved permanently, not temporarily like a 302 indicates).

Now, Delphi doesn't have an automatic way of sending a 301 Response, so we have to manually do it:

#### Sending a custom response and code

```
// This action is going to send the web browser a 301 code indicating  
// a permanent move to a new URL.  
Response.ReasonString := 'Moved Permanently';  
Response.StatusCode := 301;  
// Location is the permanent new location; add it as a custom header  
Response.CustomHeaders.Values['Location'] :=  
    'http://www.borland.com';  
Handled := True;
```

That's it! You should be able to easily extend this to send any custom response code and message.

## Article #20901: Debugging an ISAPI DLL with Delphi under NT 4.0 for IIS version 4

# How to debug an ISAPI DLL with Delphi under NT 4.0 with IIS version 4

1. Make sure that the user name you use to do all your developing with for WinNT, has Administrator rights. You need to add some settings to the user, and in order to do so the user must have Administrator rights.
2. Run the User manager for the user that is going to do the debugging. Start | Programs | Administrative Tools (Common) | User Manager. On the Menu bar select Policies | User Rights. Make sure the Show Advanced User Rights box is checked. Hit the down arrow and scroll through the listing of the different Rights, you should see what you need to add.

Give this user the following permissions:

Log on as a Service  
Act as part of the operating system  
Generate security audits

3. You will need IIS to run as a process instead of a service. To do this run the registry file labeled: Regproc.reg. This file will make the necessary changes to you registry that makes IIS run as a process. The other registry file: Regserv.reg, will undo the changes made by the previous registry file.

Run as a Process: Regproc.reg (to be able to debug run this one)

Run as a Service: Regserv.reg (this will undo the previous reg setting)

4. Now stop these services and set them to manual: WWW publishing service, FTP Service and IIS Admin.
5. Restart your computer.
6. Open Delphi and from the menu bar, select Project | Options -> Linker and select Use Include remote debugger symbols option.
7. Now in Delphi, open the DLL project and use the following parameters:

Run: C:\Winnt\system32\inetsrv\inetinfo.exe  
Parameters: -e w3svc

## Article #21772: Deploying a Delphi/VisiBroker Application

This article discusses the process of deploying a Delphi application that uses CORBA. Often there is confusion over what part Delphi plays versus what part VisiBroker plays, and exactly what is needed from each. This document will attempt to clarify this.

Deploying a Delphi/CORBA app is not an exact science. Much depends on what components you are using, and what files already exist on the deployment machine. For the purpose of this article it is assumed you are deploying to a machine which contains Windows NT and nothing else. It is also assumed that you know how to create a Delphi CORBA application, and how to deploy a basic Delphi application without CORBA. When deploying a Delphi application you must use a Borland certified deployment utility such as InstallShield Express. Using this utility helps insure that the Delphi files your application needs are included in your deployment.

### Background Information

VisiBroker for Delphi uses the VisiBroker C++ ORB. The C++ ORB has been encapsulated with Delphi code. This code is contained in the library orbpas50.dll. This approach provides the Delphi community with a fast and stable industry-standard ORB and avoids the need to develop and maintain a new ORB from scratch.

Applications built with VisiBroker for Delphi require both the VisiBroker for Delphi runtime and the VisiBroker for C++ runtime. Orbpas50.dll is a Delphi wrapper around the C++ VisiBroker run time DLL (orb\_br.dll). The CORBA objects are created in the C++ ORB in the same way as they would be for a pure C++ client and a proxy for the object is maintained on the Delphi side. When a method is invoked on the proxy from a Delphi executable the proxy in turn invokes the same method on the C++ object.

### Deployment

One of the mysteries surrounding Delphi/VisiBroker deployment is who is responsible for providing what? VisiBroker states that the components necessary to deploy a VisiBroker application are a subset of their full development kit. The software associated with a deployment license is already a part of the development kit. That's fine if you are purchasing VisiBroker separately as a product, but what if you have purchased Delphi 5 Enterprise which comes with all the VisiBroker stuff you need to create and deploy an application? In this case you must still purchase a VisiBroker license, but not the development kit. They do not provide much information in their documentation on Visibroker redistribution, partly because there is no general answer. Deployment questions depend on the application and what you need to deploy. So even though you are paying for the VisiBroker license you will be getting everything else you need from Delphi.

Your deployment needs to include whatever is required to run your application. For a client, this usually involves the application executables plus the orb library (orb\_br.dll plus orbpas50.dll and cp3245mt.dll – See table below). For a server, it includes the server applications, orb library, and

optionally an osagent, OAD, and IREP servers. Osagent, OAD and IREP do not necessarily need to be running on the server, but can be running anywhere on the network where they are visible to the application. If an Object Activation Daemon (OAD) is installed then the implementation repository should be initialized using the oadutil tool. Oadutil and irep require a java vm also (this will already exist on a machine with Delphi 5). Details of OAD are not covered in this document.

VisiBroker can be installed from the Delphi CD by doing a custom install or the necessary files can be included with your deployment (see Environment below for registry settings). The default location for these files on your development machine is C:\Program Files\Borland\vbroker. For development and testing purposes a VisiBroker license is not needed. For your "real world" applications you will need to acquire a VisiBroker deployment license from Inprise. VisiBroker is licensed using a server-based licensing scheme so developing VisiBroker for Delphi applications that integrate with existing applications for which you already have a license may not require additional licenses. Consult your VisiBroker license for complete details. Also note that if you have a multi-tier MIDAS application you will also need to purchase MIDAS licenses for each MIDAS server you deploy [[more info](#)].

## Deployment summary

File Name	Client	Server	Default location (Delphi 5 installation)	Comments
orbpas50.dll	X	X	C:\Program Files\Borland\Delphi5\Bin	Delphi 5 CORBA layer.
orbpas33.dll	X	X	C:\Program Files\Borland\Delphi5\Bin	This file is not required for all deployments. It comes with the <u>Visibroker 3.3 for Delphi update</u> . Provides additional functionality and works in conjunction with existing DLLs.
cp3245mt.dll	X	X	C:\Program Files\Borland\Delphi5\Bin	C++ Builder Runtime Library.
borlndmm.dll	X	X	C:\Program Files\Borland\Delphi5\Bin	Used by cp3245mt.dll and orbpas50.dll.
orb_br.dll	X	X	C:\Program Files\Borland\vbroker\Bin.	VisiBroker runtime Library.
OSAGENT		X	C:\Program Files\Borland\vbroker\Bin	One copy needs to be running per network.
IREP		X	C:\Program Files\Borland\vbroker\Bin	One per network – optional.
OAD		X	C:\Program Files\Borland\vbroker\Bin	One per network – optional.

## Environment

Here is environment information that should be used in your deployment. This is what the installer does to the environment and to the Windows Registry during installation of VisiBroker for Delphi.

The following environment variable is modified (if the user approves):

PATH=<vbroker installation root>bin;%path%

### Windows Registry Settings

HKEY\_LOCAL\_MACHINE\SOFTWARE\Visigenic Software Inc\VisiBroker3.0

OSAGENT\_PORT=14000 (default)

Pathname=<vbroker installation root>

vbc="" (used during uninstall)

vbj="" (used during uninstall)

VBROKER\_ADM=<vbroker installation root>adm

VisiBroker Developer for Java 3.0 key=

### NT Services - OSAgent

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\services\osagent

DisplayName "VisiBroker Smart Agent"

ImagePath "<vbroker installation root>\bin\osagent.exe"

ObjectName "Domain Nameusername"

### NT Services - OAD

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\services\load

Display Name "VisiBroker Activation Daemon"

ImagePath "<vbroker installation root>\bin\load.exe"

ObjectName "Domain Nameusername"

The NT Service installation is done using dlls( register.dll ) packaged with the installer.

The Services are installed with SERVICE\_ALL\_ACCESS, SERVICE\_INTERACTIVE\_PROCESS | SERVICE\_WIN32\_OWN\_PROCESS, SERVICE\_DEMAND\_START and SERVICE\_ERROR\_CRITICAL flags to CreateService.

The services run under LocalSystem account.

## Troubleshooting

Error "NO\_IMPLEMENT"

This means the client app cannot find the server and could be caused by a multitude of reasons.

Run OSFIND.EXE. If you don't see your server listed you are not set up correctly.

Other options:

- \* Is the DOS path correct
- \* Are all DLLs present on correct machines (see table)?

## Article #22507: Problems comparing floating point numbers.

Because of the way floating point numbers are represented by the computer there can be inconsistencies when comparing two numbers that appear to be identical. Unlike integers, IEEE floating point numbers are only approximates, not exact numbers. The need to convert the numbers to a form the computer can store in binary leads to minor precision or round-off deviations. For example 1.3 may really be represented as 1.299999999999.

There may particularly be problems when using conversion functions such as `StrToFloat`, `TextToFloat` and `StrToCurr`. Therefore you should never use `=` or `<>` to compare two floating point numbers. Instead, subtract the two numbers and compare them against a very small number.

Example:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  f1, f2 : double;
begin
  f1 := 1.3000000;
  f2 := 1.2999999;
  if abs(f1-f2) < 0.00001
  then ShowMessage('f1 and f2 are equal')
  else ShowMessage('f1 and f2 are not equal');
end;
```

## Article #23024: How to debug ISAPI DLL's on Windows 2000 with IIS5

### How to debug ISAPI DLL's on Windows 2000 with IIS 5

by Corbin Dunn

1. In the "Administrative Tools" portion of the "Control Panel", start the "Internet Services Manager." Right click on your website and select "Properties":

2. On the "Home Directory" tab, set "Application Protection" to "Low (IIS Process)":

## IIS Process

This causes IIS load ISAPI DLL's inside of its process, allowing you to debug them. Close this dialog, but not the IIS Manager program.

3. Expand your website and right click on the "Scripts" virtual directory (or, whatever directory your ISAPI DLL's will be put into). Again, set the "Application Protection" to "Low (IIS Process)" for the virtual directory (similar to step 2).

**Important - if you don't do this you will probably not be able to load your ISAPI DLL.** You can now close the IIS Manager.

4. In the "Administrative Tools" portion of the "Control Panel" select click on the "Services" and for each of the following services, make sure that they are "Stopped" and that the "Startup Type" is set to Manual:

- Simple Mail Transport Protocol (SMTP)
- World Wide Web Publishing Service
- FTP Publishing Service
- IIS Admin Service

Close the Services Window.

**If after you reboot the IIS Admin Service has started, then try making the Startup Type be Disabled - then reboot and make sure that it has not started. If it has, you won't be able to debug.**

5. Run "Local Security Policy" from the "Administrative Tools" folder. Expand "Local Policies", and then click on "User Rights Assignment". In the right hand panel, you should see "Act as part of the operating system". Double click on it, and select "Add..." to add a user to the list. Add your current user to the list that you intend to debug with (for example, I added the user cdunn, which is my main login to my Windows 2000 machine). Close this window after adding the user.

Set OS stuff

6. Reboot to make the previous step take effect.

7. Merge the file IISProcess.reg to merge the proper registry settings that make IIS run as a process on your system (so you can debug). Important: If you installed IIS into somewhere other than the default directory, you will have to modify this file. The default location is: C:\WinNT\system32\inetsrv". Use IISService.reg to set the registry settings back as a service.

*NOTE:* These files are on code central as a zip file, but, if you download them individually, you will have to rename the downloaded file to the right name. It may prompt you to name it "getfile.reg", but rename this to "IISService.reg" or "IISProcess.reg".

---

### **In Delphi:**

1. In your ISAPI DLL project, go to the "Project Options" and on the "Directories/Conditionals" tab, set the "Output directory" to be "C:\Inetpub\Scripts" or whatever directory you put your ISAPI dll's in. Also, make sure you have all debugging information turned on.

2. Select Run->Parameters from the IDE menu. Set the Host Application to be: "c:\winnt\system32\inetsrv\inetinfo.exe" (without the quotes - assuming this is where you installed IIS). Set the Parameters to be "-e w3svc" (without the quotes).

3. You should now be able to select "Run" and have Delphi start in debug mode. Put a breakpoint somewhere in your source code. Now, using a web browser, browse to your ISAPI DLL (such as http://localhost/scripts/project1.dll), and it should stop on the breakpoint.

4. Use Ctrl-F2 to stop the web server and end a debugging session.

---

### **Trouble shooting**

If you get an error about: *"A required privilege is not held by the client."* then you probably haven't done step 3, or you are trying to debug in a scripts directory that hasn't had step 3 done on it. Or, you have not rebooted at some point.

If the debugger starts and stops right away, then you probably have inetinfo.exe running. Run the Task Manager and look

for inetinfo.exe running. Try to kill it. If you can't it is currently running as a service. Try shutting it down in the services. If it is stuck on "Starting" the service, then run IISService.reg and reboot. After rebooting, stop the service. Then run IISProcess.reg and try debugging.

When releasing your ISAPI DLL application, be sure to undo what you did in these steps to not hinder performance on your DLL.

## Article #26048: Problems using dcomcnfg to configure ActiveX library objects (DLLs).

Issues relating to configuring DCOM for ActiveX Library objects.

### Description of problem:

After successfully building and registering the server object DLL (e.g. ActiveX Library with Automation object), the Client application produces a 'Class not found' error message when attempting a remote DCOM connection using CreateRemote(). Server applications created as executables (e.g. Application with Automation object) do not appear to have this problem.

The crux of this issue is that, in order to make DCOM work, the COM object must be properly configured using an external utility. Unfortunately, the default utility for configuring DCOM (dcomcnfg.exe) does not seem to *reliably* locate COM library objects (DLLs), but is only able to find COM executable object (EXE). Furthermore, even when it does display the library, there seems to be no way from within the utility to configure the object to make it work. The reason for this is because the dcomcnfg utility does not allow specification of a surrogate process to host the DLL object for the Inproc Server.

The workaround is to download and install OLEview (free):

<http://www.microsoft.com/com/resources/oleview.asp>

Now, the critical step is specifying that the implementation utilize a surrogate process for hosting the DLL. This may be done in the following way:

1. Register the DLL using regsvr32
2. Run OLEview.
3. In the left panel, expand 'All Objects,' and select your server object.
4. In the right panel, select the 'Implementation' tab.
5. Then select the sub-tab 'Inproc Server'
6. Check 'Use Surrogate Process'

This may need to be done on each computer that will be hosting the server. You will also need to register the DLL on each system before you can use the Client application. Finally, if you receive errors regarding access rights, you may need to specify 'Launch Permissions' and 'Access Permissions' in OLEview.

**Article #26277: Creating transparent windows**

**Creating Transparent Windows**  
*And moving around the children on that window*  
**by Corbin Dunn**

[Download the sample source code and project for this article.](#)

You may have seen some windows that have transparent portions, and wonder how you can do that in Delphi. It is quite easy, and there are several different ways to achieve the affect such as below:

The first way you could go about this is by adding the `WS_EX_TRANSPARENT` style to your window. This will work, but it will not have all the desired effects, and Microsoft recommends using the

WS\_EX\_TRANSPARENT style for modal windows that have a short life.

The second way of doing this is with Windows 2000's new Layered Windows feature. However, doing this will limit your application to only run on Windows 2000.

The third approach is the one chosen in this article. You can use the Windows API call SetWindowRgn to specify the exact portion of the window that you want seen. One of the tough parts is creating a region that contains all child windows that you want seen. The solution is to go through all visible Controls on the form, and create one gigantic region that combines all these small regions. Here is how to do this:

```
procedure TForm1.SetRegions;
var
  I: Integer;
  RgnAll, RgnCtrl: HRGN;
begin
  RgnAll := 0;
  for I := 0 to ControlCount - 1 do
  begin
    with Controls[I] do
    begin
      if Visible then
      begin
        // Create a region for each given visible control
        RgnCtrl := CreateRectRgn(Left, Top, Left + Width, Top +
Height);
        // Combine the region with all previous ones, if available
        if (RgnCtrl <> 0) and (RgnAll <> 0) then
        begin
          CombineRgn(RgnAll, RgnAll, RgnCtrl, RGN_OR);
          DeleteObject(RgnCtrl);
        end
        else
          RgnAll := RgnCtrl; // This is the first region being created
        end;
      end;
    end;
  // Now, set the RgnAll as what we see for the Window
  if RgnAll <> 0 then
  begin
    (*
    From SetWindowRgn in the help file:
    "After a successful call to SetWindowRgn,
    the operating system owns the region specified
    by the region handle hRgn. The operating system
    does not make a copy of the region. Thus, you
```

*should not make any further function calls with this region handle. In particular, do not close this region handle."*

*So don't call DeleteObject on RgnAll after using it for SetWindowRgn (thanks to Richard Albury for pointing this out!) A previous version of this article made this mistake.*

