- Delegation of shard node replication via active passive HA solutions.
- Shard builds via replication into Spider tables is interesting when you can route READS to a pool of Spider nodes reattaching the shards.

What are the most used architectures for Spider Map Reduce?

- Map reduce in Spider is limited to a single table. Building spider on top of some views can eliminate the need to use joins.
- Replication to universal tables to every shard is commonly used to enable the views on each shard.

What about Grants on shards?

- When using MRR and BKA (and you do so with network storage), when Spider needs to create temporary tables on

the backends, use the CREATE TEMPORARY TABLES privilege. Spider can still switch to a lower performance solution using spider_bka_mode=2, or Query push down or range predicate using spider_bka_mode=0

5.3.22.1 Storage Engine FAQ

Are storage engines designed for MySQL compatible with MariaDB?

In most cases, yes. MariaDB tries to keep API compatibility with MySQL, even across major versions.

Will storage engines created for MariaDB work in MySQL?

It will mostly work. It would need #ifdef's to adjust to MySQL-5.6 API, for example, for multi-read-range API, for table discovery API, etc. But most of the code will work as is, without any changes.

Do storage engine binaries need to be recompiled for MariaDB?

Yes. You will need to recompile the storage engine against the exact version of MySQL or MariaDB you intend to run it on. This is due to the version of the server being stored in the storage engine binary, and the server will refuse to load it if it was compiled for a different version.

5.3.22.2 Engine-defined New Table/Field/Index Attributes

Contents

In MariaDB, a storage engine can allow the user to specify additional attributes per index, field, or table. The engine needs to declare what attributes it introduces.

API

There are three new members in the `handlerton` structure, they can be set in the engine's initialization function as follows:

```
example_hton->table_options= example_table_option_array;
example_hton->field_options= example_field_option_array;
example_hton->index_options= example_index_option_array;
```

The arrays are declared statically, as in the following example:

```
static MYSQL_THDVAR_ULONG(varopt_default, PLUGIN_VAR_RQCMDARG,
  "default value of the VAROPT table option", NULL, NULL, 5, 0, 100, 0);

struct ha_table_option_struct
{
  char *strparam;
  ulonglong ullparam;
  uint enumparam;
  bool boolparam;
  ulonglong varparam;
};

ha_create_table_option example_table_option_list[]=
{
  HA_TOPTION_NUMBER("NUMBER", ullparam, UINT_MAX32, 0, UINT_MAX32, 10),
  HA_TOPTION_STRING("STR", strparam),
  HA_TOPTION_ENUM("ONE_OR_TWO", enumparam, "one,two", 0),
  HA_TOPTION_BOOL("YESNO", boolparam, 1),
  HA_TOPTION_SYSVAR("VAROPT", varopt, varparam),
  HA_TOPTION_END
};
```

The engine declares a structure `ha_table_option_struct` that will hold values of these new attributes.

And it describes these attributes to MySQL by creating an array of `HA_TOPTION_*` macros. Note a detail: these macros expect a structure called `ha_table_option_struct`, if the structure is called differently, a `#define` will be needed.

There are five supported kinds of attributes:

macro name	attribure value type	corresponding C type	additional parameters of a macro
`HA_TOPTION_NUMBER`	an integer number	`unsigned long long`	a default value, minimal allowed value, maximal allowed value, a factor, that any allowed should be a multiple of.
`HA_TOPTION_STRING`	a string	`char *`	none. The default value is a null pointer.
`HA_TOPTION_ENUM`	one value from a list of allowed values	`unsigned int`	a string with a comma-separated list of allowed values, and a default value as a number, starting from 0.
`HA_TOPTION_BOOL`	a boolean	`bool`	a default value
`HA_TOPTION_SYSVAR`	defined by the system variable	defined by the system variable	system variable name

*Do **not** use `enum` for your `HA_TOPTION_ENUM` C structure members, the size of the `enum` depends on the compiler, and even on the compilation options, and the plugin API uses only types with known storage sizes.*

In all macros the first two parameters are name of the attribute as should be used in SQL in the `CREATE TABLE` statement, and the name of the corresponding member of the `ha_table_option_struct` structure.

The `HA_TOPTION_SYSVAR` stands aside a bit. It does not specify the attribute type or the default value, instead it binds the attribute to a system variable. The attribute type and the range of allowed values will be the same as of the corresponding system variable. The attribute **default value** will be the **current value** of its system variable. And unlike other attribute types that are only stored in the `.frm` file if explicitly set in the `CREATE TABLE` statement, the `HA_TOPTION_SYSVAR` attributes are always stored. If the system variable value is changed, it will not affect existing tables. Note that for this very reason, if a table was created in the old version of a storage engine, and a new version has introduced a `HA_TOPTION_SYSVAR` attribute, the attribute value in the old tables will be the **default** value of the system variable, not its **current** value.

The array ends with a `HA_TOPTION_END` macro.

Field and index (key) attributes are declared similarly using `HA_FOPTION_*` and `HA_IOPTION_*` macros.

When in a `CREATE TABLE` statement, the `::create()` handler method is called, the table attributes are available in the `table_arg->s->option_struct`, field attributes - in the `option_struct` member of the individual fields (objects of the

`Field` class), index attributes - in the `option_struct` member of the individual keys (objects of the `KEY` class).

Additionally, they are available in most other handler methods: the attributes are stored in the `.frm` file and on every open MySQL makes them available to the engine by filling the corresponding `option_struct` members of the table, fields, and keys.

The `ALTER TABLE` needs a special support from the engine. MySQL compares old and new table definitions to decide whether it needs to rebuild the table or not. As the semantics of the engine declared attributes is unknown, MySQL cannot make this decision by analyzing attribute values - this is delegated to the engine. The `HA_CREATE_INFO` structure has three new members:

```
ha_table_option_struct *option_struct;          ///< structure with parsed table options
ha_field_option_struct **fields_option_struct;  ///< array of field option structures
ha_index_option_struct **indexes_option_struct; ///< array of index option structures
```

The engine (in the `::check_if_incompatible_data()` method) is responsible for comparing new values of the attributes from the `HA_CREATE_INFO` structure with the old values from the table and returning `COMPATIBLE_DATA_NO` if they were changed in such a way that requires the table to be rebuild.

The example of declaring the attributes and comparing the values for the `ALTER TABLE` can be found in the EXAMPLE engine.

SQL

The engine declared attributes can be specified per field, index, or table in the `CREATE TABLE` or `ALTER TABLE` . The syntax is the conventional:

```
CREATE TABLE ... (
  field ... [attribute=value [attribute=value ...]],
  ...
  index ... [attribute=value [attribute=value ...]],
  ...
) ...  [attribute=value [attribute=value ...]]
```

All values must be specified as literals, not expressions. The value of a boolean option may be specified as one of YES, NO, ON, OFF, 1, or 0. A string value may be specified either quoted or not, as an identifier (if it is a valid identifier, of course). Compare with the old behavior:

```
CREATE TABLE ... ENGINE=FEDERATED CONNECTION='mysql://root@127.0.0.1';
```

where the value of the ENGINE attribute is specified not quoted, while the value of the CONNECTION is quoted.

When an attribute is set, it will be stored with the table definition and shown in the `SHOW CREATE TABLE;`
. To remove an attribute from a table definition use `ALTER TABLE`
to set its value to a `DEFAULT`
.

The values of unknown attributes or attributes with the illegal values cause an error by default. But with ALTER TABLE one can change the storage engine and some previously valid attributes may become unknown — to the new engine. They are not removed automatically, though, because the table might be altered back to the first engine, and these attributes will be valid again. Still SHOW CREATE TABLE will comment these unknown attributes out in the output, otherwise they would make a generated CREATE TABLE statement invalid.

With the `IGNORE_BAD_TABLE_OPTIONS`
sql mode this behavior changes. Unknown attributes do not cause an error, they only result in a warning. And SHOW CREATE TABLE will not comment them out. This mode is implicitly enabled in the replication slave thread.

5.3.22.3 Table Discovery

In MariaDB it is not always necessary to run an explicit `CREATE TABLE` statement for a table to appear. Sometimes a table may already exist in the storage engine, but the server does not know about it, because there is no `.frm` file for this table. This can happen for various reasons; for example, for a cluster engine the table might have been created in the cluster by another MariaDB server node. Or for the engine that supports table shipping a table file might have been simply copied into the MariaDB data directory. But no matter what the reason is, there is a mechanism for an engine to tell the server that the table exists. This mechanism is called **table discovery** and if an engine wants the server to discover its tables, the engine should support the table discovery API.

Contents

There are two different kinds of table discovery — a fully automatic discovery and a user-assisted one. In the former, the engine can automatically discover the table whenever an SQL statement needs it. In MariaDB, the Archive and Sequence engines support this kind of discovery. For example, one can copy a `t1.ARZ` file into the database directory and immediately start using it — the corresponding `.frm` file will be created automatically. Or one can select from say, the `seq_1_to_10` table without any explicit `CREATE TABLE` statement.

In the latter, user-assisted, discovery the engine does not have enough information to discover the table all on its own. But it can discover the table structure if the user provides certain additional information. In this case, an explicit `CREATE TABLE` statement is still necessary, but it should contain no table structure — only the table name and the table attributes. In MariaDB, the FederatedX storage engine supports this. When creating a table, one only needs to specify the `CONNECTION` attribute and the table structure — fields and indexes — will be provided automatically by the engine.

Automatic Discovery

As far as automatic table discovery is concerned, the tables, from the server point of view, may appear, disappear, or change structure anytime. Thus the server needs to be able to ask whether a given table exists and what its structure is. It needs to be notified when a table structure changes outside of the server. And it needs to be able to get a list of all (unknown to the server) tables, for statements like `SHOW TABLES`. The server does all that by invoking specific methods of the `handlerton`:

```
const char **tablefile_extensions;
int (*discover_table_names)(handlerton *hton, LEX_STRING *db, MY_DIR *dir,
                            discovered_list *result);
int (*discover_table_existence)(handlerton *hton, const char *db,
                                const char *table_name);
int (*discover_table)(handlerton *hton, THD* thd, TABLE_SHARE *share);
```

handlerton::tablefile_extensions

Engines that store tables in separate files (one table might occupy many files with different extensions, but having the same base file name) should store the list of possible extensions in the **tablefile_extensions** member of the `handlerton` (earlier this list was returned by the `handler::bas_ext()` method). This will significantly simplify the discovery implementation for these engines, as you will see below.

handlerton::discover_table_names()

When a user asks for a list of tables in a specific database — for example, by using `SHOW TABLES` or by selecting from `INFORMATION_SCHEMA.TABLES` — the server invokes **discover_table_names()** method of the `handlerton`. For convenience this method, besides the database name in question, gets the list of all files in this database directory, so that the engine can look for table files without doing any filesystem i/o. All discovered tables should be added to the `result` collector object. It is defined as

```
class discovered_list
{
  public:
  bool add_table(const char *tname, size_t tlen);
  bool add_file(const char *fname);
};
```

and the engine should call `result->add_table()` or `result->add_file()` for every discovered table (use

`add_file()` if the name to add is in the MariaDB file name encoding, and `add_table()` if it's a true table name, as shown in `SHOW TABLES`).

If the engine is file-based, that is, it has non-empty list in the `tablefile_extensions`, this method is optional. For any file-based engine that does not implement `discover_table_names()`, MariaDB will automatically discover the list of all tables of this engine, by looking for files with the extension `tablefile_extensions[0]`.

handlerton::discover_table_existence()

In some rare cases MariaDB needs to know whether a given table exists, but does not particularly care about this table structure (for example, when executing a `DROP TABLE` statement). In these cases, the server uses the **discover_table_existence()** method to find out whether a table with the given name exists in the engine.

This method is optional. For the engine that does not implement it, MariaDB will look for files with the `tablefile_extensions[0]`, if possible. But if the engine is not file-based, MariaDB will use the `discover_table()` method to perform a full table discovery. While this will allow determining correctly whether a table exists, a full discovery is usually slower than the simple existence check. In other words, engines that are not file-based might want to support `discover_table_existence()` method as a useful optimization.

handlerton::discover_table()

This is the main method of table discovery, the heart of it. The server invokes it when it wants to use the table. The **discover_table()** method gets the `TABLE_SHARE` structure, which is not completely initialized — only the table and the database name (and a path to the table file) are filled in. It should initialize this `TABLE_SHARE` with the desired table structure.

MariaDB provides convenient and easy to use helpers that allow the engine to initialize the `TABLE_SHARE` with minimal efforts. They are the `TABLE_SHARE` methods `init_from_binary_frm_image()` and `init_from_sql_statement_string()`.

TABLE_SHARE::init_from_binary_frm_image()

This method is used by engines that use "frm shipping" — such as Archive or NDB Cluster in MySQL. An frm shipping engine reads the frm file for a given table, exactly as it was generated by the server, and stores it internally. Later it can discover the table structure by using this very frm image. In this sense, a separate frm file in the database directory becomes redundant, because a copy of it is stored in the engine.

TABLE_SHARE::init_from_sql_statement_string()

This method allows initializing the `TABLE_SHARE` using a conventional SQL `CREATE TABLE` syntax.

TABLE_SHARE::read_frm_image()

Engines that use frm shipping need to get the frm image corresponding to a particular table (typically in the `handler::create()` method). They do it via the **read_frm_image()** method. It returns an allocated buffer with the binary frm image, that the engine can use the way it needs.

TABLE_SHARE::free_frm_image()

The frm image that was returned by `read_frm_image()` must be freed with the **free_frm_image()**.

HA_ERR_TABLE_DEF_CHANGED

One of the consequences of automatic discovery is that the table definition might change when the server doesn't expect it to. Between two `SELECT` queries, for example. If this happens, if the engine detects that the server is using an outdated version of the table definition, it should return a **HA_ERR_TABLE_DEF_CHANGED** handler error. Depending on when in the query processing this error has happened, MariaDB will either re-discover the table and execute the query with the correct table structure, or abort the query and return an error message to the user.

TABLE_SHARE::tabledef_version

The previous paragraph doesn't cover one important question — how can the engine know that the server uses an outdated table definition? The answer is — by checking the **tabledef_version**, the table definition version. Every table gets a unique `tabledef_version` value. Normally it is generated automatically when a table is created. When a table is discovered the engine can force it to have a specific `tabledef_version` value (simply by setting it in the `TABLE_SHARE` before calling the `init_from_binary_frm_image()` or `init_from_sql_statement_string()` methods).

Now the engine can compare the table definition version that the server is using (from any handler method it can be accessed as `this->table->s->tabledef_version`) with the version of the actual table definition. If they differ — it is `HA_ERR_TABLE_DEF_CHANGED`.

Assisted discovery

Assisted discovery is a lot simpler from the server point of view, a lot more controlled. The table cannot appear or disappear at will, one still needs explicit DDL statements to manipulate it. There is only one new handlerton method that the server uses to discover the table structure when a user has issued an explicit `CREATE TABLE` statement without declaring any columns or indexes.

```
int (*discover_table_structure)(handlerton *hton, THD* thd,
                                TABLE_SHARE *share, HA_CREATE_INFO *info);
```

The assisted discovery API is pretty much independent from the automatic discovery API. An engine can implement either of them or both (or none); there is no requirement to support automatic discovery if only assisted discovery is needed.

handlerton::discover_table_structure()

Much like the `discover_table()` method, the **discover_table_structure()** handlerton method gets a partially initialized `TABLE_SHARE` with the table name, database name, and a path to table files filled in, but without a table structure. Unlike `discover_table()`, here the `TABLE_SHARE` has all the engine-defined table attributes in the the `TABLE_SHARE::option_struct` structure. Based on the values of these attributes the `discover_table_structure()` method should initialize the `TABLE_SHARE` with the desired set of fields and keys. It can use `TABLE_SHARE` helper methods `init_from_binary_frm_image()` and `init_from_sql_statement_string()` for that.

The role of `.frm` files

Before table discovery was introduced, MariaDB used `.frm` files to store the table definition. But now the engine can store the table definition (if the engine supports automatic discovery, of course), and `.frm` files become redundant. Still, the server *can* use `.frm` files for such an engine — but they are no longer the only source of the table definition. Now `.frm` files are merely a *cache* of the table definition, while the original authoritative table definition is stored in the engine. Like any cache, its purpose is to reduce discovery attempts for a table. The engine decides whether it makes sense to cache table definition in the `.frm` file or not (see the second argument for the `TABLE_SHARE::init_from_binary_frm_image()`). For example, the Archive engine uses `.frm` cache, while the Sequence engine does not. In other words, MariaDB creates `.frm` files for Archive tables, but not for Sequence tables.

The cache is completely transparent for a user; MariaDB makes sure that it always stores the actual table definition and invalidates the `.frm` file automatically when it becomes out of date. This can happen, for example, if a user copies a new Archive table into the datadir and forgets to delete the `.frm` file of the old table with the same name.

5.3.23 Converting Tables from MyISAM to InnoDB

Contents

The task

You have decided to change one or more tables from MyISAM to InnoDB. That should be as simple as `ALTER TABLE foo ENGINE=InnoDB`. But you have heard that there might be some subtle issues.

This describes possible issues that may arise and what to do about them.

Recommendation. One way to assist in searching for issues in is to do (at least in *nix)

```
mysqldump --no-data --all-databases >schemas
egrep 'CREATE|PRIMARY' schemas    # Focusing on PRIMARY KEYs
egrep 'CREATE|FULLTEXT' schemas   # Looking for FULLTEXT indexes
egrep 'CREATE|KEY' schemas        # Looking for various combinations of indexes
```

Understanding how the indexes work will help you better understand what might run faster or slower in InnoDB.

INDEX Issues

(Most of these Recommendations and some of these Facts have exceptions.)

Fact. Every InnoDB table has a PRIMARY KEY. If you do not provide one, then the first non-NULL UNIQUE key is used. If that can't be done, then a 6-byte, hidden, integer is provided.

Recommendation. Look for tables without a PRIMARY KEY. Explicitly specify a PRIMARY KEY, even if it's an artificial AUTO_INCREMENT. This is not an absolute requirement, but it is a stronger admonishment for InnoDB than for MyISAM. Some day you may need to walk through the table; without an explicit PK, you can't do it.

Fact. The fields of the PRIMARY KEY are included in each Secondary key.

- Check for redundant indexes with this in mind.

  ```
  PRIMARY KEY(id),
  INDEX(b), -- effectively the same as INDEX(b, id)
  INDEX(b, id) -- effectively the same as INDEX(b)
  ```

  (Keep one of the INDEXes, not both)

- Note subtle things like

  ```
  PRIMARY KEY(id),
  UNIQUE(b), -- keep for uniqueness constraint
  INDEX(b, id) -- DROP this one
  ```

- Also, since the PK and the data coexist:

  ```
  PRIMARY KEY(id),
  INDEX(id, b) -- DROP this one; it adds almost nothing
  ```

Contrast. This feature of MyISAM is not available in InnoDB; the value of 'id' will start over at 1 for each different value of 'abc':

```
id INT UNSIGNED NOT NULL AUTO_INCREMENT,
PRIMARY KEY (abc, id)
```

A way to simulate the MyISAM 'feature' might be something like: What you want is this, but it won't work because it is referencing the table twice:

```
INSERT INTO foo
    (other, id, ...)
    VALUES
    (123, (SELECT MAX(id)+1 FROM foo WHERE other = 123), ...);
```

Instead, you need some variant on this. (You may already have a BEGIN...COMMIT.)

```
BEGIN;
SELECT @id := MAX(id)+1 FROM foo WHERE other = 123 FOR UPDATE;
INSERT INTO foo
    (other, id, ...)
    VALUES
    (123, @id, ...);
COMMIT;
```

Having a transaction is mandatory to prevent another thread from grabbing the same id.

Recommendation. Look for such PRIMARY KEYs. If you find such, ponder how to change the design. There is no straightforward workaround. However, the following may be ok. (Be sure that the datatype for id is big enough since it won't start over.):

```
id INT UNSIGNED NOT NULL AUTO_INCREMENT,
PRIMARY KEY (abc, id),
UNIQUE(id)
```

Recommendation. Keep the PRIMARY KEY short. If you have Secondary keys, remember that they include the fields of the PK. A long PK would make the Secondary keys bulky. Well, maybe not — if the is a lot of overlap in fields. Example: `PRIMARY KEY(a,b,c), INDEX(c,b,a)` — no extra bulk.

Recommendation. Check AUTO_INCREMENT sizes.

- BIGINT is almost never needed. It wastes at least 4 bytes per row (versus INT).
- Always use UNSIGNED and NOT NULL.
- MEDIUMINT UNSIGNED (16M max) might suffice instead of INT
- Be sure to be pessimistic — it is painful to ALTER.

Contrast. "Vertical Partitioning". This is where you artificially split a table to move bulky columns (eg, a BLOB) into another, parallel, table. It is beneficial in MyISAM to avoid stepping over the blob when you don't need to read it. InnoDB stores BLOB and TEXT differently — 767 bytes are in the record, the rest is in some other block. So, it may (or may not) be worth putting the tables back together. Caution: An InnoDB row is limited to 8KB, and the 767 counts against that.

Fact. FULLTEXT (prior to MariaDB 10.0.5) and SPATIAL indexes are not available in InnoDB. Note that MyISAM and InnoDB FULLTEXT indexes use different stopword lists and different system variables.

Recommendation. Search for such indexes. Keep such tables in MyISAM. Better yet, do Vertical Partitioning (see above) to split out the minimum number of columns from InnoDB.

Fact. The maximum length of an INDEX is different between the Engines. (This change is not likely to hit you, but watch out.) MyISAM allows 1000 bytes; InnoDB allows 767 bytes, just big enough for a

```
VARCHAR(255) CHARACTER SET utf8.

ERROR 1071 (42000): Specified key was too long; max key length is 767 bytes
```

Fact. The PRIMARY KEY is included in the data. Hence, SHOW TABLE STATUS will show and `Index_length` of 0 bytes (or 16KB) for a table with no secondary indexes. Otherwise, `Index_length` is the total size for the secondary keys.

Fact. The PRIMARY KEY is included in the data. Hence, exact match by PK may be a little faster with InnoDB. And, "range" scans by PK are likely to be faster.

Fact. A lookup by Secondary Key traverses the secondary key's BTree, grabs the PRIMARY KEY, then traverses the PK's BTree. Hence, secondary key lookups are a little more cumbersome in InnoDB.

Contrast. The fields of the PRIMARY KEY are included in each Secondary key. This may lead to "Using index" (in the EXPLAIN plan) for InnoDB for cases where it did not happen in MyISAM. (This is a slight performance boost, and counteracts the double-lookup otherwise needed.) However, when "Using index" would be useful on the PRIMARY KEY, MyISAM would do an "index scan", yet InnoDB effectively has to do a "table scan".

Same as MyISAM. Almost always

```
INDEX(a)   -- DROP this one because the other one handles it.
INDEX(a,b)
```

Contrast. The data is stored in PK order. This means that "recent" records are 'clustered' together at the end. This may give you better 'locality of reference' than in MyISAM.

Same as MyISAM. The optimizer almost never uses two indexes in a single SELECT. (5.1 will occasionally do "index merge".) SELECT in subqueries and UNIONs can independently pick indexes.

Subtle issue. When you DELETE a row, the AUTO_INCREMENT id will be burned. Ditto for REPLACE, which is a DELETE plus an INSERT.

Very subtle issue. Replication occurs on COMMIT. If you have multiple threads using transactions, the AUTO_INCREMENTs can arrive at a slave out of order. One transaction BEGINs, grabs an id. Then another transaction grabs an id but COMMITs before the first finishes.

Same as MyISAM. "Prefix" indexing is usually bad in both InnoDB and MyISAM. Example: `INDEX(foo(30))`

Non-INDEX Issues

Disk space for InnoDB is likely to be 2-3 times as much as for MyISAM.

MyISAM and InnoDB use RAM radically differently. If you change all your tables, you should make significant adjustments:

- key_buffer_size — small but non-zero; say, 10M;
- innodb_buffer_pool_size — 70% of available RAM

InnoDB has essentially no need for CHECK, OPTIMIZE, or ANALYZE. Remove them from your maintenance scripts. (No real harm if you keep them.)

Backup scripts may need checking. A MyISAM table can be backed up by copying three files. With InnoDB this is only possible if innodb_file_per_table is set to 1. Before MariaDB 10.0, capturing a table or database for copying from production to a development environment was not possible. Change to mysqldump. Since MariaDB 10.0 a hot copy can be created - see Backup and restore overview.

Before MariaDB 5.5, the DATA DIRECTORY table option was not supported for InnoDB. Since MariaDB 5.5 it is supported, but only in CREATE TABLE. INDEX DIRECTORY has no effect, since InnoDB does not use separate files for indexes. To better balance the workload through several disks, the paths of some InnoDB log files can also be changed.

Understand autocommit and BEGIN/COMMIT.

- (default) autocommit = 1: In the absence of any BEGIN or COMMIT statements, every statement is a transaction by itself. This is close to the MyISAM behavior, but is not really the best.
- autocommit = 0: COMMIT will close a transaction and start another one. To me, this is kludgy.
- (recommended) BEGIN...COMMIT gives you control over what sequence of operation(s) are to be considered a transaction and "atomic". Include the ROLLBACK statement if you need to undo stuff back to the BEGIN.

Perl's DBIx::DWIW and Java's JDBC have API calls to do BEGIN and COMMIT. These are probably better than 'executing' BEGIN and COMMIT.

Test for errors everywhere! Because InnoDB uses row-level locking, it can stumble into deadlocks that you are not expecting. The engine will automatically ROLLBACK to the BEGIN. The normal recovery is to redo, beginning at the BEGIN. Note that this is a strong reason to have BEGINs.

LOCK/UNLOCK TABLES — remove them. Replace them (sort of) with BEGIN ... COMMIT. (LOCK will work if innodb_table_locks is set to 1, but it is less efficient, and may have subtle issues.)

In 5.1, ALTER ONLINE TABLE can speed up some operations significantly. (Normally ALTER TABLE copies the table over and rebuilds the indexes.)

The "limits" on virtually everything are different between MyISAM and InnoDB. Unless you have huge tables, wide rows, lots of indexes, etc, you are unlikely to stumble into a different limit.

Mixture of MyISAM and InnoDB? This is OK. But there are caveats.

- RAM settings should be adjusted to accordingly.
- JOINing tables of different Engines works.
- A transaction that affects tables of both types can ROLLBACK InnoDB changes, but will leave MyISAM changes intact.
- Replication: MyISAM statements are replicated when finished; InnoDB statements are held until the COMMIT.

FIXED (vs DYNAMIC) is meaningless in InnoDB.

PARTITION — You can partition MyISAM and InnoDB tables. Remember the screwball rule: You must either

- have no UNIQUE (or PRIMARY) keys, or
- have the value you are "partitioning on" in every UNIQUE key.

The former is not advised for InnoDB. The latter is messy if you want an AUTO_INCREMENT.

PRIMARY KEY in PARTITION — Since every key must include the field on which you are PARTITIONing, how can AUTO_INCREMENT work? Well, there seems to be a convenient special case:

- This works: PRIMARY KEY(autoinc, partition_key)
- This does not work for InnoDB: PRIMARY KEY(partition_key, autoinc)

That is, an AUTO_INCREMENT will correctly increment, and be unique across all PARTITINOs, when it is the first field of the PRIMARY KEY, but not otherwise.

5.3.24 Machine Learning with MindsDB

Contents

Overview

MindsDB is a third-party application that interfaces with MariaDB Server to provide Machine Learning capabilities through SQL. The interface is done via the Connect Storage Engine.

Installation

To get a functional MariaDB - MindsDB installation, one needs to install the following components:

- **MindsDB**: follow the instructions in the project's official documentation.
- **Connect Storage Engine** must be enabled for the integration to work. See installing the connect storage engine.

MindsDB connects to MariaDB Server via a regular user to setup a dedicated database called `mindsdb`. Which user will be used is specified within MindsDB's configuration file.

For example, if MindsDB is installed locally, one can create a user called `mindsdb@localhost`. MindsDB only authenticates via the mysql_native_password plugin, hence one must set a password for the user:

```
CREATE USER mindsdb@localhost;
SET PASSWORD for mindsdb@localhost=PASSWORD("password");
```

The user must be granted the global FILE privilege and all privileges on the `mindsdb` database.

```
GRANT FILE on *.* to mindsdb@localhost;
GRANT ALL on mindsdb.* to mindsdb@localhost;
```

Assuming MindsDB is in the python path one can start up MindsDB with the following parameters:

```
python -m mindsdb --config=$CONFIG_PATH --api=http,mysql
```

Make sure `$CONFIG_PATH` points to the appropriate MindsDB configuration file.

Usage

Always consult the project's official documentation for up-to-date usage scenarios as MindsDB is an actively developed project.

For a step-by-step example, you can consult the following blog post.

If the connection between MindsDB and MariaDB is successful, you should see the `mindsdb` database present and two tables within it: `commands` and `predictors`.

MindsDB, as an AutoML framework does all the work when it comes to training the AI model. What is necessary is to pass it the initial data, which MindsDB retrieves via a SELECT statement. This can be done by inserting into the `predictors` table.

```
INSERT INTO `predictors`
       (`name`, `predict`, `select_data_query`)
VALUES ('bikes_model', 'count', 'SELECT * FROM test.bike_data');
```

The values inserted into predictors act as a command instructing MindsDB to:

1. Train a model called 'bikes_model'
2. From the input data, learn to predict the 'count' column.
3. The input data is generated via the select statement 'SELECT * FROM test.bike_data'. The `select_data_query` should be a valid select that MindsDB can run against MariaDB.

5.4 Plugins

MariaDB supports the use of plugins, software components that may be added to the core software without having to rebuild the MariaDB server from source code. Therefore, plugins can be loaded at start-up, or loaded and unloaded while the server is running without interruption. Plugins are commonly used for adding desired storage engines, additional security requirements, and logging special information about the server.

Plugin Overview

Basics of listing, installing and uninstalling plugins.

Information on Plugins

Information on installed and disabled plugins on a MariaDB Server.

Plugin SQL Statements

List of SQL statements related to plugins.

Creating and Building Plugins

Plugins related to MariaDB replication and other replication cluster systems.

Storage Engines
Various storage engines available for MariaDB.

Other Plugins
Information on installing and using other plugins.

There are 5 related questions.

5.4.1 Plugin Overview

Contents

Plugins are server components that enhance MariaDB in some way. These can be anything from new storage engines, plugins for enhancing full-text parsing, or even small enhancements, such as a plugin to get a timestamp as an integer.

Querying Plugin Information

There are a number of ways to see which plugins are currently active.

A server almost always has a large number of active plugins, because the server contains a large number of built-in plugins, which are active by default and cannot be uninstalled.

Querying Plugin Information with `SHOW PLUGINS`

The SHOW PLUGINS statement can be used to query information about all active plugins.

For example:

```
SHOW PLUGINS\G;
*********************** 1. row ***********************
   Name: binlog
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
*********************** 2. row ***********************
   Name: mysql_native_password
 Status: ACTIVE
   Type: AUTHENTICATION
Library: NULL
License: GPL
*********************** 3. row ***********************
   Name: mysql_old_password
 Status: ACTIVE
   Type: AUTHENTICATION
Library: NULL
License: GPL
...
```

If a plugin's `Library` column has a `NULL` value, then the plugin is built-in, and it cannot be uninstalled.

Querying Plugin Information with information_schema.PLUGINS

The information_schema.PLUGINS table can be queried to get more detailed information about plugins.

For example:

```
SELECT * FROM information_schema.PLUGINS\G
...
*************************** 6. row ***************************
           PLUGIN_NAME: CSV
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: STORAGE ENGINE
   PLUGIN_TYPE_VERSION: 100003.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: Brian Aker, MySQL AB
    PLUGIN_DESCRIPTION: CSV storage engine
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: FORCE
       PLUGIN_MATURITY: Stable
   PLUGIN_AUTH_VERSION: 1.0
*************************** 7. row ***************************
           PLUGIN_NAME: MEMORY
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: STORAGE ENGINE
   PLUGIN_TYPE_VERSION: 100003.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: MySQL AB
    PLUGIN_DESCRIPTION: Hash based, stored in memory, useful for temporary tables
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: FORCE
       PLUGIN_MATURITY: Stable
   PLUGIN_AUTH_VERSION: 1.0
...
```

If a plugin's `PLUGIN_LIBRARY` column has the `NULL` value, then the plugin is built-in, and it cannot be uninstalled.

Querying Plugin Information with `mysql.plugin`

The mysql.plugin table can be queried to get information about installed plugins.

This table only contains information about plugins that have been installed via the following methods:

- The INSTALL SONAME statement.
- The INSTALL PLUGIN statement.

- The mariadb-plugin utility.

This table does not contain information about:

- Built-in plugins.
- Plugins loaded with the --plugin-load-add option.
- Plugins loaded with the --plugin-load option.

This table only contains enough information to reload the plugin when the server is restarted, which means it only contains the plugin name and the plugin library.

For example:

```
SELECT * FROM mysql.plugin;

+------+------------+
| name | dl         |
+------+------------+
| PBXT | libpbxt.so |
+------+------------+
```

Installing a Plugin

There are three primary ways to install a plugin:

- A plugin can be installed dynamically with an SQL statement.
- A plugin can be installed with a mariadbd option, but it requires a server restart.
- A plugin can be installed with the mariadb-plugin utility, while the server is completely offline.

When you are installing a plugin, you also have to ensure that:

- The server's plugin directory is properly configured, and the plugin's library is in the plugin directory.
- The server's minimum plugin maturity is properly configured, and the plugin is mature enough to be installed.

Installing a Plugin Dynamically

A plugin can be installed dynamically by executing either the INSTALL SONAME or the INSTALL PLUGIN statement.

If a plugin is installed with one of these statements, then a record will be added to the mysql.plugins table for the plugin. This means that the plugin will automatically be loaded every time the server restarts, unless specifically uninstalled or deactivated.

Installing a Plugin with `INSTALL SONAME`

You can install a plugin dynamically by executing the INSTALL SONAME statement. INSTALL SONAME installs all plugins from the given plugin library. This could be required for some plugin libraries.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the server_audit audit plugin), you could execute the following:

```
INSTALL SONAME 'server_audit';
```

Installing a Plugin with `INSTALL PLUGIN`

You can install a plugin dynamically by executing the INSTALL PLUGIN statement. INSTALL PLUGIN installs a single plugin from the given plugin library.

For example, to install the server_audit audit plugin from the `server_audit` plugin library, you could execute the following:

```
INSTALL PLUGIN server_audit SONAME 'server_audit';
```

Installing a Plugin with Plugin Load Options

A plugin can be installed with a mariadbd option by providing either the --plugin-load-add or the --plugin-load option.

If a plugin is installed with one of these options, then a record will **not** be added to the mysql.plugins table for the plugin. This means that if the server is restarted without the same option set, then the plugin will **not** automatically be loaded.

Installing a Plugin with `--plugin-load-add`

You can install a plugin with the --plugin-load-add option by specifying the option as a command-line argument to mariadbd or by specifying the option in a relevant server option group in an option file.

The --plugin-load-add option uses the following format:

- Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
- Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
- Multiple plugins can be specified by separating them with semicolons.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the `server_audit` audit plugin) and also the `ed25519` authentication plugin from the `auth_ed25519` plugin library, you could set the option to the following values on the command-line:

```
$ mariadbd --user=mysql --plugin-load-add='server_audit' --plugin-load-add='ed25519=auth_ed25519'
```

You could also set the option to the same values in an option file:

```
[mariadb]
...
plugin_load_add = server_audit
plugin_load_add = ed25519=auth_ed25519
```

Special care must be taken when specifying both the --plugin-load option and the --plugin-load-add option together. The --plugin-load option resets the plugin load list, and this can cause unexpected problems if you are not aware. The --plugin-load-add option does **not** reset the plugin load list, so it is much safer to use. See Specifying Multiple Plugin Load Options for more information.

Installing a Plugin with `--plugin-load`

You can install a plugin with the --plugin-load option by specifying the option as a command-line argument to mariadbd or by specifying the option in a relevant server option group in an option file.

The --plugin-load option uses the following format:

- Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
- Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
- Multiple plugins can be specified by separating them with semicolons.

For example, to install all plugins in the `server_audit` plugin library (which is currently only the `server_audit` audit plugin) and also the `ed25519` authentication plugin from the `auth_ed25519` plugin library, you could set the option to the following values on the command-line:

```
$ mariadbd --user=mysql --plugin-load='server_audit;ed25519=auth_ed25519'
```

You could also set the option to the same values in an option file:

```
[mariadb]
...
plugin_load = server_audit;ed25519=auth_ed25519
```

Special care must be taken when specifying the `--plugin-load` option multiple times, or when specifying both the `--plugin-load` option and the `--plugin-load-add` option together. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use. See Specifying Multiple Plugin Load Options for more information.

Specifying Multiple Plugin Load Options

Special care must be taken when specifying the `--plugin-load` option multiple times, or when specifying both the `--plugin-load` option and the `--plugin-load-add` option. The `--plugin-load` option resets the plugin load list, and

this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use.

This can have the following consequences:

- If the `--plugin-load` option is specified **multiple times**, then only the last instance will have any effect. For example, in the following case, the first instance of the option is reset:

```
[mariadb]
...
plugin_load = server_audit
plugin_load = ed25519=auth_ed25519
```

- If the `--plugin-load` option is specified **after** the `--plugin-load-add` option, then it will also reset the changes made by that option. For example, in the following case, the `--plugin-load-add` option does not do anything, because the subsequent `--plugin-load` option resets the plugin load list:

```
[mariadb]
...
plugin_load_add = server_audit
plugin_load = ed25519=auth_ed25519
```

- In contrast, if the `--plugin-load` option is specified **before** the `--plugin-load-add` option, then it will work fine, because the `--plugin-load-add` option does not reset the plugin load list. For example, in the following case, both plugins are properly loaded:

```
[mariadb]
...
plugin_load = server_audit
plugin_load_add = ed25519=auth_ed25519
```

Installing a Plugin with mariadb-plugin

A plugin can be installed with the mariadb-plugin utility if the server is completely offline.

The syntax is:

```
mariadb-plugin [options] <plugin> ENABLE|DISABLE
```

For example, to install the server_audit audit plugin, you could execute the following:

```
mariadb-plugin server_audit ENABLE
```

If a plugin is installed with this utility, then a record will be added to the mysql.plugins table for the plugin. This means that the plugin will automatically be loaded every time the server restarts, unless specifically uninstalled or deactivated.

Configuring the Plugin Directory

When a plugin is being installed, the server looks for the plugin's library in the server's plugin directory. This directory is configured by the `plugin_dir` system variable. This can be specified as a command-line argument to `mariadbd` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_dir = /usr/lib64/mysql/plugin
```

Configuring the Minimum Plugin Maturity

When a plugin is being installed, the server compares the plugin's maturity level against the server's minimum allowed plugin maturity. This can help prevent users from using unstable plugins on production servers. This minimum plugin maturity is configured by the `plugin_maturity` system variable. This can be specified as a command-line argument to `mariadbd` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_maturity = stable
```

Configuring Plugin Activation at Server Startup

A plugin will be loaded by default when the server starts if:

- The plugin was installed with the INSTALL SONAME statement.
- The plugin was installed with the INSTALL PLUGIN statement.
- The plugin was installed with the mariadb-plugin utility.
- The server is configured to load the plugin with the --plugin-load-add option.
- The server is configured to load the plugin with the --plugin-load option.

This behavior can be changed with special options that take the form `--plugin-name`. For example, for the `server_audit` audit plugin, the special option is called --server-audit.

The possible values for these special options are:

Option Value	Description
`OFF`	Disables the plugin without removing it from the mysql.plugins table.
`ON`	Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
`FORCE`	Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
`FORCE_PLUS_PERMANENT`	Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME `or` UNINSTALL PLUGIN while the server is running.

A plugin's status can be found by looking at the `PLUGIN_STATUS` column of the information_schema.PLUGINS table.

Uninstalling Plugins

Plugins that are found in the mysql.plugin table, that is those that were installed with INSTALL SONAME, INSTALL PLUGIN or mariadb-plugin can be uninstalled in one of two ways:

- The UNINSTALL SONAME or the UNINSTALL PLUGIN statement while the server is running
- With mariadb-plugin while the server is offline.

Plugins that were enabled as a `--plugin-load` option do not need to be uninstalled. If `--plugin-load` is omitted the next time the server starts, or the plugin is not listed as one of the `--plugin-load` entries, the plugin will not be loaded.

UNINSTALL PLUGIN uninstalls a single installed plugin, while UNINSTALL SONAME uninstalls all plugins belonging to a given library.

5.4.2 Information on Plugins

Contents

1. MariaDB Plugin Maturity

MariaDB Plugin Maturity

The following table lists the various plugins included in MariaDB ordered by their maturity. Note that maturity will differ across MariaDB versions - see below for an easy way to get a complete list of plugins and their maturity in your version of MariaDB:

Plugin	Version	Maturity	Version
Archive	3.0	Stable	
Aria	1.5	Stable	
Audit Plugin	1.4	Stable	
aws_key_management	1.0	Stable	
binlog	1.0	Stable	
Blackhole	1.0	Stable	
Connect	1.7	Stable	MariaDB 10.4.12, MariaDB 10.3.22
CLIENT_STATISTICS	2.0	Stable	
cracklib_password_check	1.0	Stable	
CSV	1.0	Stable	
DISKS	1.1	Stable	MariaDB 10.4.7, MariaDB 10.3.17
ed25519	1.1	Stable	MariaDB 10.4.0
FederatedX[1]	2.1	Stable	
Feedback	1.1	Stable	
file_key_management	1.0	Stable	
gssapi	1.0	Stable	
INDEX_STATISTICS	2.0	Stable	
INET6	1.0	Stable	MariaDB 10.5.12
InnoDB	10.*	Stable	
LOCALES	1.0	Stable	
Memory	1.0	Stable	
METADATA_LOCK_INFO	0.1	Stable	
MRG_MyISAM	1.0	Stable	
Mroonga	7.7	Stable	
MyISAM	1.0	Stable	
MyRocks	1.0	Stable	MariaDB 10.3.7
mysql_json	0.1	Stable	MariaDB 10.5.17
mysql_native_password	1.0	Stable	
mysql_old_password	1.0	Stable	
named_pipe	1.0	Stable	
pam	1.0	Stable	
password_reuse_check	2.0	Stable	MariaDB 10.8.7, MariaDB 10.9.5, MariaDB 10.10.2
partition	1.0	Stable	
Performance_Schema	0.1	Stable	
QUERY_CACHE_INFO	1.1	Stable	
query_response_time	1.0	Stable	
S3	1.0	Stable	MariaDB 10.5.12
semisync	1.0	Stable	Built-in, no longer a plugin from MariaDB 10.3.3
Sequence	1.0	Stable	
SERVER_AUDIT	1.4	Stable	

simple_password_check	1.0	Stable	
Spider	3.3	Stable	<= MariaDB 10.4, MariaDB 10.5.7
SQL_ERROR_LOG	1.0	Stable	
TABLE_STATISTICS	2.0	Stable	
USER_STATISTICS	2.0	Stable	
user_variables	1.0	Stable	MariaDB 10.3.13
TokuDB	4.0	Stable	Disabled in MariaDB 10.5 and removed in MariaDB 10.6
unix_socket	1.0	Stable	
UUID	1.0	Stable	MariaDB 10.9.1
wsrep	1.0	Stable	
WSREP_INFO	1.0	Stable	
Plugin	**Version**	**Maturity**	**From**
Federated [2]	1.0	Gamma	
OQGraph	3.0	Gamma	
Sphinx	2.0	Gamma	
Plugin	**Version**	**Maturity**	**From**
Columnstore	1.0	Beta	MariaDB 10.5.4
handlersocket	1.0	Beta	
Plugin	**Version**	**Maturity**	**From**
Cassandra	0.1	Experimental	Removed in MariaDB 10.6
debug_key_management	1.0	Experimental	
example_key_management	1.0	Experimental	
Plugin	**Version**	**Maturity**	**Version**

Execute the following on your MariaDB server to get a complete list of plugins and their maturity for your version of MariaDB:

```
SELECT plugin_name, plugin_version, plugin_maturity
FROM information_schema.plugins
ORDER BY plugin_name;
```

Writing Plugins for MariaDB
Writing plugins for MariaDB.

2.1.2.8.5.2 Specifying Which Plugins to Build

5.4.4.2 Writing Plugins for MariaDB

Contents

About

Generally speaking, writing plugins for MariaDB is very similar to writing plugins for MySQL.

Authentication Plugins

See Pluggable Authentication.

Storage Engine Plugins

Storage engines can extend `CREATE TABLE` syntax with optional index, field, and table attribute clauses. See Extending CREATE TABLE for more information.

See Storage Engine Development.

Information Schema Plugins

Information Schema plugins can have their own FLUSH and SHOW statements. See FLUSH and SHOW for Information Schema plugins.

Encryption Plugins

Encryption plugins in MariaDB are used for the data at rest encryption feature. They are responsible for both key management and for the actual encryption and decryption of data.

Plugin Declaration Structure

The MariaDB plugin declaration differs from the MySQL plugin declaration in the following ways:

1. it has no useless 'reserved' field (the very last field in the MySQL plugin declaration)
2. it has a 'maturity' declaration
3. it has a field for a text representation of the version field

MariaDB can load plugins that only have the MySQL plugin declaration but both `PLUGIN_MATURITY` and `PLUGIN_AUTH_VERSION` will show up as 'Unknown' in the INFORMATION_SCHEMA.PLUGINS table.

For compiled-in (not dynamically loaded) plugins, the presence of the MariaDB plugin declaration is mandatory.

Example Plugin Declaration

The MariaDB plugin declaration looks like this:

```
/* MariaDB plugin declaration */
maria_declare_plugin(example)
{
   MYSQL_STORAGE_ENGINE_PLUGIN, /* the plugin type (see include/mysql/plugin.h) */
   &example_storage_engine_info, /* pointer to type-specific plugin descriptor   */
   "EXAMPLEDB", /* plugin name */
   "John Smith",  /* plugin author */
   "Example of plugin interface", /* the plugin description */
   PLUGIN_LICENSE_GPL, /* the plugin license (see include/mysql/plugin.h) */
   example_init_func,   /* Pointer to plugin initialization function */
   example_deinit_func,  /* Pointer to plugin deinitialization function */
   0x0001 /* Numeric version 0xAABB means AA.BB version */,
   example_status_variables,  /* Status variables */
   example_system_variables,  /* System variables */
   "0.1 example",  /* String version representation */
   MariaDB_PLUGIN_MATURITY_EXPERIMENTAL /* Maturity (see include/mysql/plugin.h)*/
}
maria_declare_plugin_end;
```

5.4.5 MariaDB Audit Plugin

Contents

MariaDB and MySQL are used in a broad range of environments, but if you needed to record user access to be in compliance with auditing regulations for your organization, you would previously have had to use other database solutions. To meet this need, though, MariaDB has developed the MariaDB Audit Plugin. Although the MariaDB Audit Plugin has some unique features available only for MariaDB, it can be used also with MySQL.

Basically, the purpose of the MariaDB Audit Plugin is to log the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local `syslogd`.

The MariaDB Audit Plugin works with MariaDB, MySQL (as of, version 5.5.34 and 10.0.7) and Percona Server. MariaDB started including by default the Audit Plugin from versions 10.0.10 and 5.5.37, and it can be installed in any version from MariaDB 5.5.20.

Additional documentation

Below are links to additional documentation on the MariaDB Audit Plugin. They explain in detail how to install, configure and use the Audit Plugin.

5.4.5.1 MariaDB Audit Plugin - Installation

The `server_audit` plugin logs the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local syslogd.

Contents

Locating the Plugin

The `server_audit` plugin's shared library is included in MariaDB packages as the `server_audit.so` or `server_audit.dll` shared library on systems where it can be built.

The plugin must be located in the plugin directory, the directory containing all plugin libraries for MariaDB. The path to this directory is configured by the `plugin_dir` system variable. To see the value of this variable and thereby determine the file path of the plugin library, execute the following SQL statement:

```
SHOW GLOBAL VARIABLES LIKE 'plugin_dir';

+---------------+--------------------------+
| Variable_name | Value                    |
+---------------+--------------------------+
| plugin_dir    | /usr/lib64/mysql/plugin/ |
+---------------+--------------------------+
```

Check the directory returned at the filesystem level to make sure that you have a copy of the plugin library, `server_audit.so` or `server_audit.dll`, depending on your system. It's included in recent installations of MariaDB. If you do not have it, you should upgrade MariaDB.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'server_audit';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = server_audit
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'server_audit';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Prohibiting Uninstallation

The `UNINSTALL SONAME` or `UNINSTALL PLUGIN` statements may be used to uninstall plugins. For the `server_audit` plugin, you might want to disable this capability. To prevent the plugin from being uninstalled, you could set the the `server_audit` option to `FORCE_PLUS_PERMANENT` in a relevant server option group in an option file after the plugin is loaded once:

```
[mariadb]
...
plugin_load_add = server_audit
server_audit=FORCE_PLUS_PERMANENT
```

Once you've added the option to the server's option file and restarted the server, the plugin can't be uninstalled. If someone tries to uninstall the audit plugin, then an error message will be returned. Below is an example of the error message:

```
UNINSTALL PLUGIN server_audit;

ERROR 1702 (HY000):
Plugin 'server_audit' is force_plus_permanent and can not be unloaded
```

For more information on `FORCE_PLUS_PERMANENT` and other option values for the `server_audit` option, see Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

5.4.5.2 MariaDB Audit Plugin - Configuration

After the audit plugin has been installed and loaded, there will be some new global variables within MariaDB. These can be used to configure many components, limits, and methods related to auditing the server. You may set these variables related to the logs, such as their location, size limits, rotation parameters, and method of logging information. You may also set what information is logged, such connects, disconnects, and failed attempts to connect. You can also have the audit plugin log queries, read and write access to tables. So as not to overload your logs, the audit plugin can be configured based on lists of users. You can include or exclude the activities of specific users in the logs.

To see a list of audit plugin-related variables on the server and their values, execute the follow while connected to the server:

```
SHOW GLOBAL VARIABLES LIKE 'server_audit%';

+-------------------------------+-----------------------+
| Variable_name                 | Value                 |
+-------------------------------+-----------------------+
| server_audit_events           | CONNECT,QUERY,TABLE   |
| server_audit_excl_users       |                       |
| server_audit_file_path        | server_audit.log      |
| server_audit_file_rotate_now  | OFF                   |
| server_audit_file_rotate_size | 1000000               |
| server_audit_file_rotations   | 9                     |
| server_audit_incl_users       |                       |
| server_audit_logging          | ON                    |
| server_audit_mode             | 0                     |
| server_audit_output_type      | file                  |
| server_audit_query_log_limit  | 1024                  |
| server_audit_syslog_facility  | LOG_USER              |
| server_audit_syslog_ident     | mysql-server_auditing |
| server_audit_syslog_info      |                       |
| server_audit_syslog_priority  | LOG_INFO              |
+-------------------------------+-----------------------+
```

The values of these variables can be changed by an administrator with the `SUPER` privilege, using the `SET` statement. Below is an example of how to disable audit logging:

```
SET GLOBAL server_audit_logging=OFF;
```

Although it is possible to change all of the variables shown above, some of them may be reset when the server restarts. Therefore, you may want set them in the configuration file (e.g., `/etc/my.cnf.d/server.cnf`) to ensure the values are the same after a restart:

```
[server]
...
server_audit_logging=OFF
…
```

For the reason given in the paragraph above, you would not generally set variables related to the auditing plugin using the `SET` statement. However, you might do so to test settings before making them more permanent. Since one cannot always restart the server, you would use the `SET` statement to change immediately the variables and then include the same settings in the configuration file so that the variables are set again as you prefer when the server is restarted.

Configuring Logs and Setting Other Variables

Of all of the server variables you can set, you may want to set initially the server_audit_events variable to tell the Audit Plugin which events to log. The Log Settings documentation page describes in detail the choices you have and provides examples of log entries related to them.

You can see a detailed list of system variables related to the MariaDB Audit Plugin on the System Variables documentation page. Status variables related to the Audit Plugin are listed and explained on the Status Variables documentation page.

5.4.5.3 MariaDB Audit Plugin - Log Settings

Events that are logged by the MariaDB Audit Plugin are grouped generally into different types: connect, query, and table events. To log based on these types of events, set the variable, server_audit_events to `CONNECT`, `QUERY`, or `TABLE`. To

have the Audit Plugin log more than one type of event, put them in a comma-separated list like so:

```
SET GLOBAL server_audit_events = 'CONNECT,QUERY,TABLE';
```

Contents

You can put the equivalent of this in the configuration file like so:

```
[mysqld]
...
server_audit_events=connect,query
```

By default, logging is set to `OFF`. To enable it, set the server_audit_logging variable to `ON`. Note that if the query cache is enabled, and a query is returned from the query cache, no `TABLE` records will appear in the log since the server didn't open or access any tables and instead relied on the cached results. So you may want to disable query caching.

There are actually a few types of events that may be logged, not just the three common ones mentioned above. A full list of related system variables is detailed on the Server_Audit System Variables page, and status variables on the Server_Audit Status Variables page of this documentation. Some of the major ones are highlighted below:

Type	Description
CONNECT	Connects, disconnects and failed connects—including the error code
QUERY	Queries executed and their results in plain text, including failed queries due to syntax or permission errors
TABLE	Tables affected by query execution
QUERY_DDL	Similar to `QUERY`, but filters only DDL-type queries (`CREATE`, `ALTER`, `DROP`, `RENAME` and `TRUNCATE`). There are some exceptions however. `RENAME USER` is not logged, while `CREATE/DROP [PROCEDURE / FUNCTION / USER]` are only logged from MariaDB 10.2.38, MariaDB 10.3.29, MariaDB 10.4.22, MariaDB 10.5.13 and MariaDB 10.6.5. In earlier versions they are not logged. See MDEV-23457.
QUERY_DML	Similar to `QUERY`, but filters only DML-type queries (`DO`, `CALL`, `LOAD DATA/XML`, `DELETE`, `INSERT`, `SELECT`, `UPDATE`, `HANDLER` and `REPLACE` statements)
QUERY_DML_NO_SELECT	Similar to `QUERY_DML`, but doesn't log SELECT queries. (since version 1.4.4) (`DO`, `CALL`, `LOAD DATA/XML`, `DELETE`, `INSERT`, `UPDATE`, `HANDLER` and `REPLACE` statements)
QUERY_DCL	Similar to `QUERY`, but filters only DCL-type queries (`CREATE USER`, `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE` and `SET PASSWORD` statements)

Since there are other types of queries besides DDL and DML, using the `QUERY_DDL` and `QUERY_DML` options together is not equivalent to using `QUERY`. Starting in version 1.3.0 of the Audit Plugin, there is the `QUERY_DCL` option for logging DCL types of queries (e.g., `GRANT` and `REVOKE` statements). In the same version, the server_audit_query_log_limit variable was added to be able to set the length of a log record. Previously, a log entry would be truncated due to long query strings.

Logging Connect Events

If the Audit Plugin has been configured to log connect events, it will log connects, disconnects, and failed connects. For a failed connection, the log includes the error code.

It's possible to define a list of users for which events can be excluded or included for tracing their database activities. This list will be ignored, though, for the loggings of connect events. This is because auditing standards distinguish between technical and physical users. Connects need to be logged for all types of users; access to objects need to be logged only for physical users.

Logging Query Events

If `QUERY`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DML_NO_SELECT`, and/or `QUERY_DCL` event types are enabled, then the corresponding types of queries that are executed will be logged for defined users. The queries will be logged exactly as they are executed, in plain text. This is a security vulnerability: anyone who has access to the log files will be able to read the queries. So make sure that only trusted users have access to the log files and that the files are in a protected location. An alternative is to use `TABLE` event type instead of the query-related event types.

Queries are also logged if they cannot be executed, if they're unsuccessful. For example, a query will be logged because of a syntax error or because the user doesn't have the privileges necessary to access an object. These queries can be parsed by the error code that's provided in the log.

You may find failed queries to be more interesting: They can reveal problems with applications (e.g., an SQL statement in an application that doesn't match the current schema). They can also reveal if a malicious user is guessing at the names of tables and columns to try to get access to data.

Below is an example in which a user attempts to execute an `UPDATE` statement on a table for which he does not have permission:

```
UPDATE employees
SET salary = salary * 1.2
WHERE emp_id = 18236;

ERROR 1142 (42000):
UPDATE command denied to user 'bob'@'localhost' for table 'employees'
```

Looking in the Audit Plugin log (`server_audit.log`) for this entry, you can see the following entry:

```
20170817 11:07:18,ip-172-30-0-38,bob,localhost,15,46,QUERY,company,
'UPDATE employees SET salary = salary * 1.2 WHERE emp_id = 18236',1142
```

This log entry would be on one line, but it's reformatted here for better rendering. Looking at this log entry, you can see the date and time of the query, followed by the server host, the user and host for the account. Next is the connection and query identification numbers (i.e., `15` and `46`). After the log event type (i.e., `QUERY`), the database name (i.e., `company`), the query, and the error number is recorded.

Notice that the last value in the log entry is `1142` . That's the error number for the query. To find failed queries, you would look for two elements: the notation indicating that it's a `QUERY` entry, and the last value for the entry. If the query is successful, the value will be `0` .

Queries Not Included in Subordinate Query Event Types

Note that the `QUERY` event type will log queries that are not included in any of the subordinate `QUERY_*` event types, such as:

- CREATE FUNCTION
- DROP FUNCTION
- CREATE PROCEDURE
- DROP PROCEDURE
- SET
- CHANGE MASTER TO
- FLUSH
- KILL
- CHECK
- OPTIMIZE
- LOCK
- UNLOCK
- ANALYZE
- INSTALL PLUGIN
- UNINSTALL PLUGIN
- INSTALL SONAME
- UNINSTALL SONAME
- EXPLAIN

Logging Table Events

MariaDB has the ability to record table events in the logs—this is not a feature of MySQL. This feature is the only way to log which tables have been accessed through a view, a stored procedure, a stored function, or a trigger. Without this feature, a log entry for a query shows only the view, stored procedure or function used, not the underlying tables. Of course, you could

create a custom application to parse each query executed to find the SQL statements used and the tables accessed, but that would be a drain on system resources. Table event logging is much simpler: it adds a line to the log for each table accessed, without any parsing. It includes notes as to whether it was a read or a write.

If you want to monitor user access to specific databases or tables (e.g., `mysql.user`), you can search the log for them. Then if you want to see a query which accessed a certain table, the audit log entry will include the query identificaiton number. You can use it to search the same log for the query entry. This can be useful when searching a log containing tens of thousands of entries.

Because of the `TABLE` option, you may disable query logging and still know who accessed which tables. You might want to disable `QUERY` event logging to prevent sensitive data from being logged. Since *table* event logging will log who accessed which table, you can still watch for malicious activities with the log. This is often enough to fulfill auditing requirements.

Below is an example with both `TABLE` and `QUERY` events logging. For this scenario, suppose there is a VIEW in which columns are selected from a few tables in a `company` database. The underlying tables are related to sensitive employee information, in particular salaries. Although we may have taken precautions to ensure that only certain user accounts have access to those tables, we will monitor the Audit Plugin logs for anyone who queries them—directly or indirectly through a view.

```
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees_salaries,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,ref_job_titles,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,org_departments,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,QUERY,company,
'SELECT * FROM employee_pay WHERE title LIKE \'%Executive%\'  OR title LIKE \'%Manager%\'',0
```

Although the user executed only one SELECT statement, there are multiple entries to the log: one for each table accessed and one entry for the query on the view, (i.e., `employee_pay`). We know primarily this is all for one query because they all have the same connection and query identification numbers (i.e., `29` and `913`).

Logging User Activities

The Audit Plugin will log the database activities of all users, or only the users that you specify. A database activity is defined as a *query* event or a *table* event. *Connect* events are logged for all users.

You may specify users to include in the log with the `server_audit_incl_users` variable or exclude users with the `server_audit_excl_users` variable. This can be useful if you would like to log entries, but are not interested in entries from trusted applications and would like to exclude them from the logs.

You would typically use either the `server_audit_incl_users` variable or the `server_audit_excl_users` variable. You may, though, use both variables. If a username is inadvertently listed in both variables, database activities for that user will be logged because `server_audit_incl_users` takes priority.

Although MariaDB considers a user as the combination of the username and hostname, the Audit Plugin logs only based on the username. MariaDB uses both the username and hostname so as to grant privileges relevant to the location of the user. Privileges are not relevant though for tracing the access to database objects. The host name is still recorded in the log, but logging is not determined based on that information.

The following example shows how to add a new username to the `server_audit_incl_users` variable without removing previous usernames:

```
SET GLOBAL server_audit_incl_users = CONCAT(@@global.server_audit_incl_users, ',Maria');
```

Remember to add also any new users to be included in the logs to the same variable in MariaDB configuration file. Otherwise, when the server restarts it will discard the setting.

Excluding or Including Users

By default events from all users are logged, but certain users can be excluded from logging by using the server_audit_excl_users variable. For example, to exclude users *valerianus* and *rocky* from having their events logged:

```
server_audit_excl_users=valerianus,rocky
```

This option is primarily used to exclude the activities of trusted applications.

Alternatively, server_audit_incl_users can be used to specifically include users. Both variables can be used, but if a user appears on both lists, server_audit_incl_users has a higher priority, and their activities will be logged.

Note that `CONNECT` events are always logged for all users, regardless of these two settings. Logging is also based on username only, not the username and hostname combination that MariaDB uses to determine privileges.

5.4.5.4 MariaDB Audit Plugin - Location and Rotation of Logs

Contents

Logs can be written to a separate file or to the system logs. If you prefer to have the logging separated from other system information, the value of the variable, server_audit_output_type should be set to `file`. Incidentally, `file` is the only option on Windows systems.

You can force a rotation by enabling the server_audit_file_rotate_now variable like so:

```
SET GLOBAL server_audit_file_rotate_now = ON;
```

Separate log files

In addition to setting server_audit_output_type, you will have to provide the file path and name of the audit file. This is set in the variable, server_audit_file_path. You can set the file size limit of the log file with the variable, server_audit_file_rotate_size.

So, if rotation is on and the log file has reached the size limit you set, a copy is created with a consecutive number as extension, the original file will be truncated to be used for the auditing again. To limit the number of log files created, set the variable, server_audit_file_rotations. You can force log file rotation by setting the variable, server_audit_file_rotate_now to a value of `ON`. When the number of files permitted is reached, the oldest file will be overwritten. Below is an example of how the variables described above might be set in a server's configuration files:

```
[mysqld]
...
server_audit_file_rotate_now=ON
server_audit_file_rotate_size=1000000
server_audit_file_rotations=5
...
```

System logs

For security reasons, it's better sometimes to use the system logs instead of a local file owned by the `mysql` user. To do this, the value of server_audit_output_type needs to be set to `syslog`. Advanced configurations, such as using a remote `syslogd` service, are part of the `syslogd` configuration.

The variables, server_audit_syslog_ident and server_audit_syslog_info can be used to identify a system log entry made by the audit plugin. If a remote `syslogd` service is used for several MariaDB servers, these same variables are also used to identify the MariaDB server.

Below is an example of a system log entry taken from a server which had server_audit_syslog_ident set to the default value of `mysql -server_auditing`, and server_audit_syslog_info set to `<prod1>`.

```
Aug 717:19:58localhostmysql- server_auditing:
<prod1> localhost.localdomain,root,localhost,1,7,
QUERY, mysql, 'SELECT * FROM user',0
```

Although the default values for server_audit_syslog_facility and server_audit_syslog_priority should be sufficient in most cases, they can be changed based on the definition in `syslog.h` for the functions `openlog()` and `syslog()`.

5.4.5.5 MariaDB Audit Plugin - Log Format

The audit plugin logs user access to MariaDB and its objects. The audit trail (i.e., audit log) is a set of records, written as a list of fields to a file in a plain-text format. The fields in the log are separated by commas. The format used for the plugin's own log file is slightly different from the format used if it logs to the system log because it has its own standard format. The general format for the logging to the plugin's own file is defined like the following:

```
[timestamp],[serverhost],[username],[host],[connectionid],
[queryid],[operation],[database],[object],[retcode]
```

If the server_audit_output_type variable is set to `syslog` instead of the default, `file`, the audit log file format will be as follows:

```
[timestamp][syslog_host][syslog_ident]:[syslog_info][serverhost],[username],[host],
[connectionid],[queryid],[operation],[database],[object],[retcode]
```

Item logged	Description
timestamp	Time at which the event occurred. If syslog is used, the format is defined by `syslogd`.
syslog_host	Host from which the syslog entry was received.
syslog_ident	For identifying a system log entry, including the MariaDB server.
syslog_info	For providing information for identifying a system log entry.
serverhost	The MariaDB server host name.
username	Connected user.
host	Host from which the user connected.
connectionid	Connection ID number for the related operation.
queryid	Query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines will be added.
operation	Recorded action type: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, DROP.
database	Active database (as set by USE).
object	Executed query for QUERY events, or the table name in the case of TABLE events.
retcode	Return code of the logged operation.

Various events will result in different audit records. Some events will not return a value for some fields (e.g., when the active database is not set when connecting to the server).

Below is a generic example of the output for connect events, with placeholders representing data. These are events in which a user connected, disconnected, or tried unsuccessfully to connect to the server.

```
[timestamp],[serverhost],[username],[host],[connectionid],0,CONNECT,[database],,0
[timestamp],[serverhost],[username],[host],[connectionid],0,DISCONNECT,,,0
[timestamp],[serverhost],[username],[host],[connectionid],0,FAILED_CONNECT,,,[retcode]
```

Here is the one audit record generated for each query event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],QUERY,[database],[object],
[retcode]
```

Below are generic examples of records that are entered in the audit log for each type of table event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],CREATE,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],READ,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],WRITE,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],ALTER,[database],[object],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],RENAME,[database],
[object_old]|[database_new].[object_new],
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],DROP,[database],[object],
```

Starting in version 1.2.0, passwords are hidden in the log for certain types of queries. They are replaced with asterisks for `GRANT`, `CREATE USER`, `CREATE MASTER`, `CREATE SERVER`, and `ALTER SERVER` statements. Passwords, however, are not replaced for the `PASSWORD()` and `OLD_PASSWORD()` functions when they are used inside other SQL statements (i.e., SET PASSWORD`)`.

5.4.5.6 MariaDB Audit Plugin - Versions

Below is a list of the releases of the MariaDB Audit Plugin, the most recent version first, and in which versions of MariaDB each plugin version was included.

Version	Introduced
1.4.13	MariaDB 10.2.38, MariaDB 10.3.29, MariaDB 10.4.19, MariaDB 10.5.10
1.4.10	MariaDB 10.2.35, MariaDB 10.3.26, MariaDB 10.5.7
1.4.7	MariaDB 10.1.41, MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7
1.4.5	MariaDB 10.2.24, MariaDB 10.3.15, MariaDB 10.4.5
1.4.4	MariaDB 5.5.61, MariaDB 10.0.36, MariaDB 10.1.34, MariaDB 10.2.15, MariaDB 10.3.7, MariaDB 10.4.0
1.4.0	MariaDB 5.5.48, MariaDB 10.0.24, MariaDB 10.1.11
1.3.0	MariaDB 5.5.43, MariaDB 10.0.18, MariaDB 10.1.5
1.2.0	MariaDB 5.5.42, MariaDB 10.0.17, MariaDB 10.1.4
1.1.7	MariaDB 5.5.38, MariaDB 10.0.11, MariaDB 10.1.0
1.1.6	MariaDB 5.5.37, MariaDB 10.0.10
1.1.5	MariaDB 10.0.09
1.1.4	MariaDB 5.5.36
1.1.3	MariaDB 5.5.34, MariaDB 10.0.7

5.4.5.7 MariaDB Audit Plugin Options and System Variables

Contents

There are a several options and system variables related to the MariaDB Audit Plugin, once it has been installed. System variables can be displayed using the SHOW VARIABLES statement like so:

```
SHOW GLOBAL VARIABLES LIKE '%server_audit%';

+-------------------------------+----------------------+
| Variable_name                 | Value                |
+-------------------------------+----------------------+
| server_audit_events           | CONNECT,QUERY,TABLE  |
| server_audit_excl_users       |                      |
| server_audit_file_path        | server_audit.log     |
| server_audit_file_rotate_now  | OFF                  |
| server_audit_file_rotate_size | 1000000              |
| server_audit_file_rotations   | 9                    |
| server_audit_incl_users       |                      |
| server_audit_logging          | ON                   |
| server_audit_mode             | 0                    |
| server_audit_output_type      | file                 |
| server_audit_query_log_limit  | 1024                 |
| server_audit_syslog_facility  | LOG_USER             |
| server_audit_syslog_ident     | mysql-server_auditing |
| server_audit_syslog_info      |                      |
| server_audit_syslog_priority  | LOG_INFO             |
+-------------------------------+----------------------+
```

To change the value of one of these variables, you can use the `SET` statement, or set them at the command-line when starting MariaDB. It's recommended that you set them in the MariaDB configuration for the server like so:

```
[mariadb]
...
server_audit_excl_users='bob,ted'
...
```

System Variables

Below is a list of all system variables related to the Audit Plugin. See Server System Variables for a complete list of system variables and instructions on setting them. See also the full list of MariaDB options, system and status variables.

`server_audit_events`

- **Description:** If set, then this restricts audit logging to certain event types. If not set, then every event type is logged to the audit log. For example: *SET GLOBAL server_audit_events='connect, query'*
- **Commandline:** `--server-audit-events=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty string
- **Valid Values:**
  - `CONNECT`, `QUERY`, `TABLE` (MariaDB Audit Plugin < 1.2.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML` (MariaDB Audit Plugin >= 1.2.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DCL` (MariaDB Audit Plugin >=1.3.0)
  - `CONNECT`, `QUERY`, `TABLE`, `QUERY_DDL`, `QUERY_DML`, `QUERY_DCL`, `QUERY_DML_NO_SELECT` (MariaDB Audit Plugin >= 1.4.4)
  - See MariaDB Audit Plugin - Versions to determine which MariaDB releases contain each MariaDB Audit Plugin versions.

`server_audit_excl_users`

- **Description:** If not empty, it contains the list of users whose activity will NOT be logged. For example: `SET GLOBAL server_audit_excl_users='user_foo, user_bar'`. CONNECT records aren't affected by this variable - they are always logged. The user is still logged if it's specified in server_audit_incl_users.
- **Commandline:** `--server-audit-excl-users=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty string
- **Size limit:** 1024 characters

---

server_audit_file_path

- **Description:** When server_audit_output_type=file, sets the path and the filename to the log file. If the specified path exists as a directory, then the log will be created inside that directory with the name 'server_audit.log'. Otherwise the value is treated as a filename. The default value is 'server_audit.log', which means this file will be created in the database directory.
- **Commandline:** `--server-audit-file-path=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `server_audit.log`

---

server_audit_file_rotate_now

- **Description:** When server_audit_output_type=file, the user can force the log file rotation by setting this variable to ON or 1.
- **Commandline:** `--server-audit-rotate-now[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

server_audit_file_rotate_size

- **Description:** When server_audit_output_type=file, it limits the size of the log file to the given amount of bytes. Reaching that limit turns on the rotation - the current log file is renamed as 'file_path.1'. The empty log file is created as 'file_path' to log into it. The default value is 1000000.
- **Commandline:** `--server-audit-rotate-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1000000`
- **Range:** `100` to `9223372036854775807`

---

server_audit_file_rotations

- **Description:** When server_audit_output_type=file', this specifies the number of rotations to save. If set to 0 then the log never rotates. The default value is 9.
- **Commandline:** `--server-audit-rotations=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `9`
- **Range:** `0` to `999`

---

server_audit_incl_users

- **Description:** If not empty, it contains a comma-delimited list of users whose activity will be logged. For example: `SET GLOBAL server_audit_incl_users='user_foo, user_bar'` . CONNECT records aren't affected by this variable - they are always logged. This setting has higher priority than server_audit_excl_users. So if the same user is specified both in incl_ and excl_ lists, they will still be logged.
- **Commandline:** `--server-audit-incl-users=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty string
- **Size limit:** 1024 characters

---

server_audit_loc_info

- **Description:** Used by plugin internals. It has no useful meaning to users.
  - In earlier versions, users see it as a read-only variable.
  - In later versions, it is hidden from the user.
- **Commandline:** N/A
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** Empty string
- **Introduced:** MariaDB 10.1.12, MariaDB 10.0.24, MariaDB 5.5.48
- **Hidden:** MariaDB 10.1.18, MariaDB 10.0.28, MariaDB 5.5.53

---

server_audit_logging

- **Description:** Enables/disables the logging. Expected values are ON/OFF. For example: `SET GLOBAL server_audit_logging=on` If the server_audit_output_type is FILE, this will actually create/open the logfile so the server_audit_file_path should be properly specified beforehand. Same about the SYSLOG-related parameters. The logging is turned off by default.
- **Commandline:** `--server-audit-logging[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

server_audit_mode

- **Description:** This variable doesn't have any distinctive meaning for a user. Its value mostly reflects the server version with which the plugin was started and is intended to be used by developers for testing.
- **Commandline:** `--server-audit-mode[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `1`

---

server_audit_output_type

- **Description:** Specifies the desired output type. Can be SYSLOG, FILE or null as no output. For example: `SET GLOBAL server_audit_output_type=file` file: log records will be saved into the rotating log file. The name of the file set by server_audit_file_path variable. syslog: log records will be sent to the local syslogd daemon with the standard <syslog.h> API. The default value is 'file'.
- **Commandline:** `--server-audit-output-type=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `file`
- **Valid Values:** `SYSLOG`, `FILE`

---

server_audit_query_log_limit

- **Description:** Limit on the length of the query string in a record.
- **Commandline:** `--server-audit-query-log-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `0` to `2147483647`

---

server_audit_syslog_facility

- **Description:** SYSLOG-mode variable. It defines the 'facility' of the records that will be sent to the syslog. Later the

log can be filtered by this parameter.
- **Commandline:** `--server-audit-syslog-facility=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `LOG_USER`
- **Valid Values:** `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_SYSLOG`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, `LOG_AUTHPRIV`, `LOG_FTP`, and `LOG_LOCAL0` – `LOG_LOCAL7`.

`server_audit_syslog_ident`

- **Description:** SYSLOG-mode variable. String value for the 'ident' part of each syslog record. Default value is 'mysql-server_auditing'. New value becomes effective only after restarting the logging.
- **Commandline:** `--server-audit-syslog-ident=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `mysql-server_auditing`

`server_audit_syslog_info`

- **Description:** SYSLOG-mode variable. The 'info' string to be added to the syslog records. Can be changed any time.
- **Commandline:** `--server-audit-syslog-info=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty string

`server_audit_syslog_priority`

- **Description:** SYSLOG-mode variable. Defines the priority of the log records for the syslogd.
- **Commandline:** `--server-audit-syslog-priority=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `LOG_INFO`
- **Valid Values:** `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, `LOG_DEBUG`

Options

`server_audit`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See MariaDB Audit Plugin - Installation: Prohibiting Uninstallation for more information on one use case.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--server-audit=val`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.5.8 MariaDB Audit Plugin - Status Variables

Contents

There are a few status variables related to the MariaDB Audit Plugin, once it has been installed. These variables can be displayed using the SHOW STATUS statement like so:

```
SHOW STATUS LIKE 'server_audit%';

+----------------------------+------------------+
| Variable_name              | Value            |
+----------------------------+------------------+
| Server_audit_active        | ON               |
| Server_audit_current_log   | server_audit.log |
| Server_audit_last_error    |                  |
| Server_audit_writes_failed | 0                |
+----------------------------+------------------+
```

Status Variables

Below is a list of all status variables related to the Audit Plugin. These cannot be set: These are not to be confused with system variables, which can be set. See Server Status Variables for a complete list of status variables that can be viewed with the SHOW STATUS statement. See also the Full list of MariaDB options, system and status variables.

`Server_audit_active`

- **Description:** If the auditing is actually working. It gets the ON value when the logging is successfully started. Then it can get the OFF value if the logging was stopped or log records can't be properly stored due to file or syslog errors.
- **Data Type:** `boolean`

`Server_audit_current_log`

- **Description:** The name of the logfile or the SYSLOG parameters that are in current use.
- **Data Type:** `string`

`Server_audit_last_error`

- **Description:** If something went wrong with the logging here you can see the message.
- **Data Type:** `string`

`Server_audit_writes_failed`

- **Description:** The number of log records since last logging-start that weren't properly stored because of errors of any kind. The global value can be flushed by `FLUSH STATUS`.
- **Data Type:** `numeric`
- **Default Value:** `0`

5.4.6 Authentication Plugins

When a user attempts to log in, the authentication plugin controls how MariaDB Server determines whether the connection is from a legitimate user.

When creating or altering a user account with the GRANT, CREATE USER or ALTER USER statements, you can specify the authentication plugin you want the user account to use by providing the `IDENTIFIED VIA` clause. By default, when you create a user account without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

MariaDB starting with 10.4

In MariaDB 10.4 and later, there are some notable changes, such as:

- You can specify multiple authentication plugins for each user account.
- The `root@localhost` user created by mariadb-install-db is created with the ability to use two authentication plugins. First, it is configured to try to use the unix_socket authentication plugin. This allows the the `root@localhost` user to login without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account. Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with SET PASSWORD.

Pluggable Authentication Overview

The authentication of users is delegated to plugins.

Authentication Plugin - mysql_native_password

Uses the password hashing algorithm introduced in MySQL 4.1.

Authentication Plugin - mysql_old_password

The mysql_old_password authentication plugin uses the pre-MySQL 4.1 password hashing algorithm.

Authentication Plugin - ed25519

Uses the Elliptic Curve Digital Signature Algorithm to securely store users' passwords.

Authentication Plugin - GSSAPI

The gssapi authentication plugin uses the GSSAPI interface to authenticate with Kerberos or NTLM.

Authentication with Pluggable Authentication Modules (PAM)

Uses the Pluggable Authentication Module (PAM) framework to authenticate MariaDB users.

Authentication Plugin - Unix Socket

Uses the user name that owns the process connected to MariaDB's unix socket file.

Authentication Plugin - Named Pipe

Uses the user name that owns the process connected to MariaDB's named pipe on Windows.

Authentication Plugin - SHA-256

MySQL supports the sha256_password and caching_sha2_password authentication plugins.

There are 1 related questions.

5.4.6.1 Pluggable Authentication Overview

Contents

When a user attempts to log in, the authentication plugin controls how MariaDB Server determines whether the connection is from a legitimate user.

When creating or altering a user account with the GRANT, CREATE USER or ALTER USER statements, you can specify the authentication plugin you want the user account to use by providing the `IDENTIFIED VIA` clause. By default, when you create a user account without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

MariaDB starting with 10.4

In MariaDB 10.4 and later, there are some notable changes, such as:

- You can specify multiple authentication plugins for each user account.
- The `root@localhost` user created by mariadb-install-db is created with the ability to use two authentication plugins. First, it is configured to try to use the unix_socket authentication plugin. This allows the the `root@localhost` user to login without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account. Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with SET PASSWORD.

Supported Authentication Plugins

The authentication process is a conversation between the server and a client. MariaDB implements both server-side and client-side authentication plugins.

Supported Server Authentication Plugins

MariaDB provides seven server-side authentication plugins:

- mysql_native_password
- mysql_old_password
- ed25519
- gssapi
- pam (Unix only)
- unix_socket (Unix only)
- named_pipe (Windows only)

Supported Client Authentication Plugins

MariaDB provides eight client-side authentication plugins:

- mysql_native_password
- mysql_old_password
- client_ed25519
- auth_gssapi_client
- dialog
- mysql_clear_password
- sha256_password
- caching_sha256_password

Options Related to Authentication Plugins

Server Options Related to Authentication Plugins

MariaDB supports the following server options related to authentication plugins:

Server Option	Description
`old_passwords={1 | 0}`	If set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords, instead of the mysql_native_password authentication plugin.
`plugin_dir=path`	Path to the plugin directory. For security reasons, either make sure this directory can only be read by the server, or set `secure_file_priv`.
`plugin_maturity=level`	The lowest acceptable plugin maturity. MariaDB will not load plugins less mature than the specified level.
`secure_auth`	Connections will be blocked if they use the the mysql_old_password authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format.

Client Options Related to Authentication Plugins

Most clients and utilities support some command line arguments related to client authentication plugins:

Client Option	Description
`--connect-expired-password`	Notify the server that this client is prepared to handle expired password sandbox mode even if `--batch` was specified. From MariaDB 10.4.3.
`--default-auth=name`	Default authentication client-side plugin to use.
`--plugin-dir=path`	Directory for client-side plugins.
`--secure-auth`	Refuse to connect to the server if the server uses the mysql_old_password authentication plugin. This mode is off by default, which is a difference in behavior compared to MySQL 5.6 and later, where it is on by default.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the following options with the mysql_optionsv function:

- `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS`
- `MYSQL_PLUGIN_DIR`
- `MYSQL_DEFAULT_AUTH`
- `MYSQL_SECURE_AUTH`

For example:

```
mysql_optionsv(mysql, MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, 1);
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

Installation Options Related to Authentication Plugins

mariadb-install-db supports the following installation options related to authentication plugins:

Installation Option	Description
`--auth-root-authentication-method={normal | socket}`	If set to `normal`, it creates a `root@localhost` account that authenticates with the mysql_native_password authentication plugin and that has no initial password set, which can be insecure. If set to `socket`, it creates a `root@localhost` account that authenticates with the unix_socket authentication plugin. Set to `normal` by default. Available since MariaDB 10.1.
`--auth-root-socket-user=USER`	Used with `--auth-root-authentication-method=socket`. It specifies the name of the second account to create with SUPER privileges in addition to `root`, as well as of the system account allowed to access it. Defaults to the value of `--user`.

Extended SQL Syntax

MariaDB has extended the SQL standard GRANT, CREATE USER, and ALTER USER statements, so that they support specifying different authentication plugins for specific users. An authentication plugin can be specified with these statements by providing the `IDENTIFIED VIA` clause.

For example, the GRANT syntax is:

```
GRANT <privileges> ON <level> TO <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

And the CREATE USER syntax is:

```
CREATE USER <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

And the ALTER USER syntax is:

```
ALTER USER <user>
   IDENTIFIED VIA <plugin> [ USING <string> ]
```

The optional `USING` clause allows users to provide an authentication string to a plugin. The authentication string's format and meaning is completely defined by the plugin.

For example, for the mysql_native_password authentication plugin, the authentication string should be a password hash:

```
CREATE USER mysqltest_up1
   IDENTIFIED VIA mysql_native_password USING '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

Since mysql_native_password is the default authentication plugin, the above is just another way of saying the following:

```
CREATE USER mysqltest_up1
   IDENTIFIED BY PASSWORD '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

In contrast, for the pam authentication plugin, the authentication string should refer to a PAM service name:

```
CREATE USER mysqltest_up1
   IDENTIFIED VIA pam USING 'mariadb';
```

MariaDB starting with 10.4

In MariaDB 10.4 and later, a user account can be associated with multiple authentication plugins.

For example, to configure the `root@localhost` user account to try the unix_socket authentication plugin, followed by the mysql_native_password authentication plugin as a backup, you could execute the following:

```
CREATE USER root@localhost
   IDENTIFIED VIA unix_socket
   OR mysql_native_password USING PASSWORD("verysecret");
```

See Authentication from MariaDB 10.4 for more information.

Authentication Plugins Installed by Default

Server Authentication Plugins Installed by Default

Not all server-side authentication plugins are installed by default. If a specific server-side authentication plugin is not installed by default, then you can find the installation procedure on the documentation page for the specific authentication plugin.

MariaDB starting with 10.4

In MariaDB 10.4 and later, the following server-side authentication plugins are installed by default:

- The mysql_native_password and mysql_old_password authentication plugins authentication plugins are installed by default in all builds.
- The unix_socket authentication plugin is installed by default in all builds on Unix and Linux.
- The named_pipe authentication plugin is installed by default in all builds on Windows.

MariaDB until 10.3

In MariaDB 10.3 and below, the following server-side authentication plugins are installed by default:

- The mysql_native_password and mysql_old_password authentication plugins are installed by default in all builds.
- The unix_socket authentication plugin is installed by default in **new installations** that use the .deb packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later. See Differences in MariaDB in Debian (and Ubuntu) for more information.
- The named_pipe authentication plugin is installed by default in all builds on Windows.

Client Authentication Plugins Installed by Default

Client-side authentication plugins do not need to be *installed* in the same way that server-side authentication plugins do. If the client uses either the `libmysqlclient` or MariaDB Connector/C library, then the library automatically loads client-side authentication plugins from the library's plugin directory whenever they are needed.

Most clients and utilities support the `--plugin-dir` command line argument that can be used to set the path to the library's plugin directory:

Client Option	Description
`--plugin-dir=path`	Directory for client-side plugins.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the `MYSQL_PLUGIN_DIR` option with the mysql_optionsv function.

For example:

```
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
```

If your client encounters errors similar to the following, then you may need to set the path to the library's plugin directory:

```
ERROR 2059 (HY000): Authentication plugin 'dialog' cannot be loaded:
/usr/lib/mysql/plugin/dialog.so: cannot open shared object file: No such file or directory
```

If the client does **not** use either the `libmysqlclient` or MariaDB Connector/C library, then you will have to determine which authentication plugins are supported by the specific client library used by the client.

If the client uses either the `libmysqlclient` or MariaDB Connector/C library, but the client is not bundled with either library's *optional* client authentication plugins, then you can only use the conventional authentication plugins (like mysql_native_password and mysql_old_password) and the non-conventional authentication plugins that don't require special client-side authentication plugins (like unix_socket and named_pipe).

Default Authentication Plugin

Default Server Authentication Plugin

The mysql_native_password authentication plugin is currently the default authentication plugin in all versions of MariaDB if the old_passwords system variable is set to `0`, which is the default.

On a system with the old_passwords system variable set to `0`, this means that if you create a user account with either the GRANT or CREATE USER `statements, and if you do not specify an authentication plugin with the` IDENTIFIED VIA `clause, then MariaDB will use the mysql_native_password authentication plugin for the user account.`

For example, this user account will use the mysql_native_password authentication plugin:

```
CREATE USER username@hostname;
```

And so will this user account:

```
CREATE USER username@hostname IDENTIFIED BY 'notagoodpassword';
```

The mysql_old_password authentication plugin becomes the default authentication plugin in all versions of MariaDB if the old_passwords system variable is explicitly set to `1`.

However, the mysql_old_password authentication plugin is not considered secure, so it is recommended to avoid using this authentication plugin. To help prevent undesired use of the mysql_old_password authentication plugin, the server supports the secure_auth system variable that can be used to configured the server to refuse connections that try to use the mysql_old_password authentication plugin:

Server Option	Description
`old_passwords={1 | 0}`	If set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords, instead of the mysql_native_password authentication plugin.
`secure_auth`	Connections will be blocked if they use the the mysql_old_password authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format.

Most clients and utilities also support the `--secure-auth` command line argument that can also be used to configure the client to refuse to connect to servers that use the mysql_old_password authentication plugin:

Client Option	Description
`--secure-auth`	Refuse to connect to the server if the server uses the mysql_old_password authentication plugin. This mode is off by default, which is a difference in behavior compared to MySQL 5.6 and later, where it is on by default.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the `MYSQL_SECURE_AUTH` option with the mysql_optionsv function.

For example:

```
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

Default Client Authentication Plugin

The default client-side authentication plugin depends on a few factors.

If a client doesn't explicitly set the default client-side authentication plugin, then the client will determine which authentication plugin to use by checking the length of the scramble in the server's handshake packet.

If the server's handshake packet contains a 9-byte scramble, then the client will default to the mysql_old_password authentication plugin.

If the server's handshake packet contains a 20-byte scramble, then the client will default to the mysql_native_password authentication plugin.

Setting the Default Client Authentication Plugin

Most clients and utilities support the `--default-auth` command line argument that can be used to set the default client-side authentication plugin:

Client Option	Description
`--default-auth=name`	Default authentication client-side plugin to use.

Developers who are using MariaDB Connector/C can implement similar functionality in their application by setting the `MYSQL_DEFAULT_AUTH` option with the mysql_optionsv function.

For example:

```
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
```

If you know that your user account is configured to require a client-side authentication plugin that isn't mysql_old_password or mysql_native_password, then it can help speed up your connection process to explicitly set the default client-side authentication plugin.

According to the client-server protocol, the server first sends the handshake packet to the client, then the client replies with a packet containing the user name of the user account that is requesting access. The server handshake packet initially tells the client to use the default server authentication plugin, and the client reply initially tells the server that it will use the default client authentication plugin.

However, the server-side and client-side authentication plugins mentioned in these initial packets may not be the correct ones for this specific user account. The server only knows what authentication plugin to use for this specific user account after reading the user name from the client reply packet and finding the appropriate row for the user account in either the mysql.user table or the mysql.global_priv table, depending on the MariaDB version.

If the server finds that either the server-side or client-side default authentication plugin does not match the actual authentication plugin that should be used for the given user account, then the server restarts the authentication on either the server side or the client side.

This means that, if you know what client authentication plugin your user account requires, then you can avoid an unnecessary authentication restart and you can save two packets and two round-trips.between the client and server by configuring your client to use the correct authentication plugin by default.

Authentication Plugins

Server Authentication Plugins

`mysql_native_password`

The mysql_native_password authentication plugin uses the password hashing algorithm introduced in MySQL 4.1, which is also used by the PASSWORD() `function when old_passwords=0 is set. This hashing algorithm is based on SHA-1`.

`mysql_old_password`

The mysql_old_password authentication plugin uses the pre-MySQL 4.1 password hashing algorithm, which is also used by the OLD_PASSWORD() function and by the PASSWORD() function when old_passwords=1 is set.

`ed25519`

The ed25519 authentication plugin uses Elliptic Curve Digital Signature Algorithm to securely store users' passwords and to authenticate users. The ed25519 algorithm is the same one that is used by OpenSSH. It is based on the elliptic curve and code created by Daniel J. Bernstein.

From a user's perspective, the ed25519 authentication plugin still provides conventional password-based authentication.

`gssapi`

The gssapi authentication plugin allows the user to authenticate with services that use the Generic Security Services Application Program Interface (GSSAPI). Windows has a slightly different but very similar API called Security Support Provider Interface (SSPI).

On Windows, this authentication plugin supports Kerberos and NTLM authentication. Windows authentication is supported regardless of whether a domain is used in the environment.

On Unix systems, the most dominant GSSAPI service is Kerberos. However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The gssapi authentication plugin is most often used for authenticating with Microsoft Active Directory.

pam

The pam authentication plugin allows MariaDB to offload user authentication to the system's Pluggable Authentication Module (PAM) framework. PAM is an authentication framework used by Linux, FreeBSD, Solaris, and other Unix-like operating systems.

unix_socket

The unix_socket authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the socket system variable.

The unix_socket authentication plugin works by calling the getsockopt system call with the `SO_PEERCRED` socket option, which allows it to retrieve the `uid` of the process that is connected to the socket. It is then able to get the user name associated with that `uid`. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

For example:

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, a user `serg` is already logged into the operating system and has full shell access. He has already authenticated with the operating system and his MariaDB account is configured to use the unix_socket authentication plugin, so he does not need to authenticate again for the database. MariaDB accepts his operating system credentials and allows him to connect. However, any attempt to connect to the database as another operating system user will be denied.

named_pipe

The named_pipe authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the named_pipe system variable.

The named_pipe authentication plugin works by using named pipe impersonation and calling `GetUserName()` to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name.

For example:

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty  --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

Authentication Plugin API

The authentication plugin API is extensively documented in the source code in the following files:

- `mysql/plugin_auth.h` (server part)
- `mysql/client_plugin.h` (client part)
- `mysql/plugin_auth_common.h` (common parts)

The MariaDB source code also contains some authentication plugins that are intended explicitly to be examples for developers. They are located in `plugin/auth_examples`.

The definitions of two example authentication plugins called `two_questions` and `three_attempts` can be seen in `plugin/auth_examples/dialog_examples.c`. These authentication plugins demonstrate how to communicate with the user using the dialog client authentication plugin.

The `two_questions` authentication plugin asks the user for a password and a confirmation ("Are you sure?").

The `three_attempts` authentication plugin gives the user three attempts to enter a correct password.

The password for both of these plugins should be specified in the plain text in the `USING` clause:

```
CREATE USER insecure IDENTIFIED VIA two_questions USING 'notverysecret';
```

Dialog Client Authentication Plugin - Client Library Extension

The dialog client authentication plugin, strictly speaking, is not part of the client-server or authentication plugin API. But it can be loaded into any client application that uses the `libmysqlclient` or MariaDB Connector/C libraries. This authentication plugin provides a way for the application to customize the UI of the dialog function.