```
*)  
SetWindowRgn(Handle, RgnAll, True);  
end;  
end;
```

Note how I call DeleteObject after I was finished using the region. Not doing this will cause resource leaks on Windows. I use the API CreateRectRgn, but if you have a different shape you can use CreatePolygonRgn to customize the exact shape of the Window or Control.

One problem that you may encounter deals with moving controls on the form. If you programatically move the control (such as in an OnMouseMove event), the area behind the control will be out of the view of the control. Also, the control may not be properly painted while it is being moved. There is a simple solution for this: call SetRegions again to update the new visible area of the form, and force a repaint of the control with a call to Control.Repaint, such as below:

```
procedure TForm1.GenericMouseMove(Sender: TObject; Shift:  
TShiftState; X,  
Y: Integer);  
begin  
  // If the control wasn't moved, then exit right away  
  if (X - LastX = 0) and (Y - LastY = 0) then Exit;  
  // Move the control  
  with (Sender as TControl) do  
    begin  
      Left := Left + (X - LastX);  
      Top := Top + (Y - LastY);  
    end;  
    SetRegions;  
    (Sender as TControl).Repaint;  
end;
```

You should now be able to add transparent windows to your application. [Download the sample source code and project.](#)

## Article #26418: Creating a Web Search Wizard using the OpenTools API.

### Creating a Web Search Wizard for Delphi

By [Corbin Dunn](#)

Delphi Developer Support

Allen Bauer has written three articles for the OpenTools API with the [most recent](#) giving us some ideas on how to create a dockable IDE form. One thing that he didn't go into was how to get an expert or wizard to remember its position and state. This article goes through how I created a Web Search Expert for Delphi 5 that remembers its current position and state in the Desktop Speedsetting.

First of all, [download the complete project](#) so we are on the same playing field. I strongly recommend reading [Allen Bauer's article](#) to see how I started the project, but this isn't necessary. The key in his article is how to derive from an internal IDE form by adding DsnIDE50.dcp to the requires list of the package. After you have downloaded the source, open up the package SearchWiz.dpk.

Now, take a look at the unit SearchWizMnu. This is your normal registration unit that adds a menu item

named "Web search..." to the Delphi IDE's Help menu. One of the new things to notice is in the Register procedure I call RegisterFieldAddress passing two parameters: a string that is the SearchWizForm's ini file section (which is 'SearchWizard' in this case), and the actual address of the SearchWizForm variable:

```
procedure Register;  
begin  
    if Assigned(RegisterFieldAddress) then  
        RegisterFieldAddress(CIniSection, @SearchWizForm);  
    ...  
end;
```

Whenever a desktop is loaded, the IDE checks to see if the SearchWizForm is to be created and shown. To see how this is done, open up a .dst file. These files contain your desktop speedsettings and are located in your Delphi5\bin directory. If you don't have any, then save your desktop as something. As an example, I have a speed setting named Corbin's, so I opened up Corbin's.dst. Looking into it, I see the ini file section for my search expert (you won't see this until you have installed the Search Wizard):

```
[SearchWizard]  
Create=1  
Visible=1  
State=0  
Left=260  
Top=116  
Width=213  
Height=481  
MaxLeft=-1  
MaxTop=-1  
ClientWidth=205  
ClientHeight=457  
TBDockHeight=481  
LRDockWidth=140  
Dockable=1  
Last Query=Corbin's treehouse  
Last Search Engine=Borland Community  
Use Same Window=1  
WebBrowser Showing=1
```

Whenever I start Delphi it sees Create=1 in the ini section of my SearchWizard and automatically creates an instance of the Wizard in the SearchWizForm variable (if it is nil - this way it doesn't create multiple instances of the same form). But how does Delphi know what class type to create? Well, that is what the next line is for:

```
RegisterDesktopFormClass(TSearchWizForm, CIniSection, CIniSection);
```

```
RegisterPackageWizard(TSearchWizard.Create);
```

The call to RegisterDesktopFormClass set's TSearchWizForm as the class type to create when it reads the CIniSection and determines it should create it. RegisterPackageWizard is simply used to register my Wizard with the IDE. Finally, notice how in the finalization section of the unit I call UnRegisterFieldAddress and free my SearchWizForm variable.

### **finalization**

```
if Assigned(UnRegisterFieldAddress) then
  UnRegisterFieldAddress(@SearchWizForm);

if SearchWizForm <> nil then
begin
  SearchWizForm.Free;
  SearchWizForm := nil;
end;
```

If we don't do this, then you may get access violations and make the IDE unstable. All these functions are in DeskUtil.pas, which is inside of the IDE. If you want to see the stub for this file, [download](#) Allen's example.

Next, we want to open up the main form unit, SearchWizFrm.pas, but it uses some internal IDE forms that I got from Allen's example, and if we open up SearchWizFrm.pas it will complain about not finding the base classes. The trick here is to open up DeskForm.pas, then DockForm.pas, and finally SearchWizFrm.pas. To get my Search Wizard to remember its position and data, I overrode LoadWindowState and SaveWindowState (both of which are in TDesktopForm). In SaveWindowState we are passed a TMemIniFile from which I write my settings to. By first calling inherited SaveWindowState, TDesktopForm saves the current position and visible properties.

```
procedure TSearchWizForm.SaveWindowState(Desktop: TMemIniFile;
  isProject: Boolean);
var
  I: Integer;
begin
  inherited SaveWindowState(Desktop, IsProject);
  if SaveStateNecessary and (Desktop <> nil) then
  begin
    Desktop.WriteString(CIniSection, CIniLastSearchQuery, cmbxQuery.
Text);
    with cmbxEngines do
      Desktop.WriteString(CIniSection, CIniLastSearchEngine, Items
[ItemIndex]);
    Desktop.EraseSection(CIniSavedQueries);
    if IsProject then
```

```

    for I := 0 to cmbxQuery.Items.Count - 1 do
        Desktop.WriteString(CIniSavedQueries, IntToStr(I), cmbxQuery.
Items[I]);
        Desktop.WriteBool(CIniSection, CIniUseSameWindow, FUseSameWindow);
        Desktop.WriteBool(CIniSection, CIniWebBrowserShowing,
FWebBrowserShowing);
    end;
end;

```

Notice the variable IsProject that tells if this is a project's desktop settings (.dsk file) that is being saved. Finally, LoadWindowState does the reverse, loading in all my custom information (such as saved search engines and queries):

```

procedure TSearchWizForm.LoadWindowState(Desktop: TMemIniFile);
var
    TempList: TStringList;
    I: Integer;
begin
    inherited LoadWindowState(Desktop);

    if Desktop <> nil then
    begin
        cmbxQuery.Text := Desktop.ReadString(CIniSection,
CIniLastSearchQuery, '');
        if FSearchEngineList.IndexOfName(Desktop.ReadString(CIniSection,
CIniLastSearchEngine, '')) >= 0 then
            cmbxEngines.ItemIndex :=
                FSearchEngineList.IndexOfName(Desktop.ReadString(CIniSection,
CIniLastSearchEngine, ''));
        ...
    end;

```

After all this code was in place, one of the biggest problems that I had was getting my Search Wizard to show up when it was left open from a previous desktop. I could see my IniSection in the a project's .dsk file, but it wasn't getting shown (.dsk files are your project's current desktop) This is because I have a custom SpeedSetting that I use, and the speed setting was being set before my Search Wizard ever existed. So, after hitting "View->Desktops->Save Desktop" and saving my desktop, the Search Wizard would open when I started Delphi (or switch to that desktop).

The next thing that you will want to do is install this Wizard into the IDE. It should be as simple as clicking "Install Package" in the Package Editor window. You will notice that the usual Project->Compile (F9) option will not work because a lot of the internal code is running in the IDE. This is normal, and also makes debugging really difficult. The easiest way to do it is to place ShowMessage calls inside of function calls to see where your program is at. Or, you could log things to a file.

Once again, feel free to download the source code for this project. Open up SearchWiz.dpk and click "Install Package". Then, select "Help->Web Search..." and save your desktop if you want it to remember the wizard being open!

If you find any problems with the source code, please let me know! I also wouldn't mind getting any updates you make to enhance the Wizard...

## Article #26531: Automating Internet Explorer to POST Form Data

### Automating Internet Explorer to POST Form Data

By [Corbin Dunn](#)

Delphi Developer Support

This document is based on an example from the MSDN: [HOWTO: Automate Internet Explorer to POST Form Data](#). It shows the Delphi way of POSTing form data.

It is easy to automate Internet Explorer (IE) to send data using the POST method to any web server. This example illustrates automation of Internet Explorer (TWebBrowser) while it is embedded inside of the application, but it could easily be not shown and hidden from the user.

Internet Explorer versions 3.0, 3.01, and 3.02 do not support posting data to an HTTP server via the Navigate method. WinInet and URL Monikers are two possible alternatives. For more information on WinInet and Monikers, visit these articles on the MSDN: [Q165298 - HOWTO: Simulate a Form POST Request Using WinInet](#) and [Q165800 - SAMPLE: Using a URL Moniker to POST Data](#).

To test the example below, the following Active Server Page (ASP) should be saved to the file navpost.asp in a directory on Windows NT 4 or 2000 machine running at least Internet Information Server (IIS) version 3.0. The directory should be recognized by IIS as a virtual root with execute permission:

```
<HTML>
<%
cFlavor = Request("Flavor")
cName = Request("FName")
%>
<BODY>
Hello, <% =cName %>. <br>
One scoop of <% =cFlavor %> coming right up!
</BODY>
</HTML>
```

1. Create a new application with Delphi
2. Add two TLabel's, a TEdit, TComboBox, TWebBrowser and a TButton to the form with names and a layout similar to what is shown below:

## Form Screen Shot

In the TComboBox, add several flavors to the Items.

3. Under the implementation section of the form, add "uses HTTPApp;". HTTPApp contains the HTTPEncode function used to url-encode strings.

4. Double click on the TButton and add the following code to the OnClick event handler (I named my button btnSubmit):

```
procedure TForm1.btnSubmitClick(Sender: TObject);  
var  
    EncodedDataString: string;  
    PostData: OleVariant;  
    Headers: OleVariant;  
    I: Integer;  
begin  
    // First, create a URL encoded string of the data  
    EncodedDataString := 'FName=' + HTTPEncode(edtFirstName.Text) + '&' +  
        'Flavor=' + HttpEncode(cmbxFlavor.Text);  
    // The PostData OleVariant needs to be an array of bytes as large  
    // as the string (minus the NULL terminator)  
    PostData := VarArrayCreate([0, Length(EncodedDataString) - 1],  
varByte);  
    // Now, move the Ordinal value of the character into the PostData  
array  
    for I := 1 to Length(EncodedDataString) do
```

```
    postData[I-1] := Ord(EncodedDataString[I]);
    Headers := 'Content-Type: application/x-www-form-urlencoded' +
#10#13;
    // Finally, we just navigate to the URL. Note that you may have to
modify
    // the path to your ASP page's location.
    WebBrowser1.Navigate('http://localhost/scripts/navpost.asp',
EmptyParam,
    EmptyParam, postData, Headers);
end;
```

You should now be able to run the application and see the results.

## Article #26574: Automating Internet Explorer to Find All Links on a Web Page

### Automating Internet Explorer to Find All Links on a Web Page

By [Corbin Dunn](#)

Delphi Developer Support

You may be faced in a situation where you need to find all links on a given web page. This document describes how to find all the links by automating Internet Explorer (IE). It was written with IE 5, but the concepts should work with IE 4 too.

[Download the complete source for this project from Borland CodeCentral](#)

*Note: MSHTML\_TLB.pas is not included with the above project because it is so large and one can import it by themselves. Read this document for how to import it.*

1. First, create a new application in Delphi. I saved Form1 as MainFrm.pas, and the application as FindingLinks.dpr.
2. To get the most power out of automating IE, first import the MSHTML type library. To do this, select Project->Import Type Library:

You should now see "Microsoft HTML Object Library (Version 4.0)" listed:

## Importing the TLB

Your version may be different if you have a different version of Internet Explorer (I have 5.0). If you don't see it listed, search on your computer for **mshtml.tlb**. After you find this file, click on the "Add..." button and select **mshtml.tlb**. If you don't find **mshtml.tlb**, then you may not have IE installed, or your version is outdated (so, update IE before continuing).

Finally, select "Microsoft HTML Object Library" and then click on the "Create Unit" button. It will take quite a while to create the unit because the type library is **very** large. My MSHTML\_TLB file that it created is 241,899 lines long! This should give you an idea about much you can automate Internet Explorer.

3. Once you have control of Delphi, go back to Form1. Create a layout similar to this:

## Form Layout

with these components:

<i>Component Class</i>	<i>Name</i>	<i>Caption or Text</i>
TLabel	lblURL	URL:
TEdit	edtURL	http://www.borland. com
TButton	btnFindLinks	Find All Links
TListBox	lstbxLinks	<i>n/a</i>

4. Add **OleCtrls**, **SHDocVw**, and **OleServer** to the **uses** list of the Form1's interface section. This allows us to create an instance of TInternetExplorer, which wraps the Internet Explorer ActiveX Object. We don't want to show the Internet Explorer control in this application. If you do want to, then place a TWebBrowser control on the form, as it will work in the same way and allow you to see the resulting web page.
5. Add the following to the **private** section of your form:

```
FInternetExplorer: TInternetExplorer;  
procedure WebBrowserDocumentComplete(Sender: TObject; var  
pDisp: OleVariant;  
    var URL: OleVariant);
```

Press Ctrl-Shift-C to complete the class declaration.

## 6. Add

```
uses MSHTML_TLB, ComObj;
```

under the implementation section of Form1.

## 7. Double click on Form1 to go to the OnCreate event of the form. Add the lines:

```
FInternetExplorer := TInternetExplorer.Create(Self);  
FInternetExplorer.OnDocumentComplete :=  
WebBrowserDocumentComplete;
```

## 8. For **TForm1.WebBrowserDocumentComplete** add the following code:

```
procedure TForm1.WebBrowserDocumentComplete(Sender: TObject;  
  var pDisp: OleVariant; var URL: OleVariant);  
var  
  Doc: IHTMLDocument2;  
  ElementCollection: IHTMLCollection;  
  HtmlElement: IHTMLElement;  
  I: Integer;  
  AnchorString: string;  
begin  
  lstbxLinks.Clear;  
  // We will process the document at this time. Trying to do  
  // so earlier won't work because it hasn't fully loaded.  
  Doc := FInternetExplorer.Document as IHTMLDocument2;  
  if Doc = nil then  
    raise Exception.Create('Couldn't convert the ' +  
      'FInternetExplorer.Document to an IHTMLDocument2');  
  // First, grab all the elements on the web page  
  ElementCollection := Doc.all;  
  for I := 0 to ElementCollection.length - 1 do  
  begin  
    // Get the current element  
    HtmlElement := ElementCollection.item(I, '') as IHTMLElement;  
    // Next, check to see if it is a link (tagName will be A).  
    // You could easily find other tags (such as TABLE, FONT,  
    etc.)  
    if HtmlElement.tagName = 'A' then  
    begin  
      // Now grab the innerText for this particular link. The  
      innerText is  
      // all text that is inside of the particular tag. For  
      example,
```

```

// this would give us "Go To Borland" from the HTML:
// <a href="http://www.borland.com"><b>Go To Borland</b></
a>.
// If you want "<b>Go To Borland</b>" use innerHTML.
AnchorString := HtmlElement.innerHTML;
if AnchorString = '' then
    AnchorString := '(Empty Name)';
// We know that the element is an IHTMLAnchorElement since
the tagName
// is 'A'.
AnchorString := AnchorString + ' - ' +
    (HtmlElement as IHTMLAnchorElement).href;
lstbxLinks.Items.Add(AnchorString);
end;
end;
end;

```

9. Next, double click on TButton **btnFindLinks** and add the following code in the **OnClick** event:

```

// Simply browse to the given page
FInternetExplorer.Navigate(edtURL.Text, EmptyParam, EmptyParam,
    EmptyParam, EmptyParam);

```

10. Compile the application and run it. It will probably take a while to compile because it has to compile the large MSHTML\_TLB.pas file. You will probably get a lot of warnings about the MSHTML\_TLB.pas file which you can ignore. You should then be able to find all links on a given web page by clicking the button. If you get a Variant exception when running in debug mode, you can ignore it (it doesn't effect anything).

## Article #26652: Random Images Screen Saver - a complete screen saver example

### Random Images Screen Saver in Delphi

By [Corbin Dunn](#)

Delphi Developer Support

There are some older documents on our site that describe how to go about writing a 32-bit screen saver with Delphi. I decided to update them with a completely new example that addresses several issues in some other screen savers.

First you will want to [download the complete source from CodeCentral](#) so you can follow along.

If you are new to creating a screen saver, there are certain things you have to do. First, you have to process command line switches and start your screen saver in the right "mode" depending on what was passed to it. For example, if you are passed /c as a parameter, you should start in the "Configure" mode. Inside my sample source code, I have a **ScreenSaverUtils** unit that takes care of the command line processing and some other utility routines. Inside the interface notice the global variables and function:

```
type
  TScreenSaverMode = (ssPassword, ssPreview, ssConfigure, ssRun);
var
  ScreenSaverMode: TScreenSaverMode;
  ParentSaverHandle: THandle = 0;

procedure SetScreenSaverMode;
```

Calling **SetScreenSaverMode** as the first thing in the screen savers .dpr file will cause ScreenSaverMode and optionally ParentSaverHandle (if present) to be properly set. I can then use it in the .dpr file to create the screen saver form, or the configuration form:

```
begin
  // First, process the Params passed to see
  // what mode the screen saver is to run in
  // This set's the global variable's ScreenSaverMode
  // and ParentHandle. If the mode was to set the password,
  // a call to this function will never return (it calls Halt).
  SetScreenSaverMode;

  Randomize;
  Application.Initialize;
  Application.Title := 'Random Images Screen Saver';
```

```

// Remove the start bar button
SetWindowLong(Application.Handle, GWL_EXSTYLE, WS_EX_TOOLWINDOW);
if ScreenSaverMode = ssConfigure then
begin
    // Create the configure form to configure the screen saver
    Application.CreateForm(TConfigureForm, ConfigureForm);
end
else
begin
    // We are either doing a preview or actually running the screen
saver
    Application.CreateForm(TMainForm, MainForm);
end;
Application.Run;
end.

```

**ConfigureForm** configures some registry settings for the screen saver. When the user selects "Settings..." from inside of the Display Properties of the control panel the configuration form will be shown. Some screen saver's don't modally show their configuration form, so it is possible to configure two screen savers at the same time. To correct this problem, I had to use the **ParentSaverHandle**, which should be properly set up after a call to **SetScreenSaverMode**. Inside of **TConfigureForm.FormCreate** I have:

```

if ParentSaverHandle <> 0 then
begin
    EnableWindow(GetParent(ParentSaverHandle), False);
end;

```

**ParentSaverHandle** is the handle to the little mini-desktop window that we are to draw a little "preview" on in the Display Properties dialog box. The parent of this little window is the actual Display Properties dialog box. The call to **GetParent** retrieves the Display Properties dialog box, and **EnableWindow** actually disables the window (making the configuration form modal). Notice the corresponding code in **TConfigureForm.FormDestroy** that re-enables the Display Properties dialog and brings it to the front:

```

if ParentSaverHandle <> 0 then
begin
    // The parent of the handle passed to us is
    // the main Properties dialog box
    EnableWindow(GetParent(ParentSaverHandle), True);
    SetForegroundWindow(GetParent(ParentSaverHandle));
end;

```

The next thing to take a look at is the main screen saver form: **MainForm**, inside of **MainFrm.pas**. This

form is created when the **ScreenSaverMode** is **ssRun** or **ssPreview**. When it is **ssRun**, we want the screen saver to:

1. Run in full screen mode
2. Hide the mouse
3. Close when the mouse is moved or a key is pressed
4. Prompt for a password on Windows 95/98/Me

To make it run in full screen mode, I set the **BorderStyle** property of **MainForm** to be **bsNone** and the **FormStyle** to be **fsStayOnTop**. Then, in the **OnCreate** event I have something close to this:

```
Top := 0;
Left := 0;
Width := Screen.Width;
Height := Screen.Height;
if ScreenSaverMode = ssRun then
begin
    SystemParametersInfo(SPI_SCREENSAVER_RUNNING, 1, @Dummy, 0);
    SetCapture(Self.Handle);
    ShowCursor(False);
end
```

Setting the width and height based on the Screen's properties makes it take up the full screen. The call to **SystemParametersInfo** is a crude way of telling Windows that the screen saver is running. **SetCapture** allows us to get all mouse movements, and **ShowCursor(False)**; hides the cursor. The **OnDestroy** event simply undoes all these things.

To test for key's being pressed, I simply call **Close** in the **OnKeyDown** event. Mouse movements are a little trickier because we want to have a certain tolerance to mouse movement. Take a look at **TMainForm.FormMouseMove** for how to do this.

Next, we have to prompt for a password, if this option is turned on (in Windows 95/98/Me only - Windows NT and 2000 do it for you). In the **OnCloseQuery** event I simply call the function **PromptIfPasswordNeeded** from **ScreenSaverUtils.pas**. If the function returns True, then **CanClose** is set to True and the screen saver will exit.

The actual drawing for the screen saver is done by timer events. The code is rather simple, and is left for you to examine yourself. Basically, you just draw whatever you want to the **MainForm**'s **Canvas**.

The next bit of trouble is to create the little preview in the Display Properties dialog box. If the **ScreenSaverMode** is **ssPreview**, then the **OnCreate** event of the **MainForm** set's the Application to not show the **MainForm** (with **Application.ShowMainForm := False**) and then calls **TMainForm.DoPreviewDrawing**. Here is this function:

```

procedure TMainForm.DoPreviewDrawing;
var
  Rect: TRect;
  Bitmap: TBitmap;
  Canvas: TCanvas;
begin
  FreeMutex; // Free the mutex so that the screen saver will actually
run in preview
  Canvas := TCanvas.Create;
  try
    Canvas.Handle := GetDC(ParentSaverHandle);
    try
      GetWindowRect(ParentSaverHandle, Rect);
      ...
      while IsWindowVisible(ParentSaverHandle) do
        begin
          // Drawing to Canvas.Handle will create your preview
          ...
        end;
      finally
        ReleaseDC(ParentSaverHandle, Canvas.Handle);
      end;
    finally
      Canvas.Free;
    end;
  Application.Terminate; // Done with the preview, so quit
end;

```

First, notice the call to **FreeMutex**, which is inside of the unit **SingleInstance**. This unit allows only one instance of the screen saver to run at any time. If we don't do this, then every screen saver timeout period, Windows will start a new instance of your screen saver, even if it is already running! The call to **FreeMutex** allows the Preview button to work correctly inside of the Display Settings dialog box (otherwise, timing issues will not allow it to show).

We get the Device Context (DC) from the little preview window that was passed to the Application via parameters. Setting the **TCanvas**'s Handle allows us to easily draw to it with a familiar Delphi class. Once the **ParentSaverHandle** window is not visible anymore, we terminate the application. The code to do the actual drawing is left out for simplicity.

Inside of the Display Properties dialog box you may have noticed that some screen savers specify a long name for the screen saver. In particular, it is different from just the executable's name. Microsoft claims that you can set this by creating a string table resource with an ID of 1 a value of whatever string you want. The included text file **delphi\_string\_table.rc** can be compiled into a resource (.res) file with the included **create\_res.bat** (you may have to modify the path information if you installed Delphi 5 into a

different location). Inside of the project's source I then have {\$R delphi\_string\_table.RES} to link in the resource. However, this doesn't always work. To make it work on Windows 2000/NT I discovered that the screen saver's executable name MUST be less than 8 characters long, AND all lowercase. I have no idea why this is required, but it seems to work.

Finally, you should be able to compile the source and you will have a nice little sample screen saver.

## Article #26693: Using blocking sockets inside of a thread, and simulating HTTP requests

Using blocking sockets inside of a thread, and simulating HTTP requests

By [Corbin Dunn](#)

Delphi Developer Support

This article covers how to send an HTTP request to a web server, and work with the response. All of the data transfer is done with a blocking socket inside of a thread.

[Download this example from Borland CodeCentral](#)

You may have a couple questions at this point. Such as, **what is a blocking socket and why would I use it?**

A blocking function call is one that doesn't return until the function is totally complete. In other words, all reading and writing occurs synchronously. For sockets, this means that a call to the **recv** function will not return until all the data has been received. If a socket is set to non-blocking, a call to **recv** will return very quickly, returning the data that is ready at that time of the call. **Delphi's TClientSocket** is by default a non-blocking socket because the **ClientType** property set to **ctNonBlocking**. With the non-blocking socket you use the **OnRead** and **OnWrite** events to read and write to the socket. Basically, Windows sends your application a message when data is ready to read or write to the socket. If you set the **ClientType** to **ctBlocking**, then your application will freeze until the data has been read. The way to prevent this from happening is to put the **TClientSocket** in a thread.

If you go to <http://www.census.gov/ftp/pub/genealogy/names/> you will notice that there are a couple of text files named [dist.male.first](#) and [dist.female.first](#). They contain a list of the most frequent names in the 1990 Census. This example will send an HTTP request to [www.census.gov](http://www.census.gov) and get on of those two text files. It will then process the data and place it into a TListView. You can even search for your name.

Here is a screen shot of the example we will be working on:

If you want to just dig apart the code yourself, then [download it now](#). Otherwise, here are some step by step instructions on how I created the example.

1. First create a new application in Delphi. Rename the form to "**MainForm**" and save it in **MainFrm.pas**. Save the project as "**YourName.dpr**."
2. Next, add **ScktComp** to the uses list of **MainFrm.pas**.
3. We need to create a TThread that does the blocking socket work. Under the **type** keyword, but above the **MainForm** class, add:

```
TSocketThread = class(TThread)
private
    FClientSocket: TClientSocket;
    FData: string;
    FLastException: Exception;
    FGender: string;
    procedure SetGender(const Value: string);
protected
    procedure Execute; override;
    procedure HandleThreadException;
    procedure ThreadDone;
public
```

```

    constructor Create;
    destructor Destroy; override;
    property Gender: string read FGender write SetGender;
end;

```

Press Ctrl-Shift-C to complete the class.

4. In the **implementation** section, add the following code for your constructor and destructor:

```

constructor TSocketThread.Create;
begin
    inherited Create(True); // Initially suspended
    FreeOnTerminate := True;
    FClientSocket := TClientSocket.Create(nil);
    FClientSocket.Host := 'www.census.gov';
    FClientSocket.Port := 80; // HTTP port
    FClientSocket.ClientType := ctBlocking; // Blocking, so it is
in a thread
end;

destructor TSocketThread.Destroy;
begin
    FClientSocket.Free;
    inherited;
end;

```

The constructor will simply create the **TClientSocket** that will connect to [www.census.gov](http://www.census.gov) on the HTTP port (80), with a blocking socket. The **destructor** cleans up the allocated memory.

5. Now, standard TThread programming means that we will put our threaded code inside of the **Execute** procedure. To use a blocking socket, we have to use the **TWinSocketStream** class. The **TWinSocketStream** allows us to easily write to the socket and allow a timeout in case something goes wrong. Our **Execute** procedure will simply connect to the server, create a **TWinSocketStream**, and then read data until zero bytes are returned from a read, or the socket is closed. Zero bytes will be returned from a read when there is no more data available to read. Also, the HTTP port will be closed by the server when no more data is available. Here is the code:

```

procedure TSocketThread.Execute;
var
    Buffer: array[0..1024-1] of Char;
    SockStream: TWinSocketStream;
    RequestString: string;
begin
    try
        FClientSocket.Active := True;

```

```

FData := '';
FillChar(Buffer, SizeOf(Buffer), #0);

// Create the socket stream with a 1 minute timeout
SockStream := TWinSocketStream.Create(FClientSocket.Socket,
60000);
try
    RequestString := Format('GET /ftp/pub/genealogy/names/dist.
%s.first HTTP/1.0'#13#10#13#10,
    [FGender]);
    // Send the HTTP request
    SockStream.Write(RequestString[1], Length(RequestString));
    // Read the response in 1024 chunks
    while (SockStream.Read(Buffer, SizeOf(Buffer)) <> 0) do
    begin
        FData := FData + Buffer;
        FillChar(Buffer, SizeOf(Buffer), #0);
        // Check for termination of the thread or closure of the
socket
        if Terminated or not FClientSocket.Active then
            Exit;
        end;
    finally
        SockStream.Free;
        if FClientSocket.Active then
            FClientSocket.Active := False;
        end;
    except
        on E: Exception do
        begin
            if not(ExceptObject is EAbort) then
            begin
                FLastException := E;
                Synchronize(HandleThreadException);
            end;
        end;
    end;
    // Tell the main form that we are done
    Synchronize(ThreadDone);
end;

procedure TSocketThread.HandleThreadException;
begin
    Application.ShowException(FLastException);
end;

```

First of all, notice how I wrap all the operations in a **try..except** block. Any exceptions are handled via a call to **Synchronize** to prevent any multi-threaded problems from happening. For more information about how and why to do this read my article [How to handle exceptions in TThread objects.](#)

You will probably also notice my use of the **FGender** private data field. It contains a string of either "male" or "female" so that we can access the right file on the server depending on what the user selected. It is set via the **Gender** property's **write** procedure:

```

procedure TSocketThread.SetGender(const Value: string);
begin
    if (Value = 'male') or (Value = 'female') then
        FGender := Value
    else
        raise Exception.CreateFmt('Unknown gender (%s) to search
for',
            [Value]);
end;

```

6. The last thing that the **TSocketThread**'s **Execute** procedure does is call **ThreadDone** inside of **Synchronize** to make it thread safe. The code is as follows:

```

procedure TSocketThread.ThreadDone;
begin
    // The VCL is not thread safe. Accessing MainForm from inside
    // a thread would be bad, unless if it is inside a procedure
    // that was called via Synchronize.
    MainForm.ProcessData(FData);
end;

```

7. **ProcessData** is a function that we will add to the **MainForm**.
8. Now, the next thing to do is to set up **MainForm** to use the thread class that we just created. First, lay out some components on the form to make it look like the screen shot above.

**Here are the components and names that I used:**

<i>Component Class</i>	<i>Name</i>	<i>Caption or Text</i>
TRadioButton	rdbtnMaleNames	Male First Names
TRadioButton	rdbtnFemaleNames	Female First Names

TButton	btnGetData	Get Data From census. gov
TLabel	lblStatus	lblStatus (set at runtime)
TLabel	lblSearch	Search:
TEdit	edtSearch	CORBIN
TButton	btnFindIt	Find It
TListView	lstvwNames	n/a
Set the <b>ViewStyle</b> property for <b>lstvwNames</b> to be <b>vsReport</b> . Double click on <b>lstvwNames</b> and add four <b>columns</b> : Name, Percent of Population, Total Percent, and Rank.		

9. Double click on **btnGetData** and add the following code to create an instance of our **TSocketThread**:

```

procedure TMainForm.btnGetDataClick(Sender: TObject);
begin
    btnGetData.Enabled := False;
    // Create a thread
    with TSocketThread.Create do
        begin
            if rdbtnMaleNames.Checked then
                Gender := 'male'
            else
                Gender := 'female';
            Resume;
        end;
    end;

```

Remember that **rdbtnMaleNames** is the name of the **TRadioButton** on the form.

10. The next thing we need to do is process the data returned. The thread will call **MainForm.ProcessData(FData)** after it has received all its data. We need to add this procedure to the **MainForm**'s class interface. Since the **TSocketThread** is declared in the same unit, we can put the **ProcessData** procedure in the private section of **TMainForm**. Also add a **TStringList** to store some extra data later on:

```

private
    FNamesList: TStringList;
    procedure ProcessData(Data: string);

```

Press Ctrl-Shift-C to complete the class.

11. HTTP responses will have a header that we don't really care about. The start of data is immediately following two carriage-return newline pairs (ASCII #13#10). I simply use **Pos** to find this location and start processing the data after it:

```
procedure TMainForm.ProcessData(Data: string);  
var  
    DataStart: Integer;  
    CurrentPos: PChar;  
    Name: string;  
    ListItem: TListItem;  
  
    function ReadNextToken: string;  
    begin  
        Result := '';  
        // All tokens are delimited by whitespace.  
        // First, pass over any whitespace at the start.  
        while (CurrentPos^ in [#10, #13, ' ']) do  
            Inc(CurrentPos);  
  
        // Read in characters until we hit some more whitespace  
        while not (CurrentPos^ in [' ', #0, #10, #13]) do  
            begin  
                Result := Result + CurrentPos^;  
                Inc(CurrentPos);  
            end;  
        end;  
  
begin  
    // This is a very simple parser.  
  
    // First, we must skip the response header (it will have 2  
CRLF pairs before  
// the start of the data).  
  