In order to use the dialog client authentication plugin to communicate with the user in a customized way, the application will need to implement a function with the following signature:

```
extern "C" char *mysql_authentication_dialog_ask(
  MYSQL *mysql, int type, const char *prompt, char *buf, int buf_len)
```

The function takes the following arguments:

- The connection handle.
- A question "type", which has one of the following values:
  - `1` - Normal question
  - `2` - Password (no echo)
- A prompt.
- A buffer.
- The length of the buffer.

The function returns a pointer to a string of characters, as entered by the user. It may be stored in `buf` or allocated with `malloc()`.

Using this function a GUI application can pop up a dialog window, a network application can send the question over the network, as required. If no `mysql_authentication_dialog_ask` function is provided by the application, the dialog client authentication plugin falls back to fputs() and fgets().

Providing this callback is particularly important on Windows, because Windows GUI applications have no associated console and the default dialog function will not be able to reach the user. An example of Windows GUI client that does it correctly is HeidiSQL.

5.4.6.2 Authentication Plugin - mysql_native_password

The `mysql_native_password` authentication plugin is the default authentication plugin that will be used for an account created when no authentication plugin is explicitly mentioned and old_passwords=0 is set. It uses the password hashing algorithm introduced in MySQL 4.1, which is also used by the PASSWORD() function when old_passwords=0 is set. This hashing algorithm is based on SHA-1.

It is not recommended to use the `mysql_native_password` authentication plugin for new installations that require **high password security**. If someone is able to both listen to the connection protocol and get a copy of the mysql.user table, then the person would be able to use this information to connect to the MariaDB server. The ed25519

authentication plugin is a more modern authentication plugin that provides simple password authentication using a more secure algorithm.

Contents

Installing the Plugin

The `mysql_native_password` authentication plugin is statically linked into the server, so no installation is necessary.

Creating Users

The easiest way to create a user account with the `mysql_native_password` authentication plugin is to make sure that old_passwords=0 is set, and then create a user account via CREATE USER that does not specify an authentication plugin, but does specify a password via the IDENTIFIED BY clause. For example:

```
SET old_passwords=0;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT. For example:

```
SET old_passwords=0;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the IDENTIFIED BY PASSWORD clause, and MariaDB will validate whether the password hash is one that is compatible with `mysql_native_password`. For example:

```
SET old_passwords=0;

SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+

CREATE USER username@hostname
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

Similar to all other authentication plugins, you could also specify the name of the plugin in the IDENTIFIED VIA clause while providing the password hash as the `USING` clause. For example:

```
CREATE USER username@hostname
  IDENTIFIED VIA mysql_native_password USING '*54958E764CE10E50764C2EECBB71D01F08549980';
```

Changing User Passwords

You can change a user account's password with the SET PASSWORD statement while providing the plain-text password as an argument to the PASSWORD() function. For example:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the ALTER USER statement. You would have to make sure that old_passwords=0 is set, and then you would have to specify a password via the IDENTIFIED BY clause. For example:

```
SET old_passwords=0;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_native_password` authentication plugin:

- `mysql_native_password`

When connecting with a client or utility to a server as a user account that authenticates with the `mysql_native_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the `mysql_native_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or MariaDB Connector/C, so this is not usually necessary.

`mysql_native_password`

The `mysql_native_password` client authentication plugin hashes the password before sending it to the server.

Support in Client Libraries

The `mysql_native_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

Known Old Issues (Only Relevant for Old Installations)

Mismatches Between Password and authentication_string Columns

For compatibility reasons,the `mysql_native_password` authentication plugin tries to read the password hash from both the `Password` and `authentication_string` columns in the mysql.user table. This has caused issues in the past if one of the columns had a different value than the other.

Starting with MariaDB 10.2.19 and MariaDB 10.3.11, CREATE USER, ALTER USER, GRANT, and SET PASSWORD will set both columns whenever an account's password is changed.

See MDEV-16774 for more information.

5.4.6.3 Authentication Plugin - mysql_old_password

The `mysql_old_password` authentication plugin is the default authentication plugin that will be used for an account created when no authentication plugin is explicitly mentioned and `old_passwords=1` is set. It uses the pre-MySQL 4.1 password hashing algorithm, which is also used by the `OLD_PASSWORD()` function and by the `PASSWORD()` function when `old_passwords=1` is set.

It is not recommended to use the `mysql_old_password` authentication plugin for new installations. The password hashing algorithm is no longer as secure as it used to be, and the plugin is primarily provided for backward-compatibility. The `ed25519` authentication plugin is a more modern authentication plugin that provides simple password authentication.

Contents

Installing the Plugin

The `mysql_old_password` authentication plugin is statically linked into the server, so no installation is necessary.

Creating Users

The easiest way to create a user account with the `mysql_old_password` authentication plugin is to make sure that `old_passwords=1` is set, and then create a user account via `CREATE USER` that does not specify an authentication plugin, but does specify a password via the `IDENTIFIED BY` clause. For example:

```
SET old_passwords=1;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If `SQL_MODE` does not have `NO_AUTO_CREATE_USER` set, then you can also create the user via `GRANT`. For example:

```
SET old_passwords=1;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the `IDENTIFIED BY PASSWORD` clause, and MariaDB will validate whether the password hash is one that is compatible with `mysql_old_password`. For example:

```
SET old_passwords=1;
Query OK, 0 rows affected (0.000 sec)

SELECT PASSWORD('mariadb');
+---------------------+
| PASSWORD('mariadb') |
+---------------------+
| 021bec665bf663f1    |
+---------------------+
1 row in set (0.000 sec)

CREATE USER username@hostname IDENTIFIED BY PASSWORD '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

Similar to all other authentication plugins, you could also specify the name of the plugin in the `IDENTIFIED VIA` clause while providing the password hash as the `USING` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA mysql_old_password USING '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

Changing User Passwords

You can change a user account's password with the `SET PASSWORD` statement while providing the plain-text password as an argument to the `PASSWORD()` function. For example:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the `ALTER USER` statement. You would have to make sure that `old_passwords=1` is set, and then you would have to specify a password via the `IDENTIFIED BY` clause. For example:

```
SET old_passwords=1;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_old_password` authentication plugin:

- `mysql_old_password`

When connecting with a client or utility to a server as a user account that authenticates with the `mysql_old_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the `mysql_old_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or MariaDB Connector/C, so this is not usually necessary.

`mysql_old_password`

The `mysql_old_password` client authentication plugin hashes the password before sending it to the server.

Support in Client Libraries

The `mysql_old_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

5.4.6.4 Authentication Plugin - ed25519

MySQL has used SHA-1 based authentication since version 4.1. Since MariaDB 5.2 this authentication plugin has been called mysql_native_password. Over the years as computers became faster, new attacks on SHA-1 were being developed. Nowadays SHA-1 is no longer considered as secure as it was in 2001. That's why the `ed25519` authentication plugin was created.

The `ed25519` authentication plugin uses Elliptic Curve Digital Signature Algorithm (ECDSA) to securely store users' passwords and to authenticate users. The ed25519 algorithm is the same one that is used by OpenSSH. It is based on the elliptic curve and code created by Daniel J. Bernstein.

From a user's perspective, the `ed25519` authentication plugin still provides conventional password-based authentication.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default as `auth_ed25519.so` or `auth_ed25519.dll` depending on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'auth_ed25519';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = auth_ed25519
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'auth_ed25519';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

MariaDB starting with 10.4

In MariaDB 10.4 and later, you can create a user account by executing the CREATE USER statement and providing the IDENTIFIED VIA clause followied by the the name of the plugin, which is `ed25519` , and providing the the `USING` clause followed by the PASSWORD() function with the plain-text password as an argument. For example:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

MariaDB until 10.3

In MariaDB 10.3 and before, the PASSWORD() function and SET PASSWORD statement did not work with the `ed25519` authentication plugin. Instead, you would have to use the UDF that comes with the authentication plugin to calculate the password hash. For example:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing:

```
SELECT ed25519_password("secret");
+-----------------------------------------------+
| SELECT ed25519_password("secret");            |
+-----------------------------------------------+
| ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY |
+-----------------------------------------------+
```

Now you can use it to create the user account using the new password hash.

To create a user account via CREATE USER, specify the name of the plugin in the IDENTIFIED VIA clause while providing the password hash as the `USING` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via GRANT. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

Note that users require a password in order to be able to connect. It is possible to create a user without specifying a password, but they will be unable to connect.

Changing User Passwords

MariaDB starting with 10.4

In MariaDB 10.4 and later, you can change a user account's password by executing the SET PASSWORD statement followed by the PASSWORD() function and providing the plain-text password as an argument. For example:

```
SET PASSWORD =  PASSWORD('new_secret')
```

You can also change the user account's password with the ALTER USER statement. You would have to specify the name of the plugin in the IDENTIFIED VIA clause while providing the plain-text password as an argument to the PASSWORD() function in the `USING` clause. For example:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('new_secret');
```

MariaDB until 10.3

In MariaDB 10.3 and before, the PASSWORD() function and SET PASSWORD statement did not work with the `ed25519` authentication plugin. Instead, you would have to use the UDF that comes with the authentication plugin to calculate the password hash. For example:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing:

```
SELECT ed25519_password("secret");
+-----------------------------------------------+
| SELECT ed25519_password("secret");            |
+-----------------------------------------------+
| ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY |
+-----------------------------------------------+
```

Now you can change the user account's password using the new password hash.

You can change the user account's password with the ALTER USER statement. You would have to specify the name of the plugin in the IDENTIFIED VIA clause while providing the password hash as the `USING` clause. For example:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519
  USING 'ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY';
```

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `ed25519` authentication plugin:

- `client_ed25519`

When connecting with a client or utility to a server as a user account that authenticates with the `ed25519` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

`client_ed25519`

The `client_ed25519` client authentication plugin hashes and signs the password using the Elliptic Curve Digital Signature Algorithm (ECDSA) before sending it to the server.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `ed25519` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/C 3.1.0.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `ed25519` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/ODBC 3.1.2.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `ed25519` authentication since MariaDB Connector/J 2.2.1.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `ed25519` authentication since MariaDB Connector/Node.js 2.1.0.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `ed25519` authentication since MySqlConnector 0.56.0.

The connector implemented support for this authentication plugin in a separate NuGet package called MySqlConnector.Authentication.Ed25519. After the package is installed, your application must call `Ed25519AuthenticationPlugin.Install` to enable it.

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.4.0
1.0	Stable	MariaDB 10.3.8, MariaDB 10.2.17, MariaDB 10.1.35
1.0	Beta	MariaDB 10.2.5, MariaDB 10.1.22

Options

`ed25519`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--ed25519=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.6.5 Authentication Plugin - GSSAPI

The `gssapi` authentication plugin allows the user to authenticate with services that use the Generic Security Services Application Program Interface (GSSAPI). Windows has a slightly different but very similar API called Security Support Provider Interface (SSPI). The GSSAPI is a standardized API described in RFC2743 and RFC2744. The client and

server negotiate using a standardized protocol described in RFC7546.

On Windows, this authentication plugin supports Kerberos and NTLM authentication. Windows authentication is supported regardless of whether a domain is used in the environment.

On Unix systems, the most dominant GSSAPI service is Kerberos. However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The `gssapi` authentication plugin is most often used for authenticating with Microsoft Active Directory.

This article gives instructions on configuring the `gssapi` authentication plugin for MariaDB for passwordless login.

Contents

Installing the Plugin's Package

Since MariaDB 10.11, on Windows, the plugin is included in the server, and there is no need for separate installation.

The `gssapi` authentication plugin's shared library is included in MariaDB packages as the `auth_gssapi.so` or `auth_gssapi.dll` shared library on systems where it can be built.

Installing on Linux

The `gssapi` authentication plugin is included in binary tarballs on Linux.

Installing with a Package Manager

The `gssapi` authentication plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

```
sudo yum install MariaDB-gssapi-server
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using `apt-get`. For example:

```
sudo apt-get install mariadb-plugin-gssapi-server
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `zypper`. For example:

```
sudo zypper install MariaDB-gssapi-server
```

Installing on Windows

Since MariaDB 10.11, the plugin is included in the server, and there is no need for separate installation.

Before MariaDB 10.11, the `gssapi` authentication plugin is included in MSI and ZIP packages on Windows.

Installing the Plugin

Since MariaDB 10.11, on Windows, the plugin is included in the server, and there is no need for separate installation.

Before MariaDB 10.11 on Windows, and on other operating systems, although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'auth_gssapi';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = auth_gssapi
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'auth_gssapi';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Configuring the Plugin

If the MariaDB server is running on Unix, then some additional configuration steps will need to be implemented in order to use the plugin.

If the MariaDB server is running on Windows, then no special configuration steps will need to be implemented in order to use the plugin, as long as the following is true:

- The Windows server is joined to a domain.
- The MariaDB server process is running as either a NetworkService Account or a Domain User Account.

Creating a Keytab File on Unix

If the MariaDB server is running on Unix, then the KDC server will need to create a keytab file for the MariaDB server. The keytab file contains the service principal name, which is the identity that the MariaDB server will use to communicate with the KDC server. The keytab will need to be transferred to the MariaDB server, and the `mysqld` server process will need read access to this keytab file.

How this keytab file is generated depends on whether the KDC server is **Microsoft Active Directory KDC** or **MIT Kerberos KDC**.

Creating a Keytab File with Microsoft Active Directory

If you are using **Microsoft Active Directory KDC**, then you may need to create a keytab using the `ktpass.exe` utility on a Windows host. The service principal will need to be mapped to an existing domain user. To do so, follow the steps listed below.

Be sure to replace the following items in the step below:

- Replace `${HOST}` with the fully qualified DNS name for the MariaDB server host.
- Replace `${DOMAIN}` with the Active Directory domain.
- Replace `${AD_USER}` with the existing domain user.
- Replace `${PASSWORD}` with the password for the service principal.

To create the service principal, execute the following:

```
ktpass.exe /princ mariadb/${HOST}@${DOMAIN} /mapuser ${AD_USER} /pass ${PASSWORD} /out
mariadb.keytab /crypto all /ptype KRB5_NT_PRINCIPAL /mapop set
```

Creating a Keytab File with MIT Kerberos

If you are using **MIT Kerberos KDC**, then you can create a keytab file using the `kadmin` utility. To do so, follow the steps listed below.

In the following steps, be sure to replace `${HOST}` with the fully qualified DNS name for the MariaDB server host.

First, create the service principal using the `kadmin` utility. For example:

```
kadmin -q "addprinc -randkey mariadb/${HOST}"
```

Then, export the newly created user to the keytab file using the `kadmin` utility. For example:

```
kadmin -q "ktadd -k /path/to/mariadb.keytab mariadb/${HOST}"
```

More details can be found at the following links:

- MIT Kerberos Documentation: Database administration
- MIT Kerberos Documentation: Application servers

Configuring the Path to the Keytab File on Unix

If the MariaDB server is running on Unix, then the path to the keytab file that was previously created can be set by configuring the `gssapi_keytab_path` system variable. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
gssapi_keytab_path=/path/to/mariadb.keytab
```

Configuring the Service Principal Name

The service principal name can be set by configuring the `gssapi_principal_name` system variable. This can be specified

as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
gssapi_principal_name=service_principal_name/host.domain.com@REALM
```

If a service principal name is not provided, then the plugin will try to use `mariadb/host.domain.com@REALM` by default.

If the MariaDB server is running on Unix, then the plugin needs a service principal name in order to function.

If the MariaDB server is running on Windows, then the plugin does not usually need a service principal in order to function. However, if you want to use one anyway, then one can be created with the `setspn` utility.

Different KDC implementations may use different canonical forms to identify principals. See RFC2744: Section 3.10 to learn what the standard says about principal names.

More details can be found at the following links:

- Active Directory Domain Services: Service Principal Names
- MIT Kerberos Documentation: Realm configuration decisions
- MIT Kerberos Documentation: Principal names and DNS

Creating Users

To create a user account via `CREATE USER`, specify the name of the plugin in the `IDENTIFIED VIA` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi;
```

If `SQL_MODE` does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via `GRANT`. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA gssapi;
```

You can also specify the user's realm for MariaDB with the `USING` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi USING 'username@EXAMPLE.COM';
```

The format of the realm depends on the specific authentication mechanism that is used. For example, the format would need to be `machine\\username` for Windows users authenticating with NTLM.

If the realm is not provided in the user account's definition, then the realm is **not** used for comparison. Therefore, 'usr1@EXAMPLE.COM', 'usr1@EXAMPLE.CO.UK' and 'mymachine\usr1' would all identify as the following user account:

```
CREATE USER usr1@hostname IDENTIFIED VIA gssapi;
```

Creating Users Identified Via Group Membership or SID (Windows-specific)

Since 10.6.0, on Windows only, it is possible to login using a AD or local group-membership. This is achieved by using GROUP prefix in IDENTIFIED ... AS

```
CREATE USER root IDENTIFIED VIA gssapi as 'GROUP:Administrators'
CREATE USER root IDENTIFIED VIA gssapi as 'GROUP:BUILTIN\\Administrators'
```

Effect of the above definition is that every user that identifies as member of group Administrators can login using user name root, passwordless.

User can also login using own or group SID

```
CREATE USER root IDENTIFIED VIA gssapi as 'SID:S-1-5-32-544'
```

Using SIDs will perform slightly faster than using name (since it will spare translation between SID and name which is otherwise done), also SIDs immune against user or group renaming.

Passwordless login on Windows

MariaDB starting with 10.11

From MariaDB 10.11, on Windows, in addition to the usual authentication with a password, passwordless authentication is permitted, when creating the 'root' user during install.

This works in a similar manner to Unix socket authentication. However, since auth_gssapi, unlike unix_socket, requires client support, to avoid failures when MariaDB is used with 3rd party drivers, authentication on Windows first attempts password-based native_authentication, and only if it fails, falls back to passwordless auth_gssapi.

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides one client authentication plugin that is compatible with the `gssapi` authentication plugin:

- `auth_gssapi_client`

When connecting with a client or utility to a server as a user account that authenticates with the `gssapi` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

`auth_gssapi_client`

The `auth_gssapi_client` client authentication plugin receives the principal name from the server, and then uses either the `gss_init_sec_context` function (on Unix) or the `InitializeSecurityContext` function (on Windows) to establish a security context on the client.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `gssapi` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/C 3.0.1.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `gssapi` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/ODBC 3.0.0.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `gssapi` authentication since MariaDB Connector/J 1.4.0. Current documentation can be found here.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js does not yet support `gssapi` authentication. See CONJS-72 for more information.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `gssapi` authentication since MySqlConnector 0.47.0.

The support is transparent. Normally, the connector only needs to be provided the correct user name, and no other parameters are required.

However, this connector also supports the `ServerSPN` connection string parameter, which can be used for mutual authentication.

.NET specific problems/workarounds

When connecting from Unix client to Windows server with ADO.NET, in an Active Directory domain environment, be aware that .NET Core on Unix does not support principal names in UPN(User Principal Name) form, which is default on Windows (e.g machine$@domain.com) . Thus, upon encountering an authentication exception with "server not found in Kerberos database", use one of workarounds below

- Force host-based SPN on server side.
  - For example, this can be done by setting the `gssapi_principal_name` system variable to `HOST/machine` in a server option group in an option file.
- Pass host-based SPN on client side.
  - For example, this can be done by setting the connector's `ServerSPN` connection string parameter to `HOST/machine` .

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.15
1.0	Beta	MariaDB 10.1.11

System Variables

gssapi_keytab_path

- **Description:** Defines the path to the server's keytab file.
  - This system variable is only meaningful on **Unix**.
  - See Creating a Keytab File on Unix and Configuring the Path to the Keytab File on Unix for more information.
- **Commandline:** `--gssapi-keytab-path`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** ''
- **Introduced:** MariaDB 10.1.11

---

gssapi_principal_name

- **Description:** Name of the service principal.
  - See Configuring the Service Principal Name for more information.
- **Commandline:** `--gssapi-principal-name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** ''
- **Introduced:** MariaDB 10.1.11

---

gssapi_mech_name

- **Description:** Name of the SSPI package used by server. Can be either 'Kerberos' or 'Negotiate'. Set it to 'Kerberos', to prevent less secure NTLM in domain environments, but leave it as default (Negotiate) to allow non-domain environments (e.g if server does not run in a domain environment).
  - This system variable is only meaningful on **Windows**.
- **Commandline:** `--gssapi-mech-name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `Negotiate`
- **Valid Values:** `Kerberos` , `Negotiate`
- **Introduced:** MariaDB 10.1.11

Options

gssapi

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--gssapi=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- **Introduced:** MariaDB 10.1.11

5.4.6.6 Authentication with Pluggable Authentication Modules (PAM)

Authentication Plugin - PAM

Uses the Pluggable Authentication Module (PAM) framework to authenticate MariaDB users.

User and Group Mapping with PAM

Configure PAM to map a given PAM user or group to a different MariaDB user.

Configuring PAM Authentication and User Mapping with Unix Authentication

Walkthrough configuration of PAM authentication and user mapping with Unix authentication.

Configuring PAM Authentication and User Mapping with LDAP Authentication

Configuring PAM authentication and user mapping with LDAP authentication.

5.4.6.6.1 Authentication Plugin - PAM

The `pam` authentication plugin allows MariaDB to offload user authentication to the system's Pluggable Authentication Module (PAM) framework. PAM is an authentication framework used by Linux, FreeBSD, Solaris, and other Unix-like operating systems.

> **Note:** Windows does not support PAM, so the `pam` authentication plugin does not support Windows. However, one can use a MariaDB client on Windows to connect to MariaDB server that is installed on a Unix-like operating system and that is configured to use the `pam` authentication plugin. For an example of how to do this, see the blog post: MariaDB: Improve Security with Two-Step Verification.

Contents

Use Cases

PAM makes it possible to implement various authentication scenarios of different complexity. For example,

- Authentication using passwords from `/etc/shadow` (indeed, this is what a default PAM configuration usually does). See the pam_unix PAM module.
- Authentication using LDAP. See the pam_ldap PAM module.
- Authentication using Microsoft's Active Directory. See the pam_lsass, pam_winbind, and pam_centrifydc PAM modules.
- Authentication using one-time passwords (even with SMS confirmation!). See the pam_google_authenticator and pam_securid PAM modules.
- Authentication using SSH keys. See the pam_ssh PAM module.
- User and group mapping. See the pam_user_map PAM module.
- Combining different authentication modules in interesting ways in a PAM service.
- Password expiration.

- Limiting access by time, date, day of the week, etc. See the pam_time PAM module.
- Logging every login attempt.
- and so on, the list is in no way exhaustive.

Installing the Plugin

The `pam` authentication plugin's library is provided in binary packages in all releases on Linux.

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'auth_pam';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = auth_pam
```

Installing the v1 Plugin

MariaDB starting with 10.4.0

Starting in MariaDB 10.4.0, the `auth_pam` shared library actually refers to version `2.0` of the `pam` authentication plugin. MariaDB 10.4.0 and later also provides version `1.0` of the plugin as the `auth_pam_v1` shared library.

In MariaDB 10.4.0 and later, if you need to install version `1.0` of the authentication plugin instead of version `2.0`, then you can do so. For example, with INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'auth_pam_v1';
```

Or by specifying in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = auth_pam_v1
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'auth_pam';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Uninstalling the v1 Plugin

If you installed version `1.0` of the authentication plugin, then you can uninstall that by executing a similar statement for `auth_pam_v1`. For example:

```
UNINSTALL SONAME 'auth_pam_v1';
```

Configuring PAM

The `pam` authentication plugin tells MariaDB to delegate the authentication to the PAM authentication framework. How exactly that authentication is performed depends on how PAM was configured.

Configuring the PAM Service

PAM is divided into `services`. PAM services are configured by PAM configuration files. Typically, the global PAM configuration file is located at `/etc/pam.conf` and PAM directory-based configuration files for individual services are located in `/etc/pam.d/`.

If you want to use a PAM service called `mariadb` for your MariaDB PAM authentication, then the PAM configuration file for that service would also be called `mariadb`, and it would typically be located at `/etc/pam.d/mariadb`.

For example, here is a minimal PAM service configuration file that performs simple password authentication with UNIX passwords:

```
auth required pam_unix.so audit
account required pam_unix.so audit
```

Let's breakdown this relatively simple PAM service configuration file.

Each line of a PAM service configuration file has the following general format:

type control module-path module-arguments

The above PAM service configuration file instructs the PAM authentication framework that for successful **authentication** (i.e. type=auth), it is **required** that the `pam_unix.so` PAM module returns a success.

The above PAM service configuration file also instructs the PAM authentication framework that for an **account** (i.e. type=account) to be valid, it is **required** that the `pam_unix.so` PAM module returns a success.

PAM also supports session and password types, but MariaDB's `pam` authentication plugin does not support those.

The above PAM service configuration file also provides the `audit` module argument to the `pam_unix` PAM module. The pam_unix manual says that this module argument enables extreme debug logging to the syslog.

On most systems, you can find many other examples of PAM service configuration files in your `/etc/pam.d/` directory.

Configuring the pam_unix PAM Module

If you configure PAM to use the pam_unix PAM module (as in the above example), then you might notice on some systems that this will fail by default with errors like the following:

```
Apr 14 12:56:23 localhost unix_chkpwd[3332]: check pass; user unknown
Apr 14 12:56:23 localhost unix_chkpwd[3332]: password check failed for user (alice)
Apr 14 12:56:23 localhost mysqld: pam_unix(mysql:auth): authentication failure; logname= uid=991
euid=991 tty= ruser= rhost=  user=alice
```

The problem is that on some systems, the `pam_unix` PAM module needs access to `/etc/shadow` in order to function, and most systems only allow `root` to access that file by default.

Newer versions of PAM do not have this limitation, so you may want to try upgrading your version of PAM to see if that fixes the issue.

If that does not work, then you can work around this problem by giving the user that runs mysqld access to `/etc/shadow`. For example, if the `mysql` user runs mysqld, then you could do the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

And then you would have to restart the server.

At that point, the server should be able to read `/etc/shadow`.

MariaDB starting with 10.4.0

Starting in MariaDB 10.4.0, the `pam` authentication plugin uses a setuid wrapper to perform its PAM checks, so it should not need any special workarounds to perform privileged operations, such as reading `/etc/shadow` when using the `pam_unix` PAM module. See MDEV-7032 for more information.

Creating Users

Similar to all other authentication plugins, to create a user in MariaDB which uses the `pam` authentication plugin, you would execute CREATE USER while specifying the name of the plugin in the IDENTIFIED VIA clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA pam;
```

If SQL_MODE does not have `NO_AUTO_CREATE_USER` set, then you can also create the user this way with GRANT. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA pam;
```

You can also specify a PAM service name for MariaDB to use by providing it with the `USING` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA pam USING 'mariadb';
```

This line creates a user that needs to be authenticated via the `pam` authentication plugin using the PAM service name `mariadb`. As mentioned in a previous section, this service's configuration file will typically be present in `/etc/pam.d/mariadb`.

If no service name is specified, then the plugin will use `mysql` as the default PAM service name.

Client Authentication Plugins

For clients that use the `libmysqlclient` or MariaDB Connector/C libraries, MariaDB provides two client authentication plugins that are compatible with the `pam` authentication plugin:

- `dialog`
- `mysql_clear_password`

When connecting with a client or utility to a server as a user account that authenticates with the `pam` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mariadb --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

Both the `dialog` and the `mysql_clear_password` client authentication plugins transmit the password to the server in clear text. Therefore, when you use the `pam` authentication plugin, it is incredibly important to encrypt client connections using TLS to prevent the clear-text passwords from being seen by unauthorized users.

`dialog`

Usually the `pam` authentication plugin uses the `dialog` client authentication plugin to communicate with the user. This client authentication plugin allows MariaDB to support arbitrarily complex PAM configurations with regular or one-time passwords, challenge-response, multiple questions, or just about anything else. When using a MariaDB client library, there is no need to install or enable anything — the `dialog` client authentication plugin is loaded by the client library completely automatically and transparently for the application.

The `dialog` client authentication plugin was developed by MariaDB, so MySQL's clients and client libraries as well as third party applications that bundle MySQL's client libraries do not support the `dialog` client authentication plugin out of the box. If the server tells an unsupported client to use the `dialog` client authentication plugin, then the client is likely to throw an error like the following:

```
ERROR 2059 (HY000): Authentication plugin 'dialog' cannot be loaded:
/usr/lib/mysql/plugin/dialog.so: cannot open shared object file: No such file or directory
```

For some libraries or applications, this problem can be fixed by copying `dialog.so` or `dialog.dll` from a MariaDB client installation that is compatible with the system into the system's MySQL client authentication plugin directory. However, not all clients are compatible with the `dialog` client authentication plugin, so this may not work for every client.

If your client does not support the `dialog` client authentication plugin, then you may need to use the mysql_clear_password client authentication plugin instead.

The `dialog` client authentication plugin transmits the password to the server in clear text. Therefore, when you use

the `pam` authentication plugin, it is incredibly important to encrypt client connections using TLS to prevent the clear-text passwords from being seen by unauthorized users.

`mysql_clear_password`

Users can instruct the `pam` authentication plugin to use the `mysql_clear_password` client authentication plugin instead of the dialog client authentication plugin by configuring the pam_use_cleartext_plugin system variable on the server. It can be set in a relevant server option group in an option file. For example:

```
[mariadb]
...
pam_use_cleartext_plugin
```

It is important to note that the `mysql_clear_password` plugin has very limited functionality.

- The `mysql_clear_password` client authentication plugin only supports PAM services that require password-based authentication.
- The `mysql_clear_password` client authentication plugin also only supports PAM services that ask the user a single question.
- If the PAM service requires challenge-responses, multiple questions, or other similar complicated authentication schemes, then the PAM service is not compatible with `mysql_clear_password` client authentication plugin. In that case, the dialog client authentication plugin will have to be used instead.

The `mysql_clear_password` client authentication plugin transmits the password to the server in clear text. Therefore, when you use the `pam` authentication plugin, it is incredibly important to encrypt client connections using TLS to prevent the clear-text passwords from being seen by unauthorized users.

Compatiblity with MySQL Clients and Client Libraries

The `mysql_clear_password` client authentication plugin is similar to MySQL's mysql_clear_password client authentication plugin.

The `mysql_clear_password` client authentication plugin is compatible with MySQL clients and most MySQL client libraries, while the dialog client authentication plugin is not always compatible with them. Therefore, the `mysql_clear_password` client authentication plugin is most useful if you need some kind of MySQL compatibility in your environment, but you still want to use the `pam` authentication plugin.

Even though the `mysql_clear_password` client authentication plugin is compatible with MySQL clients and most MySQL client libraries, the `mysql_clear_password` client authentication plugin may be disabled by default by these clients and client libraries. For example, MySQL's version of the mysql command-line client has the --enable-cleartext-plugin option that must be set in order to use the `mysql_clear_password` client authentication plugin. For example:

```
mysql --enable-cleartext-plugin --user=alice -p
```

Other clients may require other methods to enable the authentication plugin. For example, MySQL Workbench has a checkbox titled **Enable Cleartext Authentication Plugin** under the **Advanced** tab on the connection configuration screen.

For applications that use MySQL's `libmysqlclient`, the authentication plugin can be enabled by setting the `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option with the `mysql_options()` function. For example:

```
mysql_options(mysql, MYSQL_ENABLE_CLEARTEXT_PLUGIN, 1);
```

For MySQL compatibility, MariaDB Connector/C also allows applications to set the `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option with the mysql_optionsv function. However, this option does not actually do anything in MariaDB Connector/C, because the `mysql_clear_password` client authentication plugin is always enabled for MariaDB clients and client libraries.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `pam` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/C 2.1.0, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `pam` authentication using the client authentication plugins mentioned in the previous section since MariaDB Connector/ODBC 1.0.0, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `pam v1` authentication since MariaDB Connector/J 1.4.0, regardless of the value of the pam_use_cleartext_plugin system variable.

MariaDB Connector/J supports `pam v2` authentication since MariaDB Connector/J 2.4.4, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `pam` authentication since MariaDB Connector/Node.js 0.7.0, regardless of the value of the pam_use_cleartext_plugin system variable.

Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports `pam` authentication since MySqlConnector 0.20.0, but only if the pam_use_cleartext_plugin system variable is enabled on the server.

Logging

PAM Module Logging

Errors and messages from PAM modules are usually logged using the syslog daemon with the `authpriv` facility. To determine the specific log file where the `authpriv` facility is logged, you can check rsyslog.conf.

On RHEL, CentOS, Fedora, and other similar Linux distributions, the default location for these messages is usually `/var/log/secure`.

On Debian, Ubuntu, and other similar Linux distributions, the default location for these messages is usually `/var/log/auth.log`.

For example, the syslog can contain messages like the following when MariaDB's `pam` authentication plugin is configured to use the pam_unix PAM module, and the user enters an incorrect password:

```
Jan  9 05:35:41 ip-172-30-0-198 unix_chkpwd[1205]: password check failed for user (foo)
Jan  9 05:35:41 ip-172-30-0-198 mysqld: pam_unix(mariadb:auth): authentication failure; logname=
uid=997 euid=997 tty= ruser= rhost=  user=foo
```

PAM Authentication Plugin's Debug Logging

MariaDB's `pam` authentication plugin can also log additional verbose debug logging to the error log. This is only done if the plugin is a debug build and if pam_debug is set.

The output looks like this:

```
PAM: pam_start(mariadb, alice)
PAM: pam_authenticate(0)
PAM: conv: send(Enter PASSCODE:)
PAM: conv: recv(123456789)
PAM: pam_acct_mgmt(0)
PAM: pam_get_item(PAM_USER)
PAM: status = 0 user = ��\>
```

Custom Logging with pam_exec

The pam_exec PAM module can be used to implement some custom logging. This can be very useful when debugging

certain kinds of issues.

For example, first, create a script that writes the log output:

```
tee /tmp/pam_log_script.sh <<EOF
#!/bin/bash
echo "\${PAM_SERVICE}:\${PAM_TYPE} - \${PAM_RUSER}@\${PAM_RHOST} is authenticating as \${PAM_USER
EOF
chmod 0775 /tmp/pam_log_script.sh
```

And then change the PAM service configuration to execute the script using the pam_exec PAM module. For example:

```
auth optional pam_exec.so log=/tmp/pam_output.txt /tmp/pam_log_script.sh
auth required pam_unix.so audit
account optional pam_exec.so log=/tmp/pam_output.txt /tmp/pam_log_script.sh
account required pam_unix.so audit
```

Whenever the above PAM service is used, the output of the script will be written to `/tmp/pam_output.txt`. It may look similar to this:

```
*** Tue May 14 14:53:23 2019
mariadb:auth - @ is authenticating as alice
*** Tue May 14 14:53:25 2019
mariadb:account - @ is authenticating as alice
*** Tue May 14 14:53:28 2019
mariadb:auth - @ is authenticating as alice
*** Tue May 14 14:53:31 2019
mariadb:account - @ is authenticating as alice
```

User and Group Mapping

Even when using the `pam` authentication plugin, the authenticating PAM user account still needs to exist in MariaDB, and the account needs to have privileges in the database. Creating these MariaDB accounts and making sure the privileges are correct can be a lot of work. To decrease the amount of work involved, some users would like to be able to map a PAM user to a different MariaDB user. For example, let's say that `alice` and `bob` are both DBAs. It would be nice if each of them could log into MariaDB with their own PAM username and password, while MariaDB sees both of them as the same `dba` user. That way, there is only one MariaDB account to keep track of. See User and Group Mapping with PAM for more information on how to do this.

PAM Modules

There are many PAM modules. The ones described below are the ones that have been seen most often by MariaDB.

pam_unix

The pam_unix PAM module provides support for Unix password authentication. It is the default PAM module on most systems.

For a tutorial on setting up PAM authentication and user or group mapping with Unix authentication, see Configuring PAM Authentication and User Mapping with Unix Authentication.

pam_user_map

The pam_user_map PAM module was developed by MariaDB to support user and group mapping.

pam_ldap

The pam_ldap PAM module provides support for LDAP authentication.

For a tutorial on setting up PAM authentication and user or group mapping with LDAP authentication, see Configuring PAM Authentication and User Mapping with LDAP Authentication.

This can also be configured for Active Directory authentication.

pam_sss

The pam_sss PAM module provides support for authentication with System Security Services Daemon (SSSD).

This can be configured for Active Directory authentication.

pam_lsass

The `pam_lsass` PAM module provides support for Active Directory authentication. It is provided by PowerBroker Identity Services – Open Edition.

pam_winbind

The pam_winbind PAM module provides support for Active Directory authentication. It is provided by winbindd from the samba suite.

This PAM module converts all provided user names to lowercase. There is no way to disable this functionality. If you do not want to be forced to use all lowercase user names, then you may need to configure the pam_winbind_workaround system variable. See MDEV-18686 for more information.

pam_centrifydc

The pam_centrifydc PAM module provides support for Active Directory authentication. It integrates with the commercial Active Directory Bridge from Centrify.

pam_krb5

The pam_krb5 PAM module provides support for Kerberos authentication.

This can be configured for Active Directory authentication.

pam_google_authenticator

The `pam_google_authenticator` PAM module provides two-factor identification with Google Authenticator. It is from Google's google-authenticator-libpam open-source project. The PAM module should work with the open-source mobile apps built by Google's google-authenticator and google-authenticator-android projects as well as the the closed source Google Authenticator mobile apps that are present in each mobile app store.

For an example of how to use this PAM module, see the blog post: MariaDB: Improve Security with Two-Step Verification.

pam_securid

The `pam_securid` PAM module provides support for multi-factor authentication. It is part of the commercial RSA SecurID Suite.

Note that current versions of this module are not safe for multi-threaded environments, and the vendor does not officially support the product on MariaDB. See MDEV-10361 about that. However, the module may work with MariaDB 10.4.0 and above.

pam_ssh

The pam_ssh PAM module provides authentication using SSH keys.

pam_time

The pam_time PAM module provides time-controlled access.

Known Issues

Multi-Threaded Issues

MariaDB is a multi-threaded program, which means that different connections concurrently run in different threads. Current versions of MariaDB's `pam` authentication plugin execute PAM module code in the server address space. This means that any PAM modules used with MariaDB must be safe for multi-threaded environments. Otherwise, if multiple clients try to authenticate with the same PAM module in parallel, undefined behavior can occur. For example, the `pam_fprintd` PAM module is not safe for multi-threaded environments, and if you use it with MariaDB, you may experience server crashes.

MariaDB starting with 10.4.0

Starting in MariaDB 10.4.0, the `pam` authentication plugin isolates PAM module code from the server address space, so even PAM modules that are known to be unsafe for multi-threaded environments should not cause issues with MariaDB. See MDEV-15473 for more information.

Conflicts with Password Validation

When a password validation plugin is enabled, MariaDB won't allow an account to be created if the password validation plugin says that the account's password is too weak. This creates a problem for accounts that authenticate with the `pam` authentication plugin, since MariaDB has no knowledge of the user's password. When a user tries to create an account that authenticates with the `pam` authentication plugin, the password validation plugin would throw an error, even with strict_password_validation=OFF set.

The workaround is to uninstall the password validation plugin with UNINSTALL PLUGIN, and then create the account, and then reinstall the password validation plugin with INSTALL PLUGIN.

For example:

```
INSTALL PLUGIN simple_password_check SONAME 'simple_password_check';
Query OK, 0 rows affected (0.002 sec)

SET GLOBAL strict_password_validation=OFF;
Query OK, 0 rows affected (0.000 sec)

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
UNINSTALL PLUGIN simple_password_check;
Query OK, 0 rows affected (0.000 sec)

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
Query OK, 0 rows affected (0.000 sec)

INSTALL PLUGIN simple_password_check SONAME 'simple_password_check';
Query OK, 0 rows affected (0.001 sec)
```

MariaDB starting with 10.4.0

Starting in MariaDB 10.4.0, accounts that authenticate with the `pam` authentication plugin should be exempt from password validation checks. See MDEV-12321 and MDEV-10457 for more information.

SELinux

SELinux may cause issues when using the `pam` authentication plugin. For example, using pam_unix with the `pam` authentication plugin while SELinux is enabled can sometimes lead to SELinux errors involving unix_chkpwd, such as the following::

```
Apr 14 12:37:59 localhost setroubleshoot: Plugin Exception restorecon_source
Apr 14 12:37:59 localhost setroubleshoot: SELinux is preventing /usr/sbin/unix_chkpwd from
execute access on the file . For complete SELinux messages. run sealert -l c56fe6e0-c78c-4bdb-
a80f-27ef86a1ea85
Apr 14 12:37:59 localhost python: SELinux is preventing /usr/sbin/unix_chkpwd from execute
access on the file .

*****  Plugin catchall (100. confidence) suggests   **************************

If you believe that unix_chkpwd should be allowed execute access on the  file by default.
Then you should report this as a bug.
You can generate a local policy module to allow this access.
Do
allow this access for now by executing:
# grep unix_chkpwd /var/log/audit/audit.log | audit2allow -M mypol
# semodule -i mypol.pp
```

Sometimes issues like this can be fixed by updating the system's SELinux policies. You may be able to update the policies using audit2allow. See SELinux: Generating SELinux Policies with audit2allow for more information.

If you can't get the `pam` authentication plugin to work with SELinux at all, then it can help to disable SELinux entirely. See SELinux: Changing SELinux's Mode for information on how to do this.

Memory Overcommit

On MariaDB 10.4 and later you may run into authentication failures with the following log message in the MariaDB error log:

```
pam: cannot exec /usr/lib64/mysql/plugin/auth_pam_tool_dir/auth_pam_tool (errno: 12 "Cannot alloc
```

This can happen on operating system setups that are configured to prevent memory overcommit. When the MariaDB server process spawns the `auth_pam_tool` helper process there's a brief period where the new process inherits the memory of the MariaDB process before releasing that memory and executing the new command. When having a MariaDB server configured to use more than 50% of the server machnines RAM -- which is common for dedicated database servers -- this duplication would lead to an over-commit situation.

Starting with MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, and MariaDB 10.7.4, we changed to use `posix_spawn()` instead of the classic `fork();exec()` to prevent this, but systems with older glibc versions prior to 2.26 still use `fork();exec()` to implement `posix_spawn()` internally and so are still affected; this is for example still the case on RedHat Enterprise Linux 7.

To solve this you can either:

- change the `vm.overcommit_memory` kernel setting to allow memory overcommit
- install the older `auth_pam_v1` plugin version that does not spawn a helper process (but may run into problems with file permissions or multi threading with some PAM modules)

- Configuring PAM Authentication and User Mapping with LDAP Authentication

Versions

Version	Status	Introduced
2.0	Beta	MariaDB 10.4.0
1.0	Stable	MariaDB 10.0.10
1.0	Beta	MariaDB 5.2.10

System Variables

`pam_debug`

- **Description:** Enables verbose debug logging to the error log for all authentication handled by the plugin.
  - This system variable is only available when the plugin is a debug build.
- **Commandline:** `--pam-debug`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.2.2, MariaDB 10.1.17

`pam_use_cleartext_plugin`

- **Description:** Use the mysql_clear_password client authentication plugin instead of the dialog client authentication plugin. This may be needed for compatibility reasons, but it only supports simple PAM configurations that don't require any input besides a password.
- **Commandline:** `--pam-use-cleartext-plugin`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`

- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.1.1, MariaDB 5.5.32

`pam_winbind_workaround`

- **Description:** Configures the authentication plugin to compare the user name provided by the client with the user name returned by the PAM module in a case insensitive manner. This may be needed if you use the pam_winbind PAM module, which is known to convert all user names to lowercase, and which does not allow this behavior to be disabled.
- **Commandline:** `--pam-winbind-workaround`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.4.5, MariaDB 10.3.15, MariaDB 10.2.24, MariaDB 10.1.39

Options

`pam`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--pam=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.6.6.2 User and Group Mapping with PAM

Even when using the `pam` authentication plugin, the authenticating PAM user account still needs to exist in MariaDB, and the account needs to have privileges in the database. Creating these MariaDB accounts and making sure the privileges are correct can be a lot of work. To decrease the amount of work involved, some users would like to be able to map a PAM user to a different MariaDB user. For example, let's say that `alice` and `bob` are both DBAs. It would be nice if each of them could log into MariaDB with their own PAM username and password, while MariaDB sees both of them as the same `dba` user. That way, there is only one MariaDB account to keep track of.

Although most PAM modules usually do not do things like this, PAM supports the ability to change the user name in the process of authentication.The MariaDB `pam` authentication plugin fully supports this feature of PAM.

Contents

The pam_user_map PAM Module

Rather than building user and group mapping into the `pam` authentication plugin, MariaDB thought that it would cover the most use cases and offer the most flexibility to offload this functionality to an external PAM module. The `pam_user_map` PAM module was implemented by MariaDB to facilitate this. This PAM module can be configured in the PAM service used by the `pam` authentication plugin, just like other PAM modules.

Lack of Support for MySQL/Percona Group Mapping Syntax

Unlike MariaDB, MySQL and Percona implemented group mapping in their PAM authentication plugins. If you've read through MySQL's PAM authentication documentation on group mapping or Percona's PAM authentication documentation on group mapping, you've probably seen syntax where the group mappings are provided in the `CREATE USER` statement like this:

```
CREATE USER ''@''
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

Since MariaDB's user and group mapping is performed by an external PAM module, MariaDB's `pam` authentication plugin does not support this syntax. Instead, the user and group mappings for the `pam_user_map` PAM module are configured in an external configuration file. This is discussed in a later section.

Installing the pam_user_map PAM Module

The `pam_user_map` PAM module gets installed as part of all our MariaDB server packages since MariaDB 10.5, and was added since 10.2.31, 10.3.22, and 10.4.12 in previous MariaDB major releases where it was not present from the beginning.

Some Linux distributions have not picked up this change in their own packages yet, so when e.g. installing MariaDB server from stock Ubuntu packages on Ubuntu 20.04LTS you still won't have the `pam_user_map` module installed even though the MariaDB server installed is more recent than MariaDB 10.3.22.

When using such an installation, and not being able to switch to our own MariaDB package repositories, it may be necessary to compile the PAM module from source as described in the next section, or to manually extract it from one of our server packages and copy it to the target system.

Installing the pam_user_map PAM Module from Source

Installing Compilation Dependencies

Before the module can be compiled from source, you may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, you need to install `gcc`, `pam-devel` and `MariaDB-devel`. For example:

```
sudo yum install gcc pam-devel MariaDB-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, you need to install `gcc`, `libpam0g-dev`. For example:

```
sudo apt-get install gcc libpam0g-dev libmariadb-dev
```

Compiling and Installing the pam_user_map PAM Module

The `pam_user_map` PAM module can be built by downloading `plugin/auth_pam/mapper/pam_user_map.c` file from the MariaDB source tree and compiling it after minor adjustments. Once it is built, it can be installed to the system's PAM module directory, which is typically `/lib64/security/` .

For example: (replace 10.4 in the URL with the actual server versions)

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
sed -ie 's/config_auth_pam/plugin_auth_common/' pam_user_map.c
gcc -I/usr/include/mysql/ pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

You will also need to adjust the major version number in the URL on the first line to match your installed MariaDB version, and the #-I# include path argument on the `gcc` line, as depending on operating system and MariaDB server version the plugin_auth_common.h file may be installed in different directories than `/usr/include/mysql/`

Configuring the pam_user_map PAM Module

The `pam_user_map` PAM module uses the configuration file at the path `/etc/security/user_map.conf` to determine its user and group mappings. The file's format is described below.

To map a specific PAM user to a specific MariaDB user:

```
orig_pam_user_name: mapped_mariadb_user_name
```

Or to map any PAM user in a specific PAM group to a specific MariaDB user, the group name is prefixed with `@` :

```
@orig_pam_group_name: mapped_mariadb_user_name
```

For example, here is an example `/etc/security/user_map.conf` :

```
============================================================
#comments and empty lines are ignored
john: jack
bob:  admin
top:  accounting
@group_ro: readonly
```

Configuring PAM

With user and group mapping, configuring PAM is done similar to how it is normally done with the `pam` authentication plugin. However, when configuring the PAM service, you will have to add an `auth` line for the `pam_user_map` PAM module to the service's PAM configuration file. For example:

```
auth required pam_unix.so audit
auth required pam_user_map.so
account required pam_unix.so audit
```

Creating Users

With user and group mapping, creating users is done similar to how it is normally done with the `pam` authentication plugin. However, one major difference is that you will need to `GRANT` the `PROXY` privilege on the mapped user to the original user.

For example, if you have the following configured in `/etc/security/user_map.conf` :

```
foo: bar
@dba:dba
```

Then you could execute the following to grant the relevant privileges:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;

CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Note that the `''@'%'` account is a special catch-all anonymous account. Any login by a user that has no more specific account match in the system will be matched by this anonymous account.

Also note that you might not be able to create the `''@'%'` anonymous account by default on some systems without doing some extra steps first. See Fixing a Legacy Default Anonymous Account for more information.

Verifying that Mapping is Occurring

In case any user mapping is performed, the original user name is returned by the SQL function `USER()`, while the authenticated user name is returned by the SQL function `CURRENT_USER()`. The latter actually defines what privileges are available to a connected user.

For example, if we have the following configured:

```
foo: bar
```

Then the following output would verify that it is working properly:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` PAM user was properly mapped to the `bar` MariaDB user by looking at the return value of `CURRENT_USER()`.

Logging

By default, the `pam_user_map` PAM module does not perform any logging. However, if you want to enable debug logging, then you can add the `debug` module argument to the service's PAM configuration file. For example:

```
auth required pam_unix.so audit
auth required pam_user_map.so debug
account required pam_unix.so audit
```

When debug logging is enabled, the `pam_user_map` PAM module will write log entries to the same syslog location as other PAM modules, which is typically `/var/log/secure` on many systems.

For example, this debug log output can look like the following:

```
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'alice'.
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 2 groups
[alice,dba].
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group
'dba': YES
Jan  9 05:42:13 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'dba'
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'bob'.
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 2 groups
[bob,dba].
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group
'dba': YES
Jan  9 05:43:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'dba'
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Opening file
'/etc/security/user_map.conf'.
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Incoming username 'foo'.
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User belongs to 1 group
[foo].
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if user is in group
'dba': NO
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): Check if username 'foo': YES
Jan  9 06:08:36 ip-172-30-0-198 mysqld: pam_user_map(mariadb:auth): User mapped as 'bar'
```

Known Issues

PAM User with Same Name as Mapped MariaDB User Must Exist

With user and group mapping, any PAM user or any PAM user in a given PAM group can be mapped to a specific MariaDB user account. However, due to the way PAM works, a PAM user with the same name as the mapped MariaDB user account must exist.

For example, if the configuration file for the PAM service file contained the following:

```
auth required pam_sss.so
auth required pam_user_map.so debug
account sufficient pam_unix.so
account sufficient pam_sss.so
```

And if `/etc/security/user_map.conf` contained the following:

```
@dba: dba
```

Then any PAM user in the PAM group `dba` would be mapped to the MariaDB user account `dba`. But if a PAM user with the name `dba` did not also exist, then the `pam_user_map` PAM module's debug logging would write errors to the syslog like the following:

```
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Opening file
'/etc/security/user_map.conf'.
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Incoming username 'alice'.
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): User belongs to 4 groups
[dba,mongod,mongodba,mysql].
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): Check if user is in group 'mysql':
YES
Sep 27 17:17:05 dbserver1 mysqld: pam_user_map(mysql:auth): User mapped as 'dba'
Sep 27 17:17:05 dbserver1 mysqld: pam_unix(mysql:account): could not identify user (from
getpwnam(dba))
Sep 27 17:17:05 dbserver1 mysqld: pam_sss(mysql:account): Access denied for user dba: 10 (User
not known to the underlying authentication module)
Sep 27 17:17:05 dbserver1 mysqld: 2018-09-27 17:17:05 72 [Warning] Access denied for user
'alice'@'localhost' (using password: NO)
```

In the above log snippet, notice that both the `pam_unix` and the `pam_sss` PAM modules are complaining that the `dba` PAM user does not appear to exist, and that these complaints cause the PAM authentication process to fail, which causes the MariaDB authentication process to fail as well.

This can be fixed by creating a PAM user with the same name as the mapped MariaDB user account, which is `dba` in this case.

You may also be able to work around this problem by essentially disabling PAM's account verification for the service with the `pam_permit` PAM module. For example, in the above case, that would be:

```
auth required pam_sss.so
auth required pam_user_map.so debug
account required pam_permit.so
```

See MDEV-17315 for more information.

- Configuring PAM Authentication and User Mapping with Unix Authentication
- Configuring PAM Authentication and User Mapping with LDAP Authentication

5.4.6.6.3 Configuring PAM Authentication and User Mapping with Unix Authentication

In this article, we will walk through the configuration of PAM authentication using the `pam` authentication plugin and user and group mapping with the `pam_user_map` PAM module. The primary authentication will be handled by the `pam_unix` PAM module, which performs standard Unix password authentication.

Contents

Hypothetical Requirements

In this walkthrough, we are going to assume the following hypothetical requirements:

- The Unix user `foo` should be mapped to the MariaDB user `bar`. (`foo: bar`)
- Any Unix user in the Unix group `dba` should be mapped to the MariaDB user `dba`. (`@dba: dba`)

Creating Our Unix Users and Groups

Let's go ahead and create the Unix users and groups that we are using for this hypothetical scenario.

First, let's create the the `foo` user and a couple users to go into the `dba` group. Note that each of these users needs a password.

```
sudo useradd foo
sudo passwd foo
sudo useradd alice
sudo passwd alice
sudo useradd bob
sudo passwd bob
```

And then let's create our `dba` group and add our two users to it:

```
sudo groupadd dba
sudo usermod -a -G dba alice
sudo usermod -a -G dba bob
```

We also need to create Unix users with the same name as the `bar` and `dba` MariaDB users. See here to read more about why. No one will be logging in as these users, so they do not need passwords.

```
sudo useradd bar
sudo useradd dba -g dba
```

Installing the pam_user_map PAM Module

Next, let's install the pam_user_map PAM module.

Before the module can be compiled from source, we may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install `gcc` and `pam-devel`:

```
sudo yum install gcc pam-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, we need to install `gcc` and `libpam0g-dev`:

```
sudo apt-get install gcc libpam0g-dev
```

And then we can build and install the library with the following:

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
gcc pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

Configuring the pam_user_map PAM Module

Next, let's configure the pam_user_map PAM module based on our hypothetical requirements.

The configuration file for the `pam_user_map` PAM module is `/etc/security/user_map.conf`. Based on our hypothetical requirements, ours would look like:

```
foo: bar
@dba:dba
```

Installing the PAM Authentication Plugin

Next, let's install the `pam` authentication plugin.

Log into the MariaDB Server and execute the following:

```
INSTALL SONAME 'auth_pam';
```

Configuring the PAM Service

Next, let's configure the PAM service. We will call our service `mariadb`, so our PAM service configuration file will be located at `/etc/pam.d/mariadb` on most systems.

Since we are only doing Unix authentication with the `pam_unix` PAM module and group mapping with the `pam_user_map` PAM module, our configuration file would look like this:

```
auth required pam_unix.so audit
auth required pam_user_map.so
account required pam_unix.so audit
```

Configuring the pam_unix PAM Module

The `pam_unix` PAM module adds some additional configuration steps on a lot of systems. We basically have to give the user that runs `mysqld` access to `/etc/shadow`.

If the `mysql` user is running `mysqld`, then we can do that by executing the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

The server needs to be restarted for this change to take affect.

Creating MariaDB Users

Next, let's create the MariaDB users. Remember that our PAM service is called `mariadb`.

First, let's create the MariaDB user for the user mapping: `foo: bar`

That means that we need to create a `bar` user:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;
```

And then let's create the MariaDB user for the group mapping: `@dba: dba`

That means that we need to create a `dba` user:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;
```

And then to allow for the user and group mapping, we need to create an anonymous user that authenticates with the `pam` authentication plugin that is also able to `PROXY` as the `bar` and `dba` users. Before we can create the proxy user, we might need to clean up some defaults:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

And then let's create the anonymous proxy user:

```
CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Testing our Configuration

Next, let's test out our configuration by verifying that mapping is occurring. We can verify this by logging in as each of our users and comparing the return value of `USER()`, which is the original user name and the return value of `CURRENT_USER()`, which is the authenticated user name.

First, let's test out our `foo` user:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` Unix user was properly mapped to the `bar` MariaDB user by looking at the return value of `CURRENT_USER()`.

Then let's test out our `alice` user in the `dba` group:

```
$ mysql -u alice -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 19
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+---------------------------------------------------+----------------+
| USER()                                            | CURRENT_USER() |
+---------------------------------------------------+----------------+
| alice@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+---------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

And then let's test out our `bob` user in the `dba` group:

```
$ mysql -u bob -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 20
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-------------------------------------------------+----------------+
| USER()                                          | CURRENT_USER() |
+-------------------------------------------------+----------------+
| bob@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `alice` and `bob` Unix users in the `dba` Unix group were properly mapped to the `dba` MariaDB user by looking at the return values of `CURRENT_USER()`.

5.4.6.6.4 Configuring PAM Authentication and User Mapping with LDAP Authentication

In this article, we will walk through the configuration of PAM authentication using the `pam` authentication plugin and user and group mapping with the `pam_user_map` PAM module. The primary authentication will be handled by the `pam_ldap` PAM module, which performs LDAP authentication. We will also set up an OpenLDAP server.

Contents

Hypothetical Requirements

In this walkthrough, we are going to assume the following hypothetical requirements:

- The LDAP user `foo` should be mapped to the MariaDB user `bar`. (`foo: bar`)
- Any LDAP user in the LDAP group `dba` should be mapped to the MariaDB user `dba`. (`@dba: dba`)

Setting up the OpenLDAP Server

Before we can use LDAP authentication, we first need to set up our OpenLDAP Server. This is usually done on a server that is completely separate from the database server.

Installing the OpenLDAP Server and Client Components

On the server acting as the OpenLDAP Server, first, we need to install the OpenLDAP components.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, that would go like this:

```
sudo yum install openldap openldap-servers openldap-clients nss-pam-ldapd
```

Configuring the OpenLDAP Server

Next, let's to configure the OpenLDAP Server. The easiest way to do that is to copy the template configuration file that is included with the installation. In many installations, that will be at `/usr/share/openldap-servers/DB_CONFIG.example`. For example:

```
sudo cp /usr/share/openldap-servers/DB_CONFIG.example /var/lib/ldap/DB_CONFIG
sudo chown ldap. /var/lib/ldap/DB_CONFIG
```

Configuring the OpenLDAP Port

Sometimes it is useful to change the port used by OpenLDAP. For example, some cloud environments block well-known authentication services, so they block the default LDAP port.

On some systems, the port can be changed by setting `SLAPD_URLS` in `/etc/sysconfig/slapd`:

```
SLAPD_URLS="ldapi:/// ldap://0.0.0.0:3306/"
```

I used `3306` because that is the port that is usually used by `mysqld`, so I know that it is not blocked.

Starting the OpenLDAP Server

Next, let's start the OpenLDAP Server and configure it to start on reboot. On `systemd` systems, that would go like this:

```
sudo systemctl start slapd
sudo systemctl enable slapd
```

Installing the Standard LDAP objectClasses

In order to use LDAP for authentication, we also need to install some standard `objectClasses`, such as `posixAccount` and `posixGroup`. In LDAP, things like `objectClasses` are defined in `LDIF` files. In many installations, these specific `objectClasses` are defined in `/etc/openldap/schema/nis.ldif`. `nis.ldif` also depends on `core.ldif` and `cosine.ldif`. However, `core.ldif` is usually installed by default.

We can install them with `ldapmodify`:

```
sudo ldapmodify -a -Y EXTERNAL -H ldapi:/// -f /etc/openldap/schema/cosine.ldif
sudo ldapmodify -a -Y EXTERNAL -H ldapi:/// -f /etc/openldap/schema/nis.ldif
```

Creating the LDAP Directory Manager User

Next, let's create a directory manager user. We can do this by using OpenLDAP's olc configuration system to change the `olcRootDN` directive to the DN of the directory manager user, which means that the user will be a privileged LDAP user that is not subject to access controls. We will also set the root password for the user by changing the `olcRootPW` directive.

We will also set the DN suffix for our backend LDAP database by changing the `olcSuffix` directive.

Let's use the `slappasswd` utility to generate a password hash from a clear-text password. Simply execute:

```
slappasswd
```

This utility should provide a password hash that looks kind of like this: `{SSHA}AwT4jrvmokeCkbDrFAnGvzzjCMb7bvEl`

OpenLDAP's olc configuration system also uses `LDIF` files. Now that we have the password hash, let's create an `LDIF` file to create the directory manager user:

```
tee ~/setupDirectoryManager.ldif <<EOF
dn: olcDatabase={1}monitor,cn=config
changetype: modify
replace: olcAccess
olcAccess: {0}to *
    by dn.base="gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth" read
    by dn.base="cn=Manager,dc=support,dc=mariadb,dc=com" read
    by * none

dn: olcDatabase={2}hdb,cn=config
changetype: modify
replace: olcSuffix
olcSuffix: dc=support,dc=mariadb,dc=com

dn: olcDatabase={2}hdb,cn=config
changetype: modify
replace: olcRootDN
olcRootDN: cn=Manager,dc=support,dc=mariadb,dc=com

dn: olcDatabase={2}hdb,cn=config
changetype: modify
add: olcRootPW
olcRootPW: {SSHA}AwT4jrvmokeCkbDrFAnGvzzjCMb7bvEl

dn: olcDatabase={2}hdb,cn=config
changetype: modify
add: olcAccess
olcAccess: {0}to attrs=userPassword,shadowLastChange
    by   dn="cn=Manager,dc=support,dc=mariadb,dc=com" write
    by anonymous auth
    by self write
    by * none
olcAccess: {1}to dn.base=""
    by * read
olcAccess: {2}to *
    by dn="cn=Manager,dc=support,dc=mariadb,dc=com" write
    by * read
EOF
```

Note that I am using the `dc=support,dc=mariadb,dc=com` domain for my directory. You can change this to whatever is relevant to you.

Now let's run the ldif file with `ldapmodify` :

```
sudo ldapmodify -Y EXTERNAL -H ldapi:/// -f ~/setupDirectoryManager.ldif
```

We will use the new directory manager user to make changes to the LDAP directory after this step.

Creating the Structure of the Directory

Next, let's create the structure of the directory by creating parts of our tree.

```
tee ~/setupDirectoryStructure.ldif <<EOF
dn: dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: dcObject
objectclass: organization
o: MariaDB Support Team
dc: support

dn: cn=Manager,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalRole
cn: Manager
description: Directory Manager

dn: ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: Groups

dn: ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: organizationalUnit
ou: System Users
EOF
```

Now let's use our new directory manager user and run the `LDIF` file with `ldapmodify`:

```
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/setupDirectoryStructure.ldif
```

Creating the LDAP Users and Groups

Let's go ahead and create the LDAP users and groups that we are using for this hypothetical scenario.

First, let's create the the `foo` user:

```
tee ~/createFooUser.ldif <<EOF
dn: uid=foo,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: foo
uid: foo
uidNumber: 16859
gidNumber: 100
homeDirectory: /home/foo
loginShell: /bin/bash
gecos: foo
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createFooUser.ldif
```

Then let's create a couple users to go into the `dba` group:

```
tee ~/createDbaUsers.ldif <<EOF
dn: uid=gmontee,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: gmontee
uid: gmontee
uidNumber: 16860
gidNumber: 100
homeDirectory: /home/gmontee
loginShell: /bin/bash
gecos: gmontee
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0

dn: uid=bstillman,ou=People,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: bstillman
uid: bstillman
uidNumber: 16861
gidNumber: 100
homeDirectory: /home/bstillman
loginShell: /bin/bash
gecos: bstillman
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createDbaUsers.ldif
```

Note that each of these users needs a password, so we can set it for each user with `ldappasswd`:

```
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=foo,ou=People,dc=support,dc=mariadb,dc=com
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=gmontee,ou=People,dc=support,dc=mariadb,dc=com
ldappasswd -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -S
uid=bstillman,ou=People,dc=support,dc=mariadb,dc=com
```

And then let's create our `dba` group

```
tee ~/createDbaGroup.ldif <<EOF
dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: posixGroup
gidNumber: 678
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createDbaGroup.ldif
```

And then let's add our two users to it:

```
tee ~/addUsersToDbaGroup.ldif <<EOF
dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
changetype: modify
add: memberuid
memberuid: gmontee

dn: cn=dba,ou=Groups,dc=support,dc=mariadb,dc=com
changetype: modify
add: memberuid
memberuid: bstillman
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/addUsersToDbaGroup.ldif
```

We also need to create LDAP users with the same name as the `bar` and `dba` MariaDB users. See here to read more about why. No one will be logging in as these users, so they do not need passwords. Instead of the `People organizationalUnit`, we will create them in the `System Users organizationalUnit`.

```
tee ~/createSystemUsers.ldif <<EOF
dn: uid=bar,ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: bar
uid: bar
uidNumber: 16862
gidNumber: 100
homeDirectory: /home/bar
loginShell: /bin/bash
gecos: bar
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0

dn: uid=dba,ou=System Users,dc=support,dc=mariadb,dc=com
objectClass: top
objectClass: account
objectClass: posixAccount
objectClass: shadowAccount
cn: dba
uid: dba
uidNumber: 16863
gidNumber: 100
homeDirectory: /home/dba
loginShell: /bin/bash
gecos: dba
userPassword: {crypt}x
shadowLastChange: -1
shadowMax: -1
shadowWarning: 0
EOF
ldapmodify -a -x -D cn=Manager,dc=support,dc=mariadb,dc=com -W -f ~/createSystemUsers.ldif
```

Setting up the MariaDB Server

At this point, we can move onto setting up the MariaDB Server.

Installing LDAP and PAM Libraries

First, we need to make sure that the LDAP and PAM libraries are installed.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install the following packages:

```
sudo yum install openldap-clients nss-pam-ldapd pam pam-devel
```

Configuring LDAP

Next, let's configure LDAP on the system. We can use `authconfig` for this:

```
sudo authconfig --enableldap \
   --enableldapauth \
   --ldapserver="ldap://172.30.0.238:3306" \
   --ldapbasedn="dc=support,dc=mariadb,dc=com" \
   --enablemkhomedir \
   --update
```

Be sure to replace `--ldapserver` and `--ldapbasedn` with values that are relevant for your environment.

Installing the pam_user_map PAM Module

The following steps apply to MariaDB Server in versions 10.2.32.7, 10.3.23., 10.4.13.6, 10.5.2 and earlier. In later releases, the pam_user_map PAM module is now included in the base install.

Next, let's install the pam_user_map PAM module.

Before the module can be compiled from source, we may need to install some dependencies.

On RHEL, CentOS, and other similar Linux distributions that use RPM packages, we need to install `gcc` and `pam-devel`:

```
sudo yum install gcc pam-devel
```

On Debian, Ubuntu, and other similar Linux distributions that use DEB packages, we need to install `gcc` and `libpam0g-dev`:

```
sudo apt-get install gcc libpam0g-dev
```

And then we can build and install the library with the following:

```
wget https://raw.githubusercontent.com/MariaDB/server/10.4/plugin/auth_pam/mapper/pam_user_map.c
gcc pam_user_map.c -shared -lpam -fPIC -o pam_user_map.so
sudo install --mode=0755 pam_user_map.so /lib64/security/
```

Configuring the pam_user_map PAM Module

Next, let's configure the pam_user_map PAM module based on our hypothetical requirements.

The configuration file for the `pam_user_map` PAM module is `/etc/security/user_map.conf`. Based on our hypothetical requirements, ours would look like:

```
foo: bar
@dba:dba
```

Installing the PAM Authentication Plugin

Next, let's install the `pam` authentication plugin.

Log into the MariaDB Server and execute the following:

```
INSTALL SONAME 'auth_pam';
```

Configuring the PAM Service

Next, let's configure the PAM service. We will call our service `mariadb`, so our PAM service configuration file will be located at `/etc/pam.d/mariadb` on most systems.

Configuring PAM to Allow Only LDAP Authentication

Since we are only doing LDAP authentication with the `pam_ldap` PAM module and group mapping with the `pam_user_map` PAM module, our configuration file would look like this:

```
auth required pam_ldap.so
auth required pam_user_map.so
account required pam_ldap.so
```

Configuring PAM to Allow LDAP and Local Unix Authentication

If we want to allow authentication from LDAP users **and** from local Unix users through `pam_unix`, while giving priority to the local users, then we could do this instead:

```
auth [success=1 new_authtok_reqd=1 default=ignore] pam_unix.so audit
auth required pam_ldap.so try_first_pass
auth required pam_user_map.so
account sufficient pam_unix.so audit
account required pam_ldap.so
```

Configuring the pam_unix PAM Module

If you also want to allow authentication from local Unix users, the `pam_unix` PAM module adds some additional configuration steps on a lot of systems. We basically have to give the user that runs `mysqld` access to `/etc/shadow`.

If the `mysql` user is running `mysqld`, then we can do that by executing the following:

```
sudo groupadd shadow
sudo usermod -a -G shadow mysql
sudo chown root:shadow /etc/shadow
sudo chmod g+r /etc/shadow
```

The server needs to be restarted for this change to take affect.

Creating MariaDB Users

Next, let's create the MariaDB users. Remember that our PAM service is called `mariadb`.

First, let's create the MariaDB user for the user mapping: `foo: bar`

That means that we need to create a `bar` user:

```
CREATE USER 'bar'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'bar'@'%' ;
```

And then let's create the MariaDB user for the group mapping: `@dba: dba`

That means that we need to create a `dba` user:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;
```

And then to allow for the user and group mapping, we need to create an anonymous user that authenticates with the `pam` authentication plugin that is also able to `PROXY` as the `bar` and `dba` users. Before we can create the proxy user, we might need to clean up some defaults:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

And then let's create the anonymous proxy user:

```
CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'bar'@'%' TO ''@'%';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

Testing our Configuration

Next, let's test out our configuration by verifying that mapping is occurring. We can verify this by logging in as each of our users and comparing the return value of `USER()`, which is the original user name and the return value of `CURRENT_USER()`, which is the authenticated user name.

Testing LDAP Authentication

First, let's test out our `foo` user:

```
$ mysql -u foo -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 134
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-----------------------------------------------+----------------+
| USER()                                        | CURRENT_USER() |
+-----------------------------------------------+----------------+
| foo@ip-172-30-0-198.us-west-2.compute.internal | bar@%          |
+-----------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `foo` LDAP user was properly mapped to the `bar` MariaDB user by looking at the return value of `CURRENT_USER()`.

Then let's test out our `gmontee` user in the `dba` group:

```
$ mysql -u gmontee -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 135
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+-------------------------------------------------+----------------+
| USER()                                          | CURRENT_USER() |
+-------------------------------------------------+----------------+
| gmontee@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+-------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

And then let's test out our `bstillman` user in the `dba` group:

```
$ mysql -u bstillman -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 136
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+---------------------------------------------------+----------------+
| USER()                                            | CURRENT_USER() |
+---------------------------------------------------+----------------+
| bstillman@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+---------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `gmontee` and `bstillman` LDAP users in the `dba` LDAP group were properly mapped to the `dba` MariaDB user by looking at the return values of `CURRENT_USER()`.

Testing Local Unix Authentication

If you chose the option that also allowed local Unix authentication, then let's test that out. Let's create a Unix user and give the user a password real quick:

```
sudo useradd alice
sudo passwd alice
```

And let's also map this user to `dba`:

```
@dba:dba
foo: bar
alice: dba
```

And we know that the existing anonymous user already has the `PROXY` privilege granted to the `dba` user, so this should just work without any other configuration. Let's test it out:

```
$ mysql -u alice -h 172.30.0.198
[mariadb] Password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 141
Server version: 10.3.10-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> SELECT USER(), CURRENT_USER();
+---------------------------------------------------+----------------+
| USER()                                            | CURRENT_USER() |
+---------------------------------------------------+----------------+
| alice@ip-172-30-0-198.us-west-2.compute.internal | dba@%          |
+---------------------------------------------------+----------------+
1 row in set (0.000 sec)
```

We can verify that our `alice` Unix user was properly mapped to the `dba` MariaDB user by looking at the return values of `CURRENT_USER()`.

5.4.6.7 Authentication Plugin - Unix Socket

MariaDB starting with 10.4.3

In MariaDB 10.4.3 and later, the `unix_socket` authentication plugin is installed by default, and it is used by the `'root'@'localhost'` user account by default. See Authentication from MariaDB 10.4 for more information.

The `unix_socket` authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the socket system variable.

The `unix_socket` authentication plugin works by calling the getsockopt system call with the `SO_PEERCRED` socket option, which allows it to retrieve the `uid` of the process that is connected to the socket. It is then able to get the user name associated with that `uid`. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

The `unix_socket` authentication plugin is not suited to multiple Unix users accessing a single MariaDB user account.

Contents

Security

A `unix_socket` authentication plugin is a passwordless security mechanism. Its security is in the strength of the access to the Unix user rather than the complexity and the secrecy of the password. As the security is different from passwords, the strengths and weaknesses need to be considered, and these aren't the same in every installation.

Strengths

- Access is limited to the Unix user so, for example, a `www-data` user cannot access `root` with the `unix_socket` authentication plugin.
- There is no password to brute force.
- There is no password that can be accidentally exposed by user accident, poor security on backups, or poor security on passwords in configuration files.
- Default Unix user security is usually strong on preventing remote access and password brute force attempts.

Weaknesses

The strength of a `unix_socket` authentication plugin is effectively the strength of the security of the Unix users on the system. The Unix user default installation in most cases is sufficiently secure, however, business requirements or unskilled management may expose risks. The following is a non-exhaustive list of potential Unix user security issues that may arise.

- Common access areas without screen locks, where an unauthorized user accesses the logged in Unix user of an authorized user.
- Extensive sudo access grants that provide users with access to execute commands of a different Unix user.
- Scripts writable by Unix users other than the Unix user that are executed (cron or directly) by the unix user.
- Web pages that are susceptible to command injection, where the Unix user running the web page has elevated privileges in the database that weren't intended to be used.
- Poor Unix user password practices including weak user passwords, password exposure and password reuse accompanied by an access vulnerability/mechanism of an unauthorized user to exploit this weakness.
- Weak remote access mechanisms and network file system privileges.
- Poor user security behavior including running untrusted scripts and software.

In some of these scenarios a database password may prevent these security exploits, however it will remove all the strengths of the `unix_socket` authentication plugin previously mentioned.

Disabling the Plugin

MariaDB starting with 10.4.3

In MariaDB 10.4.3 and later, the `unix_socket` authentication plugin is installed by default, so **if you do not want it to be available by default on those versions, then you will need to disable it**.

The `unix_socket` authentication plugin is also installed by default in **new installations** that use the `.deb` packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later, so **if you do not want it to be available by default on those systems when those packages are used, then you will need to disable it**. See Differences in MariaDB in Debian (and Ubuntu) for more information.

The `unix_socket` authentication plugin can be disabled by starting the server with the `unix_socket` option set to `OFF`. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
unix_socket=OFF
```

As an alternative, the `unix_socket` option can also be set to `OFF` by pairing the option with the `disable` option prefix. For example:

```
[mariadb]
...
disable_unix_socket
```

Installing the Plugin

MariaDB starting with 10.4.3

In MariaDB 10.4.3 and later, the `unix_socket` authentication plugin is installed by default, so **this step can be skipped on those versions**.

The `unix_socket` authentication plugin is also installed by default in **new installations** that use the `.deb` packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later, so **this step can be skipped on those systems when those packages are used**. See Differences in MariaDB in Debian (and Ubuntu) for more information.

In other systems, although the plugin's shared library is distributed with MariaDB by default as `auth_socket.so`, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'auth_socket';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = auth_socket
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'auth_socket';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

To create a user account via `CREATE USER`, specify the name of the plugin in the `IDENTIFIED VIA` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA unix_socket;
```

If `SQL_MODE` does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via `GRANT`. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA unix_socket;
```

Switching to Password-based Authentication

Sometimes Unix socket authentication does not meet your needs, so it can be desirable to switch a user account back to password-based authentication. This can easily be done by telling MariaDB to use another authentication plugin for the account by executing the `ALTER USER` statement. The specific authentication plugin is specified with the `IDENTIFIED VIA` clause. For example, if you wanted to switch to the `mysql_native_password` authentication plugin, then you could execute:

```
ALTER USER root@localhost IDENTIFIED VIA mysql_native_password;
SET PASSWORD = PASSWORD('foo');
```

Note that if your operating system has scripts that require password-less access to MariaDB, then this may break those scripts. You may be able to fix that by setting a password in the `[client]` option group in your /root/.my.cnf option file. For example:

```
[client]
password=foo
```

Client Authentication Plugins

The `unix_socket` authentication plugin does not require any specific client authentication plugins. It should work with all clients.

Support in Client Libraries

The `unix_socket` authentication plugin does not require any special support in client libraries. It should work with all client libraries.

Example

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, a user `serg` is already logged into the operating system and has full shell access. He has already authenticated with the operating system and his MariaDB account is configured to use the `unix_socket` authentication plugin, so he does not need to authenticate again for the database. MariaDB accepts his operating system credentials and allows him to connect. However, any attempt to connect to the database as another operating system user will be denied.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.0.11
1.0	Beta	MariaDB 5.2.0

Options

`unix_socket`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugin` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--unix-socket=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.6.8 Authentication Plugin - Named Pipe

The `named_pipe` authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the `named_pipe` system variable.

The `named_pipe` authentication plugin works by using named pipe impersonation and calling `GetUserName()` to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'auth_named_pipe';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = auth_named_pipe
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'auth_named_pipe';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating Users

To create a user account via `CREATE USER`, specify the name of the plugin in the `IDENTIFIED VIA` clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA named_pipe;
```

If `SQL_MODE` does not have `NO_AUTO_CREATE_USER` set, then you can also create the user account via `GRANT`. For

example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA named_pipe;
```

Client Authentication Plugins

The `named_pipe` authentication plugin does not require any specific client authentication plugins. It should work with all clients.

Support in Client Libraries

The `named_pipe` authentication plugin does not require any special support in client libraries. It should work with all client libraries.

Example

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty  --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

In this example, a user `wlad` is already logged into the system. Because he has identified himself to the operating system, he does not need to do it again for the database — MariaDB trusts the operating system credentials. However, he cannot connect to the database as another user.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.11

Options

`named_pipe`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

    - There may be ambiguity between this option and the `named_pipe` system variable. See MDEV-19625 about that.
- **Commandline:** `--named-pipe=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- **Introduced:** MariaDB 10.1.11

5.4.6.9 Authentication Plugin - SHA-256

Contents

MySQL 5.6 added support for the `sha256_password` authentication plugin, and MySQL 8.0 also added support for the `caching_sha2_password` authentication plugin.

The `caching_sha2_password` plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the `default_authentication_plugin` system variable.

Support in MariaDB Server

MariaDB Server does not currently support either the `sha256_password` or the `caching_sha2_password` authentication plugins. See MDEV-9804 for more information.

MariaDB Server does not support either of these authentication plugins. This is mainly because:

- To use the protocol, one has to distribute the server's public key to all MariaDB users, which can be cumbersome and impractical.
- The server gets the password in clear text which can cause problems if the user is convinced to connect to a malicious server.

Client Authentication Plugins

For clients that use the MariaDB Connector/C library, MariaDB provides two client authentication plugins that are compatible with MySQL's SHA-256 authentication plugins:

- `sha256_password`
- `caching_sha256_password`

When connecting with a client or utility to a server as a user account that authenticates with the `sha256_password` or `caching_sha256_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

For clients that use MariaDB's `libmysqlclient` library instead of MariaDB Connector/C, these client authentication plugins are not supported.

`sha256_password`

The `sha256_password` client authentication plugin is compatible with MySQL's `sha256_password` authentication plugin, which was added in MySQL 5.6.

`caching_sha256_password`

The `caching_sha256_password` client authentication plugin is compatible with MySQL's `caching_sha2_password` authentication plugin, which was added in MySQL 8.0.

The `caching_sha2_password` plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the `default_authentication_plugin` system variable.

Support in Client Libraries

Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports `sha256_password` and `caching_sha2_password` authentication using the client authentication plugins mentioned in the previous section.

It has supported the `sha256_password` client authentication plugin since MariaDB Connector/C 3.0.2. See CONC-229 for more information.

It has supported the `caching_sha256_password` client authentication plugin since MariaDB Connector/C 3.0.8 and MariaDB Connector/C 3.1.0. See CONC-312 for more information.

Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports `sha256_password` and `caching_sha2_password` authentication using the client authentication plugins mentioned in the previous section.

It has supported `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/ODBC 3.1.4. See ODBC-241 for more information.

Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/J 2.5.0. See CONJ-327 and CONJ-663 for more information.

Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports `sha256_password` and `caching_sha2_password` authentication since MariaDB Connector/Node.js 2.5.0. See CONJS-76 and CONJS-77 for more information.

5.4.7 Password Validation Plugins

Simple Password Check Plugin

This plugin checks that passwords meet certain simple criteria.

Cracklib Password Check Plugin

This plugin checks password strength using the CrackLib library.

Password Reuse Check Plugin

Plugin for preventing password reuse.

Password Validation Plugin API

Allows the creation of password validation plugins to check user passwords as they are set.

password_reuse_check_interval

Retention period for password history.

5.4.7.1 Simple Password Check Plugin

`simple_password_check` is a password validation plugin. It can check whether a password contains at least a certain number of characters of a specific type. When first installed, a password is required to be at least eight characters, and requires at least one digit, one uppercase character, one lowercase character, and one character that is neither a digit nor a letter.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'simple_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = simple_password_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'simple_password_check';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Known Issues

Issues with PAM Authentication Plugin

Prior to MariaDB 10.4.0, all password validation plugins are incompatible with the `pam` authentication plugin. See Authentication Plugin - PAM: Conflicts with Password Validation for more information.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Beta	MariaDB 10.1.11
1.0	Alpha	MariaDB 10.1.2

System Variables

`simple_password_check_digits`

- **Description:** A password must contain at least this many digits.
- **Commandline:** `--simple-password-check-digits=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `0` to `1000`

`simple_password_check_letters_same_case`

- **Description:** A password must contain at least this many upper-case and this many lower-case letters.
- **Commandline:** `--simple-password-check-letters-same-case=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `0` to `1000`

`simple_password_check_minimal_length`

- **Description:** A password must contain at least this many characters.
- **Commandline:** `--simple-password-check-minimal-length=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `8`
- **Range:** `0` to `1000`

`simple_password_check_other_characters`

- **Description:** A password must contain at least this many characters that are neither digits nor letters.
- **Commandline:** `--simple-password-check-other-characters=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `0` to `1000`

Options

`simple_password_check`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up,

but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--simple-password-check=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.7.2 Cracklib Password Check Plugin

Contents

`cracklib_password_check` is a password validation plugin. It uses the CrackLib library to check the strength of new passwords. CrackLib is installed by default in many Linux distributions, since the system's Pluggable Authentication Module (PAM) authentication framework is usually configured to check the strength of new passwords with the `pam_cracklib` PAM module.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

The plugin requires at least cracklib 2.9.0, so it is not available on Debian/Ubuntu builds before Debian 8 Jessie/Ubuntu 14.04 Trusty, RedHat Enterprise Linux / CentOS 6.

Installing the Plugin's Package

The `cracklib_password_check` plugin's shared library is included in MariaDB packages as the `cracklib_password_check.so` or `cracklib_password_check.dll` shared library on systems where it can be built.

Installing on Linux

The `cracklib_password_check` plugin is included in `systemd` binary tarballs on Linux, but not in the older generic and `glibc_214` tarballs.

Installing with a Package Manager

The `cracklib_password_check` plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the

MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

```
sudo yum install MariaDB-cracklib-password-check
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using `apt-get`. For example:

```
sudo apt-get install mariadb-plugin-cracklib-password-check
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `zypper`. For example:

```
sudo zypper install MariaDB-cracklib-password-check
```

Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'cracklib_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = cracklib_password_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'cracklib_password_check';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Viewing CrackLib Errors

If password validation fails, then the original CrackLib error message can be viewed by executing `SHOW WARNINGS`.

Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Known Issues

Issues with PAM Authentication Plugin

Prior to MariaDB 10.4.0, all password validation plugins are incompatible with the `pam` authentication plugin. See Authentication Plugin - PAM: Conflicts with Password Validation for more information.

SELinux

When using the standard SELinux policy with the mode set to `enforcing`, `mysqld` does not have access to `/usr/share/cracklib`, and you may see the following error when attempting to use the `cracklib_password_check` plugin:

```
CREATE USER `user`@`hostname` IDENTIFIED BY 's0mePwd123.';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements

SHOW WARNINGS;
+---------+------+----------------------------------------------------------------+
| Level   | Code | Message                                                        |
+---------+------+----------------------------------------------------------------+
| Warning | 1819 | cracklib: error loading dictionary                             |
| Error   | 1819 | Your password does not satisfy the current policy requirements |
| Error   | 1396 | Operation CREATE USER failed for 'user'@'hostname'             |
+---------+------+----------------------------------------------------------------+
```

And the SELinux `audit.log` will contain errors like the following:

```
type=AVC msg=audit(1548371977.821:66): avc:  denied  { read } for  pid=3537 comm="mysqld"
name="pw_dict.pwd" dev="xvda2" ino=564747 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:object_r:crack_db_t:s0 tclass=file
type=SYSCALL msg=audit(1548371977.821:66): arch=c000003e syscall=2 success=no exit=-13
a0=7fdd2a674580 a1=0 a2=1b6 a3=1b items=0 ppid=1 pid=3537 auid=4294967295 uid=995 gid=992
euid=995 suid=995 fsuid=995 egid=992 sgid=992 fsgid=992 tty=(none) ses=4294967295 comm="mysqld"
exe="/usr/sbin/mysqld" subj=system_u:system_r:mysqld_t:s0 key=(null)
```

This can be fixed by creating an SELinux policy that allows `mysqld` to load the CrackLib dictionary. For example:

```
cd /usr/share/mysql/policy/selinux/
tee ./mariadb-plugin-cracklib-password-check.te <<EOF

module mariadb-plugin-cracklib-password-check 1.0;

require {
        type mysqld_t;
        type crack_db_t;
        class file { execute setattr read create getattr execute_no_trans write ioctl open
append unlink };
        class dir { write search getattr add_name read remove_name open };
}

allow mysqld_t crack_db_t:dir { search read open };
allow mysqld_t crack_db_t:file { getattr read open };
EOF
sudo yum install selinux-policy-devel
make -f /usr/share/selinux/devel/Makefile mariadb-plugin-cracklib-password-check.pp
sudo semodule -i mariadb-plugin-cracklib-password-check.pp
```

See MDEV-18374 for more information.

Versions

Version	Status	Introduced

1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Alpha	MariaDB 10.1.2

System Variables

`cracklib_password_check_dictionary`

- **Description:** Sets the path to the CrackLib dictionary. If not set, the default CrackLib dictionary path is used. The parameter expects the base name of a cracklib dictionary (a set of three files with endings `.hwm`, `.pwd`, `.pwi`), not a directory path.
- **Commandline:** `--cracklib-password-check-dictionary=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** Depends on the system. Often `/usr/share/cracklib/pw_dict`

Options

`cracklib_password_check`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--cracklib-password-check=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.7.3 Password Reuse Check Plugin

MariaDB starting with 10.7

`password_reuse_check` is a password validation plugin introduced in MariaDB 10.7.0.

Contents

Description

The plugin is used to prevent a user from reusing a password, which can be a requirement in some security policies. The password_reuse_check_interval system variable determines the retention period, in days, for a password. By default this is zero, meaning unlimited retention. Old passwords are stored in the mysql.password_reuse_check_history table.

Note that passwords can be directly set as a hash, bypassing the password validation, if the strict_password_validation variable is `OFF` (it is `ON` by default).

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default.

You can install the plugin dynamically, without restarting the server, by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'password_reuse_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = password_reuse_check
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'password_reuse_check';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
INSTALL SONAME 'password_reuse_check';

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
Query OK, 0 rows affected (0.038 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd2';
Query OK, 0 rows affected (0.003 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Versions

Version	Status	Introduced
1.0	Alpha	MariaDB 10.7.0
1.0	Beta	MariaDB 10.7.2
1.0	Gamma	MariaDB 10.7.4
2.0	Stable	MariaDB 10.7.7, MariaDB 10.8.7, MariaDB 10.9.5, MariaDB 10.10.2

The bump to version 2.0 required the change of the stored format to mitigate an implementation weakness (MDEV-28838) and as such the bump from 1.0 to 2.0 will invalidate previously saved password reuse protections.

5.4.7.4 Password Validation Plugin API

Contents

“Password validation” means ensuring that user passwords meet certain minimal security requirements. A dedicated plugin API allows the creation of password validation plugins that will check user passwords as they are set (in SET PASSWORD and GRANT statements) and either allow or reject them.

SQL-Level Extensions

MariaDB comes with three password validation plugins — the simple_password_check plugin, the cracklib_password_check plugin and the password_reuse_check plugin. They are not enabled by default; use INSTALL SONAME (or INSTALL PLUGIN) statement to install them.

When at least one password plugin is loaded, all new passwords will be validated and password-changing statements will fail if the password will not pass validation checks. Several password validation plugin can be loaded at the same time — in this case a password must pass **all** validation checks by **all** plugins.

Password-Changing Statements

One can use various SQL statements to change a user password:

With Plain Text Password

```
SET PASSWORD = PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = PASSWORD('plain-text password');
SET PASSWORD = OLD_PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = OLD_PASSWORD('plain-text password');
CREATE USER `user`@`host` IDENTIFIED BY 'plain-text password';
GRANT privileges TO `user`@`host` IDENTIFIED BY 'plain-text password';
```

These statements are subject to password validation. If at least one password validation plugin is loaded, plain-text passwords specified in these statements will be validated.

With Password Hash

```
SET PASSWORD = 'password hash';
SET PASSWORD FOR `user`@`host` = 'password hash';
CREATE USER `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
```

These statements can not possibly use password validation — there is nothing to validate, the original plain-text password is not available. MariaDB introduces a **strict password validation** mode — controlled by a strict_password_validation global server variable. If the strict password validation is enabled and at least one password validation plugin is loaded then these “unvalidatable” passwords will be rejected. Otherwise they will be accepted. By default a strict password validation is enabled (but note that it has no effect if no password validation plugin is loaded).

Examples

Failed password validation:

```
GRANT SELECT ON *.* to foobar IDENTIFIED BY 'raboof';
ERROR HY000: Your password does not satisfy the current policy requirements

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------+
| Level   | Code | Message                                                         |
+---------+------+-----------------------------------------------------------------+
| Warning | 1819 | cracklib: it is based on your username                          |
| Error   | 1819 | Your password does not satisfy the current policy requirements |
+---------+------+-----------------------------------------------------------------+
```

Strict password validation:

```
GRANT SELECT ON *.* TO foo IDENTIFIED BY PASSWORD '2222222222222222';
ERROR HY000: The MariaDB server is running with the --strict-password-validation option so it
cannot execute this statement
```

Plugin API

Password validation plugin API is very simple. A plugin must implement only one method — `validate_password()` . This method takes two arguments — user name and the plain-text password. And it returns 0 when the password has passed the validation and 1 otherwise,

See also `mysql/plugin_password_validation.h` and password validation plugins in `plugin/simple_password_check/` and `plugins/cracklib_password_check/` .

5.4.7.5 password_reuse_check_interval

The password_reuse_check_interval system variable is available when the password_reuse_check plugin is installed. It determines the retention period for the password history in days. Zero, the default, means passwords are never discarded.

- **Commandline:** `--password_reuse_check_interval=#`
- **Scope:** Global
- **Read-only:** No
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `36500`

5.4.8.1 Encryption Key Management

Contents

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

Choosing an Encryption Key Management Solution

How MariaDB manages encryption keys depends on which encryption key management solution you choose. Currently, MariaDB has three options:

File Key Management Plugin

The File Key Management plugin that ships with MariaDB is a basic key management and encryption plugin that reads keys from a plain-text file. It can also serve as example and as a starting point when developing a key management plugin.

For more information, see File Key Management Plugin.

AWS Key Management Plugin

The AWS Key Management plugin is a key management and encryption plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS). The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. This license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

For more information, see AWS Key Management Plugin.

Eperi Key Management Plugin

The Eperi Key Management plugin is a key management and encryption plugin that uses the eperi Gateway for Databases. The eperi Gateway for Databases stores encryption keys on the key server outside of the database server itself, which provides an extra level of security. The eperi Gateway for Databases also supports performing all data encryption operations on the key server as well, but this is optional.

For more information, see Eperi Key Management Plugin.