    DataStart := Pos(#13#10#13#10, Data);  
    if DataStart = 0 then  
        raise Exception.Create('Could not find the data in the HTTP  
response');  
  
    // lstvwNames is the name of the TListView for displaying the  
data.  
    lstvwNames.Items.BeginUpdate;  
    try  
        lstvwNames.Items.Clear;
```

```

    // FNameList is a TStringList used to keep a sorted list of
the names.
    // This way, we can do a quick locate on it.
    FNameList.Clear;

    // Start past the 2 CRLF's (4 characters) with a pointer to
that character
    CurrentPos := PChar(@Data[DataStart + 4]);
    while (CurrentPos <> nil) and (CurrentPos^ <> #0) do
    begin
        Name := ReadNextToken;
        if Name <> '' then
        begin
            // Create a list item
            ListItem := lstvwNames.Items.Add;
            ListItem.Caption := Name;
            ListItem.SubItems.Add(ReadNextToken);
            ListItem.SubItems.Add(ReadNextToken);
            ListItem.SubItems.Add(ReadNextToken);
            // Add the name to the internal list of names so we can
easily
            // search for a name.
            FNameList.Add(Name);
            // Keep a pointer to the item.
            FNameList.Objects[FNameList.Count - 1] :=
ListItem;
            lblStatus.Caption := 'Processing the data...';
            Application.ProcessMessages;
        end
        else
            Break;
        end;
    finally
        lstvwNames.Items.EndUpdate;
    end;
    // Sort the internal list of names
    FNameList.Sort;
    lblStatus.Caption := 'Done';
    btnGetData.Enabled := True;
end;

```

12. You may have noticed that we use **FNameList** without ever creating it. So, in the **OnCreate** and **OnDestroy** events for **TMainForm** add the following code:

```

procedure TMainForm.FormCreate(Sender: TObject);
begin
    lblStatus.Caption := '';
    FNamesList := TStringList.Create;
end;

```

```

procedure TMainForm.FormDestroy(Sender: TObject);
begin
    FNamesList.Free;
end;

```

13. The last thing to do is to allow the user to search for their name. Double click on **btnFindIt** and add the following code:

```

procedure TMainForm.btnFindItClick(Sender: TObject);
var
    Index: Integer;
begin
    Index := FNamesList.IndexOf(UpperCase(edtSearch.Text));
    if (Index >= 0) then
        begin
            lstvwNames.Selected := TListItem(FNamesList.Objects[Index]);
            lstvwNames.Selected.MakeVisible(False);
            lstvwNames.SetFocus;
        end
    else
        raise Exception.Create('Could not find ' + edtSearch.Text);
end;

```

Now the reason for having **FNamesList** becomes apparent!

14. You should be able to compile the application and have it work. If not, then just **download the sample project**.

That's it! If I made any errors, please [email me](#).

## Article #26736: I want to be able to use multiple aliases with a single TDatabase component.

### DESCRIPTION:

This Document will cover the following topics:

- The creation and deletion of dBase and Paradox BDE aliases in Delphi
- Using multiple aliases with one Database component
- Saving changes to the IDAPI.CFG file without using BDE Admin.

### ADDING ALIASES USING THE TSESSION COMPONENT:

Every Database application in Delphi has a default TSession component called SESSION. This Component manages all of your application's current database connections. You can also use it to add BDE aliases to the current session. This example creates a new dBase alias:

```
procedure TForm1.CreateNewAlias;
begin
  with Session do
  begin
    if not IsAlias('Deebase') then
      AddStandardAlias('DeeBase', 'c:\program files\Common files
\borland shared\data',
        'DBASE')
    else
      ShowMessage('Alias name already exists!');
  end;
end;
```

AddStandardAlias takes three string parameters. They are the name of the new alias, the path to the directory where the database resides, and the name of the driver to be used. IsAlias is a Boolean function that checks for the existence of a given Alias name.

### USING YOUR ALIAS:

Once you have created your new alias it can be used by your datasets. It is a simple matter to switch between several different aliases using one DataSet component. It requires only a reassignment of the alias.

```
procedure TForm1.OpenTable;
begin
  with Table1 do
  begin
    DatabaseName := 'DeeBase';
```

```
    TableName := 'clients.dbf';
    Active := True;
end;
end;
```

**Note:** *You do not use a full path to a file when creating a Paradox or dBase Alias. The actual file is reconciled later when a specific table is specified.*

### **SAVING YOUR ALIASES:**

Up until now, you have probably been using the BDE Administrator to change you ISAPI.CFG file. Now you can use your applications session component to do the same. Once you have created the session you want, you can permanently add them to the BDE configuration file by calling Session.SaveConfigFile.

### **DELETING ALIASES:**

Deleting BDE aliases is as simple as calling Session.DeleteAlias. Another call to SaveConfigFile will make this permanent. Use this to clean up alias that you don't want to persist after your application terminates.

### **WHOLE SOURCE EXAMPLE:**

The following is the main unit in a simple application that switches between and Paradox and dBase table while displaying the information to a TDBGrid.

```
-----Source-----
//AliasUnit.pas
unit AliasUnit;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs,
  StdCtrls, Grids, DBGrids, Db, DBTables, Menus;

type
  TForm1 = class(TForm)
    DataSource1: TDataSource;
    Table1: TTable;
    Datasel1: TDatabase;
    DBGrid1: TDBGrid;
    Button1: TButton;
    Button2: TButton;
    Label1: TLabel;
    Label2: TLabel;
  end;
end;
```

```

MainMenu1: TMainMenu;
File1: TMenuItem;
Exit1: TMenuItem;
procedure FormCreate(Sender: TObject);
procedure ParadoxButtonClick(Sender: TObject);
procedure DBaseButtonClick(Sender: TObject);
procedure FormClose(Sender: TObject; var Action: TCloseAction);
procedure Exit1Click(Sender: TObject);
private
  { Private declarations }
public
  { Public declarations }
end;

```

```

var
  Form1: TForm1;

```

```

implementation

```

```

{$R *.DFM}

```

```

procedure TForm1.FormCreate(Sender: TObject);
begin
  //Create the two session aliases
  with Session do
  begin
    if not IsAlias('Pdox') then
AddStandardAlias('PDox','c:\program files\common files\borland shared
\data','Paradox');
    if not IsAlias('Deebase') then
      AddStandardAlias('deeBase','c:\program files\common files
\borland shared\data','DBASE');
    end;
  end;
end;

```

```

procedure TForm1.ParadoxButtonClick(Sender: TObject);
begin
  //hook up the db to the new alias
  with Databasel do
  begin
    Connected := False;
    AliasName := 'PDox';
  end;
  //setup and activate table
  with Table1 do

```

```

begin
    TableName := 'country.db';
    Active := True;
end;
end;

procedure TForm1.DBaseButtonClick(Sender: TObject);
begin
    //hook up the db to the new alias
    with Database1 do
    begin
        Connected := False;
        AliasName := 'deebase';
    end;
    //setup and activate table
    with Table1 do
    begin
        TableName := 'clients.dbf';
        Active := True;
    end;
end;

procedure TForm1.FormClose(Sender: TObject; var Action: TCloseAction);
begin
    with Session do
    begin
        DeleteAlias('PDox');
        DeleteAlias('deeBase');
        SaveConfigFile;
    end;
end;

procedure TForm1.Exit1Click(Sender: TObject);
begin
    Close;
end;

end.

```

## Article #26876: Use the Windows API to generate a list of available Network Resources.

### QUESTION:

How can I get a list of the computer names from Network Neighborhood?

### ANSWER:

Windows provides a set of API functions that allow enumeration of Network Resources. There are three basic steps to follow:

The first step is to call *WNetOpenEnum()*:

```
DWORD WNetOpenEnum(  
    DWORD dwScope,           // scope of enumeration  
    DWORD dwType,            // resource types to list  
    DWORD dwUsage,           // resource usage to list  
    LPNETRESOURCE lpNetResource, // resource structure  
    LPHANDLE lpEnum          // enumeration handle buffer  
);
```

The parameters passed into *WNetOpenEnum* determine what type of enumeration you will get. In this example *dwScope* is set to *RESOURCE\_CONTEXT*. This should limit *WNetEnumResource()* to finding only Network resources within your workgroup, which should be the list of computers retrieved from "Computers Near Me". Setting *dwType* to *RESOURCE\_DISK* keeps *WNetResource()* from returning any printers, etc. Check the on line help for more documentation on *WNetOpenEnum()*.

Once *WNetOpenEnum()* has been called the next step is to to enumerate the handle passed into *WNetOpenEnum()*, *lpEnum*. This is done through a call to *WNetEnumResource()*:

```
DWORD WNetEnumResource(  
    HANDLE hEnum,           // handle to enumeration  
    LPDWORD lpcCount,       // entries to list  
    LPVOID lpBuffer,        // buffer  
    LPDWORD lpBufferSize    // buffer size  
);
```

*WNetEnumResource()* also takes a pointer to an array of Network Resources, *lpBuffer*, which will be stuffed chuck full of yummy network goodness.

Finally, a call to *WNetCloseEnum()* should be made to close the resource handle:

```
DWORD WNetCloseEnum(  
    HANDLE hEnum // handle to enumeration  
);
```

Here is an example that I ported from Microsoft's Web site [Seen Here](#). I have changed the example to get the computers in the current workgroup, *RESOURCE\_CONTEXT*, instead of grabbing all available global resources.

In my example I use an array of TNetResource as opposed to allocating space for a pointer. I also used *FillChar()* to initialize the array. These are the main differences from my example and Microsoft's.

```
function EnumerateFunc( hwnd: HWND; hdc: HDC ; lptr: PNetResource ): Boolean;
const
    cbBuffer : DWORD          = 16384;          // 16K is a good size
var
    hEnum, dwResult, dwResultEnum : DWORD;
    lptrLocal : array
        [0..16384 div SizeOf(TNetResource)] of TNetResource;    // pointer to
enumerated structures
    i : integer;
    cEntries : Longint;
begin
    centries := -1;                                // enumerate all possible entries

    // Call the WNetOpenEnum function to begin the enumeration.
    dwResult := WNetOpenEnum(
        RESOURCE_CONTEXT, // Enumerate currently connected
resources.
        RESOURCETYPE_DISK, // all resources
        0, // enumerate all resources
        lptr, // NULL first time the function is
called
        hEnum // handle to the resource
    );

    if (dwResult <> NO_ERROR) then
    begin
        // Process errors with an application-defined error handler
        Result := False;
        Exit;
    end;

    // Initialize the buffer.
    FillChar( lptrLocal, cbBuffer, 0 );

    // Call the WNetEnumResource function to continue
    // the enumeration.
    dwResultEnum := WNetEnumResource(hEnum, // resource handle
        DWORD(cEntries), // defined locally as -1
        @lptrLocal, // LPNETRESOURCE
        cbBuffer); // buffer size

    // This is just printing
    for i := 0 to cEntries - 1 do
    begin
```

```
// loop through each structure and
// get remote name of resource... lpnrLocal[i].lpRemoteName)
end;

// Call WNetCloseEnum to end the enumeration.
dwResult := WNetCloseEnum(hEnum);

if(dwResult <> NO_ERROR) then
begin
    // Process errors... some user defined function here
    Result := False;
end
else
    Result := True;
end;
```

## Article #26977: Finding the Windows task bar using the SHAppBarMessage API call

### Finding the Windows task bar

By [Corbin Dunn](#)

Delphi Developer Support

You may have come across a need to find the Windows task bar. This can be a simple task with Delphi. The Windows API call **SHAppBarMessage** allows you to get information about the task bar (also called the app bar by some). Visit [here on the MSDN](#) to find out more information about what you can do with this call. This document concentrates on passing it a message of ABM\_GETTASKBARPOS.

If you would like to follow along, you can create a new Application, or you can [download the complete source](#) from Borland's CodeCentral.

The first thing you may be wondering is what unit the API call is in. On the MSDN one can find out that it is declared in shellapi.h. In Delphi, it is in ShellApi.pas, so add **ShellApi** to your **uses** list. We can then code up a simple function that finds its position and bounding rectangle:

```
// FindTaskBar returns the Task Bar's position, and fills in  
// ARect with the current bounding rectangle.  
function FindTaskBar(var ARect: TRect): Integer;  
var  
    AppData: TAppBarData;  
begin  
    // 'Shell_TrayWnd' is the name of the task bar's window  
    AppData.Hwnd := FindWindow('Shell_TrayWnd', nil);  
    if AppData.Hwnd = 0 then  
        RaiseLastWin32Error;  
    AppData.cbSize := SizeOf(TAppBarData);  
    // SHAppBarMessage will return False (0) when an error  
    // happens.  
    if SHAppBarMessage(ABM_GETTASKBARPOS, AppData) = 0 then  
        raise Exception.Create('SHAppBarMessage returned false when  
trying ' +  
        'to find the Task Bar's position');  
    // Otherwise, we had success, so fill in the results.  
    Result := AppData.uEdge;  
    ARect := AppData.rc;  
end;
```

Once you have added this code to your application, you can use the function. Add a TLabel and a

TButton to your form. Then, in the button click, add the following code:

```
procedure TForm1.Button1Click(Sender: TObject);  
var  
    Rect: TRect;  
    DestLeft: Integer;  
    DestTop: Integer;  
begin  
    DestLeft := Left;  
    DestTop := Top;  
    case FindTaskBar(Rect) of  
        ABE_BOTTOM:  
            begin  
                DestLeft := Trunc((Screen.Width - Width) / 2.0);  
                DestTop := Rect.Top - Height;  
            end;  
        ABE_LEFT:  
            begin  
                DestTop := Trunc((Screen.Height - Height) / 2.0);  
                DestLeft := Rect.Right;  
            end;  
        ABE_RIGHT:  
            begin  
                DestTop := Trunc((Screen.Height - Height) / 2.0);  
                DestLeft := Rect.Left - Width;  
            end;  
        ABE_TOP:  
            begin  
                DestLeft := Trunc((Screen.Width - Width) / 2.0);  
                DestTop := Rect.Bottom;  
            end;  
    end;  
    Labell.Caption := Format('Found at Top: %d Left: %d Bottom: %d  
Right: %d)',  
        [Rect.Top, Rect.Left, Rect.Bottom, Rect.Right]);  
    // Move us to the task bar  
    while (Left <> DestLeft) or (Top <> DestTop) do  
    begin  
        if Left < DestLeft then  
            Left := Left + 1  
        else if Left <> DestLeft then  
            Left := Left - 1;  
  
        if Top < DestTop then  
            Top := Top + 1
```

```
else if Top <> DestTop then
```

```
    Top := Top - 1;
```

```
    Application.ProcessMessages;
```

```
end;
```

```
end;
```

That's it! You should now be able to find the task bars current position.

## Article #27126: Writing COM Automation Events

### WHAT IS AN AUTOMATION EVENT?

The typical COM Client/Server model that you have probably worked with before allows the client to call the server through a supported interface. This is fine when a client calls the server to perform an action or retrieve data, but what about when the server wants to ask things of the client? Incoming interfaces are just that: incoming. There is no way for the server to talk to any of its clients. This is where the Server Events model comes into play. A Server that supports Events not only responds to calls from the client, but can also report status and make its own requests of the client. For Example: A client makes a request for the server to download a file. Instead of waiting for the server to finish this download before continuing (as with the previous model), the client can go about another task. When the server is done, it can fire an Event that lets the client know it is finished, thus allowing the client to respond accordingly.

### HOW DO THEY DO IT?

The way in which a client is called by the server is not too much different in concept from the reverse. The server defines and fires events while the client is responsible for connecting to and implementing events. This is accomplished through an *events interface* or *outgoing interface* defined in the server object's type library. Now before we really get started, it's time for some terminology.

*Connection Point*: An entity describing the access to an events interface.

*Event Source*: An object that defines an outgoing interface and fires events, typically the Automation Server.

*Event Sink*: An object that implements an event interface and responds to events, typically the client.

*Advise*: Linking a sink to a connection point so that the sink's methods can be accessed by the source.

These are the main pieces of the Events model. If I were to sum this article up in one sentence it would be this: Simply put, an event sink will connect to a source via a connection point, thereby allowing the source to fire events implemented by the sink. My Goal now is to step through a simple server and client. The client will have a button that will call a server method. This method will simply fire and event that the client will catch and report via a memo control.

### LET'S WRITE THE SERVER

Any Automation server that wants to communicate using events needs to define an outgoing interface, and must implement an incoming interface for finding and attaching to those interfaces. This incoming interface is `IConnectionPointContainer`. The client will use this interface to find or enumerate the connection points supported by the sink with the `FindConnectionPoint` and `EnumConnectionPoints` methods. An `IConnectionPoint` connection point will be returned, from which the client can then call `Advise()` to advise its sink to the connection point. Both of these

interfaces are defined in `ACTIVEX.PAS`. You don't have to do it manually thankfully. The Automation Wizard will do all this for you.

So let's begin. Open a New Application and drop a `TMemo` on the form. Now go to **New|Automation Object** to start the Automation Wizard. Here you are asked for a `coClass` name. This example will use `SimpleEventServer`. Before clicking OK, check the box marked **Generate Event Support Code**. This is the implementation for your `IConnectionPointContainer` related things as described in the above paragraph (POOF!!! Delphi Magic!!!). The result will be a unit containing your `TSimpleServer` object and its `coClass` definitions. Delphi will also generate a Type Library that includes the typical dual incoming interfaces `ISimpleEventServer` and `ISimpleEventServerDisp`, plus one you have not seen before, your outgoing events interface `ISimpleEventServerEvents`.

`ISimpleEventServer` now needs to expose a method for our client to call. Open the Type Library Editor (if it is not open already) and add a method `CallServer()`. Now we need to define an event for the server to fire, so we will add the method `EventFired()` to the `ISimpleEventServerEvents`. With this done, click on the Refresh Implementation button and then go back to the source unit for your server. You'll notice that a method has been added. When the client calls the server, the server will inform the user via its memo, then fire the `EventFired` event. Implement it as follows:

```
procedure CallServer; safecall;
begin
  Form1.Memo1.Lines.Add('I have been called by a client');
  if FEvents <> nil then
  begin
    FEvents.EventFired;
    Form1.Memo1.Lines.Add('I am firing an Event');
  end;
end;
```

*NOTE: FEvents is our outgoing interface. Notice that we check it before we fire the event off it. This ensures that a client is actually listening. If it has not been advised to a client sink, it will return NIL.*

With that squared away, the Server is complete! Build and run it once to register it with the system.

## THE CLIENT

Start a new application and add a `TMemo` and a button. Now go to the Unit source and add the TLB unit of your server to the `USES` clause so we can have access to those types and methods. Your main form object will need fields to hold the interfaces to the Server object and the event sink. Declare them in the private field as follows:

```

...
private
    { Private declarations }
    FServer: ISimpleEventServer;
    FEventSink: IUnknown;
    FConnectionToken: integer;
...

```

Once this groundwork is complete, we can start on the only difficult task in COM events: The implementation of the Event Sink. It starts by defining the Event Sink Object, which is an automation object, and therefore must implement IDispatch. The job of the Event Sink is to delegate calls to itself by the server through its `Invoke()` method. It then calls the local implementation for the event. To enforce a level of separation here, we will leave these implementations in the main unit and hold a reference to the main form in the sink object to call them off of. Here is the Event Sink Definition:

```

TEventSink = class(TInterfacedObject, IUnknown, IDispatch)
private
    FController: TForm2;
    {IUnknown methods}
    function QueryInterface(const IID: TGUID; out Obj): HRESULT;
stdcall;
    {IDispatch}
    function GetTypeInfoCount(out Count: Integer): HRESULT; stdcall;
    function GetTypeInfo(Index, LocaleID: Integer; out TypeInfo):
HRESULT; stdcall;
    function GetIDsOfNames(const IID: TGUID; Names: Pointer;
        NameCount, LocaleID: Integer; DispIDs: Pointer): HRESULT;
stdcall;
    function Invoke(DispID: Integer; const IID: TGUID; LocaleID:
Integer;
        Flags: Word; var Params; VarResult, ExcepInfo, ArgErr:
Pointer): HRESULT; stdcall;
public
    constructor Create(Controller: TForm2);
end;

```

Most of these methods do not need to be implemented. Making them simply return `S_OK` will do fine, for all except `QueryInterface()` and `Invoke()`. These methods are used by the server to obtain interfaces and call your event handlers.