Using Multiple Encryption Keys

Key management and encryption plugins support using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

The support for multiple keys opens up some potential use cases. For example, let's say that a hypothetical key management and encryption plugin is configured to provide two encryption keys. One encryption key might be intended for

"low security" tables. It could use short keys, which might not be rotated, and data could be encrypted with a fast encryption algorithm. Another encryption key might be intended for "high security" tables. It could use long keys, which are rotated often, and data could be encrypted with a slower, but more secure encryption algorithm. The user would specify the identifier of the key that they want to use for different tables, only using high level security where it's needed.

There are two encryption key identifiers that have special meanings in MariaDB. Encryption key `1` is intended for encrypting system data, such as InnoDB redo logs, binary logs, and so on. It must always exist when data-at-rest encryption is enabled. Encryption key `2` is intended for encrypting temporary data, such as temporary files and temporary tables. It is optional. If it doesn't exist, then MariaDB uses encryption key `1` for these purposes instead.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

Encryption key rotation is optional in MariaDB Server. Key rotation is only supported if the backend key management service (KMS) supports key rotation, and if the corresponding key management and encryption plugin for MariaDB also supports key rotation. When a key management and encryption plugin supports key rotation, users can opt to rotate one or more encryption keys, which creates a new version of each rotated encryption key.

Key rotation allows users to improve data security in the following ways:

- If the server is configured to automatically re-encrypt table data with the newer version of the encryption key after the key is rotated, then that prevents an encryption key from being used for long periods of time.
- If the server is configured to simultaneously encrypt table data with multiple versions of the encryption key after the key is rotated, then that prevents all data from being leaked if a single encryption key version is compromised.

The InnoDB storage engine has background encryption threads that can automatically re-encrypt pages when key rotations occur.

The Aria storage engine does not currently have a similar mechanism to re-encrypt pages in the background when key rotations occur.

Support for Key Rotation in Encryption Plugins

Encryption Plugins with Key Rotation Support

- The AWS Key Management Service (KMS) supports encryption key rotation, and the corresponding AWS Key Management Plugin also supports encryption key rotation.
- The eperi Gateway for Databases supports encryption key rotation, and the corresponding Eperi Key Management Plugin also supports encryption key rotation.

Encryption Plugins without Key Rotation Support

- The File Key Management Plugin does not support encryption key rotation, because it does not use a backend key management service (KMS).

Encryption Plugin API

New key management and encryption plugins can be developed using the encryption plugin API.

5.4.8.2 File Key Management Encryption Plugin

Contents

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

The File Key Management plugin that ships with MariaDB is a key management and encryption plugin that reads encryption keys from a plain-text file.

Overview

The File Key Management plugin is the easiest key management and encryption plugin to set up for users who want to use data-at-rest encryption. Some of the plugin's primary features are:

- It reads encryption keys from a plain-text key file.
- As an extra protection mechanism, the plain-text key file can be encrypted.
- It supports multiple encryption keys.
- It does **not** support key rotation.
- It supports two different algorithms for encrypting data.

It can also serve as an example and as a starting point when developing a key management and encryption plugin with the encryption plugin API.

Installing the File Key Management Plugin's Package

The File Key Management plugin is included in MariaDB packages as the `file_key_management.so` or `file_key_management.dll` shared library. The shared library is in the main server package, so no additional package installations are necessary. The plug-in must be installed into MariaDB however as follows.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. The plugin can be installed by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = file_key_management
```

Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that data-at-rest encryption is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'file_key_management';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Creating the Key File

In order to encrypt your tables with encryption keys using the File Key Management plugin, you first need to create the file that contains the encryption keys. The file needs to contain two pieces of information for each encryption key. First, each encryption key needs to be identified with a 32-bit integer as the key identifier. Second, the encryption key itself needs to be provided in hex-encoded form. These two pieces of information need to be separated by a semicolon. For example, the file is formatted in the following way:

```
<encryption_key_id1>;<hex-encoded_encryption_key1>
<encryption_key_id2>;<hex-encoded_encryption_key2>
```

You can also optionally encrypt the key file to make it less accessible from the file system. That is explained further in the section below.

The File Key Management plugin uses Advanced Encryption Standard (AES) to encrypt data, which supports 128-bit, 192-bit, and 256-bit encryption keys. Therefore, the plugin also supports 128-bit, 192-bit, and 256-bit encryption keys.

You can generate random encryption keys using the `openssl rand` command. For example, to create a random 256-bit (32-byte) encryption key, you would run the following command:

```
$ openssl rand -hex 32
a7addd9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
```

The key file still needs to have a key identifier for each encryption key added to the beginning of each line. Key identifiers do not need to be contiguous.

For example, to append three new encryption keys to a new key file, you could execute the following:

```
$ (echo -n "1;" ; openssl rand -hex 32 ) | sudo tee -a  /etc/mysql/encryption/keyfile
$ (echo -n "2;" ; openssl rand -hex 32 ) | sudo tee -a  /etc/mysql/encryption/keyfile
$ (echo -n "100;" ; openssl rand -hex 32 ) | sudo tee -a  /etc/mysql/encryption/keyfile
```

The new key file would look something like the following after this step:

```
1;a7addd9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
2;49c16acc2dffe616710c9ba9a10b94944a737de1beccb52dc1560abfdd67388b
100;8db1ee74580e7e93ab8cf157f02656d356c2f437d548d5bf16bf2a56932954a3
```

The key identifiers give you a way to reference the encryption keys from MariaDB. In the example above, you could reference these encryption keys using the key identifiers `1`, `2` or `100` with the `ENCRYPTION_KEY_ID` table option or with system variables such as `innodb_default_encryption_key_id`. You do not necessarily need multiple encryption keys--the encryption key with the key identifier `1` is the only mandatory encryption key.

Configuring the Path to an Unencrypted Key File

If the key file is unencrypted, then the File Key Management plugin only requires the `file_key_management_filename` system variable to be configured.

This system variable can be specified as command-line arguments to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile
```

Note that the `loose` option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

Encrypting the Key File

By enabling the File Key Management plugin and setting the appropriate path on the `file_key_management_filename` system variable, you can begin using the plugin to manage your encryption keys. But, there is a security risk in doing so, given that the keys are stored in plain text on your system. You can reduce this exposure using file permissions, but it's better to encrypt the whole key file to further restrict access.

There are some important details to keep in mind about encrypting the key file, such as:

- The only algorithm that MariaDB currently supports to encrypt the key file is Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).
- The encryption key size can be 128-bits, 192-bits, or 256-bits.
- The encryption key is created from the SHA-1 hash of the encryption password.
- The encryption password has a max length of 256 characters.

You can generate a random encryption password using the `openssl rand` command. For example, to create a random 256 character encryption password, you could execute the following:

```
$ sudo openssl rand -hex 128 > /etc/mysql/encryption/keyfile.key
```

You can encrypt the key file using the `openssl enc` command. For example, to encrypt the key file with the encryption password created in the previous step, you could execute the following:

```
$ sudo openssl enc -aes-256-cbc -md sha1 \
   -pass file:/etc/mysql/encryption/keyfile.key \
   -in /etc/mysql/encryption/keyfile \
   -out /etc/mysql/encryption/keyfile.enc
```

Running this command reads the unencrypted `keyfile` file created above and creates a new encrypted `keyfile.enc` file, using the encryption password stored in `keyfile.key`. Once you've finished preparing your system, you can delete the unencrypted `keyfile` file, as it's no longer necessary.

Configuring the Path to an Encrypted Key File

If the key file is encrypted, then the File Key Management plugin requires both the `file_key_management_filename` and the `file_key_management_filekey` system variables to be configured.

The `file_key_management_filekey` system variable can be provided in two forms:

- It can be the actual plain-text encryption password. This is not recommended, since the plain-text encryption password would be visible in the output of the `SHOW VARIABLES` statement.
- If it is prefixed with `FILE:`, then it can be a path to a file that contains the plain-text encryption password.

These system variables can be specified as command-line arguments to `mysqld` or they can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
```

Note that the `loose` option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

Choosing an Encryption Algorithm

The File Key Management plugin currently supports two encryption algorithms for encrypting data: `AES_CBC` and `AES_CTR`. Both of these algorithms use Advanced Encryption Standard (AES) in different modes. AES uses 128-bit blocks, and supports 128-bit, 192-bit, and 256-bit keys. The modes are:

- The `AES_CBC` mode uses AES in the Cipher Block Chaining (CBC) mode.
- The `AES_CTR` mode uses AES in two slightly different modes in different contexts. When encrypting tablespace pages (such as pages in InnoDB, XtraDB, and Aria tables), it uses AES in the Counter (CTR) mode. When encrypting temporary files (where the cipher text is allowed to be larger than the plain text), it uses AES in the authenticated Galois/Counter Mode (GCM).

The recommended algorithm is `AES_CTR`, but this algorithm is only available when MariaDB is built with recent versions of OpenSSL. If the server is built with wolfSSL or yaSSL, then this algorithm is not available. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

Configuring the Encryption Algorithm

The encryption algorithm can be configured by setting the `file_key_management_encryption_algorithm` system variable.

This system variable can be set to one of the following values:

System Variable Value	Description
`AES_CBC`	Data is encrypted using AES in the Cipher Block Chaining (CBC) mode. This is the default value.
`AES_CTR`	Data is encrypted using AES either in the Counter (CTR) mode or in the authenticated Galois/Counter Mode (GCM) mode, depending on context. This is only supported in some builds. See the previous section for more information.

This system variable can be specified as command-line arguments to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
loose_file_key_management_encryption_algorithm = AES_CTR
```

Note that the `loose` option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

> Note that this variable does not affect the algorithm that MariaDB uses to decrypt the key file. This variable only affects the encryption algorithm that MariaDB uses to encrypt and decrypt data. The only algorithm that MariaDB currently supports to encrypt the key file is Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).

Using the File Key Management Plugin

Once the File Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table `t` will be encrypted using the encryption key from the key file.

For more information on how to use encryption, see Data at Rest Encryption.

Using Multiple Encryption Keys

The File Key Management Plugin supports using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

The File Key Management plugin does not currently support key rotation. See MDEV-20713 for more information.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13

1.0	Alpha	MariaDB 10.1.3

System Variables

file_key_management_encryption_algorithm

- **Description:** This system variable is used to determine which algorithm the plugin will use to encrypt data.
  - The recommended algorithm is `AES_CTR`, but this algorithm is only available when MariaDB is built with recent versions of OpenSSL. If the server is built with wolfSSL or yaSSL, then this algorithm is not available. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Commandline:** `--file-key-management-encryption-algorithm=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `AES_CBC`
- **Valid Values:** `AES_CBC`, `AES_CTR`

---

file_key_management_filekey

- **Description:** This system variable is used to determine the encryption password that is used to decrypt the key file defined by `file_key_management_filename`.
  - If this system variable's value is prefixed with `FILE:`, then it is interpreted as a path to a file that contains the plain-text encryption password.
  - If this system variable's value is **not** prefixed with `FILE:`, then it is interpreted as the plain-text encryption password. However, this is not recommended.
  - The encryption password has a max length of 256 characters.
  - The only algorithm that MariaDB currently supports when decrypting the key file is Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES). The encryption key size can be 128-bits, 192-bits, or 256-bits. The encryption key is calculated by taking a SHA-1 hash of the encryption password.
- **Commandline:** `--file-key-management-filekey=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** (empty)

---

file_key_management_filename

- **Description:** This system variable is used to determine the path to the file that contains the encryption keys. If `file_key_management_filekey` is set, then this file can be encrypted with Cipher Block Chaining (CBC) mode of Advanced Encryption Standard (AES).
- **Commandline:** `--file-key-management-filename=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** (empty)

Options

file_key_management

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--file-key-management=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.8.3 Hashicorp Key Management Plugin

MariaDB starting with 10.9

The Hashicorp Key Management Plugin is used to implement encryption using keys stored in the Hashicorp Vault KMS. For more information, see Hashicorp Vault and MariaDB, and for how to install Vault, see Install Vault, as well as MySQL/MariaDB Database Secrets Engine.

Contents

The current version of this plugin implements the following features:

- Authentication is done using the Hashicorp Vault's token authentication method;
- If additional client authentication is required, then the path to the CA authentication bundle file may be passed as a plugin parameter;
- The creation of the keys and their management is carried out using the Hashicorp Vault KMS and their tools;
- The plugin uses libcurl (https) as an interface to the HashiCorp Vault server;
- JSON parsing is performed through the JSON service (through the include/mysql/service_json.h);
- HashiCorp Vault 1.2.4 was used for development and testing.

Since we require support for key versioning, the key-value storage must be configured in Hashicorp Vault as a key-value storage that uses the interface of the second version. For example, you can create it as follows:

```
~$ vault secrets enable -path /test -version=2 kv
```

Key names must correspond to their numerical identifiers. Key identifiers itself, their possible values and rules of use are described in more detail in the MariaDB main documentation.

From the point of view of the key-value storage (in terms of Hashicorp Vault), the key is a secret containing one key-value pair with the name "data" and a value representing a binary string containing the key value, for example:

```
~$ vault kv get /test/1

====== Metadata ======
Key              Value
---              -----
created_time     2019-12-14T14:19:19.42432951Z
deletion_time    n/a
destroyed        false
version          1

==== Data ====
Key     Value
---     -----
data    0123456789ABCDEF0123456789ABCDEF
```

Keys values are strings containing binary data. MariaDB currently uses the AES algorithm with 256-bit keys as the default encryption method. In this case, the keys that will be stored in the Hashicorp Vault should be 32-byte strings. Most likely you will use some utilities for creating and administering keys designed to work with Hashicorp Vault. But in the simplest case, keys can be created from the command line through the vault utility, for example, as follows:

```
~$ vault kv put /test/1 data="0123456789ABCDEF0123456789ABCDEF"
```

If you use default encryption (AES), you should ensure that the key length is 32 bytes, otherwise it may fail to use InnoDB as a data storage.

The plugin currently does not unseal Hashicorp Vault on its own, you must do this in advance and on your own.

To use Hashicorp Vault KMS, the plugin must be preloaded and activated on the server. Most of its parameters should not be changed during plugin operation and therefore must be preconfigured as part of the server configuration through configuration file or command line options:

```
--plugin-load-add=hashicorp_key_management.so
--loose-hashicorp-key-management
--loose-hashicorp-key-management-vault-url="$VAULT_ADDR/v1/test"
--loose-hashicorp-key-management-token="$VAULT_TOKEN"
```

Options

The plugin supports the following parameters, which must be set in advance and cannot be changed during server operation:

`hashicorp-key-management-vault-url`

- **Description:** HTTP[s] URL that is used to connect to the Hashicorp Vault server. It must include the name of the scheme (`https://` for a secure connection) and, according to the API rules for storages of the key-value type in Hashicorp Vault, after the server address, the path must begin with the "/v1/" string (as prefix), for example: `https://127.0.0.1:8200/v1/my_secrets` . By default, the path is not set, therefore you must replace with the correct path to your secrets.
- **Commandline:** `--[loose-]hashicorp-key-management-vault-url="<url>"`

`hashicorp-key-management-token`

- **Description:** Authentication token that passed to the Hashicorp Vault in the request header. By default, this parameter contains an empty string, so you must specify the correct value for it, otherwise the Hashicorp Vault server will refuse authorization.
- **Commandline:** `--[loose-]hashicorp-key-management-token="<token>"`

`hashicorp-key-management-vault-ca`

- **Description:** Path to the Certificate Authority (CA) bundle (is a file that contains root and intermediate certificates). By default, this parameter contains an empty string, which means no CA bundle.
- **Commandline:** `--[loose-]hashicorp-key-management-vault-ca="<path>"`

`hashicorp-key-management-timeout`

- **Description:** Set the duration (in seconds) for the Hashicorp Vault server connection timeout. The default value is 15 seconds. The allowed range is from 1 to 86400 seconds. The user can also specify a zero value, which means the default timeout value set by the libcurl library (currently 300 seconds).
- **Commandline:** `--[loose-]hashicorp-key-management-timeout=<timeout>`

`hashicorp-key-management-retries`

- **Description:** Number of server request retries in case of timeout. Default is three retries.
- **Commandline:** `----[loose-]hashicorp-key-management-retries=<retries>`

`hashicorp-key-management-caching-enabled`

- **Description:** Enable key caching (storing key values received from the Hashicorp Vault server in the local memory). By default caching is enabled.
- **Commandline:** `--[loose-]hashicorp-key-management-caching-enabled="on"|"off"`

`hashicorp-key-management-use-cache-on-timeout`

- **Description:** This parameter instructs the plugin to use the key values or version numbers taken from the cache in the event of a timeout when accessing the vault server. By default this option is disabled. Please note that key values or version numbers will be read from the cache when the timeout expires only after the number of attempts to read them from the storage server that specified by the --[loose-]hashicorp-key-management-retries parameter has been exhausted.
- **Commandline:** `--[loose-]hashicorp-key-management-use-cache-on-timeout="on"|"off"`

`hashicorp-key-management-cache-timeout`

- **Description:** The time (in milliseconds) after which the value of the key stored in the cache becomes invalid and an attempt to read this data causes a new request send to the vault server. By default, cache entries become invalid after 60,000 milliseconds (after one minute). If the value of this parameter is zero, then the keys will always be considered invalid, but they still can be used if the vault server is unavailable and the corresponding cache operating mode (--[loose-]hashicorp-key-management-use-cache-on-timeout="on") is enabled.
- **Commandline:** `--[loose-]hashicorp-key-management-cache-timeout=<timeout>`

`hashicorp-key-management-cache-version-timeout`

- **Description:** The time (in milliseconds) after which the information about latest version number of the key (which stored in the cache) becomes invalid and an attempt to read this information causes a new request send to the vault server. If the value of this parameter is zero, then information about latest key version numbers always considered invalid, unless there is no communication with the vault server and use of the cache is allowed when the server is unavailable. By default, this parameter is zero, that is, the latest version numbers for the keys stored in the cache are considered always invalid, except when the vault server is unavailable and use of the cache is allowed on server failures.
- **Commandline:** `--[loose-]hashicorp-key-management-cache-version-timeout=<timeout>`

`hashicorp-key-management-check-kv-version`

- **Description:** This parameter enables ("on", this is the default value) or disables ("off") checking the kv storage version during plugin initialization. The plugin requires storage to be version 2 or older in order for it to work properly.
- **Commandline:** `--[loose-]hashicorp-key-management-check-kv-version="on"|"off"`

5.4.8.4 AWS Key Management Encryption Plugin

Contents

Due to license incompatibilities between the MariaDB server source code and the Amazon AWS C++ SDK we can only

distribute the plugin in source code form, and not as ready-to-use binaries. See Installing the Plugin's Package for details.

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

The AWS Key Management plugin is a key management and encryption plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS).

Overview

The AWS Key Management plugin uses the Amazon Web Services (AWS) Key Management Service (KMS) to generate and store AES keys on disk, in encrypted form, using the Customer Master Key (CMK) kept in AWS KMS. When MariaDB Server starts, the plugin will decrypt the encrypted keys, using the AWS KMS "Decrypt" API function. MariaDB data will then be encrypted and decrypted using the AES key. It supports multiple encryption keys. It supports key rotation.

Tutorials

Tutorials related to the AWS Key Management plugin can be found at the following pages:

- Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide
- Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage

Preparation

- Before you use the plugin, you need to create a Customer Master Key (CMK). Create a key using the AWS Console as described in the AMS KMS developer guide.
- The easiest way to give the AWS key management plugin access to the key is to create an IAM Role with access to the key, and to apply that IAM Role to an EC2 instance where MariaDB Server runs.
- Make sure that MariaDB Server runs under the correct AWS identity that has access to the above key. For example, you can store the AWS credentials in a AWS credentials file for the user who runs `mysqld`. More information about the credentials file can be found in the AWS CLI Getting Started Guide.

Installing the Plugin's Package

The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. This license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

Installing from Source

When compiling MariaDB from source, the AWS Key Management plugin is not built by default in MariaDB 10.1, but it is built by default in MariaDB 10.2 and later, on systems that support it.

Compilation is controlled by the following `cmake` arguments:

- `-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC` to build a loadable plugin library
- `-DAWS_SDK_EXTERNAL_PROJECT=ON` to download the AWS C++ SDK code
- `-DNOT_FOR_DISTRIBUTION=ON` to confirm that you know to not distribute the resulting binaries

The plugin uses AWS C++ SDK, which introduces the following restrictions:

- The plugin can only be built on Windows, Linux and macOS.
- The plugin requires that one of the following compilers is used: `gcc` 4.8 or later, `clang` 3.3 or later, Visual Studio 2013 or later.
- On Unix, the `libcurl` development package (e.g. `libcurl3-dev` on Debian Jessie), `uuid` development package and `openssl` need to be installed.
- You may need to use a newer version of `cmake` than is provided by default in your OS.

You do not need to download / install the AWS C++ SDK yourself, the correct version of the SDK github repository will be cloned into the build directory at build time, and only the libraries for AWS components actually needed by the key management plugin will be built, which takes much less time than building the full AWS C++ SDK.

Building on Linux

With all prerequisites installed the actual build process pretty much comes down to:

```
# clone the MariaDB Server source code repository
git clone https://github.com/MariaDB/server.git
cd server

# prepare the build
mkdir _build
cd _build
cmake .. -DNOT_FOR_DISTRIBUTION=ON \
  -DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC \
  -DAWS_SDK_EXTERNAL_PROJECT=1

# build the plugin only
cd plugin/aws_key_management
make
```

Cmake will print the following warning as part of its output, please take it serious and do not distribute the `aws_key_management.so` file to any third parties:

You have linked MariaDB with Apache 2.0 libraries! You may not distribute the resulting binary. If you do, you will put yourself into a legal problem with the Free Software Foundation.

After `make` succeeded you can copy the created `aws_key_management.so` plugin library file to the plugin directory of your actual MariaDB Server machines installation, e.g. `/usr/lib64/mysql/plugin` on RedHat/Fedora based systems or `/usr/lib/mysql/plugin` on Debian based systems.

Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = aws_key_management
```

Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that data-at-rest encryption is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'aws_key_management';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Configuring the AWS Key Management Plugin

To enable the AWS Key Management plugin, you also need to set the plugin's system variables. The `aws_key_management_master_key_id` system variable is the primary one to set. These system variables can be

specified as command-line arguments to `mysqld` or they can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
aws_key_management_master_key_id=alias/<your key's alias>
```

Once you've updated the configuration file, restart the MariaDB server to apply the changes and make the key management and encryption plugin available for use.

Using the AWS Key Management Plugin

Once the AWS Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table `t` will be encrypted using the encryption key generated by AWS.

For more information on how to use encryption, see Data at Rest Encryption.

Using Multiple Encryption Keys

The AWS Key Management Plugin supports using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier. If a previously unused identifier is used, then the plugin will automatically generate a new key.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

The AWS Key Management plugin does support key rotation. To rotate a key, set the `aws_key_management_rotate_key` system variable. For example, to rotate key with ID 2:

```
SET GLOBAL aws_key_management_rotate_key=2;
```

Or to rotate all keys, set the value to -1:

```
SET GLOBAL aws_key_management_rotate_key=-1;
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.2.6, MariaDB 10.1.24
1.0	Beta	MariaDB 10.1.18
1.0	Experimental	MariaDB 10.1.13

System Variables

`aws_key_management_key_spec`

- **Description:** Encryption algorithm used to create new keys
- **Commandline:** `--aws-key-management-key-spec=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `AES_128`
- **Valid Values:** `AES_128` , `AES_256`

aws_key_management_log_level

- **Description:** Dump log of the AWS SDK to MariaDB error log. Permitted values, in increasing verbosity, are **Off** (default), **Fatal**, **Error**, **Warn**, **Info**, **Debug**, and **Trace**.
- **Commandline:** `--aws-key-management-log-level=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `Off`
- **Valid Values:** `Off`, `Fatal`, `Warn`, `Info`, `Debug` and `Trace`

aws_key_management_master_key_id

- **Description:** AWS KMS Customer Master Key ID (ARN or alias prefixed by alias/) for the master encryption key. Used to create new data keys. If not set, no new data keys will be created.
- **Commandline:** `--aws-key-management-master-key-id=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:**

aws_key_management_mock

- **Description:** Mock AWS KMS calls (for testing). Must be enabled at compile-time.
- **Commandline:** `--aws-key-management-mock`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Valid Values:** `OFF`, `ON`

aws_key_management_region

- **Description:** AWS region name, e.g us-east-1 . Default is SDK default, which is us-east-1.
- **Commandline:** `--aws-key-management-region=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `'us-east-1'`

aws_key_management_request_timeout

- **Description:** Timeout in milliseconds for create HTTPS connection or execute AWS request. Specify 0 to use SDK default.
- **Commandline:** `--aws-key-management-request-timeout=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `integer`
- **Default Value:** 0

aws_key_management_rotate_key

- **Description:** Set this variable to a data key ID to perform rotation of the key to the master key given in `aws_key_management_master_key_id` . Specify -1 to rotate all keys.
- **Commandline:** `--aws-key-management-rotate-key=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `integer`

- **Default Value:**

Options

`aws_key_management`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--aws-key-management=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF` , `ON` , `FORCE` , `FORCE_PLUS_PERMANENT`

5.4.8.5 Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide

Contents

Overview

MariaDB contains a robust, full instance, at-rest encryption. This feature uses a flexible plugin interface to allow actual encryption to be done using a key management approach that meets the customer's needs. MariaDB Server, starting with MariaDB 10.2, includes a plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS) to facilitate separation of responsibilities and remote logging & auditing of key access requests.

Rather than storing the encryption key in a local file, this plugin keeps the master key in AWS KMS. When you first start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB connects to AWS KMS and has the service decrypt the locally-stored key(s). The decrypted key is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

This guide is based on CentOS 7, using systemd with SELinux enabled. Some steps will differ if you use other operating systems or configurations.

Installing the Plugin's Package

The AWS Key Management plugin depends on the AWS SDK for C++, which uses the Apache License, Version 2.0. This license is not compatible with MariaDB Server's GPL 2.0 license, so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

Installing from Source

When compiling MariaDB from source, the AWS Key Management plugin is not built by default in MariaDB 10.1, but it is built by default in MariaDB 10.2 and later, on systems that support it.

Compilation is controlled by the `-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC -DAWS_SDK_EXTERNAL_PROJECT=1` cmake arguments.

The plugin uses AWS C++ SDK, which introduces the following restrictions:

- The plugin can only be built on Windows, Linux and macOS.
- The plugin requires that one of the following compilers is used: `gcc` 4.8 or later, `clang` 3.3 or later, Visual Studio 2013 or later.
- On Unix, the `libcurl` development package (e.g. `libcurl3-dev` on Debian Jessie), `uuid` development package and `openssl` need to be installed.
- You may need to use a newer version of cmake than is provided by default in your OS.

Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = aws_key_management
```

Sign up for Amazon Web Services

If you already have an AWS account, you can skip this section.

1. Load http://aws.amazon.com/.
2. Click "Create a Free Account" and complete the steps.
3. You'll need to enter credit card information. Charges related only to your use of the AWS KMS service should be limited to about $1/month for the single master key we will create. If you use other services, additional charges may apply. Consult AWS Cloud Pricing Principles https://aws.amazon.com/pricing/ for more information about pricing of AWS services.
4. You'll need to complete the AWS identify verification process.

Create an IAM User and/or Role

After creating an account or logging in to an existing account, follow these steps to create an IAM User or Role with restricted privileges that will use (but not administer) your master encryption key.

If you intend to run MariaDB Server on an EC2 instance, you should create a Role (or modify an existing Role already attached to your instance). If you intent to run MariaDB Server outside of AWS, you may want to create a User.

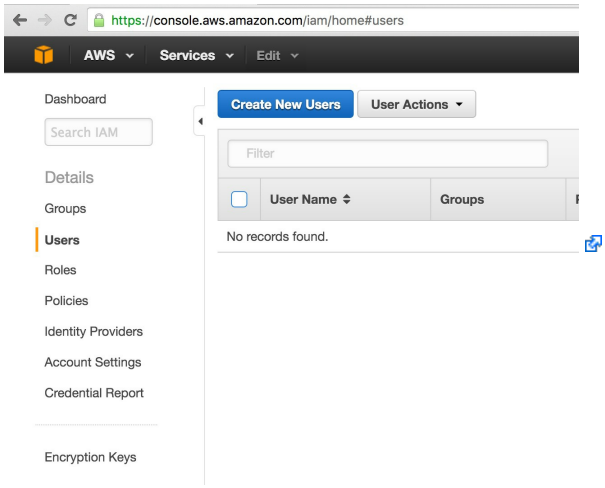
Creating an IAM Role

1. Load the Identity and Access Management Console at https://console.aws.amazon.com/iam/.
2. Click "Roles" in the left-hand sidebar
3. Click "Create new role"

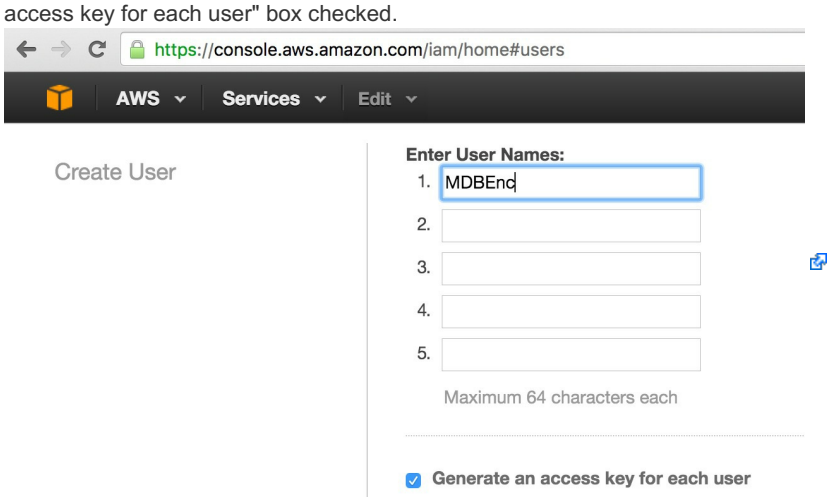
4. Select "AWS Service Role"
5. Click the "Select" button next to "Amazon EC2 / Allows EC2 instances to call AWS services on your behalf."
6. Do not select any policies on the "Attach Policy" screen. Click "Next Step"
7. Click "Next Step"
8. Give your Role a "Role name"
9. Click "Create role"

Creating an IAM User

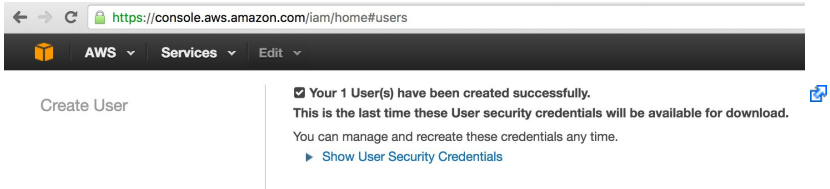
1. Load the Identity and Access Management Console at https://console.aws.amazon.com/iam/.
2. Click "Users" in the left-hand sidebar.



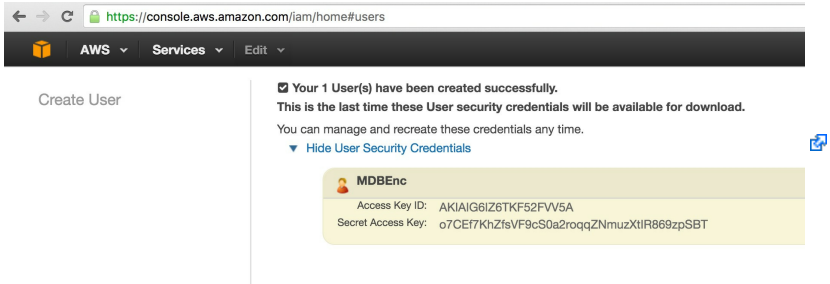
3. Click the "Create New Users" button
4. Enter a single User Name of your choosing. We'll use "MDBEnc" for this demonstration. Keep the "Generate an access key for each user" box checked.



5. Click "Create".
6. Click "Show User Security Credentials".



7. Copy the Access Key ID and Secret Access Key. Optionally, you can click "Download Credentials". We will need these in order for local programs to interact with AWS using its API.



8. Create a file on your computer to hold the credentials for this user. We'll use this file later. It should have this structure:

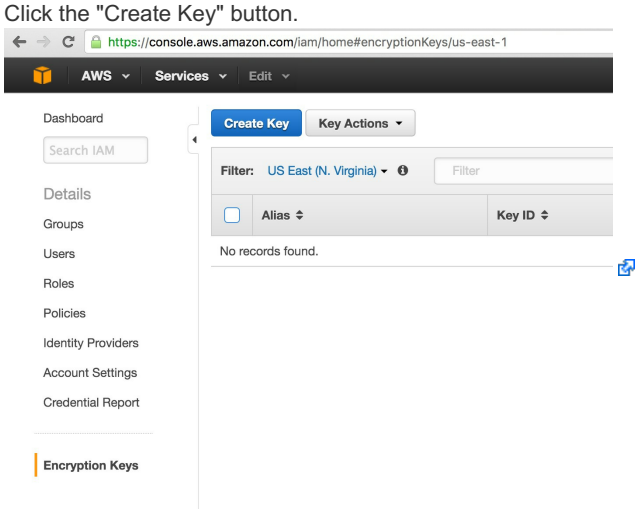
```
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = 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
```

9. Click "Close". If prompted because you did not Download Credentials, ensure that you've saved them somewhere, and click "Close".

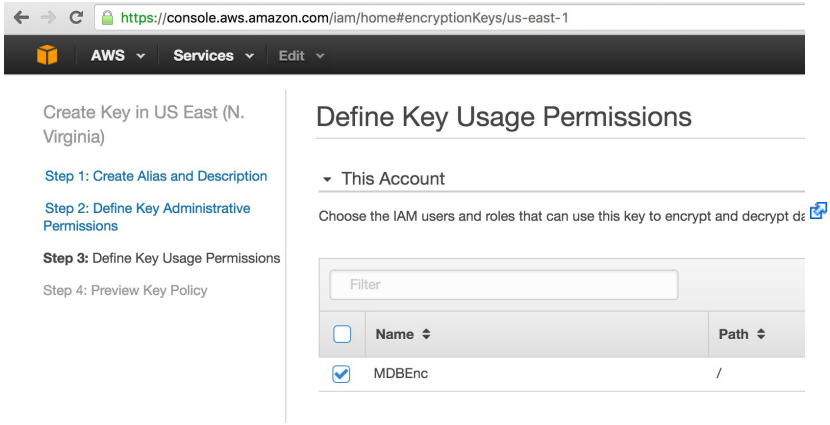
Create a Master Encryption Key

Now, we'll create a master encryption key. This key can *never* be retrieved by *any* application or user. This key is used remotely to encrypt (and decrypt) the actual encryption keys that will be used by MariaDB. If this key is deleted or you lose access to it, you will be unable to use the contents of your MariaDB data directory.

1. Click "Encryption Keys" in the left-hand sidebar.
2. Click the "Get Started Now" button.
3. Use the "Filter" dropdown to choose the region where you'd like to create your master key.
4. Click the "Create Key" button.

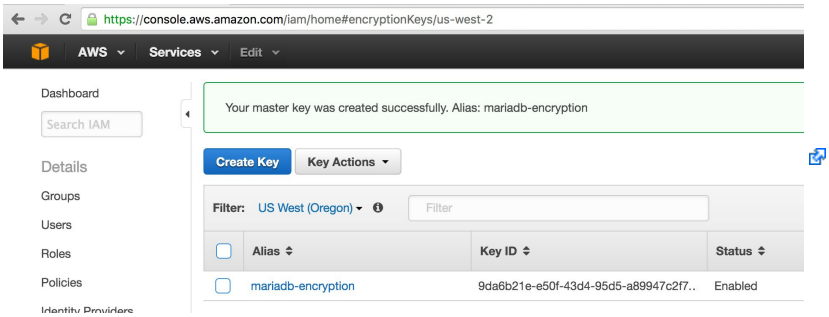


5. Enter an Alias and Description of your choosing.
6. Click "Next Step".
7. Do **not** check the box to make your IAM Role or IAM User user a Key Administrator.
8. Click "Next Step" again.
9. Check the boxes to give your IAM Role and/or IAM User permissions to use this key.



10. Click "Next Step".
11. Click "Finish".

You should now see your key listed in the console:



You'll use the "Alias" you provided when you configure MariaDB later.

We now have a Customer Master Key and an IAM user that has privileges to access it using access credentials. This is enough to begin using the AWS KMS plugin.

Configure AWS Credentials

There are a number of ways to give the IAM credentials to the AWS KMS plugin. The plugin supports reading credentials from all standard locations used across the various AWS API clients.

The easiest approach is to run MariaDB Server in an EC2 instance that has an IAM Role with User access to the CMK you wish to use. You can give key access privileges to a Role already attached to your EC2 instance, or you can create a new IAM Role and attach it to an already-running EC2 instance. If you've done that, no further credentials management is required and you do not need to create a `credentials` file.

If you're not running MariaDB Server on an EC2 instance, you can also place the credentials in the MariaDB data directory. The AWS API client looks for a `credentials` file in the `.aws` subdirectory of the home directory of the user running the client process. In the case of MariaDB, its home directory is its `datadir`.

1. Create a `credentials` file that MariaDB can read. Use the region you selected when creating the key. Master keys cannot be used across regions. For example:

```
$ cat /var/lib/mysql/.aws/credentials
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = o7CEf7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT
region = us-east-1
```

2. Change the permissions of the file so that it it is owned by, and can only be read by, the `mysql` user:

```
chown mysql /var/lib/mysql/.aws/credentials
chmod 600 /var/lib/mysql/.aws/credentials
```

Configure MariaDB

1. Create a new option file to tell MariaDB to enable encryption functionality and to use the AWS KMS plugin. Create a new file under `/etc/my.cnf.d/` (or wherever your OS may have you create such files) with contents like this:

```
[mariadb]
plugin_load_add = aws_key_management
aws-key-management = FORCE_PLUS_PERMANENT
aws-key-management-master-key-id = alias/mariadb-encryption
aws-key-management-region = us-east-1
!include /etc/my.cnf.d/enable_encryption.preset
```

1. Append the "Alias" value you copied above to `alias/` to use as the value for the `aws-key-management-master-key-id` option.

Note that you **must** include `aws-key-management-region` in your .cnf file if you are not using the us-east-1 region.

Now, you have told MariaDB to use the AWS KMS plugin and you've put credentials for the plugin in a location where the plugin will find them. The /etc/my.cnf.d/enable_encryption.preset file contains a set of options that enable all available encryption functionality.

When you start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB must connect to AWS KMS and have the service decrypt the locally-stored key. The decrypted version is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

SELinux and Outbound Connections from MariaDB

Because MariaDB needs to connect to the AWS KMS service, you must ensure that the host has outbound network connectivity over port 443 to AWS and you must ensure that local policies allow the MariaDB server process to make those outbound connections. By default, SELinux restricts MariaDB from making such connections.

The most simple way to cause SELinux to allow outbound HTTPS connections from MariaDB is to enable to mysql_connect_any boolean, like this:

```
setsebool -P mysql_connect_any 1
```

There are more complex alternatives that have a more granular effect, but those are beyond the scope of this document.

Start MariaDB

Start MariaDB using the `systemctl` tool:

```
systemctl start mariadb
```

If you do not use systemd, you may have to start MariaDB using some other mechanism.

You should see journal output similar to this:

```
# journalctl --no-pager -o cat -u mariadb.service

[Note] /usr/sbin/mysqld (mysqld 10.1.9-MariaDB-enterprise-log) starting as process 19831 ...
[Note] AWS KMS plugin: generated encrypted datakey for key id=1, version=1
[Note] AWS KMS plugin: loaded key 1, version 1, key length 128 bit
[Note] InnoDB: Using mutexes to ref count buffer pool pages
[Note] InnoDB: The InnoDB memory heap is disabled
[Note] InnoDB: Mutexes and rw_locks use GCC atomic builtins
[Note] InnoDB: Memory barrier is not used
[Note] InnoDB: Compressed tables use zlib 1.2.7
[Note] InnoDB: Using CPU crc32 instructions
[Note] InnoDB: Initializing buffer pool, size = 2.0G
[Note] InnoDB: Completed initialization of buffer pool
[Note] InnoDB: Highest supported file format is Barracuda.
[Note] InnoDB: 128 rollback segment(s) are active.
[Note] InnoDB: Waiting for purge to start
[Note] InnoDB:  Percona XtraDB (http://www.percona.com) 5.6.26-74.0 started; log sequence number
[Note] InnoDB: Dumping buffer pool(s) not yet started
[Note] Plugin 'FEEDBACK' is disabled.
[Note] AWS KMS plugin: generated encrypted datakey for key id=2, version=1
[Note] AWS KMS plugin: loaded key 2, version 1, key length 128 bit
[Note] Using encryption key id 2 for temporary files
[Note] Server socket created on IP: '::'.
[Note] Reading of all Master_info entries succeded
[Note] Added new Master_info '' to hash table
[Note] /usr/sbin/mysqld: ready for connections.
```

Note the several lines of output that refer explicitly to the "AWS KMS plugin". You can see that the plugin generates a "datakey", loads that data key, and then later generates and loads a second data key. The 2nd data key is used to encrypt temporary files and temporary tables.

You can see the encrypted keys stored on-disk in the datadir:

```
# ls -l /var/lib/mysql/aws*
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1
```

Note that those keys are not useful alone. They are encrypted. When MariaDB starts up, the AWS KMS plugin decrypts those keys by interacting with AWS KMS.

For maximum security, you should start from an empty datadir and run mariadb-install-db after configuring encryption. Then you should re-import your data so that it is fully encrypted. Use `sudo` to run `mariadb-install-db` so that it finds your credentials file:

```
# sudo -u mysql mariadb-install-db
Installing MariaDB/MySQL system tables in '/var/lib/mysql' ...
2016-02-25 23:16:06 139731553998976 [Note] /usr/sbin/mysqld (mysqld 10.1.11-MariaDB-enterprise-
log) starting as process 39551 ...
2016-02-25 23:16:07 139731553998976 [Note] AWS KMS plugin: generated encrypted datakey for key
id=1, version=1
2016-02-25 23:16:07 139731553998976 [Note] AWS KMS plugin: loaded key 1, version 1, key length
128 bit
...
```

Create Encrypted Tables

With `innodb-encrypt-tables=ON`, new InnoDB tables will be encrypted by default, using the key ID set in `innodb_default_encryption_key_id` (default 1). With `innodb-encrypt-tables=FORCE` enabled, it is not possible to manually bypass encryption when creating a table.

You can cause the AWS KMS plugin to create new encryption keys at-will by specifying a new ENCRYPTION_KEY_ID when creating a table:

```
MariaDB [test]> create table t1 (id serial, v varchar(32)) ENCRYPTION_KEY_ID=3;
Query OK, 0 rows affected (0.91 sec)
```

```
[Note] AWS KMS plugin: generated encrypted datakey for key id=3, version=1
[Note] AWS KMS plugin: loaded key 3, version 1, key length 128 bit
```

```
# ls -l /var/lib/mysql/aws*
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1
-rw-rw----. 1 mysql mysql 188 Feb 25 19:10 /var/lib/mysql/aws-kms-key.3.1
```

Read more about encrypting data in the Data at Rest Encryption section of the MariaDB Documentation.

AWS KMS Plugin Option Reference

- `aws_key_management_master_key_id`: AWS KMS Customer Master Key ID (ARN or alias prefixed by `alias/`) for master encryption key. Used to create new data keys. If not set, no new data keys will be created.
- `aws_key_management_rotate_key`: Set this variable to a data key ID to perform rotation of the key to the master key given in `aws_key_management_master_key_id`. Specify -1 to rotate all keys.
- `aws_key_management_key_spec`: Encryption algorithm used to create new keys. Allowed values are AES_128 (default) or AES_256.
- `aws_key_management_log_level`: Logging for AWS API. Allowed values, in increasing verbosity, are "Off" (default), "Fatal", "Error", "Warn", "Info", "Debug", and "Trace".

Next Steps

For more information about advanced usage, including strategies to manage credentials, enforce separation of responsibilities, and even require 2-factor authentication to start your MariaDB server, please review Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage.

5.4.8.6 Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage

Contents

This document assumes you've already set up an Amazon Web Services (AWS) account, created a master key in the Key Management Service (KMS), and have done the basic work to set up the MariaDB AWS KMS plugin. These steps are all described in Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide.

Ultimately, keeping all the credentials required to read the key on a single host means that a user who has gained access to the host has enough information to read the encrypted files in the datadir, read the encrypted keys from the datadir, interact with AWS KMS to decrypt the encrypted keys, and then used the decrypted keys to decrypt the encrypted data.

Theoretically, a superuser can read the memory of the MariaDB server process to read the decrypted keys or restart MariaDB with password authentication disabled in order to dump data, or add new users to MariaDB in order to allow a user to connect and dump the data. Resolving these issues is beyond the scope of this document. A user who gains root access to your operating system or root access to your MariaDB server will have the ability to decrypt your data. Plan accordingly.

Managing AWS credentials

Putting the AWS credentials in a file inside the MariaDB home directory is not ideal. By default, any user with the FILE privilege can read any files that the MariaDB server has permission to read, which would include the credentials file. To protect against this, you should set `secure_file_priv` to restrict the location the server will allow a user to read from when executing `LOAD DATA INFILE` or the `LOAD_FILE()` function.

But putting them in other locations requires passing additional data to the server, which in the case of CentOS 7 requires customizing the systemd startup procedure. This is most easily done by creating a "drop-in" file in /etc/systemd/system/mariadb.service.d/. The file should end in ".conf" but can otherwise be named whatever you like. After making any changes to systemd files, execute `systemctl daemon-reload` and then start (or restart) the service as usual.

You can place the credentials file in a location of your choosing and then refer to that file by setting the `AWS_CREDENTIAL_PROFILES_FILE` environment variable in the drop-in file:

```
[Service]
Environment=AWS_CREDENTIAL_PROFILES_FILE=/etc/aws-kms-credentials
```

The credentials file will need to be readable by the "mysql" user, but it does not need to be readable by any other user.

AWS credentials can also be put directly into a "drop-in" systemd file that will be read when starting the MariaDB service:

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf
[Service]
Environment=AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
Environment=AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV
```

However, any OS user can read this information from systemd, which could be considered a security risk. Another solution is to put the credentials in a separate file that is only readable by root and then refer to that file using an `EnvironmentFile` directive in a drop-in systemd file.

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.env
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV

# chown root /etc/systemd/system/mariadb.service.d/aws-kms.env
# chmod 600 /etc/systemd/system/mariadb.service.d/aws-kms.env

# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf
[Service]
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env
```

That has the advantage the the credentials can only be read directly by root. systemd adds those variables to the environment of the MariaDB server when starting it, and MariaDB can use the credentials to interact with AWS. Note, though, that any process running as the "mysql" user can still read the credentials from the proc filesystem on Linux.

```
$ whoami
mysql
$ cat /proc/$(pgrep mysqld)/environ | tr '\0' '\n' | grep AWS
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV
```

AWS KMS Key Policy

AWS KMS allows flexible, user-editable key policy. This offers fine-grained control over which users can operate on keys. The possibilities range from simply restricting which IP addresses are allowed to perform operations on the key, to requiring a MFA (Multi-Factor Authentication) device to use the key, to enforcing separation of responsibilities by creating an additional user with limited privileges to enable and disable the key. All 3 of these options will be outlined in this section.

For more details about customizing the Key Policy for your master keys, please consult the AWS Key Management Service Key Policy documentation.

Source IP restrictions

A simple, common-sense restriction to put in place is to restrict the range of IP addresses that are allowed to use your master key. This way, even if someone obtains API credentials, they'll be unable to use them to decrypt your encryptions keys from a different host.

To restrict API access from only a specific IP address or range of IP addresses, you'll need to manually edit the key policy.

1. Load the IAM console at https://console.aws.amazon.com/iam/.
2. Click "Encryption Keys" in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled "Switch to policy view", to the right of the heading of the "Key Policy" section.
5. Locate the section that contains `"Sid": "Allow use of the key"`.
6. Add this text below the `"Sid"` line:

```
"Condition": {
  "IpAddress": {
    "aws:SourceIp": [
      "10.1.2.3/32"
    ]
  }
},
```

   ... replacing `10.1.2.3/32` above with an IP address or range of IP addresses in CIDR format. For example, a single address would be `192.168.12.34/32`, while a range of addresses might be `192.168.0.0/24`.
7. Click "Save Changes".
8. Click "Proceed" if prompted with a warning about using the default view in the future.

Access to the API will now be restricted to requests coming from the IP address or range of IP addresses specified in the policy.

Using a Multi-Factor Authentication (MFA) device

One approach is to modify the key policy for the master key so that MFA (Multi-Factor Authentication) is required in order to use the key. This is achieved with a wrapper that handles prompting the user for an MFA token, acquires temporary, limited-privilege credentials from the AWS Security Token Service (STS), and puts those credentials into the environment of the MariaDB server process. The credentials can expire after as little as 15 minutes.

To require an MFA token for users of the key, you'll need to manually edit the key policy.

1. Load the IAM console at https://console.aws.amazon.com/iam/.
2. Click "Encryption Keys" in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled "Switch to policy view", to the right of the heading of the "Key Policy" section.
5. Locate the section that contains `"Sid": "Allow use of the key"`.
6. Add this text below the `"Sid"` line:

```
"Condition": {
  "Bool": {
    "aws:MultiFactorAuthPresent": "True"
  }
},
```

7. Click "Save Changes".
8. Click "Proceed" if prompted with a warning about using the default view in the future.

Now, add an MFA device for your user. You'll need to have a hardware MFA device or an application such as Google Authenticator installed on your smartphone.

1. Click "Users" in the left-hand sidebar.
2. Click the name of your user.
3. Click the "Security Credentials" tab.
4. In the "Sign-In Credentials" section, click the "Manage MFA Device" button.
5. Complete the steps to activate your MFA device.
6. Copy the ARN for your MFA device. You will need to use this when configuring the wrapper program.

Now, set up the wrapper program.

1. Copy the iam-kms-wrapper file to /usr/local/bin/, and ensure that it is executable.
2. Create a drop-in systemd config file in `/etc/systemd/system/mariadb.service.d/`:

```
[Service]
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env
ExecStart=
ExecStart=/usr/local/bin/iam-kms-wrapper --config=/etc/my.cnf.d/iam-kms-wrapper.config /usr/
```

3. Execute `systemctl daemon-reload`.
4. Create a file at `/etc/my.cnf.d/iam-kms-wrapper.config` with these contents, using the ARN for your MFA device as the value for `kms_mfa_id`:

```
[kms]
kms_mfa_id = arn:aws:iam::551888187628:mfa/MDBEnc
kms_mfa_socket = /tmp/kms_mfa_socket
```

When you start the MariaDB service now, the wrapper will temporarily create a socket file at the location given by the `kms_mfa_socket` option. The wrapper will read the MFA code from the socket and will use it to authenticate to KMS. To give the MFA code, simply write the digits to the socket file using `echo`: `echo 111676 > /tmp/kms_mfa_socket`.

The `systemctl` command will block until MariaDB starts, so you will need to write the code to the socket file via a separate terminal.

Note that the temporary credentials put into the environment of the MariaDB process will expire after a period of time defined by the request to the AWS Security Token Service (STS). In the example below, they will expire after 900 seconds. After that time, MariaDB may be unable to generate new encrypted data keys, which means that, for example, an attempt to create a table with a previously-unused key ID would fail.

Wrapper program example

Here's an example wrapper program written in go. Build this into an executable named `iam-kms-wrapper` and use it as instructed above. This could of course be written in any language for which an appropriate AWS SDK exists, but go has the benefit of compiling to a static binary, which means you do not have to worry about interpreter versions or installing complex dependencies on the host that runs your MariaDB server.

```
package main

import (
    "syscall"
    "os"
    "log"
    "flag"
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/aws/awserr"
    "github.com/aws/aws-sdk-go/service/sts"
    "github.com/robfig/config"
)

func main() {

    config_file_p := flag.String("config", "", "location of the config file")
    flag.Parse()

    if flag.NArg() < 1 {
        log.Fatal("Command to wrap must be given as first command-line argument")
    }

    cmd := flag.Arg(0)
    args := flag.Args()[0:]

    conf, err := config.ReadDefault(*config_file_p)
    if err != nil {
        log.Fatal(err)
    }

    kms_mfa_id, err := conf.String("kms","kms_mfa_id")
    mfa_socket_file, err := conf.String("kms","kms_mfa_socket")

    sess := session.New()
    svc := sts.New(sess)

    syscall.Umask(0044)
```

```
    log.Printf("Reading MFA token from %s\n",mfa_socket_file)

    if err := syscall.Mknod(mfa_socket_file, syscall.S_IFIFO|uint32(os.FileMode(0622)), 0); err
!= nil {
        log.Fatal(err)
    }

    file, err := os.Open(mfa_socket_file)
    if err != nil {
        log.Fatal(err)
    }

    token := make([]byte, 6)

    if _, err := file.Read(token); err != nil {
        log.Fatal(err)
    }

    file.Close()

    if err := syscall.Unlink(mfa_socket_file); err != nil {
        log.Fatal(err)
    }

    mfa_token := string(token)

    token_params := &sts.GetSessionTokenInput{
        DurationSeconds: aws.Int64(900),
        SerialNumber:    aws.String(kms_mfa_id),
        TokenCode:       aws.String(mfa_token),
    }

    resp, err := svc.GetSessionToken(token_params)
    if err != nil {
        if awsErr, ok := err.(awserr.Error); ok {
            // Prints out full error message, including original error if there was one.
            log.Fatal("Error:", awsErr.Error())
        } else {
            log.Fatal("Error:", err.Error())
        }
    }

    creds := resp.Credentials

    os.Setenv("AWS_ACCESS_KEY_ID",*creds.AccessKeyId)
    os.Setenv("AWS_SECRET_ACCESS_KEY",*creds.SecretAccessKey)
    os.Setenv("AWS_SESSION_TOKEN",*creds.SessionToken)

    execErr := syscall.Exec(cmd, args, os.Environ())
    if execErr != nil {
        panic(execErr)
    }
}
```

Disabling keys when not needed

Another possibility is to use the API to disable access to the master key and enable it only when a trusted administrator knows that the MariaDB service needs to be started. A specialized tool on a separate host could be used to enable the key for a very short period of time while the service starts and then quickly disable the key.

To do this, you can create an extra IAM User that can only use the kms:EnableKey and kms:DisableKey API endpoints for your key. This user will not be able to encrypt or decrypt any data using the key.

First, create a new user.

1. Load the IAM console at https://console.aws.amazon.com/iam/.
2. Click "Users" in the left-hand sidebar.
3. Click "Create New Users".
4. Enter a new user name. (The examples will use "MDBEncAdmin".)
5. Click "Show User Security Credentials".
6. Copy the credentials and put them in a `credentials` file with this structure:

```
[MDBEncAdmin]
aws_access_key_id=AKIAJMPPNO7EBKABCDEF
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXRlkdM0aAylgabCDef
```

7. Click "Close".
8. Click "Close" again if prompted.
9. Click the name of your new user to open the details view.
10. Copy the "User ARN" value for your user (for example "arn:aws:iam::551888181234:user/MDBEncAdmin"). You will need this for the next step.

Now, give the new user permission to perform API operations on your key.

1. Click "Encryption Keys" in the left-hand sidebar.
2. Click the name of your key to open the details view.
3. Click "Switch to policy view" if it is not already open. (The "policy view" is a large text field that contains JSON describing the key policy.)
4. Create a new item in the `Statement` array with this structure:

```
    {
      "Sid": "Allow Enable and Disable of the key",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::551888181234:user/MDBEncAdmin"
      },
      "Action": [
        "kms:EnableKey",
        "kms:DisableKey"
      ]
    },
```

   ...so that your Key Policy looks like this:

```
{
  "Version": "2012-10-17",
  "Id": "key-consolepolicy-2",
  "Statement": [
    {
      "Sid": "Allow Enable and Disable of the key",
      "Effect": "Allow",
      "Principal": {
      ...
```

5. Click "Save Changes".

You've now added a new IAM user and you've given that user privileges to enable and disable your key. This user will be able to perform those operations using the AWS CLI or via a script of your own design using the AWS API. For example, using the AWS CLI:

```
$ cat ~/.aws/credentials
[MDBEncAdmin]
aws_access_key_id=AKIAJMPPNO7EBKABCDEF
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXRlkdM0aAylgabCDef

$ AWS_PROFILE=MDBEncAdmin aws --region us-east-1 kms disable-key --key-id arn:aws:kms:us-east-
1:551888181234:key/abcdf8f6-084b-4cff-99ca-abcdef6c7907c
```

In order for MariaDB to start, this new user will have to enable the master key, then the DBA can start MariaDB, and this user can once again disable the master key after the service has started. Note that in this workflow, MariaDB will be unable to create new encryption keys, such as would be done when a user creates a table that refers to a non-existent key ID. The AWS KMS plugin will encounter an error if it tries to generate a new encryption key while the master key is disabled. In that scenario, the key administrator would have to enable the key before the operation could succeed. Here's what you should expect to see in the journal if MariaDB tries to interact with a disabled master key:

```
[ERROR] AWS KMS plugin : GenerateDataKeyWithoutPlaintext failed : DisabledException - Unable to
parse ExceptionName: DisabledException Message: arn:aws:kms:us-east-1:551888181234:key/abcdf8f6-
084b-4cff-99ca-abcdef6c7907c is disabled.
```

Adding MFA

It's also possible to add MFA to this technique so that the user that enables & disables the master key has to authenticate using an MFA device. Adapt the instructions in the MFA section above to add MFA to the policy section for the user with EnableKey and DisableKeys privileges, add an MFA device for that user, use Security Token Service (STS) to get temporary security credentials, and then use those credentials to make the API calls. Here's an example Python script that follows that workflow:

```
#!/usr/bin/env python

import boto3
import sys

# Command-line argument processing should be more robust than this...
action= sys.argv[1]
mfa_token= sys.argv[2]

# These should perhaps go into a config file instead of here
mfa_serial= 'arn:aws:iam::551888181234:mfa/MDBEncAdmin'
key_id= 'arn:aws:kms:us-east-1:551888181234:key/abcdf8f6-084b-4cff-99ca-abcdef6c7907c'

# Make the connection to the Security Token Service to get temporary credentials
token_client= boto3.client('sts')
token_response= token_client.get_session_token(
    DurationSeconds= 900,
    SerialNumber= mfa_serial,
    TokenCode= mfa_token
)

cred= token_response['Credentials']

# Start new session using temporary, MFA-authenticated credentials
kms_session= boto3.session.Session(
    aws_access_key_id= cred['AccessKeyId'],
    aws_secret_access_key= cred['SecretAccessKey'],
    aws_session_token= cred['SessionToken'],
    region_name= key_id.split(':')[3]
)

# Start KMS client and execute operation against key
kms_client= kms_session.client('kms')
if action == 'enable' or action == 'e':
    action_f= kms_client.enable_key
elif action == 'disable' or action == 'd':
    action_f= kms_client.disable_key
else:
    raise Exception('Action must be either "disable" or "enable"')

action_f(KeyId=key_id)
```

```
$ AWS_PROFILE=MDBEncAdmin python kms-manage-key disable 575290
$ AWS_PROFILE=MDBEncAdmin python kms-manage-key enable 799870
```

Logging and auditing

CloudTrail

Amazon's CloudTrail service creates JSON-formatted text log files for every API interaction. Enabling CloudTrail requires S3, which incurs additional fees.

First, enable CloudTrail and add a trail.

1. Load the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. If you've never used CloudTrail before, click "Get Started Now".
3. Enter a value for "trail name". This example uses "mariadb-encryption-key".
4. Create a new S3 bucket, using a globally unique name, or use an existing S3 bucket, according to your needs.
5. Click "Turn On".

If you navigate to the S3 bucket you created, you should find log files that contain JSON-formatted descriptions of your API interactions.

CloudWatch

Amazon's CloudWatch service allows you to create alarms and event rules that monitor log information.

First, send your CloudTrail logs to CloudWatch.

1. Load the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. Click "Trails" in the left-hand navigation sidebar.
3. Click the name of your trail to open the Configuration view.
4. In the "CloudWatch Logs" section, click "Configure".
5. Click "Continue".
6. Click "Allow".

Now, set up an SNS topic to facilitate email notifications.

1. Open https://console.aws.amazon.com/sns/.
2. *Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key!*
3. Click "Get Started" is prompted.
4. Click "Events" in the left-hand sidebar.
5. Click "Create new topic".
6. Enter a *Topic name* of your choosing.
7. Enter a *Display name* of your choosing.
8. Click "Create topic".
9. Click the ARN of your new SNS topic.
10. Click "Create Subscription".
11. Select "Email" from the Protocol dropdown.
12. Enter the desired notification email address in the Endpoint field.
13. Wait for the confirmation email to show up and follow the instructions.

Now, configure CloudWatch and create an Event Rule.

1. Open https://console.aws.amazon.com/cloudwatch/.
2. *Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key and your SNS topic!*
3. Click "Events" in the left-hand sidebar.
4. Click "Create rule".
5. Choose "AWS API call" from the "Select event source" dropdown.
6. Choose "KMS" from the "Service name" dropdown.
7. Decide which operations should trigger the event. (You can eep "Any operation" selected for simplicity.)
8. Click "Add target".
9. Select "SNS target" from the dropdown.
10. Select the SNS topic you created in the previous steps.
11. Click "Configure details".
12. Enter a *Name* and *Description* of your choosing.
13. Click "Create rule".

You should now get emails any time someone executes API calls on the KMS service in the region where you've created the CloudWatch Event rule. That means you should get email any time the key is enabled or disabled, and any time the AWS KMS plugin generates new keys or decrypts the keys stored on disk on the MariaDB server.

You may also wish to create an event rule (or an additional event) that matches only when an unauthorized user tries to access the key. You might accomplish that by manually editing the Event selector of the rule to look something like this:

```
{
  "detail-type": [
    "AWS API Call via CloudTrail"
  ],
  "detail": {
    "eventSource": [
      "kms.amazonaws.com"
    ],
    "errorCode": [
      "AccessDenied",
      "UnauthorizedOperation"
    ]
  }
}
```

The emails are formatted as JSON. Further customization of the CloudWatch email workflow is beyond the scope of this document.

There are many other workflows available using CloudWatch, including workflows with alarms and dashboards. Those are beyond the scope of this document.

5.4.8.7 Eperi Key Management Encryption Plugin

Eperi's Key Management Plugin Package no longer appears to be available.

Contents

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

The Eperi Key Management plugin is a key management and encryption plugin that integrates with eperi Gateway for Databases.

Overview

The Eperi Key Management plugin is one of the key management and encryption plugins that can be set up for users who want to use data-at-rest encryption. Some of the plugin's primary features are:

- It reads encryption keys from eperi Gateway for Databases.
- It supports multiple encryption keys.
- It supports key rotation.
- It supports two different algorithms for encrypting data.

The eperi Gateway for Databases stores encryption keys on the key server outside of the database server itself, which provides an extra level of security. The eperi Gateway for Databases also supports performing all data encryption operations on the key server as well, but this is optional.

It also provides the following benefits:

- Key management outside the database
- No keys on database server hard disk
- Graphical user interface for configuration
- Encryption and decryption outside the database, supporting HSM's for maximum security.

Support for MariaDB is provided in eperi Gateway for Databases 3.4.

Installing the Eperi Key Management Plugin's Package

For information on how to install the package, see Eperi's documentation at the Eperi Customer Portal.

Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. The plugin can be installed by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = eperi_key_management_plugin
```

Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that data-at-rest encryption is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'eperi_key_management_plugin';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Configuring the Eperi Key Management Plugin

For information on how to configure the plugin, see Eperi's documentation at the Eperi Customer Portal.

Using the Eperi Key Management Plugin

Once the Eperi Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table `t` will be encrypted using the encryption key from the key server.

For more information on how to use encryption, see Data at Rest Encryption.

Using Multiple Encryption Keys

The Eperi Key Management Plugin supports using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

When encrypting InnoDB tables, the key that is used to encrypt tables can be changed.

When encrypting Aria tables, the key that is used to encrypt tables cannot currently be changed.

Key Rotation

The Eperi Key Management plugin supports key rotation.

Versions

Version	Status	Introduced
1.0	Unknown	eperi Gateway for Databases 3.4.0

System Variables

`eperi_key_management_plugin_databaseId`

- **Description:** Determines the database ID which is processed in the eperi Gateway.
- **Commandline:** `--eperi-key-management-plugin-databaseid=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `integer`
- **Default Value:** `1`

---

eperi_key_management_plugin_encryption_algorithm

- **Description:** This system variable is used to determine which algorithm the plugin will use to encrypt data.
  - The recommended algorithm is `AES_CTR`, but this algorithm is only available when MariaDB is built with recent versions of OpenSSL. If the server is built with wolfSSL or yaSSL, then this algorithm is not available. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Commandline:** `--eperi-key-management-plugin-encryption-algorithm=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `AES_CBC`
- **Valid Values:** `AES_CBC`, `AES_CTR`

---

eperi_key_management_plugin_encryption_mode

- **Description:** Encryption mode.
- **Commandline:** `--eperi-key-management-plugin-encryption-mode=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enumerated`
- **Default Value:** `database`
- **Valid Values:** `database`, `gateway`

---

eperi_key_management_plugin_osslmt

- **Description:** Determines, whether the plugin should register callback functions for OpenSSL thread support.
- **Commandline:** `--eperi-key-management-plugin-osslmt=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `0` (Linux), `1` (Windows)

---

eperi_key_management_plugin_port

- **Description:** Listener port for plugin.
- **Commandline:** `--eperi-key-management-plugin-port=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `integer`
- **Default Value:** `14332`

---

eperi_key_management_plugin_url

- **Description:** URL to key server. The expected format of the URL is <host>:<port>. The port number is optional, and the port number defaults to 14333 if it is not specified.
- **Commandline:** `--eperi-key-management-plugin-url=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `NULL`

eperi_key_management_plugin_url_check_disabled

- **Description:** Determines, whether the connection between plugin and eperi Gateway is tested at server startup.
- **Commandline:** `--eperi-key-management-plugin-url-check-disabled=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `1`

Options

eperi_key_management_plugin

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--eperi-key-management-plugin=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.8.8 Encryption Plugin API

Contents

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

See Data at Rest Encryption and Encryption Key Management for more information.

Encryption Plugin API

The Encryption plugin API was created to allow a plugin to:

- implement key management, provide encryption keys to the server on request and change them according to internal policies.
- implement actual data encryption and decryption with the algorithm defined by the plugin.

This is how the API reflects that:

```
/* Returned from get_latest_key_version() */
#define ENCRYPTION_KEY_VERSION_INVALID (~(unsigned int)0)
#define ENCRYPTION_KEY_NOT_ENCRYPTED (0)

#define ENCRYPTION_KEY_SYSTEM_DATA 1
#define ENCRYPTION_KEY_TEMPORARY_DATA 2

/* Returned from get_key()  */
#define ENCRYPTION_KEY_BUFFER_TOO_SMALL (100)

#define ENCRYPTION_FLAG_DECRYPT 0
#define ENCRYPTION_FLAG_ENCRYPT 1
#define ENCRYPTION_FLAG_NOPAD 2

struct st_mariadb_encryption {
  int interface_version; /**< version plugin uses */

  /******************** KEY MANAGEMENT ***********************************/

  /**
    Function returning latest key version for a given key id.

    @return A version or ENCRYPTION_KEY_VERSION_INVALID to indicate an error.
  */
  unsigned int (*get_latest_key_version)(unsigned int key_id);

  /**
    Function returning a key for a key version

    @param key_id       The requested key id
    @param version      The requested key version
    @param key          The key will be stored there. Can be NULL -
                        in which case no key will be returned
    @param key_length   in: key buffer size
                        out: the actual length of the key

    This method can be used to query the key length - the required
    buffer size - by passing key==NULL.

    If the buffer size is less than the key length the content of the
    key buffer is undefined (the plugin is free to partially fill it with
    the key data or leave it untouched).

    @return 0 on success, or
            ENCRYPTION_KEY_VERSION_INVALID, ENCRYPTION_KEY_BUFFER_TOO_SMALL
            or any other non-zero number for errors
  */
  unsigned int (*get_key)(unsigned int key_id, unsigned int version,
                          unsigned char *key, unsigned int *key_length);

  /******************** ENCRYPTION ***********************************/
  /*
    The caller uses encryption as follows:
      1. Create the encryption context object of the crypt_ctx_size() bytes.
      2. Initialize it with crypt_ctx_init().
      3. Repeat crypt_ctx_update() until there are no more data to encrypt.
      4. Write the remaining output bytes and destroy the context object
         with crypt_ctx_finish().
  */

  /**
    Returns the size of the encryption context object in bytes
  */
  unsigned int (*crypt_ctx_size)(unsigned int key_id, unsigned int key_version);
  /**
    Initializes the encryption context object.
  */
  int (*crypt_ctx_init)(void *ctx, const unsigned char *key, unsigned int klen,
                        const unsigned char *iv, unsigned int ivlen, int flags,
                        unsigned int key_id, unsigned int key_version);
  /**
    Processes (encrypts or decrypts) a chunk of data
```

```
    Writes the output to th dst buffer. note that it might write
    more bytes that were in the input. or less. or none at all.
  */
  int (*crypt_ctx_update)(void *ctx, const unsigned char *src,
                          unsigned int slen, unsigned char *dst,
                          unsigned int *dlen);
  /**
    Writes the remaining output bytes and destroys the encryption context

    crypt_ctx_update might've cached part of the output in the context,
    this method will flush these data out.
  */
  int (*crypt_ctx_finish)(void *ctx, unsigned char *dst, unsigned int *dlen);
  /**
    Returns the length of the encrypted data

    It returns the exact length, given only the source length.
    Which means, this API only supports encryption algorithms where
    the length of the encrypted data only depends on the length of the
    input (a.k.a. compression is not supported).
  */
  unsigned int (*encrypted_length)(unsigned int slen, unsigned int key_id,
                                   unsigned int key_version);
};
```

The first method is used for key rotation. A plugin that doesn't support key rotation — for example, **file_key_management** — can return a fixed version for any valid key id. Note that it still has to return an error for an invalid key id. The version `ENCRYPTION_KEY_NOT_ENCRYPTED` means that the data should not be encrypted.

The second method is used for key management, the server uses it to retrieve the key corresponding to a specific key identifier and a specific key version.

The last five methods deal with encryption. Note that they take the key to use and key identifier and version. This is needed because the server can derive a session-specific, user-specific, or a tablespace-specific key from the original encryption key as returned by `get_key()`, so the `key` argument doesn't have to match the encryption key as the plugin knows it. On the other hand, the encryption algorithm may depend on the key identifier and version (and in the **example_key_management** plugin it does) so the plugin needs to know them to be able to encrypt the data.

Encryption methods are optional — if unset (as in the **debug_key_management** plugin), the server will fall back to AES_CBC.

Current Encryption Plugins

The MariaDB source tree has four encryption plugins. All these plugins are fairly simple and can serve as good examples of the Encryption plugin API.

file_key_management

It reads encryption keys from a plain-text file. It supports two different encryption algorithms. It supports multiple encryption keys. It does not support key rotation. See the File Key Management Plugin article for more details.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Alpha	MariaDB 10.1.3

aws_key_management

The AWS Key Management plugin uses the Amazon Web Services (AWS) Key Management Service (KMS) to generate and store AES keys on disk, in encrypted form, using the Customer Master Key (CMK) kept in AWS KMS. When MariaDB Server starts, the plugin will decrypt the encrypted keys, using the AWS KMS "Decrypt" API function. MariaDB data will then be encrypted and decrypted using the AES key. It supports multiple encryption keys. It supports key rotation.

See the AWS Key Management Plugin article for more details.

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.2.6, MariaDB 10.1.24
1.0	Beta	MariaDB 10.1.18
1.0	Experimental	MariaDB 10.1.13

example_key_management

Uses random time-based generated keys, ignores key identifiers, supports key versions and key rotation. Uses AES_ECB and AES_CBC as encryption algorithms and changes them automatically together with key versions.

Versions

Version	Status	Introduced
1.0	Experimental	MariaDB 10.1.3

debug_key_management

Key is generated from the version, user manually controls key rotation. Only supports key identifier 1, uses only AES_CBC.

Versions

Version	Status	Introduced
1.0	Experimental	MariaDB 10.1.3

Encryption Service

Encryption is generally needed on the very low level **inside the storage engine**. That is, the storage engine needs to support encryption and have access to the encryption and key management functionality. The usual way for a plugin to access some functionality in the server is via a *service*. In this case the server provides the Encryption Service for storage engines (and other interested plugins) to use. These service functions are directly hooked into encryption plugin methods (described above).

Service functions are declared as follows:

```
unsigned int encryption_key_get_latest_version(unsigned int key_id);
unsigned int encryption_key_get(unsigned int key_id, unsigned int key_version,
                                unsigned char *buffer, unsigned int *length);
unsigned int encryption_ctx_size(unsigned int key_id, unsigned int key_version);
int encryption_ctx_init(void *ctx, const unsigned char *key, unsigned int klen,
                        const unsigned char *iv, unsigned int ivlen, int flags,
                        unsigned int key_id, unsigned int key_version);
int encryption_ctx_update(void *ctx, const unsigned char *src,
                          unsigned int slen, unsigned char *dst,
                          unsigned int *dlen);
int encryption_ctx_finish(void *ctx, unsigned char *dst, unsigned int *dlen);
unsigned int encryption_encrypted_length(unsigned int slen, unsigned int key_id,
                                         unsigned int key_version);
```

There are also convenience helpers to check for a key or key version existence and to encrypt or decrypt a block of data with one function call.

```
unsigned int encryption_key_id_exists(unsigned int id);
unsigned int encryption_key_version_exists(unsigned int id,
                                           unsigned int version);
int encryption_crypt(const unsigned char *src, unsigned int slen,
                     unsigned char *dst, unsigned int *dlen,
                     const unsigned char *key, unsigned int klen,
                     const unsigned char *iv, unsigned int ivlen, int flags,
                     unsigned int key_id, unsigned int key_version);
```

5.4.9 MariaDB Replication & Cluster Plugins

Semisynchronous Replication

Semisynchronous replication.

WSREP_INFO Plugin

Adds two new Information Schema tables, WSREP_MEMBERSHIP and WSREP_STATUS.

3.1.24 Semisynchronous Replication

5.4.9.2 WSREP_INFO Plugin

The `WSREP_INFO` plugin library contains the following plugins:

- `WSREP_MEMBERSHIP`
- `WSREP_STATUS`

The `WSREP_MEMBERSHIP` plugin creates the WSREP_MEMBERSHIP table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW WSREP_MEMBERSHIP statement.

The `WSREP_STATUS` plugin creates the WSREP_STATUS table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW WSREP_STATUS statement.

These tables and statements provide information about Galera. Only users with the SUPER privilege can access this information.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'wsrep_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = wsrep_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'wsrep_info';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SHOW TABLES FROM information_schema LIKE 'WSREP%';
+---------------------------------------+
| Tables_in_information_schema (WSREP%) |
+---------------------------------------+
| WSREP_STATUS                          |
| WSREP_MEMBERSHIP                      |
+---------------------------------------+
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Alpha	MariaDB 10.1.2

Options

wsrep_membership

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--wsrep-membership=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

---

wsrep_status

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--wsrep-status=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.3 Storage Engines

5.4.11 Other Plugins

Compression Plugins

Five MariaDB compression libraries are available as plugins.

Disks Plugin

Shows metadata about disks on the system.

Feedback Plugin

Collect and send user statistics.

Locales Plugin

List compiled-in locales.

METADATA_LOCK_INFO Plugin

Active metadata locks.

MYSQL_JSON

Converting MySQL's JSON data type to MariaDB's format.

Query Cache Information Plugin

Examines the contents of the query cache.

Query Response Time Plugin

Records statistics on the time to execute queries on MariaDB Server.

SQL Error Log Plugin

Records SQL-level errors to a log file.

User Statistics

User Statistics.

User Variables Plugin

User Variables plugin.

There are 1 related questions.

5.4.11.1 Feedback Plugin

> The Feedback plugin is not currently working.

The `feedback` plugin is designed to collect and, optionally, upload configuration and usage information to MariaDB.org or to any other configured URL.

The `feedback` plugin exists in all MariaDB versions.

MariaDB is distributed with this plugin included, but it is not enabled by default. On Windows, this plugin is part of the server and has a special checkbox in the installer window. Either way, you need to explicitly install and enable it in order for feedback data to be sent.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'feedback';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = feedback
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'feedback';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Enabling the Plugin

You can enable the plugin by setting the `feedback` option to `ON` in a relevant server option group in an option file. For example:

```
[mariadb]
...
feedback=ON
```

In Windows, the plugin can also be enabled during a new MSI installation. The MSI GUI installation provides the "Enable feedback plugin" checkbox to enable the plugin. The MSI command-line installation provides the FEEDBACK=1 command-line option to enable the plugin.

See the next section for how to verify the plugin is installed and active and (if needed) install the plugin.

Verifying the Plugin's Status

To verify whether the `feedback` plugin is installed and enabled, execute the `SHOW PLUGINS` statement or query the `information_schema.plugins` table. For example:

```
SELECT plugin_status FROM information_schema.plugins
  WHERE plugin_name = 'feedback';
```

If that `SELECT` returns no rows, then you still need to install the plugin.

When the plugin is installed and enabled, you will see:

```
SELECT plugin_status FROM information_schema.plugins
  WHERE plugin_name = 'feedback';
+---------------+
| plugin_status |
+---------------+
| ACTIVE        |
+---------------+
```

If you see `DISABLED` instead of `ACTIVE`, then you still need to enable the plugin.

Collecting Data

The `feedback` plugin will collect:

- Certain rows from SHOW STATUS and SHOW VARIABLES.
- All installed plugins and their versions.
- System information such as CPU count, memory, architecture, and OS/linux distribution.
- The feedback_server_uid, which is a SHA1 hash of the MAC address of the first network interface and the TCP port that the server listens on.

The `feedback` plugin creates the FEEDBACK table in the INFORMATION_SCHEMA database. To see the data that has been collected by the plugin, you can execute:

```
SELECT * FROM information_schema.feedback;
```

Only the contents of this table are sent to the feedback_url.

MariaDB stores collation usage statistics. Each collation that has been used by the server will have a record in "SELECT * FROM information_schema.feedback" output, for example:

```
+----------------------------------------+---------------------+
| VARIABLE_NAME                          | VARIABLE_VALUE      |
+----------------------------------------+---------------------+
| Collation used utf8_unicode_ci         | 10                  |
| Collation used latin1_general_ci       | 20                  |
+----------------------------------------+---------------------+
```

Collations that have not been used will not be included into the result.

Sending Data

The `feedback` plugin sends the data using a `POST` request to any URL or a list of URLs that you specify by setting the feedback_url system variable. By default, this is set to the following URL:

- https://mariadb.org/feedback_plugin/post

Both HTTP and HTTPS protocols are supported.

If HTTP traffic requires a proxy in your environment, then you can specify the proxy by setting the feedback_http_proxy system variable.

If the feedback_url system variable is not set to an empty string, then the plugin will automatically send a report to all URLs in the list a few minutes after the server starts up and then once a week after that.

If the feedback_url system variable is set to an empty string, then the plugin will **not** automatically send any data. This may be necessary if outbound HTTP communication from your database server is not permitted. In this case, you can still upload the data manually, if you'd like.

First, generate the report file with the MariaDB command-line mariadb client:

```
$ mariadb -e 'select * from information_schema.feedback' > report.txt
```

Then you can upload the generated `report.txt` here using your web browser.

Or you can do it from the command line with tools such as curl. For example:

```
$ curl -F data=@report.txt https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the INFORMATION_SCHEMA.FEEDBACK table and that no private or sensitive information is being sent.

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.0.10
1.1	Beta	MariaDB 5.5.20, MariaDB 5.3.3

System Variables

feedback_http_proxy

- **Description:** Proxy server for use when http calls cannot be made, such as in a firewall environment. The format is `host:port`.
- **Commandline:** `--feedback-http=proxy=value`
- **Read-only:** Yes
- **Data Type:** string
- **Default Value:** `''` (empty)

---

feedback_send_retry_wait

- **Description:** Time in seconds before retrying if the plugin failed to send the data for any reason.
- **Commandline:** `--feedback-send-retry-wait=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:** `60`
- **Valid Values:** `1` to `86400`

---

feedback_send_timeout

- **Description:** An attempt to send the data times out and fails after this many seconds.
- **Commandline:** `--feedback-send-timeout=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:** `60`
- **Valid Values:** `1` to `86400`

---

feedback_server_uid

- **Description:** Automatically calculated server unique id hash.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string

---

feedback_url

- **Description:** URL to which the data is sent. More than one URL, separated by spaces, can be specified. Set it to an empty string to disable data sending.
- **Commandline:** `--feedback-url=url`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string
- **Default Value:** `https://mariadb.org/feedback_plugin/post`

feedback_user_info

- **Description:** The value of this option is not used by the plugin, but it is included in the feedback data. It can be used to add any user-specified string to the report. This could be used to help to identify it. For example, a support contract number, or a computer name (if you collect reports internally by specifying your own `feedback-url`).
- **Commandline:** `--feedback-user-info=string`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string
- **Default Value:** Empty string

Options

feedback

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--feedback=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF` , `ON` , `FORCE` , `FORCE_PLUS_PERMANENT`

5.4.11.2 Locales Plugin

The `LOCALES` plugin creates the LOCALES table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW LOCALES statement.The table and statement can be queried to see all locales that are compiled into the server.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by

executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'locales';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = locales
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'locales';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SELECT * FROM INFORMATION_SCHEMA.LOCALES;
+-----+-------+---------------------------------------+-----------------------+----------------
-----+---------------+--------------+------------------------+
| ID  | NAME  | DESCRIPTION                           | MAX_MONTH_NAME_LENGTH |
MAX_DAY_NAME_LENGTH | DECIMAL_POINT | THOUSAND_SEP | ERROR_MESSAGE_LANGUAGE |
+-----+-------+---------------------------------------+-----------------------+----------------
-----+---------------+--------------+------------------------+
|   0 | en_US | English - United States               |                     9 |
9 | .             | ,            | english                |

```

Versions

Version	Status	Introduced

1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 10.0.4

Options

`locales`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--locales=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.3 METADATA_LOCK_INFO Plugin

The `METADATA_LOCK_INFO` plugin creates the METADATA_LOCK_INFO table in the INFORMATION_SCHEMA database. This table shows active metadata locks. The table will be empty if there are no active metadata locks.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'metadata_lock_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = metadata_lock_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'metadata_lock_info';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Examples

Viewing all Metadata Locks

```
SELECT * FROM information_schema.metadata_lock_info;
+-----------+-------------------------+--------------+----------------------+--------------
---+-------------+
| THREAD_ID | LOCK_MODE               | LOCK_DURATION | LOCK_TYPE            | TABLE_SCHEMA
| TABLE_NAME  |
+-----------+-------------------------+--------------+----------------------+--------------
---+-------------+
|        31 | MDL_INTENTION_EXCLUSIVE  | MDL_EXPLICIT  | Global read lock     |
|             |
|        31 | MDL_INTENTION_EXCLUSIVE  | MDL_EXPLICIT  | Commit lock          |
|             |
|        31 | MDL_INTENTION_EXCLUSIVE  | MDL_EXPLICIT  | Schema metadata lock | dbname
|             |
|        31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT  | Table metadata lock  | dbname
| exotics     |
+-----------+-------------------------+--------------+----------------------+--------------
---+-------------+
4 rows in set (0.00 sec)
```

Matching Metadata Locks with Threads and Queries

```
SELECT
CONCAT('Thread ',P.ID,' executing "',P.INFO,'" IS LOCKED BY Thread ',
M.THREAD_ID) WhoLocksWho
FROM INFORMATION_SCHEMA.PROCESSLIST P,
INFORMATION_SCHEMA.METADATA_LOCK_INFO M
WHERE LOCATE(lcase(LOCK_TYPE), lcase(STATE))>0;
+-------------------------------------------------------------------------------------+
| WhoLocksWho                                                                         |
+-------------------------------------------------------------------------------------+
| Thread 3 executing "INSERT INTO foo ( b ) VALUES ( 'FOO' )" IS LOCKED BY Thread 2 |
+-------------------------------------------------------------------------------------+
1 row in set (0.00 sec)

SHOW PROCESSLIST;
+----+------+-----------+------+---------+------+-------------------------------+-------------
---------------------------+----------+
| Id | User | Host      | db   | Command | Time | State                         | Info
| Progress |
+----+------+-----------+------+---------+------+-------------------------------+-------------
---------------------------+----------+
|  2 | root | localhost | test | Sleep   |  123 |                               | NULL
|    0.000 |
|  3 | root | localhost | test | Query   |  103 | Waiting for global read lock | INSERT INTO
foo ( b ) VALUES ( 'FOO' ) |    0.000 |
|  4 | root | localhost | test | Query   |    0 | init                          | SHOW
PROCESSLIST                        |    0.000 |
+----+------+-----------+------+---------+------+-------------------------------+-------------
---------------------------+----------+
3 rows in set (0.00 sec)
```

Versions

Version	Status	Introduced
0.1	Stable	MariaDB 10.1.13

0.1	Beta	MariaDB 10.0.10
0.1	Alpha	MariaDB 10.0.7

Options

`metadata_lock_info`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--metadata-lock-info=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.4 MYSQL_JSON

MariaDB starting with 10.5.7

The `TYPE_MYSQL_JSON` plugin was first released in MariaDB 10.5.7.

The JSON type in MySQL stores the JSON object in its own native form, while in MariaDB the JSON type is a LONGTEXT. Opening a table with a JSON type created in MySQL would result in an error:

```
select * from mysql_json_table;
ERROR 4161 (HY000): Unknown data type: 'MYSQL_JSON'
```

The mysql_json plugin is used to make it easier to upgrade to MariaDB.

Installing

Installing can be done in a number of ways, for example:

```
install soname 'type_mysql_json';
```

See Making MariaDB understand MySQL JSON for a full description.

5.4.11.5 Query Cache Information Plugin

The `QUERY_CACHE_INFO` plugin creates the QUERY_CACHE_INFO table in the INFORMATION_SCHEMA database. This table shows all queries in the query cache. Querying this table acquires the query cache lock and will result in lock waits for queries that are using or expiring from the query cache. You must have the PROCESS privilege to query this table.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'query_cache_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = query_cache_info
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'query_cache_info';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
select statement_schema, statement_text, result_blocks_count,
  result_blocks_size from information_schema.query_cache_info;
+------------------+------------------+---------------------+--------------------+
| statement_schema | statement_text   | result_blocks_count | result_blocks_size |
+------------------+------------------+---------------------+--------------------+
| test             | select * from t1 |                   1 |                512 |
+------------------+------------------+---------------------+--------------------+
```

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.1.13
1.1	Gamma	MariaDB 10.1.8
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 5.5.31

Options

query_cache_info

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or

UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--query-cache-info=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.6 Query Response Time Plugin

The `query_response_time` plugin creates the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database. The plugin also adds the SHOW QUERY_RESPONSE_TIME and FLUSH QUERY_RESPONSE_TIME statements.

The slow query log provides exact information about queries that take a long time to execute. However, sometimes there are a large number of queries that each take a very short amount of time to execute. This feature provides a tool for analyzing that information by counting and displaying the number of queries according to the the length of time they took to execute.

This feature is based on Percona's Response Time Distribution.

Contents

Installing the Plugin

This shared library actually consists of two different plugins:

- `QUERY_RESPONSE_TIME` - An INFORMATION_SCHEMA plugin that exposes statistics.
- `QUERY_RESPONSE_TIME_AUDIT` - audit plugin, collects statistics.

Both plugins need to be installed to get meaningful statistics.

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'query_response_time';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = query_response_time
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'query_response_time';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Response Time Distribution

The user can define time intervals that divide the range 0 to positive infinity into smaller intervals and then collect the number of commands whose execution times fall into each of those intervals.

Each interval is described as:

```
(range_base ^ n; range_base ^ (n+1)]
```

The range_base is some positive number (see Limitations). The interval is defined as the difference between two nearby powers of the range base.

For example, if the range base=10, we have the following intervals:

```
(0; 10 ^ -6], (10 ^ -6; 10 ^ -5], (10 ^ -5; 10 ^ -4], ...,
  (10 ^ -1; 10 ^1], (10^1; 10^2]...(10^7; positive infinity]
```

or

```
(0; 0.000001], (0.000001; 0.000010], (0.000010; 0.000100], ...,
  (0.100000; 1.0]; (1.0; 10.0]...(1000000; positive infinity]
```

For each interval, a count is made of the queries with execution times that fell into that interval.

You can select the range of the intervals by changing the range base. For example, for base range=2 we have the following intervals:

```
(0; 2 ^ -19], (2 ^ -19; 2 ^ -18], (2 ^ -18; 2 ^ -17], ...,
  (2 ^ -1; 2 ^1], (2 ^ 1; 2 ^ 2]...(2 ^ 25; positive infinity]
```

or

```
(0; 0.000001], (0.000001, 0.000003], ...,
  (0.25; 0.5], (0.5; 2], (2; 4]...(8388608; positive infinity]
```

Small numbers look strange (i.e., don't look like powers of 2), because we lose precision on division when the ranges are calculated at runtime. In the resulting table, you look at the high boundary of the range.

For example, you may see:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
+----------------+-------+----------------+
| TIME           | COUNT | TOTAL          |
+----------------+-------+----------------+
|       0.000001 |     0 |       0.000000 |
|       0.000010 |    17 |       0.000094 |
|       0.000100 |  4301 |       0.236555 |
|       0.001000 |  1499 |       0.824450 |
|       0.010000 | 14851 |      81.680502 |
|       0.100000 |  8066 |     443.635693 |
|       1.000000 |     0 |       0.000000 |
|      10.000000 |     0 |       0.000000 |
|     100.000000 |     1 |      55.937094 |
|    1000.000000 |     0 |       0.000000 |
|   10000.000000 |     0 |       0.000000 |
|  100000.000000 |     0 |       0.000000 |
| 1000000.000000 |     0 |       0.000000 |
| TOO LONG       |     0 | TOO LONG       |
+----------------+-------+----------------+
```

This means there were:

```
* 17 queries with 0.000001 < query execution time < = 0.000010 seconds; total execution time of
the 17 queries = 0.000094 seconds

* 4301 queries with 0.000010 < query execution time < = 0.000100 seconds; total execution time
of the 4301 queries = 0.236555 seconds

* 1499 queries with 0.000100 < query execution time < = 0.001000 seconds; total execution time
of the 1499 queries = 0.824450 seconds

* 14851 queries with 0.001000 < query execution time < = 0.010000 seconds; total execution time
of the 14851 queries = 81.680502 seconds

* 8066 queries with 0.010000 < query execution time < = 0.100000 seconds; total execution time
of the 8066 queries = 443.635693 seconds

* 1 query with 10.000000 < query execution time < = 100.0000 seconds; total execution time of
the 1 query = 55.937094 seconds
```

Using the Plugin

Using the Information Schema Table

You can get the distribution by querying the the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database. For example:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
```

You can also write more complex queries. For example:

```
SELECT c.count, c.time,
(SELECT SUM(a.count) FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME as a
   WHERE a.count != 0) as query_count,
(SELECT COUNT(*)     FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME as b
  WHERE b.count != 0) as not_zero_region_count,
(SELECT COUNT(*)     FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME) as region_count
FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME as c
  WHERE c.count > 0;
```

Note: If query_response_time_stats is set to `ON` , then the execution times for these two SELECT queries will also be collected.

Using the SHOW Statement

As an alternative to the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database, you can also use the SHOW QUERY_RESPONSE_TIME statement. For example:

```
SHOW QUERY_RESPONSE_TIME;
```

Flushing Plugin Data

Flushing the plugin data does two things:

- Clears the collected times from the QUERY_RESPONSE_TIME table in the INFORMATION_SCHEMA database.
- Reads the value of query_response_time_range_base and uses it to set the range base for the table.

Plugin data can be flushed with the FLUSH QUERY_RESPONSE_TIME statement. For example:

```
FLUSH QUERY_RESPONSE_TIME;
```

Setting the query_response_time_flush system variable has the same effect. For example:

```
SET GLOBAL query_response_time_flush=1;
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 10.0.4

System Variables

query_response_time_flush

- **Description:** Updating this variable flushes the statistics and re-reads query_response_time_range_base.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

query_response_time_range_base

- **Description:** Select base of log for `QUERY_RESPONSE_TIME` ranges. WARNING: variable change takes affect only after flush.
- **Commandline:** `--query-response-time-range-base=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `2` to `1000`

---

query_response_time_exec_time_debug

- **Description:** Pretend queries take this many microseconds. When 0 (the default) use the actual execution time.
  - This system variable is only available when the plugin is a debug build.
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `31536000`

---

query_response_time_stats

- **Description:** Enable or disable query response time statistics collecting
- **Commandline:** `query-response-time-stats[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

Options

query_response_time

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

        - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--query-response-time=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

---

query_response_time_audit

- **Description:** Controls how the server should treat the plugin when the server starts up.
    - Valid values are:
        - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
        - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
        - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--query-response-time-audit=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.7 SQL Error Log Plugin

Contents

The `SQL_ERROR_LOG` plugin collects errors sent to clients in a log file defined by sql_error_log_filename, so that they can later be analyzed. The log file can be rotated if sql_error_log_rotate is set.

Errors are logged as they happen and an error will be logged even if it was handled by a condition handler and was never technically *sent* to the client.

Comments are also logged, which can make the log easier to search. But this is only possible if the client does not strip the comments away. For example, mysql command-line client only leaves comments when started with the --comments option.

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'sql_errlog';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = sql_errlog
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'sql_errlog';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Things logged

The current log format before 10.10 is:

```
Time User Error_code: Error_message : Query
```

Starting from 10.11 the format is:

```
Time User Type Error_code: Error_message : Query
```

Each separated by a space or : as above

Option	Description	Version
Time	Time (YYYY-MM-DD hh-mm-ss)	5.5.22
User	privilege_user [login_user_name] @ hostname [ip]	5.5.22
Type	ERROR or WARNING	10.11.6
Error_code	OS error, MariaDB storage engine code (120-199) or MariaDB internal error code (1000-)	5.5.22
Query	Query text	5.5.22

Example of logs

```
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1146: Table 'test.t_doesnt_exist' doesn't exi
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1064: You have an error in your SQL syntax; c
2023-10-31 15:54:37 root[root] @ localhost [] ERROR 1146: Table 'test.temptab' doesn't exist : SE
2023-11-01 11:31:15 [monty] @ storm [192.168.0.12] ERROR 1051: Unknown table 'test.t1' : drop tab
```

Example usage

```
install plugin SQL_ERROR_LOG soname 'sql_errlog';
Query OK, 0 rows affected (0.00 sec)

use test;
Database changed

set sql_mode='STRICT_ALL_TABLES,NO_ENGINE_SUBSTITUTION';
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE foo2 (id int) ENGINE=WHOOPSIE;
ERROR 1286 (42000): Unknown storage engine 'WHOOPSIE'
\! cat data/sql_errors.log
2013-03-19  9:38:40 msandbox[msandbox] @ localhost [] ERROR 1286: Unknown storage engine
'WHOOPSIE' : CREATE TABLE foo2 (id int) ENGINE=WHOOPSIE
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 5.5.22

System Variables

sql_error_log

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--sql-error-log=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

---

sql_error_log_filename

- **Description:** The name of the logfile. Rotation of it will be named like *`sql_error_log_filename`*`.001`
- **Commandline:** `--sql-error-log-filename=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `sql_errors.log`

---

sql_error_log_rate

- **Description:** The rate of logging. `SET sql_error_log_rate=300;` means that one of 300 errors will be written to the log.
  If `sql_error_log_rate` is `0` the logging is disabled.
  The default rate is `1` (every error is logged).
- **Commandline:** `--sql-error-log-rate=#`
- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`

---

sql_error_log_rotate

- **Description:** This is the 'write-only' variable. Assigning TRUE to this variable forces the log rotation.
- **Commandline:** `--sql-error-log-rotate={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

sql_error_log_rotations

- **Description:** The number of rotations. When rotated, the current log file is stored and the new empty one created. The sql_error_log_rotations logs are stored, older are removed.
  The default number of rotations is `9` .
- **Commandline:** `--sql-error-log-rotations`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `9`
- **Range:** `1` to `999`

---

sql_error_log_size_limit

- **Description:** The limitation for the size of the log file. After reaching the specified limit, the log file is rotated. 1M limit set by default.
- **Commandline:** `--sql-error-log-size-limit=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1000000`
- **Range:** `100` to `9223372036854775807`

---

sql_error_log_warnings

- **Description:** If set, log warnings in addition to errors.
- **Commandline:** `--sql-error-log-warnings={0,1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.11.6

3.3.4.6.6 User Statistics

5.4.11.9 User Variables Plugin

The `user_variables` plugin creates the USER_VARIABLES table in the INFORMATION_SCHEMA database. This table contains information about user-defined variables.

Contents

Installing the Plugin

In current versions, the `user_variables` plugin is statically linked into the server by default, so it does not need to be installed.

Prior to MariaDB 10.2.6, although the plugin's shared library is distributed with MariaDB by default, the plugin was not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'user_variables';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = user_variables
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'user_variables';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Examples

```
SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| var           | 0              | INT           | utf8               |
| var2          | abc            | VARCHAR       | utf8               |
+---------------+----------------+---------------+--------------------+
```

Flushing User-Defined Variables

User-defined variables are reset and the Information Schema table emptied with the FLUSH USER_VARIABLES statement.

```
SET @str = CAST(123 AS CHAR(5));

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| str           | 123            | VARCHAR       | utf8mb3            |
+---------------+----------------+---------------+--------------------+

FLUSH USER_VARIABLES;

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
Empty set (0.000 sec)
```

Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.3.13
1.0	Gamma	MariaDB 10.2.6
1.0	Alpha	MariaDB 10.2.0

Options

`user_variables`

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--user-variables=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.10 Disks Plugin

The `DISKS` plugin creates the DISKS table in the INFORMATION_SCHEMA database. This table shows metadata about disks on the system.

Before MariaDB 10.4.7, MariaDB 10.3.17 and MariaDB 10.2.26, this plugin did **not** check user privileges. When it is enabled, **any** user can query the `INFORMATION_SCHEMA.DISKS` table and see all the information it provides.

Since MariaDB 10.4.7, MariaDB 10.3.17 and MariaDB 10.2.26, it required the FILE privilege.

The plugin only works on Linux.

Contents

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN. For example:

```
INSTALL SONAME 'disks';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = disks
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN. For example:

```
UNINSTALL SONAME 'disks';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Example

```
SELECT * FROM information_schema.DISKS;

+-----------+-------+----------+---------+-----------+
| Disk      | Path  | Total    | Used    | Available |
+-----------+-------+----------+---------+-----------+
| /dev/vda1 | /     | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /boot | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /etc  | 26203116 | 2178424 |  24024692 |
+-----------+-------+----------+---------+-----------+
```

Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26, MariaDB 10.1.41
1.0	Beta	MariaDB 10.3.6, MariaDB 10.2.14, MariaDB 10.1.32

Options

disks

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - OFF - Disables the plugin without removing it from the mysql.plugins table.
    - ON - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - FORCE - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - FORCE_PLUS_PERMANENT - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.

    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--disks=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

5.4.11.11 Compression Plugins

MariaDB starting with 10.7.0
Compressions plugins were added in a MariaDB 10.7.0 preview release.

Contents

The various MariaDB storage engines, such as InnoDB, RocksDB, Mroonga, can use different compression libraries.

Before MariaDB 10.7.0, each separate library would have to be compiled in in order to be available for use, resulting in numerous runtime/rpm/deb dependencies, most of which would never be used by users.

From MariaDB 10.7.0, five additional MariaDB compression libraries (besides the default zlib) are available as plugins (note that these affect InnoDB and Mroonga only; RocksDB still uses the compression algorithms from its own library):

- bzip2
- lzma
- lz4
- lzo
- snappy

Installing

Depending on how MariaDB was installed, the libraries may already be available for installation, or may first need to be installed as .deb or .rpm packages, for example:

```
apt-get install mariadb-plugin-provider-lz4
```

Once available, install as a plugin, for example:

```
INSTALL SONAME 'provider_lz4';
```

The compression algorithm can then be used, for example, in InnoDB compression:

```
SET GLOBAL innodb_compression_algorithm = lz4;
```

Upgrading

When upgrading from a release without compression plugins, if a non-zlib compression algorithm was used, those tables will be unreadable until the appropriate compression library is installed. mariadb-upgrade should be run. The `--force` option (to run mariadb-check) or `mariadb-check` itself will indicate any problems with compression, for example:

```
Warning  : MariaDB tried to use the LZMA compression, but its provider plugin is not loaded

Error    : Table 'test.t' doesn't exist in engine

status   : Operation failed
```

or

```
Error    : Table test/t is compressed with lzma, which is not currently loaded.
  Please load the lzma provider plugin to open the table

error    : Corrupt
```

In this case, the appropriate compression plugin should be installed, and the server restarted.

6 Training & Tutorials

This section provides tutorials for those who want to learn about MariaDB and related software.

Beginner MariaDB Articles
Tutorials for newcomers and beginners to MariaDB.

Basic MariaDB Articles
Basic tutorials -- more advanced than beginner.

Intermediate MariaDB Articles
Intermediate level tutorials for MariaDB developers and administrators.

Advanced MariaDB Articles
Tutorial articles for advanced MariaDB developers and administrators.

Books on MariaDB

Beginner Books
List of books on MariaDB for newcomers and beginners.

Intermediate and Advanced Books
List of books on MariaDB for intermediate and advanced developers and administrators.

Books on MariaDB Code
List of books on coding MariaDB Server and plugins.

6.1 Beginner MariaDB Articles

These tutorial articles were written for those who very little about databases and nothing about MariaDB. They are articles for newcomers and beginners.

A MariaDB Primer
A 10-minute primer on using MariaDB.

MariaDB Basics
Basic article on using MariaDB.

Getting Data from MariaDB
Extensive tutorial on using the SELECT statement.

Adding and Changing Data in MariaDB
Tutorial on using INSERT and UPDATE statements.

Altering Tables in MariaDB
Tutorial on using the ALTER TABLE statement.

Changing Times in MariaDB
Tutorial on using various time and date functions in MariaDB.

Doing Time with MariaDB
Tutorial about temporal data types and functions.

Importing Data into MariaDB
Tutorial on using the LOAD DATA INFILE statement.

Making Backups with mariadb-dump
Tutorial article on how to make back-ups with mariadb-dump.

MariaDB String Functions
Extensive tutorial on how to use several string functions.

Restoring Data from Dump Files

Tutorial on how to restore data from a mariadb-dump backup.

Basic SQL Statements

Basic SQL statements for structuring and manipulating data.

Connecting to MariaDB

Connecting to MariaDB with the basic connection parameters.

External Tutorials

Links to external MariaDB, MySQL and SQL tutorials.

Useful MariaDB Queries

Quick reference of commonly-used MariaDB queries.

6.1.1 A MariaDB Primer

Contents

This primer is designed to teach you the basics of getting information into and out of an existing MariaDB database using the mariadb command-line client program. It's not a complete reference and will not touch on any advanced topics. It is just a quick jump-start into using MariaDB.

Logging into MariaDB

Log into your MariaDB server from the command-line like so:

```
mariadb -u user_name -p -h ip_address db_name
```

Replace *user_name* with your database username. Replace *ip_address* with the host name or address of your server. If you're accessing MariaDB from the same server you're logged into, then don't include `-h` and the *ip_address*. Replace *db_name* with the name of the database you want to access (such as *test*, which sometimes comes already created for testing purposes - note that Windows does not create this database, and some setups may also have removed the `test` database by running mariadb-secure-installation, in which case you can leave the *db_name* out).

When prompted to enter your password, enter it. If your login is successful you should see something that looks similar to this:

```
MariaDB [test]>
```

This is where you will enter in all of your SQL statements. More about those later. For now, let's look at the components of the prompt: The "MariaDB" part means you that you are connected to a MariaDB database server. The word between the brackets is the name of your default database, the *test* database in this example.

The Basics of a Database

To make changes to a database or to retrieve data, you will need to enter an SQL statement. SQL stands for Structured Query Language. An SQL statement that requests data is called a query. Databases store information in tables. They're are similar to spreadsheets, but much more efficient at managing data.

Note that the *test* database may not contain any data yet. If you want to follow along with the primer, copy and paste the following into the mariadb client. This will create the tables we will use and add some data to them. Don't worry about understanding them yet; we'll get to that later.

```
CREATE DATABASE IF NOT EXISTS test;

USE test;

CREATE TABLE IF NOT EXISTS books (
  BookID INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
  Title VARCHAR(100) NOT NULL,
  SeriesID INT, AuthorID INT);

CREATE TABLE IF NOT EXISTS authors
(id INT NOT NULL PRIMARY KEY AUTO_INCREMENT);

CREATE TABLE IF NOT EXISTS series
(id INT NOT NULL PRIMARY KEY AUTO_INCREMENT);

INSERT INTO books (Title,SeriesID,AuthorID)
VALUES('The Fellowship of the Ring',1,1),
      ('The Two Towers',1,1), ('The Return of the King',1,1),
      ('The Sum of All Men',2,2), ('Brotherhood of the Wolf',2,2),
      ('Wizardborn',2,2), ('The Hobbbit',0,1);
```

Notice the semi-colons used above. The mariadb client lets you enter very complex SQL statements over multiple lines. It won't send an SQL statement until you type a semi-colon and hit [Enter].

Let's look at what you've done so far. Enter the following:

```
SHOW TABLES;

+---------------+
| Tables_in_test |
+---------------+
| authors        |
| books          |
| series         |
+---------------+
3 rows in set (0.00 sec)
```

Notice that this displays a list of the tables in the database. If you didn't already have tables in your `test` database, your results should look the same as above. Let's now enter the following to get information about one of these tables:

```
DESCRIBE books;

+----------+-------------+------+-----+---------+----------------+
| Field    | Type        | Null | Key | Default | Extra          |
+----------+-------------+------+-----+---------+----------------+
| BookID   | int(11)     | NO   | PRI | NULL    | auto_increment |
| Title    | varchar(100) | NO   |     | NULL    |                |
| SeriesID | int(11)     | YES  |     | NULL    |                |
| AuthorID | int(11)     | YES  |     | NULL    |                |
+----------+-------------+------+-----+---------+----------------+
```

The main bit of information of interest to us is the *Field* column. The other columns provide useful information about the structure and type of data in the database, but the *Field* column gives us the names, which is needed to retrieve data from the table.

Let's retrieve data from the `books` table. We'll do so by executing a SELECT statement like so:

```
SELECT * FROM books;

+--------+---------------------------+----------+----------+
| BookID | Title                     | SeriesID | AuthorID |
+--------+---------------------------+----------+----------+
|      1 | The Fellowship of the Ring |        1 |        1 |
|      2 | The Two Towers             |        1 |        1 |
|      3 | The Return of the King     |        1 |        1 |
|      4 | The Sum of All Men         |        2 |        2 |
|      5 | Brotherhood of the Wolf    |        2 |        2 |
|      6 | Wizardborn                 |        2 |        2 |
|      7 | The Hobbbit                |        0 |        1 |
+--------+---------------------------+----------+----------+
7 rows in set (0.00 sec)
```

This SQL statement or query asks the database to show us all of the data in the `books` table. The wildcard ('`*`') character indicates to select all columns.

Inserting Data

Suppose now that we want to add another book to this table. We'll add the book, *Lair of Bones*. To insert data into a table, you would use the INSERT statement. To insert information on a book, we would enter something like this:

```
INSERT INTO books (Title, SeriesID, AuthorID)
VALUES ("Lair of Bones", 2, 2);

Query OK, 1 row affected (0.00 sec)
```

Notice that we put a list of columns in parentheses after the name of the table, then we enter the keyword `VALUES` followed by a list of values in parentheses--in the same order as the columns were listed. We could put the columns in a different order, as long as the values are in the same order as we list the columns. Notice the message that was returned indicates that the execution of the SQL statement went fine and one row was entered.

Execute the following SQL statement again and see what results are returned:

```
SELECT * FROM books;
```

You should see the data you just entered on the last row of the results. In looking at the data for the other books, suppose we notice that the title of the seventh book is spelled wrong. It should be spelled *The Hobbit*, not *The Hobbbit*. We will need to update the data for that row.

Modifying Data

To change data in a table, you will use the UPDATE statement. Let's change the spelling of the book mentioned above. To do this, enter the following:

```
UPDATE books
SET Title = "The Hobbit"
WHERE BookID = 7;

Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

Notice the syntax of this SQL statement. The `SET` clause is where you list the columns and the values to set them. The `WHERE` clause says that you want to update only rows in which the `BookID` column has a value of `7`, of which there are only one. You can see from the message it returned that one row matched the `WHERE` clause and one row was changed. There are no warnings because everything went fine. Execute the SELECT from earlier to see that the data changed.

As you can see, using MariaDB isn't very difficult. You just have to understand the syntax of SQL since it doesn't allow for typing mistakes or things in the wrong order or other deviations.

6.1.2 MariaDB Basics

Contents

Connecting to MariaDB

MariaDB is a database system, a database server. To interface with the MariaDB server, you can use a client program, or you can write a program or script with one of the popular programming languages (e.g., PHP) using an API (Application Programming Interface) to interface with the MariaDB server. For the purposes of this article, we will focus on using the

default client that comes with MariaDB called `mariadb`. With this client, you can either enter queries from the command-line, or you can switch to a terminal, that is to say, monitor mode. To start, we'll use the latter.

From the Linux command-line, you would enter the following to log in as the root user and to enter monitor mode:

```
mariadb -u root -p -h localhost
```

The `-u` option is for specifying the user name. You would replace `root` here if you want to use a different user name. This is the MariaDB user name, not the Linux user name. The password for the MariaDB user `root` will probably be different from the Linux user `root`. Incidentally, it's not a good security practice to use the `root` user unless you have a specific administrative task to perform for which only `root` has the needed privileges.

The `-p` option above instructs the `mariadb` client to prompt you for the password. If the password for the `root` user hasn't been set yet, then the password is blank and you would just hit [Enter] when prompted. The `-h` option is for specifying the host name or the IP address of the server. This would be necessary if the client is running on a different machine than the server. If you've secure-shelled into the server machine, you probably won't need to use the host option. In fact, if you're logged into Linux as `root`, you won't need the user option—the `-p` is all you'll need. Once you've entered the line above along with the password when prompted, you will be logged into MariaDB through the client. To exit, type quit or exit and press [Enter].

Creating a Structure

In order to be able to add and to manipulate data, you first have to create a database structure. Creating a database is simple. You would enter something like the following from within the mariadb client:

```
CREATE DATABASE bookstore;

USE bookstore;
```

This very minimal, first SQL statement will create a sub-directory called bookstore on the Linux filesystem in the directory which holds your MariaDB data files. It won't create any data, obviously. It'll just set up a place to add tables, which will in turn hold data. The second SQL statement above will set this new database as the default database. It will remain your default until you change it to a different one or until you log out of MariaDB.

The next step is to begin creating tables. This is only a little more complicated. To create a simple table that will hold basic data on books, we could enter something like the following:

```
CREATE TABLE books (
isbn CHAR(20) PRIMARY KEY,
title VARCHAR(50),
author_id INT,
publisher_id INT,
year_pub CHAR(4),
description TEXT );
```

This SQL statement creates the table books with six fields, or rather columns. The first column (isbn) is an identification number for each row—this name relates to the unique identifier used in the book publishing business. It has a fixed-width character type of 20 characters. It will be the primary key column on which data will be indexed. The column data type for the book title is a variable width character column of fifty characters at most. The third and fourth columns will be used for identification numbers for the author and the publisher. They are integer data types. The fifth column is used for the publication year of each book. The last column is for entering a description of each book. It's a TEXT data type, which means that it's a variable width column and it can hold up to 65535 bytes of data for each row. There are several other data types that may be used for columns, but this gives you a good sampling.

To see how the table we created looks, enter the following SQL statement:

```
DESCRIBE books;
+-------------+-------------+------+-----+---------+-------+
| Field       | Type        | Null | Key | Default | Extra |
+-------------+-------------+------+-----+---------+-------+
| isbn        | char(20)    | NO   | PRI | NULL    |       |
| title       | varchar(50) | YES  |     | NULL    |       |
| author_id   | int(11)     | YES  |     | NULL    |       |
| publisher_id | int(11)    | YES  |     | NULL    |       |
| year_pub    | char(4)     | YES  |     | NULL    |       |
| description | text        | YES  |     | NULL    |       |
+-------------+-------------+------+-----+---------+-------+
```

To change the settings of a table, you can use the ALTER TABLE statement. I'll cover that statement in another article. To delete a table completely (including its data), you can use the DROP TABLE statement, followed by the table name. Be careful with this statement since it's not reversible.

The next table we'll create for our examples is the authors table to hold author information. This table will save us from having to enter the author's name and other related data for each book written by each author. It also helps to ensure consistency of data: there's less chance of inadvertent spelling deviations.

```
CREATE TABLE authors
(author_id INT AUTO_INCREMENT PRIMARY KEY,
name_last VARCHAR(50),
name_first VARCHAR(50),
country VARCHAR(50) );
```

We'll join this table to the books table as needed. For instance, we would use it when we want a list of books along with their corresponding authors' names. For a real bookstore's database, both of these tables would probably have more columns. There would also be several more tables. For the examples that follow, these two tables as they are will be enough.

Minor Items

Before moving on to the next step of adding data to the tables, let me point out a few minor items that I've omitted mentioning. SQL statements end with a semi-colon (or a \G). You can spread an SQL statement over multiple lines. However, it won't be passed to the server by the client until you terminate it with a semi-colon and hit [Enter]. To cancel an SQL statement once you've started typing it, enter `\c` and press [Enter].

As a basic convention, reserved words are printed in all capital letters. This isn't necessary, though. MariaDB is case-insensitive with regards to reserved words. Database and table names, however, are case-sensitive on Linux. This is because they reference the related directories and files on the filesystem. Column names aren't case sensitive since they're not affected by the filesystem, per se. As another convention, we use lower-case letters for structural names (e.g., table names). It's a matter of preference for deciding on names.

Entering Data

The primary method for entering data into a table is to use the INSERT statement. As an example, let's enter some information about an author into the authors table. We'll do that like so:

```
INSERT INTO authors
(name_last, name_first, country)
VALUES('Kafka', 'Franz', 'Czech Republic');
```

This will add the name and country of the author Franz Kafka to the authors table. We don't need to give a value for the author_id since that column was created with the AUTO_INCREMENT option. MariaDB will automatically assign an identification number. You can manually assign one, especially if you want to start the count at a higher number than 1 (e.g., 1000). Since we are not providing data for all of the columns in the table, we have to list the columns for which we are giving data and in the order that the data is given in the set following the VALUES keyword. This means that we could give the data in a different order.

For an actual database, we would probably enter data for many authors. We'll assume that we've done that and move on to entering data for some books. Below is an entry for one of Kafka's books:

```
INSERT INTO books
(title, author_id, isbn, year_pub)
VALUES('The Castle', '1', '0805211063', '1998');
```

This adds a record for Kafka's book, *The Castle*. Notice that we mixed up the order of the columns, but it still works because both sets agree. We indicate that the author is Kafka by giving a value of 1 for the author_id. This is the value that was assigned by MariaDB when we entered the row for Kafka earlier. Let's enter a few more books for Kafka, but by a different method:

```
INSERT INTO books
(title, author_id, isbn, year_pub)
VALUES('The Trial', '1', '0805210407', '1995'),
('The Metamorphosis', '1', '0553213695', '1995'),
('America', '1', '0805210644', '1995');
```

In this example, we've added three books in one statement. This allows us to give the list of column names once. We also give the keyword `VALUES` only once, followed by a separate set of values for each book, each contained in parentheses and separated by commas. This cuts down on typing and speeds up the process. Either method is fine and both have their

advantages. To be able to continue with our examples, let's assume that data on thousands of books has been entered. With that behind us, let's look at how to retrieve data from tables.

Retrieving Data

The primary method of retrieving data from tables is to use a SELECT statement. There are many options available with the SELECT statement, but you can start simply. As an example, let's retrieve a list of book titles from the books table:

```
SELECT title
FROM books;
```

This will display all of the rows of books in the table. If the table has thousands of rows, MariaDB will display thousands. To limit the number of rows retrieved, we could add a LIMIT clause to the SELECT statement like so:

```
SELECT title
FROM books
LIMIT 5;
```

This will limit the number of rows displayed to five. To be able to list the author's name for each book along with the title, you will have to join the books table with the authors table. To do this, we can use the JOIN clause like so:

```
SELECT title, name_last
FROM books
JOIN authors USING (author_id);
```

Notice that the primary table from which we're drawing data is given in the `FROM` clause. The table to which we're joining is given in the JOIN clause along with the commonly named column (i.e., author_id) that we're using for the join.

To retrieve the titles of only books written by Kafka based on his name (not the author_id), we would use the `WHERE` clause with the SELECT statement. This would be entered like the following:

```
SELECT title AS 'Kafka Books'
FROM books
JOIN authors USING (author_id)
WHERE name_last = 'Kafka';

+-------------------+
| Kafka Books       |
+-------------------+
| The Castle        |
| The Trial         |
| The Metamorphosis |
| America           |
+-------------------+
```

This statement will list the titles of Kafka books stored in the database. Notice that I've added the `AS` parameter next to the column name title to change the column heading in the results set to Kafka Books. This is known as an alias. Looking at the results here, we can see that the title for one of Kafka's books is incorrect. His book Amerika is spelled above with a "c" in the table instead of a "k". This leads to the next section on changing data.

Changing & Deleting Data

In order to change existing data, a common method is to use the UPDATE statement. When changing data, though, we need to be sure that we change the correct rows. In our example, there could be another book with the title *America* written by a different author. Since the key column isbn has only unique numbers and we know the ISBN number for the book that we want to change, we can use it to specify the row.

```
UPDATE books
SET title = 'Amerika'
WHERE isbn = '0805210644';
```

This will change the value of the title column for the row specified. We could change the value of other columns for the same row by giving the column = value for each, separated by commas.

If we want to delete a row of data, we can use the DELETE statement. For instance, suppose that our fictitious bookstore has decided no longer to carry books by John Grisham. By first running a SELECT statement, we determine the identification number for the author to be 2034. Using this author identification number, we could enter the following:

```
DELETE FROM books
WHERE author_id = '2034';
```

This statement will delete all rows from the table books for the author_id given. To do a clean job of it, we'll have to do the same for the authors table. We would just replace the table name in the statement above; everything else would be the same.

Conclusion

This is a very basic primer for using MariaDB. Hopefully, it gives you the idea of how to get started with MariaDB. Each of the SQL statements mentioned here have several more options and clauses each. We will cover these statements and others in greater detail in other articles. For now, though, you can learn more about them from experimenting and by further reading of the Knowledge Base online documentation. A downloadable PDF of much of the documentation is available here.

6.1.3 Getting Data from MariaDB

Contents

The simplest way to retrieve data from MariaDB is to use the SELECT statement. Since the SELECT statement is an essential SQL statement, it has many options available with it. It's not necessary to know or use them all—you could execute very basic SELECT statements if that satisfies your needs. However, as you use MariaDB more, you may need more powerful SELECT statements. In this article we will go through the basics of SELECT and will progress to more involved SELECT statements;we will move from the beginner level to the more intermediate and hopefully you will find some benefit from this article regardless of your skill level. For absolute beginners who are just starting with MariaDB, you may want to read the MariaDB Basics article.

Basic Elements

The basic, minimal elements of the SELECT statement call for the keyword `SELECT`, of course, the columns to select or to retrieve, and the table from which to retrieve rows of data. Actually, for the columns to select, we can use the asterisk as a wildcard to select all columns in a particular table. Using a database from a fictitious bookstore, we might enter the following SQL statement to get a list of all columns and rows in a table containing information on books:

```
SELECT * FROM books;
```

This will retrieve all of the data contained in the `books` table. If we want to retrieve only certain columns, we would list them in place of the asterisk in a comma-separated list like so:

```
SELECT isbn, title, author_id
FROM books;
```

This narrows the width of the results set by retrieving only three columns, but it still retrieves all of the rows in the table. If the table contains thousands of rows of data, this may be more data than we want. If we want to limit the results to just a few books, say five, we would include what is known as a LIMIT clause:

```
SELECT isbn, title, author_id
FROM books
LIMIT 5;
```

This will give us the first five rows found in the table. If we want to get the next ten found, we would add a starting point parameter just before the number of rows to display, separated by a comma:

```
SELECT isbn, title, author_id
FROM books
LIMIT 5, 10;
```

Selectivity and Order

The previous statements have narrowed the number of columns and rows retrieved, but they haven't been very selective. Suppose that we want only books written by a certain author, say Dostoevsky. Looking in the authors table we find that his author identification number is 4729. Using a `WHERE` clause, we can retrieve a list of books from the database for this particular author like so:

```
SELECT isbn, title
FROM books
WHERE author_id = 4729
LIMIT 5;
```

I removed the author_id from the list of columns to select, but left the basic LIMIT clause in because we want to point out that the syntax is fairly strict on ordering of clauses and flags. You can't enter them in any order. You'll get an error in return.

The SQL statements we've looked at thus far will display the titles of books in the order in which they're found in the database. If we want to put the results in alphanumeric order based on the values of the title column, for instance, we would add an ORDER BY clause like this:

```
SELECT isbn, title
FROM books
WHERE author_id = 4729
ORDER BY title ASC
LIMIT 5;
```

Notice that the ORDER BY clause goes after the `WHERE` clause and before the LIMIT clause. Not only will this statement display the rows in order by book title, but it will retrieve only the first five based on the ordering. That is to say, MariaDB will first retrieve all of the rows based on the `WHERE` clause, order the data based on the ORDER BY clause, and then display a limited number of rows based on the LIMIT clause. Hence the reason for the order of clauses. You may have noticed that we slipped in the ASC flag. It tells MariaDB to order the rows in ascending order for the column name it follows. It's not necessary, though, since ascending order is the default. However, if we want to display data in descending order, we would replace the flag with `DESC`. To order by more than one column, additional columns may be given in the ORDER BY clause in a comma separated list, each with the `ASC` or `DESC` flags if preferred.

Friendlier and More Complicated

So far we've been working with one table of data containing information on books for a fictitious bookstore. A database will usually have more than one table, of course. In this particular database, there's also one called authors in which the name and other information on authors is contained. To be able to select data from two tables in one SELECT statement, we will have to tell MariaDB that we want to join the tables and will need to provide a join point. This can be done with a JOIN clause as shown in the following SQL statement, with the results following it:

```
SELECT isbn, title,
CONCAT(name_first, ' ', name_last) AS author
FROM books
JOIN authors USING (author_id)
WHERE name_last = 'Dostoevsky'
ORDER BY title ASC
LIMIT 5;

+------------+-----------------------+-------------------+
| isbn       | title                 | author            |
+------------+-----------------------+-------------------+
|  0553212168 | Brothers Karamozov    | Fyodor Dostoevsky |
|  0679420290 | Crime & Punishment    | Fyodor Dostoevsky |
|  0553211757 | Crime & Punishment    | Fyodor Dostoevsky |
|  0192834118 | Idiot                 | Fyodor Dostoevsky |
|  067973452X | Notes from Underground | Fyodor Dostoevsky |
+------------+-----------------------+-------------------+
5 rows in set (0.00 sec)
```

Our SELECT statement is getting hefty, but it's the same one to which we've been adding. Don't let the clutter fluster you. Looking for the new elements, let's focus on the JOIN clause first. There are a few possible ways to construct a join. This method works if you're using a newer version of MariaDB and if both tables contain a column of the same name and value. Otherwise you'll have to redo the JOIN clause to look something like this:

```
...
JOIN authors ON author_id = row_id
...
```

This excerpt is based on the assumption that the key field in the authors table is not called author_id, but row_id instead. There's much more that can be said about joins, but that would make for a much longer article. If you want to learn more on joins, look at MariaDB's documentation page on JOIN syntax.

Looking again at the last full SQL statement above, you must have spotted the CONCAT() function that we added to the on-going example statement. This string function takes the values of the columns and strings given and pastes them together, to give one neat field in the results. We also employed the AS parameter to change the heading of the results set for the field to author. This is much tider. Since we joined the books and the authors tables together, we were able to search for books based on the author's last name rather than having to look up the author ID first. This is a much friendlier method, albeit more complicated. Incidentally, we can have MariaDB check columns from both tables to narrow our search. We would just add *column* = *value* pairs, separated by commas in the WHERE clause. Notice that the string containing the author's name is wrapped in quotes—otherwise, the string would be considered a column name and we'd get an error.

The name Dostoevsky is sometimes spelled Dostoevskii, as well as a few other ways. If we're not sure how it's spelled in the authors table, we could use the LIKE operator instead of the equal-sign, along with a wildcard. If we think the author's name is probably spelled either of the two ways mentioned, we could enter something like this:

```
SELECT isbn, title,
CONCAT(name_first, ' ', name_last) AS author
FROM books
JOIN authors USING (author_id)
WHERE name_last LIKE 'Dostoevsk%'
ORDER BY title ASC
LIMIT 5;
```

This will match any author last name starting with Dostoevsk. Notice that the wildcard here is not an asterisk, but a percent-sign.

Some Flags

There are many flags or parameters that can be used in a SELECT statement. To list and explain all of them with examples would make this a very lengthy article. The reality is that most people never use some of them anyway. So, let's take a look at a few that you may find useful as you get more involved with MariaDB or if you work with large tables on very active servers.

The first flag that may be given, it goes immediately after the `SELECT` keyword, is `ALL`. By default, all rows that meet the requirements of the various clauses given are selected, so this isn't necessary. If instead we would only want the first occurrence of a particular criteria to be displayed, we could add the DISTINCT option. For instance, for authors like Dostoevsky there will be several printings of a particular title. In the results shown earlier you may have noticed that there were two copies of *Crime & Punishment* listed, however they have different ISBN numbers and different publishers. Suppose that for our search we only want one row displayed for each title. We could do that like so:

```
SELECT DISTINCT isbn, title
FROM books
JOIN authors USING (author_id)
WHERE name_last = 'Dostoevsky'
ORDER BY title;
```

We've thinned out the ongoing SQL statement a bit for clarity. This statement will result in only one row displayed for *Crime & Punishment* and it will be the first one found.

If we're retrieving data from an extremely busy database, by default any other SQL statements entered simultaneously which are changing or updating data will be executed before a SELECT statement. SELECT statements are considered to be of lower priority. However, if we would like a particular SELECT statement to be given a higher priority, we can add the keyword HIGH_PRIORITY. Modifying the previous SQL statement for this factor, we would enter it like this:

```
SELECT DISTINCT HIGH_PRIORITY isbn, title
FROM books
JOIN authors USING (author_id)
WHERE name_last = 'Dostoevsky'
ORDER BY title;
```

You may have noticed in the one example earlier in which the results are shown, that there's a status line displayed that specifies the number of rows in the results set. This is less than the number of rows that were found in the database that met the statement's criteria. It's less because we used a LIMIT clause. If we add the SQL_CALC_FOUND_ROWS flag just before the column list, MariaDB will calculate the number of columns found even if there is a LIMIT clause.

```
SELECT SQL_CALC_FOUND_ROWS isbn, title
FROM books
JOIN authors USING (author_id)
WHERE name_last = 'Dostoevsky'
LIMIT 5;
```

To retrieve this information, though, we will have to use the FOUND_ROWS() function like so:

```
SELECT FOUND_ROWS();

+--------------+
| FOUND_ROWS() |
+--------------+
|           26 |
+--------------+
```

This value is temporary and will be lost if the connection is terminated. It cannot be retrieved by any other client session. It relates only to the current session and the value for the variable when it was last calculated.

Conclusion

There are several more parameters and possibilities for the SELECT statement that we had to skip to keep this article a reasonable length. A popular one that we left out is the GROUP BY clause for calculating aggregate data for columns (e.g., an average). There are several flags for caching results and a clause for exporting a results set to a text file. If you would like to learn more about SELECT and all of the options available, look at the on-line documentation for SELECT statements.

6.1.4 Adding and Changing Data in MariaDB

Contents

There are several ways to add and to change data in MariaDB. There are a few SQL statements that you can use, each with a few options. Additionally, there are twists that you can do by mixing SQL statements together with various clauses. In this article, we will explore the ways in which data can be added and changed in MariaDB.

Adding Data

To add data to a table in MariaDB, you will need to use the INSERT statement. Its basic, minimal syntax is the command INSERT followed by the table name and then the keyword VALUES with a comma separated list of values contained in parentheses:

```
INSERT table1
VALUES('text1','text2','text3');
```

In this example, text is added to a table called table1, which contains only three columns —the same number of values that we're inserting. The number of columns must match. If you don't want to insert data into all of the columns of a table, though, you could name the columns desired:

```
INSERT INTO table1
(col3, col1)
VALUES('text3','text1');
```

Notice that the keyword `INTO` was added here. This is optional and has no effect on MariaDB. It's only a matter of grammatical preference. In this example we not only name the columns, but we list them in a different order. This is acceptable to MariaDB. Just be sure to list the values in the same order. If you're going to insert data into a table and want to specify all of the values except one (say the key column since it's an auto-incremented one), then you could just give a value of DEFAULT to keep from having to list the columns. Incidentally, you can give the column names even if you're naming all of them. It's just unnecessary unless you're going to reorder them as we did in this last example.

When you have many rows of data to insert into the same table, it can be more efficient to insert all of the rows in one SQL

statement. Multiple row insertions can be done like so:

```
INSERT IGNORE
INTO table2
VALUES('id1','text','text'),
('id2','text','text'),
('id2','text','text');
```

Notice that the keyword VALUES is used only once and each row is contained in its own set of parentheses and each set is separated by commas. We've added an intentional mistake to this example: We are attempting to insert three rows of data into table2 for which the first column happens to be a `UNIQUE` key field. The third row entered here has the same identification number for the key column as the second row. This would normally result in an error and none of the three rows would be inserted. However, since the statement has an `IGNORE` flag, duplicates will be ignored and not inserted, but the other rows will still be inserted. So, the first and second rows above will be inserted and the third one won't.

Priority

An INSERT statement takes priority over read statements (i.e., SELECT statements). An INSERT will lock the table and force other clients to wait until it's finished. On a busy MariaDB server that has many simultaneous requests for data, this could cause users to experience delays when you run a script that performs a series of INSERT statements. If you don't want user requests to be put on hold and you can wait to insert the data, you could use the `LOW_PRIORITY` flag:

```
INSERT LOW_PRIORITY
INTO table1
VALUES('text1','text2','text3');
```

The `LOW_PRIORITY` flag will put the INSERT statement in queue, waiting for all current and pending requests to be completed before it's performed. If new requests are made while a low priority statement is waiting, then they are put ahead of it in the queue. MariaDB does not begin to execute a low priority statement until there are no other requests waiting. Once the transaction begins, though, the table is locked and any other requests for data from the table that come in after it starts must wait until it's completed. Because it locks the table, low priority statements will prevent simultaneous insertions from other clients even if you're dealing with a MyISAM table. Incidentally, notice that the `LOW_PRIORITY` flag comes before the `INTO`.

One potential inconvenience with an `INSERT LOW_PRIORITY` statement is that the client will be tied up waiting for the statement to be completed successfully. So if you're inserting data into a busy server with a low priority setting using the mariadb client, your client could be locked up for minutes, maybe hours depending on how busy your server is at the time. As an alternative either to making other clients with read requests wait or to having your client wait, you can use the DELAYED flag instead of the `LOW_PRIORITY` flag:

```
INSERT DELAYED
INTO table1
VALUES('text1','text2','text3');
```

MariaDB will take the request as a low priority one and put it on its list of tasks to perform when it has a break. However, it will immediately release the client so that the client can go on to enter other SQL statements or even exit. Another advantage of this method is that multiple `INSERT DELAYED` requests are batched together for block insertion when there is a gap, making the process potentially faster than `INSERT LOW_PRIORITY`. The flaw in this choice, however, is that the client is never told if a delayed insertion is successfully made or not. The client is informed of error messages when the statement is entered—the statement has to be valid before it will be queued—but it's not told of problems that occur after it's accepted. This brings up another flaw: delayed insertions are stored in the server's memory. So if the MariaDB daemon (mariadbd) dies or is manually killed, then the transactions are lost and the client is not notified of the failure. So DELAYED is not always a good alternative.

Contingent Additions

As an added twist to INSERT, you can combine it with a SELECT statement. Suppose that you have a table called employees which contains employee information for your company. Suppose further that you have a column to indicate whether an employee is on the company's softball team. However, you one day decide to create a separate database and table for the softball team's data that someone else will administer. To get the database ready for the new administrator, you have to copy some data for team members to the new table. Here's one way you can accomplish this task:

```
INSERT INTO softball_team
(last, first, telephone)
SELECT name_last, name_first, tel_home
FROM company.employees
WHERE softball='Y';
```

In this SQL statement the columns in which data is to be inserted into are listed, then the complete SELECT statement follows with the appropriate WHERE clause to determine if an employee is on the softball team. Since we're executing this statement from the new database and since the table employees is in a separate database called company, we have to specify it as you see here. By the way, INSERT...SELECT statements cannot be performed on the same table.

Replacement Data

When you're adding massive amounts of data to a table that has a key field, as mentioned earlier, you can use the `IGNORE` flag to prevent duplicates from being inserted, but still allow unique rows to be entered. However, there may be times when you actually want to replace the rows with the same key fields with the new ones. In such a situation, instead of using INSERT you can use a REPLACE statement:

```
REPLACE LOW_PRIORITY
INTO table2 (id, col1, col2)
VALUES('id1','text','text'),
('id2','text','text'),
('id3','text','text');
```

Notice that the syntax is the same as an INSERT statement. The flags all have the same effect, as well. Also, multiple rows may be inserted, but there's no need for the `IGNORE` flag since duplicates won't happen—the originals are just overwritten. Actually, when a row is replaced, it's first deleted completely and the new row is then inserted. Any columns without values in the new row will be given the default values for the columns. None of the values of the old row are kept. Incidentally, REPLACE will also allow you to combine it with a SELECT statement as we saw with the INSERT statement earlier.

Updating Data

If you want to change the data contained in existing records, but only for certain columns, then you would need to use an UPDATE statement. The syntax for UPDATE is a little bit different from the syntax shown before for INSERT and REPLACE statements:

```
UPDATE LOW_PRIORITY table3
SET col1 = 'text-a', col2='text-b'
WHERE id < 100;
```

In the SQL statement here, we are changing the value of the two columns named individually using the `SET` clause. Incidentally, the `SET` clause optionally can be used in INSERT and REPLACE statements, but it eliminates the multiple row option. In the statement above, we're also using a `WHERE` clause to determine which records are changed: only rows with an id that has a value less than 100 are updated. Notice that the `LOW_PRIORITY` flag can be used with this statement, too. The `IGNORE` flag can be used, as well.

A useful feature of the UPDATE statement is that it allows the use of the current value of a column to update the same column. For instance, suppose you want to add one day to the value of a date column where the date is a Sunday. You could do the following:

```
UPDATE table5
SET col_date = DATE_ADD(col_date, INTERVAL 1 DAY)
WHERE DAYOFWEEK(col_date) = 1;
```

For rows where the day of the week is Sunday, the DATE_ADD() function will take the value of col_date before it's updated and add one day to it. MariaDB will then take this sum and set col_date to it.

There are a couple more twists that you can now do with the UPDATE statement: if you want to update the rows in a specific order, you can add an ORDER BY clause. You can also limit the number of rows that are updated with a LIMIT clause. Below is an example of both of these clauses:

```
UPDATE LOW_PRIORITY table3
SET col1='text-a', col2='text-b'
WHERE id < 100
ORDER BY col3 DESC
LIMIT 10;
```

The ordering can be descending as indicated here by the `DESC` flag, or ascending with either the ASC flag or by just leaving it out, as ascending is the default. The LIMIT clause, of course, limits the number of rows affected to ten here.

If you want to refer to multiple tables in one UPDATE statement, you can do so like this:

```
UPDATE table3, table4
SET table3.col1 = table4.col1
WHERE table3.id = table4.id;
```

Here we see a join between the two tables named. In table3, the value of col1 is set to the value of the same column in table4 where the values of id from each match. We're not updating both tables here; we're just accessing both. We must specify the table name for each column to prevent an ambiguity error. Incidentally, ORDER BY and LIMIT clauses aren't allowed with multiple table updates.

There's another combination that you can do with the INSERT statement that we didn't mention earlier. It involves the UPDATE statement. When inserting multiple rows of data, if you want to note which rows had potentially duplicate entries and which ones are new, you could add a column called status and change it's value accordingly with a statement like this one:

```
INSERT IGNORE INTO table1
(id, col1, col2, status)
VALUES('1012','text','text','new'),
('1025,'text','text','new'),
('1030','text','text','new')
ON DUPLICATE KEY
UPDATE status = 'old';
```

Because of the `IGNORE` flag, errors will not be generated, duplicates won't be inserted or replaced, but the rest will be added. Because of the ON DUPLICATE KEY, the column status of the original row will be set to old when there are duplicate entry attempts. The rest will be inserted and their status set to new.

Conclusion

As you can see from some of these SQL statements, MariaDB offers you quite a few ways to add and to change data. In addition to these methods, there are also some bulk methods of adding and changing data in a table. You could use the LOAD DATA INFILE statement and the mariadb-dump command-line utility. These methods are covered in another article on Importing Data into MariaDB.

6.1.5 Altering Tables in MariaDB

Contents

Despite a MariaDB developer's best planning, occasionally one needs to change the structure or other aspects of tables. This is not very difficult, but some developers are unfamiliar with the syntax for the functions used in MariaDB to accomplish this. And some changes can be very frustrating. In this article we'll explore the ways to alter tables in MariaDB and we'll give some precautions about related potential data problems.

Before Beginning

For the examples in this article, we will refer to a database called `db1` containing a table called `clients`. The `clients` table is for keeping track of client names and addresses. To start off, we'll enter a DESCRIBE statement to see what the table looks like:

```
DESCRIBE clients;

+-------------+-------------+------+-----+---------+-------+
| Field       | Type        | Null | Key | Default | Extra |
+-------------+-------------+------+-----+---------+-------+
| cust_id     | int(11)     |      | PRI | 0       |       |
| name        | varchar(25) | YES  |     | NULL    |       |
| address     | varchar(25) | YES  |     | NULL    |       |
| city        | varchar(25) | YES  |     | NULL    |       |
| state       | char(2)     | YES  |     | NULL    |       |
| zip         | varchar(10) | YES  |     | NULL    |       |
| client_type | varchar(4)  | YES  |     | NULL    |       |
+-------------+-------------+------+-----+---------+-------+
```

This is a very simple table that will hold very little information. However, it's sufficient for the examples here in which we will change several of its columns. Before doing any structural changes to a table in MariaDB, especially if it contains data, one should make a backup of the table to be changed. There are a few ways to do this, but some choices may not be permitted by your web hosting company. Even if your database is on your own server, though, the mariadb-dump utility is typically the best tool for making and restoring backups in MariaDB, and it's generally permitted by web hosting companies. To backup the clients table with mariadb-dump, we will enter the following from the command-line:

```
mariadb-dump --user='username' --password='password' --add-locks db1 clients > clients.sql
```

As you can see, the username and password are given on the first line. On the next line, the `--add-locks` option is used to lock the table before backing up and to unlock automatically it when the backup is finished. There are many other options in mariadb-dump that could be used, but for our purposes this one is all that's necessary. Incidentally, this statement can be entered in one line from the shell (i.e., not from the `mariadb` client), or it can be entered on multiple lines as shown here by using the back-slash (i.e., `/`) to let the shell know that more is to follow. On the third line above, the database name is given, followed by the table name. The redirect (i.e., `>`) tells the shell to send the results of the dump to a text file called `clients.sql` in the current directory. A directory path could be put in front of the file name to create the file elsewhere. If the table should need to be restored, the following can be run from the shell:

```
mariadb --user='username' --password='password' db1 < clients.sql
```

Notice that this line does not use the `mariadb-dump` utility. It uses the `mariadb` client from the outside, so to speak. When the dump file (`clients.sql`) is read into the database, it will delete the `clients` table and it's data in MariaDB before restoring the backup copy with its data. So be sure that users haven't added data in the interim. In the examples in this article, we are assuming that there isn't any data in the tables yet.

Basic Addition and More

In order to add a column to an existing MariaDB table, one would use the ALTER TABLE statement. To demonstrate, suppose that it has been decided that there should be a column for the client's account status (i.e., active or inactive). To make this change, the following is entered:

```
ALTER TABLE clients
ADD COLUMN status CHAR(2);
```

This will add the column `status` to the end with a fixed width of two characters (i.e., *AC* for active and *IA* for inactive). In looking over the table again, it's decided that another field for client apartment numbers or the like needs to be added. That data could be stored in the address column, but it would better for it to be in a separate column. An ALTER TABLE statement could be entered like above, but it will look tidier if the new column is located right after the address column. To do this, we'll use the `AFTER` option:

```
ALTER TABLE clients
ADD COLUMN address2 varchar(25)
AFTER address;
```

By the way, to add a column to the first position, you would replace the last line of the SQL statement above to read like this:

```
...
FIRST;
```

Before moving on, let's take a look at the table's structure so far:

```
DESCRIBE clients;

+-------------+-------------+------+-----+---------+-------+
| Field       | Type        | Null | Key | Default | Extra |
+-------------+-------------+------+-----+---------+-------+
| cust_id     | int(11)     |      | PRI | 0       |       |
| name        | varchar(25) | YES  |     | NULL    |       |
| address     | varchar(25) | YES  |     | NULL    |       |
| address2    | varchar(25) | YES  |     | NULL    |       |
| city        | varchar(25) | YES  |     | NULL    |       |
| state       | char(2)     | YES  |     | NULL    |       |
| zip         | varchar(10) | YES  |     | NULL    |       |
| client_type | varchar(4)  | YES  |     | NULL    |       |
| status      | char(2)     | YES  |     | NULL    |       |
+-------------+-------------+------+-----+---------+-------+
```

Changing One's Mind

After looking over the above table display, it's decided that it might be better if the status column has the choices of 'AC' and 'IA' enumerated. To make this change, we'll enter the following SQL statement:

```
ALTER TABLE clients
CHANGE status status enum('AC','IA');
```

Notice that the column name status is specified twice. Although the column name isn't being changed, it still must be respecified. To change the column name (from `status` to `active`), while leaving the enumerated list the same, we specify the new column name in the second position:

```
ALTER TABLE clients
CHANGE status active ENUM('AC','IA');
```

Here we have the current column name and then the new column name, along with the data type specifications (i.e., `ENUM`), even though the result is only a name change. With the `CHANGE` clause everything must be stated, even items that are not to be changed.

In checking the table structure again, more changes are decided on: The column address is to be renamed to address1 and changed to forty characters wide. Also, the enumeration of active is to have 'yes' and 'no' choices. The problem with changing enumerations is that data can be clobbered in the change if one isn't careful. We've glossed over this possibility before because we are assuming that clients is empty. Let's take a look at how the modifications suggested could be made with the table containing data:

```
ALTER TABLE clients
CHANGE address address1 varchar(40),
MODIFY active enum('yes','no','AC','IA');

UPDATE clients
SET active = 'yes'
WHERE active = 'AC';

UPDATE clients
SET active = 'no'
WHERE active = 'IA';

ALTER TABLE clients
MODIFY active enum('yes','no');
```

The first SQL statement above changes address and modifies active in preparation for the transition. Notice the use of a `MODIFY` clause. It works the same as `CHANGE`, but it is only used for changing data types and not column names. Therefore, the column name isn't respecified. Notice also that there is a comma after the CHANGE clause. You can string several `CHANGE` and `MODIFY` clauses together with comma separators. We've enumerated both the new choices and the old ones to be able to migrate the data. The two UPDATE statements are designed to adjust the data accordingly and the last ALTER TABLE statement is to remove the old enumerated choices for the status column.

In talking to the boss, we find out that the `client_type` column isn't going to be used. So we enter the following in MariaDB:

```
ALTER TABLE clients
DROP client_type;
```

This deletes `client_type` and its data, but not the whole table, obviously. Nevertheless, it is a permanent and non-reversible action; there won't be a confirmation request when using the mariadb client. This is how it is with all MariaDB DROP statements and clauses. So be sure that you want to delete an element and its data before using a `DROP`. As mentioned earlier, be sure that you have a backup of your tables before doing any structured changes.

The Default

You may have noticed that the results of the DESCRIBE statements shown before have a heading called 'Default' and just about all of the fields have a default value of NULL. This means that there are no default values and a null value is allowed and will be used if a value isn't specified when a row is created. To be able to specify a default value other than NULL, an ALTER TABLE statement can be entered with a `SET` clause. Suppose we're located in Louisiana and we want a default value of 'LA' for state since that's where our clients are usually located. We would enter the following to set the default:

```
ALTER TABLE clients
ALTER state SET DEFAULT 'LA';
```

Notice that the second line starts with `ALTER` and not `CHANGE`. If we change our mind about having a default value for state, we would enter the following to reset it back to NULL (or whatever the initial default value would be based on the data type):

```
ALTER TABLE clients
ALTER state DROP DEFAULT;
```

This particular `DROP` doesn't delete data, by the way.

Indexes

One of the most irritating tasks in making changes to a table for newcomers is dealing with indexes. If they try to rename a column that is indexed by only using an ALTER TABLE statement like we used earlier, they will get a frustrating and confusing error message:

```
ALTER TABLE clients
CHANGE cust_id client_id INT
PRIMARY KEY;

ERROR 1068: Multiple primary key defined
```

If they're typing this column change from memory, they will wear themselves out trying different deviations thinking that they remembered the syntax wrong. What most newcomers to MariaDB don't seem to realize is that the index is separate from the indexed column. To illustrate, let's take a look at the index for clients by using the SHOW INDEX statement:

```
SHOW INDEX FROM clientsG;

*************************** 1. row ***************************
           Table: clients
      Non_unique: 0
        Key_name: PRIMARY
    Seq_in_index: 1
     Column_name: cust_id
       Collation: A
     Cardinality: 0
        Sub_part: NULL
          Packed: NULL
         Comment:
1 row in set (0.00 sec)
```

The text above shows that behind the scenes there is an index associated with `cust_id`. The column `cust_id` is not the index. Incidentally, the G at the end of the SHOW INDEX statement is to display the results in portrait instead of landscape format. Before the name of an indexed column can be changed, the index related to it must be eliminated. The index is not automatically changed or deleted. Therefore, in the example above, MariaDB thinks that the developer is trying to create another primary key index. So, a `DROP` clause for the index must be entered first and then a `CHANGE` for the column name can be made along with the establishing of a new index:

```
ALTER TABLE clients
DROP PRIMARY KEY,
CHANGE cust_id
client_id INT PRIMARY KEY;
```

The order of these clauses is necessary. The index must be dropped before the column can be renamed. The syntax here is for a `PRIMARY KEY`. There are other types of indexes, of course. To change a column that has an index type other than a `PRIMARY KEY`. Assuming for a moment that `cust_id` has a `UNIQUE` index, this is what we would enter to change its name:

```
ALTER TABLE clients
DROP UNIQUE cust_id
CHANGE cust_id
client_id INT UNIQUE;
```

Although the index type can be changed easily, MariaDB won't permit you to do so when there are duplicate rows of data and when going from an index that allows duplicates (e.g., `INDEX`) to one that doesn't (e.g., `UNIQUE`). If you actually do want to eliminate the duplicates, though, you can add the `IGNORE` flag to force the duplicates to be deleted:

```
ALTER IGNORE TABLE clients
DROP INDEX cust_id
CHANGE cust_id
client_id INT UNIQUE;
```

In this example, we're not only changing the indexed column's name, but we're also changing the index type from `INDEX` to `UNIQUE`. And, again, the `IGNORE` flag tells MariaDB to ignore any records with duplicate values for `cust_id`.

Renaming & Shifting Tables

The previous sections covered how to make changes to columns in a table. Sometimes you may want to rename a table. To change the name of the `clients` table to client_addresses we enter this:

```
RENAME TABLE clients
TO client_addresses;
```

The RENAME TABLE statement will also allows a table to be moved to another database just by adding the receiving database's name in front of the new table name, separated by a dot. Of course, you can move a table without renaming it. To move the newly named `client_addresses` table to the database db2, we enter this:

```
RENAME TABLE client_addresses
TO db2.client_addresses;
```

Finally, with tables that contain data (excluding InnoDB tables), occasionally it's desirable to resort the data within the table. Although the ORDER BY clause in a SELECT statement can do this on the fly as needed, sometimes developers want to do this somewhat permanently to the data within the table based on a particular column or columns. It can be done by entering the following:

```
ALTER TABLE client_addresses
ORDER BY city, name;
```

Notice that we're sorting by the city first and then by the client's name. Now when the developer enters a SELECT statement without an ORDER BY clause, the results are already ordered by the default of city and then name, at least until more data is added to the table.

This is not applicable to InnoDB tables, the default, which are ordered according to the clustered index, unless the primary key is defined on the specific columns.

Summation

Good planning is certainly important in developing a MariaDB database. However, as you can see, MariaDB is malleable enough that it can be reshaped without much trouble. Just be sure to make a backup before restructuring a table and be sure to check your work and the data when you're finished. With all of this in mind, you should feel comfortable in creating tables since they don't have to be perfect from the beginning.

6.1.6 Changing Times in MariaDB

Contents

The article entitled, Doing Time with MariaDB dealt with time and date columns in MariaDB and how to selectively retrieve and format time and date elements. This article will go a little further by exploring special functions that are available in MariaDB to modify time and date.

The Nature of Time

For most of us, there is a morning and an afternoon in each day. Days are measured in either two twelve-hour blocks or one twenty-four-hour block. There are twelve months in a year, with each month consisting of thirty or thirty-one days. The only exception is the month of February which contains twenty-eight days usually, but once every four years it contains twenty-nine. While this all may be rather natural, putting it into a computer program can make it seem very unnatural and frustrating.

For the scenario in this article we have a MariaDB database in which customers enter work requests through the web. When they enter a trouble ticket, a record is entered into a MariaDB table called, tickets. This record contains several fields, one of which is the date that the ticket was entered called ticket_date. Another contains the time the ticket was entered. It's called simply, entered. Yet another column is called promised; it's the time that the customer was promised that their problem would be resolved. Both the entered and the promised columns are time data type columns. The value of entered is determined from the current time of the server. The value of promised is determined by adding a number of hours to the value of entered, depending on the urgency of the ticket set by the customer. For instance, tickets marked "ASAP" are to be completed within two hours according to our company's policy. This all works nicely in testing, but occasionally customers create tickets at odd times and on odd days.

Around the Clock

Setting aside the potential problems for a moment, let's look at a simple example of how we might add tickets. Suppose we wanted to write a CGI script (in Perl or PHP) that will allow users to create tickets on-line any time. We might use the following SQL statement in our script:

```
INSERT INTO tickets
(client_id, urgency, trouble,
ticket_date, entered, promised)
VALUES('$client_id', '$urgency', '$trouble',
CURDATE(), CURTIME(),
SEC_TO_TIME(TIME_TO_SEC(CURTIME()) + 7200));
```

If you're unfamiliar with INSERT statements and the use of script variables (e.g., $client_id), you may want to go back and read an earlier article (MariaDB Basics) in this series which explains both. For the purposes of this article, however, let's focus on the minor formula in the SQL statement above for calculating the promised time, the last line. The TIME_TO_SEC( ) function converts a time to seconds so that a calculation may be performed. In this case, the current time is converted to seconds. The formula above then adds 7200 seconds (which is two hours) to that. In order to insert the seconds sum into a time column (i.e., promised), it needs to be converted to a time format. Hence, the calculation is wrapped up in the SEC_TO_TIME( ) function.

As nice as the SQL statement above is, a problem arises when a customer runs it at 11:00 p.m (or 23:00 in MariaDB time) and the promised time is to be two hours later. The SQL statement above will calculate a promised time of 25:00. What time is that in human or computer terms? As humans, we know that it's meant to be 1:00 a.m., but MariaDB will need this clarified. One solution would be to place the time formula above inside of an IF clause in MariaDB. To do this, the last line of the SQL statement would be replaced with these lines:

```
...
IF((TIME_TO_SEC(CURTIME()) + 7200) < 86400,
SEC_TO_TIME(TIME_TO_SEC(CURTIME()) + 7200),
SEC_TO_TIME((TIME_TO_SEC(CURTIME()) + 7200) - 86400)));
```

The first element in the IF clause is the test. The second piece is the value used if the test passes. The third is the value if the test fails. So, if the total seconds is less than 86,400 (i.e., the number of seconds in one day), then the total seconds of the current time, converted to the time format is to be used. Otherwise, the total seconds of the current time minus 86,400 seconds, converted to the time format is to be used. Incidentally, there's an extra closing parenthesis at the end of this SQL

statement excerpt because there was an opening one as part of the `VALUES` clause that's not shown here. Although the statement above works, it's a bit excessive and can be accomplished a little more succinctly if one reconsiders the purpose of the IF clause.

What we're trying to determine in the IF clause is the number of seconds into the day in which the work was promised to be done, meaning the excess amount of time of the day (i.e., one hour). For such a calculation, the modulo division operator (i.e., the `%`) can be used. The modulo division operator will give the remainder of a division. For instance, the result of `SELECT 14 % 5;` is `4`. That is to say, 5 goes into 14 two complete times with 4 left over. As another example, the result of `SELECT 3 % 5;` is 3; that is to say, 5 goes into 3 zero times with 3 left over. Using this arithmetic operator in the time formula above, we can eliminate the IF clause and use the following to accomplish our task:

```
...
SEC_TO_TIME((TIME_TO_SEC(CURTIME()) + 7200) % 86400));
```

If the current time is 23:00, then the time in seconds will be 82,800. The formula above will add 7200 to 82,800 to make 90,000 seconds. The modulo division operator will divide 86,400 into 90,000 one time, giving a remainder of 3600 seconds. The SEC_TO_TIME function will then convert 3600 seconds to one hour or 1:00 a.m.

Today or Tomorrow?

There is a problem with the results from the formula at the end of the previous section. If the customer is promised 1:00 a.m., is that time today or tomorrow? Again, as humans we know that since the promised time must be after the entered time, it must be 1:00 a.m. on the following day. Since computers don't make these assumptions, though, we'll have to make some adjustments to the tickets table and the SQL statement. To be able to record the date and time in each column, we'll first change the column types of entered and promised from time to datetime. We'll do the following SQL statements to migrate the data and to clean up the table:

```
ALTER TABLE tickets,
CHANGE COLUMN entered entered_old TIME,
CHANGE COLUMN promised promised_old TIME,
ADD COLUMN entered DATETIME,
ADD COLUMN promised DATETIME;

UPDATE tickets
SET entered = CONCAT(ticket_date, ' ', entered_old),
promised = CONCAT(ticket_date, ' ', promised_old);

ALTER TABLE tickets,
DROP COLUMN entered_old,
DROP COLUMN promised_old,
DROP COLUMN ticket_date;
```

The first SQL statement above alters the table to change the names of the time columns temporarily and to add the new columns with datetime types. If we were instead just to change the existing time columns to datetime types without this two step process, the data would be clobbered and reset to all zeros. The next SQL statement copies the values of the ticket_date column and pastes it together with the value of one of the old time columns to come up with the new date and time value for the entered and promised dates and times. The flaw in this statement, of course, is that it doesn't deal with the problems with some promised times that the previous layout caused. In fact, it reinforces it by giving a 1:00 a.m. promised time the date of the entered time. This will either have to be fixed manually if it's important to the developer, or with a script that will compare the two time columns. Either way, it's a little out of the scope of this article, so we'll move on. The last SQL statement above deletes the old time columns and the old date column now that the data has been migrated. By the way, it's a good practice to backup the data before altering a table. Also, you probably would run a SELECT statement before the last SQL statement above to check the migrated data before dropping the old columns.

Having changed the column types, we can now use the function DATE_ADD( ), which can deal with times that exceed twenty-four hours so that the problem with times straddling the midnight hour won't reoccur. Therefore, our on-going SQL statement becomes this:

```
INSERT INTO tickets
(client_id, urgency, trouble,
entered, promised)
VALUES('$client_id', '$urgency', '$trouble',
NOW(),
DATE_ADD(NOW(), INTERVAL 2 HOUR));
```

First notice that the field ticket_date was eliminated and CURTIME() was replaced with NOW( ), which provides the date and time in one. In the last line we see DATE_ADD( ): an interval of two hours is added to the date and time now (or rather when the record is created). If the time rolls into the next day, then the date is advanced by one and the correct hour is set accordingly.

The DATE_ADD( ) function will also allow for the addition of minutes. The directive `HOUR` would be replaced with `MINUTE`. To add both hours and minutes (e.g., two hours and thirty minutes), the last line of the SQL statement above could read like this:

```
...
DATE_ADD(NOW(), INTERVAL '2:30' HOUR_MINUTE));
```

If the time in which the statement is run is 11:00 p.m., the result would be 1:30 a.m. on the next day.

Around the Calendar

The dilemma that can occur with calculations involving hours that wrap around the clock, can similarly occur with calculations involving days that roll into a new month. This problem was fairly easy to resolve with an arithmetic operator when dealing with a constant like the number of seconds in a day. However, a formula to deal with the various number of days in each month would be very lengthy. For instance, if we were simply to add five days to the date February 27, we would get February 32. Imagine trying to create an SQL statement to figure out whether that's supposed to be March 1, 2, 3, or 4--depending on whether the previous month is a regular month with 30 or 31 days, or the one irregular month with 28 or 29 days, depending on the year.

Fortunately (as you probably have already guessed), DATE_ADD( ) will solve the month dilemma, as well. If instead of promising that tickets will be resolved within a couple hours of the time they are entered, we promise resolution within five days, the SQL statement would look like this:

```
INSERT INTO tickets
(client_id, urgency, trouble,
entered, promised)
VALUES('$client_id', '$urgency', '$trouble',
NOW(),
DATE_ADD(NOW(), INTERVAL 5 DAY));
```

If this statement is run on February 27, then the value of promised would be March 3 or 4, depending on whether it is a leap year. Which one will be determined by the DATE_ADD( ) function, requiring no fancy formula.

Just as hours and minutes can be mixed with DATE_ADD( ), days and hours can be mixed, as well. To make the value of promised two days and six hours from now, the last line of the SQL statement above would read like this:

```
...
DATE_ADD(NOW(), INTERVAL '2 6' DAY_HOUR));
```

The function DATE_ADD( ) will also allow the addition of months and of years. For instance, to increase the date by one year and two months, the SQL statement would be adjusted to look like this:

```
...
DATE_ADD(NOW(), INTERVAL '1 2' YEAR_MONTH));
```

This increases the year by one and the month by two. These intervals have no effect on time or day values, though. So, if the value of NOW( ) is `2017-09-15 23:00`, then the value of promised would become 2018-11-15 23:00, regardless of whether next year is a leap year and regardless of the number of days in each intervening month.

Stepping Back

It stands to reason that if one wants to add days to the current date, then one will want to subtract days in an equally agreeable manner. For subtracting days we can still use the DATE_ADD function. Just put a negative sign in front of the interval value like this:

```
...
DATE_ADD(NOW(), INTERVAL -5 DAY));
```

This will give a value five days before the current date. An alternative would be to use the DATE_SUB( ) function which subtracts from the date given. The above amendment (subtracting five days from the current date) could be entered like so:

```
...
DATE_SUB(NOW(), INTERVAL 5 DAY));
```

Notice that the 5 is not preceded by a negative sign. If it were, it would have the effect of adding five days.

Conclusion

This article along with the previous one on time and date in MariaDB in no way exhaust the topic. There are many more functions and tricks to manipulating temporal values in MariaDB, not to mention what can be done with the extension of a script using a programming language like PHP. Plus, new functions are occasionally being added to MariaDB.

6.1.7 Doing Time with MariaDB

Contents

The recording of date and time in a MariaDB database is a very common requirement. For gathering temporal data, one needs to know which type of columns to use in a table. More importantly is knowing how to record chronological data and how to retrieve it in various formats. Although this is a seemingly basic topic, there are many built-in time functions that can be used for more accurate SQL statements and better formatting of data. In this article we will explore these various aspects of how to do time with MariaDB.

About Time

Since date and time are only numeric strings, they can be stored in a regular character column. However, by using temporal data type columns, you can make use of several built-in functions offered by MariaDB. Currently, there are five temporal data types available: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. The `DATE` column type is for recording the date only and is basically in this format: `yyyy-mm-dd`. The `TIME` column type is for recording time in this format: `hhh:mm:ss`. To record a combination of date and time, there is the `DATETIME` column type: `yyyy-mm-dd hh:mm:ss`. The `TIMESTAMP` column is similar to `DATETIME`, but it's a little limited in its range of allowable time. It starts at the Unix epoc time (i.e., 1970-01-01) and ends at the end of 2037. Finally, the `YEAR` data type is for recording only the year in a column: `yy` or `yyyy`. For the examples in this article, `DATE`, `TIME`, and `DATETIME` columns will be used. The database that will be referenced is for a fictitious psychiatry practice that keeps track of its patients and billable hours in MariaDB.

Telling Time

To record the current date and time in a MariaDB table, there are a few built-in functions that may be used. First, to record the date there are the functions CURRENT_DATE and CURDATE( ) (depending on your style), which both produce the same results (e.g., 2017-08-01). Notice that CURDATE( ) requires parentheses and the other does not. With many functions a column name or other variables are placed inside of the parentheses to get a result. With functions like CURDATE( ), there is nothing that may go inside the parenthesis. Since these two functions retrieve the current date in the format of the `DATE` column type, they can be used to fill in a `DATE` column when inserting a row:

```
INSERT INTO billable_work
(doctor_id, patient_id, session_date)
VALUES('1021', '1256', CURRENT_DATE);
```

The column *session_date* is a `DATE` column. Notice that there are no quotes around the date function. If there were it would be taken as a literal value rather than a function. Incidentally, I've skipped discussing how the table was set up. If you're not familiar with how to set up a table, you may want to read the MariaDB Basics article. To see what was just recorded by the INSERT statement above, the following may be entered (results follow):

```
SELECT rec_id, doctor_id,
patient_id, session_date
FROM billable_work
WHERE rec_id=LAST_INSERT_ID();

+--------+-----------+------------+--------------+
| rec_id | doctor_id | patient_id | session_date |
+--------+-----------+------------+--------------+
|   2462 | 1021      | 1256       | 2017-08-23   |
+--------+-----------+------------+--------------+
```

Notice in the billable_work table that the primary key column (i.e., `rec_id`) is an automatically generated and incremental

number column (i.e., `AUTO_INCREMENT`). As long as another record is not created or the user does not exit from the mariadb client or otherwise end the session, the LAST_INSERT_ID( ) function will retrieve the value of the `rec_id` for the last record entered by the user.

To record the time of an appointment for a patient in a time data type column, CURRENT_TIME or CURTIME( ) are used in the same way to insert the time. The following is entered to update the row created above to mark the starting time of the appointment—another SELECT statement follows with the results:

```
UPDATE billable_work
SET session_time=CURTIME()
WHERE rec_id='2462';

SELECT patient_id, session_date, session_time
FROM billable_work
WHERE rec_id='2462';

+------------+--------------+--------------+
| patient_id | session_date | session_time |
+------------+--------------+--------------+
| 1256       | 2017-08-23   | 10:30:23     |
+------------+--------------+--------------+
```

The column session_time is a time column. To record the date and time together in the same column, CURRENT_TIMESTAMP or SYSDATE( ) or NOW( ) can be used. All three functions produce the same time format: `yyyy-mm-dd hh:mm:ss`. Therefore, the column's data type would have to be `DATETIME` to use them.

How to get a Date

Although MariaDB records the date in a fairly agreeable format, you may want to present the date when it's retrieved in a different format. Or, you may want to extract part of the date, such as only the day of the month. There are many functions for reformatting and selectively retrieving date and time information. To start off with, let's select a column with a data type of `DATE` and look at the functions available for retrieving each component. To extract the year, there's the YEAR( ) function. For extracting just the month, the MONTH( ) function could be called upon. And to grab the day of the month, DAYOFMONTH( ) will work. Using the record entered above, here's what an SQL statement and its results would look like in which the session date is broken up into separate parts, but in a different order:

```
SELECT MONTH(session_date) AS Month,
DAYOFMONTH(session_date) AS Day,
YEAR(session_date) AS Year
FROM billable_work
WHERE rec_id='2462';

+-------+------+------+
| Month | Day  | Year |
+-------+------+------+
|     8 |   23 | 2017 |
+-------+------+------+
```

For those who aren't familiar with the keyword `AS`, it's used to label a column's output and may be referenced within an SQL statement. Splitting up the elements of a date can be useful in analyzing a particular element. If the bookkeeper of the fictitious psychiatry office needed to determine if the day of the week of each session was on a Saturday because the billing rate would be higher (time and a half), the DAYOFWEEK( ) function could be used. To spice up the examples, let's wrap the date function up in an IF( ) function that tests for the day of the week and sets the billing rate accordingly.

```
SELECT patient_id AS 'Patient ID',
session_date AS 'Date of Session',
IF(DAYOFWEEK(session_date)=6, 1.5, 1.0)
  AS 'Billing Rate'
FROM billable_work
WHERE rec_id='2462';

+------------+-----------------+--------------+
| Patient ID | Date of Session | Billing Rate |
+------------+-----------------+--------------+
|       1256 |    2017-08-23   |          1.5 |
+------------+-----------------+--------------+
```

Since we've slipped in the IF( ) function, we should explain it's format. The test condition is listed first within the parentheses. In this case, the test is checking if the session date is the sixth day of the week. Then, what MariaDB should

display is given if the test passes, followed by the result if it fails.

Similar to the DAYOFWEEK( ) function, there's also WEEKDAY( ). The only difference is that for DAYOFWEEK( ) the first day of the week is Sunday—with WEEKDAY( ) the first day is Monday. Both functions represent the first day with 0 and the last with `6`. Having *Saturday* and *Sunday* symbolized by `5` and `6` can be handy in constructing an IF statement that has a test component like "`WEEKDAY(session_date) > 4`" to determine if a date is a weekend day. This is cleaner than testing for values of `0` and `6`.

There is a function for determining the day of the year: DAYOFYEAR( ). It's not used often, but it is available if you ever need it. Occasionally, though, knowing the quarter of a year for a date can be useful for financial accounting. Rather than set up a formula in a script to determine the quarter, the QUARTER( ) function can do this easily. For instance, suppose an accountant wants a list of a doctor's sessions for each patient for the previous quarter. These three SQL statements could be entered in sequence to achieve the results that follow:

```
SET @LASTQTR:=IF((QUARTER(CURDATE())-1)=0,
4, QUARTER(CURDATE())-1);

SET @YR:=IF(@LASTQTR=4,
YEAR(NOW())-1, YEAR(NOW()));

SELECT patient_id AS 'Patient ID',
COUNT(session_time)
  AS 'Number of Sessions'
FROM billable_work
WHERE QUARTER(session_date) = @LASTQTR
  AND YEAR(session_date) = @YR
  AND doctor_id='1021'
GROUP BY patient_id
ORDER BY patient_id LIMIT 5;

+------------+--------------------+
| Patient ID | Number of Sessions |
+------------+--------------------+
| 1104       |                 10 |
| 1142       |                  7 |
| 1203       |                 18 |
| 1244       |                  6 |
| 1256       |                 12 |
+------------+--------------------+
```

This example is the most complicated so far. But it's not too difficult to understand if we pull it apart. The first SQL statement sets up a user variable containing the previous quarter (i.e., 1, 2, 3, or 4). This variable will be needed in the other two statements. The IF( ) clause in the first statement checks if the quarter of the current date minus one is zero. It will equal zero when it's run during the first quarter of a year. During a first quarter, of course, the previous quarter is the fourth quarter of the previous year. So, if the equation equals zero, then the variable `@LASTQTR` is set to `4`. Otherwise, `@LASTQTR` is set to the value of the current quarter minus one. The second statement is necessary to ensure that the records for the correct year are selected. So, if `@LASTQTR` equals four, then `@YR` needs to equal last year. If not, `@YR` is set to the current year. With the user variables set to the correct quarter and year, the SELECT statement can be entered. The COUNT( ) function counts the number of appointments that match the `WHERE` clause for each patient based on the GROUP BY clause. The `WHERE` clause looks for sessions with a quarter that equals `@LASTQTR` and a year that equals `@YR`, as well as the doctor's identification number. In summary, what we end up with is a set of SQL statements that retrieve the desired information regardless of which quarter or year it's entered.

What is the Time?

The last section covered how to retrieve pieces of a date column. Now let's look at how to do the same with a time column. To extract just the hour of a time saved in MariaDB, the HOUR( ) function could be used. For the minute and second, there's MINUTE( ) and SECOND( ). Let's put them all together in one straightforward SELECT statement:

```
SELECT HOUR(session_time) AS Hour,
MINUTE(session_time) AS Minute,
SECOND(session_time) AS Second
FROM billable_work
WHERE rec_id='2462';

+------+--------+--------+
| Hour | Minute | Second |
+------+--------+--------+
|   10 |     30 |     00 |
+------+--------+--------+
```

Date & Time Combined

All of the examples given so far have involved separate columns for date and time. The EXTRACT( ) function, however, will allow a particular component to be extracted from a combined column type (i.e., `DATETIME` or `TIMESTAMP`). The format is `EXTRACT(date_type FROM date_column)` where *date_type* is the component to retrieve and *date_column* is the name of the column from which to extract data. To extract the year, the *date_type* would be `YEAR`; for month, `MONTH` is used; and for day, there's `DAY`. To extract time elements, `HOUR` is used for hour, `MINUTE` for minute, and `SECOND` for second. Although that's all pretty simple, let's look at an example. Suppose the table billable_work has a column called `appointment` (a `datetime` column) that contains the date and time for which the appointment was scheduled (as opposed to the time it actually started in `session_time`). To get the hour and minute for a particular date, the following SQL statement will suffice:

```
SELECT patient_name AS Patient,
EXTRACT(HOUR FROM appointment) AS Hour,
EXTRACT(MINUTE FROM appointment) AS Minute
FROM billable_work, patients
WHERE doctor_id='1021'
  AND EXTRACT(MONTH FROM appointment)='8'
  AND EXTRACT(DAY FROM appointment)='30'
  AND billable_work.patient_id =
    patients.patient_id;
```

This statement calls upon another table (`patients`) which holds patient information such as their names. It requires a connecting point between the tables (i.e., the `patient_id` from each table). If you're confused on how to form relationships between tables in a SELECT statement, you may want to go back and read the Getting Data from MariaDB article. The SQL statement above would be used to retrieve the appointments for one doctor for one day, giving results like this:

```
+-------------------+------+--------+
| Patient           | Hour | Minute |
+-------------------+------+--------+
| Michael Zabalaoui |   10 |     00 |
| Jerry Neumeyer    |   11 |     00 |
| Richard Stringer  |   13 |     30 |
| Janice Sogard     |   14 |     30 |
+-------------------+------+--------+
```

In this example, the time elements are separated and they don't include the date. With the EXTRACT( ) function, however, you can also return combined date and time elements. There is `DAY_HOUR` for the day and hour; there's `DAY_MINUTE` for the day, hour, and minute; `DAY_SECOND` for day, hour, minute, and second; and `YEAR_MONTH` for year and month. There are also some time only combinations: `HOUR_MINUTE` for hour and minute; `HOUR_SECOND` for hour, minute, and second; and `MINUTE_SECOND` for minute and second. However, there's not a `MONTH_DAY` to allow the combining of the two extracts in the `WHERE` clause of the last SELECT statement above. Nevertheless, we'll modify the example above and use the `HOUR_MINUTE` date_type to retrieve the hour and minute in one resulting column. It would only require the second and third lines to be deleted and replaced with this:

```
...
EXTRACT(HOUR_MINUTE FROM appointment)
  AS Appointment
...

+-------------------+-------------+
| Patient           | Appointment |
+-------------------+-------------+
| Michael Zabalaoui |        1000 |
| Jerry Neumeyer    |        1100 |
| Richard Stringer  |        1330 |
| Janice Sogard     |        1430 |
+-------------------+-------------+
```

The problem with this output, though, is that the times aren't very pleasing looking. For more natural date and time displays, there are a few simple date formatting functions available and there are the DATE_FORMAT( ) and TIME_FORMAT( ) functions.

Fine Time Pieces

The simple functions that we mentioned are used for reformatting the output of days and months. To get the date of patient

sessions for August, but in a more wordier format, MONTHNAME( ) and DAYNAME( ) could be used:

```
SELECT patient_name AS Patient,
CONCAT(DAYNAME(appointment), ' - ',
  MONTHNAME(appointment), ' ',
  DAYOFMONTH(appointment), ', ',
  YEAR(appointment)) AS Appointment
FROM billable_work, patients
WHERE doctor_id='1021'
  AND billable_work.patient_id =
    patients.patient_id
  AND appointment>'2017-08-01'
  AND appointment<'2017-08-31'
LIMIT 1;

+------------------+----------------------------+
| Patient          | Appointment                |
+------------------+----------------------------+
| Michael Zabalaoui | Wednesday - August 30, 2017 |
+------------------+----------------------------+
```

In this statement the CONCAT( ) splices together the results of several date functions along with spaces and other characters. The EXTRACT( ) function was eliminated from the `WHERE` clause and instead a simple numeric test for sessions in August was given. Although EXTRACT( ) is fairly straightforward, this all can be accomplished with less typing by using the DATE_FORMAT( ) function.

The DATE_FORMAT( ) function has over thirty options for formatting the date to your liking. Plus, you can combine the options and add your own separators and other text. The syntax is `DATE_FORMAT(date_column, 'options & characters')` . As an example, let's reproduce the last SQL statement by using the DATE_FORMAT( ) function for formatting the date of the appointment and for scanning for appointments in July only:

```
SELECT patient_name AS Patient,
DATE_FORMAT(appointment, '%W - %M %e, %Y')
  AS Appointment
FROM billable_work, patients
WHERE doctor_id='1021'
  AND billable_work.patient_id =
    patients.patient_id
  AND DATE_FORMAT(appointment, '%c') = 8
LIMIT 1;
```

This produces the exact same output as above, but with a more succinct statement. The option `%W` gives the name of the day of the week. The option `%M` provides the month's name. The option `%e` displays the day of the month (`%d` would work, but it left-pads single-digit dates with zeros). Finally, `%Y` is for the four character year. All other elements within the quotes (i.e., the spaces, the dash, and the comma) are literal characters for a nicer display.

With DATE_FORMAT( ), time elements of a field also can be formatted. For instance, suppose we also wanted the hour and minute of the appointment. We would only need to change the second line of the SQL statement above (to save space, patient_name was eliminated):

```
SELECT
DATE_FORMAT(appointment, '%W - %M %e, %Y at %r')
  AS Appointment
...