```

function TEventSink.QueryInterface(const IID: TGUID; out Obj): HRESULT;
stdcall;
begin
    if GetInterFace(IID, Obj) then

```

```

    Result := S_OK
else if IsEqualIID(IID, ISimpleEventServerEvents) then
    Result := QueryInterface(IDispatch, Obj)
else
    Result := E_NOINTERFACE;
end;

```

This method first takes care its own IDispatch and IUnknown, then it recurses to get the outgoing interface if being queried for ISimpleEventServerEvents.

```

function TEventSink.Invoke(DispID: integer; const IID: TGUID;
LocaleID: integer; Flags: Word; var Params; VarResult, ExcepInfo,
ArgErr: Pointer): HRESULT;
begin
    Result := S_OK;
    case DispID of
        1: FController.OnEventFired;
    end;
end;

```

The case statement above would, of course, have more statements if we had more events, but this interface and sink only support one. Note that Invoke ( ) calls our handler through a local reference to the main form object where our event handler resides. The Event Sink constructor should handle setting this up:

```

constructor TEventSink.Create(Controller: TForm2);
begin
    inherited Create;
    FController := Controller;
end;

```

With the methods and objects in place, all that is left is to connect sink to source! We will do this in the Client's OnCreate event handler:

```

procedure TForm2.FormCreate(Sender: TObject);
begin
    FServer := CoSimpleEventServer.Create;
    FEventSink := TEventSink.Create(form2);
    InterfaceConnect(FServer, ISimpleEventServerEvents, FEventSink,
FconnectionToken);
end;

```

*NOTE: Remember the FEventSink is an IUnknown, and we are receiving and interface from the*

*TEventSink constructor, not a standard reference. This will allow us to advise a connection point to it.*

First, we create our server using its coClass. Then we create an instance of our Event sink. As I said earlier, the `InterfaceConnect()` method is easier to use, but you lose some functionality and understanding. You can use it here by passing in your server's interface, the IID of the events interface you are querying for, the `IUnknown` of your newly created event sink, and an integer representing the connection. You **MUST** hold onto this integer if you wish to properly unadvise the connection. You can disconnect by simply calling `InterfaceDisconnect()` using the token integer you received from your `InterfaceConnect()` call.

Now compile and run the client. The server should start and that's it! You are now connected and listening for events! Click the client's button to test your event.

## **SOURCE UNITS EXAMPLES**

Below are the units Server Object and Client Object units. Ommited is the Main form of the server.

\*\*\*\*\*

```
-----source-----  
  
//SrvUnit2.pas  
//Contains the Automation Server Object  
unit SrvUnit2;  
  
interface  
  
uses  
    ComObj, ActiveX, AxCtrls, Classes, SrvEvent_TLB, StdVcl, Srvunit1;  
  
type  
    TSimpleEventServer = class(TAutoObject, IConnectionPointContainer,  
ISimpleEventServer)  
    private  
        { Private declarations }  
        FConnectionPoints: TConnectionPoints;  
        FConnectionPoint: TConnectionPoint;  
        FEvents: ISimpleEventServerEvents;  
        { note: FEvents maintains a *single* event sink. For access to  
more  
        than one event sink, use FConnectionPoint.SinkList, and iterate  
        through the list of sinks. }  
    public  
        procedure Initialize; override;
```

```

protected
  { Protected declarations }
  property ConnectionPoints: TConnectionPoints read
FConnectionPoints
  implements IConnectionPointContainer;
  procedure EventSinkChanged(const EventSink: IUnknown); override;
  procedure CallServer; safecall;
end;

implementation

uses ComServ;

procedure TSimpleEventServer.EventSinkChanged(const EventSink:
IUnknown);
begin
  FEvents := EventSink as ISimpleEventServerEvents;
end;

procedure TSimpleEventServer.Initialize;
begin
  inherited Initialize;
  FConnectionPoints := TConnectionPoints.Create(Self);
  if AutoFactory.EventTypeInfo <> nil then
    FConnectionPoint := FConnectionPoints.CreateConnectionPoint(
      AutoFactory.EventIID, ckSingle, EventConnect)
  else FConnectionPoint := nil;
end;

procedure TSimpleEventServer.CallServer;
begin
  Form1.Mem1.Lines.Add('I have been called by a client');
  if FEvents <> nil then
    begin
      FEvents.EventFired;
      Form1.Mem1.Lines.Add('I am firing an Event');
    end;
end;

initialization
  TAutoObjectFactory.Create(ComServer, TSimpleEventServer,
Class_SimpleEventServer,

## Article #27132: Creating a file browser for Linux using Kylix

### Creating a file browser for Linux using Kylix

By [Corbin Dunn](#)

Delphi Developer Support

One of the first things that I wanted to do with Kylix was create a simple Linux file browser such as this:

I am only going to cover the general outline of how I made this project, so [download the complete source](#) from CodeCentral. I realize that it is a zip file, and Linux users like tar.gz'd files, but CodeCentral stores everything as zips. The [KDE Archiver](#) program allows you to easily unzip files on Linux.

I started the project by putting down a TTreeView on the form and set its Align property to allLeft. The TTreeView will hold the current directory tree. Next, I put down a TSplitter, so the user could resize the components at run time. Then, I put down a TListView, which will hold the files for the currently selected directory.

The first problem is finding directories. I could find all directories on the entire system when the application starts, but this would be very time consuming. Plus, the user may not expand all directories. So, I need to keep track of whether or not a user has opened up a given directory. TTreeNode's have a Data property that allows the programmer to store whatever information they want in it. I decided to create a new TTreeFolderData class that stores information about a given TTreeNode:

```
TTreeFolderData = class
private
  FPath: string;
  FHasSubFolders: Boolean;
  FOpened: Boolean;
public
  constructor Create(const Path: string);
  destructor Destroy; override;
  property Path: string read FPath write FPath;
  property HasSubFolders: Boolean read FHasSubFolders write FHasSubFolders;
  property Opened: Boolean read FOpened write FOpened;
end;
```

In my Form's OnCreate event, I call a LoadTreeDirectory procedure that fills in the root TTreeNode of the TTreeView:

```
procedure TMainForm.LoadTreeDirectory;
var
  RootNode: TTreeNode;
  TreeFolderData: TTreeFolderData;
begin
  trvwLocal.Items.BeginUpdate; // trvwLocal is my TTreeView on the left
  try
    trvwLocal.Items.Clear;
    RootNode := trvwLocal.Items.Add(nil, 'Root');
    RootNode.ImageIndex := 0;
    TreeFolderData := TTreeFolderData.Create(PathDelim);
    TreeFolderData.Opened := True;
    RootNode.Data := TreeFolderData;
    AddSubFolders(PathDelim, RootNode);
    RootNode.Expand(False);
  finally
    trvwLocal.Items.EndUpdate;
  end;
end;
```

The **AddSubFolders** procedure simply takes a given path and node, and finds all folders that exist in it. I simply use our standard FindFirst and FindNext procedures, looking for faDirectory's:

```
procedure TMainForm.AddSubFolders(const Directory: string;
  ParentNode: TTreeNode);
var
  SearchRec: TSearchRec;
  Attributes: Integer;
```

```

NewNode: TTreeNode;
TreeFolderData: TTreeFolderData;
begin
  trvwLocal.Items.BeginUpdate;
  try
    // First, delete any subfolders from the parent node.
    if ParentNode <> nil then
      ParentNode.DeleteChildren;

    Attributes := faAnyFile;
    if FindFirst(IncludeTrailingPathDelimiter(Directory) + '*',
      Attributes, SearchRec) = 0 then
    begin
      repeat
        if (SearchRec.Attr and faDirectory) > 0 then
          if (SearchRec.Name <> '.') and (SearchRec.Name <> '..') then
            begin
              NewNode := trvwLocal.Items.AddChild(ParentNode, SearchRec.Name);
              NewNode.ImageIndex := 0;
              TreeFolderData := TTreeFolderData.Create(
                IncludeTrailingPathDelimiter(Directory) + SearchRec.Name);
              NewNode.Data := TreeFolderData;

              if HasSubFolder(TreeFolderData.Path) then
                begin
                  TreeFolderData.HasSubFolders := True;
                  // Add a fake child so the + appears
                  trvwLocal.Items.AddChild(NewNode, '+').ImageIndex := 0;
                end
              end;
            until FindNext(SearchRec) <> 0;
            FindClose(SearchRec);
          end;
        finally
          trvwLocal.Items.EndUpdate;
        end;
      end;
    end;
end;

```

One thing to notice is the call to my **HasSubFolder** function. By checking to see if a given folder has a subfolder, I can add a fake child node so the + appears in the TTreeView. To dynamically fill in the sub folders when the user expands the plus, I have the following code in the TTreeView OnExpanded event:

```

procedure TMainForm.trvwLocalExpanded(Sender: TObject; Node: TTreeNode);
var
  TreeFolderData: TTreeFolderData;
begin
  TreeFolderData := TTreeFolderData(Node.Data);
  if not TreeFolderData.Opened then
    begin
      TreeFolderData.Opened := True;
    end;
end;

```

```

    AddSubFolders(TreeFolderData.Path, Node);
end;
Node.ImageIndex := 1;
end;

```

Finally, when a directory is selected in the TTreeView, I need to update the TListView on the right with the selected directories contents. In the TTreeView's OnChange event I use the TTreeFolderData to find what path the current node contains, and then fill in the TListView with my FindFiles event:

```

procedure TMainForm.trvwLocalChange(Sender: TObject; Node: TTreeNode);
begin
    if Node <> nil then
        FindFiles(TTreeFolderData(Node.Data).Path);
end;

procedure TMainForm.FindFiles(const Directory: string);
var
    SearchRec: TSearchRec;
    Attributes: Integer;
    Pixmap: QPixmapH;
begin
    // Find files for the local folder to be added to the list view
    lstvwLocal.Items.BeginUpdate;
    try
        lstvwLocal.Items.Clear;
        Attributes := faAnyFile;
        if FindFirst(IncludeTrailingPathDelimiter(Directory) + '*',
            Attributes, SearchRec) = 0 then
            begin
                repeat
                    if (SearchRec.Attr and faDirectory) = 0 then
                        begin
                            with lstvwLocal.Items.Add do
                                begin
                                    Caption := SearchRec.Name;
                                    ImageIndex := 0;
                                    SubItems.Add(IntToStr(SearchRec.Size));
                                    SubItems.Add(DateTimeToStr(FileDateToDateTime(SearchRec.Time)));
                                    // Work around for a bug in setting the image to nothing
                                    // Search the community site for information on how to modify
                                    // the VCL to have this fix.
                                    Pixmap := QPixmap_create;
                                    QListViewItem_setPixmap(Handle, 1, Pixmap);
                                    QListViewItem_setPixmap(Handle, 2, Pixmap);
                                    QPixmap_destroy(Pixmap);
                                end;
                            end;
                        until FindNext(SearchRec) <> 0;
                        FindClose(SearchRec);
                    end;
                end;
            end;

```

```
finally  
    lstvwLocal.Items.EndUpdate;  
end;  
end;
```

That should pretty much be it! There are some other minor things I am leaving out, so [download the complete source](#) from CodeCentral and dig into it.

## Article #27182: CLX styles demo for Kylix

### Clx styles demo for Kylix

By [Corbin Dunn](#)

Delphi Developer Support

Qt styles are what a lot of people know as "Themes". You can easily control the entire look of your application by providing your own custom drawing events, or using one of the built in default styles. This demo gives a complete example of how to do custom drawing and change the theme.

**First, download the complete source from Borland CodeCentral.** CodeCentral only supports zip files, and under Linux I recommend using [KDE's Archiver](#) to open the zip. In this article I will only cover some of the highlights of styles.

First, take a look at the **Default Styles** menu item. This allows you to easily select any of the built in Qt styles, such as the QtSGI theme seen below:

The code to set a theme is quite simple:

```
procedure TMainForm.mnuQtSgiClick(Sender: TObject);  
begin  
    Application.Style.DefaultStyle := dsQtSGI;  
    (Sender as TMenuItem).Checked := True;  
    RefreshChildren(True);  
end;
```

The **RefreshChildren** function is one that I wrote. It removes any custom bitmaps that the other options may have set. Control-click **dsQtSGI** to see all the other predefined themes.

Next, take a look at the ability to set a background bitmap for controls:

It is pretty easy to set a bitmap for all controls using the **Application.Palette**. Calling `Application.Palette.SetBitmap` takes three parameters. The first is the color group. I only set the `cgActive` color group, and the screen shot is not active, so some controls are not painted with the bitmap. A `TColorRole` is the next parameter which tells the Palette what role the bitmap should be applied to (such as the foreground, background, shadows, etc.). Finally, the third parameter is the bitmap you want to assign to it. I have a generic `TMenuItem` `OnClick` event that

does this for me. Also note how I manually set some bitmaps to controls. You could give each control a different bitmap, if you like.

```
procedure TMainForm.mnuSetBitmapsClick(Sender: TObject);  
var  
    ColorRole: TColorRole;  
    Bitmap: TBitmap;  
begin  
    if Sender = mnuLiteWood then  
        Bitmap := FBitLiteWood // These bitmaps are loaded in the FormCreate  
    else if Sender = mnuDarkWood then  
        Bitmap := FBitDarkWood  
    else if Sender = mnuShinyWood then  
        Bitmap := FBitShinyWood  
    else  
        Bitmap := FBitLiteGranite;  
  
    Application.Palette.BeginUpdate;  
    try  
        for ColorRole := crForeground to crHighlightText do  
            Application.Palette.SetBitmap(cgActive, ColorRole, Bitmap);  
    finally  
        Application.Palette.EndUpdate;  
    end;  
    // Manually assign bitmaps to some controls that don't do it  
    // automatically.  
    chkbxNormal.Bitmap := Bitmap;  
    chkbxkTriState.Bitmap := Bitmap;  
    TrackBar1.Bitmap := Bitmap;  
    RefreshChildren(False);  
end;
```

The next thing to take a look at is the **Application.Style** events. Take a look at all the available events in QStyle.pas. Doing drawing in these events controls the entire look and feel of your application. For example, when the **Draw Menu Items** menu item is clicked, I set the events to some of my own procedures:

```
procedure TMainForm.mnuDrawMenuItemsClick(Sender: TObject);  
begin  
    mnuDrawMenuItems.Checked := not mnuDrawMenuItems.Checked;  
    if mnuDrawMenuItems.Checked then  
        begin  
            Application.Style.DrawMenuFrame := DrawMenuFrame;  
            Application.Style.BeforeDrawMenuItem := BeforeDrawMenuItem;  
        end  
    else  
        begin  
            Application.Style.DrawMenuFrame := nil;  
            Application.Style.BeforeDrawMenuItem := nil;  
        end  
    end;
```

```
end;  
end;
```

The other menu items in **Custom Styles** have similar code.