+-----------------------------------------+
| Appointment                             |
+-----------------------------------------+
| Wednesday - August 30, 2017 at 02:11:19 AM |
+-----------------------------------------+
```

The word at was added along with the formatting option `%r` which gives the time with AM or PM at the end.

Although it may be a little confusing at first, once you've learned some of the common formatting options, DATE_FORMAT( ) is much easier to use than EXTRACT( ). There are many more options to DATE_FORMAT( ) that we haven't mentioned. For a complete list of the options available, see the DATE_FORMAT( ) documentation page.

Clean up Time

In addition to DATE_FORMAT( ), MariaDB has a comparable built-in function for formating only time: TIME_FORMAT( ).

The syntax is the same and uses the same options as DATE_FORMAT( ), except only the time related formatting options apply. As an example, here's an SQL statement that a doctor might use at the beginning of each day to get a list of her appointments for the day:

```
SELECT patient_name AS Patient,
TIME_FORMAT(appointment, '%l:%i %p')
  AS Appointment
FROM billable_work, patients
WHERE doctor_id='1021'
  AND billable_work.patient_id =
    patients.patient_id
  AND DATE_FORMAT(appointment, '%Y-%m-%d') =
    CURDATE();

+------------------+-------------+
| Patient          | Appointment |
+------------------+-------------+
| Michael Zabalaoui |    10:00 AM |
| Jerry Neumeyer    |    11:00 AM |
| Richard Stringer  |    01:30 PM |
| Janice Sogard     |    02:30 PM |
+------------------+-------------+
```

The option `%l` provides the hours 01 through 12. The `%p` at the end indicates (with the AM or PM) whether the time is before or after noon. The `%i` option gives the minute. The colon and the space are for additional display appeal. Of course, all of this can be done exactly the same way with the DATE_FORMAT( ) function. As for the DATE_FORMAT( ) component in the WHERE clause here, the date is formatted exactly as it will be with CURDATE( ) (i.e., 2017-08-30) so that they may be compared properly.

Time to End

Many developers use PHP, Perl, or some other scripting language with MariaDB. Sometimes developers will solve retrieval problems with longer scripts rather than learn precisely how to extract temporal data with MariaDB. As you can see in several of the examples here (particularly the one using the QUARTER( ) function), you can accomplish a great deal within MariaDB. When faced with a potentially complicated SQL statement, try creating it in the mariadb client first. Once you get what you need (under various conditions) and in the format desired, then copy the statement into your script. This practice can greatly help you improve your MariaDB statements and scripting code.

6.1.8 Importing Data into MariaDB

Contents

When a MariaDB developer first creates a MariaDB database for a client, often times the client has already accumulated data in other, simpler applications. Being able to convert data easily to MariaDB is critical. In the previous two articles of this MariaDB series, we explored how to set up a database and how to query one. In this third installment, we will introduce some methods and tools for bulk importing of data into MariaDB. This isn't an overly difficult task, but the processing of large amounts of data can be intimidating for a newcomer and and as a result it can be a barrier to getting started with MariaDB. Additionally, for intermediate developers, there are many nuances to consider for a clean import, which is especially important for automating regularly scheduled imports. There are also restraints to deal with that may be imposed on a developer when using a web hosting company.

Foreign Data Basics

Clients sometimes give developers raw data in formats created by simple database programs like MS Access ®. Since non-technical clients don't typically understand database concepts, new clients often give me their initial data in Excel spreadsheets. Let's first look at a simple method for importing data. The simplest way to deal with incompatible data in any format is to load it up in its original software and to export it out to a delimited text file. Most applications have the ability to export data to a text format and will allow the user to set the delimiters. We like to use the bar (i.e., `|` , a.k.a. pipe) to separate fields and the line-feed to separate records.

For the examples in this article, we will assume that a fictitious client's data was in Excel and that the exported text file will be named `prospects.txt`. It contains contact information about prospective customers for the client's sales department, located on the client's intranet site. The data is to be imported into a MariaDB table called `prospect_contact`, in a database called `sales_dept`. To make the process simpler, the order and number of columns in MS Excel ® (the format of the data provided by the client) should be the same as the table into which the data is going to be imported. So if prospect_contact has columns that are not included in the spreadsheet, one would make a copy of the spreadsheet and add the missing columns and leave them blank. If there are columns in the spreadsheet that aren't in `prospect_contact`, one would either add them to the MariaDB table, or, if they're not to be imported, one would delete the extra columns from the spreadsheet. One should also delete any headings and footnotes from the spreadsheet. After this is completed then the data can be exported. Since this is Unix Review, we'll skip how one would export data in Excel and assume that the task was accomplished easily enough using its export wizard.

The next step is to upload the data text file to the client's web site by FTP. It should be uploaded in ASCII mode. Binary mode may send binary hard-returns for row-endings. Also, it's a good security habit to upload data files to non-public directories. Many web hosting companies provide virtual domains with a directory like `/public_html`, which is the document root for the Apache web server; it typically contains the site's web pages. In such a situation, `/` is a virtual root containing logs and other files that are inaccessible to the public. We usually create a directory called `tmp` in the virtual root directory to hold data files temporarily for importing into MariaDB. Once that's done, all that's required is to log into MariaDB with the mariadb client as an administrative user (if not root, then a user with `FILE` privileges), and run the proper SQL statement to import the data.

Loading Data Basics

The LOAD DATA INFILE statement is the easiest way to import data from a plain text file into MariaDB. Below is what one would enter in the mariadb client to load the data in the file called prospects.txt into the table `prospect_contact`:

```
LOAD DATA INFILE '/tmp/prospects.txt'
INTO TABLE prospect_contact
FIELDS TERMINATED BY '|';
```

Before entering the statement above, the MariaDB session would, of course, be switched to the sales_dept database with a USE statement. It is possible, though, to specify the database along with the table name (e.g., `sales_dept.prospect_contact`). If the server is running Windows, the forward slashes are still used for the text file's path, but a drive may need to be specified at the beginning of the path: '`c:/tmp/prospects.txt`'. Notice that the SQL statement above has `|` as the field delimiter. If the delimiter was [TAB]—which is common—then one would replace `|` with `\t` here. A line-feed (`\n`) isn't specified as the record delimiter since it's assumed. If the rows start and end with something else, though, then they will need to be stated. For instance, suppose the rows in the text file start with a double-quote and end with a double-quote and a Windows hard-return (i.e., a return and a line-feed). The statement would need to read like this:

```
LOAD DATA INFILE '/tmp/prospects.txt'
INTO TABLE prospect_contact
FIELDS TERMINATED BY '|'
LINES STARTING BY '"'
TERMINATED BY '"\r\n';
```

Notice that the starting double-quote is inside of single-quotes. If one needs to specify a single-quote as the start of a line, one could either put the one single-quote within double-quotes or one could escape the inner single-quote with a back-slash, thus telling MariaDB that the single-quote that follows is to be taken literally and is not part of the statement, per se:

```
...
LINES STARTING BY '\''
...
```

Duplicate Rows

If the table prospect_contact already contains some of the records that are about to be imported from prospects.txt (that is to say, records with the same primary key), then a decision should be made as to what MariaDB is to do about the duplicates. The SQL statement, as it stands above, will cause MariaDB to try to import the duplicate records and to create duplicate rows in prospect_contact for them. If the table's properties are set not to allow duplicates, then MariaDB will kick out errors. To get MariaDB to replace the duplicate existing rows with the ones being imported in, one would add the `REPLACE` just before the `INTO TABLE` clause like this:

```
LOAD DATA INFILE '/tmp/prospects.txt'
REPLACE INTO TABLE prospect_contact
FIELDS TERMINATED BY '|'
LINES STARTING BY '"'
TERMINATED BY '"\n';
```

To import only records for prospects that are not already in prospect_contact, one would substitute REPLACE with the `IGNORE` flag. This instructs MariaDB to ignore records read from the text file that already exist in the table.

Live Data

For importing data into a table while it's in use, table access needs to be addressed. If access to the table by other users may not be interrupted, then a `LOW_PRIORITY` flag can be added to the LOAD DATA INFILE statement. This tells MariaDB that the loading of this data is a low priority. One would only need to change the first line of the SQL statement above to set its priority to low:

```
LOAD DATA LOW_PRIORITY INFILE '/tmp/prospects.txt'
...
```

If the `LOW_PRIORITY` flag isn't included, the table will be locked temporarily during the import and other users will be prevented from accessing it.

Being Difficult

I mentioned earlier that uploading of the text file should not be done in binary mode so as to avoid the difficulties associated with Windows line endings. If this is unavoidable, however, there is an easy way to import binary row-endings with MariaDB. One would just specify the appropriate hexadecimals for a carriage-return combined with a line-feed (i.e., `CRLF`) as the value of `TERMINATED BY` :

```
...
TERMINATED BY 0x0d0a;
```

Notice that there are intentionally no quotes around the binary value. If there were, MariaDB would take the value for text and not a binary code. The semi-colon is not part of the value; it's the SQL statement terminator.

Earlier we also stated that the first row in the spreadsheet containing the column headings should be deleted before exporting to avoid the difficulty of importing the headings as a record. It's actually pretty easy to tell MariaDB to just skip the top line. One would add the following line to the very end of the LOAD DATA INFILE statement:

```
...
IGNORE 1 LINES;
```

The number of lines for MariaDB to ignore can, of course, be more than one.

Another difficulty arises when some Windows application wizards export data with each field surrounded by double-quotes, as well as around the start and end of records. This can be a problem when a field contains a double-quote. To deal with this, some applications use back-slash (\) to escape embedded double-quotes, to indicate that a particular double-quote is not a field ending but part of the field's content. However, some applications will use a different character (like a pound-sign) to escape embedded quotes. This can cause problems if MariaDB isn't prepared for the odd escape-character. MariaDB will think the escape character is actually text and the embedded quote-mark, although it's escaped, is a field ending. The unenclosed text that follows will be imported into the next column and the remaining columns will be one column off, leaving the last column not imported. As maddening as this can be, it's quite manageable in MariaDB by adding an `ENCLOSED BY` and an `ESCAPED BY` clause:

```
LOAD DATA LOW_PRIORITY INFILE '/tmp/prospects.txt'
REPLACE INTO TABLE prospect_contact
FIELDS TERMINATED BY '"'
ENCLOSED BY '"' ESCAPED BY '#'
LINES STARTING BY '"'
TERMINATED BY '"\n'
IGNORE 1 LINES;
```

In the *Foreign Data Basics* section above, we said that the columns in the spreadsheet should be put in the same order and quantity as the receiving table. This really isn't necessary if MariaDB is cued in as to what it should expect. To illustrate, let's assume that prospect_contact has four columns in the following order: `row_id` , `name_first` , `name_last` , `telephone` . Whereas, the spreadsheet has only three columns, differently named, in this order: `Last Name` , `First Name` ,

`Telephone`. If the spreadsheet isn't adjusted, then the SQL statement will need to be changed to tell MariaDB the field order:

```
LOAD DATA LOW_PRIORITY INFILE '/tmp/prospects.txt'
REPLACE INTO TABLE sales_dept.prospect_contact
FIELDS TERMINATED BY 0x09
ENCLOSED BY '"' ESCAPED BY '#'
TERMINATED BY 0x0d0a
IGNORE 1 LINES
(name_last, name_first, telephone);
```

This SQL statement tells MariaDB the name of each table column associated with each spreadsheet column in the order that they appear in the text file. From there it will naturally insert the data into the appropriate columns in the table. As for columns that are missing like row_id, MariaDB will fill in those fields with the default value if one has been supplied in the table's properties. If not, it will leave the field as NULL. Incidentally, we slipped in the binary `[TAB] (0x09)` as a field delimiter.

mariadb-import

For some clients and for certain situations it may be of value to be able to import data into MariaDB without using the mariadb client. This could be necessary when constructing a shell script to import text files on an automated, regular schedule. To accomplish this, the mariadb-import (`mysqlimport` before MariaDB 10.5) utility may be used as it encompasses the LOAD DATA INFILE statement and can easily be run from a script. So if one wants to enter the involved SQL statement at the end of the last section above, the following could be entered from the command-line (i.e., not in the mariadb client):

```
mariadb-import --user='marie_dyer' --password='angelle1207' \
--fields-terminated-by=0x09 --lines-terminated-by=0x0d0a \
--replace --low-priority --fields-enclosed-by='"' \
 --fields-escaped-by='#' --ignore-lines='1' --verbose \
--columns='name_last, name_first, telephone' \
sales_dept '/tmp/prospect_contact.txt'
```

Although this statement is written over several lines here, it either has to be on the same line when entered or a space followed by a back-slash has to be entered at the end of each line (as seen here) to indicate that more follows. Since the above is entered at the command-line prompt, the user isn't logged into MariaDB. Therefore the first line contains the user name and password for mariadb-import to give to MariaDB. The password itself is optional, but the directive `--password` (without the equal sign) isn't. If the password value is not given in the statement, then the user will be prompted for it. Notice that the order of directives doesn't matter after the initial command, except that the database and file name go last. Regarding the file name, its prefix must be the same as the table—the dot and the extension are ignored. This requires that `prospects.txt` be renamed to `prospect_contact.txt`. If the file isn't renamed, then MariaDB would create a new table called prospects and the `--replace` option would be pointless. After the file name, incidentally, one could list more text files, separated by a space, to process using mariadb-import. We've added the `--verbose` directive so as to be able to see what's going on. One probably would leave this out in an automated script. By the way, `--low-priority` and `--ignore-lines` are available.

Web Hosting Restraints

Some web hosting companies do not allow the use of LOAD DATA INFILE or mariadb-import statements due to security vulnerabilities in these statements for them. To get around this, some extra steps are necessary to avoid having to manually enter the data one row at a time. First, one needs to have MariaDB installed on one's local workstation. For simplicity, we'll assume this is done and is running Linux on the main partition and MS Windows® on an extra partition. Recapping the on-going example of this article based on these new circumstances, one would boot up into Windows and start MS Excel®, load the client's spreadsheet into it and then run the export wizard as before—saving the file prospects.txt to the 'My Documents' directory. Then one would reboot into Linux and mount the Windows partition and copy the data text file to `/tmp` in Linux, locally. Next one would log into the local (not the client's) MariaDB server and import the text file using a LOAD DATA INFILE as we've extensively outline above. From there one would exit MariaDB and export the data out of MariaDB using the mariadb-dump utility locally, from the command-line like this:

```
mariadb-dump --user='root' --password='geronimo' sales_dept prospect_contact > /tmp/prospects.sql
```

This creates an interesting text file complete with all of the SQL commands necessary to insert the data back into MariaDB one record, one INSERT at a time. When you run mariadb-import, it's very educational to open up it in a text editor to see what it generates.

After creating this table dump, one would upload the resulting file (in ASCII mode) to the `/tmp` directory on the client's web server. From the command prompt on the client's server one would enter the following:

```
mariadb --user='marie_dyer' --password='angelle12107' sales_dept < '/tmp/prospects.sql'
```

This line along with the mariadb-dump line show above are simple approaches. Like the Windows application wizard, with mariadb-dump one can specify the format of the output file and several other factors. One important factor related to the scenario used in this article is the CREATE TABLE statement that will be embedded in the mariadb-dump output file. This will fail and kick out an error because of the existing table prospect_contact in the client's database. To limit the output to only INSERT statements and no CREATE TABLE statements, the mariadb-dump line would look like this:

```
mariadb-dump -u marie_dyer -p --no-create-info sales_dept prospect_contact > /tmp/prospects.sql
```

Notice that we've used acceptable abbreviations for the user name and the password directives. Since the password was given here, the user will be prompted for it.

The mariadb-dump utility usually works pretty well. However, one feature it's lacking at this time is a `REPLACE` flag as is found in the LOAD DATA INFILE statement and with the mariadb-import tool. So if a record already exists in the `prospect_contact`, it won't be imported. Instead it will kick out an error message and stop at that record, which can be a mess if one has imported several hundred rows and have several hundred more to go. One easy fix for this is to open up `prospects.sql` in a text editor and do a search on the word `INSERT` and replace it with `REPLACE`. The syntax of both of these statements are the same, fortunately. So one would only need to replace the keyword for new records to be inserted and for existing records to be replaced.

Concluding Observations and Admissions

It's always amazing to me how much can be involved in the simplest of statements in MariaDB. MariaDB is deceptively powerful and feature rich. One can keep the statements pretty minimal or one can develop a fairly detailed, single statement to allow for accuracy of action. There are many other aspects of importing data into MariaDB that we did not address—in particular dealing with utilities. We also didn't talk about the Perl modules that could be used to convert data files. These can be useful in scripting imports. There are many ways in which one can handle importing data. Hopefully, this article has presented most of the basics and pertinent advanced details that may be of use to most MariaDB developers.

6.1.9 Making Backups with mariadb-dump

Contents

One of the best utilities to use to make a backup copy of a server's MariaDB's data is mariadb-dump (previously called mysqldump, which still works as a symlink). It comes with MariaDB, so it costs you nothing more. Best of all it doesn't require you to shut down MariaDB services to make a backup. It works very simply: it retrieves the data and schema from each database and table and builds a data text file outside of MariaDB. This data text file (known as a dump file) will contain the SQL statements necessary to reconstruct the databases and data. If you were to open a dump file generated by mariadb-dump, you would see CREATE TABLE statements and a multitude of INSERT statements, one for each row of data.

Backing Up Everything

To export all of the databases in MariaDB using mariadb-dump, the following would be entered from the filesystem command-line:

```
mariadb-dump -u admin_backup -p -x -A > /data/backup/dbs.sql
```

The first set of options here (`-u admin_backup -p`) tell MariaDB that this utility is to be executed by the user *admin_backup* and that the user needs to be prompted for a password, which will have to be typed in on the next line when asked. Incidentally, although you might be tempted to just use the root user, you should create a special administrative user as we're using here. If the dump is to be executed by cron by way of a shell script, this option can be changed to `-pmypwd`, where *mypwd* is the password—there's no space between the `-p` and the password. The `-x` option has MariaDB lock all of the tables before performing the backup. The lock won't be released until the process is finished. To bundle INSERT statements together for each table, we've added the `-e` option. This extended insert option will cause the dump file to be

smaller and allow any possible future restores to be executed faster. The `-A` option specifies that all databases are to be exported. Finally, the greater-than sign is a shell redirect of the standard output (STDOUT) to the path and file named after it.

The example given for backing up all database is the short hand version. The convention is migrating to longer options, not the single letter options. In fact, some are being deprecated and won't be available in the future. So, the above could and should be entered like this:

```
mariadb-dump --user=admin_backup --password --lock-tables --all-databases > /data/backup/dbs.sql
```

The longer option names are easier to follow and to remember. Again, if the backup is to be executed by a shell script, the user's password should be listed: `--password=mypwd`. Notice that the equal-sign is added when the password is given with the long option name.

Just One Database

Backing up all of the databases at once with mariadb-dump may result in one large dump file. This could be take longer to complete the backup and make restoration a bit cumbersome later. Therefore, it might be more useful to stagger backups based on databases, making for possbily several smaller files. You could then backup larger databases during slower traffic times. You might also backup critical databases or ones that are changed much during slower times of the day so that you don't dimish user interaction.

To export only one database and not all, enter something like the following from the command-line:

```
mariadb-dump --user=admin_backup --password --lock-tables --databases db1 > /data/backup/db1.sql
```

The only significant difference in this line is that the `-A` option has been replaced with `-B` and the database to be exported has been given. To export multiple databases, just enter them after the `-B` option, separated by spaces (e.g., `-B db1 db2`).

Dumping Tables

For very large databases, you may want to backup the data based on tables rather than the whole database. You could backup weekly an entire database and then only backup daily individual tables for which data changes often. To backup just one table, the following could be entered from the command line:

```
mariadb-dump --user=admin_backup --password --lock-tables db1 table1 > /data/backup/db1_table1.sq
```

First notice that the `--databases` option has not been included in the line above. The utility assumes that the first name given is a database and the second name is a table name and not another database. To backup multiple tables from a database, just list them after the database name, separated by spaces (e.g., db1 table1 table2).

Conclusion

As you can see from this article, mariadb-dump is easy to use and very powerful. In fact, it can clobber your data if you're not careful. Therefore, you should practice using it on a test database—a test server even—a few times until you're comfortable with making backups and restoring them. Don't wait until you've lost your data and in a panic to restore your data to find out that you haven't been backing up your data properly or that you don't know how to fine tune data restoration. Develop some skills in advance and in a safe and controlled way. To learn how to restore dump files, see Restoring Data From Dump Files.

6.1.10 MariaDB String Functions

Contents

MariaDB has many built-in functions that can be used to manipulate strings of data. With these functions, one can format data, extract certain characters, or use search expressions. Good developers should be aware of the string functions that are available. Therefore, in this article we will go through several string functions, grouping them by similar features, and provide examples of how they might be used.

Formatting

There are several string functions that are used to format text and numbers for nicer display. A popular and very useful function for pasting together the contents of data fields with text is the CONCAT() function. As an example, suppose that a table called contacts has a column for each sales contact's first name and another for the last name. The following SQL statement would put them together:

```
SELECT CONCAT(name_first, ' ', name_last)
AS Name
FROM contacts;
```

This statement will display the first name, a space, and then the last name together in one column. The AS clause will change the column heading of the results to Name.

A less used concatenating function is CONCAT_WS(). It will put together columns with a separator between each. This can be useful when making data available for other programs. For instance, suppose we have a program that will import data, but it requires the fields to be separated by vertical bars. We could just export the data, or we could use a SELECT statement like the one that follows in conjunction with an interface written with an API language like Perl:

```
SELECT CONCAT_WS('|', col1, col2, col3)
FROM table1;
```

The first element above is the separator. The remaining elements are the columns to be strung together.

If we want to format a long number with commas every three digits and a period for the decimal point (e.g., 100,000.00), we can use the function FORMAT() like so:

```
SELECT CONCAT('$', FORMAT(col5, 2))
FROM table3;
```

In this statement, the CONCAT() will place a dollar sign in front of the numbers found in the `col5` column, which will be formatted with commas by FORMAT(). The `2` within the FORMAT() stipulates two decimal places.

Occasionally, one will want to convert the text from a column to either all upper-case letters or all lower-case letters. In the example that follows, the output of the first column is converted to upper-case and the second to lower-case:

```
SELECT UCASE(col1),
LCASE(col2)
FROM table4;
```

When displaying data in forms, it's sometimes useful to pad the data displayed with zeros or dots or some other filler. This can be necessary when dealing with VARCHAR columns where the width varies to help the user to see the column limits. There are two functions that may be used for padding: LPAD() and RPAD().

```
SELECT RPAD(part_nbr, 8, '.') AS 'Part Nbr.',
LPAD(description, 15, '_') AS Description
FROM catalog;
```

In this SQL statement, dots are added to the right end of each part number. So a part number of "H200" will display as "H200....", but without the quotes. Each part's description will have under-scores preceding it. A part with a description of "brass hinge" will display as "brass hinge".

If a column is a CHAR data-type, a fixed width column, then it may be necessary to trim any leading or trailing spaces from displays. There are a few functions to accomplish this task. The LTRIM() function will eliminate any leading spaces to the left. So " `H200` " becomes " `H200` ". For columns with trailing spaces, spaces on the right, RTRIM() will work: " `H500` "

becomes " `H500` ". A more versatile trimming function, though, is TRIM(). With it one can trim left, right or both. Below are a few examples:

```
SELECT TRIM(LEADING '.' FROM col1),
TRIM(TRAILING FROM col2),
TRIM(BOTH '_' FROM col3),
TRIM(col4)
FROM table5;
```

In the first TRIM() clause, the padding component is specified; the leading dots are to be trimmed from the output of `col1`. The trailing spaces will be trimmed off of `col2` —space is the default. Both leading and trailing under-scores are trimmed from `col3` above. Unless specified, BOTH is the default. So leading and trailing spaces are trimmed from `col4` in the statement here.

Extracting

When there is a need to extract specific elements from a column, MariaDB has a few functions that can help. Suppose a column in the table contacts contains the telephone numbers of sales contacts, including the area-codes, but without any dashes or parentheses. The area-code of each could be extracted for sorting with the LEFT() and the telephone number with the RIGHT() function.

```
SELECT LEFT(telephone, 3) AS area_code,
RIGHT(telephone, 7) AS tel_nbr
FROM contacts
ORDER BY area_code;
```

In the LEFT() function above, the column telephone is given along with the number of characters to extract, starting from the first character on the left in the column. The RIGHT() function is similar, but it starts from the last character on the right, counting left to capture, in this statement, the last seven characters. In the SQL statement above, area_code is reused to order the results set. To reformat the telephone number, it will be necessary to use the SUBSTRING() function.

```
SELECT CONCAT('(', LEFT(telephone, 3), ') ',
SUBSTRING(telephone, 4, 3), '-',
MID(telephone, 7)) AS 'Telephone Number'
FROM contacts
ORDER BY LEFT(telephone, 3);
```

In this SQL statement, the CONCAT() function is employed to assemble some characters and extracted data to produce a common display for telephone numbers (e.g., (504) 555-1234). The first element of the CONCAT() is an opening parenthesis. Next, a LEFT() is used to get the first three characters of telephone, the area-code. After that a closing parenthesis, along with a space is added to the output. The next element uses the SUBSTRING() function to extract the telephone number's prefix, starting at the fourth position, for a total of three characters. Then a dash is inserted into the display. Finally, the function MID() extracts the remainder of the telephone number, starting at the seventh position. The functions MID() and SUBSTRING() are interchangeable and their syntax are the same. By default, for both functions, if the number of characters to capture isn't specified, then it's assumed that the remaining ones are to be extracted.

Manipulating

There are a few functions in MariaDB that can help in manipulating text. One such function is REPLACE(). With it every occurrence of a search parameter in a string can be replaced. For example, suppose we wanted to replace the title *Mrs.* with *Ms.* in a column containing the person's title, but only in the output. The following SQL would do the trick:

```
SELECT CONCAT(REPLACE(title, 'Mrs.', 'Ms.'),
' ', name_first, ' ', name_last) AS Name
FROM contacts;
```

We're using the ever handy CONCAT() function to put together the contact's name with spaces. The REPLACE() function extracts each title and replaces *Mrs.* with *Ms.*, where applicable. Otherwise, for all other titles, it displays them unchanged.

If we want to insert or replace certain text from a column (but not all of its contents), we could use the INSERT() function in conjunction with the LOCATE() function. For example, suppose another contacts table has the contact's title and full name in one column. To change the occurrences of Mrs. to Ms., we could not use REPLACE() since the title is embedded in this example. Instead, we would do the following:

```
SELECT INSERT(name, LOCATE(name, 'Mrs.'), 4, 'Ms.')
FROM contacts;
```

The first element of the INSERT() function is the column. The second element which contains the LOCATE() is the position in the string that text is to be inserted. The third element is optional; it states the number of characters to overwrite. In this case, Mrs. which is four characters is overwritten with Ms. (the final element), which is only three. Incidentally, if 0 is specified, then nothing is overwritten, text is inserted only. As for the LOCATE() function, the first element is the column and the second the search text. It returns the position within the column where the text is found. If it's not found, then 0 is returned. A value of 0 for the position in the INSERT() function negates it and returns the value of name unchanged.

On the odd chance that there is a need to reverse the content of a column, there's the REVERSE() function. You would just place the column name within the function. Another minor function is the REPEAT() function. With it a string may be repeated in the display:

```
SELECT REPEAT(col1, 2)
FROM table1;
```

The first component of the function above is the string or column to be repeated. The second component states the number of times it's to be repeated.

Expression Aids

The function CHAR_LENGTH() is used to determine the number of characters in a string. This could be useful in a situation where a column contains different types of information of specific lengths. For instance, suppose a column in a table for a college contains identification numbers for students, faculty, and staff. If student identification numbers have eight characters while others have less, the following will count the number of student records:

```
SELECT COUNT(school_id)
AS 'Number of Students'
FROM table8
WHERE CHAR_LENGTH(school_id)=8;
```

The COUNT() function above counts the number of rows that meet the condition of the `WHERE` clause.

In a SELECT statement, an ORDER BY clause can be used to sort a results set by a specific column. However, if the column contains IP addresses, a simple sort may not produce the desired results:

```
SELECT ip_address
FROM computers WHERE server='Y'
ORDER BY ip_address LIMIT 3;

+-------------+
| ip_address  |
+-------------+
| 10.0.1.1    |
| 10.0.11.1   |
| 10.0.2.1    |
+-------------+
```

In the limited results above, the IP address 10.0.2.1 should be second. This happens because the column is being sorted lexically and not numerically. The function INET_ATON() will solve this sorting problem.

```
SELECT ip_address
FROM computers WHERE server='Y'
ORDER BY INET_ATON(ip_address) LIMIT 3;
```

Basically, the INET_ATON() function will convert IP addresses to regular numbers for numeric sorting. For instance, if we were to use the function in the list of columns in a SELECT statement, instead of the `WHERE` clause, the address 10.0.1.1 would return 167772417, 10.0.11.1 will return 167774977, and 10.0.2.1 the number 167772673. As a complement to INET_ATON(), the function INET_ATON() will translate these numbers back to their original IP addresses.

MariaDB is fairly case insensitive, which usually is fine. However, to be able to check by case, the STRCMP() function can be used. It converts the column examined to a string and makes a comparison to the search parameter.

```
SELECT col1, col2
FROM table6
WHERE STRCMP(col3, 'text')=0;
```

If there is an exact match, the function STRCMP() returns 0. So if `col3` here contains "Text", it won't match. Incidentally, if `col3` alphabetically is before the string to which it's compared, a `-1` will be returned. If it's after it, a `1` is returned.

When you have list of items in one string, the SUBSTRING_INDEX() can be used to pull out a sub-string of data. As an example, suppose we have a column which has five elements, but we want to retrieve just the first two elements. This SQL statement will return them:

```
SELECT SUBSTRING_INDEX(col4, '|', 2)
FROM table7;
```

The first component in the function above is the column or string to be picked apart. The second component is the delimiter. The third is the number of elements to return, counting from the left. If we want to grab the last two elements, we would use a negative two to instruct MariaDB to count from the right end.

Conclusion

There are more string functions available in MariaDB. A few of the functions mentioned here have aliases or close alternatives. There are also functions for converting between ASCII, binary, hexi-decimal, and octal strings. And there are also string functions related to text encryption and decryption that were not mentioned. However, this article has given you a good collection of common string functions that will assist you in building more powerful and accurate SQL statements.

6.1.11 Restoring Data from Dump Files

Contents

If you lose your data in MariaDB, but have been using mariadb-dump (previously called mysqldump) to make regular backups of your data in MariaDB, you can use the dump files to restore your data. This is the point of the back-ups, after all. To restore a dump file, it's just a matter of having the mariadb client execute all of the SQL statements that the file contains. There are some things to consider before restoring from a dump file, so read this section all of the way through before restoring. One simple and perhaps clumsy method to restore from a dump file is to enter something like the following:

```
mariadb --user admin_restore --password < /data/backup/db1.sql
```

Again, this is not using mariadb-dump. The mariadb-dump utility is only for making back-up copies, not restoring databases. Instead, you would use the mariadb client, which will read the dump file's content in order to batch execute the SQL statements that it contains. Notice that the redirect for `STDOUT` is not used here, but the redirect for the standard input (`STDIN`); the less-than sign is used since the dump file is an input source. Also, notice that in this example a database isn't specified. That's given within the dump file. You may want to stop MariaDB before doing a restore, and then start it again when done.

Restoring One Table

The problem with restoring from a dump file is that you may overwrite tables or databases that you wish you hadn't. For instance, your dump file might be a few days old and only one table may have been lost. If you restore all of the databases or all of the tables in a database, you would be restoring the data back to it's state at the time of the backup, a few days before. This could be quite a disaster. This is why dumping by database and table can be handy. However, that could be cumbersome.

A simple and easy method of limiting a restoration would be to create temporarily a user who only has privileges for the table you want to restore. You would enter a GRANT statement like this:

```
GRANT SELECT
ON db1.* TO 'admin_restore_temp'@'localhost'
IDENTIFIED BY 'its_pwd';

GRANT ALL ON db1.table1
TO 'admin_restore_temp'@'localhost';
```

These two SQL statements allow the temporary user to have the needed SELECT privileges on all of the tables of `db1` and `ALL` privileges for the `table1` table. Now when you restore the dump file containing the whole `db1` database, only `table1` will be replaced with the back-up copy. Of course, MariaDB will generate errors. To overlook the errors and to proceed with the restoration of data where no errors are generated (i.e., `table1`), use the `--force` option. Here's what you would enter at the command-line for this situation:

```
mariadb --user admin_restore_temp --password --force < /data/backup/db1.sql
```

6.1.12 Basic SQL Queries: A Quick SQL Cheat Sheet

Contents

This page lists the most important SQL statements and contains links to their documentation pages. If you need a basic tutorial on how to use the MariaDB database server and how to execute simple commands, see A MariaDB Primer.

Also see Common MariaDB Queries for examples of commonly-used queries.

Defining How Your Data Is Stored

- CREATE DATABASE is used to create a new, empty database.
- DROP DATABASE is used to completely destroy an existing database.
- USE is used to select a default database.
- CREATE TABLE is used to create a new table, which is where your data is actually stored.
- ALTER TABLE is used to modify an existing table's definition.
- DROP TABLE is used to completely destroy an existing table.
- DESCRIBE shows the structure of a table.

Manipulating Your Data

- SELECT is used when you want to read (or select) your data.
- INSERT is used when you want to add (or insert) new data.
- UPDATE is used when you want to change (or update) existing data.
- DELETE is used when you want to remove (or delete) existing data.
- REPLACE is used when you want to add or change (or replace) new or existing data.
- TRUNCATE is used when you want to empty (or delete) all data from the template.

Transactions

- START TRANSACTION is used to begin a transaction.
- COMMIT is used to apply changes and end transaction.
- ROLLBACK is used to discard changes and end transaction.

A Simple Example

```
CREATE DATABASE mydb;
USE mydb;
CREATE TABLE mytable ( id INT PRIMARY KEY, name VARCHAR(20) );
INSERT INTO mytable VALUES ( 1, 'Will' );
INSERT INTO mytable VALUES ( 2, 'Marry' );
INSERT INTO mytable VALUES ( 3, 'Dean' );
SELECT id, name FROM mytable WHERE id = 1;
UPDATE mytable SET name = 'Willy' WHERE id = 1;
SELECT id, name FROM mytable;
DELETE FROM mytable WHERE id = 1;
SELECT id, name FROM mytable;
DROP DATABASE mydb;
SELECT count(1) from mytable; gives the number of records in the table
```

6.1.13 Connecting to MariaDB

Contents

This article covers connecting to MariaDB and the basic connection parameters. If you are completely new to MariaDB, take a look at A MariaDB Primer first.

In order to connect to the MariaDB server, the client software must provide the correct connection parameters. The client software will most often be the mariadb client, used for entering statements from the command line, but the same concepts apply to any client, such as a graphical client, a client to run backups such as mariadb-dump, etc. The rest of this article assumes that the mariadb command line client is used.

If a connection parameter is not provided, it will revert to a default value.

For example, to connect to MariaDB using only default values with the mariadb client, enter the following from the command line:

```
mariadb
```

In this case, the following defaults apply:

- The host name is `localhost`.
- The user name is either your Unix login name, or `ODBC` on Windows.
- No password is sent.
- The client will connect to the server with the default socket, but not any particular database on the server.

These defaults can be overridden by specifying a particular parameter to use. For example:

```
mariadb -h 166.78.144.191 -u username -ppassword database_name
```

In this case:

- `-h` specifies a host. Instead of using `localhost`, the IP `166.78.144.191` is used.
- `-u` specifies a user name, in this case `username`
- `-p` specifies a password, `password`. Note that for passwords, unlike the other parameters, there cannot be a space between the option (`-p`) and the value (`password`). It is also not secure to use a password in this way, as other users on the system can see it as part of the command that has been run. If you include the `-p` option, but leave out the password, you will be prompted for it, which is more secure.
- The database name is provided as the first argument after all the options, in this case `database_name`.
- It will connect with the default tcp_ip port, 3306

Connection Parameters

host

```
--host=name
-h name
```

Connect to the MariaDB server on the given host. The default host is `localhost`. By default, MariaDB does not permit remote logins - see Configuring MariaDB for Remote Client Access.

password

```
--password[=passwd]
-p[passwd]
```

The password of the MariaDB account. It is generally not secure to enter the password on the command line, as other users on the system can see it as part of the command that has been run. If you include the `-p` or `--password` option, but leave out the password, you will be prompted for it, which is more secure.

pipe

```
--pipe
-W
```

On Windows systems that have been started with the `--enable-named-pipe` option, use this option to connect to the server using a named pipe.

port

```
--port=num
-P num
```

The TCP/IP port number to use for the connection. The default is `3306`.

protocol

```
--protocol=name
```

Specifies the protocol to be used for the connection for the connection. It can be one of `TCP`, `SOCKET`, `PIPE` or `MEMORY` (case-insensitive). Usually you would not want to change this from the default. For example on Unix, a Unix socket file (`SOCKET`) is the default protocol, and usually results in the quickest connection.

- `TCP`: A TCP/IP connection to a server (either local or remote). Available on all operating systems.
- `SOCKET`: A Unix socket file connection, available to the local server on Unix systems only. If socket is not specified with --socket, in a config file or with the environment variable `MYSQL_UNIX_PORT` then the default `/tmp/mysql.sock` will be used.
- `PIPE`. A named-pipe connection (either local or remote). Available on Windows only.
- `MEMORY`. Shared-memory connection to the local server on Windows systems only.

shared-memory-base-name

```
--shared-memory-base-name=name
```

Only available on Windows systems in which the server has been started with the `--shared-memory` option, this specifies the shared-memory name to use for connecting to a local server. The value is case-sensitive, and defaults to `MARIADB`.

socket

```
--socket=name
-S name
```

For connections to localhost, this specifies either the Unix socket file to use (default `/tmp/mysql.sock`), or, on Windows where the server has been started with the `--enable-named-pipe` option, the name (case-insensitive) of the named pipe to use (default `MARIADB`).

TLS Options

A brief listing is provided below. See Secure Connections Overview and TLS System Variables for more detail.

ssl

```
--ssl
```

Enable TLS for connection (automatically enabled with other TLS flags). Disable with ' `--skip-ssl` '

ssl-ca

```
--ssl-ca=name
```

CA file in PEM format (check OpenSSL docs, implies `--ssl`).

ssl-capath

```
--ssl-capath=name
```

CA directory (check OpenSSL docs, implies `--ssl`).

ssl-cert

```
--ssl-cert=name
```

X509 cert in PEM format (implies `--ssl`).

ssl-cipher

```
--ssl-cipher=name
```

TLS cipher to use (implies `--ssl`).

ssl-key

```
--ssl-key=name
```

X509 key in PEM format (implies `--ssl`).

ssl-crl

```
--ssl-crl=name
```

Certificate revocation list (implies `--ssl`).

ssl-crlpath

```
--ssl-crlpath=name
```

Certificate revocation list path (implies `--ssl`).

ssl-verify-server-cert

```
--ssl-verify-server-cert
```

Verify server's "Common Name" in its cert against hostname used when connecting. This option is disabled by default.

user

```
--user=name
-u name
```

The MariaDB user name to use when connecting to the server. The default is either your Unix login name, or `ODBC` on Windows. See the GRANT command for details on creating MariaDB user accounts.

Option Files

It's also possible to use option files (or configuration files) to set these options. Most clients read option files. Usually, starting a client with the `--help` option will display which files it looks for as well as which option groups it recognizes.

6.1.14 External Tutorials

Contents

Here are some links to external MariaDB, MySQL and SQL tutorials that may be of interest

MariaDB-Focused Tutorials

- Tutorialspoint MariaDB tutorial for beginners
- MariaDB Tutorial by "Tech on the net"
- Learn MySQL / MariaDB for Beginners
- MariaDB Tutorial from javatpoint

MySQL-Focused Tutorials (But Should Work For MariaDB Too)

- mysqltutorial. Site with a lot of MySQL usage information and also how to connect to MySQL from different programming languages.
- MySQL Tutorial for Beginners Learn in 7 Days
- MySQL Tutorial from javatpoint
- MySQL Tutorial from w3resource
- MySQL by Examples for Beginners
- MySQL Tutorial – A Beginner's Guide To Learn MySQL
- Php/MySQL Tutorial from tizag
- PHP & MySQL Tutorial from siteground

General SQL Tutorials

- w3schools general SQL tutorial
- sqltutorial. Helps you get started with SQL quickly and effectively through many practical examples.

6.1.15 Useful MariaDB Queries

Contents

This page is intended to be a quick reference of commonly-used and/or useful queries in MariaDB.

Creating a Table

```
CREATE TABLE t1 ( a INT );
CREATE TABLE t2 ( b INT );
CREATE TABLE student_tests (
 name CHAR(10), test CHAR(10),
 score TINYINT, test_date DATE
);
```

See CREATE TABLE for more.

Inserting Records

```
INSERT INTO t1 VALUES (1), (2), (3);
INSERT INTO t2 VALUES (2), (4);

INSERT INTO student_tests
 (name, test, score, test_date) VALUES
 ('Chun', 'SQL', 75, '2012-11-05'),
 ('Chun', 'Tuning', 73, '2013-06-14'),
 ('Esben', 'SQL', 43, '2014-02-11'),
 ('Esben', 'Tuning', 31, '2014-02-09'),
 ('Kaolin', 'SQL', 56, '2014-01-01'),
 ('Kaolin', 'Tuning', 88, '2013-12-29'),
 ('Tatiana', 'SQL', 87, '2012-04-28'),
 ('Tatiana', 'Tuning', 83, '2013-09-30');
```

See INSERT for more.

Using AUTO_INCREMENT

The AUTO_INCREMENT attribute is used to automatically generate a unique identity for new rows.

```
CREATE TABLE student_details (
 id INT NOT NULL AUTO_INCREMENT, name CHAR(10),
 date_of_birth DATE, PRIMARY KEY (id)
);
```

When inserting, the id field can be omitted, and is automatically created.

```
INSERT INTO student_details (name,date_of_birth) VALUES
 ('Chun', '1993-12-31'),
 ('Esben','1946-01-01'),
 ('Kaolin','1996-07-16'),
 ('Tatiana', '1988-04-13');

SELECT * FROM student_details;
+----+---------+---------------+
| id | name    | date_of_birth |
+----+---------+---------------+
|  1 | Chun    | 1993-12-31    |
|  2 | Esben   | 1946-01-01    |
|  3 | Kaolin  | 1996-07-16    |
|  4 | Tatiana | 1988-04-13    |
+----+---------+---------------+
```

See AUTO_INCREMENT for more.

Querying from two tables on a common value

```
SELECT * FROM t1 INNER JOIN t2 ON t1.a = t2.b;
```

This kind of query is called a join - see JOINS for more.

Finding the Maximum Value

```
SELECT MAX(a) FROM t1;
+--------+
| MAX(a) |
+--------+
|      3 |
+--------+
```

See the MAX() function for more, as well as Finding the maximum value and grouping the results below for a more practical example.

Finding the Minimum Value

```
SELECT MIN(a) FROM t1;
+--------+
| MIN(a) |
+--------+
|      1 |
+--------+
```

See the MIN() function for more.

Finding the Average Value

```
SELECT AVG(a) FROM t1;
+--------+
| AVG(a) |
+--------+
| 2.0000 |
+--------+
```

See the AVG() function for more.

Finding the Maximum Value and Grouping the Results

```
SELECT name, MAX(score) FROM student_tests GROUP BY name;
+---------+------------+
| name    | MAX(score) |
+---------+------------+
| Chun    |         75 |
| Esben   |         43 |
| Kaolin  |         88 |
| Tatiana |         87 |
+---------+------------+
```

See the MAX() function for more.

Ordering Results

```
SELECT name, test, score FROM student_tests ORDER BY score DESC;
+---------+--------+-------+
| name    | test   | score |
+---------+--------+-------+
| Kaolin  | Tuning |    88 |
| Tatiana | SQL    |    87 |
| Tatiana | Tuning |    83 |
| Chun    | SQL    |    75 |
| Chun    | Tuning |    73 |
| Kaolin  | SQL    |    56 |
| Esben   | SQL    |    43 |
| Esben   | Tuning |    31 |
+---------+--------+-------+
```

See ORDER BY for more.

Finding the Row with the Minimum of a Particular Column

In this example, we want to find the lowest test score for any student.

```
SELECT name,test, score FROM student_tests WHERE score=(SELECT MIN(score) FROM student);
+-------+--------+-------+
| name  | test   | score |
+-------+--------+-------+
| Esben | Tuning |    31 |
+-------+--------+-------+
```

Finding Rows with the Maximum Value of a Column by Group

This example returns the best test results of each student:

```
SELECT name, test, score FROM student_tests st1 WHERE score = (
  SELECT MAX(score) FROM student st2 WHERE st1.name = st2.name
);
+---------+--------+-------+
| name    | test   | score |
+---------+--------+-------+
| Chun    | SQL    |    75 |
| Esben   | SQL    |    43 |
| Kaolin  | Tuning |    88 |
| Tatiana | SQL    |    87 |
+---------+--------+-------+
```

Calculating Age

The TIMESTAMPDIFF function can be used to calculate someone's age:

```
SELECT CURDATE() AS today;
+------------+
| today      |
+------------+
| 2014-02-17 |
+------------+

SELECT name, date_of_birth, TIMESTAMPDIFF(YEAR,date_of_birth,'2014-08-02') AS age
  FROM student_details;
+---------+---------------+------+
| name    | date_of_birth | age  |
+---------+---------------+------+
| Chun    | 1993-12-31    |   20 |
| Esben   | 1946-01-01    |   68 |
| Kaolin  | 1996-07-16    |   18 |
| Tatiana | 1988-04-13    |   26 |
+---------+---------------+------+
```

See TIMESTAMPDIFF() for more.

Using User-defined Variables

This example sets a user-defined variable with the average test score, and then uses it in a later query to return all results above the average.

```
SELECT @avg_score:= AVG(score) FROM student_tests;
+-------------------------+
| @avg_score:= AVG(score) |
+-------------------------+
|            67.000000000 |
+-------------------------+

SELECT * FROM student_tests WHERE score > @avg_score;
+---------+--------+-------+------------+
| name    | test   | score | test_date  |
+---------+--------+-------+------------+
| Chun    | SQL    |    75 | 2012-11-05 |
| Chun    | Tuning |    73 | 2013-06-14 |
| Kaolin  | Tuning |    88 | 2013-12-29 |
| Tatiana | SQL    |    87 | 2012-04-28 |
| Tatiana | Tuning |    83 | 2013-09-30 |
+---------+--------+-------+------------+
```

User-defined variables can also be used to add an incremental counter to a resultset:

```
SET @count = 0;

SELECT @count := @count + 1 AS counter, name, date_of_birth FROM student_details;
+---------+---------+---------------+
| counter | name    | date_of_birth |
+---------+---------+---------------+
|       1 | Chun    | 1993-12-31    |
|       2 | Esben   | 1946-01-01    |
|       3 | Kaolin  | 1996-07-16    |
|       4 | Tatiana | 1988-04-13    |
+---------+---------+---------------+
```

See User-defined Variables for more.

View Tables in Order of Size

Returns a list of all tables in the database, ordered by size:

```
SELECT table_schema as `DB`, table_name AS `Table`,
  ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
  FROM information_schema.TABLES
  ORDER BY (data_length + index_length) DESC;

+--------------------+---------------------------------------+-----------+
| DB                 | Table                                 | Size (MB) |
+--------------------+---------------------------------------+-----------+
| wordpress          | wp_simple_history_contexts            |      7.05 |
| wordpress          | wp_posts                              |      6.59 |
| wordpress          | wp_simple_history                     |      3.05 |
| wordpress          | wp_comments                           |      2.73 |
| wordpress          | wp_commentmeta                        |      2.47 |
| wordpress          | wp_simple_login_log                   |      2.03 |
...
```

Removing Duplicates

This example assumes there's a unique ID, but that all other fields are identical. In the example below, there are 4 records, 3 of which are duplicates, so two of the three duplicates need to be removed. The intermediate SELECT is not necessary, but demonstrates what is being returned.

```
CREATE TABLE t (id INT, f1 VARCHAR(2));

INSERT INTO t VALUES (1,'a'), (2,'a'), (3,'b'), (4,'a');

SELECT * FROM t t1, t t2 WHERE t1.f1=t2.f1 AND t1.id<>t2.id AND t1.id=(
  SELECT MAX(id) FROM t tab WHERE tab.f1=t1.f1
);
+------+------+------+------+
| id   | f1   | id   | f1   |
+------+------+------+------+
|    4 | a    |    1 | a    |
|    4 | a    |    2 | a    |
+------+------+------+------+

DELETE FROM t WHERE id IN (
  SELECT t2.id FROM t t1, t t2 WHERE t1.f1=t2.f1 AND t1.id<>t2.id AND t1.id=(
    SELECT MAX(id) FROM t tab WHERE tab.f1=t1.f1
  )
);
Query OK, 2 rows affected (0.120 sec)

SELECT * FROM t;
+------+------+
| id   | f1   |
+------+------+
|    3 | b    |
|    4 | a    |
+------+------
```

6.2 Basic MariaDB Articles

These articles are at a basic level. They are more advanced than beginners and less advanced than intermediate developers and administrators.

Basic SQL Debugging

An introductory tutorial on debugging MariaDB.

Configuring MariaDB for Remote Client Access

How to configure MariaDB for remote client access.

Creating & Using Views

A tutorial on creating and using views.

Getting Started with Indexes

Extensive tutorial on creating indexes for tables.

Joining Tables with JOIN Clauses

An introductory tutorial on using the JOIN clause.

The Essentials of an Index

Explains the basics of a table index.

Troubleshooting Connection Issues

Common problems when trying to connect to MariaDB.

6.2.1 Basic SQL Debugging

Contents

Designing Queries

Following a few conventions makes finding errors in queries a lot easier, especially when you ask for help from people who might know SQL, but know nothing about your particular schema. A query easy to read is a query easy to debug. Use whitespace to group clauses within the query. Choose good table and field aliases to add clarity, not confusion. Choose the syntax that supports the query's meaning.

Using Whitespace

A query hard to read is a query hard to debug. White space is free. New lines and indentation make queries easy to read, particularly when constructing a query inside a scripting language, where variables are interspersed throughout the query.

There is a syntax error in the following. How fast can you find it?

```
SELECT u.id, u.name, alliance.ally FROM users u JOIN alliance ON
(u.id=alliance.userId) JOIN team ON (alliance.teamId=team.teamId
WHERE team.teamName='Legionnaires' AND u.online=1 AND ((u.subscription='paid'
AND u.paymentStatus='current') OR u.subscription='free') ORDER BY u.name;
```

Here's the same query, with correct use of whitespace. Can you find the error faster?

```
SELECT
    u.id
    , u.name
    , alliance.ally
FROM
    users u
    JOIN alliance ON (u.id = alliance.userId)
    JOIN team ON (alliance.teamId = team.teamId
WHERE
    team.teamName = 'Legionnaires'
    AND u.online = 1
    AND (
        (u.subscription = 'paid' AND u.paymentStatus = 'current')
        OR
        u.subscription = 'free'
    )
ORDER BY
    u.name;
```

Even if you don't know SQL, you might still have caught the missing ')' following team.teamId.

The exact formatting style you use isn't so important. You might like commas in the select list to follow expressions, rather than precede them. You might indent with tabs or with spaces. Adherence to some particular form is not important. Legibility is the only goal.

Table and Field Aliases

Aliases allow you to rename tables and fields for use within a query. This can be handy when the original names are very long, and is required for self joins and certain subqueries. However, poorly chosen aliases can make a query harder to debug, rather than easier. Aliases should reflect the original table name, not an arbitrary string.

Bad:

```
SELECT *
FROM
    financial_reportQ_1 AS a
    JOIN sales_renderings AS b ON (a.salesGroup = b.groupId)
    JOIN sales_agents AS c ON (b.groupId = c.group)
WHERE
    b.totalSales > 10000
    AND c.id != a.clientId
```

As the list of joined tables and the WHERE clause grow, it becomes necessary to repeatedly look back to the top of the query to see to which table any given alias refers.

Better:

```
SELECT *
FROM
    financial_report_Q_1 AS frq1
    JOIN sales_renderings AS sr ON (frq1.salesGroup = sr.groupId)
    JOIN sales_agents AS sa ON (sr.groupId = sa.group)
WHERE
    sr.totalSales > 10000
    AND sa.id != frq1.clientId
```

Each alias is just a little longer, but the table initials give enough clues that anyone familiar with the database only need see the full table name once, and can generally remember which table goes with which alias while reading the rest of the query.

Placing JOIN conditions

The manual warns against using the JOIN condition (that is, the ON clause) for restricting rows. Some queries, particularly those using implicit joins, take the opposite extreme - all join conditions are moved to the WHERE clause. In consequence, the table relationships are mixed with the business logic.

Bad:

```
SELECT *
FROM
    family,
    relationships
WHERE
    family.personId = relationships.personId
    AND relationships.relation = 'father'
```

Without digging through the WHERE clause, it is impossible to say what links the two tables.

Better:

```
SELECT *
FROM
    family
    JOIN relationships ON (family.personId = relationships.personId)
WHERE
    relationships.relation = 'father'
```

The relation between the tables is immediately obvious. The WHERE clause is left to limit rows in the result set.

Compliance with such a restriction negates the use of the comma operator to join tables. It is a small price to pay. Queries should be written using the explicit JOIN keyword anyway, and the two should never be mixed (unless you like rewriting all your queries every time a new version changes operator precedence).

Finding Syntax Errors

Syntax errors are among the easiest problems to solve. MariaDB provides an error message showing the exact point where the parser became confused. Check the query, including a few words before the phrase shown in the error message. Most syntax and parsing errors are obvious after a second look, but some are more elusive, especially when the error text seems empty, points to a valid keyword, or seems to error on syntax that appears exactly correct.

Interpreting the Empty Error

Most syntax errors are easy to interpret. The error generally details the exact source of the trouble. A careful look at the query, with the error message in mind, often reveals an obvious mistake, such as mispelled field names, a missing 'AND', or an extra closing parenthesis. Sometimes the error is a little less helpful. A frequent, less-than-helpful message:

```
ERROR 1064: You have an error in your SQL syntax; check the manual that corresponds to your
MariaDB server version for the right syntax to use near ' ' at line 1
```

The empty ' ' can be disheartening. Clearly there is an error, but where? A good place to look is at the end of the query. The ' ' suggests that the parser reached the end of the statement while still expecting some syntax token to appear.

Check for missing closers, such as ' and):

```
SELECT * FROM someTable WHERE field = 'value
```

Look for incomplete clauses, often indicated by an exposed comma:

```
SELECT * FROM someTable WHERE field = 1 GROUP BY id,
```

Checking for keywords

MariaDB allows table and field names and aliases that are also reserved words. To prevent ambiguity, such names must be enclosed in backticks (`):

```
SELECT * FROM actionTable WHERE `DELETE` = 1;
```

If the syntax error is shown near one of your identifiers, check if it appears on the reserved word list.

A text editor with color highlighting for SQL syntax helps to find these errors. When you enter a field name, and it shows up in the same color as the SELECT keyword, you know something is amiss. Some common culprits:

- **DESC** is a common abbreviation for "description" fields. It means "descending" in a MariaDB **ORDER** clause.
- **DATE**, **TIME**, and **TIMESTAMP** are all common field names. They are also field types.
- **ORDER** appears in sales applications. MariaDB uses it to specify sorting for results.

Some keywords are so common that MariaDB makes a special allowance to use them unquoted. My advice: don't. If it's a keyword, quote it.

Version specific syntax

As MariaDB adds new features, the syntax must change to support them. Most of the time, old syntax will work in newer versions of MariaDB. One notable exception is the change in precedence of the comma operator relative to the JOIN keyword in version 5.0. A query that used to work, such as

```
SELECT * FROM a, b JOIN c ON a.x = c.x;
```

will now fail.

More common, however, is an attempt to use new syntax in an old version. Web hosting companies are notoriously slow to upgrade MariaDB, and you may find yourself using a version several years out of date. The result can be very frustrating when a query that executes flawlessly on your own workstation, running a recent installation, fails completely in your production environment.

This query fails in any version of MySQL prior to 4.1, when subqueries were added to the server:

```
SELECT * FROM someTable WHERE someId IN (SELECT id FROM someLookupTable);
```

This query fails in some early versions of MySQL, because the JOIN syntax did not originally allow an ON clause:

```
SELECT * FROM tableA JOIN tableB ON tableA.x = tableB.y;
```

Always check the installed version of MariaDB, and read the section of the manual relevant for that version. The manual usually indicates exactly when particular syntax became available for use.

6.2.2 Configuring MariaDB for Remote Client Access

Contents

Some MariaDB packages bind MariaDB to 127.0.0.1 (the loopback IP address) by default as a security measure using the bind-address configuration directive. Old MySQL packages sometimes disabled TCP/IP networking altogether using the skip-networking directive. Before going in to how to configure these, let's explain what each of them actually does:

- skip-networking is fairly simple. It just tells MariaDB to run without any of the TCP/IP networking options.
- bind-address requires a little bit of background information. A given server usually has at least two networking interfaces (although this is not required) and can easily have more. The two most common are a *Loopback* network device and a physical *Network Interface Card* (NIC) which allows you to communicate with the network. MariaDB is bound to the loopback interface by default because it makes it impossible to connect to the TCP port on the server from a remote host (the bind-address must refer to a local IP address, or you will receive a fatal error and MariaDB will not start). This of course is not desirable if you want to use the TCP port from a remote host, so you must remove this bind-address directive or replace it either 0.0.0.0 to listen on all interfaces, or the address of a specific public interface.

MariaDB starting with 10.11

Multiple comma-separated addresses can now be given to `bind_address` to allow the server to listen on more than one specific interface while not listening on others.

If bind-address is bound to 127.0.0.1 (localhost), one can't connect to the MariaDB server from other hosts or from the same host over TCP/IP on a different interface than the loopback (127.0.0.1). This for example will not work (connecting with a hostname that points to a local IP of the host):

```
(/my/maria-10.11) ./client/mariadb --host=myhost --protocol=tcp --port=3306 test
ERROR 2002 (HY000): Can't connect to MySQL server on 'myhost' (115)
(/my/maria-10.11) telnet myhost 3306
Trying 192.168.0.11...
telnet: connect to address 192.168.0.11: Connection refused
```

Using 'localhost' works when binding with `bind_address` :

```
(my/maria-10.11) ./client/mariadb --host=localhost --protocol=tcp --port=3306 test
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MariaDB monitor.  Commands end with ; or \g.
...
```

Finding the Defaults File

To enable MariaDB to listen to remote connections, you need to edit your defaults file. See Configuring MariaDB with my.cnf for more detail.

Common locations for defaults files:

```
  * /etc/my.cnf                              (*nix/BSD)
  * $MYSQL_HOME/my.cnf                       (*nix/BSD) *Most Notably /etc/mysql/my.cnf
  * SYSCONFDIR/my.cnf                        (*nix/BSD)
  * DATADIR\my.ini                           (Windows)
```

You can see which defaults files are read and in which order by executing:

```
shell> mariadbd --help --verbose
mariadbd  Ver 10.11.5-MariaDB for linux-systemd on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: ./mariadbd [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf /etc/mysql/my.cnf ~/.my.cnf
```

The last line shows which defaults files are read.

Editing the Defaults File

Once you have located the defaults file, use a text editor to open the file and try to find lines like this under the [mysqld] section:

```
[mysqld]
   ...
   skip-networking
   ...
   bind-address = <some ip-address>
   ...
```

(The lines may not be in this order, and the order doesn't matter.)

If you are able to locate these lines, make sure they are both commented out (prefaced with hash (#) characters), so that they look like this:

```
[mysqld]
   ...
   #skip-networking
   ...
   #bind-address = <some ip-address>
   ...
```

(Again, the order of these lines don't matter)

Alternatively, just add the following lines **at the end** of your .my.cnf (notice that the file name starts with a dot) file in your home directory or alternative **last** in your /etc/my.cnf file.

```
[mysqld]
skip-networking=0
skip-bind-address
```

This works as one can have any number of [mysqld] sections.

Save the file and restart the mariadbd daemon or service (see Starting and Stopping MariaDB).

You can check the options mariadbd is using by executing:

```
shell> ./sql/mariadbd --print-defaults
./sql/mariadbd would have been started with the following arguments:
--bind-address=127.0.0.1 --innodb_file_per_table=ON --server-id=1 --skip-bind-address ...
```

It doesn't matter if you have the original --bind-address left as the later --skip-bind-address will overwrite it.

Granting User Connections From Remote Hosts

Now that your MariaDB server installation is setup to accept connections from remote hosts, we have to add a user that is allowed to connect from something other than 'localhost' (Users in MariaDB are defined as 'user'@'host', so 'chadmaynard'@'localhost' and 'chadmaynard'@'1.1.1.1' (or 'chadmaynard'@'server.domain.local') are different users that can have completely different permissions and/or passwords.

To create a new user:

- log into the mariadb command line client (or your favorite graphical client if you wish)

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 36
Server version: 5.5.28-MariaDB-mariadb1~lucid mariadb.org binary distribution

Copyright (c) 2000, 2012, Oracle, Monty Program Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

- if you are interested in viewing any existing remote users, issue the following SQL statement on the mysql.user table:

```
SELECT User, Host FROM mysql.user WHERE Host <> 'localhost';
+--------+-----------+
| User   | Host      |
+--------+-----------+
| daniel | %         |
| root   | 127.0.0.1 |
| root   | ::1       |
| root   | gandalf   |
+--------+-----------+
4 rows in set (0.00 sec)
```

(If you have a fresh install, it is normal for no rows to be returned)

Now you have some decisions to make. At the heart of every grant statement you have these things:

- list of allowed privileges
- what database/tables these privileges apply to
- username
- host this user can connect from
- and optionally a password

It is common for people to want to create a "root" user that can connect from anywhere, so as an example, we'll do just that, but to improve on it we'll create a root user that can connect from anywhere on my local area network (LAN), which has addresses in the subnet 192.168.100.0/24. This is an improvement because opening a MariaDB server up to the Internet and granting access to all hosts is bad practice.

```
GRANT ALL PRIVILEGES ON *.* TO 'root'@'192.168.100.%'
  IDENTIFIED BY 'my-new-password' WITH GRANT OPTION;
```

(% is a wildcard)

For more information about how to use GRANT, please see the GRANT page.

At this point we have accomplished our goal and we have a user 'root' that can connect from anywhere on the 192.168.100.0/24 LAN.

Port 3306 is Configured in Firewall

One more point to consider whether the firewall is configured to allow incoming request from remote clients:

On RHEL and CentOS 7, it may be necessary to configure the firewall to allow TCP access to MariaDB from remote hosts. To do so, execute both of these commands:

```
firewall-cmd --add-port=3306/tcp
firewall-cmd --permanent --add-port=3306/tcp
```

Caveats

- If your system is running a software firewall (or behind a hardware firewall or NAT) you must allow connections

destined to TCP port that MariaDB runs on (by default and almost always 3306).

- To undo this change and not allow remote access anymore, simply remove the `skip-bind-address` line or uncomment the bind-address line in your defaults file. The end result should be that you should have in the output from `./sql/mariadbd --print-defaults` the option `--bind-address=127.0.0.1` and no `--skip-bind-address`.

The initial version of this article was copied, with permission, from http://hashmysql.org/wiki/Remote_Clients_Cannot_Connect on 2012-10-30.

6.2.3 Creating & Using Views

Contents

A Tutorial Introduction

Up-front warning: This is the beginning of a very basic tutorial on views, based on my experimentation with them. This tutorial assumes that you've read the appropriate tutorials up to and including More Advanced Joins (or that you understand the concepts behind them). This page is intended to give you a general idea of how views work and what they do, as well as some examples of when you could use them.

Requirements for This Tutorial

In order to perform the SQL statements in this tutorial, you will need access to a MariaDB database and you will need the CREATE TABLE and CREATE VIEW privileges on this table.

The Employee Database

First, we need some data we can perform our optimizations on, so we'll recreate the tables from the More Advanced Joins tutorial, to provide us with a starting point. If you have already completed that tutorial and have this database already, you can skip ahead.

First, we create the table that will hold all of the employees and their contact information:

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM;
```

Next, we add a few employees to the table:

```
INSERT INTO `Employees` (`First_Name`, `Last_Name`, `Position`, `Home_Address`, `Home_Phone`)
VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456'),
  ('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349'),
  ('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329'),
  ('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478');
```

Now, we create a second table, containing the hours which each employee clocked in and out during the week:

```
CREATE TABLE `Hours` (
  `ID` TINYINT(3) UNSIGNED NOT NULL,
  `Clock_In` DATETIME NOT NULL,
  `Clock_Out` DATETIME NOT NULL
) ENGINE=MyISAM;
```

Finally, although it is a lot of information, we add a full week of hours for each of the employees into the second table that we created:

```
INSERT INTO `Hours`
VALUES ('1', '2005-08-08 07:00:42', '2005-08-08 17:01:36'),
  ('1', '2005-08-09 07:01:34', '2005-08-09 17:10:11'),
  ('1', '2005-08-10 06:59:56', '2005-08-10 17:09:29'),
  ('1', '2005-08-11 07:00:17', '2005-08-11 17:00:47'),
  ('1', '2005-08-12 07:02:29', '2005-08-12 16:59:12'),
  ('2', '2005-08-08 07:00:25', '2005-08-08 17:03:13'),
  ('2', '2005-08-09 07:00:57', '2005-08-09 17:05:09'),
  ('2', '2005-08-10 06:58:43', '2005-08-10 16:58:24'),
  ('2', '2005-08-11 07:01:58', '2005-08-11 17:00:45'),
  ('2', '2005-08-12 07:02:12', '2005-08-12 16:58:57'),
  ('3', '2005-08-08 07:00:12', '2005-08-08 17:01:32'),
  ('3', '2005-08-09 07:01:10', '2005-08-09 17:00:26'),
  ('3', '2005-08-10 06:59:53', '2005-08-10 17:02:53'),
  ('3', '2005-08-11 07:01:15', '2005-08-11 17:04:23'),
  ('3', '2005-08-12 07:00:51', '2005-08-12 16:57:52'),
  ('4', '2005-08-08 06:54:37', '2005-08-08 17:01:23'),
  ('4', '2005-08-09 06:58:23', '2005-08-09 17:00:54'),
  ('4', '2005-08-10 06:59:14', '2005-08-10 17:00:12'),
  ('4', '2005-08-11 07:00:49', '2005-08-11 17:00:34'),
  ('4', '2005-08-12 07:01:09', '2005-08-12 16:58:29'),
  ('5', '2005-08-08 07:00:04', '2005-08-08 17:01:43'),
  ('5', '2005-08-09 07:02:12', '2005-08-09 17:02:13'),
  ('5', '2005-08-10 06:59:39', '2005-08-10 17:03:37'),
  ('5', '2005-08-11 07:01:26', '2005-08-11 17:00:03'),
  ('5', '2005-08-12 07:02:15', '2005-08-12 16:59:02'),
  ('6', '2005-08-08 07:00:12', '2005-08-08 17:01:02'),
  ('6', '2005-08-09 07:03:44', '2005-08-09 17:00:00'),
  ('6', '2005-08-10 06:54:19', '2005-08-10 17:03:31'),
  ('6', '2005-08-11 07:00:05', '2005-08-11 17:02:57'),
  ('6', '2005-08-12 07:02:07', '2005-08-12 16:58:23');
```

Working with the Employee Database

In this example, we are going to assist Human Resources by simplifying the queries that their applications need to perform. At the same time, it's going to enable us to abstract their queries from the database, which allows us more flexibility in maintaining it.

Filtering by Name, Date and Time

In the previous tutorial, we looked at a JOIN query that displayed all of the lateness instances for a particular employee. In this tutorial, we are going to abstract that query somewhat to provide us with all lateness occurrences for all employees, and then standardize that query by making it into a view.

Our previous query looked like this:

```
SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59';
```

The result:

```
+------------+-----------+---------------------+---------------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           |
+------------+-----------+---------------------+---------------------+
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |
+------------+-----------+---------------------+---------------------+
```

Refining Our Query

The previous example displays to us all of Heimholtz's punch-in times that were after seven AM. We can see here that Heimholz has been late twice within this reporting period, and we can also see that in both instances, he either left exactly on time or he left early. Our company policy, however, dictates that late instances must be made up at the end of one's shift, so we want to exclude from our report anyone whose clock-out time was greater than 10 hours and one minute after their clock-in time.

```
SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`,
  (TIMESTAMPDIFF(MINUTE,`Hours`.`Clock_Out`,`Hours`.`Clock_In`) + 601) as Difference
FROM `Employees`
INNER JOIN `Hours` USING (`ID`)
WHERE DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59'
AND TIMESTAMPDIFF(MINUTE,`Hours`.`Clock_Out`,`Hours`.`Clock_In`) > -601;
```

This gives us the following list of people who have violated our attendance policy:

```
+------------+-----------+---------------------+---------------------+------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           | Difference |
+------------+-----------+---------------------+---------------------+------------+
| Mustapha   | Mond      | 2005-08-12 07:02:29 | 2005-08-12 16:59:12 |          4 |
| Henry      | Foster    | 2005-08-11 07:01:58 | 2005-08-11 17:00:45 |          2 |
| Henry      | Foster    | 2005-08-12 07:02:12 | 2005-08-12 16:58:57 |          4 |
| Bernard    | Marx      | 2005-08-09 07:01:10 | 2005-08-09 17:00:26 |          1 |
| Lenina     | Crowne    | 2005-08-12 07:01:09 | 2005-08-12 16:58:29 |          3 |
| Fanny      | Crowne    | 2005-08-11 07:01:26 | 2005-08-11 17:00:03 |          2 |
| Fanny      | Crowne    | 2005-08-12 07:02:15 | 2005-08-12 16:59:02 |          4 |
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |          4 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |          4 |
+------------+-----------+---------------------+---------------------+------------+
```

The Utility of Views

We can see in the previous example that there have been several instances of employees coming in late and leaving early. Unfortunately, we can also see that this query is getting needlessly complex. Having all of this SQL in our application not only creates more complex application code, but also means that if we ever change the structure of this table we're going to have to change what is becoming a somewhat messy query. This is where views begin to show their usefulness.

Creating the Employee Tardiness View

Creating a view is almost exactly the same as creating a SELECT statement, so we can use our previous SELECT statement in the creation of our new view:

```
CREATE SQL SECURITY INVOKER VIEW Employee_Tardiness AS
SELECT
   `Employees`.`First_Name`,
   `Employees`.`Last_Name`,
   `Hours`.`Clock_In`,
   `Hours`.`Clock_Out`,
(TIMESTAMPDIFF(MINUTE,`Hours`.`Clock_Out`,`Hours`.`Clock_In`) + 601) as Difference
FROM `Employees`
INNER JOIN `Hours` USING (`ID`)
WHERE DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59'
AND TIMESTAMPDIFF(MINUTE,`Hours`.`Clock_Out`,`Hours`.`Clock_In`) > -601;
```

Note that the first line of our query contains the statement 'SQL SECURITY INVOKER' - this means that when the view is accessed, it runs with the same privileges that the person accessing the view has. Thus, if someone without access to our Employees table tries to access this view, they will get an error.

Other than the security parameter, the rest of the query is fairly self explanatory. We simply run 'CREATE VIEW <view-name> AS' and then append any valid SELECT statement, and our view is created. Now if we do a SELECT from the view, we can see we get the same results as before, with much less SQL:

```
SELECT * FROM Employee_Tardiness;
```

```
+------------+-----------+---------------------+---------------------+------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           | Difference |
+------------+-----------+---------------------+---------------------+------------+
| Mustapha   | Mond      | 2005-08-12 07:02:29 | 2005-08-12 16:59:12 |          5 |
| Henry      | Foster    | 2005-08-11 07:01:58 | 2005-08-11 17:00:45 |          3 |
| Henry      | Foster    | 2005-08-12 07:02:12 | 2005-08-12 16:58:57 |          5 |
| Bernard    | Marx      | 2005-08-09 07:01:10 | 2005-08-09 17:00:26 |          2 |
| Lenina     | Crowne    | 2005-08-12 07:01:09 | 2005-08-12 16:58:29 |          4 |
| Fanny      | Crowne    | 2005-08-09 07:02:12 | 2005-08-09 17:02:13 |          1 |
| Fanny      | Crowne    | 2005-08-11 07:01:26 | 2005-08-11 17:00:03 |          3 |
| Fanny      | Crowne    | 2005-08-12 07:02:15 | 2005-08-12 16:59:02 |          5 |
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |          5 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |          5 |
+------------+-----------+---------------------+---------------------+------------+
```

Now we can even perform operations on the table, such as limiting our results to just those with a Difference of at least five minutes:

```
SELECT * FROM Employee_Tardiness WHERE Difference >=5;
```

```
+------------+-----------+---------------------+---------------------+------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           | Difference |
+------------+-----------+---------------------+---------------------+------------+
| Mustapha   | Mond      | 2005-08-12 07:02:29 | 2005-08-12 16:59:12 |          5 |
| Henry      | Foster    | 2005-08-12 07:02:12 | 2005-08-12 16:58:57 |          5 |
| Fanny      | Crowne    | 2005-08-12 07:02:15 | 2005-08-12 16:59:02 |          5 |
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |          5 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |          5 |
+------------+-----------+---------------------+---------------------+------------+
```

Other Uses of Views

Aside from just simplifying our application's SQL queries, there are also other benefits that views can provide, some of which are only possible by using views.

Restricting Data Access

For example, even though our Employees database contains fields for Position, Home Address, and Home Phone, our query does not allow for these fields to be shown. This means that in the case of a security issue in the application (for example, an SQL injection attack, or even a malicious programmer), there is no risk of disclosing an employee's personal

information.

Row-level Security

We can also define separate views to include a specific WHERE clause for security; for example, if we wanted to restrict a department head's access to only the staff that report to him, we could specify his identity in the view's CREATE statement, and he would then be unable to see any other department's employees, despite them all being in the same table. If this view is writeable and it is defined with the CASCADE clause, this restriction will also apply to writes. This is actually the only way to implement row-level security in MariaDB, so views play an important part in that area as well.

Pre-emptive Optimization

We can also define our views in such a way as to force the use of indexes, so that other, less-experienced developers don't run the risk of running un-optimized queries or JOINs that result in full-table scans and extended locks. Expensive queries, queries that SELECT *, and poorly thought-out JOINs can not only slow down the database entirely, but can cause inserts to fail, clients to time out, and reports to error out. By creating a view that is already optimized and letting users perform their queries on that, you can ensure that they won't cause a significant performance hit unnecessarily.

Abstracting Tables

When we re-engineer our application, we sometimes need to change the database to optimize or accommodate new or removed features. We may, for example, want to normalize our tables when they start getting too large and queries start taking too long. Alternately, we may be installing a new application with different requirements alongside a legacy application. Unfortunately, database redesign will tend to break backwards-compatibility with previous applications, which can cause obvious problems.

Using views, we can change the format of the underlying tables while still presenting the same table format to the legacy application. Thus, an application which demands username, hostname, and access time in string format can access the same data as an application which requires firstname, lastname, user@host, and access time in Unix timestamp format.

Summary

Views are an SQL feature that can provide a lot of versatility in larger applications, and can even simplify smaller applications further. Just as stored procedures can help us abstract out our database logic, views can simplify the way we access data in the database, and can help un-complicate our queries to make application debugging easier and more efficient.

3.3.3.2 Getting Started with Indexes

6.2.5 Joining Tables with JOIN Clauses

In the absence of a more tutorial-level document, here is a simple example of three basic JOIN types, which you can experiment with in order to see what the different joins accomplish:

```
CREATE TABLE t1 ( a INT );
CREATE TABLE t2 ( b INT );
INSERT INTO t1 VALUES (1), (2), (3);
INSERT INTO t2 VALUES (2), (4);
SELECT * FROM t1 INNER JOIN t2 ON t1.a = t2.b;
SELECT * FROM t1 CROSS JOIN t2;
SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.b;
SELECT * FROM t2 LEFT JOIN t1 ON t1.a = t2.b;
```

The first two SELECTs are (unfortunately) commonly written with an older form:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
SELECT * FROM t1, t2;
```

What you can see from this is that an **INNER JOIN** produces a result set containing only rows that have a match, in both tables (t1 and t2), for the specified join condition(s).

A **CROSS JOIN** produces a result set in which every row in each table is joined to every row in the other table; this is also called a **cartesian product**. In MariaDB the CROSS keyword can be omitted, as it does nothing. Any JOIN without an ON clause is a CROSS JOIN.

The **LEFT JOIN** is an **outer join**, which produces a result set with all rows from the table on the "left" (t1); the values for the columns in the other table (t2) depend on whether or not a match was found. If no match is found, all columns from that table are set to NULL for that row.

The **RIGHT JOIN** is similar to the LEFT JOIN, though its resultset contains all rows from the right table, and the left table's columns will be filled with NULLs when needed.

JOINs can be concatenated to read results from three or more tables.

Here is the output of the various SELECT statements listed above:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.a = t2.b;
------ ------
| a    | b    |
------ ------
|    2 |    2 |
------ ------
1 row in set (0.00 sec)

SELECT * FROM t1 CROSS JOIN t2;
------ ------
| a    | b    |
------ ------
|    1 |    2 |
|    2 |    2 |
|    3 |    2 |
|    1 |    4 |
|    2 |    4 |
|    3 |    4 |
------ ------
6 rows in set (0.00 sec)

SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.b;
------ ------
| a    | b    |
------ ------
|    1 | NULL |
|    2 |    2 |
|    3 | NULL |
------ ------
3 rows in set (0.00 sec)

SELECT * FROM t2 LEFT JOIN t1 ON t1.a = t2.b;
------ ------
| b    | a    |
------ ------
|    2 |    2 |
|    4 | NULL |
------ ------
2 rows in set (0.00 sec)
```

That should give you a bit more understanding of how JOINS work!

6.2.6 The Essentials of an Index

Imagine you've created a table with the following rows (this is the same table as used in the More Advanced Joins tutorial).

```
+----+------------+-----------+-------------------------+----------------------------+------------
| ID | First_Name | Last_Name | Position                | Home_Address               | Home_Phone
+----+------------+-----------+-------------------------+----------------------------+------------
|  1 | Mustapha   | Mond      | Chief Executive Officer | 692 Promiscuous Plaza      | 326-555-349
|  2 | Henry      | Foster    | Store Manager           | 314 Savage Circle          | 326-555-384
|  3 | Bernard    | Marx      | Cashier                 | 1240 Ambient Avenue        | 326-555-845
|  4 | Lenina     | Crowne    | Cashier                 | 281 Bumblepuppy Boulevard  | 328-555-234
|  5 | Fanny      | Crowne    | Restocker               | 1023 Bokanovsky Lane       | 326-555-632
|  6 | Helmholtz  | Watson    | Janitor                 | 944 Soma Court             | 329-555-247
+----+------------+-----------+-------------------------+----------------------------+------------
```

Now, imagine you've been asked to return the home phone of Fanny Crowne. Without indexes, the only way to do it is to go through every row until you find the matching first name and surname. Now imagine there are millions of records and you can see that, even for a speedy database server, this is highly inefficient.

The answer is to sort the records. If they were stored in alphabetical order by surname, even a human could quickly find a record amongst a large number. But we can't sort the entire record by surname. What if we want to also look a record by ID, or by first name? The answer is to create separate indexes for each column we wish to sort by. An index simply contains the sorted data (such as surname), and a link to the original record.

For example, an index on Last_Name:

```
+-----------+----+
| Last_Name | ID |
+-----------+----+
| Crowne    |  4 |
| Crowne    |  5 |
| Foster    |  2 |
| Marx      |  3 |
| Mond      |  1 |
| Watson    |  6 |
+-----------+----+
```

and an index on Position

```
+-------------------------+----+
| Position                | ID |
+-------------------------+----+
| Cashier                 |  3 |
| Cashier                 |  4 |
| Chief Executive Officer |  1 |
| Janitor                 |  6 |
| Restocker               |  5 |
| Store Manager           |  2 |
+-------------------------+----+
```

would allow you to quickly find the phone numbers of all the cashiers, or the phone number of the employee with the surname Marx, very quickly.

Where possible, you should create an index for each column that you search for records by, to avoid having the server read every row of a table.

See CREATE INDEX and Getting Started with Indexes for more information.

6.2.7 Troubleshooting Connection Issues

Contents

If you are completely new to MariaDB and relational databases, you may want to start with the MariaDB Primer. Also, make sure you understand the connection parameters discussed in the Connecting to MariaDB article.

There are a number of common problems that can occur when connecting to MariaDB.

Server Not Running in Specified Location

If the error you get is something like:

```
mariadb -uname -p -uname -p
ERROR 2002 (HY000): Can't connect to local MySQL server through
  socket '/var/run/mysqld/mysqld.sock' (2 "No such file or directory")
```

or

```
mariadb -uname -p --port=3307 --protocol=tcp
ERROR 2003 (HY000): Can't connect to MySQL server on  'localhost'
  (111 "Connection refused")
```

the server is either not running, or not running on the specified port, socket or pipe. Make sure you are using the correct host, port, pipe, socket and protocol options, or alternatively, see Getting, Installing and Upgrading MariaDB, Starting and Stopping MariaDB or Troubleshooting Installation Issues.

The socket file can be in a non-standard path. In this case, the `socket` option is probably written in the my.cnf file. Check that its value is identical in the [mysqld] and [client] sections; if not, the client will look for a socket in a wrong place.

If unsure where the Unix socket file is running, it's possible to find this out, for example:

```
netstat -ln | grep mysqld
unix  2      [ ACC ]     STREAM     LISTENING     33209505 /var/run/mysqld/mysqld.sock
```

Unable to Connect from a Remote Location

Usually, the MariaDB server does not by default accept connections from a remote client or connecting with tcp and a hostname and has to be configured to permit these.

```
(/my/maria-10.4) ./client/mysql --host=myhost --protocol=tcp --port=3306 test
ERROR 2002 (HY000): Can't connect to MySQL server on 'myhost' (115)
(/my/maria-10.4) telnet myhost 3306
Trying 192.168.0.11...
telnet: connect to address 192.168.0.11: Connection refused
(/my/maria-10.4) perror 115
OS error code 115:  Operation now in progress
```

To solve this, see Configuring MariaDB for Remote Client Access

Authentication Problems

Note that from MariaDB 10.4.3, the unix_socket authentication plugin is enabled by default on Unix-like systems. This uses operating system credentials when connecting to MariaDB via the local Unix socket file. See unix_socket authentication plugin for instructions on connecting and on switching to password-based authentication as well as Authentication from MariaDB 10.4 for an overview of the MariaDB 10.4 changes..

Authentication is granted to a particular username/host combination. `user1'@'localhost'` , for example, is not the same as `user1'@'166.78.144.191'` . See the GRANT article for details on granting permissions.

Passwords are hashed with PASSWORD function. If you have set a password with the SET PASSWORD statement, the PASSWORD function must be used at the same time. For example, `SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass')` rather than just `SET PASSWORD FOR 'bob'@'%.loc.gov' = 'newpass'` ;

Problems Exporting Query Results

If you can run regular queries, but get an authentication error when running the SELECT ... INTO OUTFILE, SELECT ...

INTO DUMPFILE or LOAD DATA INFILE statements, you do not have permission to write files to the server. This requires the FILE privilege. See the GRANT article.

Access to the Server, but not to a Database

If you can connect to the server, but not to a database, for example:

```
USE test;
ERROR 1044 (42000): Access denied for user 'ian'@'localhost' to database 'test'
```

or can connect to a particular database, but not another, for example `mariadb -uname -p -u name db1` works but not `mariadb -uname -p -u name db2`, you have not been granted permission for the particular database. See the GRANT article.

Option Files and Environment Variables

It's possible that option files or environment variables may be providing incorrect connection parameters. Check the values provided in any option files read by the client you are using (see mysqld Configuration Files and Groups and the documentation for the particular client you're using - see Clients and Utilities).

Option files can usually be suppressed with `no-defaults` option, for example:

```
mariadb-import --no-defaults ...
```

Unable to Connect to a Running Server / Lost root Password

If you are unable to connect to a server, for example because you have lost the root password, you can start the server without using the privilege tables by running the --skip-grant-tables option, which gives users full access to all tables. You can then run FLUSH PRIVILEGES to resume using the grant tables, followed by SET PASSWORD to change the password for an account.

localhost and %

You may have created a user with something like:

```
CREATE USER melisa identified by 'password';
```

This creates a user with the '%' wildcard host.

```
select user,host from mysql.user where user='melisa';
+--------+------+
| user   | host |
+--------+------+
| melisa | %    |
+--------+------+
```

However, you may still be failing to login from localhost. Some setups create anonymous users, including localhost. So the following records exist in the user table:

```
select user,host from mysql.user where user='melisa' or user='';
+--------+-----------+
| user   | host      |
+--------+-----------+
| melisa | %         |
|        | localhost |
+--------+-----------+
```

Since you are connecting from localhost, the anonymous credentials, rather than those for the 'melisa' user, are used. The solution is either to add a new user specific to localhost, or to remove the anonymous localhost user.

6.3 Intermediate MariaDB Articles

These are articles for intermediate level MariaDB developers and administrators.

Database Theory

Articles on hierarchical, network and relational databases.

Starting and Stopping MariaDB

Articles related to starting and stopping MariaDB Server.

6.3.1 Database Theory

Just as perhaps we take movie special effects for granted until we see what state of the art was in previous eras, so we can't fully appreciate the power of relational databases without seeing what preceded them.

Relational databases allow any table to relate to any other table through means of common fields. It is a highly flexible system, and most modern databases are relational.

Introduction to Relational Databases

Brief introduction to the concept of a relational database.

Exploring Early Database Models

Before relational databases there were a number of other models

Understanding the Hierarchical Database Model

The earliest model was the hierarchical database model, resembling an upside-down tree.

6.3.1.1 Introduction to Relational Databases

Contents

What is a Database?

The easiest way to understand a database is as a collection of related files. Imagine a file (either paper or digital) of sales orders in a shop. Then there's another file of products, containing stock records. To fulfil an order, you'd need to look up the product in the order file and then look up and adjust the stock levels for that particular product in the product file. A database

and the software that controls the database, called a *database management system* (DBMS), helps with this kind of task.

Most databases today are *relational* databases, named such because they deal with tables of data related by a common field. For example, Table 1 below shows the product table, and Table 2 shows the invoice table. As you can see, the relation between the two tables is based on the common field `product_code`. Any two tables can relate to each other simply by having a field in common.

Table 1

Product_code	Description	Price
A416	Nails, box	$0.14
C923	Drawing pins, box	$0.08

Table 2

Invoice_code	Invoice_line	*Product_code*	Quantity
3804	1	A416	10
3804	2	C923	15

Database Terminology

Let's take a closer look at the previous two tables to see how they are organized:

- Each table consists of many *rows* and *columns*.
- Each new row contains data about one single *entity* (such as one product or one order line). This is called a *record*. For example, the first row in Table 1 is a record; it describes the A416 product, which is a box of nails that costs fourteen cents. The terms *row* and *record* are interchangeable.
- Each column (also called an *attribute*) contains one piece of data that relates to the record, called a *tuple*. Examples of attributes are the quantity of an item sold or the price of a product. An attribute, when referring to a database table, is called a *field*. For example, the data in the *Description* column in Table 1 are fields. The terms *attribute* and *field* are interchangeable.

Given this kind of structure, the database gives you a way to manipulate this data: SQL. SQL (structured query language) is a powerful way to search for records or make changes. Almost all DBMSs use SQL, although many have added their own enhancements to it. This means that when you learn SQL while using MariaDB, almost all of it is not specific to MariaDB and can be used with other relational databases as well, such as PostgreSQL, MySQL, Oracle and SQL Server. MariaDB was originally-created as a drop-in replacement to MySQL, so MariaDB and MySQL are particularly close.

6.3.1.2 Exploring Early Database Models

Before the advent of databases, the only way to store data was from unrelated files. Programmers had to go to great lengths to extract the data, and their programs had to perform complex parsing and relating.

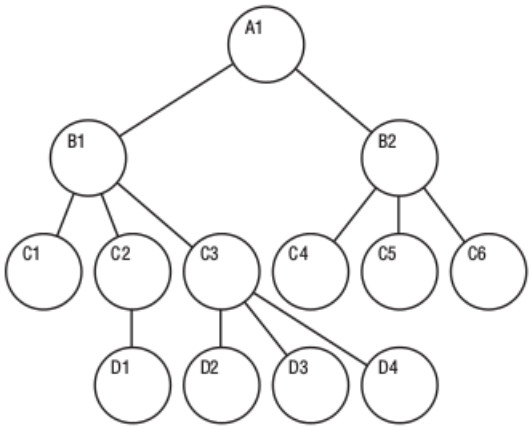
Languages such as Perl, with its powerful regular expressions ideal for processing text, have made the job a lot easier than before; however, accessing the data from files is still a challenging task. Without a standard way to access data, systems are more prone to errors, are slower to develop, and are more difficult to maintain. Data redundancy (where data is duplicated unnecessarily) and poor data integrity (where data is not changed in all locations, leading to wrong or outdated data being supplied) are frequent consequences of the file access method of data storage. For these reasons, database management systems (DBMSs) were developed to provide a standard and reliable way to access and update data. They provide an intermediary layer between the application and the data, and the programmer is able to concentrate on developing the application, rather than worrying about data access issues.

A *database model* is a logical model concerned with how the data is represented. Instead of database designers worrying about the physical storage of data, the database model allows them to look at a higher, more conceptual level, reducing the gap between the real-world problem for which the application is being developed and the technical implementation.

There are a number of database models. The next two articles cover two common models; the hierarchical database model and the network database model. After that comes the one MariaDB, along with most modern DBMSs uses, the relational model.

6.3.1.3 Understanding the Hierarchical Database Model

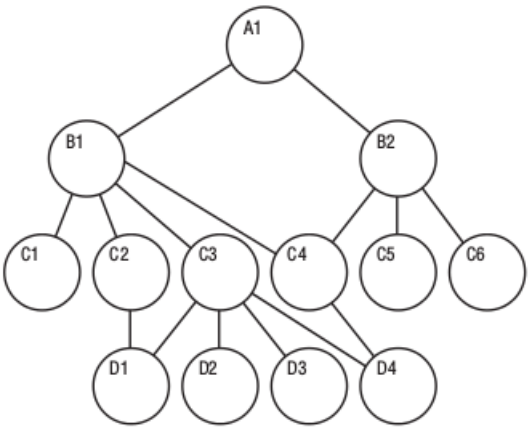
The earliest model was the hierarchical database model, resembling an upside-down tree. Files are related in a parent-child manner, with each parent capable of relating to more than one child, but each child only being related to one parent. Most of you will be familiar with this kind of structure—it's the way most file systems work. There is usually a root, or top-level, directory that contains various other directories and files. Each subdirectory can then contain more files and directories, and so on. Each file or directory can only exist in one directory itself—it only has one parent. As you can see in the image below *A1* is the root directory, and its children are *B1* and *B2*. *B1* is a parent to *C1*, *C2*, and *C3*, which in turn has children of its own.



This model, although being a vast improvement on dealing with unrelated files, has some serious disadvantages. It represents one-to-many relationships well (one parent has many children; for example, one company branch has many employees), but it has problems with many-to-many relationships. Relationships such as that between a product file and an orders file are difficult to implement in a hierarchical model. Specifically, an order can contain many products, and a product can appear in many orders. Also, the hierarchical model is not flexible because adding new relationships can result in wholesale changes to the existing structure, which in turn means all existing applications need to change as well. This is not fun when someone has forgotten a table and wants it added to the system shortly before the project is due to launch! And developing the applications is complex because the programmer needs to know the data structure well in order to traverse the model to access the needed data. As you've seen in the earlier chapters, when accessing data from two related tables, you only need to know the fields you require from those two tables. In the hierarchical model, you'd need to know the entire chain between the two. For example, to relate data from *A1* and *D4*, you'd need to take the route: *A1*, *B1*, *C3* and *D4*.

6.3.1.4 Understanding the Network Database Model

The network database model was a progression from the hierarchical database model and was designed to solve some of that model's problems, specifically the lack of flexibility. Instead of only allowing each child to have one parent, this model allows each child to have multiple parents (it calls the children *members* and the parents *owners*). It addresses the need to model more complex relationships such as the orders/parts many-to-many relationship mentioned in the hierarchical article. As you can see in the figure below, *A1* has two members, *B1* and *B2*. *B1.* is the owner of *C1*, *C2*, *C3* and *C4*. However, in this model, *C4* has two owners, *B1* and *B2*.



Of course, this model has its problems, or everyone would still be using it. It is more difficult to implement and maintain, and, although more flexible than the hierarchical model, it still has flexibility problems, Not all relations can be satisfied by assigning another owner, and the programmer still has to understand the data structure well in order to make the model efficient.

6.3.1.5 Understanding the Relational Database Model

The relational database model was a huge leap forward from the network database model. Instead of relying on a parent-child or owner-member relationship, the relational model allows any file to be related to any other by means of a common field. Suddenly, the complexity of the design was greatly reduced because changes could be made to the database schema without affecting the system's ability to access data. And because access was not by means of paths to and from files, but from a direct relationship between files, new relations between these files could easily be added.

In 1970, when E.F. Codd developed the model, it was thought to be impractical. The increased ease of use comes at a large performance penalty, and the hardware in those days was not able to implement the model. Since then, of course, hardware has taken huge strides to where today, even the simplest computers can run sophisticated relational database management systems.

Relational databases go hand-in-hand with the development of SQL. The simplicity of SQL - where even a novice can learn to perform basic queries in a short period of time - is a large part of the reason for the popularity of the relational model.

The two tables below relate to each other through the *product_code* field. Any two tables can relate to each other simply by creating a field they have in common.

Table 1

Product_code	Description	Price
A416	Nails, box	$0.14
C923	Drawing pins, box	$0.08

Table 2

Invoice_code	Invoice_line	*Product_code*	Quantity
3804	1	A416	10
3804	2	C923	15

6.3.1.6 Relational Databases: Basic Terms

The relational database model uses certain terms to describe its components:

- *Data* are the values kept in the database. On their own, the data means very little. `CA 684-213` is an example of data in a DMV (Division of Motor Vehicles) database.
- *Information* is processed data. For example, `CA 684-213` is the car registration number of a car belonging to Lyndon Manson, in a DMV database.
- A *database* is a collection of *tables*, also called *entities*.
- Each table is made up of *records* (the horizontal rows in the table, also called *tuples*). Each record should be unique, and can be stored in any order in the table.
- Each record is made up of *fields* (which are the vertical columns of the table, also called *attributes*). Basically, a record is one fact (for example, one customer or one sale).
- These fields can be of various *types*. MariaDB has many types (see Data Types for a list), but generally types fall into three kinds: character, numeric, and date. For example, a customer name is a character field, a customer's birthday is a date field, and a customer's number of children is a numeric field.
- The range of allowed values for a field is called the *domain* (also called a *field specification*). For example, a credit card field may be limited to only the values `Mastercard`, `Visa` and `Amex`.
- A field is said to contain a *null* value when it contains nothing at all. Null fields can create complexities in calculations and have consequences for data accuracy. For this reason, many fields are specifically set not to contain null values.
- A *key* accesses specific records in a table.
- An *index* is a mechanism to improve the performance of a database. Indexes are often confused with keys. Indexes are, strictly speaking, part of the physical structure, and keys are part of the logical structure. You'll often see the terms used interchangeably, however, including throughout this Knowledge Base.
- A *view* is a virtual table made up of a subset of the actual tables.
- A *one-to-one* (1:1) relationship is where for each instance of the first table in a relationship, only one instance of the second table exists, An example of this would be a case where a chain of stores carries a vending machine. Each vending machine can only be in one store, and each store carries only one vending machine.

- A *one-to-many* (1:N) relationship is where for each instance of the first table in a relationship, many instances of the second table exist. This is a common kind of relationship. An example is the relationship between a sculptor and their sculptures. Each sculptor may have created many sculptures, but each sculpture has been created by only one sculptor.

- A *many-to-many* (M:N) relationship occurs where, for each instance of the first table, there are many instances of the second table, and for each instance of the second table, there are many instances of the first. For example, a student can have many lecturers, and a lecturer can have many students.

- A *mandatory* relationship exists where for each instance of the first table in a relationship, one or more instances of the second *must* exist. For example, for a music group to exist, there must exist at least one musician in that group.
- An *optional* relationship is where for each instance of the first table in a relationship, there *may* exist instances of the second. For example, if an author can be listed in the database without having written a book (in other words, a prospective author), that relationship is optional. The reverse isn't necessarily true though. For example, for a book to be listed, it must have an author.
- *Data integrity* refers to the condition where data is accurate, valid, and consistent. An example of poor integrity would be if a customer telephone number is stored differently in two different locations. Another is where a course record contains a reference to a lecturer who is no longer present at the school. Database normalization is a technique that assists you to minimize the risk of these sorts of problems.

6.3.1.7 Relational Databases: Table Keys

A *key*, or *index*, as the term itself indicates, unlocks access to the tables. If you know the key, you know how to identify specific records and the relationships between the tables.

Each key consists of one or more fields, or field prefix. The order of columns in an index is significant. Each key has a name.

A *candidate key* is a field, or combination of fields, that uniquely identifies a record. It cannot contain a null value, and its value must be unique. (With duplicates, you would no longer be identifying a unique record).

A *primary key* (PK) is a candidate key that has been designated to identify unique records in the table throughout the database structure.

A *surrogate key* is a primary key that contains unique values automatically generated by the database system - usually, integer numbers. A surrogate key has no meaning, except uniquely identifying a record. This is the most common type of primary key.

For example, see the following table:

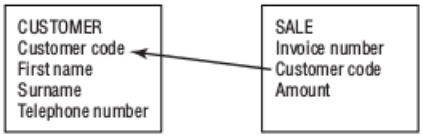
Customer_code	First_name	Surname	Telephone_number
1	Ariane	Edison	448-2143
2	Georgei	Edison	448-2142
3	Abbas	Edison	9231-5312

At first glance, there are two possible candidate keys for this table. Either *customer_code* or a combination of *first_name*, *surname* and *telephone_number* would suffice. It is always better to choose the candidate key with the least number of fields for the primary key, so you would choose *customer_code* in this example (note that it is a surrogate key). Upon reflection, there is also the possibility of the second combination not being unique. The combination of *first_name*, *surname* and *telephone_number* could in theory be duplicated, such as where a father has a son of the same name who is contactable at the same telephone number. This system would have to expressly exclude this possibility for these three fields to be considered for the status of primary key.

There may be many Ariane Edisons, but you avoid confusion by assigning each a unique number. Once a primary key has been created, the remaining candidates are labeled as *alternate keys*.

6.3.1.8 Relational Databases: Foreign Keys

You already know that a relationship between two tables is created by assigning a common field to the two tables (see Relational Databases: Table Keys). This common field must be a primary key to one table. Consider a relationship between a *customer* table and a *sale* table. The relationship is not much good if instead of using the primary key, *customer_code*, in the *sale* table, you use another field that is not unique, such as the customer's first name. You would be unlikely to know for sure which customer made the sale in that case. So, in the table below, *customer_code* is called the *foreign_key* in the *sale* table; in other words, it is the primary key in a foreign table.



Foreign keys allow for something called *referential integrity*. What this means is that if a foreign key contains a value, this value refers to an existing record in the related table. For example, take a look at the tables below:

Lecturer table

Code	First Name	Surname
1	Anne	Cohen
2	Leonard	Clark
3	Vusi	Cave

Course table

Course Title	Lecturer Code
Introduction to Programming	1
Information Systems	2
Systems Software	3

Referential integrity exists here, as all the lecturers in the *course* table exist in the *lecturer* table. However, let's assume Anne Cohen leaves the institution, and you remove her from the lecturer table. In a situation where referential integrity is not enforced, she would be removed from the lecturer table, but not from the course table, as shown below:

Lecturer table

Code	First Name	Surname
2	Leonard	Clark
3	Vusi	Cave

Course table

Course Title	Lecturer Code
Introduction to Programming	1
Information Systems	2
Systems Software	3

Now, when you look up who lectures *Introduction to Programming*, you are sent to a non-existent record. This is called poor data intregrity.

Foreign keys also allow *cascading* deletes and updates. For example, if Anne Cohen leaves, taking the Introduction to Programming Course with her, all trace of her can be removed from both the *lecturer* and *course* table using one statement. The delete *cascades* through the relevant tables, removing all relevant records.

Foreign keys can also contain null values, indicating that no relationship exists.

6.3.1.9 Relational Databases: Views

Views are virtual tables. They are only a structure, and contain no data. Their purpose is to allow a user to see a subset of the actual data. A view can consist of a subset of one table. For example, the *student view*, below, is a subset of the *student table*.

Student View
First name
Surname
Grade

Student Table
Student_id
First name
Surname
Grade
Address
Telephone

This view could be used to allow other students to see their fellow student's marks but not allow them access to personal information.

Alternatively, a view could be a combination of a number of tables, such as the view below:

Student View
First name
Surname
Grade

Student Table
Student_id
First name
Surname
Address
Telephone

Course Table
Course_id
Course description

Grade Table
Student_id
Course_id
Grade

Views are also useful for security. In larger organizations, where many developers may be working on a project, views allow developers to access only the data they need. What they don't need, even if it is in the same table, is hidden from them, safe from being seen or manipulated. It also allows queries to be simplified for developers. For example, without the view, a developer would have to retrieve the fields in the view with the following sort of query

```
SELECT first_name, surname, course_description, grade FROM student, grade, course
  WHERE grade.student_id = student.student_id AND grade.course_id = course.course_id
```

With the view, a developer could do the same with the following:

```
SELECT first_name, surname, course_description, grade FROM student_grade_view
```

Much simpler for a junior developer who hasn't yet learned to do joins, and it's just less hassle for a senior developer too!

For more use cases, see the Views Tutorial.

6.3.1.10 Database Design

Articles about the database design process

Database Design: Overview

Databases exist because of the need to change data into information

Database Lifecycle

Like everything else, databases have a finite lifespan

Database Design Phase 1: Analysis

Defining problems, possibilities, constraints, objectives and agreeing on the scope

Database Design Phase 2: Conceptual Design

Requirements identified in the previous phase are used as the basis to develop the new system

Database Design Phase 2: Logical and Physical Design

After conceptual design, it's time to convert to the logical and physical design

Database Design Phase 3: Implementation

Install the DBMS and load the data

Database Design Phase 4: Testing

Testing performance, security, and integrity of the data

Database Design Phase 5: Operation

Rolling out for everyday use

Database Design Phase 6: Maintenance

Maintaining indexes, optimizing tables, adding and removing users, changing passwords

Database Design Example Phase 1: Analysis

Walking through the database design process with a step-by-step example

Database Design Example Phase 2: Design

Poet Circle logical design and identifying the initial entities

Database Design Example Phase 3: Implementation

Creating the Poet's Circle tables

Database Design Example Phases 4-6: Testing, Operation and Maintenance

Testing, rolling out and maintenance of the Poet's Circle database.

6.3.1.10.1 Database Design: Overview

Databases exist because of the need to change data into information. Data are the raw and unprocessed facts. Information is obtained by processing the data into something useful. For example, millions of names and telephone numbers in a phone book are data. Information is the telephone number of the fire department when your house is burning down.

A database is a large repository of facts, designed in such a way that processing the facts into information is easy. If the phone book was structured in a less convenient way, such as with names and numbers placed in chronological order according to when the numbers were issued, converting the data into information would be much more difficult. Not knowing when the fire department was issued their latest number, you could search for days, and by the time you find the number your house would be a charred pile of ash. So, it's a good thing the phone book was designed as it was.

A database is much more flexible; a similar set of data to what's in a phone book could be ordered by MariaDB according to name, telephone number, address as well as chronologically. But databases are of course more complex, containing many different kinds of information. People, job titles and a company's products can all mingle to provide complex information. But

this complexity makes the design of databases more complex as well. Poor design could make for slow queries, or it could even make certain kinds of information impossible to reach. This section of the Knowledge Base features articles about good database design, specifically:

- The database lifecycle
- Entity-relationship modeling
- Common mistakes in database design
- Real-world example: creating a publishing tracking system
- Concurrency control with transactions

6.3.1.10.2 Database Lifecycle

> This article follows on from Database Design: Overview.

Like everything else, databases have a finite lifespan. They are born in a flush of optimism and make their way through life achieving fame, fortune, and peaceful anonymity, or notoriety as the case may be, before fading out once more. Even the most successful database at some time is replaced by another, more flexible and up-to-date structure, and so begins life anew. Although exact definitions differ, there are generally six stages of the database lifecycle.

Analysis

The analysis phase is where the stakeholders are interviewed and any existing system is examined to identify problems, possibilities and constraints. The objectives and scope of the new system are determined.

Design

The design phase is where a conceptual design is created from the previously determined requirements, and a logical and physical design are created that will ready the database for implementation.

Implementation

The implementation phase is where the database management system (DBMS) is installed, the databases are created, and the data are loaded or imported.

Testing

The testing phase is where the database is tested and fine-tuned, usually in conjunction with the associated applications.

Operation

The operation phase is where the database is working normally, producing information for its users.

Maintenance

The maintenance phase is where changes are made to the database in response to new requirements or changed operating conditions (such as heavier load).

Database development is not independent of systems development, often being one component of the greater systems development process. The stages of systems development basically mirror the stages of a database lifecycle but are a superset. Whereas database design deals with designing the system to store the data, systems design is also concerned with the processes that will impact on the data.

6.3.1.10.3 Database Design Phase 1: Analysis

> This article follows on from Database Lifecycle.

Your existing system can no longer cope. It's time to move on. Perhaps the existing paper system is generating too many errors, or the old Perl script based on flat files can no longer handle the load. Or perhaps an existing news database is struggling under its own popularity and needs an upgrade. This is the stage where the existing system is reviewed.

Depending on the size of the project, the designer may be an individual, responsible for the database implementation and coding, or may be a whole team of analysts. For now, the term *designer* will represent all these possibilities.

The following are the steps in the Analysis Phase.

1. Analyze the organization
2. Define any problems, possibilities or constraints
3. Define the objectives
4. Agree on the scope

When reviewing a system, the designer needs to look at the bigger picture - not just the hardware or existing table structures, but the whole situation of the organization calling for the redesign. For example, a large bank with centralized management would have a different structure and a different way of operating from a decentralized media organization, where anyone can post news onto a website. This may seem trivial, but understanding the organization you're building the database for is vital. to designing a good database for it. The same demands in the bank and media organizations should lead to different designs because the organizations are different. In other words, a solution that was constructed for the bank cannot be unthinkingly implemented for the media organization, even when the situation seems similar. A culture of central control at the bank may mean that news posted on the bank website has to be moderated and authorized by central management, or may require the designer to keep detailed audit trails of who modified what and when. On the flip-side, the media organization may be more laissez-faire and will be happy with news being modified by any authorized editor.

Understanding an organization's culture helps the designers ask the right questions. The bank may not ask for an audit trail, it may simply expect it; and when the time comes to roll out the implementation, the audit trail would need to be patched on, requiring more time and resources.

Once you understand the organization structure, you can question the users of any existing system as to what their problems and needs are, as well as what constraints will exist then. You need to question different role players, as each can add new understanding as to what the database may need. For example, the media organization's marketing department may need detailed statistics about the times of day certain articles are read. You may also be alerted to possible future requirements. Perhaps the editorial department is planning to expand the website, which will give them the staff to cross-link web articles. Keeping this future requirement in mind could make it easier to add the cross-linking feature when the time comes.

Constraints can include hardware ("We have to use our existing database server") or people ("We only have one data capturer on shift at any one time"). Constraints also refer to the limitations on values. For example, a student's grade in a university database may not be able to go beyond 100 percent, or the three categories of seats in a theatre database are small, medium and large.

It is rarely sufficient to rely on one level of management, or an individual, to supply objectives and current problems, except in the smallest of organizations. Top management may be paying for the database design, but lower levels will need to use it, and their input is probably even more important for a successful design.

Of course, although anything is possible given infinite time and money, this is (usually) never forthcoming. Determining scope, and formalizing it, is an important part of the project. If the budget is for one month's work but the ideal solution requires three, the designer must make clear these constraints and agree with the project owners on which facets are not going to be implemented.

6.3.1.10.4 Database Design Phase 2: Conceptual Design

This article follows on from Database Design Phase 1: Analysis.

Contents

The design phase is where the requirements identified in the previous phase are used as the basis to develop the new system. Another way of putting it is that the business understanding of the data structures is converted to a technical understanding. The *what* questions ("What data are required? What are the problems to be solved?") are replaced by the *how* questions ("How will the data be structured? How is the data to be accessed?")

This phase consists of three parts: the conceptual design, the logical design and the physical design. Some methodologies merge the logical design phase into the other two phases. This section is not aimed at being a definitive discussion of database design methodologies (there are whole books written on that!); rather it aims to introduce you to the topic.

Conceptual design

The purpose of the conceptual design phase is to build a conceptual model based upon the previously identified requirements, but closer to the final physical model. A commonly-used conceptual model is called an *entity-relationship* model.

Entities and attributes

Entities are basically people, places, or things you want to keep information about. For example, a library system may have the *book*, *library* and *borrower* entities. Learning to identify what should be an entity, what should be a number of entities, and what should be an *attribute* of an entity takes practice, but there are some good rules of thumb. The following questions can help to identify whether something is an entity:

- Can it vary in number independently of other entities? For example, *person height* is probably not an entity, as it cannot vary in number independently of *person*. It is not fundamental, so it cannot be an entity in this case.
- Is it important enough to warrant the effort of maintaining. For example *customer* may not be important for a small grocery store and will not be an entity in that case, but it will be important for a video store, and will be an entity in that case.
- Is it its own thing that cannot be separated into subcategories? For example, a car-rental agency may have different criteria and storage requirements for different kinds of vehicles. *Vehicle* may not be an entity, as it can be broken up into *car* and *boat*, which are the entities.
- Does it list a type of thing, not an instance? The video game *blow-em-up 6* is not an entity, rather an instance of the *game* entity.
- Does it have many associated facts? If it only contains one attribute, it is unlikely to be an entity. For example, *city* may be an entity in some cases, but if it contains only one attribute, *city name*, it is more likely to be an attribute of another entity, such as *customer*.

The following are examples of entities involving a university with possible attributes in parentheses.

- **Course** (name, code, course prerequisites)
- **Student** (first_name, surname, address, age)
- **Book** (title, ISBN, price, quantity in stock)

An instance of an entity is one particular occurrence of that entity. For example, the student Rudolf Sono is one instance of the student entity. There will probably be many instances. If there is only one instance, consider whether the entity is warranted. The top level usually does not warrant an entity. For example, if the system is being developed for a particular university, *university* will not be an entity because the whole system is for that one university. However, if the system was developed to track legislation at all universities in the country, then *university* would be a valid entity.

Relationships

Entities are related in certain ways. For example, a borrower may belong to a library and can take out books. A book can be found in a particular library. Understanding what you are storing data about, and how the data relate, leads you a large part of the way to a physical implementation in the database.

There are a number of possible relationships:

Mandatory

For each instance of entity A, there must exist one or more instances of entity B. This does not necessarily mean that for each instance of entity B, there must exist one or more instances of entity A. Relationships are optional or mandatory in one direction only, so the A-to-B relationship can be optional, while the B-to-A relationship is mandatory.

Optional

For each instance of entity A, there may or may not exist instances of entity B.

One-to-one (1:1)

This is where for each instance of entity A, there exists one instance of entity B, and vice-versa. If the relationship is optional, there can exist zero or one instances, and if the relationship is mandatory, there exists one and only one instance of the associated entity.

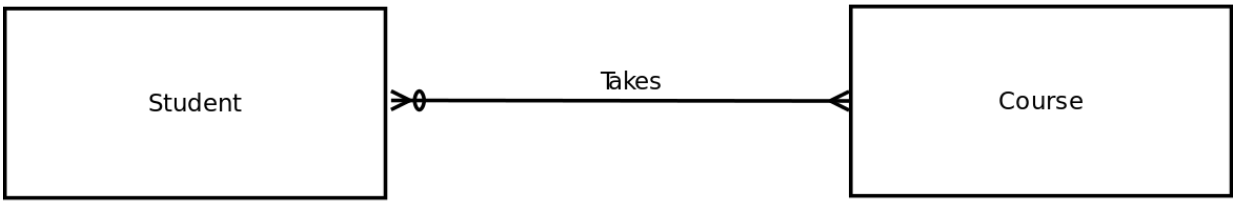
One-to-many (1:M)

For each instance of entity A, many instances of entity B can exist, which for each instance of entity B, only one instance of entity A exists. Again, these can be optional or mandatory relationships.

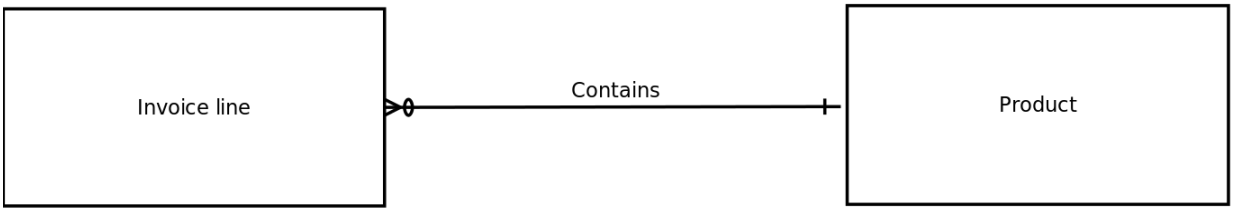
Many-to-many (M:N)

For each instance of entity A, many instances of entity B can exist, and vice versa. These can be optional or mandatory relationships.

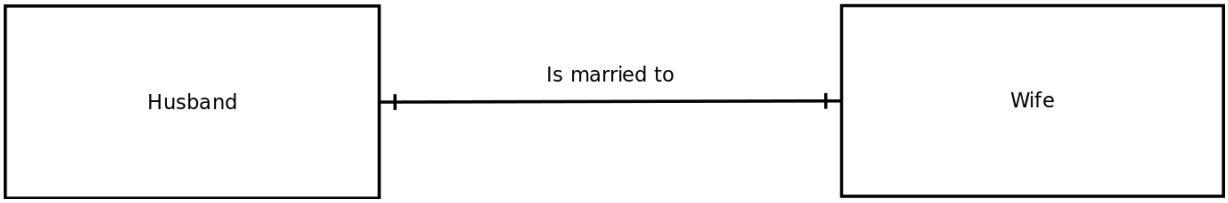
There are numerous ways of showing these relationships. The image below shows *student* and *course* entities. In this case, each student must have registered for at least one course, but a course does not necessarily have to have students registered. The student-to-course relationship is mandatory, and the course-to-student relationship is optional.



The image below shows *invoice_line* and *product* entities. Each invoice line must have at least one product (but no more than one); however each product can appear on many invoice lines, or none at all. The *invoice_line-to-product* relationship is mandatory, while the *product-to-invoice_line* relationship is optional.



The figure below shows husband and wife entities. In this system (others are of course possible), each husband must have one and only one wife, and each wife must have one, and only one, husband. Both relationships are mandatory.



An entity can also have a relationship with itself. Such an entity is called a *recursive entity*. Take a *person* entity. If you're interested in storing data about which people are brothers, you wlll have an "is brother to" relationship. In this case, the relationship is an M:N relationship.

Conversely, a *weak entity* is an entity that cannot exist without another entity. For example, in a school, the *scholar* entity is related to the weak entity *parent/guardian*. Without the scholar, the parent or guardian cannot exist in the system. Weak entities usually derive their primary key, in part or in totality, from the associated entity. *parent/guardian* could take the primary key from the scholar table as part of its primary key (or the entire key if the system only stored one parent/guardian per scholar).

The term *connectivity* refers to the relationship classification.

The term *cardinality* refers to the specific number of instances possible for a relationship. *Cardinality limits* list the minimum and maximum possible occurrences of the associated entity. In the husband and wife example, the cardinality limit is (1,1), and in the case of a student who can take between one and eight courses, the cardinality limits would be represented as (1,8).

Developing an entity-relationship diagram

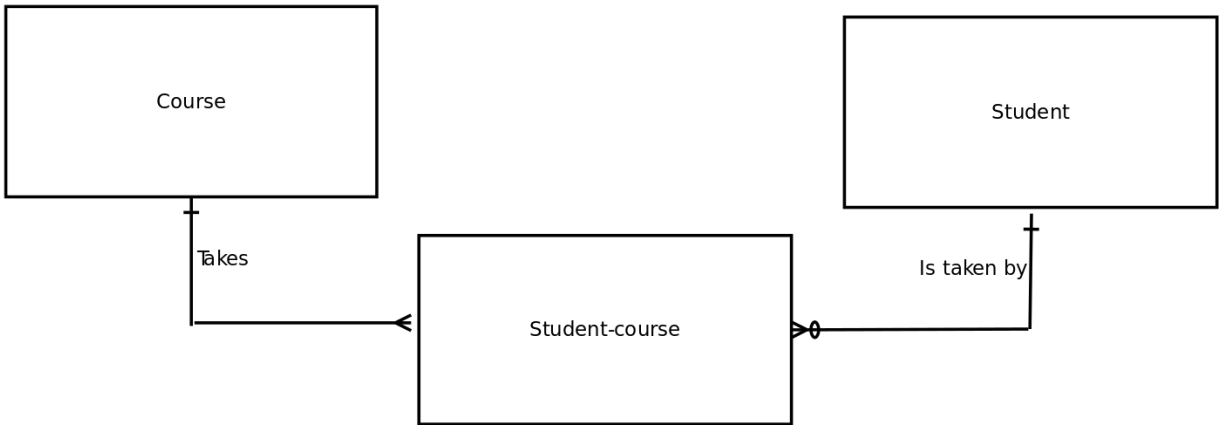
An entity-relationship diagram models how the entities relate to each other. It's made up of multiple relationships, the kind shown in the examples above. In general, these entities go on to become the database tables.

The first step in developing the diagram is to identify all the entities in the system. In the initial stage, it is not necessary to identify the attributes, but this may help to clarify matters if the designer is unsure about some of the entities. Once the entities are listed, relationships between these entities are identified and modeled according to their type: one-to-many, optional and so on. There are many software packages that can assist in drawing an entity-relationship diagram, but any graphical package should suffice.

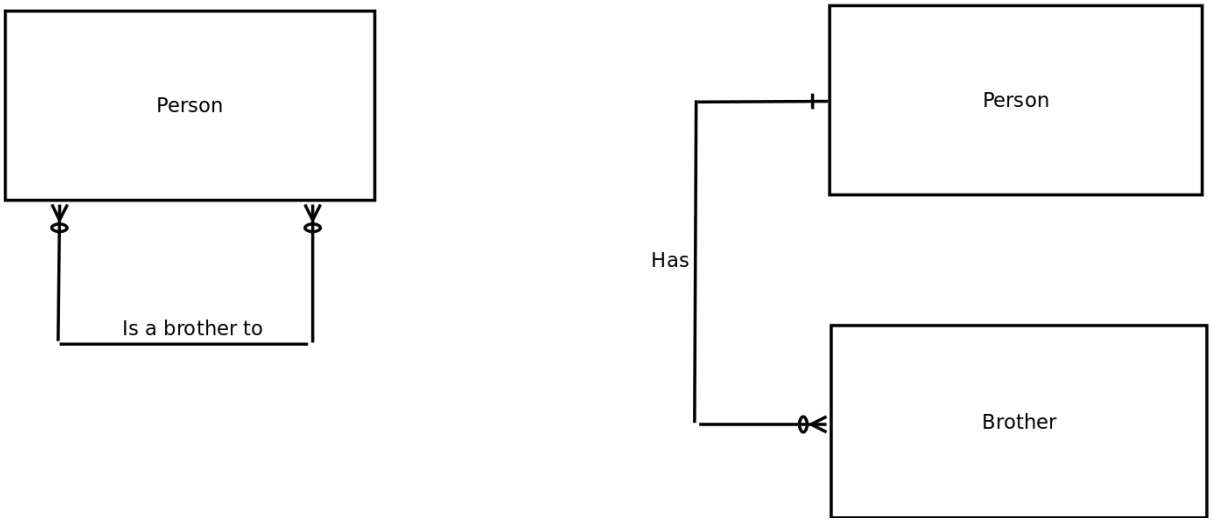
Once the initial entity-relationship diagram has been drawn, it is often shown to the stakeholders. Entity-relationship diagrams are easy for non-technical people to understand, especially when guided through the process. This can help identify any errors that have crept in. Part of the reason for modeling is that models are much easier to understand than pages of text, and they are much more likely to be viewed by stakeholders, which reduces the chances of errors slipping through to the next stage, when they may be more difficult to fix.

It is important to remember that there is no one right or wrong answer. The more complex the situation, the more possible designs that will work. Database design is an acquired skill, though, and more experienced designers will have a good idea of what works and of possible problems at a later stage, having gone through the process before.

Once the diagram has been approved, the next stage is to replace many-to-many relationships with two one-to-many relationships. A DBMS cannot directly implement many-to-many relationships, so they are decomposed into two smaller relationships. To achieve this, you have to create an *intersection*, or *composite* entity type. Because intersection entities are less "real-world" than ordinary entities, they are sometimes difficult to name. In this case, you can name them according to the two entities being intersected. For example, you can intersect the many-to-many relationship between *student* and *course* by a *student-course* entity.



The same applies even if the entity is recursive. The person entity that has an M:N relationship "is brother to" also needs an intersection entity. You can come up with a good name for the intersection entity in this case: *brother*. This entity would contain two fields, one for each person of the brother relationship — in other words, the primary key of the first brother and the primary key of the other brother.



6.3.1.10.5 Database Design Phase 2: Logical and Physical Design

This article follows on from Database Design Phase 2: Conceptual Design .

Contents

Overview

Once the conceptual design is finalized, it's time to convert this to the logical and physical design. Usually, the DBMS is chosen at this stage, depending on the requirements and complexity of the data structures. Strictly speaking, the logical design and the physical design are two separate stages, but are often merged into one. They overlap because most current DBMSs (including MariaDB) match logical records to physical records on disk on a 1:1 basis.

Each entity will become a database table, and each attribute will become a field of this table. Foreign keys can be created if the DBMS supports them and the designer decides to implement them. If the relationship is mandatory, the foreign key must be defined as *NOT NULL*, and if it's optional, the foreign key can allow nulls. For example, because of the invoice line-to-product relationship in the previous example, the product code field is a foreign key in the invoice to line table. Because the invoice line must contain a product, the field must be defined as *NOT NULL*. The default MariaDB storage engine, XtraDB, does support foreign key constraints, but some storage engines, such as MyISAM do not. The *ON DELETE CASCADE* and *ON DELETE RESTRICT* clauses are used to support foreign keys. *ON DELETE RESTRICT* means that records cannot be deleted unless all records associated with the foreign key are also deleted. In the invoice line-to-product case, *ON DELETE RESTRICT* in the invoice line table means that if a product is deleted, the deletion will not take place unless all associated invoice lines with that product are deleted as well. This avoids the possibility of an invoice line existing that points to a non-existent product. *ON DELETE CASCADE* achieves a similar effect, but more automatically (and more dangerously!). If the foreign key was declared with *ON CASCADE DELETE*, associated invoice lines would automatically be deleted if a product was deleted. *ON UPDATE CASCADE* is similar to *ON DELETE CASCADE* in that all foreign key references to a primary key are updated when the primary key is updated.

Normalizing your tables is an important step when designing the database. This process helps avoid data redundancy and improves your data integrity.

Novice database designers usually make a number of common errors. If you've carefully identified entities and attributes and you've normalized your data, you'll probably avoid these errors.

Common errors

- Keep unrelated data in different tables. People who are used to using spreadsheets often make this mistake because they are used to seeing all their data in one two-dimensional table. A relational database is much more powerful; don't 'hamstring' it in this way.
- Don't store values you can calculate. Let's say you're interested three numbers: /A, B and the product of A and B (A*B). Don't store the product. It wastes space and can easily be calculated if you need it. And it makes your database more difficult to maintain: If you change A, you also have to change all of the products as well. Why waste your database's efforts on something you can calculate when you need it?
- Does your design cater to all the conditions you've analyzed? In the heady rush of creating an entity-relationship diagram, you can easily overlook a condition. Entity-relationship diagrams are usually better at getting stakeholders to spot an incorrect rule than spot a missing one. The business logic is as important as the database logic and is more likely to be overlooked. For example, it's easy to spot that you cannot have a sale without an associated customer, but have you built in that the customer cannot be approved for a sale of less than $500 if another approved customer has not recommended them?
- Are your attributes, which are about to become field names, well chosen? Fields should be clearly named. For example, if you use *f1* and *f2* instead of *surname* and *first_name*, the time saved in less typing will be lost in looking up the correct spelling of the field, or in mistakes where a developer thought *f1* was the first name, and *f2* the surname. Similarly, try to avoid the same names for different fields. If six tables have a primary key of *code*, you're making life unnecessarily difficult. Rather, use more descriptive terms, such as *sales_code* or *customer_code*.
- Don't create too many relationships. Almost every table in a system can be related by some stretch of the imagination, but there's no need to do this. For example, a tennis player belongs to a sports club. A sports club belongs to a region. The tennis players then also belong to a region, but this relationship can be derived through the sports club, so there's no need to add another foreign key (except to achieve performance benefits for certain kinds of queries). Normalizing can help you avoid this sort of problem (and even when you're trying to optimize for speed, it's usually better to normalize and then consciously denormalize rather than not normalize at all).
- Conversely, have you catered to all relations? Do all relations from your entity-relationship diagram appear as common fields in your table structures? Have you covered all relations? Are all many-to-many relationships broken up into two one-to-many relationships, with an intersection entity?
- Have you listed all constraints? Constraints include a gender that can only be *m* or *f*, ages of schoolchildren that cannot exceed twenty, or email addresses that need to have an @ sign and at least one period (.; don't take these limits for granted. At some stage the system you will need to implement them, and you're either going to forget to do so, or have to go back and gather more data if you don't list these up front.
- Are you planning to store too much data? Should a customer be asked to supply their eye color, favorite kind of fish, and names of their grandparents if they are simply trying to register for an online newsletter? Sometimes stakeholders want too much information from their customers. If the user is outside the organization, they may not have a voice in the design process, but they should always be thought of foremost. Consider also the difficulty and time taken to capture all the data. If a telephone operator needs to take all this information down before making a sale, imagine how much slower they will be. Also consider the impact data has on database speed. Larger tables are generally slower to access, and unnecessary BLOB, TEXT and VARCHAR fields lead to record and table fragmentation.
- Have you combined fields that should be separate? Combining first name and surname into one field is a common beginner mistake. Later you'll realise that sorting names alphabetically is tricky if you've stored them as *John Ellis* and *Alfred Ntombela*. Keep distinct data discrete.
- Has every table got a primary key? There had better be a good reason for leaving out a primary key. How else are you going to identify a unique record quickly? Consider that an index speeds up access time tremendously, and when kept small it adds very little overhead. Also, it's usually better to create a new field for the primary key rather than take

existing fields. First name and surname may be unique in your current database, but they may not always be. Creating a system-defined primary key ensures it will always be unique.

- Give some thought to your other indexes. What fields are likely to be used in this condition to access the table? You can always create more fields later when you test the system, but add any you think you need at this stage.
- Are your foreign keys correctly placed? In a one-to-many relationship, the foreign key appears in the *many* table, and the associated primary key in the *one* table. Mixing these up can cause errors.
- Do you ensure referential integrity? Foreign keys should not relate to a primary key in another table that no longer exists.
- Have you covered all character sets you may need? German letters, for example, have an expanded character set, and if the database is to cater for German users it will have to take this into account. Similarly, dates and currency formats should be carefully considered if the system is to be international
- Is your security sufficient? Remember to assign the minimum permissions you can. Do not allow anyone to view a table if they do not need to do so. Allowing malicious users view data, even if they cannot change it, is often the first step in for an attacker.

6.3.1.10.6 Database Design Phase 3: Implementation

This article follows on from Database Design Phase 2: Logical and Physical Design.

The implementation phase is where you install the DBMS on the required hardware, optimize the database to run best on that hardware and software platform, and create the database and load the data. The initial data could be either new data captured directly or existing data imported from a MariaDB database or another DBMS. You also establish database security in this phase and give the various users that you've identified access applicable to their requirements. Finally, you also initiate backup plans in this phase.

The following are steps in the implementation phase:

1. Install the DBMS.
2. Tune the setup variables according to the hardware, software and usage conditions.
3. Create the database and tables.
4. Load the data.
5. Set up the users and security.
6. Implement the backup regime.

6.3.1.10.7 Database Design Phase 4: Testing

This article follows on from Database Design Phase 3: Implementation.

The testing phase is where the performance, security, and integrity of the data are tested. Usually this will occur in conjunctions with the applications that have been developed. You test the performance under various loads conditions to see how the database handles multiple concurrent connections or high volumes of updating and reading. Are the reports generated quickly enough? For example, an application designed with the old MyISAM storage engine may prove to be too slow because the impact of the updates was underestimated. The storage engine may have to be changed to XtraDB in response.

Data integrity also needs to be tested, as the application may have logical flaws that result in transactions being lost or other inaccuracies. Further, security needs to be tested to ensure that users can access and change only the data they should.

The logical or physical designs may have to be modified. Perhaps new indexes are required (which the tester may discover after careful use of MariaDB's EXPLAIN statement, for example).

The testing and fine-tuning process is an iterative one, with multiple tests performed and changes implemented.

The following are the steps in the testing phase:

1. Test the performance
2. Test the security
3. Test the data integrity
4. Fine-tune the parameters or modify the logical or physical designs in response to the tests.

6.3.1.10.8 Database Design Phase 5: Operation

This article follows on from Database Design Phase 4: Testing.

The operation phase takes place when the testing is complete and the database is ready to be rolled out for everyday use. The users of the system begin to operate the system, load data, read reports and so on. Inevitably, problems come to light. The designers need to carefully manage the database's scope at this stage, as users may expect all their desires to be pandered to. Poor database designers may find themselves extending the project well beyond their initial time estimate, and the situation may also become unpleasant if the scope has not been clearly defined and agreed upon. Project owners will feel wronged if their needs are not met, and the database designers will feel overworked and underpaid. Even when scope has been well managed, there will always be new requirements, These then lead to the next stage.

There are numerous strategies for implementing a rollout. The low-key approach often works well, where the relatively low number of users in the early stage make bug fixing easy. Hugely publicized rollouts often end with egg on the stakeholder's faces, as the best testers of all, the users, invariably find unforeseen bugs, which is best done away from the spotlight. Alternatively, rollouts can occur in a distributed manner, where a pilot branch or office is selected, and when the system has proven its stability, it's rolled out to the remaining branches.

The following are the steps in the operation phase:

1. Hand over operation of the database to the users.
2. Make any final changes based on the problems discovered by users.

6.3.1.10.9 Database Design Phase 6: Maintenance

This article follows on from Database Design Phase 5: Operation.

The database maintenance phase incorporates general maintenance, such as maintaining the indexes, optimizing the tables, adding and removing users, and changing passwords, as well as backups and restoration of backups in case of a failure. New requirements also start to be requested, and this may result in new fields, or new tables, being created.

As the new system and organization changes, the existing database becomes less and less sufficient to meet the organization's needs. For example, the media organization may be amalgamated with media bodies from other countries, requiring integration of many data sources, or the volumes and staff may expand (or reduce) dramatically. Eventually, there comes a time, whether it's 10 months after completion or 10 years, when the database system needs to be replaced. The maintenance of the existing database begins to drain more and more resources, and the effort to create a new design is matched by the current maintenance effort. As this point, the database is coming to the end of its life, and a new project begins life in the Analysis phase.

The following are the steps in the maintenance phase:

1. Maintain the indexes
2. Maintain the tables
3. Maintain the users
4. Change passwords
5. Backup
6. Restore backups
7. Change the design to meet new requirements

6.3.1.10.10 Database Design Example Phase 1: Analysis

This article follows on from Database Design Phase 6: Maintenance.

Real-world example: creating a publishing tracking system

Now let's walk through the database design process with a step-by-step example. The Poet's Circle is a publisher that publishes poetry and poetry anthologies. It is keen to develop a new system that tracks poets, poems, anthologies and sales. The following sections show the steps taken from the initial analysis to the final, working database.

Poet's circle database phase 1: analysis

The following information is gleaned from speaking to the various stakeholders at Poet's Circle. They want to develop a database system to track the poets they have recorded, the poems they write, the publications they appear in, as well as the sales to customers that these publications make.

The designer asks various questions to get more detailed information, such as "What is a poet, as far as the system goes? Does Poet's Circle keep track of poets even if they haven't written or published poems? Are publications recorded even before there are any associated poems? Does a publication consist of one poem, or many? Are potential customer's details recorded?" The following summarizes the responses in our example:

- Poet's Circle is a publisher that bases its choices of publications on an active poetry community on its website. If enough of the community wants a poem published, Poet's Circle will do so.
- A poet can be anybody who wants to be a poet, not necessarily someone who has a poem captured in the system or someone who has even written a poem.
- Poems can be submitted through a web interface, by email or on paper.
- All captured poems are written by an associated poet, whose details are already in the system. There can be no poems submitted and stored without a full set of details of the poet.
- A publication can be a single poem, a poetry anthology, or a work of literary criticism.
- Customers can sign up through a web interface and may order publications at that point in time, or express interest in receiving updates for possible later purchases.
- Sales of publications are made to customers whose details are stored in the system. There are no anonymous sales.
- A single sale can be for one publication, but many publications can also be purchased at the same time. If more than one customer is involved in this sale, Poet's Circle treats it as more than one sale. Each customer has their own sale.
- Not all publications make sales — some may be special editions, and others simply never sell any copies.

6.3.1.10.11 Database Design Example Phase 2: Design

> This article follows on from Database Design Example Phase 1: Analysis.

Based on the provided information, you can begin your logical design and should be able to identify the initial entities:

- Poet
- Poem
- Publication
- Sale
- Customer

The Poet's Circle is not an entity, or even of instance an a *publisher* entity. Only if the system were developed for many publishers would *publisher* be a valid entity.

Neither *website* nor *poetry community* are entities. There is only one website, and anyway, a website is merely a means of producing data to populate the database. There is also only one poetry community as far as this system is concerned, and there is not much you'd want to store about it.

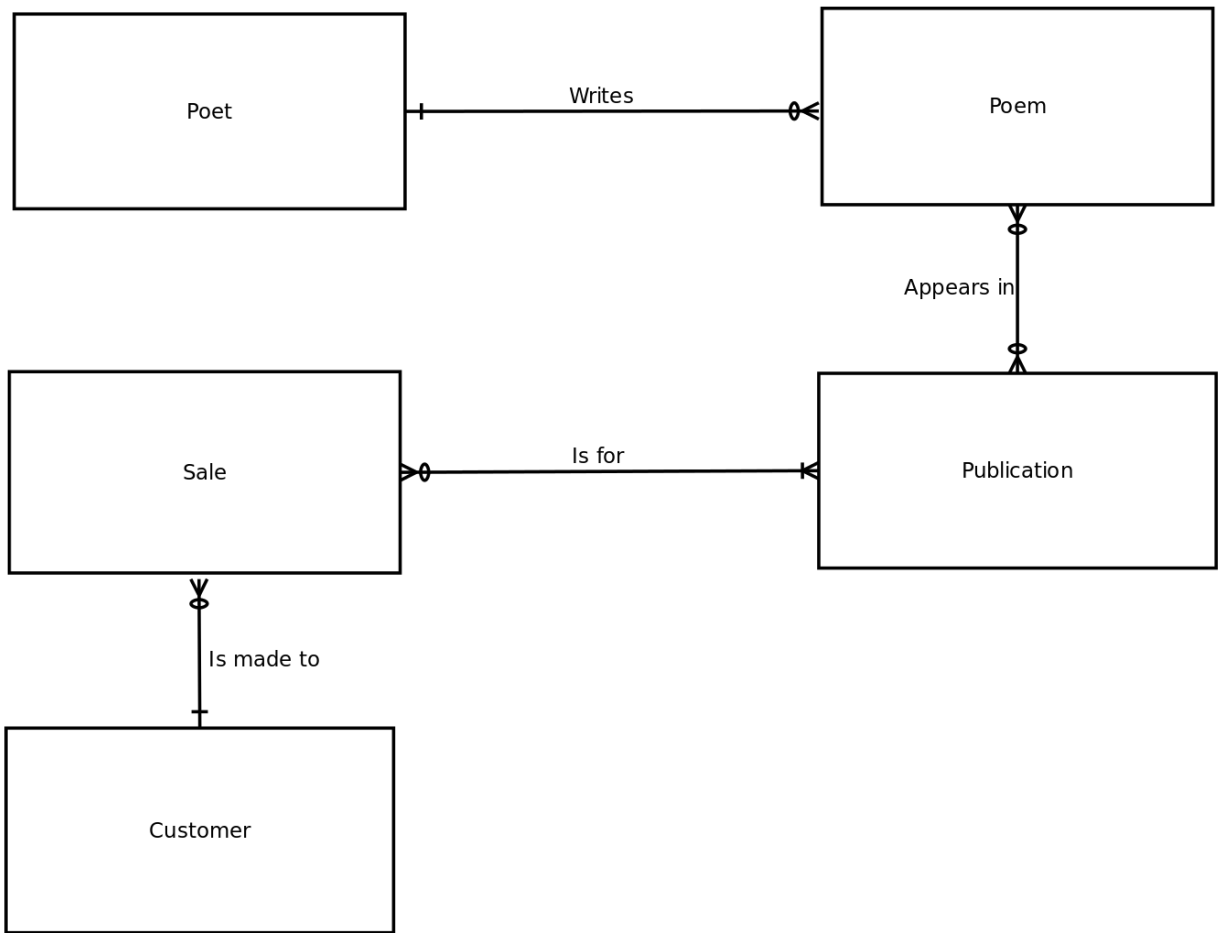
Next, you need to determine the relationship between these entities. You can identify the following:

- A poet can write many poems. The analysis identified the fact that a poet can be stored in the system even if there are no associated poems. Poems may be captured at a later point in time, or the poet may still be a potential poet. Conversely, many poets could conceivably write a poem, though the poem must have been written by at least one poet.
- A publication may contain many poems (an anthology) or just one. It can also contain no poems (poetry criticism for example). A poem may or may not appear in a publication.
- A sale must be for at least one publication, but it may be for many. A publication may or may not have made any sales.
- A customer may be made for many sales, or none at all. A sale is only made for one and only one customer.

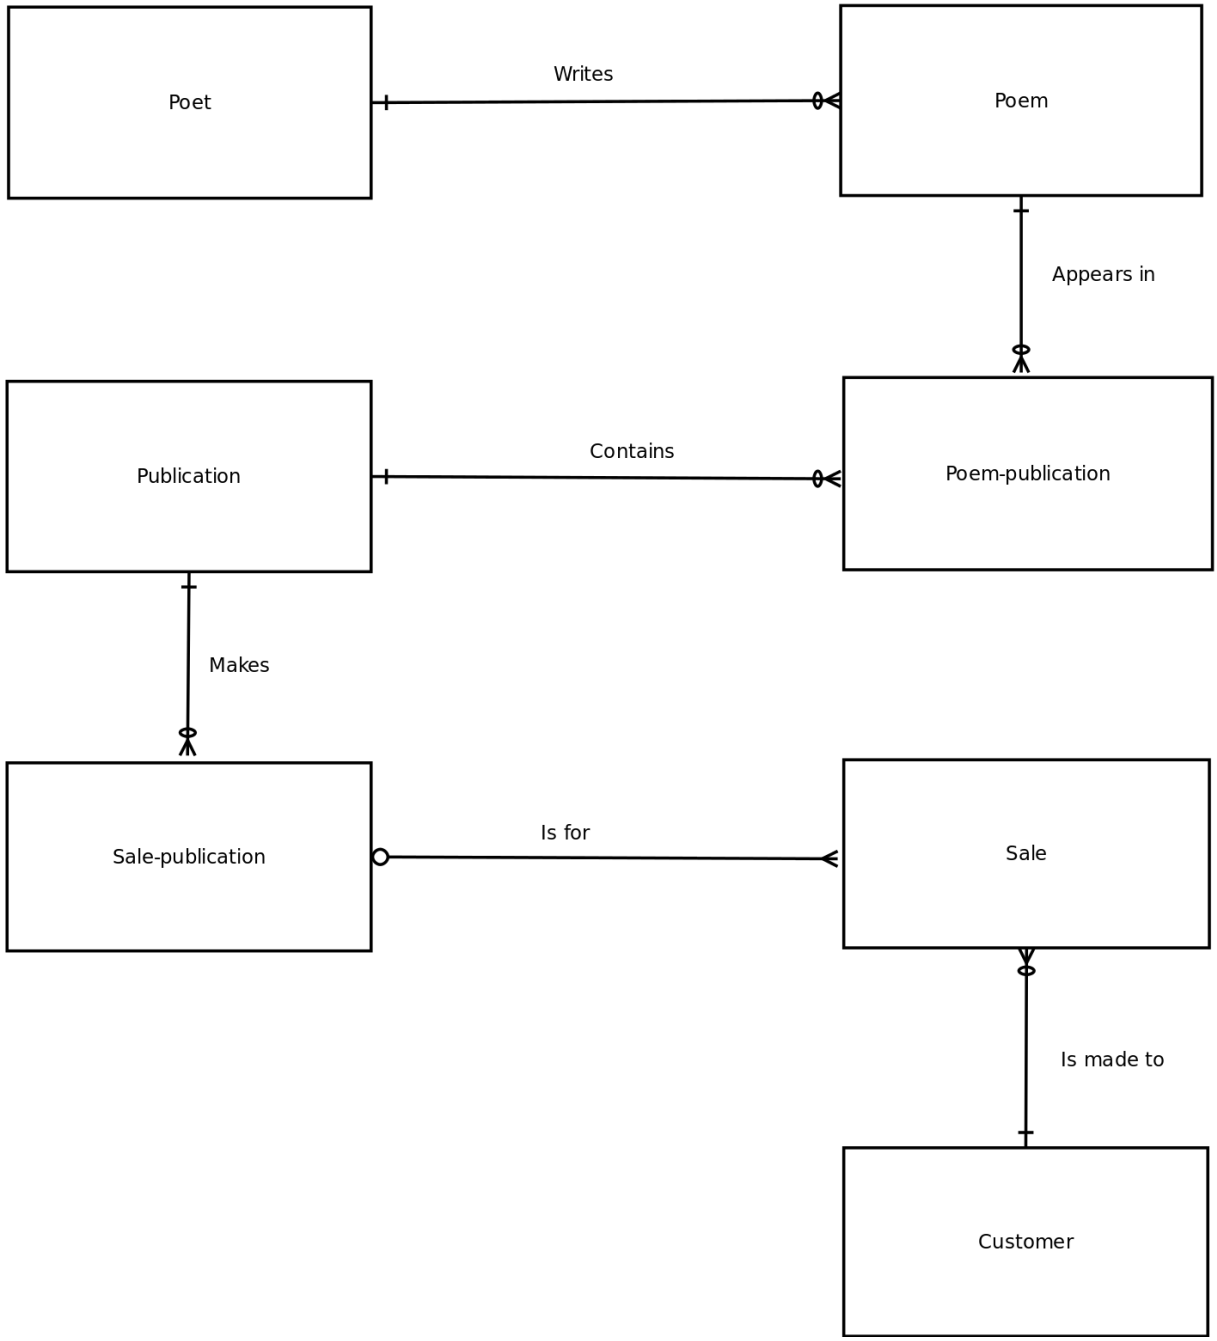
You can identify the following attributes:

- **Poet**: first name, surname, address, email address
- **Poem**: poem title, poem contents
- **Publication**: title, price
- **Sales**: date, amount
- **Customer**: first name, surname, address, email address

Based on these entities and relationships, you can construct the entity-relationship diagram shown below:



There are two many-to-many relationships in the figure above. These need to be converted into one-to-many relationships before you can implement them in a DBMS. After doing so, the intersection entities *poem-publication* and *sale-publication* are created.



Now, to begin the logical and physical design, you need to add attributes that can create the relationship between the entities and specify primary keys. You do what's usually best, and create new, unique, primary keys. The following tables show the structures for the tables created from each of the entities:

Poet table

Field	Definition
poet code	primary key, integer
first name	character (30)
surname	character (40)
address	character (100)
postcode	character (20)
email address	character (254)

Poem table

Field	Definition
poem code	primary key, integer

poem title	character(50)
poem contents	text
poet code	foreign key, integer

Poem-publication table

Field	Definition
poem code	joint primary key, foreign key, integer
publication code	joint primary key, foreign key, integer

Publication table

Field	Definition
publication code	primary key, integer
title	character(100)
price	numeric(5.2)

Sale-publication table

Field	Definition
sale code	joint primary key, foreign key, integer
publication code	joint primary key, foreign key, integer

Sale table

Field	Definition
sale code	primary key, integer
date	date
amount	numeric(10.2)
customer code	foreign key, integer

Customer table

Field	Definition
customer code	primary key, integer
first name	character (30)
surname	character (40)
address	character (100)
postcode	character (20)
email address	character (254)

MariaDB will have no problem with this, and is selected as the DBMS. Existing hardware and operating system platforms are also selected. The following section looks at the implementation and the SQL statements used to create the MariaDB tables.

6.3.1.10.12 Database Design Example Phase 3: Implementation

This article follows on from Database Design Example Phase 2: Design .

With the design complete, it's time to install MariaDB and run the CREATE statements, as follows:

```
CREATE DATABASE poets_circle;

CREATE TABLE poet (
  poet_code INT NOT NULL,
  first_name VARCHAR(30),
  surname VARCHAR(40),
  address VARCHAR(100),
  postcode VARCHAR(20),
  email VARCHAR(254),
  PRIMARY KEY(poet_code)
);

CREATE TABLE poem(
  poem_code INT NOT NULL,
  title VARCHAR(50),
  contents TEXT,
  poet_code INT NOT NULL,
  PRIMARY KEY(poem_code),
  INDEX(poet_code),
  FOREIGN KEY(poet_code) REFERENCES poet(poet_code)
);

CREATE TABLE publication(
  publication_code INT NOT NULL,
  title VARCHAR(100),
  price MEDIUMINT UNSIGNED,
  PRIMARY KEY(publication_code)
);

CREATE TABLE poem_publication(
  poem_code INT NOT NULL,
  publication_code INT NOT NULL,
  PRIMARY KEY(poem_code, publication_code),
  INDEX(publication_code),
  FOREIGN KEY(poem_code) REFERENCES poem(poem_code),
  FOREIGN KEY(publication_code) REFERENCES publication(publication_code)
);

CREATE TABLE sales_publication(
  sales_code INT NOT NULL,
  publication_code INT NOT NULL,
  PRIMARY KEY(sales_code, publication_code)
);

CREATE TABLE customer(
  customer_code INT NOT NULL,
  first_name VARCHAR(30),
  surname VARCHAR(40),
  address VARCHAR(100),
  postcode VARCHAR(20),
  email VARCHAR(254),
  PRIMARY KEY(customer_code)
);

CREATE TABLE sale(
  sale_code INT NOT NULL,
  sale_date DATE,
  amount INT UNSIGNED,
  customer_code INT NOT NULL,
  PRIMARY KEY(sale_code),
  INDEX(customer_code),
  FOREIGN KEY(customer_code) REFERENCES customer(customer_code)
);
```

6.3.1.10.13 Database Design Example Phases 4-6: Testing, Operation and Maintenance

This article follows on from Database Design Example Phase 3: Implementation.

Once the database is ready the application programs have been rolled out, it's time for the testing to begin. While the other phases of the database lifecycle can occur reasonably independently of the systems development process, part of the testing phase is how all the components run together.

Load testing may indicate that MariaDB has not been set up to handle the expected 600 concurrent connections, and the configuration file needs to be changed. Other tests may indicate that in certain circumstances, duplicate key errors are received, as the locking mechanism is not uniformly implemented, and the application does not handle locking correctly. The application needs to be fixed. Backups also need to be tested, as well as the ability to smoothly restore from backup with a minimum of downtime.

> Testing is one of the most neglected and critical phases. A designer or manager who does not properly account for testing is simply incompetent. No matter how tiny your system, make sure you allocate time for thorough testing, and time for fixing the inevitable bugs.

Once testing is complete, the system can be rolled out. You decide on a low-key rollout and give a few selected poets access to the website to upload their poems. You discover other problems. Some poets upload poems using character sets you haven't catered for, and you need to make a few tweaks to ensure these are handled correctly.

Soon enough, the system is rolled out completely. Maintenance, though, is a never-ending task, and with the immense popularity of the system, and with large numbers of updates and deletes, the system tends to become fragmented. The administrator regularly needs to take care of this, and, of course, the inevitable disk failure leads to an all-night restore session, and much thankfulness for the ease of use of mariadb-dump.

6.3.1.11 Database Normalization

This section introduces you to a powerful tool for designing databases: normalization.

Database Normalization Overview

A sample system going through the process of normalization

Database Normalization: 1st Normal Form

Moving from unnormalized to 1st normal form

Database Normalization: 2nd Normal Form

From 1st to 2nd normal form

Database Normalization: 3rd Normal Form

From 2nd to 3rd normal form

Database Normalization: Boyce-Codd Normal Form

Beyond 3rd normal form with Boyce-Codd normal form

Database Normalization: 4th Normal Form

Beyond Boyce-Codd normal form with 4th normal form

Database Normalization: 5th Normal Form and Beyond

Normal forms beyond 4th are mainly of academic interest

Understanding Denormalization

Denormalization is the process of reversing the transformations made during...

6.3.1.11.1 Database Normalization Overview

Contents

Developed in the 1970's by E.F. Codd, database normalization is standard requirement of many database designs. Normalization is a technique that can help you avoid data anomalies and other problems with managing your data. It consists of transforming a table through various stages: *1st normal form*, *2nd normal form*, *3rd normal form*, and beyond.

It aims to:

- Eliminate data redundancies (and therefore use less space)
- Make it easier to make changes to data, and avoid anomalies when doing so
- Make referential integrity constraints easier to enforce
- Produce an easily comprehensible structure that closely resembles the situation the data represents, and allows for growth

Let's begin by creating a sample set of data. You'll walk through the process of normalization first without worrying about the theory, to get an understanding of the reasons you'd want to normalize. Once you've done that, we'll introduce the theory and the various stages of normalization, which will make the whole process described below much simpler the next time you do it.

Imagine you are working on a system that records plants placed in certain locations, and the soil descriptions associated with them.

The location:

- Location Code: 11
- Location name: Kirstenbosch Gardens

contains the following three plants:

- Plant code: 431
- Plant name: Leucadendron
- Soil category: A
- Soil description: Sandstone

- Plant code: 446
- Plant name: Protea
- Soil category: B
- Soil description: Sandstone/Limestone

- Plant code: 482
- Plant name: Erica
- Soil category: C
- Soil description: Limestone

The location:

- Location Code: 12
- Location name: Karbonkelberg Mountains

contains the following two plants:

- Plant code: 431
- Plant name: Leucadendron
- Soil category: A
- Soil description: Sandstone

- Plant code: 449
- Plant name: Restio
- Soil category: B
- Soil description: Sandstone/Limestone

Tables in a relational database are in a grid, or table format (MariaDB, like most modern DBMSs is a relational database), so let's rearrange this data in the form of a tabular report:

Plant data displayed as a tabular report

Location code	Location name	Plant code	Plant name	Soil category	Soil description
11	Kirstenbosch Gardens	431	Leaucadendron	A	Sandstone
		446	Protea	B	Sandstone/limestone
		482	Erica	C	Limestone
12	Karbonkelberg Mountains	431	Leucadendron	A	Sandstone
		449	Restio	B	Sandstone/limestone

How are you to enter this data into a table in the database? You could try to copy the layout you see above, resulting in a table something like the below. The null fields reflect the fields where no data was entered.

Trying to create a table with plant data

Location code	Location name	Plant code	Plant name	Soil category	Soil description
11	Kirstenbosch Gardens	431	Leucadendron	A	Sandstone
NULL	NULL	446	Protea	B	Sandstone/limestone
NULL	NULL	482	Erica	C	Limestone
1 2	Karbonkelberg Mountains	431	Leucadendron	A	Sandstone
NULL	NULL	449	Restio	B	Sandstone/limestone

This table is not much use, though. The first three rows are actually a group, all belonging to the same location. If you take the third row by itself, the data is incomplete, as you cannot tell the location the Erica is to be found. Also, with the table as it stands, you cannot use the location code, or any other fields, as a primary key (remember, a primary key is a field, or list of fields, that uniquely identify one record). There is not much use in having a table if you can't uniquely identify each record in it.

So, the solution is to make sure each table row can stand alone, and is not part of a group, or set. To achieve this, remove the groups, or sets of data, and make each row a complete record in its own right, which results in the table below.

Each record stands alone

Location code	Location name	Plant code	Plant name	Soil category	Soil description
11	Kirstenbosch Gardens	431	Leucadendron	A	Sandstone
11	Kirstenbosch Gardens	446	Protea	B	Sandstone/limestone
11	Kirstenbosch Gardens	482	Erica	C	Limestone
12	Karbonkelberg Mountains	431	Leucadendron	A	Sandstone
12	Karbonkelberg Mountains	449	Restio	B	Sandstone/limestone

Notice that the location code cannot be a primary key on its own. It does not uniquely identify a row of data. So, the primary key must be a combination of *location code* and *plant code*. Together these two fields uniquely identify a row of data. Think about it. You would never add the same plant type more than once to a particular location. Once you have the fact that it occurs in that location, that's enough. If you want to record quantities of plants at a location - for this example, you're just interested in the spread of plants - you don't need to add an entire new record for each plant; rather, just add a quantity field. If for some reason you would be adding more than one instance of a plant/location combination, you'd need to add something else to the key to make it unique.

So, now the data can go in table format, but there are still problems with it. The table stores the information that code *11* refers to *Kirstenbosch Gardens* three times! Besides the waste of space, there is another serious problem. Look carefully at the data below.

Data anomaly

Location code	Location name	Plant code	Plant name	Soil category	Soil description
11	Kirstenbosch Gardens	431	Leucadendron	A	Sandstone
11	Kirstenbosh Gardens	446	Protea	B	Sandstone/limestone

11	Kirstenbosch Gardens	482	Erica	C	Limestone
12	Karbonkelberg Mountains	431	Leucadendron	A	Sandstone
12	Karbonkelberg Mountains	449	Restio	B	Sandstone/limestone

Did you notice anything strange? Congratulations if you did! *Kirstenbosch* is misspelled in the second record. Now imagine trying to spot this error in a table with thousands of records! By using the structure in the table above, the chances of data anomalies increases dramatically.

The solution is simple. You remove the duplication. What you are doing is looking for partial dependencies - in other words, fields that are dependent on a part of a key and not the entire key. Because both the location code and the plant code make up the key, you look for fields that are dependent only on location code or on plant name.

There are quite a few fields where this is the case. Location name is dependent on location code (plant code is irrelevant in determining project name), and plant name, soil code, and soil name are all dependent on plant number. So, take out all these fields, as shown in the table below:

Removing the fields not dependent on the entire key

Location code	Plant code
11	431
11	446
11	482
12	431
12	449

Clearly you can't remove the data and leave it out of your database completely. You take it out, and put it into a new table, consisting of the fields that have the partial dependency and the fields on which they are dependent. For each of the *key* fields in the partial dependency, you create a new table (in this case, both are already part of the primary key, but this doesn't always have to be the case). So, you identified *plant name*, *soil description* and *soil category* as being dependent on *plant code*. The new table will consist of *plant code*, as a key, as well as plant name, soil category and soil description, as shown below:

Creating a new table with location data

Plant code	Plant name	Soil category	Soil description
431	Leucadendron	A	Sandstone
446	Protea	B	Sandstone/limestone
482	Erica	C	Limestone
431	Leucadendron	A	Sandstone
449	Restio	B	Sandstone/limestone

You do the same process with the location data, shown below:

Creating a new table with location data

Location code	Location name
11	Kirstenbosch Gardens
12	Karbonkelberg Mountains

See how these tables remove the earlier duplication problem? There is only one record that contains *Kirstenbosch Gardens*, so the chances of noticing a misspelling are much higher. And you aren't wasting space storing the name in many different records. Notice that the location code and plant code fields are repeated in two tables. These are the fields that create the relation, allowing you to associate the various plants with the various locations. Obviously there is no way to remove the duplication of these fields without losing the relation altogether, but it is far more efficient storing a small code repeatedly than a large piece of text.

But the table is still not perfect. There is still a chance for anomalies to slip in. Examine the table below carefully:

Another anomaly

Plant code	Plant name	Soil category	Soil description
431	Leucadendron	A	Sandstone
446	Protea	B	Sandstone/limestone
482	Erica	C	Limestone
431	Leucadendron	A	Sandstone
449	Restio	B	Sandstone

The problem in the table above is that the Restio has been associated with Sandstone, when in fact, having a soil category of B, it should be a mix of sandstone and limestone (the soil category determines the soil description in this example). Once again you're storing data redundantly. The *soil category* to *soil description* relationship is being stored in its entirety for each plant. As before, the solution is to take out this excess data and place it in its own table. What you are in fact doing at this stage is looking for transitive relationships, or relationships where a nonkey field is dependent on another nonkey field. *Soil description*, although in one sense dependent on plant code (it did seem to be a partial dependency when we looked at it in the previous step), is actually dependent on *soil category*. So, *soil description* must be removed. Once again, take it out and place it in a new table, along with its actual key (*soil category*) as shown in the tables below:

Plant data after removing the soil description

Plant code	Plant name	Soil category
431	Leucadendron	A
446	Protea	B
482	Erica	C
449	Restio	B

Creating a new table with the soil description

Soil category	Soil description
A	Sandstone
B	Sandstone/limestone
C	Limestone

You've cut down on the chances of anomalies once again. It is now impossible to mistakenly assume soil category B is associated with anything but a mix of sandstone and limestone. The soil description to soil category relationships are stored in only one place - the new *soil* table, where you can be much more certain they are accurate.

Often, when you're designing a system you don't yet have a complete set of test data available, and it's not necessary if you understand how the data relates. This article has used the tables and their data to demonstrate the consequences of storing data in tables that were not normalized, but without them you have to rely on dependencies between fields, which is the key to database normalization.

The following articles will describe the process more formally, starting with moving from unnormalized data (or zero normal form) to first normal form.

6.3.1.11.2 Database Normalization: 1st Normal Form

> This article follows on from the Database Normalization Overview.

At first, the data structure was as follows:

- Location code
- Location name
- 1-n plant numbers (1-n is a shorthand for saying there are many occurrences of this field. In other words, it is a repeating group).

- 1-n plant names
- 1-n soil categories
- 1-n soil descriptions

This is a completely unnormalized structure - in other words, it is in *zero normal form* So, to begin the normalization process, you start by moving from zero normal form to 1st normal form.

Tables are in 1st normal form if they follow these rules:

- There are no repeating groups.
- All the key attributes are defined.
- All attributes are dependent on the primary key.

What this means is that data must be able to fit into a tabular format, where each field contains one value. This is also the stage where the primary key is defined. Some sources claim that defining the primary key is not necessary for a table to be in first normal form, but usually it's done at this stage and is necessary before we can progress to the next stage. Theoretical debates aside, you'll have to define your primary keys at this point.

> Although not always seen as part of the definition of 1st normal form, the principle of atomicity is usually applied at this stage as well. This means that all columns must contain their smallest parts, or be indivisible. A common example of this is where someone creates a *name* field, rather than *first name* and *surname* fields. They usually regret it later.

So far, the plant example has no keys, and there are repeating groups. To get it into 1st normal form, you'll need to define a primary key and change the structure so that there are no repeating groups; in other words, each row / column intersection contains one, and only one, value. Without this, you cannot put the data into the ordinary two-dimensional table that most databases require. You define location code and plant code as the primary key together (neither on its own can uniquely identify a record), and replace the repeating groups with a single-value attribute. After doing this, you are left with the structure shown in the table below (the primary key is in italics):

Plant location table
Location code
Location name
Plant code
Plant name
Soil category
Soil description

This table is now in 1st normal formal. The process for turning a table into 2nd normal form is continued in the next article.

6.3.1.11.3 Database Normalization: 2nd Normal Form

Contents

> This article follows on from Database Normalization: 1st Normal Form.

After converting to first normal form, the following table structure was achieved:

Plant location table
Location code
Location name
Plant code
Plant name
Soil category

Soil description

Is this in 2nd normal form?

A table is in 2nd normal form if:

- it is in 1st normal form
- it includes no partial dependencies (where an attribute is only dependent on part of a primary key)

> For an attribute to be only dependent on part of the primary key, the primary key must consist of more than one field. If the primary key contains only one field, the table is automatically in 2nd normal form if it is in 1st normal form

Let's examine all the fields. *Location name* is only dependent on *location code*. *Plant name*, *soil category*, and *soil description* are only dependent on *plant code* (this assumes that each plant only occurs in one soil type, which is the case in this example). So you remove each of these fields and place them in a separate table, with the key being that part of the original key on which they are dependent. For example, with *plant name*, the key is *plant code*. This leaves you with the tables below:

Plant location table with partial dependencies removed

Plant location table
Plant code
Location code

Table resulting from fields dependent on plant code

Plant table
Plant code
Plant name
Soil category
Soil description

Table resulting from fields dependent on location code

Location table
Location code
Location name

The resulting tables are now in 2nd normal form. The process for turning a table into 3rd normal form is continued in the next article.

6.3.1.11.4 Database Normalization: 3rd Normal Form

> This article follows on from Database Normalization: 2nd Normal Form.

After converting to second normal form, the following table structure was achieved:

Plant location table
Plant code
Location code

Plant table
Plant code

Plant name
Soil category
Soil description

Location table
Location code
Location name

Are these tables in 3rd normal form?

A table is in 3rd normal form if:

- it is in 2nd normal form
- it contains no transitive dependencies (where a non-key attribute is dependent on the primary key through another non-key attribute)

> If a table only contains one non-key attribute, it is obviously impossible for a non-key attribute to be dependent on another non-key attribute. Any tables where this is the case that are in 2nd normal form are then therefore also in 3rd normal form.

As only the plant table has more than one non-key attribute, you can ignore the others because they are in 3rd normal form already. All fields are dependent on the primary key in some way, since the tables are in second normal form. But is this dependency on another non-key field? *Plant name* is not dependent on either *soil category* or *soil description*. Nor is *soil category* dependent on either *soil description* or *plant name*.

However, *soil description* is dependent on *soil category*. You use the same procedure as before, removing it, and placing it in its own table with the attribute that it was dependent on as the key. You are left with the tables below:

Plant location table remains unchanged

Plant location table
Plant code
Location code

Plant table with soil description removed

Plant table
Plant code
Plant name
Soil category

The new soil table

Soil table
Soil category
Soil description

Location table remains unchanged

Location table
Location code
Location name

All of these tables are now in 3rd normal form. 3rd normal form is usually sufficient for most tables because it avoids the most common kind of data anomalies. It's suggested getting most tables you work with to 3rd normal form before you implement them, as this will achieve the aims of normalization listed in Database Normalization Overview in the vast majority of cases.

The normal forms beyond this, such as Boyce-Codd normal form and 4th normal form, are rarely useful for business applications. In most cases, tables in 3rd normal form are already in these normal forms anyway. But any skilful database practitioner should know the exceptions, and be able to normalize to the higher levels when required.

The next article covers Boyce-Codd normal form.

6.3.1.11.5 Database Normalization: Boyce-Codd Normal Form

Contents

This article follows on from Database Normalization: 3rd Normal Form

E.F. Codd and R.F. Boyce, two of the people instrumental in the development of the database model, have been honored by the name of this normal form. E.F. Codd developed and expanded the relational model, and also developed normalization for relational models in 1970, while R.F. Boyce was one of the creators of Structured Query Language (then called SEQUEL).

In spite of some resources stating the contrary, Boyce-Codd normal form is not the same as 4th normal form. Let's look at an example of data anomalies, which are presented in 3rd normal form and solved by transforming into Boyce-Codd normal form, before defining it.

Table containing data about the student, course, and instructor relationship

Student Course Instructor table
Student
Course
Instructor

Assume that the following is true for the table above:

- Each instructor takes only one course
- Each course can have one or more instructors
- Each student only has one instructor per course
- Each student can take one or more courses

What would the key be? None of the fields on their own would be sufficient to uniquely identify a records, so you have to use two fields. Which two should you use?

Perhaps *student* and *instructor* seem like the best choice, as that would allow you to determine the *course*. Or you could use *student* and *course*, which would determine the *instructor*. For now, let's use *student* and *course* as the key:

Using student and course as the key

Student Course Instructor table
Student
Course
Instructor

What normal form is this table in? It's in 1st normal form, as it has a key and no repeating groups. It's also in 2nd normal form, as the instructor is dependent on both other fields (students have many courses, and therefore instructors, and courses have many instructors). Finally, it's also in 3rd normal form, as there is only one non-key attribute.

But there are still some data anomalies. Look at the data sample below:

More data anomalies

Student	Course	Instructor
Conrad Pienaar	Biology	Nkosizana Asmal
Dingaan Fortune	Mathematics	Kader Dlamini
Gerrie Jantjies	Science	Helen Ginwala
Mark Thobela	Biology	Nkosizana Asmal
Conrad Pienaar	Science	Peter Leon
Alicia Ncita	Science	Peter Leon
Quinton Andrews	Mathematics	Kader Dlamini

The fact that Peter Leon teaches science is stored redundantly, as are Kader Dlamini with mathematics and Nkosizana Asmal with biology. The problem is that the *instructor* determines the *course*. Or put another, *course* is determined by *instructor*. The table conforms to 3rd normal form rules because no non-key attribute is dependent upon a non-key attribute! Again, you use the familiar method of removing this field and placing it into another table, along with its key:

Student Instructor table after removing Course

Student Course Instructor table
Student
Instructor

After removing the *course* field, the primary key needs to include both remaining fields to uniquely identify a record.

Resulting Instructor table

Student Course Instructor table
Instructor
Course

Although we had chosen course as part of the primary key in the original table, the instructor determines the course, which is why we make it the primary key in this table. As you can see, the redundancy problem has been solved.

Thus, a table is in Boyce-Codd normal form if:

- it is in 3rd normal form
- each determinant is a candidate key

That sounds scary! For most people new to database design, these are new terms. If you followed along with the example above, however, the terms will soon become clear:

- a *determinant* is an attribute that determines the value of another attribute.
- a *candidate key* is either the key or an alternate key (in other words, the attribute could be a key for that table)

In the initial table, *instructor* is not a candidate key (alone it cannot uniquely identify the record), yet it determines the course, so the table is not in Boyce-Codd normal form.

Let's look at the example again, and see what happens if you chose student and instructor as the key. What normal form is the table in this time?

Using student and instructor as the key

Student Course Instructor table
Student
Instructor
Course

Once again it's in 1st normal form because there is a primary key and there are no repeating groups. This time, though, it's

not in 2nd normal form because *course* is determined by only part of the key: the instructor. By removing *course* and its key, instructor, you get the structure shown below:

Removing course

Student Instructor table
Student
Instructor

Creating a new table with course

Student Course Instructor table
Instructor
Course

Either way you do it, by making sure the tables are normalized into Boyce-Codd normal form, you get the same two resulting tables. It's usually the case that when there are alternate fields to choose as a key, it doesn't matter which ones you choose initially because after normalizing you get the same results either way.

6.3.1.11.6 Database Normalization: 4th Normal Form

Contents

This article is intended to be read after the Boyce-Codd normal form article.

Let's look at the situation where redundancies can creep in even though a table is in Boyce-Codd normal form. Let's take the student / instructor / course example used in that article, but change one of the initial assumptions.

Assume that the following is true for the tables below:

- Each instructor takes only one course
- Each course can have one or more instructors
- Each student can have several instructors per course (this is different to the previous example)
- Each student can take one or more courses

Student Course Instructor data, with several instructors per course

More data anomalies

Student	Course	Instructor
Conrad Pienaar	Biology	Nkosizana Asmal
Dingaan Fortune	Mathematics	Kader Dlamini
Gerrie Jantjies	Science	Helen Ginwala
Mark Thobela	Biology	Nkosizana Asmal
Conrad Pienaar	Science	Peter Leon
Alicia Ncita	Science	Peter Leon
Quinton Andrews	Mathematics	Kader Dlamini
Dingaan Fortune	Mathematics	Helen Ginwala

The data is the same as before, except that Helen Ginwala is teaching science to Gerrie Jantjies as well as mathematics to Dingaan Fortune, and Dingaan Fortune is being taught by both Helen Ginwala and Kader Dlamini for mathematics.

The only possible key is a combination of all three attributes, as shown below. No other combination will uniquely identify a particular record.

Three attributes as key

Student Course Instructor table
Student
Instructor
Course

But this still has some potentially anomalous behavior. The fact that Kader Dlamini teaches mathematics is still stored more than once, as is the fact that Dingaan Thobela takes mathematics. The real problem is that the table stores more than one kind of fact: that of student-to-course relationship, as well as that of a student-to-instructor relationship. You can avoid this, as always, by separating the data into two tables, as shown below:

Creating a table for the student to instructor relationship

Student Instructor table
Student
Instructor

Creating a table for the student to course relationship

Student Instructor table
Student
Course

This situation exists when you have multiple multivalued dependencies. A multivalued dependency exists between two attributes when, for each value of the first attribute, there are one or more associated values of the second attribute. For each value of *student*, there were many values of *course*. This is the first multivalued dependency. Then, for each value of *student*, there are one or more associated values of *instructor*. This is the second multivalued dependency.

Thus, a table is in 4th normal form if:

- it is in Boyce-Codd normal form
- it does not contain more than one multivalued dependency

6.3.1.11.7 Database Normalization: 5th Normal Form and Beyond

Contents

This article follows on from the 4th normal form article.

There are normal forms beyond 4th that are mainly of academic interest, as the problems they exist to solve rarely appear in practice. This series won't discuss then in detail, but for those interested, the following example provides a taste.

The sales rep example

Sales rep	Company	Product

Felicia Powers	Exclusive	Books
Afzal Ignesund	Wordsworth	Magazines
Felicia Powers	Exclusive	Magazines

Usually you would store this data in one table, as you need all three records to see which combinations are valid. *Afzal Ignesund* sells magazines for *Wordsworth*, but not necessarily books. *Felicia Powers* happens to sell both books and magazines for *Exclusive*. However, let's add another condition. If a sales rep sells a certain product, and they sell it for a particular company, then they must sell that product for that company.

Let's look at a larger data set adhering to this condition:

Looking at a larger set of data

Sales rep	Company	Product
Felicia Powers	Exclusive	Books
Felicia Powers	Exclusive	Magazines
Afzal Ignesund	Wordsworth	Books
Felicia Powers	Wordsworth	Books
Felicia Powers	Wordsworth	Magazines

Now, with this extra dependency, you could normalize the table above into three separate tables without losing any facts, as shown below:

Creating a table with Sales rep and Product

Sales rep	Product
Felicia Powers	Books
Felicia Powers	Magazines
Afzal Ignesund	Books

Creating a table with Sales rep and Company

Sales rep	Company
Felicia Powers	Exclusive
Felicia Powers	Wordsworth
Afzal Ignesund	Wordsworth

Creating a table with Company and Product

Company	Product
Exclusive	Books
Exclusive	Magazines
Wordsworth	Books
Wordsworth	Magazines

Basically, a table is in 5th normal form if it cannot be made into any smaller tables with different keys (most tables can obviously be made into smaller tables with the same key!).

Beyond 5th normal form you enter the heady realms of domain key normal form, a kind of theoretical ideal. Its practical use to a database designer os similar to that of infinity to a bookkeeper - i.e. it exists in theory but is not going to be used in practice. Even the most demanding owner is not going to expect that of the bookkeeper!

For those interested in pursuing this academic and highly theoretical topic further, I suggest obtaining a copy of *An Introduction to Database Systems* by C.J. Date, at the time of writing in its 8th edition, or *Relational Theory for Computer Professionals* by the same author.

6.3.1.11.8 Understanding Denormalization

Denormalization is the process of reversing the transformations made during normalization for performance reasons. It's a topic that stirs controversy among database experts; there are those who claim the cost is too high and never denormalize, and there are those that tout its benefits and routinely denormalize.

For proponents of denormalization, the thinking is as follows: normalization creates more tables as you proceed towards higher normal forms, but more tables mean there are more joins to be made when data is retrieved, which in turn slows down your queries. For that reason, to improve the performance of certain queries, you can override the advantages to data integrity and return the data structure to a lower normal form.

A practical approach makes sense, taking into account the limitations of SQL and MariaDB in particular, but being cautious not to needless denormalize. Here are some suggestions:

- if your performance with a normalized structure is acceptable, you should not denormalize.
- if your performance is unacceptable, make sure normalizing will cause it to become acceptable. There are very likely to be other alternatives, such as better hardware, load balancing, etc. It's hard to undo structural changes later.
- be sure you are willing to trade decreased data integrity for the increase in performance.
- consider possible future scenario, where applications may place different requirements on the data. Denormalizing to enhance performance of a specific application makes your data structure dependent on that application, when in an ideal situation it will be application-independent.

The table below introduces a common structure where it may not be in your best interests to denormalize. Which normal form is it in?

Customer table
ID
First name
Surname
Address line 1
Address line 2
Town
Zip code

It must be in 1st normal form because it has a primary key and there are no repeating groups. It must be in 2nd normal form because there's only one key, so there cannot be any partial dependencies. And 3rd normal form? Are there any transitive dependencies? It looks like it. *Zip Code* is probably determined by the town attribute. To transform it into 3rd normal form, you should take out *Zi..p code*, putting it in a separate table with town as the key. In most cases, though, this is not worth doing. So although this table is not in 3rd normal form, separating the table is not worth the trouble. The more tables you have, the more joins you need to do, which slows the system down. The reason you normalize at all is to reduce the size of the tables by removing redundant data, and doing do can often speed up the system.

But you also need to look at how your tables are used. *Town* and *Zip code* would almost always be returned together, as part of the address. In most cases, the small amount of space you save by removing the duplicate town/zip code combinations would not offset the slowing down of the system because of the extra joins. In some situations, this may be useful, perhaps where you need to sort addresses according to zip codes or towns for many thousands of customers, and the distribution of data means that a query to the new, smaller table can return the results substantially quicker. In the end, experienced database designers can go beyond rigidly following the steps, as they understand how the data will be used. And that is something only experience can teach you. Normalization is just a helpful set of steps that most often produces an efficient table structure, and not a rule for database design.

> There are some scary database designs out there, almost always because of not normalizing rather than too much normalization. So if you're unsure, normalize!

6.3.1.12 ACID: Concurrency Control with Transactions

Database requests happen in linear fashion, one after another. When many users are accessing a database, or one user has a related set of requests to run, it becomes important to ensure that the results remain consistent. To achieve this, you use *transactions*, which are groups of database requests that are processed as a whole. Put another way, they are logical units of work.

To ensure data integrity, transactions need to adhere to four conditions: atomicity, consistency, isolation and durability

(ACID).

Atomicity

Atomicity means the entire transaction must complete. If this is not the case, the entire transaction is aborted. This ensures that the database can never be left with partially completed transactions, which lead to poor data integrity. If you remove money out of one bank account, for example, but the second request fails and the system cannot place the money in another bank, both requests must fail. The money cannot simply be lost, or taken from one account without going into the other.

Consistency

Consistency refers to the state the data is in when certain conditions are met. For example, one rule may be that each invoice must relate to a customer in the customer table. These rules may be broken during the course of a transaction if, for example the invoice is inserted without a related customer, which is added at a later stage in the transaction. These temporary violations are not visible outside of the transaction, and will always be resolved by the time the transaction is complete.

Isolation

Isolation means that any data being used during the processing of one transaction cannot be used by another transaction until the first transaction is complete. For example, if two people deposit $100 into another account with a balance of $900, the first transaction must add $100 to $900, and the second must add $100 to $1000. If the second transaction reads the $900 before the first transaction has completed, both transactions will seem to succeed, but $100 will have gone missing. The second transaction must wait until it alone is accessing the data.

Durability

Durability refers to the fact that once data from a transaction has been committed, its effects will remain, even after a system failure. While a transaction is under way, the effects are not persistent. If the database crashes, backups will always restore it to a consistent state prior to the transaction commencing. Nothing a transaction does should be able to change this fact.

6.4.1.1.1.1.1 Optimizer Trace Overview

MariaDB starting with 10.4.3

Optimizer Trace was introduced in MariaDB 10.4.3.

Contents

Usage

This feature produces a trace as a JSON document for any SELECT/UPDATE/DELETE containing information about decisions taken by the optimizer during the optimization phase (choice of table access method, various costs, transformations, etc). This feature helps to explain why some decisions were taken by the optimizer and why some were rejected.

Associated System Variables

- optimizer_trace='enabled=on/off'
  - Default value is off
- optimizer_trace_max_mem_size= value
  - Default value: 1048576

INFORMATION_SCHEMA.OPTIMIZER_TRACE

Each connection stores a trace from the last executed statement. One can view the trace by reading the Information Schema OPTIMIZER_TRACE table.

Structure of the optimizer trace table:

```
SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
*************************** 1. row ***************************
       Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0
```

Optimizer Trace Contents

See Optimizer Trace Guide for an overview of what one can find in the trace.

Traceable Queries

These include SELECT, UPDATE, DELETE as well as their multi-table variants and all of the preceding prefixed by EXPLAIN and ANALYZE.

Enabling Optimizer Trace

To enable optimizer trace run:

```
SET optimizer_trace='enabled=on';
```

Memory Usage

Each trace is stored as a string. It is extended (with realloc()) as the optimization progresses and appends data to it. The optimizer_trace_max_mem_size variable sets a limit on the total amount of memory used by the current trace. If this limit is reached, the current trace isn't extended (so it will be incomplete), and the MISSING_BYTES_BEYOND_MAX_MEM_SIZE column will show the number of bytes missing from this trace.

Privilege Checking

In complex scenarios where the query uses SQL SECURITY DEFINER views or stored routines, it may be that a user is denied from seeing the trace of its query because it lacks some extra privileges on those objects. In that case, the trace will be shown as empty and the INSUFFICIENT_PRIVILEGES column will show "1".

Limitations

Currently, only one trace is stored. It is not possible to trace the sub-statements of a stored routine; only the statement at the top level is traced.

6.4.1.1.1.1.2 Optimizer Trace Guide

Contents

Optimizer trace uses the JSON format. It is basically a structured log file showing what actions were taken by the query optimizer.

A Basic Example

Let's take a simple query:

```
MariaDB> explain select * from t1 where a<10;
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows | Extra
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------
|    1 | SIMPLE      | t1    | range | a             | a    | 5       | NULL | 10   | Using index
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------
```

One can see the full trace here. Taking only the component names, one gets:

```
MariaDB> select * from information_schema.optimizer_trace limit 1\G
*************************** 1. row ***************************
                            QUERY: select * from t1 where a<10
                            TRACE:
{
  "steps": [
    {
      "join_preparation": { ... }
    },
    {
      "join_optimization": {
        "select_id": 1,
        "steps": [
          { "condition_processing": { ... } },
          { "table_dependencies": [ ... ] },
          { "ref_optimizer_key_uses": [ ... ] },
          { "rows_estimation": [
              {
                "range_analysis": {
                   "analyzing_range_alternatives" : { ... },
                  "chosen_range_access_summary": { ... },
                },
                "selectivity_for_indexes" : { ... },
                "selectivity_for_columns" : { ... }
              }
            ]
          },
          { "considered_execution_plans": [ ... ] },
          { "attaching_conditions_to_tables": { ... } }
         ]
      }
    },
    {
      "join_execution": { ... }
    }
  ]
}
```

Trace Structure

For each SELECT, there are two "Steps":

- `join_preparation`
- `join_optimization`

Join preparation shows early query rewrites. `join_optmization` is where most of the query optimizations are done. They are:

- `condition_processing` - basic rewrites in WHERE/ON conditions.
- `ref_optimizer_key_uses` - Construction of possible ways to do ref and eq_ref accesses.
- `rows_estimation` - Consideration of range and index_merge accesses.
- `considered_execution_plans` - Join optimization itself, that is, choice of the join order.
- `attaching_conditions_to_tables` - Once the join order is fixed, parts of the WHERE clause are "attached" to tables to filter out rows as early as possible.

The above steps are for just one SELECT. If the query has subqueries, each SELECT will have these steps, and there will be extra steps/rewrites to handle the subquery construct itself.

Extracting Trace Components

If you are interested in some particular part of the trace, MariaDB has two functions that come in handy:

- JSON_EXTRACT extracts a part of JSON document
- JSON_DETAILED presents it in a user-readable way.

For example, the contents of the `analyzing_range_alternatives` node can be extracted like so:

```
MariaDB> select JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives'))
   ->   from INFORMATION_SCHEMA.OPTIMIZER_TRACE\G
*************************** 1. row ***************************
JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives')): [
    {
        "range_scan_alternatives":
        [
            {
                "index": "a_b_c",
                "ranges":
                [
                    "(1) <= (a,b) < (4,50)"
                ],
                "rowid_ordered": false,
                "using_mrr": false,
                "index_only": false,
                "rows": 4,
                "cost": 6.2509,
                "chosen": true
            }
        ],
        "analyzing_roworder_intersect":
        {
            "cause": "too few roworder scans"
        },
        "analyzing_index_merge_union": []
    }
]
```

Examples of Various Information in the Trace

Basic Rewrites

A lot of applications construct database query text on the fly, which sometimes means that the query has constructs that are repetitive or redundant. In most cases, the optimizer will be able to remove them. One can check the trace to be sure:

```
explain select * from t1 where not (col1 >= 3);
```

Optimizer trace will show:

```
"steps": [
  {
    "join_preparation": {
      "select_id": 1,
      "steps": [
        {
          "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1 from t1 where t1.col1 < 3
        }
```

Here, one can see that `NOT` was removed.

Similarly, one can also see that `IN(...)` with one element is the same as equality:

```
explain select * from t1 where col1  in (1);
```

will show

```
  "join_preparation": {
    "select_id": 1,
    "steps": [
      {
        "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1 from t1 where t1.col1 = 1"
```

On the other hand, converting an UTF-8 column to UTF-8 is not removed:

```
explain select * from t1 where convert(utf8_col using utf8) = 'hello';
```

will show

```
  "join_preparation": {
    "select_id": 1,
    "steps": [
      {
        "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1,t1.utf8_col AS utf8_col fro
        }
```

so redundant `CONVERT` calls should be used with caution.

VIEW Processing

MariaDB has two algorithms to handle VIEWs: merging and materialization. If you run a query that uses a VIEW, the trace will have either

```
          "view": {
            "table": "view1",
            "select_id": 2,
            "algorithm": "merged"
          }
```

or

```
        {
          "view": {
            "table": "view2",
            "select_id": 2,
            "algorithm": "materialized"
          }
        },
```

depending on which algorithm was used.

Range Optimizer - What Ranges Will Be Scanned

The MariaDB optimizer has a complex part called the Range Optimizer. This is a module that examines WHERE (and ON) clauses and constructs index ranges that need to be scanned to answer the query. The rules for constructing the ranges are quite complex.

An example: Consider a table

```
create table some_events (
  start_date date,
  end_date date,
  ...
  key (start_date, end_date)
);
```

and a query:

```
explain select * from some_events where start_date >= '2019-09-10' and end_date <= '2019-09-14';
+------+-------------+-------------+------+---------------+------+---------+------+------+-------
| id   | select_type | table       | type | possible_keys | key  | key_len | ref  | rows | Extra
+------+-------------+-------------+------+---------------+------+---------+------+------+-------
|    1 | SIMPLE      | some_events | ALL  | start_date    | NULL | NULL    | NULL | 1000 | Using
+------+-------------+-------------+------+---------------+------+---------+------+------+-------
```

One might think that the optimizer would be able to use the restrictions on both *start_date* and *end_date* to construct a narrow range to be scanned. But this is not so, one of the restrictions creates a left-endpoint range and the other one creates a right-endpoint range, hence they cannot be combined.

```
select
   JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives')) as trace
from information_schema.optimizer_trace\G
*************************** 1. row ***************************
trace: [
    {
        "range_scan_alternatives":
        [
            {
                "index": "start_date",
                "ranges":
                [
                    "(2019-09-10,NULL) < (start_date,end_date)"
                ],
...
```

the potential range only uses one of the bounds.

Ref Access Options

Index-based Nested-loops joins are called "ref access" in the MariaDB optimizer.

The optimizer analyzes the WHERE/ON conditions and collects all equality conditions that can be used by ref access using some index.

The list of conditions can be found in the `ref_optimizer_key_uses` node. (TODO example)

Join Optimization

The join optimizer's node is named `considered_execution_plans`.

The optimizer constructs the join orders in a left-to-right fashion. That is, if the query is a join of three tables:

```
select * from t1, t2, t3 where ...
```

then the optimizer will

- Pick the first table (say, it is t1),
- consider adding another table (say, t2), and construct a prefix "t1, t2"
- consider adding the third table (t3), and constructing a prefix "t1, t2, t3", which is a complete join plan Other join orders will be considered as well.

The basic operation here is: "given a join prefix of tables A,B,C ..., try adding table X to it". In JSON, it looks like this:

```
      {
        "plan_prefix": ["t1", "t2"],
        "table": "t3",
        "best_access_path": {
          "considered_access_paths": [
            {
              ...
            }
          ]
        }
      }
```

(search for `plan_prefix` followed by `table`).

If you are interested in how the join order of #t1,t2,t3# was constructed (or not constructed), you need to search for these patterns:

- `"plan_prefix":[], "table":"t1"`
- `"plan_prefix":["t1"], "table":"t2"`
- `"plan_prefix":["t1", "t2"], "table":"t3"`

6.4.1.1.1.1.3 Basic Optimizer Trace Example

```
MariaDB> set optimizer_trace='enabled=on';
```

```
MariaDB> select * from t1 where a<10;

MariaDB> select * from information_schema.optimizer_trace limit 1\G
*************************** 1. row ***************************
                            QUERY: select * from t1 where a<10
                            TRACE: {
  "steps": [
    {
      "join_preparation": {

6.4.1.1.1.1.4 How to Collect Large Optimizer Traces

Optimizer traces can be large for some queries.

In order to collect a large trace, you need to perform the following steps (using 128 MB as an example):

```
set global max_allowed_packet=128*1024*1024;
```

Reconnect specifying `--max-allowed-packet=128000000` for the client as well.

```
set optimizer_trace=1;
set optimizer_trace_max_mem_size=127*1024*1024;
```

Now, one can run the query and save the large trace.

6.4.1.1.1.1.5 Optimizer Trace for Developers

This article describes guidelines for what/how to write to Optimizer Trace when doing server development.

Basic considerations

The trace is a "structured log" of what was done by the optimizer. Prefer to do tracing as soon as a rewrite/decision is made (instead of having a separate trace_something() function).

Generally, a function should expect to find the trace in a state where we're writing an array. The rationale is that array elements are ordered, while object members are not (even if they come in a certain order in the JSON text). We're writing a log, so it's natural for different entries to form an array.

Typically you'll want to start an unnamed object, then use member names to show what kind of entry you're about to write:

```
[
  ...,  # Something before us
  {
    "my_new_rewrite": {
       "from": "foo",
       "to": "bar",
       ...
    }
  }
  ...
```

(TODO other considerations)

Making sure the trace is valid

`Json_writer_object` and `Json_writer_array` classes use RAII idiom and ensure that JSON objects and arrays are

"closed" in the reverse order they were started.

However, they do not ensure these constraints:

- JSON objects must have named members.
- JSON arrays must have unnamed members.

Tracing code has runtime checks for these. Attempt to write invalid JSON will cause assertion failure.

Test coverage

It is possible to run `mysql-test-run` with this argument

```
--mysqld=--optimizer_trace=enabled=on
```

This will run all tests with tracing on. As mentioned earlier, debug build will perform checks that we are not producing invalid trace.

The BuildBot instance at http://buildbot.askmonty.org/ also runs tests with this argument, see `mtr_opttrace` pass in kvm-fulltest and kvm-fulltest2.

Debugging

See optimizer-debugging-with-gdb/#printing-the-optimizer-trace for commands to print the trace for the current statement.

6.4.1.1.2 Using MariaDB with Your Programs (API)

Error Codes
MariaDB error codes and SQLSTATE codes

libMariaDB

libmysqld
The Embedded, Stand-Alone MariaDB Server.

Non-Blocking Client Library
Non-blocking client library documentation.

Progress Reporting
Progress reporting for long running commands.

6.4.1.1.2.1.2 Operating System Error Codes

Contents

Below is a partial list of more common Linux and Windows operating system error codes.

Linux Error Codes

The perror tool can be used to find the error message which is associated with a given error code.

Number	Error Code	Description
1	EPERM	Operation not permitted
2	ENOENT	No such file or directory
3	ESRCH	No such process
4	EINTR	Interrupted system call
5	EIO	I/O error
6	ENXIO	No such device or address
7	E2BIG	Argument list too long
8	ENOEXEC	Exec format error
9	EBADF	Bad file number
10	ECHILD	No child processes
11	EAGAIN	Try again
12	ENOMEM	Out of memory
13	EACCES	Permission denied
14	EFAULT	Bad address
15	ENOTBLK	Block device required
16	EBUSY	Device or resource busy
17	EEXIST	File exists
18	EXDEV	Cross-device link
19	ENODEV	No such device
20	ENOTDIR	Not a directory
21	EISDIR	Is a directory
22	EINVAL	Invalid argument
23	ENFILE	File table overflow
24	EMFILE	Too many open files
25	ENOTTY	Not a typewriter
26	ETXTBSY	Text file busy
27	EFBIG	File too large
28	ENOSPC	No space left on device
29	ESPIPE	Illegal seek
30	EROFS	Read-only file system
31	EMLINK	Too many links

32	EPIPE	Broken pipe
33	EDOM	Math argument out of domain of func
34	ERANGE	Math result not representable
35	EDEADLK	Resource deadlock would occur
36	ENAMETOOLONG	File name too long
37	ENOLCK	No record locks available
38	ENOSYS	Function not implemented
39	ENOTEMPTY	Directory not empty
40	ELOOP	Too many symbolic links encountered
42	ENOMSG	No message of desired type
43	EIDRM	Identifier removed
44	ECHRNG	Channel number out of range
45	EL2NSYNC	Level 2 not synchronized
46	EL3HLT	Level 3 halted
47	EL3RST	Level 3 reset
48	ELNRNG	Link number out of range
49	EUNATCH	Protocol driver not attached
50	ENOCSI	No CSI structure available
51	EL2HLT	Level 2 halted
52	EBADE	Invalid exchange
53	EBADR	Invalid request descriptor
54	EXFULL	Exchange full
55	ENOANO	No anode
56	EBADRQC	Invalid request code
57	EBADSLT	Invalid slot
59	EBFONT	Bad font file format
60	ENOSTR	Device not a stream
61	ENODATA	No data available
62	ETIME	Timer expired
63	ENOSR	Out of streams resources
64	ENONET	Machine is not on the network
65	ENOPKG	Package not installed
66	EREMOTE	Object is remote
67	ENOLINK	Link has been severed
68	EADV	Advertise error
69	ESRMNT	Srmount error
70	ECOMM	Communication error on send
71	EPROTO	Protocol error
72	EMULTIHOP	Multihop attempted
73	EDOTDOT	RFS specific error
74	EBADMSG	Not a data message
75	EOVERFLOW	Value too large for defined data type
76	ENOTUNIQ	Name not unique on network

77	EBADFD	File descriptor in bad state
78	EREMCHG	Remote address changed
79	ELIBACC	Can not access a needed shared library
80	ELIBBAD	Accessing a corrupted shared library
81	ELIBSCN	.lib section in a.out corrupted
82	ELIBMAX	Attempting to link in too many shared libraries
83	ELIBEXEC	Cannot exec a shared library directly
84	EILSEQ	Illegal byte sequence
85	ERESTART	Interrupted system call should be restarted
86	ESTRPIPE	Streams pipe error
87	EUSERS	Too many users
88	ENOTSOCK	Socket operation on non-socket
89	EDESTADDRREQ	Destination address required
90	EMSGSIZE	Message too long
91	EPROTOTYPE	Protocol wrong type for socket
92	ENOPROTOOPT	Protocol not available
93	EPROTONOSUPPORT	Protocol not supported
94	ESOCKTNOSUPPORT	Socket type not supported
95	EOPNOTSUPP	Operation not supported on transport endpoint
96	EPFNOSUPPORT	Protocol family not supported
97	EAFNOSUPPORT	Address family not supported by protocol
98	EADDRINUSE	Address already in use
99	EADDRNOTAVAIL	Cannot assign requested address
100	ENETDOWN	Network is down
101	ENETUNREACH	Network is unreachable
102	ENETRESET	Network dropped connection because of reset
103	ECONNABORTED	Software caused connection abort
104	ECONNRESET	Connection reset by peer
105	ENOBUFS	No buffer space available
106	EISCONN	Transport endpoint is already connected
107	ENOTCONN	Transport endpoint is not connected
108	ESHUTDOWN	Cannot send after transport endpoint shutdown
109	ETOOMANYREFS	Too many references: cannot splice
110	ETIMEDOUT	Connection timed out
111	ECONNREFUSED	Connection refused
112	EHOSTDOWN	Host is down
113	EHOSTUNREACH	No route to host
114	EALREADY	Operation already in progress
115	EINPROGRESS	Operation now in progress
116	ESTALE	Stale NFS file handle
117	EUCLEAN	Structure needs cleaning
118	ENOTNAM	Not a XENIX named type file
119	ENAVAIL	No XENIX semaphores available

120	EISNAM	Is a named type file
121	EREMOTEIO	Remote I/O error
122	EDQUOT	Quota exceeded
123	ENOMEDIUM	No medium found
124	EMEDIUMTYPE	Wrong medium type
125	ECANCELED	Operation Canceled
126	ENOKEY	Required key not available
127	EKEYEXPIRED	Key has expired
128	EKEYREVOKED	Key has been revoked
129	EKEYREJECTED	Key was rejected by service
130	EOWNERDEAD	Owner died
131	ENOTRECOVERABLE	State not recoverable

Windows Error Codes

For a complete list, see https://msdn.microsoft.com/en-us/library/ms681381.aspx

Number	Error Code	Description
1	ERROR_INVALID_FUNCTION	Incorrect function.
2	ERROR_FILE_NOT_FOUND	The system cannot find the file specified.
3	ERROR_PATH_NOT_FOUND	The system cannot find the path specified.
4	ERROR_TOO_MANY_OPEN_FILES	The system cannot open the file.
5	ERROR_ACCESS_DENIED	Access is denied.
6	ERROR_INVALID_HANDLE	The handle is invalid.
7	ERROR_ARENA_TRASHED	The storage control blocks were destroyed.
8	ERROR_NOT_ENOUGH_MEMORY	Not enough storage is available to process this command.
9	ERROR_INVALID_BLOCK	The storage control block address is invalid.
10	ERROR_BAD_ENVIRONMENT	The environment is incorrect.
11	ERROR_BAD_FORMAT	An attempt was made to load a program with an incorrect format.
12	ERROR_INVALID_ACCESS	The access code is invalid.
13	ERROR_INVALID_DATA	The data is invalid.
14	ERROR_OUTOFMEMORY	Not enough storage is available to complete this operation.
15	ERROR_INVALID_DRIVE	The system cannot find the drive specified.
16	ERROR_CURRENT_DIRECTORY	The directory cannot be removed.
17	ERROR_NOT_SAME_DEVICE	The system cannot move the file to a different disk drive.
18	ERROR_NO_MORE_FILES	There are no more files.
19	ERROR_WRITE_PROTECT	The media is write protected.
20	ERROR_BAD_UNIT	The system cannot find the device specified.
21	ERROR_NOT_READY	The device is not ready.
22	ERROR_BAD_COMMAND	The device does not recognize the command.
23	ERROR_CRC	Data error (cyclic redundancy check).
24	ERROR_BAD_LENGTH	The program issued a command but the command length is incorrect.

25	ERROR_SEEK	The drive cannot locate a specific area or track on the disk.
26	ERROR_NOT_DOS_DISK	The specified disk or diskette cannot be accessed.
27	ERROR_SECTOR_NOT_FOUND	The drive cannot find the sector requested.
28	ERROR_OUT_OF_PAPER	The printer is out of paper.
29	ERROR_WRITE_FAULT	The system cannot write to the specified device.
30	ERROR_READ_FAULT	The system cannot read from the specified device.
31	ERROR_GEN_FAILURE	A device attached to the system is not functioning.
32	ERROR_SHARING_VIOLATION	The process cannot access the file because it is being used by another process.
33	ERROR_LOCK_VIOLATION	The process cannot access the file because another process has locked a portion of the file.
34	ERROR_WRONG_DISK	The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.
36	ERROR_SHARING_BUFFER_EXCEEDED	Too many files opened for sharing.
38	ERROR_HANDLE_EOF	Reached the end of the file.
39	ERROR_HANDLE_DISK_FULL	The disk is full.
87	ERROR_INVALID_PARAMETER	The parameter is incorrect.
112	ERROR_DISK_FULL	The disk is full.
123	ERROR_INVALID_NAME	The file name, directory name, or volume label syntax is incorrect.
1450	ERROR_NO_SYSTEM_RESOURCES	Insufficient system resources exist to complete the requested service.

6.4.1.1.2.1.3 SQLSTATE

SQLSTATE is a code which identifies SQL error conditions. It composed by five characters, which can be numbers or uppercase ASCII letters. An SQLSTATE value consists of a class (first two characters) and a subclass (last three characters).

There are three important standard classes. They all indicate in which logical group of errors the condition falls. They match to a particular keyword which can be used with DECLARE HANDLER. Also, the SQLSTATE class determines the default value for the MYSQL_ERRNO and MESSAGE_TEXT condition properties.

- '00' means 'success'. It can not be set in any way, and can only be read via the API.
- '01' contains all warnings, and matches to the SQLWARNING keyword. The default MYSQL_ERRNO is 1642 and default MESSAGE_TEXT is 'Unhandled user-defined warning condition'.
- '02' is the NOT FOUND class. The default MYSQL_ERRNO is 1643 and default MESSAGE_TEXT is 'Unhandled user-defined not found condition'.
- All other classes match the SQLEXCEPTION keyword. The default MYSQL_ERRNO is 1644 and default MESSAGE_TEXT is 'Unhandled user-defined exception condition'.

The subclass, if it is set, indicates a particular condition, or a particular group of conditions within the class. However the '000' sequence means 'no subclass'.

For example, if you try to SELECT from a table which does not exist, a 1109 error is produced, with a '42S02' SQLSTATE. '42' is the class and 'S02' is the subclass. This value matches to the SQLEXCEPTION keyword. When FETCH is called for a cursor which has already reached the end, a 1329 error is produced, with a '02000' SQLSTATE. The class is '02' and there is no subclass (because '000' means 'no subclass'). It can be handled by a NOT FOUND handlers.

The standard SQL specification says that classes beginning with 0, 1, 2, 3, 4, A, B, C, D, E, F and G are reserved for standard-defined classes, while other classes are vendor-specific. It also says that, when the class is standard-defined, subclasses starting with those characters (except for '000') are standard-defined subclasses, while other subclasses are vendor-defined. However, MariaDB and MySQL do not strictly obey this rule.

To read the SQLSTATE of a particular condition which is in the diagnostics area, the GET DIAGNOSTICS statement can be used: the property is called RETURNED_SQLSTATE. For user-defined conditions (SIGNAL and RESIGNAL statements), a SQLSTATE value must be set via the SQLSTATE clause. However, SHOW WARNINGS and SHOW ERRORS do not display the SQLSTATE.

For user-defined conditions, MariaDB and MySQL recommend the '45000' SQLSTATE class.

'HY000' is called the "general error": it is the class used for builtin conditions which do not have a specific SQLSTATE class.

A partial list of error codes and matching SQLSTATE values can be found in the page MariaDB Error Codes.

6.4.1.1.2.2 Progress Reporting

Contents

MariaDB supports progress reporting for some long running commands.

What is Progress Reporting?

Progress reporting means that:

- There is a `Progress` column in SHOW PROCESSLIST which shows the total progress (0-100%)
- INFORMATION_SCHEMA.PROCESSLIST has three columns which allow you to see in which process stage we are and how much of that stage is completed:
  - `STAGE`
  - `MAX_STAGE`
  - `PROGRESS` (within current stage).
- The client receives progress messages which it can display to the user to indicate how long the command will take.

We have separate progress reporting for stages because different stages take different amounts of time.

Supported Commands

Currently, the following commands can send progress report messages to the client:

- ALTER TABLE
- CREATE INDEX
- DROP INDEX
- LOAD DATA INFILE (not `LOAD DATA LOCAL INFILE`, as in that case we don't know the size of the file).

Some Aria storage engine operations also support progress messages:

- CHECK TABLE
- REPAIR TABLE
- ANALYZE TABLE
- OPTIMIZE TABLE

Limitations

Although the above commands support progress reporting, there are some limitations to what progress is reported. To be specific, when executing one of these commands against an InnoDB table with ALGORITHM=INPLACE (which is the default in MariaDB 10.0+), progress is only reported during the merge sort phase while reconstructing indexes.

Enabling and Disabling Progress Reporting

`mysqld` (the MariaDB server) automatically sends progress report messages to clients that support the new protocol, using the value of the progress_report_time variable. They are sent every max(`global.progress_report_time` , `progress_report_time`) seconds (by default 5). You can disable the sending of progress report messages to the client by setting either the local variable (affects only the current connection) or the global variable (affects all connections) to `0` .

If the extra column in `SHOW PROCESSLIST` gives you a compatibility problem, you can disable it by starting `mysqld` with the `--old` flag.

Clients Which Support Progress Reporting

- The `mariadb` command line client
- The `mytop` that comes with MariaDB has a `'%'` column which shows the progress.

Progress Reporting in the mysql Command Line Client

Progress reporting is enabled by default in the mariadb client. You can disable it with `--disable-progress-reports`. It is automatically disabled in batch mode.

When enabled, for every supported command you get a progress report like:

```
ALTER TABLE my_mail ENGINE=aria;
Stage: 1 of 2 'copy to tmp table'  5.37% of stage done
```

This is updated every progress_report_time seconds (the default is 5). If the global `progress_report_time` is higher, this will be used. You can also disable error reporting by setting the variable to `0`.

How to Add Support for Progress Reporting to a Client

You need to use the MariaDB 5.3 or later client library. You can check that the library supports progress reporting by doing:

```
#ifdef CLIENT_PROGRESS
```

To enable progress reporting to the client you need to add `CLIENT_PROGRESS` to the `connect_flag` in `mysql_real_connect()`:

```
mysql_real_connect(mysql, host, user, password,
                   database, opt_mysql_port, opt_mysql_unix_port,
                   connect_flag | CLIENT_PROGRESS);
```

Then you need to provide a callback function for progress reports:

```
static void report_progress(const MYSQL *mysql, uint stage, uint max_stage,
                            double progress, const char *proc_info,
                            uint proc_info_length);

mysql_options(&mysql, MYSQL_PROGRESS_CALLBACK, (void*) report_progress);
```

The above `report_progress` function will be called for each progress message.

This is the implementation used by `mysql.cc`:

```
uint last_progress_report_length;

static void report_progress(const MYSQL *mysql, uint stage, uint max_stage,
                            double progress, const char *proc_info,
                            uint proc_info_length)
{
  uint length= printf("Stage: %d of %d '%.*s' %6.3g%% of stage done",
                      stage, max_stage, proc_info_length, proc_info,
                      progress);
  if (length < last_progress_report_length)
    printf("%*s", last_progress_report_length - length, "");
  putc('\r', stdout);
  fflush(stdout);
  last_progress_report_length= length;
}
```

If you want only one number for the total progress, you can calculate it with:

```
double total_progress=
 ((stage -1) / (double) max_stage * 100.00 + progress / max_stage);
```

Note: `proc_info` is totally independent of stage. You can have many different `proc_info` values within a stage. The idea behind `proc_info` is to give the user more information about what the server is doing.

How to Add Support for Progress Reporting to a Storage Engine

The functions to use for progress reporting are:

```
void thd_progress_init(MYSQL_THD thd, unsigned int max_stage);
```

Initialize progress reporting with stages. This is mainly used for commands that are totally executed within the engine, like `CHECK TABLE`. You should not use this for operations that could be called by, for example, `ALTER TABLE` as this has already called the function.

`max_stage` is the number of stages your storage engine will have.