The actual implementation is pretty easy. All you have to do is write code using the standard TCanvas and TFont:

```
procedure TMainForm.DrawMenuFrame(Sender: TObject; Canvas: TCanvas;  
  const R: TRect; LineWidth: Integer; var DefaultDraw: Boolean);
```

```
begin  
  Canvas.Pen.Color := clRed;  
  Canvas.Rectangle(R);
```

```
end;
```

```
procedure TMainForm.BeforeDrawMenuItem(Sender, Source: TObject;  
  Canvas: TCanvas; Highlighted, Enabled: Boolean; const Rect: TRect;  
  Checkable: Boolean; CheckMaxWidth, LabelWidth: Integer;  
  var DefaultDraw: Boolean);
```

```
var  
  Item: TMenuItem;  
  TempRect: TRect;  
  Text: string;  
  TextLeft: Integer;  
  TextTop: Integer;  
  AmpPos: Integer;
```

```
begin  
  DefaultDraw := False;  
  Item := Source as TMenuItem;
```

```
if Highlighted then
```

```
begin  
  Canvas.Brush.Color := clBlack;  
  Canvas.Font.Color := clWhite;
```

```
end
```

```
else
```

```
begin  
  Canvas.Brush.Color := clWhite;  
  Canvas.Font.Color := clBlack;
```

```
end;
```

```
Canvas.FillRect(Rect);
```

```
Canvas.Pen.Style := psSolid;  
TempRect := GetNewRect(Rect);  
Frame3d(Canvas, TempRect, clBlack, clGray, 1);
```

```
TextTop := Rect.Top + (Rect.Bottom - Rect.Top - Canvas.TextHeight('X'))  
div 2;  
if Item.Checked then
```

```

Canvas.Draw(Rect.Left, TextTop, FBitMenuCheck);

AmpPos := Pos('&', Item.Caption);
if AmpPos <> 0 then
begin
  // Output the part before the &
  Text := Copy(Item.Caption, 1, AmpPos-1);
  TextLeft := Rect.Left + FBitMenuCheck.Width;
  Canvas.TextOut(TextLeft, TextTop, Text);
  TextLeft := TextLeft + Canvas.TextWidth(Text);
  // Output the "shortcut character bolded
  Canvas.Font.Style := Canvas.Font.Style + [fsBold];
  Canvas.TextOut(TextLeft, TextTop, Item.Caption[AmpPos+1]);
  TextLeft := TextLeft + Canvas.TextWidth(Item.Caption[AmpPos+1]);
  // Output the rest of the text past the shortcut character
  Canvas.Font.Style := Canvas.Font.Style - [fsBold];
  Text := Copy(Item.Caption, AmpPos + 2, Length(Item.Caption) - AmpPos -
1);
  Canvas.TextOut(TextLeft, TextTop, Text);
end
else
  Canvas.TextOut(Rect.Left + FBitMenuCheck.Width, TextTop, Item.Caption);

  if Item.Count > 0 then
    Canvas.Draw(Rect.Right - FBitArrowBmp.Width - 2, Rect.Top + 2,
FBitArrowBmp);
end;

```

For more examples of custom drawing, [download the complete source](#) from Borland CodeCentral.

## Article #27363: Using queued components in Delphi

Queued Components are feature of COM+ based on Microsoft Message Queuing Services (MSMQ). They provide an easy way to invoke and execute components asynchronously. Processing can occur without regard to the availability or accessibility of either the sender or the receiver.

In COM terms, a queue is a storage area that saves messages for later retrieval. Queuing provides a mechanism for connectionless communication. That is, the sender and receiver are not connected directly and communicate only through queues. Queuing provides a way to hold the information until the receiver is ready to obtain it. The sender and receiver are indirectly communicating so that each can operate independently, unaffected by the other. Here is a simple example of creating and using a queued component in Delphi 6.

First we will **create a server**. All methods in your interfaces must use IN parameters only. Methods can not have return values. This is because there is no "real-time" connection between the client and server. Since you don't know exactly when the call will be processed the client cannot sit waiting for a response from the server.

In Delphi 6 go to File | New | Other | ActiveX and open a new ActiveX Library. Next go back to this same menu option and add an Automation Object. Select a name for your server object. I used QdComponent. Leave the other options at the default and click OK. You should now see the type library editor. Add a new method here by clicking the interface IQdComponent and then clicking the green icon at the top for adding a new method. Call it Task1 and add a parameter called SendMessage. Make this parameter of type BSTR (WideString in Delphi). If you have your type library options set to show Pascal code (in Environment options) then this is what the text for your method should look like:

```
procedure Task1(TaskMessage: WideString) [dispid $00000001]; safecall;
```

Save your project. I called my project MyQdServer and my implementation unit (Unit1 by default) I named QdServer. Fill in the implementation code for the procedure TQdComponent.Task1 in unit QdServer. My component will simply display a message that is sent via the MessageString parameter. Compile, save all and close. Here is what the server unit looks like:

```
unit QdServer;  
{ $WARN SYMBOL_PLATFORM OFF }  
interface  
uses  
  ComObj, ActiveX, MyQdServer_TLB, StdVcl, Dialogs;  
type  
  TQdComponent = class(TAutoObject, IQdComponent)  
  protected  
    procedure Task1(const TaskMessage: WideString); safecall;
```

```

    { Protected declarations }
end;
implementation
uses ComServ;
procedure TQdComponent.Task1(const TaskMessage: WideString);
begin
    ShowMessage(TaskMessage)
end;
initialization
    TAutoObjectFactory.Create(ComServer, TQdComponent,
Class_QdComponent,
    ciMultiInstance, tmApartment);
end.

```

### Installing the server

In the control panel go to the Component Services tool. Expand the tree in order to see "COM+ Application". Right click on this folder and choose New | Application. Choose "Create an empty application" and follow the prompts. When you are done find your new application listed below, right-click on it and go to properties. Go to the Queuing tab and check both check boxes - Queued and Listen. Listen means that any incoming messages on this queue will be processed immediately when it is active.

Under your new application right click on Components and choose New | Component. Choose "Install new component(s)" and follow the prompts to find and install your DLL. Next expand the tree to show the interfaces and right click on IQdComponent to show the properties. Click the Queuing tab and check "Queued". If you see an error message Stating that MSMQ is not running then you probably do not have it installed. It is not installed by default and can be installed by going to Add/Remove programs if you have your OS CDs.

### Creating a Client

Create a new Delphi Application. Add MyQdServer\_TLB to your uses clause. Add a TButton and a TEdit. You will need to create your object when your application starts. To do this you will use a Moniker which specifies the component information. The syntax for this is shown in the FormShow event handler below. This moniker can also contain *Server.InterfaceName* instead of the GUID/CLSID.

```

unit Unit1;
interface
uses
    Windows, Messages, SysUtils, Variants, Classes, Graphics, Controls,
Forms,
    Dialogs, StdCtrls, ComObj, ActiveX, MyQdServer_TLB;
type
    TForm1 = class(TForm)
        Edit1: TEdit;
        Button1: TButton;
        procedure Button1Click(Sender: TObject);
    end;

```

```

    procedure FormShow(Sender: TObject);
private
    { Private declarations }
    QInterface : IQdComponent;
public
    { Public declarations }
end;
var
    Form1: TForm1;
implementation
{$R *.dfm}
Function NewCoGetObject(pazName: PWideChar; pBindOptions: PBindOpts;
    const iid: TIID; out ppv): HRESULT; stdcall; external 'ole32.
dll'
    name 'CoGetObject';
procedure TForm1.Button1Click(Sender: TObject);
begin
    QInterface.Task1(Edit1.Text);
    Edit1.Clear;
end;
procedure TForm1.FormShow(Sender: TObject);
var
    QMoniker : PWideChar;
begin
    QMoniker := 'Queue:/new:{A7ECB8CA-9BBB-4BAB-B018-33210095AE34}';
    OleCheck(NewCoGetObject(QMoniker, nil, IQdComponent, QInterface));
end;
end.

```

Run the client and send a text string. You will notice the message does not appear because you have not started the server. There are a few ways to start the server. The simplest is to go back to the component services in control panel, find your server, right click on it and choose 'Start'. After you start the server the message should appear.

## Article #27366: Calculating Business Days on Oracle

There are quite a number of examples already on the web for calculating business days on Oracle. Here are some links to what I found:

<http://www.arrowsent.com/oratip/tip6.htm>

<http://www.orsweb.com/memberarea/downloads/source/87.htm>

<http://dco-proxima.dco.pima.edu/oracle/tfts/PRE00136.HTM>

However, none of these did exactly what I needed for a job I was doing. What's different about my environment is the need to consider multiple geographic regions and to consider work hours and that different regions might have different work hours.

Here are the deciding factors for how this function decides what to do with timestamp after hours (both weekends and during the week)

- If the start date is after the end of the work day, and before midnight, it is advanced to the beginning of next work day.
- If the start date is before the beginning of the day (and therefore after midnight), it is advanced to the beginning of the current work day.
- If the start date is on a Saturday, it is advanced to the beginning of work day on the following Monday.
- If the start date is on a Sunday, it is advanced to the beginning of work day on the following Monday.
- If the end date is after the end of the work day, and before midnight, it is moved to the end of the day.
- If the start date is before the beginning of the day (and therefore after midnight), it is advanced to the beginning of the current work day.
- If the start date is on a Friday or Saturday it is moved to end of the previous Friday.

This function does not consider holidays, but could be modified to do so if you had a holiday table.

```
CREATE OR REPLACE FUNCTION bdays(start_date IN DATE, end_date IN
DATE, region IN CHAR)
RETURN NUMBER
IS
    retval NUMBER(15,7);
    new_start_date date;
    new_end_date date;
    bdaystart number(15,15);
    bdayend number(15,15);
BEGIN
    new_start_date := start_date;
```

```

new_end_date := end_date;
-- set defaults for business day start and end. Can be overridden per
region
bdaystart := 7/24;
bdayend := 17/24;
if region='Europe' then
    new_start_date := new_start_date + 9/24;
    new_end_date := new_end_date + 9/24;
    bdaystart := 9/24;
    bdayend := 18.5/24;
end if;
if region='Asia-Pac' then
    new_start_date := new_start_date + 15/24;
    new_end_date := new_end_date + 15/24;
end if;
--Start After end of day, make start be start of next day
if new_start_date-trunc(new_start_date)>bdayend then
    new_start_date := TRUNC(new_start_date+1)+bdaystart;
end if;
--Start before start of day, make start be start of same day
if new_start_date-trunc(new_start_date) < bdaystart then
    new_start_date := TRUNC(new_start_date) + bdaystart;
end if;
--Start Saturday, make start be Monday start of day
if to_char(new_start_date,'D')=7 THEN
    new_start_date := TRUNC(new_start_date+2)+bdaystart;
END IF;
--Start Sunday, make start be Monday start of day
if to_char(new_start_date,'D')=1 THEN
    new_start_date := TRUNC(new_start_date+1)+bdaystart;
END IF;
-- end after end of day, make end be end of day same day
if new_end_date-trunc(new_end_date) > bdayend then
    new_end_date := trunc(new_end_date) + bdayend;
end if;
-- end before start of day, make end be start of day the same day
if new_end_date-trunc(new_end_date) < bdaystart then
    new_end_date := trunc(new_end_date) + bdaystart;
end if;
--end on Saturday, make it be the end of the day on Friday
if to_char(new_end_date,'D')=7 then
    new_end_date := trunc(new_end_date-1) + bdayend;
end if;
--end on Sunday, make it be the end of the day on Friday
if to_char(new_end_date,'D')=1 then

```

```
    new_end_date := trunc(new_end_date-2) + bdayend;
end if;
--factor out weekend days
retval := new_end_date - new_start_date -
((TRUNC(new_end_date,'D') - TRUNC(new_start_date,'D'))/7)*2;
-- if holidays were to be calculated, the calculation would go here
-- if end is during nonbusiness hours, difference could be negative
if retval < 0 then
    retval := 0;
end if;
RETURN(retval);
END;
```

## Article #27462: Streaming Bitmaps and other Binary Data to BLOB Fields

If you are reading this article you have probably discovered that reading and writing to and from BLOB fields is not as straight forward as their counterparts, integer and character. The wonderful implicit assignments to integer and character fields just don't exist. Don't despair. Accessing data in a BLOB is not as simple as other field types, but is by no means difficult.

### TBLOBStream

The main difference in accessing BLOB data is the use of streams for the actual data transfer. Once you have a reference to your Dataset's BLOB field, you open a stream to it by passing that reference to TBLOBStream's Create method. TBLOBStream descends from TStream and encapsulates the operations that allow your applications to read from or write to Binary Large Object(BLOB) fields.

There are a few things that you should take into consideration when creating your BLOB streams(s). One is that you should make sure to create a new instance of TBLOBStream for every field you plan to read from and free it when you are done. That other is that even though TBLOBStream lets you create instances of it to use with any kind of DataSet, it is best to instead call the particular DataSet's CreateBLOBStream method. It works exactly like TBLOBStream.Create, but it instantiates an object specific for that Dataset(TTable,TQuery). My examples will uses this method.

### A Simple Example: Streaming Bitmaps

While BLOBs can hold many different kinds of data, including MEMOs and... well just about anything you want, my example will focus on the streaming of bitmap files. These concepts hold true for all types of data.

### Using the BDE

First, start a new Delphi application and drop on your database components for your connection. This will include a TDataBase and TQuery. Hook your Query to your Database object and set it's RequestLive property to true, since we will be inserting data. Now we will write your bitmap image to you database field. First we will want a Bitmap to work with. After declaring a TBitmap, create it and load a file with your favorite picture into it.

```
MyFavoriteBitmap := TBitmap.Create;  
MyFavoriteBitmap.LoadFromFile('drive:pathMyFavoriteBitmap.bmp');
```

Once you have a Bitmap ready and waiting, you can go ahead and create your BLOB stream. To do this, you will need to get a reference to your blobfield from the query. If you know the name for the field, TDataSet.FindByName is the easiest. Now Pass this reference into CreateBLOBStream along with the BlobStreamMode(bmRead,bmWrite,bmReadWrite), which will return reference to a TStream. We are going to use this to actually stream the file using TBitmap's SaveToStream method.

```

procedure SavePictureToDatabase;
var
  BlobField: TField;
  BS: TStream;
begin
  with Query1 do
    begin
      Insert;
      BlobField := FieldByName('picturefield');
      BS := CreateBlobStream(BlobField,bmWrite);
      Bitmap.SavetoStream(BS);
      Post;
    end;
  end;

```

**Using dbExpress** Those of you using the new dbExpress components will find the process is identical with a few minor exceptions. If you are using TSQLQuery or TSQLTable, you are enjoying their extremely fast execution for your reporting applications. But since they do not cache their data, there is no way for you to edit any records, let alone your BLOBS. Don't forget that you must use TSQLClientDataSet instead of TSQLDataSet's to achieve this functionality. In code, the difference is trivial for writing your picture to a database.

```

procedure SavePictureToDatabase;
var
  BlobField: TField;
  BS: TStream;
begin
  with SQLClientDataSet1 do
    begin
      Insert;
      BlobField := FieldByName('picturefield');
      BS := CreateBlobStream(BlobField,bmWrite);
      Bitmap.SavetoStream(BS);
      Post;
    end;
  end;

```

When you are ready to read your bitmap back out, use the built in TBitmap method and you are set.

```

Blobfield := FieldbyName('picturefield');
BS := CreateBlobStream(BlobField,bmReadWrite);
MyFavoriteBitmap.LoadFromStream(BS);

```

**Other types of binary data**

When moving in large chunks of data that do not have convenient loading and saving methods like TBitmap, you must employ the TStream methods (Read, ReadBuffer, Write, WriteBuffer) manually. You can even stream components and their properties using WriteComponent and ReadComponent, were you so inclined.

```
var
  MyComponent: TMyComponent //any TComponent
begin
  MyComponent := TMyComponent.Create;
  MyComponent.aProperty := aValue;
  BS := CreateBlobStream(Blobfield,bmReadWrite);
  BS.WriteComponent(MyComponent);
end;
```

There you have it. A quick intro to using BLOBs to store binary data. I think the moral of the story is quite clear: Don't take candy from strangers', kids.

## Article #27508: How can I change a folders Icon in Delphi?

### QUESTION:

How change the appearance of a folder icon?

### ANSWER:

The process of changing a folder's icon is pretty easy and there are a couple of ways that you can do it. In this article I'll show you how you can do it programmatically. I am only going to cover the general outline of how I made this project, so you can [download the complete source](#) from CodeCentral.

The first step is to create a Desktop.ini file and place it in the directory that you want to have a custom icon. In my project I used a TIniFile and pass it the path of the directory to which I am going to change the Icon.

Next you will want to start writing out <key>=<value> pairs to the .ini file. Before doing this you may want to add the option to use custom Folder.htt templates. If this is the case then you will want to write out the following <key>=<value> pairs (don't mind the GUID looking things, don't change them either):

```
[ExtShellFolderViews]
Default={5984FFE0-28D4-11CF-AE66-08002B2E1262}
{5984FFE0-28D4-11CF-AE66-08002B2E1262}={5984FFE0-28D4-11CF-AE66-08002B2E1262}
[ {5984FFE0-28D4-11CF-AE66-08002B2E1262} ]
PersistMoniker=file://Folder.htt
```

In Delphi the code would look something like this:

```
with iniFile do
begin
  //Next three lines are window specific and shouldn't be changed..
  WriteString('ExtShellFolderViews',
'Default', '{5984FFE0-28D4-11CF-AE66-08002B2E1262}' );
  WriteString('ExtShellFolderViews', '{5984FFE0-28D4-11CF-AE66-08002B2E1262}',
' {5984FFE0-28D4-11CF-AE66-08002B2E1262}' );
  WriteString('{5984FFE0-28D4-11CF-AE66-08002B2E1262}', 'PersistMoniker', 'file://
Folder.htt');
  UpdateFile; //For Windows 98/95
end;
```

If you don't want to worry about Folder.htt templates then ignore the code above. The important part is to specify the icon and its index. In the Desktop.ini file the <key>=<value> pairs should look something like this:

```
[.ShellClassInfo]
IconFile=C:\LocationofFolder.ico
IconIndex=0
InfoTip=Delphi is the coolest IDE ever!
```

The IconFile value should be the path to a .dll, .ico, or .exe. If the icon resides within a dll then IconIndex value should match its entry within the dll. In Delphi the code to do this is as follows:

```
with iniFile do
begin
  //These are the lines that will change the icon
  WriteString('.ShellClassInfo', 'IconFile', editIconPath.Text);
  WriteString('.ShellClassInfo', 'IconIndex', editIconIndex.Text);
  WriteString('.ShellClassInfo', 'InfoTip', 'Use Delphi because it
rocks!');
  UpdateFile;
end;
```

Now that the Desktop.ini file has been created you will need to change the attributes of the folder and apply the system flag. I found that I had to set the system flag for both the folder and the folders parent in order to view the icon correctly. (This way if a subfolder had a custom icon, the icon would show up in the left hand pain of Windows Explorer.) To set the file attribute I used *SetFileAttribute()*. Here is an example of how to do it in Delphi:

```
//Next we need to set the system attribute for the folder and its parent
SetFileAttributes(PChar(edFolderPath.Text), FILE_ATTRIBUTE_SYSTEM);
if Length(edFolderPath.Text) > 3 then //If not at the root of a disk...
begin
  //LastChar is a funtion that I wrote which returns an index of the last occurance
  of symbol in a string...
  //This way I can easily get the parent Directory path... unless the parent is the
  root of the disk...
  tempDir := Copy( edFolderPath.Text, 1,LastChar(edFolderPath.Text, '\')-1);
  SetFileAttributes(PChar(tempDir), FILE_ATTRIBUTE_SYSTEM);
end;
```

## Article #27879: Using a TreeView in conjunction with a Master Detail relationship.

You can download a sample project from Code Central [here](#). Using a TTreeView to illustrate the relationship of master-detail query can greatly add to the user interface of you application. Not only does this process add to the UI, but it is also easy to do!

Lets say there are two tables on a form, the first table is linked to DBDemos->Customer and the other table is linked to DBDemos->Orders. (The shared key is on "CustNo")

### Filling the TreeView with the Master Information

We'd like the TreeView to list all of the Customer Company Names, so in the main forms **OnShow()** method we can iterate through the master dataset and fill the TreeView. Here is the code for the Form's OnShow event.

```
procedure TMainFrm.FormShow(Sender: TObject);
var
  tnCompany: TTreeNode;
begin
  tbCustomer.Active := True;
  tbOrders.Active := True;
  tbCustomer.DisableControls;
  tbCustomer.First;
  while not tbCustomer.Eof do
  begin
    tnCompany := TreeView1.Items.Add(nil, tbCustomer.Fields[1].AsString);
    //tnCompany.Data := ...Could set the pointer to point to something relevant to
the field...

    //When user clicks on it we will try to expand and fill with orders...
    //This gives the appearance that there are sub items to add...
    TreeView1.Items.AddChild(tnCompany, ' ');
    tbCustomer.Next;
  end;
  tbCustomer.First;
  tbCustomer.EnableControls;
end;
```

You'll notice that no assignment to the Node's **Data** property was made. The Data pointer can be used to store custom data, which in this case could have been used to hold record information. To do this one could create a custom class, or record, and copy the data into an instance of the class/record, and then point the Data property at the newly created instance. You'll also notice that we add a child node underneath the current node. This is done to give the appearance that there is additional information to be gotten from the current node.

### Adding Detail Information to Parent Nodes.

When the user clicks on the plus sign of a particular customer in the TreeView, we would like an event to grab the orders for that customer. In this example the TreeView's **OnExpanding()** is the perfect event to use. The idea is to locate the record in the master dataset and then iterate through the detail's dataset adding child nodes in the TreeView for each new record we encounter. Here is the code for the **OnExpanding** event.

```

procedure TForm1.TreeView1Expanding(Sender: TObject; Node: TTreeNode;
  var AllowExpansion: Boolean);
var
  oldCursor: TCursor;
  bkmrkCust, bkmrkOrd: TBookmark; //needed to restore original state.
begin
  //Save state..
  oldCursor := Screen.Cursor;
  bkmrkCust := tbCustomer.GetBookmark;
  bkmrkOrd := tbOrders.GetBookmark;

  //Begin query
  Screen.Cursor := crSQLWait;
  if tbCustomer.Locate('Company',VarArrayOf([Node.Text]),[loCaseInsensitive]) then
  begin
    // Note this doesn't take car of the times when a user clicks on the same node
more that once....
    //need to add logic to determine whether or not a node has been filled with
data...
    //this could be done with the data property
    Node.Item[0].Delete; //Remove the temporary subitem created earlier...

    while not tbOrders.Eof do
    begin
      //Whatever node we are at we can now add child nodes... until the end of the
dataset is reached
      TreeView1.Items.AddChild(node,tbOrders.Fields[0].AsString);
      tbOrders.Next;
    end;
  end
  else
    Node.Item[0].Delete; //In case there were no items for this particular customer

  //Return Datasets to original state
  tbCustomer.GotoBookmark(bkmrkCust);
  tbOrders.GotoBookmark(bkmrkOrd);

  //free up resources
  tbCustomer.FreeBookmark(bkmrkCust);
  tbOrders.FreeBookmark(bkmrkOrd);

  Screen.Cursor := oldCursor;
  TreeView1.Invalidate; //Be sure to repaint the TreeView when done...
end;

```

Notice that there is no logic currently in place to determine if the node has already been expanded or not, which will cause the child list to grow each time it is expanded. Again we could use the result from **AddChild()** to store record specific data in the node's Data property.

## Article #27953: Retrieving a list of installed Applications on Windows

Here is a method for retrieving a list of installed applications on a particular machine running a Windows OS.

1. Start up Delphi.
2. Select File | New Application.
3. Add Registry to the uses of your new Unit.
4. Place a TListBox (ListBox1) component on your form.
5. Place a TButton (Button1) in your form.
6. Place the following code in the OnClick event of the Button1:

```
procedure TForm1.Button1Click(Sender: TObject);  
const  
    REGKEYAPPS = '\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall';  
  
var  
    reg      : TRegistry;  
    List1    : TStringList;  
    List2    : TStringList;  
    i, n     : integer;  
  
begin  
    reg      := TRegistry.Create;  
    List1    := TStringList.Create;  
    List2    := TStringList.Create;  
  
    {Load all the subkeys}  
    with reg do  
    begin  
        RootKey := HKEY_LOCAL_MACHINE;  
        OpenKey(REGKEYAPPS, false);  
        GetKeyNames(List1);  
    end;  
    {Load all the Value Names}  
    for i := 0 to List1.Count -1 do
```

**begin**

```
reg.OpenKey(REGKEYAPPS + ' ' + List1.Strings[i],false);  
reg.GetValueNames(List2);
```

```
{We will show only if there is 'DisplayName'}
```

```
n := List2.IndexOf('DisplayName');
```

```
if (n <> -1) and (List2.IndexOf('UninstallString') <> -1) then
```

```
begin
```

```
ListBox1.Items.Add((reg.ReadString(List2.Strings[n])));
```

```
end;
```

```
end;
```

```
List.Free;
```

```
List2.Free;
```

```
reg.CloseKey;
```

```
reg.Destroy;
```

```
end;
```

## Article #28258: Working with TMultiReadExclusiveWriteSynchronizer

### Working with TMultiReadExclusiveWriteSynchronizer

By [Justin Swett](#)

Delphi Developer Support

There will undoubtedly come a time when the need for developing a multi threaded application is a necessary. In some cases the use of a TMultiReadExclusiveWriteSynchronizer (TMREWS for short) will improve the performance of your threads, and therefore improve the performance of your application. (As a parenthetical side note, don't you just love saying "TMultiReadExclusiveWriteSynchronizer!") This article will cover the basics of using a TMREWS and point out some not so obvious pitfalls to avoid. You can [download](#) the complete project here.

#### When to use a TMultiReadExclusiveWriteSynchronizer

As the name of the component implies, a TMREWS should be used when there is much reading and little writing to be done. In addition, the READ operations should be kept to a MINIMUM otherwise your write threads could be left waiting indefinitely. If there are going to be equal amounts of READING and WRITING then you might want to consider using critical sections instead.

#### Creating a Thread Class that uses the TMREWS

One of the first things to do is declare a TMREWS. If you downloaded the complete project, you'll see a global lock declared inside the implementation section of the thread unit. It doesn't matter where the lock is declared so long as the following criteria are met:

- Threads can access the lock.
- The lock has been instantiated.  
(Use initialization section and finalization for this)
- Threads can access memory that you are trying to read/write to.

Once the lock has been declared you can create your thread class. You will need to override the Execute procedure, which is where you will be using TMREWS lock. Here is an example of an execute procedure using the TMREWS:

```
procedure TWorkerThread.Execute;  
begin  
  { Place thread code here }  
  while not Terminated do  
  begin  
    //Updates form that thread is "sleeping"  
    Synchronize(Sleeping);  
    //Sleep thread momentarily, for illustrative purposes  
    Pause;  
  
    //Update form that thread is "waiting"
```

```

Synchronize(Waiting);

//check to make sure thread hasn't been terminated
if Terminated then exit;

//if reader then
if (fThreadType = ttRead) and (not Terminated) then
begin
    globalLock.BeginRead;
    //wrap endRead in try finally... otherwise deadlock could occur
    try
        Synchronize(Reading);    //Still important to synchronize VCL calls
        Pause;                    //represents thread work being done
        Synchronize(DoneReading);
    finally
        globalLock.EndRead;
    end;
end
//if writer then
else if (fThreadType = ttWrite) and (not Terminated) then
begin
    globalLock.BeginWrite;
    //wrap in a try finally to prevent deadlock
    try
        Synchronize(Writing);
        Pause; // represents data manipulation
        Synchronize(DoneWriting);
    finally
        globalLock.EndWrite;
    end
else
    exit;
end;
end;

```

Notice that the work done after Begin'X' is wrapped in a try finally. This ensures that that the appropriate End'X' will get called if any exceptions are raised . If an exception is raised then other threads might not be able obtain locks. If there is no chance of an exception being raised, then removing the try finally for performance reasons would be acceptable.

Make sure any memory being referenced by your threads is sandwiched with calls to the TMREWS BeginREAD/WRITE and EndREAD/WRITE, otherwise your work of making your data thread safe is forfeited.

## **"Lock it up Chris, I'm about to..."**

TMREWS allows you to promote a READ lock to a WRITE lock if the same thread were to make such a request. Although this can be advantageous it can also cause two threads to lock up on each other. For example, two instances of a thread type are instantiated with an Execute method which promotes a read lock to a write lock. If the first thread calls BeginWrite after the second thread has called BeginWrite then the first thread is blocked. The second thread will at some point attempt to call BeginWrite, which will also get blocked. Now the two threads are waiting for the other to release the lock.

Another situation will arise where several Read threads are running and perhaps just a few Write threads. Whenever a Read thread calls BeginRead a Read lock is granted... so long as there isn't a Write lock currently out. If a Write thread were to call BeginWrite while a Read thread had the lock it could potentially be wait indefinitely, while other read threads obtain Read locks. Requests for locks are not queued, so this isn't a bug and is in fact as designed.

## **Summary**

Using the TMultiReadExclusiveWriteSynchronizer (just had to say it one more time) is fairly simple. To use them successfully you should call BeginRead/Write matched with the appropriate EndRead/Write. You should also check you read locks out for as little time as possible if you want your write threads to complete their execution.

## Article #28325: Encrypting and Decrypting strings in Delphi.

### QUESTION:

How can I encrypt and decrypt string values?

### ANSWER:

There are a number of ways to do this, below is a code sample that demonstrates one of the ways. Start with a form, and drop three Edit components, and two buttons. Add the EnDeCrypt function to the TForm1 class declaration in the type portion of the Unit. Omitting the TForm. section of the declaration. Then add the function in the implementation section of the Unit as shown below. Now double click each of the buttons and add the code as shown below. Run the project, in the Edit1 text area type in a word and click Button1. Now click Button2, you should see your word encrypted in Edit2 text and decrypted in Edit3 text. This should give you a basic idea on how Encryption works.

```
type
  TForm1 = class(TForm)
    Button1: TButton;
    Edit1: TEdit;
    Edit2: TEdit;
    Button2: TButton;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    function EnDeCrypt(const Value : String) : String;
    procedure Button2Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

function TForm1.EnDeCrypt(const Value : String) : String;
var
  CharIndex : integer;
```

```
begin
  Result := Value;
  for CharIndex := 1 to Length(Value) do
    Result[CharIndex] := chr(not(ord(Value[CharIndex])));
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit2.Text := EnDeCrypt(Edit1.Text);
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit3.Text := EnDeCrypt(Edit2.Text);
end;
```

## Article #28416: How to debug a COM+ component in Delphi.

Assuming you have already created a COM+ component in Delphi, these are steps for debugging:

1. In Delphi, go into the menu option Project | Options | Linker and setting the Include remote debug symbols option.
2. Go into the menu option Run | Parameters.  
On the Local tab, under Host Application enter **C:\WINNT\system32\dllhost.exe**  
Under Parameters enter **/ProcessID:{GUID}**  
where *GUID* is the Application ID for your application.

This GUID can be obtained by going into Control Panel | Administrative Tools | Component Services  
Locate the COM+ application under Component Services | Computer and open its properties.  
On the first page below, the description box, is the Application ID.

After you have entered these parameters you can run the app (F9) to begin debugging.

## Article #28452: How to control user input into a TEdit component.

### QUESTION:

How can I control user input to a TEdit component?

### ANSWER:

There are a number of ways to do this. Below the code samples explore restricting user input to only allow numbers to be added into the TEdit component. You can extend the functionality to include other keys, incorporate other restrictions. The first sample only allows positive integers to be entered into the TEdit component. Add the code below to the OnKeyPress event handler.

```
procedure TForm1.Edit1KeyPress(Sender: TObject; var Key: Char);  
begin  
  if not (Key in [#8, '0'..'9']) then  
  begin //Backspace is #8.  
    ShowMessage('Please enter the corect input');  
    Key := #0; //Pass in #0 to disregard the key after it's use.  
  end;  
end;
```

If you want to add more functionality, you could also allow users to enter Decimal numbers. Below is the code sample that does this.

```
procedure TForm1.Edit1KeyPress(Sender: TObject; var Key: Char);  
begin  
  if not (Key in [#8, '0'..'9', DecimalSeparator]) then  
  begin  
    ShowMessage('Please enter a number. Wrong input: ' + Key);  
    Key := #0;  
  end//End first if.  
  else  
  if (Key = DecimalSeparator) and (Pos(Key, Edit1.Text) > 0) then  
  begin  
    ShowMessage('Please enter a number. Wrong input: ' + Key);  
    Key := #0;  
  end//End second if.  
  
end;
```

Now you can add more functionality, by allowing the user to add Negative numbers. Below is a code sample that does this.

```
procedure TForm1.Edit1KeyPress(Sender: TObject; var Key: Char);  
begin  
if not (Key in [#8, '0'..'9', '-', DecimalSeparator]) then
```

```
begin
  ShowMessage('Wrong input' + Key);
  Key := #0;
end;//End first if.
else
  if ((Key = DecimalSeparator) or (Key = '-')) and (Pos(Key, Edit1.Text) > 0)
then
  begin
    ShowMessage('Wrong input ' + Key);
    Key := #0;
  end;//End second if.
  else
    if (Key = '-') and (Edit1.SelStart <> 0) then
    begin
      ShowMessage('Please add at the beginning of the number: ' + Key);
      Key := #0;
    end;//End third if.
  end;
```

## Article #28502: How to use a parameterized query with a Remote Data Service.

There is a demo that comes with Delphi which uses TRDSCConnection to connect to the DBDEMOS database using ADO. We are going to modify the server part of this by adding a Command object, as well as few other objects. We will be using Command.Execute instead of Result.Open. It is possible to execute a query without using a Command object by passing a query string to the Execute method of a Connection object or to the Open method of a Recordset object, but a Command object is required when you want to use query parameters.

Below is the code used to create a parameterized query using an ADO Command object. To test out this code just open the RDS demo: C:\Program Files\Borland\Delphi6\Demos\Ado\Rds. Replace the code for function TRDSAppServer.Get\_Employee: \_Recordset; with the code below.

```
function TRDSAppServer.Get_Employee: _Recordset;
var
  ConnStr: WideString;
  CMD : _command;
  vRecsAffected, vParams: OleVariant;
  aConnection: _Connection;
begin
  ConnStr := 'FILE NAME=' + DataLinkDir + 'DBDEMOS.UDL';
  aConnection := CoConnection.Create;
  aConnection.ConnectionString := ConnStr;
  aConnection.Open(ConnStr, '', '', -1);
  CMD := CoCommand.Create;
  CMD.Set_ActiveConnection(aConnection);
  CMD.CommandType := adCmdText;
  CMD.CommandText := 'SELECT * FROM Employee WHERE EmpNo = :EmpNo';
  Result := CoRecordSet.Create;
  Result.CursorLocation := adUseClient;
  Result.CursorType := adOpenForwardOnly;
  Result.LockType := adLockOptimistic;
  vRecsAffected := -1;
  vParams := CMD.CreateParameter('EmpNo', adInteger, adParamInput, 0,
4);
  Result := CMD.Execute(vRecsAffected, vParams, adCmdText);
end;
```

You can use code completion in Delphi to find the meaning of each of the parameters - just hold the cursor over the procedure name. The key to using a query with ADO, whether you are using the result set's open method or the Command object, is the command option adCmdText. Stored procedures can

also be used to execute queries. In this case calling open with the command option of adCmdStoredProc will work, and will not require the Command object.

When running this program you may get the error "Dataset does not support bookmarks, which are required for multi-record data controls". As far as I can tell, this is a problem with the OLE provider, not with Delphi. To avoid this do not use a DBGrid. Use other data-aware components instead (just drag the fields from the fields editor onto the form).

For more information on ADO Commands see the [ADO API Reference](#) on the Microsoft web site.

For more about RDS go [here](#)

.

## Article #28614: Configuring NSAPI servers to handle ISAPI DLL requests

For ISAPI DLLs to work with an NSAPI server such as Netscape server and IPlanet, a MIME type must be assigned to the ISAPIs. Borland provides an ISAPI adapter DLL named ISAPITER.DLL located in your C++Builder or Delphi directory under `\bin\NetscpXX` (where X is the server version). The server must be set to use this DLL to handle requests for ISAPI DLLs. The following steps accomplish this task:

1. Copy ISAPITER.DLL from the Delphi or C++Builder `bin\netscpXX` directory to `C:\Netscape\Server\Nsapi\Examples` (actual directories may vary based on server versions and installation locations).
2. In the server's OBJ.CONF file, find this line:

```
fn=load-types mime-types=mime.types
```

and insert the following line after it:

```
Init funcs="handle-isapi,check-isapi,log-isapi" fn="load-modules"  
shlib="c:/netscape/server/nsapi/examples/ISAPIter.dll"
```

3. In OBJ.CONF, find the section:

```
<Object name=default>
```

Within this section, find the line reading:

```
NameTrans fn=document-root root="C:/Netscape/Server/docs"
```

and insert this line directly above it:

```
NameTrans from="/scripts" fn="pfx2dir" dir="C:/Netscape/Server/  
docs/scripts"  
name="isapi"
```

4. At the end of OBJ.CONF insert:

```
<Object name="isapi">  
  PathCheck fn="check-isapi"  
  ObjectType fn="force-type" type="magnus-internal/isapi"  
  Service fn="handle-isapi"  
</Object>
```

5. Append the following line to the end of the server's MIME.TYPES file:

```
type=magnus-internal/isapi exts=dll
```

## Article #28663: How to Surface Errors in WebSnap and Still Retain Field Values.

by,  
[Justin Swett](#)

A common task in web applications is validating data whenever a user submits something to your site. In most cases the web application does some kind of processing on the data and either rejects the data, or hums along merrily.

In cases where the user enters invalid data it is often required to relate this problem back to the user. In some cases some of the data is correct and doesn't need to be reentered. From a user's standpoint it makes sense to retain field values that don't need to be reentered.

WebSnap offers a way to validate the data and surface errors when they occur, as well as retain field values. This article will cover the steps necessary to perform such a task in Delphi. A sample program can be downloaded [here](#).

**Some knowledge of WebSnap would be advisable before reading this document. It is assumed that you know how to create AdapterFields and AdapterActions as well as how to incorporate them in the server script through the Web Page Editor.**

You WebSnap application should have a WebModule with an AdapterPageProducer and Adapter on it. The Adapter will need at least one AdapterField and one AdapterAction. Once you have created an AdapterForm you should "Add Component" (to the AdapterForm) and add an AdapterErrorList. To validate the data we will put code in the Adapter's OnBeforeExecute event and add errors to the AdapterErrorList. This event fires before the AdapterAction's Execute method fires and provides a way to prevent the Execute method from executing all together. Below is a example of some code that would be executed in the OnBeforeExecute event:

```
procedure TSomeForm.Adapter1BeforeExecuteAction(Sender, Action: TObject;
  Params: TStrings; var Handled: Boolean);
begin
  //BeforeExecute is called each time an Action gets executed.
  //for this reason we have to check which action we are in and make sure it is the
one we
  //want to validate.
  if TAdapterAction(Action).ActionName = 'adpActSubmit' then
  begin
    if (adpFldSomeInt.ActionValue <> nil) and (adpFldSomeInt.ActionValue.ValueCount
  > 0) then
    begin
      try
        //Simple check to see if field can be converted to an integer...
        StrToInt( adpFldSomeInt.ActionValue.Values[0] );
      except on E: Exception do
        begin
          //if there is an exception raised during the conversion then we can
surface this
          //through our Adapter.Errors property
          Adapter1.Errors.AddError(
            Format('%s is not an integer', [adpFldSomeInt.ActionValue.Values
  [0]]));
          //Next we would like to reflect the data that the user entered
          Adapter1.EchoActionFieldValues := True;
          //Finally stop the chain of events here to prevent the actual action from
executing...
          Handled := True;
        end
      end
    end
  end
```

```
        end;
    end;
end
else
begin
    Adapter1.Errors.AddError('Please enter an integer!');
    Adapter1.EchoActionFieldValues := True;
    Handled := True;
end;
end;
end;
```

In the example we tested the ActionValue of the adapter field to see if it was a valid integer. If for some reason the value couldn't be converted to an integer then an exception would have been raised. When we handle the exception we can add strings to the Adapter's Errors property and notify the user of their mistake(s).

The next step is to preserve the Field Values, which is done with the Adapter's EchoActionFieldValues property. Setting this property to True will display the values that were initially entered on the form the next time the user sees it.

Finally, the Handled property must be set to True if an error occurs. If this variable is set to False then the AdapterAction's Execute method will be called. If this variable is set to True the chain of events stops after OnBeforeExecute has finished. Validation can be done from within the Execute method, however you will not be able to surface any errors. You'll also notice in the Adapter's OnBeforeExecute that a parameter named Action was passed in. This variable can be cast to a TAdapterAction and the ActionName can be retrieved. This is useful since OnBeforeExecute will fire for every Action and you may only want to perform certain checks for certain actions.

You will now be able to create web forms and validate the data.

## Article #28936: How to change the default printer from Delphi.

Changing the default printer in Windows 2000 requires changing the registry key HKEY\_CURRENT\_USER\Software\Microsoft\Windows NT\CurrentVersion\Windows\Device. This can be done from Delphi using Windows API calls.

Below is an entire unit you can copy. Start a new application and add 2 TButtons, 1 TLabel and 1 TListBox. Save and compile. Then replace all of the code in your Unit1 with the code below. Then be sure to double click each button to set the event handler.

**unit** Unit1;

**interface**

**uses**

Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms, Dialogs, StdCtrls;

**const**

MAXPRINTERBUFFER = 8000;

MAXPRINTERNAME = 500;

MAXPRINTERINFO = 50;

**type**

TPrinterBuffer = **array**[0..MAXPRINTERBUFFER - 1] **of** char;

TForm1 = **class**(TForm)

Listbox1: TListBox;

Button2: TButton;

Button1: TButton;

Label1: TLabel;

**procedure** Button2Click(Sender: TObject);

**procedure** GetPrinterNames;

**function** ParseNames(**const** namebuffer: TPrinterBuffer; var startPos: integer): **string**;

**function** SetPrinter(**const** PrinterName : **String**) : boolean;

**procedure** Button1Click(Sender: TObject);

**private**

{ *Private declarations* }

**public**

{ *Public declarations* }

**end**;

**var**

Form1: TForm1;

```
printerNames: TStringList;  
defaultPrinter: integer;
```

## implementation

```
{$R *.DFM}
```

```
procedure TForm1.Button2Click(Sender: TObject);
```

```
var
```

```
  x : integer;
```

```
begin
```

```
  try
```

```
  for x := 0 to printerNames.Count -1 do begin
```

```
    if ListBox1.Selected[x] then begin
```

```
      if (SetPrinter(ListBox1.Items.Strings[x]))
```

```
      then label1.Caption := 'Printer set to ' + ListBox1.Items.Strings[x]
```

```
      else label1.Caption := 'Printer not set';
```

```
    end;
```

```
  end;
```

```
  except
```

```
    label1.Caption := 'An error occured while setting the printer';
```

```
  end;
```

```
end;
```

```
procedure TForm1.GetPrinterNames;
```

```
var
```

```
  buffer: TPrinterBuffer;
```

```
  currPos: integer;
```

```
  printerName: string;
```

```
begin
```

```
  printerNames.Free;
```

```
  printerNames := TStringList.Create;
```

```
  if GetProfileString(PChar('PrinterPorts'), nil, '', buffer, MAXPRINTERBUFFER) > 0 then
```

```
  begin
```

```
    currPos := 0;
```

```
    while (true) do
```

```
      begin
```

```
        printerName := ParseNames(buffer, currPos);
```

```
        if printerName <> '' then
```

```
          printerNames.Add(printerName)
```

```
      else
```

```
        break;
```

```
      end;
```

```
  end;
```

```
end;
```

```

function TForm1.ParseNames(const namebuffer: TPrinterBuffer;
var startPos: integer): string;
var
  i, j, NameLength: integer;
  str: string;
begin
  result := "";
  if (startPos > High(namebuffer)) or (namebuffer[startPos] = Chr(0))
  then
    exit;
  for i := startPos to High(namebuffer) do begin
    if namebuffer[i] = Chr(0)
    then begin
      nameLength := i - startPos;
      SetLength(str, nameLength);
      for j := 0 to nameLength - 1 do
        str[j+1] := namebuffer[startPos + j];
      result := str;
      startPos := i + 1;
      break;
    end;
  end;
end;

```

```

function TForm1.SetPrinter(const PrinterName: String): boolean;
var
  s2 : string;
  dum1 : Pchar;
  xx, qq : integer;
const
  cs1 : pchar = 'Windows';
  cs2 : pchar = 'Device';
  cs3 : pchar = 'Devices';
  cs4 : pchar = #0;

```

```

begin
  xx := 254;
  GetMem( dum1, xx);
  Result := False;
  try
    qq := GetProfileString( cs3, pchar( printerName ), #0, dum1, xx);
    if (qq > 0) and (trim( strpas( dum1 )) <> "")
    then begin
      s2 := PrinterName + ',' + strpas( dum1 );
    end;
  except
  end;

```

```

while GetProfileString( cs1, cs2, cs4, dum1, xx) > 0 do
  WriteProfileString( cs1, cs2, #0);
WriteProfileString( cs1, cs2, pchar( s2 ));
case Win32Platform of
  VER_PLATFORM_WIN32_NT :
    // SendMessage( HWND_BROADCAST, WM_WININICHANGE, 0, LongInt(cs1));
    // VER_PLATFORM_WIN32_WINDOWS :
    // SendMessage( HWND_BROADCAST, WM_SETTINGCHANGE, 0, LongInt(cs1));
  end;
  Result := True;
end;
finally
  FreeMem( dum1 );
end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  GetPrinterNames;
  Listbox1.Items.AddStrings(PrinterNames);
end;

end.

```

This sample is for Windows 2000 or NT but you should be able to adapt this code to your needs. The call to SendMessage notifies any other apps that are running that the default printer has changed. Sometimes this can cause the app to "freeze" because it is waiting for a reply from each app (which it may never get) so the code is commented out here. You can determine whether you need it or not.

## Article #28956: How to programmatically open and close the CD-Rom drive.

### Question

### How can you use Delphi to open and close the CD-Rom drive?

### ANSWER:

Start Delphi and select File | New | Application. In Unit1.pas add MMSystem to the uses. Drop two buttons on your form. Name the first button **btnOpen** and name the second button **btnClose**. Change the caption of btnOpen to **Open** and the caption of btnClose to **Close**. Add the following code to the btnOpen OnClick event:

```
procedure TForm1.btnOpenClick(Sender: TObject);  
begin  
    mciSendString('Set cdaudio door open wait', nil, 0, 0);  
end;
```

Now add the following code to the btnClose OnClick event:

```
procedure TForm1.btnCloseClick(Sender: TObject);  
begin  
    mciSendString('Set cdaudio door closed wait', nil, 0, 0);  
end;
```

The code I just demonstrated will open up the default CD-Rom drive. What if you have a CD-Rom drive along with a CD-Burner? Here is an example of how you would do that. In the btnOpen OnClick event, place the following code:

```
procedure TForm1.btnOpenClick(Sender: TObject);  
begin  
    // Open drive X: (X being the letter of the drive you wish to open)  
    mciSendString('open cdaudio!X: alias driveX', nil, 0, 0);  
    mciSendString('set driveX door open wait', nil, 0, 0);  
end;
```

Now go ahead and add the following to the btnClose OnClick Event:

```
procedure TForm1.btnCloseClick(Sender: TObject);  
begin  
    // Close drive X:  
    mciSendString('set driveX door closed wait', nil, 0, 0);  
end;
```

## Article #29028: Revamp Your Main Menu with Delphi 7

Revamp your applications using Delphi 7

By

[Justin Swett](#)

Borland Developer Support

Delphi 7 introduces the ability to add Windows XP styling to your ActionToolBar and ActionMainMenuBar through the ActionManager. This document will demonstrate how to use **ActionMainMenuBar** to create a XP styled menu with sub menu's.

### Enable XP Style

The first step is to create a New Application (File | New | Application )and drop an **ActionManager** on the Form. Next you should set the *Style* property of the ActionManager to *XP Style*.

### Creating Menu's and Sub Menu's

With the ActionManager on the Form we can now drop a **ActionMainMenuBar** and begin making our menu system. ActionMainMenuBar is located on the Additional tab of the component palette. The ActionManager comes with Standard Actions, which are useful for many applications, however, the Standard Actions are not fine tuned enough for the needs of every application. In order to make a customized menu system you will need to create a new Category. The Standard Actions serve as an example since they are grouped by category, such as actions listed in the category of File, or Edit.

Lets create a menu for the File category and then add a sub menu called *Some Category*. Double click on the ActionManager component to bring up the default editor. Next Select *New Standard Action*, and choose the *File* category and all of its Actions, then click "OK".

First create a new action from the ActionManager editor.

ListView of the Standard Actions for the ActionManager

Now we can drag and drop the *File* category from the ActionManager's Editor to our ActionMainMenuBar, and Delphi will automatically create a menu for us.

Next lets create a sub menu. First we will want to create a new Category, which can be done by adding a new Action in the ActionManager editor. In the ActionManager editor create a *New Action* and give it a caption, a name, and some event code. Next you can select the category that the action will belong to, if the Category doesn't exist then you can manually type in the Category and it will be automatically created:

Create a New Action and set it's Category Property. If the category doesn't exist then type in a new value for it.

Go ahead and repeat the process to create some more Actions for this Category. Once the Category is complete you can drag and drop it from the **ActionManager** to the **ActionMainMenuBar**. To make a sub menu you can continue the drag process over the existing *File* menu, which will expand the *File* menu, and then drop it somewhere within its contents. The end result is show below, however the resulting colors can be changed by using a **XPColorMap** and setting the *ColorMap* of the

**ActionMainMenuBar.**

An XPColorMap can be used to alter the menu's appearance.