```
void thd_progress_report(MYSQL_THD thd, unsigned long long progress,
                         unsigned long long max_progress);
```

The above is used for reporting progress.

- `progress` is how much of the file/rows/keys you have gone through.
- `max_progress` is the max number of rows you will go through.

You can call this with varying numbers, but normally the ratio `progress/max_progress` should be increasing.

This function can be called even if you are not using stages, for example when enabling keys as part of `ALTER TABLE` or `ADD INDEX`.

```
void thd_progress_next_stage(MYSQL_THD thd);
```

To go to the next stage in a multi-stage process initiated by `thd_progress_init()`:

```
void thd_progress_end(MYSQL_THD thd);
```

End progress reporting; Sets 'Progress' back to 0 in `SHOW PROCESSLIST`.

```
const char *thd_proc_info(thd, 'stage name');
```

This sets the name of the current status/stage that is displayed in `SHOW PROCESSLIST` and in the client. It's recommended that you call this between stages and thus before `thd_progress_report()` and `thd_progress_next_stage()`.

This functions returns the last used `proc_info`. It's recommended that you restore `proc_info` to its original value when you are done processing.

Note: `thd_proc_info()` is totally independent of stage. You can have many different `proc_info` values within a stage to give the user more information about what is going on.

Examples to Look at in the MariaDB Source:

- `client/mysql.cc` for an example of how to use reporting.
- `libmysql/client.c:cli_safe_read()` to see how progress packets are handled in client
- `sql/protocol.cc::net_send_progress_packet()` for how progress packets are handled in server.

Format of Progress Packets

The progress packet is sent as an error packet with error number `65535`.

It contains the following data (in addition to the error header):

Option	Number of bytes	Other info

1	1	Number of strings. For future
Stage	1	Stage from 1 - Max_stage
Max_stage	1	Max number of stages
Progress	3	Progress in `% * 1000`
Status_length	1-2	Packet length of string in `net_field_length()` format
Status	Status_length	Status / Stage name

6.4.1.2 EXPLAIN FORMAT=JSON in MySQL

Contents

There are some things that we in MariaDB are not happy with in MySQL/Oracle's implementation of EXPLAIN FORMAT=JSON.

The most important issues are already fixed in MariaDB's EXPLAIN FORMAT=JSON implementation. See EXPLAIN FORMAT=JSON Differences From MySQL for details.

This page lists things are are not fixed yet.

Higher priority

- Better display for ORDER/GROUP BY (MDEV-6995)
- Better display for Batched Key Access plans (Plain join buffering is fixed already)

Nice to have

Show ranges being scanned

Currently, one can only find the ranges produced by the range optimizer by looking into optimizer_trace. It would be nice if EXPLAIN showed them, too

```
MySQL [dbt3sf1]> explain format=json select * from customer where c_acctbal < -1000 \G
*************************** 1. row ***************************
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "table": {
      "table_name": "customer",
      "access_type": "range",
      "possible_keys": [
        "c_acctbal",
        "i_c_acctbal_nationkey"
      ],
      "key": "c_acctbal",
      "used_key_parts": [
        "c_acctbal"
      ],
      "key_length": "9",
      "rows": 1,
      "filtered": 100,
      "index_condition": "(`dbt3sf1`.`customer`.`c_acctbal` < -(1000))"
    }
  }
}
```

Low priority

Filesort/priority queue

Neither version of EXPLAIN in 5.6 shows the "filesort with small limit" optimization. See MDEV-6430.

7 MariaDB Server Releases

You can find the release dates for all upcoming MariaDB Server releases here.

MariaDB Server 11.3
The current short-term development release series.

MariaDB Server 11.2
A current short-term stable series, maintained until November 2024.

MariaDB Server 11.1
A previous short-term stable release series, maintained until August 2024.

MariaDB Server 11.0
A previous short-term MariaDB stable release series, maintained until June 2024.

MariaDB Server 10.11
The current long-term MariaDB stable release series, maintained until February 2028.

MariaDB Server 10.10
A previous short-term MariaDB stable release series, no longer maintained.

MariaDB Server 10.9
A previous short-term MariaDB stable release series, no longer maintained.

MariaDB Server 10.8
A previous short-term MariaDB stable release series, no longer maintained.

MariaDB Server 10.7
A previous short-term MariaDB stable release series, no longer maintained.

MariaDB Server 10.6
A previous long-term MariaDB stable release series, maintained until July 2026.

MariaDB Server 10.5
A previous MariaDB stable release series, maintained until 24 June 2025.

MariaDB Server 10.4
A previous MariaDB stable release series, maintained until 18 June 2024.

MariaDB Server 10.3
A previous MariaDB stable release series, no longer maintained.

MariaDB Server 10.2
A previous MariaDB stable release series, no longer maintained.

MariaDB Server 10.1
A previous stable MariaDB release series, no longer maintained.

MariaDB Server 10.0
A previous stable MariaDB release series, no longer maintained.

MariaDB Server 5.5
A previous stable MariaDB release series, no longer maintained.

MariaDB Server 5.3
A previous stable MariaDB release series, no longer maintained.

MariaDB Server 5.2
A previous stable MariaDB release series, no longer maintained.

MariaDB Server 5.1
A previous stable MariaDB release series, no longer maintained.

MariaDB 11.3 series release notes.

7.0.0.2 Changes and Improvements in MariaDB 11.3

The most recent release of MariaDB 11.3 is:
MariaDB 11.3.1 (RC) Download Now

Contents

MariaDB 11.3 is a current short-term development series, and will be maintained for one year after its Generally Available release. See Plans for MariaDB 11.3.

New Features & Improvements

Connection Redirection

- Added a redirect mechanism using the redirect_url system variable (MDEV-15935)
- At the moment client-side support is missing

InnoDB

- Shrink temporary tablespaces without restart by setting the innodb_truncate_temporary_tablespace_now system variable. (MDEV-28699)

Replication

- Add keywords "SQL_BEFORE_GTIDS" and "SQL_AFTER_GTIDS" for START SLAVE UNTIL (MDEV-27247). SQL_BEFORE_GTIDS stops the replica when it sees gtids of the option's argument list, without executing them.

SSL/TLS

- SSL is now enabled in the server by default. No configuration necessary, if no server certificate was provided a self-signed certificate will be automatically generated by the server. See Mission Impossible: Zero-Configuration SSL on mariadb.org (MDEV-31856).
- Clients now can validate self-signed server certificates if the mysql_native_password or ed25519 authentication is used and account password is not empty (MDEV-31855).
- Clients now require SSL and have --ssl-verify-server-cert enabled by default (MDEV-31857).
- Replication clients do that too, MASTER_SSL_VERIFY_SERVER_CERT is enabled by default.
- Use `--disable-ssl` or `--disable-ssl-verify-server-cert` to revert to the old behavior.
- Clients can use new command line options --tls-fp and --tls-fplist to verify the server certificate by its fingerprint

Data Types

- INET4 data types can now be cast into INET6 types (MDEV-31626)
- This means INET4 values can be compared with INET6 values and can be inserted into INET6 columns; the server can automatically convert INET4 value into INET6 as needed.

Functions

- Key derivation function KDF for generating good encryption keys for AES_ENCRYPT (MDEV-31474)

Date and Time

- DATE_FORMAT function can now print the current time zone abbreviation and current time zone offset from UTC with `%Z` and `%z` format specifiers. (MDEV-31684)

Optimizer

- Queries like UCASE(varchar_col)=... can now use an index on `varchar_col` if its collation is case insensitive. An optimizer_switch option, sargable_casefold=ON, has been added to enable this optimization. (MDEV-31496)

Privileges

- Add a new database-level privilege, `SHOW CREATE ROUTINE` that allows one to see the routine definition even if the user isn't the routine owner (MDEV-29167)

Processlist

- Added a `SENT_ROWS` column to the Information Schema PROCESSLIST table, as well as extended the display size for the columns in processlist to ensure that most results will fit in display (MDEV-3953)

Application-Time Periods

- Add views for periods in information_schema (MDEV-22597), in particular
- New view INFORMATION_SCHEMA.PERIODS
- New view INFORMATION_SCHEMA.KEY_PERIOD_USAGE
- New columns `IS_SYSTEM_TIME_PERIOD_START` and `IS_SYSTEM_TIME_PERIOD_END` in the INFORMATION_SCHEMA.COLUMNS view

OLD_MODE

- Setting a non-default old_mode value will now always issue a deprecation warning (MDEV-31811)

Mariabackup

- mariabackup --innobackupex mode has been deprecated (MDEV-31505)

Spider

- The Spider storage engine now supports table options instead of having to encode them in COMMENT/CONNECTION strings. When any table option is specified, Spider will ignore COMMENT/CONNECTION strings at the same table/partition/subpartition. A new variable spider_ignore_comments is introduced to ignore them globally at all levels (table/partition/subpartition). Another variable, spider_suppress_comment_ignored_warning, is introduced to suppress warnings when Spider ignores COMMENT/CONNECTION strings. (MDEV-28856)

Removed

The following deprecated features and system variables have been removed (MDEV-32104):

- debug (deprecated since MariaDB 5.5.37)
- sr_YU locale (deprecated since MariaDB 10.0.11)
- "engine_condition_pushdown" in optimizer_switch (deprecated since MariaDB 10.1.1)
- date_format, datetime_format, time_format, max_tmp_tables (deprecated since MariaDB 10.1.2)
- wsrep_causal_reads (deprecated since MariaDB 10.1.3)
- "parser" in mroonga table comment (deprecated since MariaDB 10.2.11)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 11.3.

Release date: 21 Nov 2023

Do not use non-stable (non-GA) releases in production!

MariaDB 11.3 is a current short-term development series of MariaDB, and will be maintained for one year after its Generally Available release. It is an evolution of MariaDB 11.2 with several entirely new features.

MariaDB 11.3.1 is a ***Release Candidate (RC)*** release.

For an overview of MariaDB 11.3 see the What is MariaDB 11.3? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)

- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)
- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)
- UNDO logs still growing for write-intensive workloads (MDEV-32050)
  - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
  - Deprecate innodb_purge_rseg_truncate_frequency.
  - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)
- Wrong result of: `WHERE inet6_column IN ('','::1')` (MDEV-31719)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)
- Raise notes when an index cannot be used on data type mismatch (MDEV-32203)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)
- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)
- Missed kill when the SQL driver thread goes to wait for parallel slave worker queues to drain (MDEV-29974)

Galera

- Assertion `` `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' `` failed. (MDEV-24912)
- Assertion `` `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' `` failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)

- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in int wsrep::client_state::bf_abort(wsrep::seqno) (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)
- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)
- utf8mb3_key_col=utf8mb4_value cannot be used for ref access (MDEV-32113)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in spider_db_mbase_row::append_to_str | SIGSEGV's in memmove_avx_unaligned_erms from memcpy in Binary_string::q_append, in Static_binary_string::q_append and my_strntoull10rnd_8bit | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " rpm --setugids " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)

- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

Changelog

For a complete list of changes made in MariaDB 11.3.1, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 11.3.1, see the MariaDB Foundation release announcement.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.4.1 MariaDB 11.3.0 Release Notes

Release date: 20 September 2023

Do not use *alpha* releases in production!

MariaDB 11.3 is a current short-term development series of MariaDB, and will be maintained for one year after its Generally Available release. It is an evolution of MariaDB 11.2 with several entirely new features.

MariaDB 11.3.0 is a single preview release. Features are to be considered preview, and none are guaranteed to make it into MariaDB 11.3.

The preview is available as a container **quay.io/mariadb-foundation/mariadb-devel:11.3-preview**.

For an overview of MariaDB 11.3 see the What is MariaDB 11.3? page.

Thanks, and enjoy MariaDB!

Connection Redirection

- Added a redirect mechanism using the redirect_url system variable (MDEV-15935)
- At the moment client-side support is missing

InnoDB

- Shrink temporary tablespaces without restart by setting the innodb_truncate_temporary_tablespace_now system variable. (MDEV-28699)

Replication

- Add keywords "SQL_BEFORE_GTIDS" and "SQL_AFTER_GTIDS" for START SLAVE UNTIL (MDEV-27247). SQL_BEFORE_GTIDS stops the replica when it sees gtids of the option's argument list, without executing them.

SSL/TLS

- SSL is now enabled in the server by default. No configuration necessary, if no server certificate was provided a self-signed certificate will be automatically generated by the server. See Mission Impossible: Zero-Configuration SSL on mariadb.org (MDEV-31856).
- Clients now can validate self-signed server certificates if the mysql_native_password or ed25519 authentication is used and account password is not empty (MDEV-31855).
- Clients now require SSL and have --ssl-verify-server-cert enabled by default (MDEV-31857).
- Replication clients do that too, MASTER_SSL_VERIFY_SERVER_CERT is enabled by default.
- Use `--disable-ssl` or `--disable-ssl-verify-server-cert` to revert to the old behavior.
- Clients can use new command line options --tls-fp and --tls-fplist to verify the server certificate by its fingerprint

Data Types

- INET4 data types can now be cast into INET6 types (MDEV-31626)
- This means, INET4 values can be compared with INET6 values and can be inserted into INET6 columns, the server can automatically convert INET4 value into INET6 as needed.

Functions

- Key derivation function KDF for generating good encryption keys for AES_ENCRYPT (MDEV-31474)

Date and Time

- DATE_FORMAT function can now print the current time zone abbreviation and current time zone offset from UTC with `%Z` and `%z` format specifiers. (MDEV-31684)

Optimizer

- Queries like UCASE(varchar_col)=... can now use an index on `varchar_col` if its collation is case insensitive. An optimizer_switch option, sargable_casefold=ON, has been added to enable this optimization. (MDEV-31496)

Privileges

- Add a new database-level privilege, `SHOW CREATE ROUTINE` that allows to see the routine definition even if the user isn't the routine owner (MDEV-29167)

Processlist

- Added a `SENT_ROWS` column to the Information Schema PROCESSLIST table, as well as extended the display size for the columns in processlist to ensure that most results will fit in display (MDEV-3953)

Application-Time Periods

- Add views for periods in information_schema (MDEV-22597), in particular
- New view INFORMATION_SCHEMA.PERIODS
- New view INFORMATION_SCHEMA.KEY_PERIOD_USAGE
- New columns `IS_SYSTEM_TIME_PERIOD_START` and `IS_SYSTEM_TIME_PERIOD_END` in the INFORMATION_SCHEMA.COLUMNS view

OLD_MODE

- Setting a non-default old_mode value will now always issue a deprecation warning (MDEV-31811)

Mariabackup

- mariabackup --innobackupex mode has been deprecated (MDEV-31505)

Spider

- The Spider storage engine now supports table options instead of having to encode them in COMMENT/CONNECTION strings. When any table option is specified, Spider will ignore COMMENT/CONNECTION strings at the same table/partition/subpartition. A new variable spider_ignore_comments is introduced to ignore them globally at all levels (table/partition/subpartition). Another variable, spider_suppress_comment_ignored_warning, is introduced to suppress warnings when Spider ignores COMMENT/CONNECTION strings. (MDEV-28856)

Removed

The following deprecated features and system variables have been removed (MDEV-32104):

- debug (deprecated since MariaDB 5.5.37)
- sr_YU locale (deprecated since MariaDB 10.0.11)
- "engine_condition_pushdown" in optimizer_switch (deprecated since MariaDB 10.1.1)
- date_format, datetime_format, time_format, max_tmp_tables (deprecated since MariaDB 10.1.2)
- wsrep_causal_reads (deprecated since MariaDB 10.1.3)
- "parser" in mroonga table comment (deprecated since MariaDB 10.2.11)

7.0.0.5 MariaDB Server 11.2

Changes and Improvements in MariaDB 11.2

Current Version: 11.2.2 | Status: Stable (GA) | Release Date: 21 Nov 2023

Release Notes - MariaDB 11.2 Series

MariaDB 11.2 series release notes.

7.0.0.6 Changes and Improvements in MariaDB 11.2

The most recent release of MariaDB 11.2 is:
MariaDB 11.2.2 Stable (GA) Download Now
Alternate download from mariadb.org

Contents

MariaDB 11.2 is a current short-term release series, maintained until November 2024.

New Features & Improvements

Online Schema Change

- ALTER TABLE can now do most operations with `ALGORITHM=COPY, LOCK=NONE`, that is, in most cases, unless the algorithm and lock level are explicitly specified, `ALTER TABLE` will be performed using the COPY algorithm while simultaneously allowing concurrent DML statements on the altered table.

InnoDB

- The InnoDB system tablespace is now shrunk by reclaiming unused space at startup (MDEV-14795)

JSON

- JSON_TABLE now allows retrieval of the key when iterating on JSON objects (MDEV-30145)
- New functions JSON_OBJECT_FILTER_KEYS, JSON_OBJECT_TO_ARRAY and JSON_ARRAY_INTERSECT to check for JSON intersection (MDEV-26182)

Miscellaneous

- All binlog* variables are now visible as system variables, specifically binlog_do_db, binlog_ignore_db, binlog_row_event_max_size (MDEV-30188)
- ALTER TABLE IMPORT enhancement (MDEV-26137)
- Temporary tables are now displayed in the Information Schema TABLES Table, SHOW TABLES and SHOW TABLE STATUS (MDEV-12459)
- Stored programs: validation of stored program statements (MDEV-5816)
- Remove the deprecated old_alter_table variable (MDEV-30905)
- Extend AES_ENCRYPT() and AES_DECRYPT() to support an initialization vector and algorithm (MDEV-9069)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 11.2.

Alternate download from mariadb.org

Release date: 21 Nov 2023

MariaDB 11.2 is a current short-term stable series of MariaDB, maintained until November 2024. It is an evolution of MariaDB 11.1 with several entirely new features.

MariaDB 11.2.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.1 see the What is MariaDB 11.2? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)
- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)
- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)

- UNDO logs still growing for write-intensive workloads (MDEV-32050)
  - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
  - Deprecate innodb_purge_rseg_truncate_frequency.
  - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)
- Wrong result of: `WHERE inet6_column IN ('','::1')` (MDEV-31719)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)
- Raise notes when an index cannot be used on data type mismatch (MDEV-32203)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)
- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)
- Missed kill when the SQL driver thread goes to wait for parallel slave worker queues to drain (MDEV-29974)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)
- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in `int wsrep::client_state::bf_abort(wsrep::seqno)` (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)

- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)
- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)
- utf8mb3_key_col=utf8mb4_value cannot be used for ref access (MDEV-32113)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)

- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Variables

- Added the note_verbosity system variable to manage notes when an index cannot be used.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 11.2.2, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 11.2.2, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.7.2 MariaDB 11.2.1 Release Notes

The most recent release of MariaDB 11.2 is:
MariaDB 11.2.2 Stable (GA) Download Now

Alternate download from mariadb.org

Download 11.2.1 | Release Notes | Changelog | Overview of 11.2

Release date: 21 Aug 2023

Do not use non-stable (non-GA) releases in production!

MariaDB 11.2 is the current development series of MariaDB. It is an evolution of MariaDB 11.1 with several entirely new features.

MariaDB 11.2 is a ***Release Candidate (RC)*** release.

For an overview of MariaDB 11.1 see the What is MariaDB 11.2? page.

Thanks, and enjoy MariaDB!

Notable Items

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 11.2 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- In this release repositories for Debian 12 "Bookworm" have been added.
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in I_S.ROUTINES.ROUTINE_DEFINITION (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `const_item_cache == true' failed in Item_func::fix_fields (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- get_partition_set is never executed in ha_partition::multi_range_key_create_key due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a mysql_list_fields("view") call (MDEV-30159)
- I_S.parameters not immediately changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in set_global_from_ddl_log_entry (MDEV-31521)
- Assertion `0' failed in Type_handler_row::field_type upon TO_CHAR with wrong argument (MDEV-29152)
- mariadb-upgrade fails due to old_mode="" , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in my_strnncoll_binary on SELECT ... COUNT or GROUP_CONCAT (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in Item_func_round::native_op (MDEV-23838)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on SELECT (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type 'long long int' ; cast to an unsigned type to negate this value to itself in Item_func_mul::int_op and Item_func_round::int_op (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in log_sort_flush_list() in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)

- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in mysql.innodb_table_stats upon RENAME on sequence (MDEV-31607)
- Assertion `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' failed in btr_node_ptr_max_size (MDEV-19216)
- InnoDB: Failing assertion: page_type == i_s_page_type[page_type].type_value (MDEV-31386)
- btr_estimate_n_rows_in_range() accesses unfixed, unlatched page (MDEV-30648)
- MODIFY COLUMN can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion 'n & PENDING' failed in fil_space_t::set_needs_flush() (MDEV-31442)
- fil_node_open_file() releases fil_system.mutex allowing other thread to open its file node (MDEV-31256)
- ASAN errors in dict_v_col_t::detach upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- !cursor->index->is_committed() in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and mariadb-backup --prepare fail to report detailed progress (MDEV-29911)
- fil_ibd_create() may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in spider_db_open_item_field and SIGSEGV in spider_db_print_item_type, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `last_key_entry >= end_pos' failed in virtual bool JOIN_CACHE_HASHED::put_record() (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `s->table->opt_range_condition_rows <= s->found_records' failed in apply_selectivity_for_table (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- MAX_SEL_ARG memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with lower_case_table_names=2 (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in store_length, assertion failure in Type_handler_string_result::sort_length (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)

- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

For a complete list of changes made in MariaDB 11.2.1, with links to detailed information on each push, see the changelog.

7.0.0.7.3 MariaDB 11.2.0 Release Notes

The most recent release of MariaDB 11.2 is:
MariaDB 11.2.2 Stable (GA) Download Now
Alternate download from mariadb.org

Download 11.2.0 | Release Notes | Changelog | Overview of 11.2

Release date: 20 Jun 2023

Do not use *alpha* releases in production!

MariaDB 11.2 is a short-term development series of MariaDB, and will be maintained for one year after its Generally Available release. It is an evolution of MariaDB 11.1 with several entirely new features.

MariaDB 11.2.0 is a single preview release. Features are to be considered preview, and none are guaranteed to make it into MariaDB 11.2.

The preview is available as a container **quay.io/mariadb-foundation/mariadb-devel:11.2-preview**.

For an overview of MariaDB 11.2 see the What is MariaDB 11.2? page.

Thanks, and enjoy MariaDB!

InnoDB

- The InnoDB system tablespace is now shrunk by reclaiming unused space at startup (MDEV-14795)

JSON

- JSON_TABLE now allows retrieval of the key when iterating on JSON objects (MDEV-30145)
- New functions JSON_OBJECT_FILTER_KEYS, JSON_OBJECT_TO_ARRAY and JSON_ARRAY_INTERSECT to check for JSON intersection (MDEV-26182)

Miscellaneous

- All binlog* variables are now visible as system variables, specifically binlog_do_db, binlog_ignore_db, binlog_row_event_max_size (MDEV-30188)
- ALTER TABLE IMPORT enhancement (MDEV-26137)
- Temporary tables are now displayed in the Information Schema TABLES Table, SHOW TABLES and SHOW TABLE STATUS (MDEV-12459)
- Stored programs: validation of stored program statements (MDEV-5816)
- Remove the deprecated old_alter_table variable (MDEV-30905)
- Extend AES_ENCRYPT() and AES_DECRYPT() to support an initialization vector and algorithm (MDEV-9069)

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.8 MariaDB Server 11.1

Changes and Improvements in MariaDB 11.1
Current Version: 11.1.3 | Status: Stable (GA) | Release Date: 13 Nov 2023

Release Notes - MariaDB 11.1 Series
MariaDB 11.1 series release notes.

Changelogs - MariaDB 11.1 Series
MariaDB 11.1 changelogs

7.0.0.9 Changes and Improvements in MariaDB 11.1

The most recent release of MariaDB 11.1 is:
MariaDB 11.1.3 Stable (GA) Download Now
Alternate download from mariadb.org

Contents

MariaDB 11.1 is a current short-term release series, maintained until August 2024.

New Features & Improvements

JSON

- JSON_SCHEMA_VALID function for validating a JSON schema (MDEV-27128)

Optimizer

- Semi-join optimization for single-table UPDATE/DELETE statements. Update and delete statements that use subqueries can now use all subquery optimization strategies that MariaDB offers, so now if you use subqueries in UPDATE or DELETE, these statements will likely be much faster (MDEV-7487)
- Queries with the DATE or YEAR functions comparing against a constant can now make use of indexes, so these will be noticeably quicker in certain instances. For example `SELECT * FROM t2 WHERE YEAR(a) = 2019` or `SELECT * FROM t2 WHERE DATE(a) <= '2017-01-01'` (MDEV-8320)

Transactions

- The transaction_isolation option is now a system variable, and the tx_isolation system variable is deprecated (MDEV-21921)

InnoDB

- Remove innodb_defragment and related parameters (MDEV-30545)

Mariabackup

- Rename Mariabackup's xtrabackup_* files to mariadb_backup_* (MDEV-18931)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 11.1.

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 11.1 is a current short-term stable series of MariaDB, maintained until July 2024. It is an evolution of MariaDB 11.1 with several entirely new features.

MariaDB 11.1.3 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.1 see the What is MariaDB 11.1? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)
- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)

- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)
- UNDO logs still growing for write-intensive workloads (MDEV-32050)
  - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
  - Deprecate innodb_purge_rseg_truncate_frequency.
  - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)
- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)
- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in int wsrep::client_state::bf_abort(wsrep::seqno) (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)

- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)
- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)
- main.order_by_pack_big fails with view-protocol (MDEV-31460)
- mysql_install_db_win.test fails on second execution (MDEV-32232)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)

- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- type_test.type_test_double fails with 'NUMERIC_SCALE NULL' (MDEV-22243)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Variables

- Added the note_verbosity system variable to manage notes when an index cannot be used .

Security

- Fixes for the following security vulnerabilities :
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 11.1.3, with links to detailed information on each push, see the changelog .

Contributors

For a full list of contributors to MariaDB 11.1.3, see the MariaDB Foundation release announcement .

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will

be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.10.2 MariaDB 11.1.2 Release Notes

The most recent release of MariaDB 11.1 is:
MariaDB 11.1.3 Stable (GA) Download Now
Alternate download from mariadb.org

Download 11.1.2 | Release Notes | Changelog | Overview of 11.1

Release date: 21 Aug 2023

MariaDB 11.1 is a current short-term stable series of MariaDB, maintained until August 2024. It is an evolution of MariaDB 11.0 with several entirely new features.

MariaDB 11.1.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.1 see the What is MariaDB 11.1? page.

Thanks, and enjoy MariaDB!

Notable Items

Localization

- Create Swahili localization (MDEV-31530)

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 11.1 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- In this release repositories for Debian 12 "Bookworm" have been added.
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- I_S.parameters not immediately changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mariadb-upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in mysql.innodb_table_stats upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and mariadb-backup --prepare fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type` , on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)

- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `s->table->opt_range_condition_rows <= s->found_records' failed in apply_selectivity_for_table (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- MAX_SEL_ARG memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with lower_case_table_names=2 (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in store_length, assertion failure in Type_handler_string_result::sort_length (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- rpl.rpl_manual_change_index_file occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when wsrep_mode = BF_ABORT_MARIABACKUP (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure !lock.was_chosen_as_deadlock_victim in trx0trx.h:1065 (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion state() == s_aborting || state() == s_must_replay failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion !wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

For a complete list of changes made in MariaDB 11.1.2, with links to detailed information on each push, see the changelog.

7.0.0.10.3 MariaDB 11.1.1 Release Notes

The most recent release of MariaDB 11.1 is:
MariaDB 11.1.3 Stable (GA) Download Now

Alternate download from mariadb.org

Download 11.1.1 | Release Notes | Changelog | Overview of 11.1

Release date: 6 Jun 2023

Do not use non-stable (non-GA) releases in production!

MariaDB 11.1 is the current short-term development series of MariaDB, which will be maintained for one year after the Stable (GA) release. It is an evolution of MariaDB 11.0 with several entirely new features.

MariaDB 11.1.1 is a ***Release Candidate (RC)*** release.

For an overview of MariaDB 11.1 see the What is MariaDB 11.1? page.

Thanks, and enjoy MariaDB!

Notable Items

- The transaction_isolation option is now a system variable, and the tx_isolation system variable is deprecated (MDEV-21921)

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

For a complete list of changes made in MariaDB 11.1.1, with links to detailed information on each push, see the changelog.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). 7.0.0.10.4 MariaDB 11.1.0 Release Notes

The most recent release of MariaDB 11.1 is:
MariaDB 11.1.3 Stable (GA) Download Now

Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 11.1

Release date: 27 Mar 2023

Do not use *alpha* releases in production!

MariaDB 11.1 is a current development series of MariaDB, and will be maintained for one year after its Generally Available release. It is an evolution of MariaDB 11.0 with several entirely new features.

MariaDB 11.1.0 is a single preview release. Features are to be considered preview, and none are guaranteed to make it into MariaDB 11.1.

For an overview of MariaDB 11.1 see the What is MariaDB 11.1? page.

Thanks, and enjoy MariaDB!

InnoDB

- Remove innodb_defragment and related parameters (MDEV-30545)

Optimizer

- Semi-join optimization for single-table UPDATE/DELETE statements. Update and delete statements that use subqueries can now use all subquery optimization strategies that MariaDB offers, so now if you use subqueries in UPDATE or DELETE, these statements will likely be much faster (MDEV-7487)
- Queries with the DATE or YEAR functions comparing against a constant can now make use of indexes, so these will be noticeably quicker in certain instances. For example `SELECT * FROM t2 WHERE YEAR(a) = 2019` or `SELECT * FROM t2 WHERE DATE(a) <= '2017-01-01'` (MDEV-8320)

General

- ALTER ONLINE TABLE - not released in the final MariaDB 11.1 (MDEV-16329)

JSON

- JSON_SCHEMA_VALID function for validating a JSON schema (MDEV-27128)

Mariabackup

- Rename Mariabackup's xtrabackup_* files to mariadb_backup_* (MDEV-18931)

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

Contents

MariaDB 11.0 is a current short-term release series, maintained until June 2024.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.11 to MariaDB 11.0.

New Features & Improvements

Functions

- Given a time in picoseconds, the new function FORMAT_PICO_TIME returns a human-readable time value and unit indicator (MDEV-19629)

Optimizer

- Major improvements to the Optimizer. See The Optimizer Cost Model from MariaDB 11.0.

InnoDB

- The InnoDB Change Buffer has been removed (MDEV-29694)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 11.0 and Status Variables Added in MariaDB 11.0.
- The default value for innodb_undo_tablespaces has been changed from 0 to 3 (MDEV-29986)
- The following variables have been deprecated:
  - innodb_defragment
  - innodb_defragment_n_pages
  - innodb_defragment_stats_accuracy
  - innodb_defragment_fill_factor_n_recs
  - innodb_defragment_fill_factor
  - innodb_defragment_frequency
  - innodb_file_per_table
  - innodb_flush_method

- The following deprecated variables have been removed:
  - innodb_change_buffer_max_size
  - innodb_change_buffering

List of All MariaDB 11.0 Releases

Date	Release	Status	Release Notes	Changelog
13 Nov 2023	**MariaDB 11.0.4**	Stable (GA)	Release Notes	Changelog

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 11.0 is a current short-term stable series of MariaDB and will be maintained until June 2024. It is an evolution of MariaDB 10.11 with several entirely new features.

MariaDB 11.0.4 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.0 see the What is MariaDB 11.0? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)

- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)
- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)
- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)
- UNDO logs still growing for write-intensive workloads (MDEV-32050)
    - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
    - Deprecate innodb_purge_rseg_truncate_frequency.
    - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)

- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)
- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in int wsrep::client_state::bf_abort(wsrep::seqno) (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)
- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)
- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)
- main.order_by_pack_big fails with view-protocol (MDEV-31460)
- mysql_install_db_win.test fails on second execution (MDEV-32232)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- type_test.type_test_double fails with 'NUMERIC_SCALE NULL' (MDEV-22243)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Variables

- Added the note_verbosity system variable to manage notes when an index cannot be used.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 11.0.4, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 11.0.4, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.13.2 MariaDB 11.0.3 Release Notes

The most recent release of MariaDB 11.0 is:
MariaDB 11.0.4 Stable (GA) Download Now
Alternate download from mariadb.org

Download 11.0.3 | Release Notes | Changelog | Overview of 11.0

Release date: 14 Aug 2023

MariaDB 11.0 is a current short-term stable series of MariaDB and will be maintained until June 2024. It is an evolution of MariaDB 10.11 with several entirely new features.

MariaDB 11.0.3 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.0 see the What is MariaDB 11.0? page.

Thanks, and enjoy MariaDB!

Notable Items

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 11.0 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- In this release repositories for Debian 12 "Bookworm" have been added.
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)

- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mysql_upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in `mysql.innodb_table_stats` upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and `mariadb-backup --prepare` fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

For a complete list of changes made in MariaDB 11.0.3, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 11.0.3, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.13.3 MariaDB 11.0.2 Release Notes

The most recent release of MariaDB 11.0 is:
MariaDB 11.0.4 Stable (GA) Download Now
Alternate download from mariadb.org

Download 11.0.2 | Release Notes | Changelog | Overview of 11.0

Release date: 6 Jun 2023

MariaDB 11.0 is a current short-term stable series of MariaDB and will be maintained until June 2024. It is an evolution of MariaDB 10.11 with several entirely new features.

MariaDB 11.0.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 11.0 see the What is MariaDB 11.0? page.

Thanks, and enjoy MariaDB!

Notable Items

Functions

- Given a time in picoseconds, the new function FORMAT_PICO_TIME returns a human-readable time value and unit indicator (MDEV-19629)

InnoDB

- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301)
- New optimizer_switch option, hash_join_cardinality, is added. It is ON by default. When set to ON, the optimizer will produce tighter bounds for hash join output cardinality. (MDEV-30812)
- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)
- ANALYZE FORMAT=JSON now prints more information about Block Nested Loop joins: `block-nl-join` element now has `r_loops`, `r_effective_rows` and `r_other_time_ms` fields (MDEV-30806, MDEV-30830, MDEV-30972).

Variables

- New status variable: max_used_connections_time (MDEV-30543)

Changelog

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.13.4 MariaDB 11.0.1 Release Notes

Download | Release Notes | Changelog | Overview of 11.0

Release date: 22 Feb 2023

Do not use non-stable (non-GA) releases in production!

MariaDB 11.0 is the current development series of MariaDB. It is an evolution of MariaDB 10.11 with several entirely new features.

For an overview of MariaDB 11.0 see the What is MariaDB 11.0? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Remove the global sequence DICT_HDR_ROW_ID for DB_ROW_ID (MDEV-19506)
- Remove the InnoDB change buffer (MDEV-29694)
- Deprecate innodb_file_per_table (MDEV-29983)
- Set innodb_undo_tablespaces=3 by default (MDEV-29986)
- Deprecate innodb_flush_method (MDEV-30136)
- Deprecate innodb_defragment and related parameters (MDEV-30544)
- InnoDB read-ahead may cause page writes (MDEV-26790)
- Read-ahead unnecessarily allocates and frees pages when a page is in the buffer pool (MDEV-30216)
- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)
- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)
- `mariadb-backup --backup --incremental --throttle=...` hangs (MDEV-29896)
- Crash after recovery, with InnoDB: Tried to read (MDEV-30132)
- Trying to write ... bytes at ... outside the bounds (MDEV-30069)
- TRUNCATE breaks FOREIGN KEY locking (MDEV-29504, MDEV-29849)
- `INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION.NAME` is NULL for undo tablespaces (MDEV-30119)
- Fixed hangs and error handling in B-tree operations (MDEV-29603, MDEV-30400)
- InnoDB bulk insert fixes (MDEV-30047, MDEV-30321)
- InnoDB fails to start on `innodb_undo_tablespaces` mismatch (MDEV-30158)
- `mariabackup.skip_innodb` crashes when `innodb_undo_tablespaces > 0` (MDEV-30122)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- `Seconds_Behind_Master` is showed now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- mariadb-binlog --verbose is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

Docker Official Images

- 11.0, unlike previous version, no longer includes mysql named compatible executable symlinks inside the container.

Packaging

- mysql compatible symlinks are no longer installed in core package, but are delegated to a -compat package (MDEV-30203)
- Use of mysql named executables (except for Windows) will result in a deprecation warning (MDEV-29582)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Json Range only affects first row of the result set (MDEV-30304)
- In this release repositories for Fedora 37 and Ubuntu 22.10 Kinetic have been added.

Changelog

For a complete list of changes made in MariaDB 11.0.1, with links to detailed information on each push, see the changelog.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.0.13.5 MariaDB 11.0.0 Release Notes

The most recent release of MariaDB 11.0 is:
MariaDB 11.0.4 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 11.0

Release date: 27 Dec 2022

Do not use *alpha* releases in production!

MariaDB 11.0 is a current development series of MariaDB, and will be maintained for five years. It is an evolution of MariaDB 10.11 with several entirely new features.

MariaDB 11.0.0 is a single preview release. Features are to be considered preview, and none are guaranteed to make it into MariaDB 11.0.

For an overview of MariaDB 11.0 see the What is MariaDB 11.0? page.

Thanks, and enjoy MariaDB!

New optimizer cost model

This is the main change that practically defines this release. Read about new optimizer cost model on its own page.

Galera

- MDEV-22570 Implement wsrep_provider_options as plugin
- MDEV-29281 Add details about node eviction status to the JSON file with Galera node status

Removing/Deprecating old code

- MDEV-29694 Remove the InnoDB change buffer
- MDEV-30136 Deprecate innodb_flush_method
- MDEV-29983 Deprecate innodb_file_per_table
- MDEV-30128 remove support for 5.1- replication events
- MDEV-29582 deprecate mysql* names
- MDEV-29227 deprecate explicit_defaults_for_timestamp=0
- MDEV-28910 remove the 5.5.5- version hack
- MDEV-29668 SUPER no longer allows actions that have fine-grained dedicated privileges

Other changes

- MDEV-30203 Move mysql compatibility symlinks to different package
- MDEV-30153 ad hoc client versions are confusing
- MDEV-29986 Set innodb_undo_tablespaces=3 by default

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.1 MariaDB Server 10.11

Changes and Improvements in MariaDB 10.11
Current Version: 10.11.6 | Status: Stable (GA) | Release Date: 13 Nov 2023

Release Notes - MariaDB 10.11 Series
MariaDB 10.11 series release notes.

Changelogs - MariaDB 10.11 Series
MariaDB 10.11 changelogs

7.0.1.1 Changes and Improvements in MariaDB

10.11

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Contents

MariaDB 10.11 is the current long-term maintenance release series, maintained until February 2028.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.6 to MariaDB 10.11.

New Features & Improvements

This list includes features from the short-term releases MariaDB 10.7, MariaDB 10.8, MariaDB 10.9 and MariaDB 10.10.

Authentication

- GRANT to PUBLIC (MDEV-5215) (blog post)
- Separate SUPER and READ ONLY ADMIN privileges (MDEV-29596)
- bind_address now accepts a comma-separated list of addresses to bind to (MDEV-24377)
- password_reuse_check plugin is a new password validation plugin that prevents the new password from being the same as the one being used during the configurable retention period. (MDEV-9245, MariaDB 10.7)

Optimizer

- Make ANALYZE FORMAT=JSON show time spent in the query optimizer (MDEV-28926)
- Improve optimization of joins with many tables, including eq_ref tables (MDEV-28852, MariaDB 10.10)
- Table elimination does not work across derived tables (MDEV-26278, MariaDB 10.10)
- Histograms in the statistics tables are more precise and stored as JSON, not binary (MDEV-21130, MDEV-26519, blog post, MariaDB 10.8).
- Improve simple multibyte collation performance on the ASCII range (MDEV-26572, MariaDB 10.7).

Descending Indexes

- Individual columns in the index can now be explicitly sorted in the ascending or descending order. This can be useful for optimizing certain ORDER BY cases (MDEV-13756, MDEV-26938, MDEV-26939, MDEV-26996, MariaDB 10.8).

Replication

- Change defaults for CHANGE MASTER TO so that GTID-based replication is used by default if master supports it (MDEV-19801, MariaDB 10.10)
- Added global.slave_max_statement_time system variable for SQL thread to limit maximum execution time per query replicated (MDEV-27161, MariaDB 10.10)
- Deprecate MASTER_USE_GTID=Current_Pos to favor new MASTER_DEMOTE_TO_SLAVE option (MDEV-20122, MariaDB 10.10)
- Implement the --do-domain-ids, --ignore-domain-ids, and --ignore-server-ids options for mariadb-binlog (MDEV-20119, MariaDB 10.9)
- Semisync-slave server recovery is extended to work on new server_id server (MDEV-27342, MariaDB 10.9)
- mariadb-binlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed with the actual bytes (MDEV-14608, MariaDB 10.9)
- Normally, ALTER TABLE gets fully executed on the primary first and only then it is replicated and starts executing on replicas. With this feature `ALTER TABLE` gets replicated and starts executing on replicas when it *starts* executing on the primary, not when it *finishes*. This way the replication lag caused by a heavy `ALTER TABLE` can be completely eliminated (MDEV-11675, MariaDB 10.8).
- Multi-source replication supports MySQL-style CHANNEL syntax (MDEV-26307, MariaDB 10.7)

mysqlbinlog GTID support

- mariadb-binlog (or `mysqlbinlog` as it was called back when the task was created) now supports both filtering events by GTID ranges through `--start-position` and `--stop-position`, and validating a binary log's ordering of GTIDs through `--gtid-strict-mode` (MDEV-4989, MariaDB 10.8).

Galera

- Implement a method to add IPs to allowlist for Galera Cluster node addresses that can make SST/IST requests (MDEV-27246, MariaDB 10.10)
- JSON file interface to wsrep node state / SST progress logging (MDEV-26971, MariaDB 10.9)

JSON

- JSON_OVERLAPS function (MDEV-27677, MariaDB 10.9)
- Implement range notation for JSONPath (MDEV-27911, MariaDB 10.9)
- Support JSONPath negative index (MDEV-22224, MariaDB 10.9)
- JSON_EQUALS function to check for equality between JSON objects (MDEV-23143, MariaDB 10.7).
- JSON_NORMALIZE function, which recursively sorts keys and removes spaces (MDEV-16375, MariaDB 10.7)

UUID

- New UUID data type (MDEV-4958, MariaDB 10.7)

SHOW ANALYZE FORMAT=JSON

- Extend SHOW EXPLAIN to support SHOW ANALYZE [FORMAT=JSON] (MDEV-27021, MariaDB 10.9)
- Add EXPLAIN FOR CONNECTION syntax support to SHOW EXPLAIN (MDEV-10000, MariaDB 10.9)

Information Schema

- Performance Issues reading the Information Schema Parameters table (MDEV-29104)
- Full table scan in the Information Schema Parameters and Information Schema Routines tables (MDEV-20609)

System versioning

- System versioning setting, system_versioning_insert_history, to allow history modification (MDEV-16546)
- mariadb-dump: dump and restore historical data (MDEV-16029)
- Add option to dump system versioned table as of specified timestamp (MDEV-16355, MariaDB 10.7).

InnoDB

- InnoDB performance improvements (MDEV-27557, MDEV-28185, MDEV-27767, MDEV-28313, MDEV-28137, MDEV-28465, MDEV-26789, MariaDB 10.9)
- In bulk insert, pre-sort and build indexes one page at a time (MDEV-24621, MariaDB 10.7)

InnoDB Redo Log Improvements

- autosize innodb_buffer_pool_chunk_size (MDEV-25342, MariaDB 10.8).
- Improve the redo log for concurrency (MDEV-14425, MariaDB 10.8).
- Remove FIL_PAGE_FILE_FLUSH_LSN (MDEV-27199, MariaDB 10.8).

UCA14 Collation

- Add UCA-14.0.0 collations (MDEV-27009, MariaDB 10.10)
- Improve contraction performance in UCA collations (MDEV-27265, MariaDB 10.10)
- Improve UCA collation performance for utf8mb3 and utf8mb4 (MDEV-27266, MariaDB 10.10)

Windows

- Passwordless login for mariadb root user, for OS admin users (MDEV-26715)
- On newer versions of Windows (Windows 10 1903 or later), the `mariadb` client defaults to the utf8mb4 character set. Several problems with Unicode input and output in client were fixed. Command line utilities now accept all Unicode characters in user names, database names, file names etc (in the past, characters were restricted to the current ANSI codepage) (MariaDB 10.8).

Spider Storage Engine

- This was mostly internal refactoring work. As a result one can now declare Spider connections using the `REMOTE_SERVER`, `REMOTE_DATABASE`, and `REMOTE_TABLE` attributes and not abuse the `COMMENT` field for that. This works both for the whole table and per partition (MDEV-5271, MDEV-27106, MariaDB 10.8).

Convert Partitions

- ALTER TABLE ... CONVERT PARTITION .. TO TABLE (MDEV-22166, MariaDB 10.7), and
- ALTER TABLE ... CONVERT TABLE ... TO PARTITION ... (MDEV-22165) as an easy way to convert tables to partitions and back in one command, instead of a sequence of CREATE/EXCHANGE/DROP (MariaDB 10.7)

Miscellaneous

- Add RANDOM_BYTES function (MDEV-25704, MariaDB 10.10)
- The INET4 data type (MDEV-23287, MariaDB 10.10)
- Re-design the upper level of handling UPDATE and DELETE statements (MDEV-28883, MariaDB 10.10)
- Deprecate the DES_ENCRYPT/DECRYPT functions (MDEV-27104, MariaDB 10.10)
- Hashicorp Key Management Plugin for implementing encryption using keys stored in the Hashicorp Vault KMS (MDEV-19281, MariaDB 10.9)
- Stored procedures already have support for the IN, OUT and INOUT parameter qualifiers. Added as well for stored functions and (IN only) cursors (MDEV-10654). This was a contribution by ManoharKB (MariaDB 10.8).
- Add an optional argument to the CRC32() function, as well as the CRC32C() function, which uses the Castagnoli polynomial. (MDEV-27208). **Note:** The order of the 2-ary arguments was swapped after the preview release: `crc32('MariaDB')=crc32(crc32('Maria'),'DB')` (MariaDB 10.8)
- my_print_defaults now handles `--default-*` options in exactly the same way as other MariaDB tools (MDEV-26238, MariaDB 10.8).
- UCA collations are now notably faster (MDEV-27266, MDEV-27265, MariaDB 10.8).
- NATURAL_SORT_KEY function (MDEV-4742, MariaDB 10.7).
- Five **provider plugins** (bzip2, lzma, lz4, lzo, snappy) provide compression capabilities to the server and storage engines (MDEV-12933, blog post, MariaDB 10.7).
- SFORMAT function for arbitrary text formatting (MDEV-25015, MariaDB 10.7)
- GET DIAGNOSTICS supports a new condition property name `ROW_NUMBER`. In multi-row inserts it allows one to retrieve a number of a row that has caused the error (MDEV-10075, MDEV-26611, MariaDB 10.7)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.11.

- Rename slow queries variables (MDEV-7567)
  - log_slow_min_examined_row_limit (min_examined_row_limit)
  - log_slow_query (slow_query_log)
  - log_slow_query_file (slow_query_log_file). This was named log_slow_query_file_name in the MariaDB 10.11.0 preview release.
  - log_slow_query_time (long_query_time)
- replicate_rewrite_db is now a system variable, no longer just an option (MDEV-15530)
- Change default of explicit_defaults_for_timestamp to ON (MDEV-28632, MariaDB 10.10)
- --ssl option set as default for mariadb CLI (MDEV-27105, MariaDB 10.10)
- Merge (and deprecate) old to old_mode sql variable (MDEV-24920, MariaDB 10.9)
- Deprecate the keep_files_on_create variable (MDEV-23570, MariaDB 10.8).
- Deprecate wsrep_replicate_myisam (MDEV-24947, MariaDB 10.7)
- Deprecate wsrep_strict_ddl (MDEV-24843, MariaDB 10.7)

InnoDB Variables

- innodb_write_io_threads and innodb_read_io_threads are now dynamic, and their values can be changed without restarting the server (MDEV-11026)
- Removed innodb_version (MDEV-28554, MariaDB 10.10)
- Deprecated innodb_prefix_index_cluster_optimization (MariaDB 10.10)
- Deprecated innodb_change_buffering (MariaDB 10.9)
- innodb_disallow_writes removed (MDEV-25975, MariaDB 10.9)
- innodb_log_file_size is now dynamic (MDEV-27812, MariaDB 10.9)

Spider Variables

The following deprecated variables have been removed (MariaDB 10.10):

- spider_udf_ct_bulk_insert_interval
- spider_udf_ct_bulk_insert_rows
- spider_udf_ds_bulk_insert_rows
- spider_udf_ds_table_loop_mode
- spider_udf_ds_use_real_table
- spider_use_handle
- spider_udf_table_mon_mutex_count
- spider_use_handler

Security Vulnerabilities Fixed in MariaDB 10.11

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2023-22084: MariaDB 10.11.6
- CVE-2022-47015: MariaDB 10.11.3

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 10.11 is the current stable long term series of MariaDB, maintained until February 2028. It is an evolution of MariaDB 10.10 with several entirely new features.

MariaDB 10.11.6 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)

- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)
- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)
- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)
- UNDO logs still growing for write-intensive workloads (MDEV-32050)
    - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
    - Deprecate innodb_purge_rseg_truncate_frequency.
    - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)
- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)

- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)
- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in int wsrep::client_state::bf_abort(wsrep::seqno) (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)
- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)
- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)
- main.order_by_pack_big fails with view-protocol (MDEV-31460)
- mysql_install_db_win.test fails on second execution (MDEV-32232)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)

- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- type_test.type_test_double fails with 'NUMERIC_SCALE NULL' (MDEV-22243)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

SQL Error Log Plugin

- Added the sql_error_log_warnings system variable, which permits warnings to be logged in addition to errors.

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Warnings and Notes

- Added the note_verbosity system variable to manage notes when an index cannot be used.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 10.11.6, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.11.6, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.1.2.2 MariaDB 10.11.5 Release Notes

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.11.5 | Release Notes | Changelog | Overview of 10.11

Release date: 14 Aug 2023

MariaDB 10.11 is the current stable long term series of MariaDB, maintained until February 2028. It is an evolution of MariaDB 10.10 with several entirely new features.

MariaDB 10.11.5 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.11 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- In this release repositories for Debian 12 "Bookworm" have been added.
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)

- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mysql_upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UUIDs version >= 6 are now stored without byte-swapping, UUIDs with version >=8 and variant=0 are now considered invalid, old tables are supported, old (always byte swapped) and new (swapped for version < 6) UUIDs can be compared and converted transparently (MDEV-29959)
- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in `mysql.innodb_table_stats` upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and `mariadb-backup --prepare` fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.11.4 | Release Notes | Changelog | Overview of 10.11

Release date: 7 Jun 2023

MariaDB 10.11 is the current long term maintenance development series of MariaDB, maintained until February 2028. It is an evolution of MariaDB 10.10 with several entirely new features.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.1.2.4 MariaDB 10.11.3 Release Notes

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.11.3 | Release Notes | Changelog | Overview of 10.11

Release date: 10 May 2023

MariaDB 10.11 is the current long term maintenance development series of MariaDB, maintained until February 2028. It is an evolution of MariaDB 10.10 with several entirely new features.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)
- rec_get_offsets() is not optimal (MDEV-30567)
- Performance regression in fil_space_t::try_to_close() introduced in MDEV-23855 (MDEV-30775)
- InnoDB recovery hangs when buffer pool ran out of memory (MDEV-30551)
- InnoDB undo log truncation fails to wait for purge of history (MDEV-30671)
- MariaDB crash due to DB_FAIL reported for a corrupted page (MDEV-30397)
- Deadlock between INSERT and InnoDB non-persistent statistics update (MDEV-30638)
- InnoDB hang on B-tree split or merge (MDEV-29835)
- Performance regression in locking reads from secondary indexes (MDEV-30357)
- Improve adaptive flushing (MDEV-26055)
- Make page flushing even faster (MDEV-26827)
- Purge misses a chance to free not-yet-reused undo pages (MDEV-29593)
- InnoDB temporary tablespace: reclaiming of free space does not work (MDEV-26782)
- Deadlock between CHECK TABLE and bulk insert (MDEV-30798)
- UPPER() returns an empty string for U+0251 in uca1400 collations for utf8 (MDEV-30661)
- System-wide max transaction id corrupted after changing the undo tablespaces (MDEV-30311)
- Fix miscount of doublewrites by Innodb_data_written (MDEV-31124)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)
- Race condition between buffer pool flush and log file deletion in mariadb-backup --prepare (MDEV-30860)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)
- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)
- Ensured SHOW-SLAVE-STATUS is processed on the parallel slave having a necessary mutex always intialized (MDEV-30620)
- Fixed the slave applier to report a correct error when gtid_slave_pos insert fails for some (engine) reasons (MDEV-31038)
- Made parallel slave reports in performance schema consistent with that of show-slave-status (MDEV-26071)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301)
- New optimizer_switch option, hash_join_cardinality, is added. It is off by default. When set to ON, the optimizer will produce tighter bounds for hash join output cardinality. (MDEV-30812)
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- ANALYZE FORMAT=JSON now prints more information about Block Nested Loop joins: `block-nl-join` element now has `r_loops`, `r_effective_rows` and `r_other_time_ms` fields (MDEV-30806, MDEV-30972).
- A GROUP BY query with `MIN(primary_key)` in select list and `primary_key<>const` in the WHERE could produce wrong result when executed with "Using index for group-by" strategy (MDEV-30605)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Image

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)
- Added LTS tags for easier identification of LTS releases:
  - lts-jammy
  - lts

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.11 for Fedora 36.
- In this release repositories for Fedora 38 and Ubuntu 23.04 Lunar have been added.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-47015

Changelog

7.0.1.2.5 MariaDB 10.11.2 Release Notes

Download | Release Notes | Changelog | Overview of 10.11

Release date: 16 Feb 2023

MariaDB 10.11 is a long term maintenance release series of MariaDB, maintained until February 2028. It is an evolution of MariaDB 10.10 with several entirely new features.

MariaDB 10.11.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.11.1 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, Fedora, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)
- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)
- `mariadb-backup --backup --incremental --throttle=...` hangs (MDEV-29896)
- Crash after recovery, with InnoDB: Tried to read (MDEV-30132)
- Trying to write ... bytes at ... outside the bounds (MDEV-30069)
- TRUNCATE breaks FOREIGN KEY locking (MDEV-29504, MDEV-29849)
- `INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION.NAME` is NULL for undo tablespaces (MDEV-30119)
- Fixed hangs and error handling in B-tree operations (MDEV-29603, MDEV-30400)
- InnoDB bulk insert fixes (MDEV-30047, MDEV-30321)
- InnoDB fails to start on `innodb_undo_tablespaces` mismatch (MDEV-30158)
- `mariabackup.skip_innodb` crashes when `innodb_undo_tablespaces > 0` (MDEV-30122)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- mariadb-binlog --verbose is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)
- Json Range only affects first row of the result set (MDEV-30304)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.11 for Fedora 35.
- In this release repositories for Fedora 37 and Ubuntu 22.10 Kinetic have been added.

Changelog

For a complete list of changes made in MariaDB 10.11.1, with links to detailed information on each push, see the changelog.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.1.2.6 MariaDB 10.11.1 Release Notes

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.11.1 | Release Notes | Changelog | Overview of 10.11

Release date: 17 Nov 2022

Do not use non-stable (non-GA) releases in production!

MariaDB 10.11 is a current development series of MariaDB. It is an evolution of MariaDB 10.10 with several entirely new features.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Notable Items

Authentication

- bind_address now accepts a comma-separated list of addresses to bind to (MDEV-24377)

InnoDB

- Allow innodb_undo_tablespaces to be changed after database creation (MDEV-19229)

Replication

- Formerly only a server option, replicate_rewrite_db is now a global system variable (MDEV-15530)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).

- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Changelog

For a complete list of changes made in MariaDB 10.11.1, with links to detailed information on each push, see the changelog.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.1.2.7 MariaDB 10.11.0 Release Notes

The most recent release of MariaDB 10.11 is:
MariaDB 10.11.6 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.11

Release date: 26 Sep 2022

Do not use *alpha* releases in production!

MariaDB 10.11 is a current development series of MariaDB. It is an evolution of MariaDB 10.10 with several entirely new features.

Unlike recent new releases, MariaDB 10.11.0 is a single preview release. Features are to be considered preview, and none are guaranteed to make it into MariaDB 10.11.

The preview is available as a container **quay.io/mariadb-foundation/mariadb-devel:10.11-preview**.

For an overview of MariaDB 10.11 see the What is MariaDB 10.11? page.

Thanks, and enjoy MariaDB!

Authentication

- Windows - passwordless login for mariadb root user, for OS admin users, using the gssapi authentication plugin (MDEV-26715)
- GRANT to PUBLIC (MDEV-5215) (blog post)
- Separate SUPER and READ ONLY ADMIN privileges (MDEV-29596)

Optimizer

- Semi-join optimization for single-table update/delete statements (MDEV-7487)
- Allow pushdown of queries involving UNIONs in outer select to foreign engines (MDEV-25080)
- Make ANALYZE FORMAT=JSON show time spent in the query optimizer (MDEV-28926)

Information Schema

- Performance Issues reading the Information Schema Parameters table (MDEV-29104)
- Full table scan in the Information Schema Parameters and Information Schema Routines tables (MDEV-20609)

System versioning

- System versioning setting, system_versioning_insert_history, to allow history modification (MDEV-16546)
- mariadb-dump: dump and restore historical data (MDEV-16029)

InnoDB

- innodb_write_io_threads and innodb_read_io_threads are now dynamic, and their values can be changed without restarting the server (MDEV-11026)

General

- Rename slow queries variables (MDEV-7567)
  - log_slow_min_examined_row_limit (min_examined_row_limit)
  - log_slow_query (slow_query_log)
  - log_slow_query_file_name (slow_query_log_file) This will be renamed to log_slow_query_file in the next MariaDB 10.11 release.
  - log_slow_query_time (long_query_time)
- replicate_rewrite_db is now a system variable, no longer just an option (MDEV-15530)

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.2 MariaDB Server 10.10

Changes and Improvements in MariaDB 10.10
Current Version: 10.10.7 | Status: Stable (GA) | Release Date: 13 Nov 2023

Release Notes - MariaDB 10.10 Series
MariaDB 10.10 series release notes.

Changelogs - MariaDB 10.10 Series
MariaDB 10.10 changelogs

7.0.2.1 Changes and Improvements in MariaDB 10.10

MariaDB 10.10 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Contents

MariaDB 10.10 is a short-term release series, maintained until November 2023.

New Features & Improvements

Replication

- Change defaults for CHANGE MASTER TO so that GTID-based replication is used by default if master supports it (MDEV-19801)
- Added global.slave_max_statement_time system variable for SQL thread to limit maximum execution time per query replicated (MDEV-27161)
- Deprecate MASTER_USE_GTID=Current_Pos to favor new MASTER_DEMOTE_TO_SLAVE option (MDEV-20122)

Optimizer

- Improve optimization of joins with many tables, including eq_ref tables (MDEV-28852)
- Table elimination does not work across derived tables (MDEV-26278)

UCA14 Collation

- Add UCA-14.0.0 collations (MDEV-27009)
- Improve contraction performance in UCA collations (MDEV-27265)
- Improve UCA collation performance for utf8mb3 and utf8mb4 (MDEV-27266)

Galera

- Implement a method to add IPs to allowlist for Galera Cluster node addresses that can make SST/IST requests (MDEV-27246)

Miscellaneous

- Change default of explicit_defaults_for_timestamp to ON (MDEV-28632)
- --ssl option set as default for mariadb CLI (MDEV-27105)
- Add RANDOM_BYTES function (MDEV-25704)
- The INET4 data type (MDEV-23287)
- Re-design the upper level of handling UPDATE and DELETE statements (MDEV-28883)
- Deprecate the DES_ENCRYPT/DECRYPT functions (MDEV-27104)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.10.

InnoDB

- Removed innodb_version (MDEV-28554)
- Deprecated innodb_prefix_index_cluster_optimization

Spider

The following deprecated variables have been removed:

- spider_udf_ct_bulk_insert_interval
- spider_udf_ct_bulk_insert_rows
- spider_udf_ds_bulk_insert_rows
- spider_udf_ds_table_loop_mode
- spider_udf_ds_use_real_table
- spider_use_handle
- spider_udf_table_mon_mutex_count
- spider_use_handler

7.0.2.2.1 MariaDB 10.10.7 Release Notes

Download | Release Notes | Changelog | Overview of 10.10

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 10.10 is a previous short-term maintenance stable series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.7 is a ***Stable (GA)*** release.

MariaDB 10.10.7 is the last release of the MariaDB 10.10 release series.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

- As per the MariaDB Maintenance Policy, this will be the final release of MariaDB 10.10

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)
- Assertion failures in log_sort_flush_list upon crash recovery (MDEV-32029)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- Assertion `purge_sys.tail.trx_no <= purge_sys.rseg->last_trx_no()' (MDEV-30100)
- Assertion `index->is_btree() || index->is_ibuf()' failed in btr_search_guess_on_hash (MDEV-30802)
- InnoDB hang in buf_flush_wait_LRU_batch_end() (MDEV-32134)
- InnoDB may hang when running out of buffer pool (MDEV-32588)
- Corrupt index(es) on busy table when using FOREIGN KEY (MDEV-30531)
- InnoDB Recovery doesn't display encryption message when no encryption configuration passed (MDEV-31098)
- Wrong information about innodb_checksum_algorithm in the information_schema.SYSTEM_VARIABLES (MDEV-31473)
- InnoDB may fail to recover after being killed in fil_delete_tablespace() (MDEV-31826)
- Create separate tpool thread for async aio (MDEV-31095)
- UNDO logs still growing for write-intensive workloads (MDEV-32050)
  - Increase the default for innodb_purge_batch_size from 300 to 1000 (MDEV-32050)
  - Deprecate innodb_purge_rseg_truncate_frequency.
  - The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint. (MDEV-32050)
- Slow full index scan in 10.6 vs 10.5 for the (slow) I/O-bound case (MDEV-30986)
- LOAD DATA into InnoDB w/partitions: huge performance loss, affected 10.6+ (MDEV-31835)
- Disable read-ahead for temporary tablespace (MDEV-32145)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)

- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)
- jointable materialization subquery optimization ignoring errors, then failing ASSERT. (MDEV-31983)
- Server crashes in JOIN::cleanup after erroneous query with view (MDEV-32164)
- Prepared statement return wrong result (missing row) (MDEV-9938)
- Assertion `range->rows >= s->found_records' failed in best_access_path (MDEV-32682)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)
- Parallel replication lags because innobase_kill_query() may fail to interrupt a lock wait (MDEV-32096)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)
- Assertion `mode_ == m_local || transaction_.is_streaming()' failed in int wsrep::client_state::bf_abort(wsrep::seqno) (MDEV-30217)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)
- OPTIMIZE TABLE crash (MDEV-28122)
- Server crashes in Alter_info::add_stat_drop_index upon CREATE TABLE (MDEV-32449)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)

- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)
- main.order_by_pack_big fails with view-protocol (MDEV-31460)
- mysql_install_db_win.test fails on second execution (MDEV-32232)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)

- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- type_test.type_test_double fails with 'NUMERIC_SCALE NULL' (MDEV-22243)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)
- maria-install-db fails on MacOS (MDEV-31871)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf upon query from partitioned table (MDEV-32388)
- MSAN / Valgrind errors in Item_func_like::get_mm_leaf with temporal field (MDEV-32531)
- ASAN errors in base_list_iterator::next / setup_table_map upon 2nd execution of PS (MDEV-32656)
- safe_mutex: Found wrong usage of mutex 'LOCK_thd_data' and 'wait_mutex' (MDEV-32728)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Variables

- Added the note_verbosity system variable to manage notes when an index cannot be used.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 10.10.7, with links to detailed information on each push, see the changelog.

7.0.2.2.2 MariaDB 10.10.6 Release Notes

Download 10.10.6 | Release Notes | Changelog | Overview of 10.10

Release date: 14 Aug 2023

MariaDB 10.10 is a previous short-term maintenance stable series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.6 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.10 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mysql_upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UUIDs version >= 6 are now stored without byte-swapping, UUIDs with version >=8 and variant=0 are now considered invalid, old tables are supported, old (always byte swapped) and new (swapped for version < 6) UUIDs can be compared and converted transparently (MDEV-29959)
- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)

- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in `mysql.innodb_table_stats` upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- `SET GLOBAL innodb_undo_log_truncate=ON` does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and `mariadb-backup --prepare` fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)

- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

7.0.2.2.3 MariaDB 10.10.5 Release Notes

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.10.5 | Release Notes | Changelog | Overview of 10.10

Release date: 7 Jun 2023

MariaDB 10.10 is a current short-term stable series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.5 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

7.0.2.2.4 MariaDB 10.10.4 Release Notes

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.10.4 | Release Notes | Changelog | Overview of 10.10

Release date: 10 May 2023

MariaDB 10.10 is a current short-term maintenance stable series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.4 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)

- rec_get_offsets() is not optimal (MDEV-30567)
- Performance regression in fil_space_t::try_to_close() introduced in MDEV-23855 (MDEV-30775)
- InnoDB recovery hangs when buffer pool ran out of memory (MDEV-30551)
- InnoDB undo log truncation fails to wait for purge of history (MDEV-30671)
- MariaDB crash due to DB_FAIL reported for a corrupted page (MDEV-30397)
- Deadlock between INSERT and InnoDB non-persistent statistics update (MDEV-30638)
- InnoDB hang on B-tree split or merge (MDEV-29835)
- Performance regression in locking reads from secondary indexes (MDEV-30357)
- Improve adaptive flushing (MDEV-26055)
- Make page flushing even faster (MDEV-26827)
- Purge misses a chance to free not-yet-reused undo pages (MDEV-29593)
- InnoDB temporary tablespace: reclaiming of free space does not work (MDEV-26782)
- Deadlock between CHECK TABLE and bulk insert (MDEV-30798)
- UPPER() returns an empty string for U+0251 in uca1400 collations for utf8 (MDEV-30661)
- Fix miscount of doublewrites by Innodb_data_written (MDEV-31124)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)
- Race condition between buffer pool flush and log file deletion in mariadb-backup --prepare (MDEV-30860)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)
- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)
- Ensured SHOW-SLAVE-STATUS is processed on the parallel slave having a necessary mutex always intialized (MDEV-30620)
- Fixed the slave applier to report a correct error when gtid_slave_pos insert fails for some (engine) reasons (MDEV-31038)
- Made parallel slave reports in performance schema consistent with that of show-slave-status (MDEV-26071)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301).
- New optimizer_switch option, hash_join_cardinality, is added. It is off by default. When set to ON, the optimizer will produce tighter bounds for hash join output cardinality. (MDEV-30812)
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- ANALYZE FORMAT=JSON now prints more information about Block Nested Loop joins: `block-nl-join` element now has `r_loops`, `r_effective_rows` and `r_other_time_ms` fields (MDEV-30806, MDEV-30830, MDEV-30972).
- A GROUP BY query with `MIN(primary_key)` in select list and `primary_key<>const` in the WHERE could produce wrong result when executed with "Using index for group-by" strategy (MDEV-30605)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Image

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.10 for Fedora 36.
- In this release repositories for Fedora 38 and Ubuntu 23.04 Lunar have been added.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-47015

Changelog

7.0.2.2.5 MariaDB 10.10.3 Release Notes

Download | Release Notes | Changelog | Overview of 10.10

Release date: 6 Feb 2023

MariaDB 10.10 is a current short-term maintenance stable series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.3 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.10.2 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, Fedora, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)
- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)
- `mariadb-backup --backup --incremental --throttle=...` hangs (MDEV-29896)
- Crash after recovery, with InnoDB: Tried to read (MDEV-30132)
- Trying to write ... bytes at ... outside the bounds (MDEV-30069)
- TRUNCATE breaks FOREIGN KEY locking (MDEV-29504, MDEV-29849)
- `INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION.NAME` is NULL for undo tablespaces (MDEV-30119)
- Fixed hangs and error handling in B-tree operations (MDEV-29603, MDEV-30400)
- InnoDB bulk insert fixes (MDEV-30047, MDEV-30321)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- `mysqlbinlog --verbose` is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

JSON

- JSON_PRETTY added as an alias for JSON_DETAILED (MDEV-19160)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)
- Json Range only affects first row of the result set (MDEV-30304)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.10 for Fedora 35.
- In this release repositories for Fedora 37 and Ubuntu 22.10 Kinetic have been added.

Changelog

For a complete list of changes made in MariaDB 10.10.3, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.10.3, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.2.2.6 MariaDB 10.10.2 Release Notes

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.10.2 | Release Notes | Changelog | Overview of 10.10

Release date: 17 Nov 2022

MariaDB 10.10 is a current short-term series of MariaDB, maintained until November 2023. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

SSL

- The server no longer tolerates incorrectly configured SSL (MDEV-29811). If you have enabled SSL in `my.cnf` but have not configured it properly (for example, a certificate file is missing), MariaDB used to silently disable SSL, leaving you under impression that everything was fine and connections were secure. Since this release, MariaDB will fail to start if SSL is enabled, but cannot be switched on.

Backup

- Assertion on info.page_size failed in xb_delta_open_matching_space (MDEV-18589)
- Mariabackup locks database for minutes (MDEV-28772)

InnoDB

- Adaptive hash index MDEV-27700, MDEV-29384
- MVCC and locking (MDEV-29666, MDEV-27927, MDEV-28709, MDEV-29635)
- Virtual columns (MDEV-29299, MDEV-29753)
- InnoDB crash recovery fixes (MDEV-29559)
- Race condition between KILL and transaction commit (MDEV-29368)
- Implement CHECK TABLE…EXTENDED for InnoDB (MDEV-24402)
- InnoDB persistent statistics fail to update after bulk insert (MDEV-28327)
- InnoDB bulk insert bug fixes (MDEV-29570, MDEV-29761)
- InnoDB hangs on multiple concurrent requests of a cold ROW_FORMAT=COMPRESSED page (MDEV-27983)

Galera

- Galera updated to 26.4.13
- Galera server crashes after 10.3 > 10.4 upgrade (MDEV-29375)
- wsrep_incoming_addresses status variable prints 0 as port number if the port is not mentioned in wsrep_node_incoming_address system variable (MDEV-28868)

Replication

- Minor correction in unsafe warning message (MDEV-28827)
- False replication error-stop of REVOKE PRIVILEGES from a non-existing user on primary (MDEV-28530) in combination with a filtering replica is corrected
- SET DEFAULT ROLE replication is mended on a replica that filters system tables (MDEV-28294)
- XA COMMIT is not binlogged when the XA transaction has not updated any transaction engine (MDEV-25616)
- Concurrent CREATE TRIGGER statements made to binlog without any mixup (MDEV-25606)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).
- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Changelog

For a complete list of changes made in MariaDB 10.10.2, with links to detailed information on each push, see the changelog.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.2.2.7 MariaDB 10.10.1 Release Notes

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.10.1 | Release Notes | Changelog | Overview of 10.10

Release date: 22 Aug 2022

Do not use non-stable (non-GA) releases in production!

MariaDB 10.10 is a current short-term support development series of MariaDB. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.1 is a ***Release Candidate (RC)*** release.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB corruption due to lack of file locking (MDEV-28495)
- FULLTEXT search with apostrophe, and mandatory words (MDEV-20797)
- ALTER TABLE IMPORT TABLESPACE corrupts an encrypted table (MDEV-28779)
- ALTER TABLE wrong-result fix (MDEV-26294)
- Crash recovery fixes (MDEV-28668, MDEV-28731)
- DDL crash recovery fixes (MDEV-28752, MDEV-28802, MDEV-28864, MDEV-28870, MDEV-28923, MDEV-28977)
- Avoid crashes on corrupted data (MDEV-13542, MDEV-18519, MDEV-21098, MDEV-22388, MDEV-28457, MDEV-28950)
- Bulk load bug fixes (MDEV-28242, MDEV-28679)
- Performance fixes (MDEV-28708, MDEV-28766)

- Remove innodb_version (MDEV-28554)
- Deprecate and ignore the parameter innodb_prefix_index_cluster_optimization (MDEV-28540)
- Some InnoDB counters are duplicating generic SHOW STATUS (MDEV-28539)
- Useless output in SHOW ENGINE INNODB STATUS (MDEV-28542)

Replication

- ER_SLAVE_INCIDENT error is specified now on slave to be seen with SHOW-SLAVE-STATUS (MDEV-21087)
- INCIDENT_EVENT is no longer binlogged when a being logged transaction can be safely rolledback (MDEV-21443)
- sequences related row-format events are made to correspond to binlog_row_image (MDEV-28487)
- Possible reason of FLUSH BINARY LOGS hang is eliminated (MDEV-28948)
- Fix out-of-order gtid error in the circular semisync setup (MDEV-28609)
- Added global.slave_max_statement_time system variable for SQL thread to limit maximum execution time per query replicated (MDEV-27161)
- Deprecate MASTER_USE_GTID=Current_Pos to favor new MASTER_DEMOTE_TO_SLAVE option (MDEV-20122)
- MASTER_USE_GTID defaults of CHANGE MASTER TO and RESET SLAVE are changed to be compatible with GTID-based replication (MDEV-19801)

Galera

- Possible to write/update with read_only=ON and not a SUPER privilege (MDEV-28546)
- Node crashes with Transport endpoint is not connected mysqld got signal 6 (MDEV-25068)
- Galera4 not able to report proper wsrep_incoming_addresses (MDEV-20627)
- Galera should replicate nextval()-related changes in sequences with INCREMENT <> 0, at least NOCACHE ones with engine=InnoDB (MDEV-27862)
- Add support for OpenSSL 3.0 in Galera (MDEV-25949)
- Implement a method to add IPs to allowlist for Galera Cluster node addresses that can make SST/IST requests (MDEV-27246)

Optimizer

- Server crash in JOIN_CACHE::free or in copy_fields (MDEV-23809)
  - Queries that use DISTINCT and an always-constant function like COLLATION(aggegate_func(...)) could cause a server crash. Note that COLLATION() is a special function - its value is constant even if its argument is not costant.
- Crash when using ANY predicand with redundant subquery in GROUP BY clause (MDEV-29139)
  - A query with a subuquery in this form could cause a crash:

```
... ANY (SELECT ... GROUP BY (SELECT redundant_subselect_here)) ...
```

- MariaDB Server SEGV on INSERT .. SELECT (MDEV-26427)
  - Certain queries in form "INSERT ... SELECT with_aggregate_or_window_func" could cause a crash.
- restore_prev_nj_state() doesn't update cur_sj_inner_tables correctly (MDEV-28749)
  - Subquery semi-join optimization could miss LooseScan or FirstMatch strategies for certain queries.
- Optimizer uses all partitions after upgrade to 10.3 (MDEV-28246)
  - For multi-table UPDATE or DELETE queries, the optimizer failed to apply Partition Pruning optimization for the table that is updated or deleted from.
- Range optimizer regression for key IN (const, ...) (MDEV-25020)
  - The issue can be observed on MariaDB 10.5.9 and later versions which have the fix for MDEV-9750. That fix introduceds optimizer_max_sel_arg_weight.
  - If one sets optimizer_max_sel_arg_weight to a very high value or zero (which means "unlimited") and runs queries that produce heavy-weight graphs, they can observe a performance slowdown, e.g.:

```
table.keyXpartY [NOT] IN ( ... )
```

- Wrong result with table elimination combined with not_null_range_scan (MDEV-28858)
  - If one runs with optimizer_switch='not_null_range_scan=on' (which is not enabled by default), a query that does a join and has const tables could produce a wrong result.
- Assertion `tmp >= 0' failed in best_access_path (MDEV-28882)
  - If one uses histogram_type=JSON_HB, has collected a histogram of that type and runs a query that selects a very narrow range near histogram end, they can hit an assertion in the optimizer due to rounding errors in the histogram causing negative selectivity.

General

- Crash in JSON_EXTRACT (MDEV-29188)
- ALTER TABLE ALGORITHM=NOCOPY does not work after upgrade (MDEV-28727)
- Server crash upon CREATE VIEW with unknown column in ON condition (MDEV-29088)
- password_reuse_check plugin mixes username and password (MDEV-28838)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.10 for Debian 10 "Buster" for ppc64el

Changelog

For a complete list of changes made in MariaDB 10.10.1, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.10.1, see the MariaDB Foundation release announcement.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). 7.0.2.2.8 MariaDB 10.10.0 Release Notes

The most recent release of MariaDB 10.10 is:
MariaDB 10.10.7 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.10.0 | Release Notes | Changelog | Overview of 10.10

Release date: 23 Jun 2022

Do not use *alpha* releases in production!

MariaDB 10.10 is a current development series of MariaDB. It is an evolution of MariaDB 10.9 with several entirely new features.

MariaDB 10.10.0 is not a single release, but is instead a number of preview releases based on feature branches. Each should be considered ***Alpha***.

For an overview of MariaDB 10.10 see the What is MariaDB 10.10? page.

Thanks, and enjoy MariaDB!

List of packages

Remember, these features are in separate *preview packages*. The subsection header text corresponds to the preview package name.

Replication

- Change defaults for CHANGE MASTER TO so that GTID-based replication is used by default if master supports it (MDEV-19801)
- Deprecate MASTER_USE_GTID=Current_Pos to favor new MASTER_DEMOTE_TO_SLAVE option (MDEV-20122)

Available as container: quay.io/mariadb-foundation/mariadb-devel:10.10-gtid

Optimizer

- Improve optimization of joins with many tables, including eq_ref tables (MDEV-28852)
- Table elimination does not work across derived tables (MDEV-26278)

Available as container: quay.io/mariadb-foundation/mariadb-devel:10.10-optimizer

UCA14 Collation

- Add UCA-14.0.0 collations (MDEV-27009)
- Improve contraction performance in UCA collations (MDEV-27265)
- Improve UCA collation performance for utf8mb3 and utf8mb4 (MDEV-27266)

Available as container: quay.io/mariadb-foundation/mariadb-devel:10.10-uca14

DDL

- ALTER ONLINE TABLE (MDEV-16329) (not included in MariaDB 10.10.1)
- Atomic CREATE OR REPLACE TABLE (MDEV-25292) (not included in MariaDB 10.10.1)

Available as container: quay.io/mariadb-foundation/mariadb-devel:10.10-ddl

Galera

- Implement a method to add IPs to allowlist for Galera Cluster node addresses that can make SST/IST requests (MDEV-27246)

Miscellaneous

- Change default of explicit_defaults_for_timestamp to ON (MDEV-28632)
- --ssl option set as default for mariadb CLI (MDEV-27105)
- Add RANDOM_BYTES function (MDEV-25704)
- The INET4 data type (MDEV-23287)
- Re-design the upper level of handling UPDATE and DELETE statements (MDEV-28883)
- Deprecate the DES_ENCRYPT/DECRYPT functions (MDEV-27104)

Available as container: quay.io/mariadb-foundation/mariadb-devel:10.10-misc

---

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3 MariaDB Server 10.9

Changes and Improvements in MariaDB 10.9
Current Version: 10.9.8 | Status: Stable (GA) | Release Date: 14 Aug 2023

Release Notes - MariaDB 10.9 Series
MariaDB 10.9 series release notes.

Changelogs - MariaDB 10.9 Series
MariaDB 10.9 changelogs

There are 1 related questions.

7.0.3.1 Changes and Improvements in MariaDB 10.9

MariaDB 10.9 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Contents

MariaDB 10.9 is a previous short-term release series. The first stable release was in August 2022, and it was maintained until August 2023.

New Features & Improvements

JSON

- JSON_OVERLAPS function (MDEV-27677)
- Implement range notation for JSONPath (MDEV-27911)
- Support JSONPath negative index (MDEV-22224)

InnoDB

- innodb_log_file_size is now dynamic (MDEV-27812)
- InnoDB performance improvements (MDEV-27557, MDEV-28185, MDEV-27767, MDEV-28313, MDEV-28137, MDEV-28465, MDEV-26789)
- innodb_disallow_writes removed (MDEV-25975)

Hashicorp Key Management Plugin

- Hashicorp Key Management Plugin for implementing encryption using keys stored in the Hashicorp Vault KMS (MDEV-19281)

Replication and Galera

- Implement the --do-domain-ids, --ignore-domain-ids, and --ignore-server-ids options for mariadb-binlog (MDEV-20119)
- Semisync-slave server recovery is extended to work on new server_id server (MDEV-27342)
- mariadb-binlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed with the actual bytes (MDEV-14608)
- JSON file interface to wsrep node state / SST progress logging (MDEV-26971)

SHOW ANALYZE FORMAT=JSON

- Extend SHOW EXPLAIN to support SHOW ANALYZE [FORMAT=JSON] (MDEV-27021)
- Add EXPLAIN FOR CONNECTION syntax support to SHOW EXPLAIN (MDEV-10000)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.9.
- Merge old to old_mode sql variable (MDEV-24920)

The following variables have been deprecated:

- innodb_change_buffering
- old (replaced by old_mode)

Security Vulnerabilities Fixed in MariaDB 10.9

For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2022-47015: MariaDB 10.9.6
- CVE-2022-38791: MariaDB 10.9.2
- CVE-2022-32091: MariaDB 10.9.2

Download | Release Notes | Changelog | Overview of 10.9

Alternate download from mariadb.org

Release date: 14 Aug 2023

MariaDB 10.9 is a previous short-term stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.8 is a ***Stable (GA)*** release.

MariaDB 10.9.8 is the last release of the MariaDB 10.9 release series.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

- As per the MariaDB Maintenance Policy, this will be the final release of MariaDB 10.9

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.9 for Ubuntu 18.04 LTS "Bionic"

and Ubuntu 22.10 "Kinetic"

- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mysql_upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UUIDs version >= 6 are now stored without byte-swapping, UUIDs with version >=8 and variant=0 are now considered invalid, old tables are supported, old (always byte swapped) and new (swapped for version < 6) UUIDs can be compared and converted transparently (MDEV-29959)
- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Duplicate entry allowed into a UNIQUE column (MDEV-31120)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in `mysql.innodb_table_stats` upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and `mariadb-backup --prepare` fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)

- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)
- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

7.0.3.2.2 MariaDB 10.9.7 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.7 | Release Notes | Changelog | Overview of 10.9

Release date: 7 Jun 2023

MariaDB 10.9 is the current short-term maintenance stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.7 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

For a complete list of changes made in MariaDB 10.9.7, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.7, see the MariaDB Foundation release announcement.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3.2.3 MariaDB 10.9.6 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.6 | Release Notes | Changelog | Overview of 10.9

Release date: 10 May 2023

MariaDB 10.9 is the current short-term maintenance stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.6 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)
- rec_get_offsets() is not optimal (MDEV-30567)
- Performance regression in fil_space_t::try_to_close() introduced in MDEV-23855 (MDEV-30775)
- InnoDB recovery hangs when buffer pool ran out of memory (MDEV-30551)
- InnoDB undo log truncation fails to wait for purge of history (MDEV-30671)
- MariaDB crash due to DB_FAIL reported for a corrupted page (MDEV-30397)
- Deadlock between INSERT and InnoDB non-persistent statistics update (MDEV-30638)
- InnoDB hang on B-tree split or merge (MDEV-29835)
- Performance regression in locking reads from secondary indexes (MDEV-30357)
- Improve adaptive flushing (MDEV-26055)
- Make page flushing even faster (MDEV-26827)
- Purge misses a chance to free not-yet-reused undo pages (MDEV-29593)
- InnoDB temporary tablespace: reclaiming of free space does not work (MDEV-26782)
- Deadlock between CHECK TABLE and bulk insert (MDEV-30798)
- Fix miscount of doublewrites by Innodb_data_written (MDEV-31124)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)
- Race condition between buffer pool flush and log file deletion in mariadb-backup --prepare (MDEV-30860)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)

- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)
- Ensured SHOW-SLAVE-STATUS is processed on the parallel slave having a necessary mutex always intialized (MDEV-30620)
- Fixed the slave applier to report a correct error when gtid_slave_pos insert fails for some (engine) reasons (MDEV-31038)
- Made parallel slave reports in performance schema consistent with that of show-slave-status (MDEV-26071)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301).
- New optimizer_switch option, hash_join_cardinality , is added. It is off by default. When set to ON, the optimizer will produce tighter bounds for hash join output cardinality. (MDEV-30812)
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- ANALYZE FORMAT=JSON now prints more information about Block Nested Loop joins: `block-nl-join` element now has `r_loops` , `r_effective_rows` and `r_other_time_ms` fields (MDEV-30806 , MDEV-30972).
- A GROUP BY query with `MIN(primary_key)` in select list and `primary_key<>const` in the WHERE could produce wrong result when executed with "Using index for group-by" strategy (MDEV-30605)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Image

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.9 for Fedora 36.
- In this release repositories for Fedora 38 and Ubuntu 23.04 Lunar have been added.

Security

- Fixes for the following security vulnerabilities :
  - CVE-2022-47015

Changelog

For a complete list of changes made in MariaDB 10.9.6, with links to detailed information on each push, see the changelog .

7.0.3.2.4 MariaDB 10.9.5 Release Notes

Download | Release Notes | Changelog | Overview of 10.9

Release date: 6 Feb 2023

MariaDB 10.9 is the current short-term maintenance stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.5 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.9.4 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, Fedora, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)
- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)
- `mariadb-backup --backup --incremental --throttle=...` hangs (MDEV-29896)
- Crash after recovery, with InnoDB: Tried to read (MDEV-30132)
- Trying to write ... bytes at ... outside the bounds (MDEV-30069)
- TRUNCATE breaks FOREIGN KEY locking (MDEV-29504, MDEV-29849)
- `INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION.NAME` is NULL for undo tablespaces (MDEV-30119)
- Fixed hangs and error handling in B-tree operations (MDEV-29603, MDEV-30400)
- InnoDB bulk insert fixes (MDEV-30047, MDEV-30321)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- `mysqlbinlog --verbose` is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

JSON

- JSON_PRETTY added as an alias for JSON_DETAILED (MDEV-19160)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)
- Json Range only affects first row of the result set (MDEV-30304)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.9 for Fedora 35.
- In this release repositories for Fedora 37 and Ubuntu 22.10 Kinetic have been added.

Changelog

For a complete list of changes made in MariaDB 10.9.5, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.5, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3.2.5 MariaDB 10.9.4 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.4 | Release Notes | Changelog | Overview of 10.9

Release date: 7 Nov 2022

MariaDB 10.9 is the current short-term maintenance stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.4 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

SSL

- The server no longer tolerates incorrectly configured SSL (MDEV-29811). If you have enabled SSL in `my.cnf` but have not configured it properly (for example, a certificate file is missing), MariaDB used to silently disable SSL, leaving you under impression that everything was fine and connections were secure. Since this release, MariaDB will fail to start if SSL is enabled, but cannot be switched on.

Backup

- Assertion on info.page_size failed in xb_delta_open_matching_space (MDEV-18589)
- Mariabackup locks database for minutes (MDEV-28772)

InnoDB

- Adaptive hash index MDEV-27700, MDEV-29384
- MVCC and locking (MDEV-29666, MDEV-27927, MDEV-28709, MDEV-29635)
- Virtual columns (MDEV-29299, MDEV-29753)
- InnoDB crash recovery fixes (MDEV-29559)
- Race condition between KILL and transaction commit (MDEV-29368)
- Implement CHECK TABLE…EXTENDED for InnoDB (MDEV-24402)

- InnoDB persistent statistics fail to update after bulk insert (MDEV-28327)
- InnoDB bulk insert bug fixes (MDEV-29570, MDEV-29761)

Galera

- Galera updated to 26.4.13
- Galera server crashes after 10.3 > 10.4 upgrade (MDEV-29375)
- wsrep_incoming_addresses status variable prints 0 as port number if the port is not mentioned in wsrep_node_incoming_address system variable (MDEV-28868)

Replication

- XA COMMIT is not binlogged when the XA transaction has not updated any transaction engine (MDEV-25616)
- Concurrent CREATE TRIGGER statements made to binlog without any mixup (MDEV-25606)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).
- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Changelog

For a complete list of changes made in MariaDB 10.9.4, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.4, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3.2.6 MariaDB 10.9.3 Release Notes

The most recent release of MariaDB 10.9 is:

MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.3 | Release Notes | Changelog | Overview of 10.9

Release date: 19 Sep 2022

MariaDB 10.9 is the current short-term maintenance stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.3 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

Issues Fixed

- Assertion mysql_mutex_assert_owner(&log_sys.flush_order_mutex) failed in mtr_t::commit() (MDEV-29383)
- Frequent "Data structure corruption" in InnoDB after OOM (MDEV-29374)
- Recovery or backup of instant ALTER TABLE is incorrect (MDEV-29438)
- InnoDB Temporary Tablespace (ibtmp1) is continuously growing (MDEV-28240)
- Full text index corruption if shutdown before changes are fully flushed (MDEV-29342)
- JSON_VALUE() does not parse NULL properties properly (MDEV-27151)
- InnoDB hangs on multiple concurrent requests of a cold ROW_FORMAT=COMPRESSED page (MDEV-27983)

Changelog

For a complete list of changes made in MariaDB 10.9.3, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.3, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3.2.7 MariaDB 10.9.2 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.2 | Release Notes | Changelog | Overview of 10.9

Release date: 22 Aug 2022

MariaDB 10.9 is a current stable series of MariaDB, maintained until August 2023. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.2 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB corruption due to lack of file locking (MDEV-28495)
- FULLTEXT search with apostrophe, and mandatory words (MDEV-20797)
- ALTER TABLE IMPORT TABLESPACE corrupts an encrypted table (MDEV-28779)
- ALTER TABLE wrong-result fix (MDEV-26294)
- Crash recovery fixes (MDEV-28668 , MDEV-28731)
- DDL crash recovery fixes (MDEV-28752 , MDEV-28802 , MDEV-28864 , MDEV-28870 , MDEV-28923 , MDEV-28977)
- Avoid crashes on corrupted data (MDEV-13542 , MDEV-18519 , MDEV-21098 , MDEV-22388 , MDEV-28457 , MDEV-28950)
- Bulk load bug fixes (MDEV-28242 , MDEV-28679)
- Performance fixes (MDEV-28708 , MDEV-28766)

Replication

- explicit_defaults_for_timestamp is stored in binlog, so that CREATE TABLE on slave would always have the same effect as on master. (MDEV-29078)
- ER_SLAVE_INCIDENT error is specified now on slave to be seen with SHOW-SLAVE-STATUS (MDEV-21087)
- INCIDENT_EVENT is no longer binlogged when a being logged transaction can be safely rolledback (MDEV-21443)
- sequences related row-format events are made to correspond to binlog_row_image (MDEV-28487)
- Possible reason of FLUSH BINARY LOGS hang is eliminated (MDEV-28948)
- Fix out-of-order gtid error in the circular semisync setup (MDEV-28609)

Galera

- Possible to write/update with read_only=ON and not a SUPER privilege (MDEV-28546)
- Node crashes with Transport endpoint is not connected mysqld got signal 6 (MDEV-25068)
- Galera4 not able to report proper wsrep_incoming_addresses (MDEV-20627)
- Galera should replicate nextval()-related changes in sequences with INCREMENT <> 0, at least NOCACHE ones with engine=InnoDB (MDEV-27862)
- Add support for OpenSSL 3.0 in Galera (MDEV-25949)

Optimizer

- Server crash in JOIN_CACHE::free or in copy_fields (MDEV-23809)
  - Queries that use DISTINCT and an always-constant function like COLLATION(aggegate_func(...)) could cause a server crash. Note that COLLATION() is a special function - its value is constant even if its argument is not costant.
- Crash when using ANY predicand with redundant subquery in GROUP BY clause (MDEV-29139)
  - A query with a subuquery in this form could cause a crash:

```
... ANY (SELECT ... GROUP BY (SELECT redundant_subselect_here)) ...
```

- MariaDB Server SEGV on INSERT .. SELECT (MDEV-26427)
  - Certain queries in form "INSERT ... SELECT with_aggregate_or_window_func" could cause a crash.
- restore_prev_nj_state() doesn't update cur_sj_inner_tables correctly (MDEV-28749)
  - Subquery semi-join optimization could miss LooseScan or FirstMatch strategies for certain queries.
- Optimizer uses all partitions after upgrade to 10.3 (MDEV-28246)
  - For multi-table UPDATE or DELETE queries, the optimizer failed to apply Partition Pruning optimization for the table that is updated or deleted from.
- Range optimizer regression for key IN (const, ...) (MDEV-25020)
  - The issue can be observed on MariaDB 10.5.9 and later versions which have the fix for MDEV-9750 . That fix introduceds optimizer_max_sel_arg_weight.
  - If one sets optimizer_max_sel_arg_weight to a very high value or zero (which means "unlimited") and runs queries that produce heavy-weight graphs, they can observe a performance slowdown, e.g.:

```
table.keyXpartY [NOT] IN ( ... )
```

- Wrong result with table elimination combined with not_null_range_scan (MDEV-28858)
  - If one runs with optimizer_switch='not_null_range_scan=on' (which is not enabled by default), a query that does a join and has const tables could produce a wrong result.
- Assertion `tmp >= 0' failed in best_access_path (MDEV-28882)
  - If one uses histogram_type=JSON_HB, has collected a histogram of that type and runs a query that selects a very narrow range near histogram end, they can hit an assertion in the optimizer due to rounding errors in the histogram causing negative selectivity.

Spider

- The Spider version number now matches the server version (and the spider_version system variable removed) (MDEV-26282)
- spider_init_sql_alloc_size and spider_buffer_size have been deprecated (MDEV-27926, MDEV-28560)
- Spider's high-availability feature has been deprecated (MDEV-28479)

JSON

- JSON_TABLE: extract document fragment into JSON column (MDEV-25875)

CONNECT

- CONNECT Engine now supports INSERT IGNORE with Mysql Table type (MDEV-27766)

General

- explicit_defaults_for_timestamp now also has a session scope, not only global (MDEV-29225)
- New mariadb client option, `-enable-cleartext-plugin`. Option does not do anything, and is for MySQL-compatibility purposes only.
- Crash in JSON_EXTRACT (MDEV-29188)
- ALTER TABLE ALGORITHM=NOCOPY does not work after upgrade (MDEV-28727)
- Server crash upon CREATE VIEW with unknown column in ON condition (MDEV-29088)
- password_reuse_check plugin mixes username and password (MDEV-28838)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.9 for Debian 10 "Buster" for ppc64el

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-32082
  - CVE-2022-32089
  - CVE-2022-32081
  - CVE-2018-25032
  - CVE-2022-32091
  - CVE-2022-38791
  - CVE-2022-32084

Changelog

For a complete list of changes made in MariaDB 10.9.2, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.2, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.3.2.8 MariaDB 10.9.1 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.1 | Release Notes | Changelog | Overview of 10.9

Release date: 20 May 2022

Do not use non-stable (non-GA) releases in production!

MariaDB 10.9 is a current development series of MariaDB. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.1 is a ***Release Candidate (RC)*** release.

For an overview of MariaDB 10.9 see the What is MariaDB 10.9? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- innodb_disallow_writes removed (MDEV-25975)
- InnoDB gap locking fixes (MDEV-20605, MDEV-28422)
- InnoDB performance improvements (MDEV-27557, MDEV-28185, MDEV-27767, MDEV-28313, MDEV-28137, MDEV-28465, MDEV-26789)
- Backup regression fixes (MDEV-27919)
- InnoDB portability: FreeBSD futexes (MDEV-26476), POWER and s390x transactional memory (MDEV-27956)
- ALTER TABLE: Fixed bogus duplicate key errors (MDEV-15250)
- DDL and crash recovery fixes (MDEV-27274, MDEV-27234, MDEV-27817)
- Requests to recalculate persistent statistics were sometimes lost (MDEV-27805)
- Deprecate the parameter innodb_change_buffering (MDEV-27735)
- Allow SET GLOBAL innodb_log_file_size (MDEV-27812)

Replication

- New options for mysqlbinlog --do-domain-ids, --ignore-domain-ids, and --ignore-server-ids are implemented (MDEV-20119)
- Semisync-slave server recovery is refined to correctly rollback prepared transaction (MDEV-28461)
- Circular semisync setup endless event circulation is handled (MDEV-27760)
- Semisync-slave server recovery is extended to work on new server_id server (MDEV-27342)
- Server initialization time gtid_slave_pos purge related reason of crashing in binlog background thread is removed (MDEV-26473)
- Shutdown of the semisync master can't produce inconsistent state anymore (MDEV-11853)
- Binlogs disappear after rsync IST (MDEV-28583)
- master crash is eliminated in compressed semisync replication protocol with packet counting amendment (MDEV-25580)
- OPTIMIZE on a sequence does not cause counterfactual ER_BINLOG_UNSAFE_STATEMENT anymore (MDEV-24617)
- Automatically generated Gtid_log_list_event is made to recognize within replication event group as a formal member (MDEV-28550)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE using two or more unique key values at a time with MIXED format binlogging is corrected (MDEV-28310)

- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE stops issuing unnecessary "Unsafe statement" with MIXED binlog format (MDEV-21810)
- Incomplete replication event groups are detected to error out by the slave IO thread (MDEV-27697)
- mysqlbinlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed with the actual bytes (MDEV-14608)

Backup

- Incorrect binlogs after Galera SST using rsync and mariabackup (MDEV-27524)
- mariabackup does not detect multi-source replication slave (MDEV-21037)
- Useless warning "InnoDB: Allocated tablespace ID <id> for <tablename>, old maximum was 0" during backup stage (MDEV-27343)
- mariabackup prepare fails for incrementals if a new schema is created after full backup is taken (MDEV-28446)

Optimizer

- Query performance degradation in newer MariaDB versions when using many tables (MDEV-28073)
- A SEGV in Item_field::used_tables/update_depend_map_for_order... (MDEV-26402)
- ANALYZE FORMAT=JSON fields are incorrect for UNION ALL queries (MDEV-27699)
- Subquery in an UPDATE query uses full scan instead of range (MDEV-22377)
- Assertion `item1->type() == Item::FIELD_ITEM ... (MDEV-19398)
- Server crashes in Expression_cache_tracker::fetch_current_stats (MDEV-28268)
- MariaDB server crash at Item_subselect::init_expr_cache_tracker (MDEV-26164, MDEV-26047)
- Crash with union of my_decimal type in ORDER BY clause (MDEV-25994)
- SIGSEGV in st_join_table::cleanup (MDEV-24560)
- Assertion `!eliminated' failed in Item_subselect::exec (MDEV-28437)

Spider

- spider_crd_type and spider_crd_weight have been deprecated (MDEV-28010)

General

- Auto-create history partitions for system-versioned tables (MDEV-17554)
- mariadb-dump `--order-by-size` option (MDEV-28074)
- Server error messages are now available in Chinese (MDEV-28227)
- For RHEL/CentOS 7, non x86_64 architectures are no longer supported upstream and so our support will also be dropped with this release
- Packages for Ubuntu 22.04 LTS "Jammy" and Fedora 36 are now available in this release
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Debian 9 "Stretch", Ubuntu 21.10 "Impish", and Fedora 34

Changelog

For a complete list of changes made in MariaDB 10.9.1, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.9.1, see the MariaDB Foundation release announcement.

Do not use non-stable (non-GA) releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

7.0.3.2.9 MariaDB 10.9.0 Release Notes

The most recent release of MariaDB 10.9 is:
MariaDB 10.9.8 Stable (GA) Download Now

Download 10.9.0 | Release Notes | Changelog | Overview of 10.9

Release date: 23 March 2022

Do not use *alpha* releases in production!

MariaDB 10.9 is a current development series of MariaDB. It is an evolution of MariaDB 10.8 with several entirely new features.

MariaDB 10.9.0 is not a single release, but is instead a number of preview releases based on feature branches. Each should be considered ***Alpha***. Read more about feature preview releases here.

Thanks, and enjoy MariaDB!

List of packages

Remember, these features are in separate *preview packages*. The subsection header text corresponds to the preview package name.

JSON

- JSON_OVERLAPS function (MDEV-27677)
- Implement range notation for JSONPath (MDEV-27911)
- Support JSONPath negative index (MDEV-22224)

SHOW ANALYZE FORMAT=JSON

- Extend SHOW EXPLAIN to support SHOW ANALYZE [FORMAT=JSON] (MDEV-27021)
- Add EXPLAIN FOR CONNECTION syntax support to SHOW EXPLAIN (MDEV-10000)

Async redo log write

- Asynchronous redo log write (MDEV-26603) (not included in MariaDB 10.9.1)

Miscellaneous

- Implement the --do-domain-ids, --ignore-domain-ids, and --ignore-server-ids options for mariadb-binlog/mysqlbinlog (MDEV-20119)
- information_schema.tables.table_type now shows TEMPORARY for local temporary tables (MDEV-12459) (not included in MariaDB 10.9.1)
- Merge old to old_mode sql variable (MDEV-24920)
- Hashicorp Key Management Plugin for implementing encryption using keys stored in the Hashicorp Vault KMS (MDEV-19281)
- JSON file interface to wsrep node state / SST progress logging (MDEV-26971)
- Allow innodb_log_file_size to change without server restart (MDEV-27812)

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.4 MariaDB Server 10.8

Changes and Improvements in MariaDB 10.8

Current Version: 10.8.8 | Status: Stable (GA) | Release Date: 10 May 2023

Release Notes - MariaDB 10.8 Series

MariaDB 10.8 Series Release Notes

Changelogs - MariaDB 10.8 Series

MariaDB 10.8 changelogs

7.0.4.1 Changes and Improvements in MariaDB 10.8

MariaDB 10.8 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.8 is:
MariaDB 10.8.8 Stable (GA) Download Now

Contents

MariaDB 10.8 is a previous short-term maintenance series. The first stable release was in May 2022, and it was maintained for one year.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.7 to MariaDB 10.8.

New Features & Improvements

Stored Procedures INOUT Parameters

- Stored procedures already have support for the IN, OUT and INOUT parameter qualifiers. Added as well for stored functions and (IN only) cursors (MDEV-10654). This was a contribution by ManoharKB.

Lag free ALTER TABLE in replication

- Normally, ALTER TABLE gets fully executed on the primary first and only then it is replicated and starts executing on replicas. With this feature `ALTER TABLE` gets replicated and starts executing on replicas when it *starts* executing on

the primary, not when it *finishes*. This way the replication lag caused by a heavy `ALTER TABLE` can be completely eliminated (MDEV-11675).

Descending indexes

- Individual columns in the index can now be explicitly sorted in the ascending or descending order. This can be useful for optimizing certain ORDER BY cases (MDEV-13756, MDEV-26938, MDEV-26939, MDEV-26996).

InnoDB redo log improvements

- autosize innodb_buffer_pool_chunk_size (MDEV-25342).
- Improve the redo log for concurrency (MDEV-14425).
- Remove FIL_PAGE_FILE_FLUSH_LSN (MDEV-27199).

JSON Histograms

- Histograms in the statistics tables are more precise and stored as JSON, not binary (MDEV-21130, MDEV-26519, blog post).

Spider Storage Engine Improvements

- This was mostly internal refactoring work. As a result one can now declare Spider connections using the `REMOTE_SERVER`, `REMOTE_DATABASE`, and `REMOTE_TABLE` attributes and not abuse the `COMMENT` field for that. This works both for the whole table and per partition (MDEV-5271, MDEV-27106).

Misc. features

- Add an optional argument to the CRC32() function, as well as the CRC32C() function, which uses the Castagnoli polynomial. (MDEV-27208). **Note:** The order of the 2-ary arguments was swapped after the preview release: `crc32('MariaDB')=crc32(crc32('Maria'),'DB')`
- Deprecate the keep_files_on_create variable (MDEV-23570).
- my_print_defaults now handles `--default-*` options in exactly the same way as other MariaDB tools (MDEV-26238).
- UCA collations are now notably faster (MDEV-27266, MDEV-27265).

mysqlbinlog GTID support

- mariadb-binlog (or `mysqlbinlog` as it was called back when the task was created) now supports both filtering events by GTID ranges through `--start-position` and `--stop-position`, and validating a binary log's ordering of GTIDs through `--gtid-strict-mode` (MDEV-4989).

Windows - Improved i18n support

- On newer versions of Windows (Windows 10 1903 or later), the `mariadb` client defaults to the utf8mb4 character set. Several problems with Unicode input and output in client were fixed. Command line utilities now accept all Unicode characters in user names, database names, file names etc (in the past, characters were restricted to the current ANSI codepage).

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.8.

Security Vulnerabilities Fixed in MariaDB 10.8

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2023-5157: MariaDB 10.8.4
- CVE-2022-47015: MariaDB 10.8.8
- CVE-2022-38791: MariaDB 10.8.4
- CVE-2022-32091: MariaDB 10.8.4

- CVE-2022-32089: MariaDB 10.8.4

7.0.5 MariaDB Server 10.7

Changes and Improvements in MariaDB 10.7
Current Version: 10.7.8 | Status: Stable (GA) | Release Date: 6 Feb 2023

Release Notes - MariaDB 10.7 Series
MariaDB 10.7 Series Release Notes

Changelogs - MariaDB 10.7 Series
MariaDB 10.7 changelogs

7.0.5.1 Changes and Improvements in MariaDB 10.7

MariaDB 10.7 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.7 is:
MariaDB 10.7.8 Stable (GA) Download Now

Contents

MariaDB 10.7 is a previous short-term maintenance stable series. The first stable release was in February 2022, and it was maintained for one year.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.6 to MariaDB 10.7.

New Features & Improvements

UUID

- New UUID data type (MDEV-4958)

JSON

- JSON_EQUALS function to check for equality between JSON objects (MDEV-23143).
- JSON_NORMALIZE function, which recursively sorts keys and removes spaces (MDEV-16375)

Natural Sort

- NATURAL_SORT_KEY function (MDEV-4742).

Optimization

- Improve simple multibyte collation performance on the ASCII range (MDEV-26572).

Provider Plugins

- Five **provider plugins** (bzip2, lzma, lz4, lzo, snappy) provide compression capabilities to the server and storage engines (MDEV-12933, blog post).

SFORMAT

- SFORMAT function for arbitrary text formatting (MDEV-25015)

mariadb-dump

- Add option to dump system versioned table as of specified timestamp (MDEV-16355).

Convert Partitions

- ALTER TABLE ... CONVERT PARTITION .. TO TABLE (MDEV-22166), and
- ALTER TABLE ... CONVERT TABLE ... TO PARTITION ... (MDEV-22165) as an easy way to convert tables to

partitions and back in one command, instead of a sequence of CREATE/EXCHANGE/DROP

Password Reuse

- password_reuse_check plugin is a new password validation plugin that prevents the new password from being the same as the one being used during the configurable retention period. (MDEV-9245)

Replication

- Multi-source replication supports MySQL-style CHANNEL syntax (MDEV-26307)

InnoDB Bulk Insert

- In bulk insert, pre-sort and build indexes one page at a time (MDEV-24621)

Diagnostics

- GET DIAGNOSTICS supports a new condition property name `ROW_NUMBER`. In multi-row inserts it allows one to retrieve a number of a row that has caused the error (MDEV-10075, MDEV-26611)

Variables

The following deprecated variables have been removed :

- wsrep_replicate_myisam (MDEV-24947)
- wsrep_strict_ddl (MDEV-24843)

7.0.6.1 Changes and Improvements in MariaDB 10.6

The most recent release of MariaDB 10.6 is:

MariaDB 10.6.16 Stable (GA) Download Now

Alternate download from mariadb.org

Contents

MariaDB 10.6 is the current long-term maintenance stable version. The first stable release was in July 2021, and it will be maintained until July 2026.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.5 to MariaDB 10.6.

New Features & Improvements

Atomic DDL

- CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement is fully completed, or everything is reverted to it's original state. Note that when deleting multiple tables with DROP TABLE, only each individual drop is atomic, not the full list of tables). (MDEV-23842).

SQL Syntax

- Implement SQL-standard SELECT ... OFFSET ... FETCH (MDEV-23908)
- Add SELECT ... SKIP LOCKED syntax (InnoDB only) (MDEV-13115)
- Indexes can be ignored (MDEV-7317, MDEV-25075)
- JSON_TABLE, used to extract JSON data based on a JSON path expression and to return it as a relational table (MDEV-17399)

Oracle Compatibility

- Anonymous subqueries in a FROM clause (no AS clause) are permitted in ORACLE mode (MDEV-19162)
- ADD_MONTHS() added (MDEV-20025)
- TO_CHAR() added (MDEV-20017)
- SYS_GUID() added (MDEV-24285)
- MINUS is mapped to EXCEPT in UNION (MDEV-20021)
- ROWNUM function returns the current number of accepted rows in the current context (MDEV-24089)

InnoDB

- Optimization to speed up inserts into an empty table (MDEV-515)
- We intended to deprecate and eventually remove the InnoDB's COMPRESSED row format. The first step was to make the tables read-only by default, but this plan was abandoned from MariaDB 10.6.6 (MDEV-23497) (MDEV-27736)
- Information Schema SYS_TABLESPACES now directly reflects the filesystem, and SYS_DATAFILES has been removed (MDEV-22343)
- Defer writes to the InnoDB temporary tablespace (MDEV-12227)
- The old MariaDB 5.5-compatible `innodb` checksum is no longer supported, only `crc32`. Removed the `*innodb` and `*none` options from innodb_checksum_algorithm, and the `--strict-check` / `-C` and `--write` / `-w` options from innochecksum (MDEV-25105)

Replication, Galera and Binlog

- Increase master_host limit to 255, user to 128 (MDEV-24312)
- The wsrep_mode system variable, for turning on WSREP features which are not part of default behavior (including the experimental Aria replication) (MDEV-20008, MDEV-20715, MDEV-24946)
- The delay between binary log purges can now be specified with much greater precision. The system variable binlog_expire_logs_seconds is introduced as a form of alias for expire_logs_days, which now accepts a precision of 1/1000000 days (MDEV-19371)
- Allow transition from unencrypted to TLS Galera cluster communication without cluster downtime (MDEV-22131)

Sys Schema

- Bundle sys-schema, a collection of views, functions and procedures to help administrators get insight into database usage. (MDEV-9077)

Performance Schema

- Merged replication instrumentation and tables (MDEV-16437, MDEV-20220)

Information Schema

- The views INFORMATION_SCHEMA.KEYWORDS and INFORMATION_SCHEMA.SQL_FUNCTIONS have been added to the information schema (MDEV-25129)

Storage Engines

- TokuDB has been removed (MDEV-19780)
- CassandraSE has been removed (MDEV-23024)

Character Sets

- The `utf8` character set (and related collations) is now by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable (MDEV-8334)

General

- Bundle sys schema (MDEV-9077)
- Do not resend unchanged resultset metadata for prepared statements (MDEV-19237)
- --bind-address=hostname now listens on both IPv6 and IPv4 addresses (MDEV-6536)
- Support systemd socket activation (MDEV-5536)
- For the GSSAPI plugin, support AD or local group name, and SIDs on Windows (MDEV-23959)
- Check for $MARIADB_HOME/my.cnf (MDEV-21365)

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.6 and Status Variables Added in MariaDB 10.6.
- max_recursive_iterations has been reduced to 1000 (MDEV-17239)

InnoDB Variables

The following deprecated variables have been removed (MDEV-23397):

- innodb_adaptive_max_sleep_delay
- innodb_background_scrub_data_check_interval
- innodb_background_scrub_data_compressed
- innodb_background_scrub_data_interval
- innodb_background_scrub_data_uncompressed
- innodb_buffer_pool_instances
- innodb_commit_concurrency
- innodb_concurrency_tickets
- innodb_file_format
- innodb_large_prefix
- innodb_lock_schedule_algorithm

- innodb_log_checksums
- innodb_log_compressed_pages
- innodb_log_files_in_group
- innodb_log_optimize_ddl
- innodb_page_cleaners
- innodb_replication_delay
- innodb_scrub_log
- innodb_scrub_log_speed
- innodb_sync_array_size
- innodb_thread_concurrency
- innodb_thread_sleep_delay
- innodb_undo_logs

Security Vulnerabilities Fixed in MariaDB 10.6

For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2023-5157: MariaDB 10.6.9
- CVE-2023-22084: MariaDB 10.6.16

MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.15 | Release Notes | Changelog | Overview of 10.6

Release date: 14 Aug 2023

MariaDB 10.6 is a previous long-term series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.15 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

Upgrading from MySQL

- MariaDB now detects and converts previously incompatible MySQL partition schemes (MDEV-29253)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Ubuntu 18.04 LTS "Bionic" and Ubuntu 22.10 "Kinetic"
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)
- bzero wipes more bytes than necessary in `set_global_from_ddl_log_entry` (MDEV-31521)
- Assertion `` `0' `` failed in `Type_handler_row::field_type` upon `TO_CHAR` with wrong argument (MDEV-29152)
- mysql_upgrade fails due to `old_mode=""` , with "Cannot load from mysql.proc. The table is probably corrupted" (MDEV-28915)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- Crashing on I/O error is unhelpful (MDEV-27593)
- SIGSEGV in `log_sort_flush_list()` in InnoDB crash recovery (MDEV-31354)
- InnoDB tables are being flagged as corrupted on an I/O bound server (MDEV-31767)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- Server Status Innodb_row_lock_time% is reported in seconds (MDEV-29311)
- innochecksum dies with Floating point exception (MDEV-31641)
- Add InnoDB engine information to the slow query log (MDEV-31558)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- ER_DUP_KEY in `mysql.innodb_table_stats` upon RENAME on sequence (MDEV-31607)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- InnoDB: Failing assertion: `page_type == i_s_page_type[page_type].type_value` (MDEV-31386)
- `btr_estimate_n_rows_in_range()` accesses unfixed, unlatched page (MDEV-30648)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- ASAN errors in `dict_v_col_t::detach` upon adding key to virtual column (MDEV-31416)
- Purge trying to access freed secondary index page (MDEV-31264)
- Freed data pages are not always being scrubbed (MDEV-31253)
- InnoDB recovery hangs after reporting corruption (MDEV-31353)
- `!cursor->index->is_committed()` in row0ins.cc after update to 10.4.13 from 10.3.21 (MDEV-22739)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- InnoDB recovery and `mariadb-backup --prepare` fail to report detailed progress (MDEV-29911)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)

- Server freeze due to innodb_change_buffering and innodb_file_per_table=0 (MDEV-31088)
- Change buffer entries are left behind when freeing a page, causing secondary index corruption when the page is later reused (MDEV-31385)
- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- ANALYZE FORMAT=JSON now includes InnoDB engine statistics for each table (MDEV-31577)
- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- Calling a function from a different database in a slave side trigger crashes (MDEV-29894)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node never returns from Donor/Desynced to Synced when `wsrep_mode = BF_ABORT_MARIABACKUP` (MDEV-31737)
- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- Assertion failure `!lock.was_chosen_as_deadlock_victim in trx0trx.h:1065` (MDEV-30963)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.15, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.15, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.2 MariaDB 10.6.14 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.14 | Release Notes | Changelog | Overview of 10.6

Release date: 7 Jun 2023

Warning: This version can cause InnoDB file corruption under high I/O-bound load. Stick to an earlier release, or upgrade to a more recent release, if possible. See MDEV-31767.

MariaDB 10.6 is the current long-term series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.14 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- InnoDB hang fixes (MDEV-31158, MDEV-31343, MDEV-31350)
- Innodb_buffer_pool_read_requests is not updated correctly (MDEV-31309)
- InnoDB monitor trx_rseg_history_len was accidentally disabled by default (MDEV-31308)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.14, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.14, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.3 MariaDB 10.6.13 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.13 | Release Notes | Changelog | Overview of 10.6

Release date: 10 May 2023

MariaDB 10.6 is the current long-term series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.13 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)
- rec_get_offsets() is not optimal (MDEV-30567)
- Performance regression in fil_space_t::try_to_close() introduced in MDEV-23855 (MDEV-30775)
- InnoDB recovery hangs when buffer pool ran out of memory (MDEV-30551)
- InnoDB undo log truncation fails to wait for purge of history (MDEV-30671)
- MariaDB crash due to DB_FAIL reported for a corrupted page (MDEV-30397)
- Deadlock between INSERT and InnoDB non-persistent statistics update (MDEV-30638)
- InnoDB hang on B-tree split or merge (MDEV-29835)
- Performance regression in locking reads from secondary indexes (MDEV-30357)
- Improve adaptive flushing (MDEV-26055)
- Make page flushing even faster (MDEV-26827)
- Purge misses a chance to free not-yet-reused undo pages (MDEV-29593)
- InnoDB temporary tablespace: reclaiming of free space does not work (MDEV-26782)
- Fix miscount of doublewrites by Innodb_data_written (MDEV-31124)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)
- Race condition between buffer pool flush and log file deletion in mariadb-backup --prepare (MDEV-30860)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)
- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)
- Ensured SHOW-SLAVE-STATUS is processed on the parallel slave having a necessary mutex always intialized (MDEV-30620)
- Fixed the slave applier to report a correct error when gtid_slave_pos insert fails for some (engine) reasons (MDEV-31038)
- Made parallel slave reports in performance schema consistent with that of show-slave-status (MDEV-26071)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301).
- New optimizer_switch option, hash_join_cardinality , is added. It is off by default. When set to ON, the optimizer will produce tighter bounds for hash join output cardinality. (MDEV-30812)
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- ANALYZE FORMAT=JSON now prints more information about Block Nested Loop joins: `block-nl-join` element now has `r_loops` , `r_effective_rows` and `r_other_time_ms` fields (MDEV-30806 , MDEV-30830 , MDEV-30972).
- A GROUP BY query with `MIN(primary_key)` in select list and `primary_key<>const` in the WHERE could produce wrong result when executed with "Using index for group-by" strategy (MDEV-30605)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Image

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Fedora 36.
- In this release repositories for Fedora 38 and Ubuntu 23.04 Lunar have been added.

Security

- Fixes for the following security vulnerabilities :
  - CVE-2022-47015

Changelog

7.0.6.2.4 MariaDB 10.6.12 Release Notes

Download | Release Notes | Changelog | Overview of 10.6

Release date: 6 Feb 2023

MariaDB 10.6 is the current long-term series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.12 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.6.11 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, Fedora, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)
- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)
- `mariadb-backup --backup --incremental --throttle=...` hangs (MDEV-29896)
- Crash after recovery, with InnoDB: Tried to read (MDEV-30132)
- Trying to write ... bytes at ... outside the bounds (MDEV-30069)
- TRUNCATE breaks FOREIGN KEY locking (MDEV-29504, MDEV-29849)
- `INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION.NAME` is NULL for undo tablespaces (MDEV-30119)
- Fixed hangs and error handling in B-tree operations (MDEV-29603, MDEV-30400)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- `mysqlbinlog --verbose` is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

JSON

- JSON_PRETTY added as an alias for JSON_DETAILED (MDEV-19160)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Fedora 35.

- In this release repositories for Fedora 37 and Ubuntu 22.10 Kinetic have been added.

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.12, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.12, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.5 MariaDB 10.6.11 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.11 | Release Notes | Changelog | Overview of 10.6

Release date: 7 Nov 2022

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.11 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

SSL

- The server no longer tolerates incorrectly configured SSL (MDEV-29811). If you have enabled SSL in `my.cnf` but have not configured it properly (for example, a certificate file is missing), MariaDB used to silently disable SSL, leaving you under impression that everything was fine and connections were secure. Since this release, MariaDB will fail to start if SSL is enabled, but cannot be switched on.

Backup

- Assertion on info.page_size failed in xb_delta_open_matching_space (MDEV-18589)

InnoDB

- Adaptive hash index MDEV-27700, MDEV-29384
- MVCC and locking (MDEV-29666, MDEV-27927, MDEV-28709, MDEV-29635)
- Virtual columns (MDEV-29299, MDEV-29753)
- InnoDB crash recovery fixes (MDEV-29559)

- Race condition between KILL and transaction commit (MDEV-29368)
- Implement CHECK TABLE…EXTENDED for InnoDB (MDEV-24402)
- InnoDB persistent statistics fail to update after bulk insert (MDEV-28327)

Galera

- Galera updated to 26.4.13
- Galera server crashes after 10.3 > 10.4 upgrade (MDEV-29375)
- wsrep_incoming_addresses status variable prints 0 as port number if the port is not mentioned in wsrep_node_incoming_address system variable (MDEV-28868)

Replication

- XA COMMIT is not binlogged when the XA transaction has not updated any transaction engine (MDEV-25616)
- Concurrent CREATE TRIGGER statements made to binlog without any mixup (MDEV-25606)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).
- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.11, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.11, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.6 MariaDB 10.6.10 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.10 | Release Notes | Changelog | Overview of 10.6

Release date: 19 Sep 2022

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB, maintained until July 2026. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.10 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

Issues Fixed

- Assertion mysql_mutex_assert_owner(&log_sys.flush_order_mutex) failed in mtr_t::commit() (MDEV-29383)
- Frequent "Data structure corruption" in InnoDB after OOM (MDEV-29374)
- Recovery or backup of instant ALTER TABLE is incorrect (MDEV-29438)
- InnoDB Temporary Tablespace (ibtmp1) is continuously growing (MDEV-28240)
- Full text index corruption if shutdown before changes are fully flushed (MDEV-29342)
- JSON_VALUE() does not parse NULL properties properly (MDEV-27151)
- InnoDB hangs on multiple concurrent requests of a cold ROW_FORMAT=COMPRESSED page (MDEV-27983)

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.10, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.10, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.7 MariaDB 10.6.9 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.9 | Release Notes | Changelog | Overview of 10.6

Release date: 15 Aug 2022

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB. It is an evolution of MariaDB 10.5 with several

entirely new features.

MariaDB 10.6.8 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Regressions

Unfortunately, some bugs have been found post release, so this is updated to help avoid these issues if possible. All are fixed in MariaDB 10.6.10.

- MDEV-29374 — a crash shortly after a page merge (can be triggered by an UPDATE or DELETE or, say, rollback of an INSERT) can cause data corruption
- MDEV-29342 — if InnoDB table had a fulltext index and only one new row was inserted between the last sync (performed asynchronously by a dedicated thread) and server shutdown, the fulltext index wasn't properly updated and became out of sync with the data. Before 10.6.9 this happened silently, in 10.6.9 an assertion crashed the server after detecting the inconsistency.

Notable Items

InnoDB

- InnoDB corruption due to lack of file locking (MDEV-28495)
- FULLTEXT search with apostrophe, and mandatory words (MDEV-20797)
- ALTER TABLE IMPORT TABLESPACE corrupts an encrypted table (MDEV-28779)
- ALTER TABLE wrong-result fix (MDEV-26294)
- Crash recovery fixes (MDEV-28668, MDEV-28731)
- DDL crash recovery fixes (MDEV-28752, MDEV-28802, MDEV-28864, MDEV-28870, MDEV-28923, MDEV-28977)
- Avoid crashes on corrupted data (MDEV-13542, MDEV-18519, MDEV-21098, MDEV-22388, MDEV-28457)

Replication

- explicit_defaults_for_timestamp is stored in binlog, so that CREATE TABLE on slave would always have the same effect as on master. (MDEV-29078)
- ER_SLAVE_INCIDENT error is specified now on slave to be seen with SHOW-SLAVE-STATUS (MDEV-21087)
- INCIDENT_EVENT is no longer binlogged when a being logged transaction can be safely rolledback (MDEV-21443)
- sequences related row-format events are made to correspond to binlog_row_image (MDEV-28487)
- Possible reason of FLUSH BINARY LOGS hang is eliminated (MDEV-28948)
- Fix out-of-order gtid error in the circular semisync setup (MDEV-28609)

Galera

- Possible to write/update with read_only=ON and not a SUPER privilege (MDEV-28546)
- Node crashes with Transport endpoint is not connected mysqld got signal 6 (MDEV-25068)
- Galera4 not able to report proper wsrep_incoming_addresses (MDEV-20627)
- Galera should replicate nextval()-related changes in sequences with INCREMENT <> 0, at least NOCACHE ones with engine=InnoDB (MDEV-27862)
- Add support for OpenSSL 3.0 in Galera (MDEV-25949)

Optimizer

- Server crash in JOIN_CACHE::free or in copy_fields (MDEV-23809)
  - Queries that use DISTINCT and an always-constant function like COLLATION(aggegate_func(...)) could cause a server crash. Note that COLLATION() is a special function - its value is constant even if its argument is not costant.
- Crash when using ANY predicand with redundant subquery in GROUP BY clause (MDEV-29139)
  - A query with a subuquery in this form could cause a crash:

```
... ANY (SELECT ... GROUP BY (SELECT redundant_subselect_here)) ...
```

- MariaDB Server SEGV on INSERT .. SELECT (MDEV-26427)
  - Certain queries in form "INSERT ... SELECT with_aggregate_or_window_func" could cause a crash.
- restore_prev_nj_state() doesn't update cur_sj_inner_tables correctly (MDEV-28749)
  - Subquery semi-join optimization could miss LooseScan or FirstMatch strategies for certain queries.
- Optimizer uses all partitions after upgrade to 10.3 (MDEV-28246)
  - For multi-table UPDATE or DELETE queries, the optimizer failed to apply Partition Pruning optimization for the table that is updated or deleted from.
- Range optimizer regression for key IN (const, ...) (MDEV-25020)
  - The issue can be observed on MariaDB 10.5.9 and later versions which have the fix for MDEV-9750. That fix introduceds optimizer_max_sel_arg_weight.
  - If one sets optimizer_max_sel_arg_weight to a very high value or zero (which means "unlimited") and runs queries that produce heavy-weight graphs, they can observe a performance slowdown, e.g.:

    ```
    table.keyXpartY [NOT] IN ( ... )
    ```

- Wrong result with table elimination combined with not_null_range_scan (MDEV-28858)
  - If one runs with optimizer_switch='not_null_range_scan=on' (which is not enabled by default), a query that does a join and has const tables could produce a wrong result.

OpenSSL

- Backport OpenSSL-3.0 compatibility to 10.6 branch (MDEV-28133)

JSON

- JSON_TABLE: extract document fragment into JSON column (MDEV-25875)

CONNECT

- CONNECT Engine now supports INSERT IGNORE with Mysql Table type (MDEV-27766)

mariadb Client

- New mariadb client option, `-enable-cleartext-plugin`. Option does not do anything, and is for MySQL-compatibility purposes only.

General

- explicit_defaults_for_timestamp now also has a session scope, not only global (MDEV-29225)
- Crash in JSON_EXTRACT (MDEV-29188)
- ALTER TABLE ALGORITHM=NOCOPY does not work after upgrade (MDEV-28727)
- Server crash upon CREATE VIEW with unknown column in ON condition (MDEV-29088)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Debian 10 "Buster" for ppc64el
- Repositories for Ubuntu 22.04 and RHEL/Rocky 9 have been added in this release

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-5157
  - CVE-2022-32082
  - CVE-2022-32089
  - CVE-2022-32081
  - CVE-2018-25032
  - CVE-2022-32091
  - CVE-2022-32084
  - CVE-2022-38791

Changelog

7.0.6.2.8 MariaDB 10.6.8 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.8 | Release Notes | Changelog | Overview of 10.6

Release date: 20 May 2022

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.8 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Note that MariaDB 10.6.8 is not yet available for Ubuntu 22.04 due to MDEV-28133. MariaDB 10.6.9 will be available.

Notable Items

InnoDB

- innodb_disallow_writes removed (MDEV-25975)
- InnoDB gap locking fixes (MDEV-20605, MDEV-28422)
- InnoDB performance improvements (MDEV-27557, MDEV-28185, MDEV-27767, MDEV-28313, MDEV-28137, MDEV-28465, MDEV-26789)
- Backup regression fixes (MDEV-27919)
- InnoDB portability: FreeBSD futexes (MDEV-26476), POWER and s390x transactional memory (MDEV-27956)
- ALTER TABLE: Fixed bogus duplicate key errors (MDEV-15250)
- DDL and crash recovery fixes (MDEV-27274, MDEV-27234, MDEV-27817)
- Requests to recalculate persistent statistics were sometimes lost (MDEV-27805)

Replication

- Semisync-slave server recovery is refined to correctly rollback prepared transaction (MDEV-28461)
- Circular semisync setup endless event circulation is handled (MDEV-27760)
- Semisync-slave server recovery is extended to work on new server_id server (MDEV-27342)
- Server initialization time gtid_slave_pos purge related reason of crashing in binlog background thread is removed

(MDEV-26473)
- Shutdown of the semisync master can't produce inconsistent state anymore (MDEV-11853)
- Binlogs disappear after rsync IST (MDEV-28583)
- master crash is eliminated in compressed semisync replication protocol with packet counting amendment (MDEV-25580)
- OPTIMIZE on a sequence does not cause counterfactual ER_BINLOG_UNSAFE_STATEMENT anymore (MDEV-24617)
- Automatically generated Gtid_log_list_event is made to recognize within replication event group as a formal member (MDEV-28550)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE using two or more unique key values at a time with MIXED format binlogging is corrected (MDEV-28310)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE stops issuing unnecessary "Unsafe statement" with MIXED binlog format (MDEV-21810)
- Incomplete replication event groups are detected to error out by the slave IO thread (MDEV-27697)
- mysqlbinlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed with the actual bytes (MDEV-14608)

Backup

- Incorrect binlogs after Galera SST using rsync and mariabackup (MDEV-27524)
- mariabackup does not detect multi-source replication slave (MDEV-21037)
- Useless warning "InnoDB: Allocated tablespace ID <id> for <tablename>, old maximum was 0" during backup stage (MDEV-27343)
- mariabackup prepare fails for incrementals if a new schema is created after full backup is taken (MDEV-28446))

Optimizer

- Query performance degradation in newer MariaDB versions when using many tables (MDEV-28073)
- A SEGV in Item_field::used_tables/update_depend_map_for_order... (MDEV-26402)
- ANALYZE FORMAT=JSON fields are incorrect for UNION ALL queries (MDEV-27699)
- Subquery in an UPDATE query uses full scan instead of range (MDEV-22377)
- Assertion `item1->type() == Item::FIELD_ITEM ... (MDEV-19398)
- Server crashes in Expression_cache_tracker::fetch_current_stats (MDEV-28268)
- MariaDB server crash at Item_subselect::init_expr_cache_tracker (MDEV-26164, MDEV-26047)
- Crash with union of my_decimal type in ORDER BY clause (MDEV-25994)
- SIGSEGV in st_join_table::cleanup (MDEV-24560)
- Assertion `!eliminated' failed in Item_subselect::exec (MDEV-28437)

General

- Server error messages are now available in Chinese (MDEV-28227)
- For RHEL/CentOS 7, non x86_64 architectures are no longer supported upstream and so our support will also be dropped with this release
- Packages for Ubuntu 22.04 LTS "Jammy" and Fedora 36 are not yet available pending the resolution of MDEV-28133: *Backport OpenSSL-3.0 compatibility to 10.6 branch*
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Debian 9 "Stretch", Ubuntu 21.10 "Impish", and Fedora 34

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46669
  - CVE-2022-27376
  - CVE-2022-27377
  - CVE-2022-27378
  - CVE-2022-27379
  - CVE-2022-27380
  - CVE-2022-27381
  - CVE-2022-27382
  - CVE-2022-27383
  - CVE-2022-27384
  - CVE-2022-27386
  - CVE-2022-27387
  - CVE-2022-27444
  - CVE-2022-27445

- CVE-2022-27446
- CVE-2022-27447
- CVE-2022-27448
- CVE-2022-27449
- CVE-2022-27451
- CVE-2022-27452
- CVE-2022-27455
- CVE-2022-27456
- CVE-2022-27457
- CVE-2022-27458
- CVE-2022-32087
- CVE-2022-32086
- CVE-2022-32085
- CVE-2022-32083
- CVE-2022-32088

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.8, with links to detailed information on each push, see the changelog.

7.0.6.2.9 MariaDB 10.6.7 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.7 | Release Notes | Changelog | Overview of 10.6

Release date: 12 Feb 2022

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.7 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

- This release fixes a blocking problem with the MariaDB 10.6.6 release when manually running mariadb-upgrade. (MDEV-27789)
- See MariaDB 10.6.6 for other changes since the previous release.

InnoDB

- Set innodb_change_buffering=none by default (MDEV-27734)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46665
  - CVE-2021-46664
  - CVE-2021-46661
  - CVE-2021-46668
  - CVE-2021-46663

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.7, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.7, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.10 MariaDB 10.6.6 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.6 | Release Notes | Changelog | Overview of 10.6

Release date: 9 Feb 2022

This release is no longer available for download after a problem was noticed when manually running mariadb-upgrade. See MDEV-27789 for more details.

Please use a later release.

MariaDB 10.6 is the current long-term maintenance stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.6 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- --skip-symbolic-links does not disallow `.isl` file creation (MDEV-26870)
- Indexed CHAR columns are broken with NO_PAD collations (MDEV-25440)
- insert-intention lock conflicts with waiting ORDINARY lock (MDEV-27025)

- Crash recovery improvements (MDEV-26784, MDEV-27022, MDEV-27183, MDEV-27610)
- mariabackup skips valid .ibd file (MDEV-26326)
- Allow seamless upgrade despite ROW_FORMAT=COMPRESSED (MDEV-27736)

Galera

- Galera updated to 26.4.11
- Galera SST scripts should use ssl_capath (not ssl_ca) for CA directory (MDEV-27181)
- Alter Sequence do not replicate to another nodes with in Galera Cluster (MDEV-19353)
- Galera crash - Assertion. Possible parallel writeset problem (MDEV-26803)
- CREATE TABLE with FOREIGN KEY constraint fails to apply in parallel (MDEV-27276)
- Galera cluster node consider old server_id value even after modification of server_id `[wsrep_gtid_mode=ON]` (MDEV-26223)

Replication

- Seconds behind master corrected from artificial spikes at relay-log rotation (MDEV-16091)
- Statement rollback in binlog when transaction creates or drop temporary table is set right (MDEV-26833)
- CREATE-or-REPLACE SEQUENCE is made to binlog with the DDL flag to stabilize its parallel execution on slave (MDEV-27365)

Packaging & Misc

- prohibition running two upgrades in parallel (MDEV-27068, MDEV-27107, MDEV-27279)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Ubuntu 21.04 Hirsute, CentOS 8, and Fedora 33
- mariadb_repo_setup script updated to version 2022-02-08, with the following fixes and enhancements:
  - Default location of the script has been moved to: https://r.mariadb.com/downloads/mariadb_repo_setup (old location is deprecated, but still works)
  - The GPG keyring file, used with Debian and Ubuntu repositories, has moved to: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg and the checksum for the file can be found at: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg.sha256
  - Support for RHEL and SLES aarch64 repositories added
  - New function added to verify that the MariaDB Server version, if specified on the command line, follows the correct naming and that a corresponding repository actually exists.
  - Fixed repository pinning for Ubuntu and Debian repositories
  - MariaDB Server 10.7 is now the default server version

Docker Library

- Faster initialization by disabling binary logging during initialization (MDEV-27074)
- mysql_upgrade can be run if needed using the environment variable MARIADB_AUTO_UPGRADE=1 (MDEV-25670)
- A healthcheck script /usr/local/bin/healthcheck.sh is installed in the container with various checking options (MDEV-25434)
- mysql@localhost user is created with the environment variable MARIADB_MYSQL_LOCALHOST_USER=1 and additional grants (beyond USAGE) with MARIADB_MYSQL_LOCALHOST_GRANTS={global grant list} (MDEV-27732)
- skip innodb buffer pool loads/dumps on temporary startup/shutdown for faster startup/initialization, and accurate "healthcheck.sh --innodb_buffer_pool_loaded"
- change group ownership on datadir/socket dir (issue #401)
- log note about note on Securing system users, mysql_secure_installation not required (reddit suggestion)
- speed up Docker Library initialization of timezones (MDEV-27608, MDEV-23326)
- MariaDB names of executable programs and scripts used instead of historical mysql ones

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-24052
  - CVE-2022-24051
  - CVE-2022-24050
  - CVE-2022-24048
  - CVE-2021-46659
  - CVE-2022-0778
  - CVE-2022-21595

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.6, with links to detailed information on each push, see the changelog.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.11 MariaDB 10.6.5 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.5 | Release Notes | Changelog | Overview of 10.6

Release date: 8 Nov 2021

MariaDB 10.6 is the current stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.5 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Linux after kernel version 5.10 has a io-uring regression causing a write to storage to be lost, or not acknowledged. As such innodb_use_native_aio will default to 0 (off) until 5.16. If innodb_use_native_aio is enabled in your configuration, a warning will be logged, however it will continue with the io-uring enabled, potentially resulting in a hang, or an assertion later. The long term support kernel 5.14.14 we haven't observed failures, and 5.15.0-rc7 failures have been observed, though less frequently. If you have innodb_use_native_aio explicitly enabled, and are using watch out for a lack of InnoDB updates followed by a 10 minute timeout. See MDEV-26674 for details.
- `ALTER TABLE…IMPORT TABLESPACE` fixes (MDEV-18543, MDEV-20931, MDEV-26131, MDEV-26621)
- `innodb_undo_log_truncate` fixes (MDEV-26445, MDEV-26450, MDEV-26672, MDEV-26864)
- Page I/O performance fixes (MDEV-25215, MDEV-26547, MDEV-26626, MDEV-26819)
- Replication timeouts with `XA PREPARE` (MDEV-26682)
- Improved DDL and data dictionary (MDEV-25919)
- Performance fixes (MDEV-26356, MDEV-26467, MDEV-26826)

Replication

- Memory hogging on slave by ROW event applier is eliminated (MDEV-26712)
- `mysql --binary-mode` now properly handles `\\0` in data (MDEV-25444)
- Fixes race condition between `SHOW BINARY LOGS` and `RESET MASTER` (MDEV-20215)
- Missed statement rollback in case transaction drops or create temporary table is corrected (MDEV-26833)

Audit Plugin

- The `QUERY_DDL` server_audit_events setting now logs `CREATE/DROP [PROCEDURE / FUNCTION / USER]` statements. See MariaDB Audit Plugin - Log Settings. (MDEV-23457)

Packaging & Misc

- Session tracking flag in OK_PACKET (MDEV-26868)
- Some views force server (and mysqldump) to generate invalid SQL for their definitions (MDEV-26299)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46667
  - CVE-2021-46662
  - CVE-2022-27385
  - CVE-2022-27385
  - CVE-2022-31624

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.5, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.5, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.12 MariaDB 10.6.4 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.4 | Release Notes | Changelog | Overview of 10.6

Release date: 6 Aug 2021

Warning: This version can cause InnoDB file corruption on FreeBSD and on AIX. Stick to an earlier release, or upgrade to a more recent release, if you are running either of these environments. See MDEV-26537.

MariaDB 10.6 is the current stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.4 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB no longer acquires advisory file locks by default (MDEV-24393)
- Encryption: Automatically disable key rotation checks for file_key_management plugin (MDEV-14180)
- Some fixes from MySQL 5.7.35 (MDEV-26205)
- Fixed scrubbing on AIX (MDEV-26110)
- buf_pool.flush_list corrupted by buffer pool resizing or ROW_FORMAT=COMPRESSED (MDEV-26200)

Optimizer

- A query that uses ORDER BY .. LIMIT clause and "Range checked for each record optimization" could produce incorrect results under some circumstances (MDEV-25858)
- Queries that have more than 32 equality conditions comparing columns of different tables ("tableX.colX=tableY.colY) could cause a stack overrun in the query optimizer (MDEV-17783 , MDEV-23937)
- "Condition pushdown into derived table" optimization cannot be applied if the expression being pushed refers to a derived table column which is computed from expression that has a stored function call, @session variable reference, or other similar construct. The fix for MDEV-25969 makes it so that only the problematic part of the condition is not pushed. The rest of the condition is now pushed. (MDEV-25969)
- A query with window function on the left side of the subquery could cause a crash. (MDEV-25630)
- Fixed the issue fixed in MySQL Bug #76803: DML or locking SELECT statements that use outer joins could produce this warning in the error log: `[ERROR] InnoDB: Unlock row could not find a 3 mode lock on the record.` (MDEV-26106)

Packaging & Misc

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.6 for Ubuntu 20.10 Groovy
- Debian 11 Bullseye repositories added
- Galera updated to 26.4.9
- Linux on IBM Z (s390x) architecture added with releases on Ubuntu-20.04 Focal

Security

- Fixes for the following security vulnerabilities :
  - CVE-2021-2372
  - CVE-2021-2389

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.4, with links to detailed information on each push, see the changelog .

Contributors

For a full list of contributors to MariaDB 10.6.4, see the MariaDB Foundation release announcement .

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.13 MariaDB 10.6.3 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.3 | Release Notes | Changelog | Overview of 10.6

Release date: 6 Jul 2021

MariaDB 10.6 is the current stable series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.3 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Changes

InnoDB

- Maximum value of innodb_lock_wait_timeout is now 100000000, which means infinite timeout (MDEV-26067)
- Write performance improvements: MDEV-25954, MDEV-25948, MDEV-25113, MDEV-26004, MDEV-25801
- Atomic DDL rewrite (MDEV-25506)
- Thinly provisioned SSD support for page_compressed tables (MDEV-26029)

Replication

- Fix binlog background thread hang at shutdown (MDEV-26031)

General

- The views INFORMATION_SCHEMA.KEYWORDS and INFORMATION_SCHEMA.SQL_FUNCTIONS have been added to the information schema (MDEV-25129)
- Assertion `thd->locked_tables_mode == LTM_NONE' failed in Locked_tables_list::init_locked_tables (MDEV-25837)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-35604
  - CVE-2021-46658

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.3, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.3, see the MariaDB Foundation release announcement.

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.6.2.14 MariaDB 10.6.2 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.2 | Release Notes | Changelog | Overview of 10.6

Release date: 18 Jun 2021

MariaDB 10.6 is the current development series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.2 is a ***Release Candidate (RC)*** release.

Do not use non-stable (non-GA) releases in production!

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Register now for our MariaDB Community Server 10.6 webinar to be held 2021-06-29 and be one of the first to see the biggest features coming in MariaDB Community Server 10.6, with an exclusive opportunity to have your questions answered by MariaDB engineering and product leads.

Thanks, and enjoy MariaDB!

Notable Changes

InnoDB

- When innodb_adaptive_hash_index=OFF (the default), the following counters (which reflect btr_cur_n_non_sea) will no longer be updated (MDEV-25882):
  - adaptive_hash_index in INFORMATION_SCHEMA.INNODB_METRICS
  - Innodb_adaptive_hash_non_hash_searches in INFORMATION_SCHEMA.GLOBAL_STATUS

Replication

- Semisync replica recovery is introduced. rpl-semi-sync-slave-enabled = ON server executes a special recovery branch to guarantee its consistency with a primary server (MDEV-21117)

General

- Error messages now use "MariaDB" instead of "MySQL" (MDEV-22189)
- Implement `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK` for views (MDEV-15888)
- All statements can be prepared, except `PREPARE`, `EXECUTE`, and `DEALLOCATE / DROP PREPARE` (MDEV-16708)

Changelog

For a complete list of changes and bugfixes made in MariaDB 10.6.2, with links to detailed information on each push, see the changelog.

Contributors

7.0.6.2.15 MariaDB 10.6.1 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.1 | Release Notes | Changelog | Overview of 10.6

Release date: 21 May 2021

MariaDB 10.6 is the current development series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.1 is a ***Beta*** release.

Do not use *beta* releases in production!

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Register now for our MariaDB Community Server 10.6 webinar to be held 2021-06-29 and be one of the first to see the biggest features coming in MariaDB Community Server 10.6, with an exclusive opportunity to have your questions answered by MariaDB engineering and product leads.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

Atomic DDL

- CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement is fully completed, or everything is reverted to it's original state. Note that when deleting multiple tables with DROP TABLE, only each individual drop is atomic, not the full list of tables). (MDEV-23842).

Replication, Galera and Binlog

- The delay between binary log purges can now be specified with much greater precision. The system variable binlog_expire_logs_seconds is introduced as a form of alias for expire_logs_days, which now accepts a precision of 1/1000000 days (MDEV-19371)
- Allow transition from unencrypted to TLS Galera cluster communication without cluster downtime (MDEV-22131)
- DDL information logged on all Galera cluster nodes if wsrep_debug is set to SERVER and wsrep_OSU_method is 'TOI' (MDEV-9609)

- For the mysqlbinlog / mariadb-binlog `--base64-output` option, removed the deprecated `always` option, and changed the default to `auto` (MDEV-25222)

Oracle Compatibility

- ADD_MONTHS() added (MDEV-20025)
- TO_CHAR() added (MDEV-20017)
- SYS_GUID() added (MDEV-24285)
- MINUS is mapped to EXCEPT in UNION (MDEV-20021)
- ROWNUM function returns the current number of accepted rows in the current context (MDEV-24089)

Character Sets

- The `utf8` character set (and related collations) is now by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable (MDEV-8334)

Clients

- For clients such as mysql / mariadb, the connection property specified via the command line (e.g. --port=3306) will now force its type (MDEV-14974)

Changelog

For a complete list of changes made in MariaDB 10.6.1, with links to detailed information on each push, see the changelog.

7.0.6.2.16 MariaDB 10.6.0 Release Notes

The most recent release of MariaDB 10.6 is:
MariaDB 10.6.16 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.6.0 | Release Notes | Changelog | Overview of 10.6

Release date: 26 Apr 2021

MariaDB 10.6 is the current development series of MariaDB. It is an evolution of MariaDB 10.5 with several entirely new features.

MariaDB 10.6.0 is an ***Alpha*** release.

Do not use *alpha* releases in production!

For an overview of MariaDB 10.6 see the What is MariaDB 10.6? page.

Thanks, and enjoy MariaDB!

Notable Changes

This is the first alpha release in the MariaDB 10.6 series.

Notable changes of this release include:

SQL Syntax

- Indexes can be ignored (MDEV-7317)
- Implement SQL-standard SELECT ... OFFSET ... FETCH (MDEV-23908)
- Add SELECT ... SKIP LOCKED syntax (InnoDB only) (MDEV-13115)
- JSON_TABLE, used to extract JSON data based on a JSON path expression and to return it as a relational table (MDEV-17399)

Oracle Compatibility

- Anonymous subqueries in a FROM clause (no AS clause) are permitted in ORACLE mode

Storage Engines

- TokuDB has been removed (MDEV-19780)
- CassandraSE has been removed (MDEV-23024)

InnoDB

- Optimization to speed up inserts into an empty table (MDEV-515)
- Make InnoDB's COMPRESSED row format read-only by default (MDEV-23497)
- Information Schema SYS_TABLESPACES now directly reflects the filesystem, and SYS_DATAFILES has been removed (MDEV-22343)
- `innodb_flush_method=O_DIRECT` is enabled by default (MDEV-24854), and `liburing` replaces `libaio` on recent Linux kernels (MDEV-24883).
- The InnoDB transaction deadlock reporter was improved (MDEV-24738).
- The old MariaDB 5.5-compatible `innodb` checksum is no longer supported, only `crc32` and `full_crc32`. Removed the `*innodb` and `*none` options from innodb_checksum_algorithm, and the `--strict-check` / `-C` and `--write` / `-w` options from innochecksum (MDEV-25105)

Replication, Galera and Binlog

- Increase master_host limit to 255, user to 128 (MDEV-24312)
- The wsrep_mode system variable, for turning on WSREP features which are not part of default behavior (including the experimental Aria replication) (MDEV-20008, MDEV-20715, MDEV-24946)

Sys Schema

- Bundle sys-schema, a collection of views, functions and procedures to help administrators get insight into database usage. (MDEV-9077)

Performance Schema

- Merged replication instrumentation and tables (MDEV-16437, MDEV-20220)

General

- Do not resend unchanged resultset metadata for prepared statements (MDEV-19237)
- --bind-address=hostname now listens on both IPv6 and IPv4 addresses (MDEV-6536)
- Support systemd socket activation (MDEV-5536)
- For the GSSAPI plugin, support AD or local group name, and SIDs on Windows (MDEV-23959)
- Check for $MARIADB_HOME/my.cnf (MDEV-21365)

- max_recursive_iterations has been reduced to 1000 (MDEV-17239)
- Setting system variables to negative values will no longer set them to the maximum value (MDEV-22219)

Galera

- wsrep_mode variable for turning on WSREP features which are not part of default behavior.
- wsrep_strict_ddl has been deprecated. Use wsrep_mode=STRICT_REPLICATION instead.

InnoDB Variables

The following deprecated variables have been removed (MDEV-23397):

- innodb_adaptive_max_sleep_delay
- innodb_background_scrub_data_check_interval
- innodb_background_scrub_data_compressed
- innodb_background_scrub_data_interval
- innodb_background_scrub_data_uncompressed
- innodb_buffer_pool_instances
- innodb_commit_concurrency
- innodb_concurrency_tickets
- innodb_file_format
- innodb_large_prefix
- innodb_log_checksums
- innodb_log_compressed_pages
- innodb_log_files_in_group
- innodb_log_optimize_ddl
- innodb_page_cleaners
- innodb_replication_delay
- innodb_scrub_log
- innodb_scrub_log_speed
- innodb_thread_concurrency
- innodb_thread_sleep_delay
- innodb_undo_logs

Changelog

For a complete list of changes made in MariaDB 10.6.0, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.6.0, see the MariaDB Foundation release announcement.

Do not use *alpha* releases in production!

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7 MariaDB Server 10.5

Changes and Improvements in MariaDB 10.5

Current Version: 10.5.23 | Status: Stable (GA) | Release Date: 13 Nov 2023

Release Notes - MariaDB 10.5 Series

There are 2 related questions.

7.0.7.1 Changes and Improvements in MariaDB 10.5

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Contents

MariaDB 10.5 is a previous major stable version The first stable release was in June 2020, and it will be maintained until June 2025.

Upgrading

- See Upgrading Between Major MariaDB Versions and Upgrading from MariaDB 10.4 to MariaDB 10.5.

Implemented Features

ColumnStore

- This release of MariaDB Server includes the MariaDB ColumnStore storage engine. *Note, that plugins have independent maturity levels and MariaDB ColumnStore in 10.5.4 has **Beta** maturity.*

Binaries Named mariadb (mysql Symlinked)

- All binaries previously beginning with `mysql` now begin with `mariadb`, with symlinks for the corresponding `mysql`

command. (MDEV-21303)
- When starting the MariaDB server via the systemd service it will be started using the `mariadbd` binary name, so this will now show up in the system process list instead of `mysqld`
- Same for the `mariadbd-safe` wrapper script. Even when called via the `mysqld_safe` symlink, it will start the actual server process as `mariadbd`, not `mysqld` now. This also affects startup via system service init scripts on platforms that don't yet have switched to SystemD

INET 6 Data Type

- New INET6 data type for storing IPv6 addresses (MDEV-274)

Amazon S3

- The S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API (MDEV-22606)
- Both S3 tables and partitioned S3 tables are discoverable. This means that if you create a partitioned S3 table, both the partitioned table and its partitions can be directly used by another server that has access to the S3 storage. (MDEV-22088)

Privileges Made More Granular

- Split SUPER privilege to smaller privileges (MDEV-21743). New privileges were added so that more fine grained tuning of what each user can do can be applied:
  - BINLOG ADMIN
  - BINLOG REPLAY
  - CONNECTION ADMIN
  - FEDERATED ADMIN
  - READ_ONLY ADMIN
  - REPLICATION MASTER ADMIN
  - REPLICATION SLAVE ADMIN
  - SET USER
- The REPLICATION CLIENT privilege was renamed to BINLOG MONITOR. The old syntax is understood for compatibility (MDEV-21743).
- The SHOW MASTER STATUS statement was renamed to SHOW BINLOG STATUS (MDEV-21743). The old syntax is understood for compatibility.
- A number of statements changed the privileges that they require. The old privileges were historically inappropriately chosen in the upstream. 10.5.2 fixes this problem. Note, these changes are incompatible to previous versions. A number of GRANT commands might be needed after upgrade.
  - SHOW BINLOG EVENTS now requires the BINLOG MONITOR privilege (required REPLICATION SLAVE prior to 10.5.2).
  - SHOW SLAVE HOSTS now requires the REPLICATION MASTER ADMIN privilege (required REPLICATION SLAVE prior to 10.5.2).
  - SHOW SLAVE STATUS now requires the REPLICATION SLAVE ADMIN or the SUPER privilege (required REPLICATION CLIENT or SUPER prior to 10.5.2).
  - SHOW RELAYLOG EVENTS now requires the REPLICATION SLAVE ADMIN privilege (required REPLICATION SLAVE prior to 10.5.2).
- In order to help the server understand which version a privilege record was written by, the mysql.global_priv.priv field contains a new JSON field, `version_id` (MDEV-21704)
- SHOW PRIVILEGES now correctly lists the `Delete history` privilege, rather than displaying it as `Delete versioning rows`. (MDEV-20382)

InnoDB: Performance Improvements etc.

- Extend SHOW STATUS LIKE 'Innodb_%' (MDEV-18582)
- Clean up INFORMATION_SCHEMA.INNODB_ tables (MDEV-19940)
- Doublewrite buffer is unnecessarily used for newly (re)initialized pages (MDEV-19738)
- Defer change buffer merge until pages are requested (MDEV-19514)
- Remove dummy tablespace for the redo log (MDEV-18115)
- Optimize access to InnoDB page header fields (MDEV-21133)
- Remove multiple InnoDB buffer pool instances (MDEV-15058)
  - Columns that indicated the buffer pool instance from the Information Schema innodb_buffer_page, innodb_buffer_page_lru, innodb_buffer_pool_stats, innodb_cmpmem and innodb_cmpmem_reset tables now return a dummy value of `0`.
- Remove buf_page_t::newest_modification (MDEV-21132)
- Replace recv_sys_t::addr_hash with a std::map (MDEV-19586)

- Obsolete internal parser for FK in InnoDB (MDEV-20480)
- InnoDB thread pool for background tasks (MDEV-16264)
- An upgrade will only be possible after a clean shutdown. mariabackup --prepare will not work with backups taken before version 10.5.2.
- Efficient InnoDB redo log record format (MDEV-12353)
- Improve InnoDB redo log group commit performance (MDEV-21534)
- Do not acquire InnoDB record locks when covering table locks exist (MDEV-14479)
- Issue a message on changing deprecated innodb_log_files_in_group (MDEV-21990)
- Optimize append only files for NVDIMM (MDEV-17084)
- Avoid writing freed InnoDB pages (MDEV-15528)

InnoDB New Defaults for Variables

- innodb_adaptive_hash_index now defaults to `OFF` (MDEV-20487)
- innodb_checksum_algorithm now defaults to `full_crc32` (MDEV-19534)

InnoDB Removed or Deprecated Variables

- innodb_buffer_pool_instances
- innodb_checksums (MDEV-19534)
- innodb_locks_unsafe_for_binlog (MDEV-19544)
- innodb_log_checksums (MDEV-19543)
- innodb_log_files_in_group (MDEV-14425 & MDEV-20907)
- innodb_log_optimize_ddl (MDEV-19747)
- innodb_rollback_segments (MDEV-19570)
- innodb_scrub_log and innodb_scrub_log_speed (MDEV-21870)
- Remove INFORMATION_SCHEMA.INNODB_TABLESPACES_SCRUBBING table and deprecate and ignore:
- innodb-background-scrub-data-uncompressed
- innodb-background-scrub-data-compressed
- innodb-background-scrub-data-interval
- innodb-background-scrub-data-check-interval (MDEV-15528)
- innodb_stats_sample_pages (MDEV-19551)
- innodb_undo_logs (MDEV-19570)
- innodb_thread_concurrency
- innodb_commit_concurrency
- innodb_replication_delay
- innodb_concurrency_tickets
- innodb_thread_sleep_delay
- innodb_adaptive_max_sleep_delay (MDEV-23379)

Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables

- Memory (MDEV-16431)
- Meta data locking (MDL) (MDEV-16432)
- Prepared statements (ps) (MDEV-16433)
- [show] status instrumentation and tables (MDEV-16438)
- Stored procedures (MDEV-16434)
- Sxlocks (MDEV-16436)
- Transactions (MDEV-16435)
- User variables (MDEV-16439)

Galera: Full GTID Support

- Add full GTID support to Galera cluster (commit). With this feature all nodes in a cluster will have the same GTID for replicated events originating from the cluster. Also added a new variable, `wsrep_gtid_seq_no` , to manually update the WSREP GTID sequence number in the cluster (similar to how the `gtid_seq_no` variable is used for non-WSREP transactions).
- Add new mode to wsrep_OSU_method in which Galera checks storage engine of the affected table (MDEV-20051)
- Galera: Replicate MariaDB GTID to other nodes in the cluster (MDEV-20720)

Binary Log and Replication: More Metadata

- slave_parallel_mode now defaults to `optimistic` (MDEV-18648).
- Make REPLICA a synonym for SLAVE in SQL statements (MDEV-20601)

- `ENFORCE` option for slave_run_triggers_for_rbr (MDEV-21833)
- Extended binlog metadata (MDEV-20477) to include new fields. This was done to solve replication issues when the Master and Slave table had different definitions for a column which could lead to data loss (MDEV-19708). It also enables us to do better replication with pluggable data types in the future.
  - The new metadata fields are:
    - Signedness of Numeric Columns
    - Character Set of Character Columns and Binary Columns
    - Column Name
    - String Value of SET Columns
    - String Value of ENUM Columns
    - Primary Key
    - Character Set of SET Columns and ENUM Columns
    - Geometry Type
  - Also added a new global variable, binlog_row_metadata to control the amount of metadata logged. Possible values are:
    - `FULL` - all metadata is logged
    - `MINIMAL` - only metadata required by a worker is logged
    - `NO_LOG` - No metadata is logged (default)
- Binary log DDL entries can now be marked that they should be ignored if the target table doesn't exist (implicit `IF EXISTS`).
- mariadb-binlog output is extended to show all replication flags. Example of output: `SET @@session.foreign_key_checks=1, @@session.sql_auto_is_null=0, @@session.unique_checks=1, @@session.autocommit=1, @@session.check_constraint_checks=1, @@session.sql_if_exists=0/*!*/`.
- SHOW BINLOG EVENTS and SHOW RELAYLOG EVENTS are extended to show replication flags.

Syntax

- INSERT ... RETURNING (MDEV-10014) - returns SELECT of inserted rows (analogous to DELETE ... RETURNING)
- REPLACE ... RETURNING (MDEV-10014)
- EXCEPT ALL and INTERSECT ALL (MDEV-18844)
- Application period tables: WITHOUT OVERLAPS (MDEV-16978)
- Setup default partitions for system versioning (MDEV-19903)
- Database comments in CREATE DATABASE and ALTER DATABASE statements (MDEV-307)
- ALTER TABLE ... RENAME INDEX / KEY (MDEV-7318)
- ALTER TABLE ... RENAME COLUMN (MDEV-16290)
- ALTER TABLE and RENAME TABLE now support `IF EXISTS`.
- Add VISIBLE attribute for indexes in CREATE TABLE (MDEV-22199)
- Recursive CTE cycle detection using CYCLE clause (MDEV-20632)
- RELEASE_ALL_LOCKS hold by GET_LOCK() (MDEV-10569)
- Fix REFERENCES constraint in column definition (MDEV-20729)

JSON

- Added JSON_ARRAYAGG. This returns a JSON array containing an element for each value in a given set of JSON or SQL values. It acts on a column or an expression that evaluates to a single value.
- Added JSON_OBJECTAGG. This returns a JSON object containing key-value pairs. It takes two expressions that evaluate to a single value, or two column names, as arguments, the first used as a key, and the second as a value.

Thread Pool

- Information Schema tables (THREAD_POOL_GROUPS, THREAD_POOL_QUEUES, THREAD_POOL_STATS and THREAD_POOL_WAITS) for internals of generic thread_pool (MDEV-19313).

Performance Improvements

- Speed up binary row logging code
- Range optimizer speedups. Removed double calls to records_in_range() for some cases.
- Costs for using MEMORY tables updated to be more accurate
- Fixed that 'ref' access is preferred over 'range' for the same index.
- Improve connect speed (up to 25%). (MDEV-19515)

Query Optimizer

- Improve Protocol performance for numeric data by avoiding unnecessary character string conversions (MDEV-23162

, MDEV-23478)
- ANALYZE for statements is improved, now it also shows the time spent checking the WHERE clause and doing other auxiliary operations (MDEV-20854)
- Inferred IS NOT NULL predicates can be used by the range optimizer (MDEV-15777)
- Allow packed sort keys and values of non-sorted fields in the sort buffer (MDEV-21263 & MDEV-21580)
    - Makes filesort temporary files much smaller when VARCHAR, CHAR or BLOBs are used!

General

- The Information Schema SYSTEM_VARIABLES Table has a new column showing from which config file a variable derives its value (MDEV-12684)
- Switch Perl DBI scripts from DBD::mysql to DBD::MariaDB driver (MDEV-19755)
- The Aria max key length is now 2000 bytes, compared to 1000 bytes in MyISAM.
- DROP TABLE now reliably deletes table remnants inside a storage engine even if the .frm file is missing (MDEV-11412)
- Accelerated crc32() function for AMD64, ARMv8, POWER 8 (MDEV-22669)
- Binary tarball size has been reduced (MDEV-21943)

PCRE (Perl Compatible Regular Expressions)

- Migrate to PCRE2 (MDEV-14024), a newer version of the pcre library.

Variables

- For a list of all new variables, see System Variables Added in MariaDB 10.5 and Status Variables Added in MariaDB 10.5.
- The Information Schema SYSTEM_VARIABLES Table has a new column showing from which config file a variable derives its value (MDEV-12684).
- Port show_old_temporals from MySQL 5.6 (MDEV-19906). If set, old temporal data types (created with a pre-10.0 version of MariaDB) are displayed with a /* mariadb-5.3 */ comment.
- Numerous deprecated variables removed (MDEV-18650)
    - multi_range_count
    - thread_concurrency
    - timed_mutexes

Security Vulnerabilities Fixed in MariaDB 10.5

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2023-5157: MariaDB 10.5.17
- CVE-2023-22084: MariaDB 10.5.23

7.0.7.2.1 MariaDB 10.5.23 Release Notes

Download | Release Notes | Changelog | Overview of 10.5

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 10.5 is a previous *stable* series of MariaDB, maintained until June 2025. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.23 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)
- Race condition between page write completion and log checkpoint (MDEV-32511)
- After crash recovery, Checksum mismatch + Failing assertion: !i || prev_id + 1 == space_id, (MDEV-31851)
- Deadlock due to log_free_check(), involving trx_purge_truncate_rseg_history() and trx_undo_assign_low() (MDEV-32049)
- Write-ahead logging is broken for freed pages (MDEV-32552)
- X-lock on supremum for prepared transaction for RR (MDEV-30165)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)
- replication breaks when using optimistic replication and replica is a galera node (MDEV-31833)
- McAfee database vulnerability scan caused MariaDB crash with signal 6 (system abort) (MDEV-27004)

Data Definition

- MariaDB crash on calling function (MDEV-23902)

- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)
- vcol circular references lead to stack overflow (MDEV-31112)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2 (MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)
- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)
- main.order_by_pack_big fails with view-protocol (MDEV-31460)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)
- ASAN: heap-buffer-overflow & stack-buffer-overflow in `spider_db_mbase_row::append_to_str` | SIGSEGV's in `memmove_avx_unaligned_erms` from memcpy in `Binary_string::q_append`, in `Static_binary_string::q_append` and `my_strntoull10rnd_8bit` | Unknown error 12801 (MDEV-29502)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)

- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)
- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)
- Assertion `!m_null_value' failed in int FixedBinTypeBundle<FbtImpl>::cmp_item_fbt::compare or in cmp_item_inet6::compare (MDEV-27207)
- type_test.type_test_double fails with 'NUMERIC_SCALE NULL' (MDEV-22243)
- LeakSanitizer errors in get_quick_select or Assertion `status_var.local_memory_used == 0 || !debug_assert_on_not_freed_memory' failed (MDEV-32476)
- Update signal hander user info more compassion and correct url (MDEV-32535)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Security

- Fixes for the following security vulnerabilities :
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 10.5.23, with links to detailed information on each push, see the changelog .

Contributors

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.2 MariaDB 10.5.22 Release Notes

Download | Release Notes | Changelog | Overview of 10.5

Alternate download from mariadb.org

Release date: 14 Aug 2023

MariaDB 10.5 is a previous *stable* series of MariaDB, maintained until June 2025. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.22 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Ubuntu 18.04 LTS "Bionic"
- mariadb-dump --force doesn't ignore error as it should (MDEV-31092)
- 280 Bytes lost in mysys/array.c, mysys/hash.c, sql/sp.cc, sql/sp.cc, sql/item_create.cc, sql/item_create.cc, sql/sql_yacc.yy:10748 when using oracle sql_mode (MDEV-26186)
- SQL/PL package body does not appear in `I_S.ROUTINES.ROUTINE_DEFINITION` (MDEV-30662)
- Unexpected result when combining DISTINCT, subselect and LIMIT (MDEV-28285)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `` `const_item_cache == true' `` failed in `Item_func::fix_fields` (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- `get_partition_set` is never executed in `ha_partition::multi_range_key_create_key` due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a `mysql_list_fields("view")` call (MDEV-30159)
- `I_S.parameters` not immediatly changed updated after procedure change (MDEV-31064)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in `my_strnncoll_binary` on `SELECT ... COUNT` or `GROUP_CONCAT` (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in `Item_func_round::native_op` (MDEV-23838)
- Assertion `` `(length % 4) == 0' `` failed in `my_lengthsp_utf32` on `SELECT` (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type `'long long int'` ; cast to an unsigned type to negate this value to itself in `Item_func_mul::int_op` and `Item_func_round::int_op` (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- innochecksum dies with Floating point exception (MDEV-31641)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- innodb protection against dual processes accessing data insufficient (MDEV-31568)
- Assertion `` `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' `` failed in `btr_node_ptr_max_size` (MDEV-19216)
- `MODIFY COLUMN` can break FK constraints, and lead to unrestorable dumps (MDEV-31086)
- Recovery or backup failure after innodb_undo_log_truncate=ON (MDEV-31487)
- Assertion `'n & PENDING'` failed in `fil_space_t::set_needs_flush()` (MDEV-31442)
- `fil_node_open_file()` releases `fil_system.mutex` allowing other thread to open its file node (MDEV-31256)
- Freed data pages are not always being scrubbed (MDEV-31253)
- innodb_undo_log_truncate=ON fails to wait for purge of enough transaction history (MDEV-31355)
- SET GLOBAL innodb_undo_log_truncate=ON does not free space when no undo logs exist (MDEV-31382)
- innodb_read_ahead_threshold (linear read-ahead) does not work (MDEV-29967)
- `fil_ibd_create()` may hijack the file handle of an old file (MDEV-31347)
- innodb_undo_log_truncate=ON recovery results in a corrupted undo log (MDEV-31373)

- Foreign Key Constraint actions don't affect Virtual Column (MDEV-18114)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in `spider_db_open_item_field` and SIGSEGV in `spider_db_print_item_type`, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- Assertion `` `last_key_entry >= end_pos' `` failed in virtual bool `JOIN_CACHE_HASHED::put_record()` (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- Assertion `` `s->table->opt_range_condition_rows <= s->found_records' `` failed in `apply_selectivity_for_table` (MDEV-31449)
- Inconsistency between MRR and SQL layer costs can cause poor query plan (MDEV-31479)
- `MAX_SEL_ARG` memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with `lower_case_table_names=2` (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)
- Server crash in `store_length`, assertion failure in `Type_handler_string_result::sort_length` (MDEV-31743)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- On slave XA COMMIT/XA ROLLBACK fail to return an error in read-only mode (MDEV-30978)
- `rpl.rpl_manual_change_index_file` occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- KILL QUERY maintains nodes data consistency but breaks GTID sequence (MDEV-31075)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- InnoDB does not free UNDO after the fix of MDEV-30671 (MDEV-31234)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

7.0.7.2.4 MariaDB 10.5.20 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.20 | Release Notes | Changelog | Overview of 10.5

Release date: 10 May 2023

MariaDB 10.5 is a previous *stable* series of MariaDB, maintained until June 2025. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.20 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)
- rec_get_offsets() is not optimal (MDEV-30567)
- Performance regression in fil_space_t::try_to_close() introduced in MDEV-23855 (MDEV-30775)
- InnoDB recovery hangs when buffer pool ran out of memory (MDEV-30551)
- InnoDB undo log truncation fails to wait for purge of history (MDEV-30671)
- Fix miscount of doublewrites by Innodb_data_written (MDEV-31124)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)
- Race condition between buffer pool flush and log file deletion in mariadb-backup --prepare (MDEV-30860)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)
- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)
- Ensured SHOW-SLAVE-STATUS is processed on the parallel slave having a necessary mutex always intialized (MDEV-30620)
- Fixed the slave applier to report a correct error when gtid_slave_pos insert fails for some (engine) reasons (MDEV-31038)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301).
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- A GROUP BY query with `MIN(primary_key)` in select list and `primary_key<>const` in the WHERE could

produce wrong result when executed with "Using index for group-by" strategy (MDEV-30605)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Images

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-47015

Changelog

7.0.7.2.5 MariaDB 10.5.19 Release Notes

Download | Release Notes | Changelog | Overview of 10.5

Release date: 6 Feb 2023

MariaDB 10.5 is a previous *stable* series of MariaDB, maintained until June 2025. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.19 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.5.18 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, Fedora, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)
- innodb_undo_log_truncate=ON recovery and backup fixes (MDEV-29999, MDEV-30179, MDEV-30438)
- Upgrade after a crash is not supported (MDEV-24412)
- Remove InnoDB buffer pool load throttling (MDEV-25417)

- InnoDB shutdown hangs when the change buffer is corrupted (MDEV-30009)
- `innodb_fast_shutdown=0` fails to report change buffer merge progress (MDEV-29984)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- `mysqlbinlog --verbose` is made to show the type of compressed columns (MDEV-25277)
- Deadlock is resolved on replica involving `BACKUP STAGE BLOCK_COMMIT` and a committing user XA (MDEV-30423)

JSON

- JSON_PRETTY added as an alias for JSON_DETAILED (MDEV-19160)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Fedora 35.
- In this release repositories for Fedora 37 have been added.

Changelog

For a complete list of changes made in MariaDB 10.5.19, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.19, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.6 MariaDB 10.5.18 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.18 | Release Notes | Changelog | Overview of 10.5

Release date: 7 Nov 2022

MariaDB 10.5 is a previous *stable* series of MariaDB, maintained until June 2025. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.18 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

SSL

- The server no longer tolerates incorrectly configured SSL (MDEV-29811). If you have enabled SSL in `my.cnf` but have not configured it properly (for example, a certificate file is missing), MariaDB used to silently disable SSL, leaving you under impression that everything was fine and connections were secure. Since this release, MariaDB will fail to start if SSL is enabled, but cannot be switched on.

Backup

- mariabackup --compress hangs (MDEV-29043)
- Assertion on info.page_size failed in xb_delta_open_matching_space (MDEV-18589)

InnoDB

- InnoDB unnecessarily extends data files (MDEV-13013)
- Adaptive hash index MDEV-27700, MDEV-29384
- MVCC and locking MDEV-29666, MDEV-27927
- Virtual columns MDEV-29299, MDEV-29753
- InnoDB crash recovery fixes (MDEV-29438, MDEV-29475)
- InnoDB crash recovery fixes (MDEV-29559)
- MVCC and locking (MDEV-28709)
- Race condition between KILL and transaction commit (MDEV-29368)

Galera

- Galera updated to 26.4.13
- Galera server crashes after 10.3 > 10.4 upgrade (MDEV-29375)
- wsrep_incoming_addresses status variable prints 0 as port number if the port is not mentioned in wsrep_node_incoming_address system variable (MDEV-28868)

JSON

- JSON_VALUE() does not parse NULL properties properly (MDEV-27151)

Replication

- minor correction in unsafe warning message (MDEV-28827)
- False replication error-stop of REVOKE PRIVILEGES from a non-existing user on primary (MDEV-28530) in combination with a filtering replica is corrected
- SET DEFAULT ROLE replication is mended on a replica that filters system tables (MDEV-28294)
- XA COMMIT is not binlogged when the XA transaction has not updated any transaction engine (MDEV-25616)
- Concurrent CREATE TRIGGER statements made to binlog without any mixup (MDEV-25606)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).
- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Changelog

For a complete list of changes made in MariaDB 10.5.18, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.18, see the MariaDB Foundation release announcement.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.7 MariaDB 10.5.17 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now

Alternate download from mariadb.org

Download 10.5.17 | Release Notes | Changelog | Overview of 10.5

Release date: 15 Aug 2022

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.17 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB corruption due to lack of file locking (MDEV-28495)
- FULLTEXT search with apostrophe, and mandatory words (MDEV-20797)
- ALTER TABLE IMPORT TABLESPACE corrupts an encrypted table (MDEV-28779)

- ALTER TABLE wrong-result fix (MDEV-26294)
- Crash recovery fixes (MDEV-28668, MDEV-28731)

Replication

- explicit_defaults_for_timestamp is stored in binlog, so that `CREATE TABLE` on slave would always have the same effect as on master. (MDEV-29078)
- ER_SLAVE_INCIDENT error is specified now on slave to be seen with SHOW-SLAVE-STATUS (MDEV-21087)
- INCIDENT_EVENT is no longer binlogged when a being logged transaction can be safely rolledback (MDEV-21443)
- sequences related row-format events are made to correspond to binlog_row_image (MDEV-28487)
- Possible reason of FLUSH BINARY LOGS hang is eliminated (MDEV-28948)

Galera

- Possible to write/update with read_only=ON and not a SUPER privilege (MDEV-28546)
- Node crashes with Transport endpoint is not connected mysqld got signal 6 (MDEV-25068)
- Galera4 not able to report proper wsrep_incoming_addresses (MDEV-20627)
- Galera should replicate nextval()-related changes in sequences with INCREMENT <> 0, at least NOCACHE ones with engine=InnoDB (MDEV-27862)

Optimizer

- Server crash in JOIN_CACHE::free or in copy_fields (MDEV-23809)
  - Queries that use DISTINCT and an always-constant function like COLLATION(aggegate_func(...)) could cause a server crash. Note that COLLATION() is a special function - its value is constant even if its argument is not costant.
- Crash when using ANY predicand with redundant subquery in GROUP BY clause (MDEV-29139)
  - A query with a subuquery in this form could cause a crash:

```
... ANY (SELECT ... GROUP BY (SELECT redundant_subselect_here)) ...
```

- MariaDB Server SEGV on INSERT .. SELECT (MDEV-26427)
  - Certain queries in form "INSERT ... SELECT with_aggregate_or_window_func" could cause a crash.
- restore_prev_nj_state() doesn't update cur_sj_inner_tables correctly (MDEV-28749)
  - Subquery semi-join optimization could miss LooseScan or FirstMatch strategies for certain queries.
- Optimizer uses all partitions after upgrade to 10.3 (MDEV-28246)
  - For multi-table UPDATE or DELETE queries, the optimizer failed to apply Partition Pruning optimization for the table that is updated or deleted from.
- Range optimizer regression for key IN (const, ...) (MDEV-25020)
  - The issue can be observed on MariaDB 10.5.9 and later versions which have the fix for MDEV-9750. That fix introduceds optimizer_max_sel_arg_weight.
  - If one sets optimizer_max_sel_arg_weight to a very high value or zero (which means "unlimited") and runs queries that produce heavy-weight graphs, they can observe a performance slowdown, e.g.:

```
table.keyXpartY [NOT] IN ( ... )
```

- Wrong result with table elimination combined with not_null_range_scan (MDEV-28858)
  - If one runs with optimizer_switch='not_null_range_scan=on' (which is not enabled by default), a query that does a join and has const tables could produce a wrong result.

CONNECT

- CONNECT Engine now supports INSERT IGNORE with Mysql Table type (MDEV-27766)

mariadb Client

- New mariadb client option, `-enable-cleartext-plugin` . Option does not do anything, and is for MySQL-compatibility purposes only.

General

- explicit_defaults_for_timestamp now also has a session scope, not only global (MDEV-29225)
- MariaDB can be built with OpenSSL 3.0

- HELP was updated to include the latest content
- Crash in JSON_EXTRACT (MDEV-29188)
- ALTER TABLE ALGORITHM=NOCOPY does not work after upgrade (MDEV-28727)
- Server crash upon CREATE VIEW with unknown column in ON condition (MDEV-29088)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Debian 10 "Buster" for ppc64el

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-5157
  - CVE-2022-32082
  - CVE-2022-32089
  - CVE-2022-32081
  - CVE-2018-25032
  - CVE-2022-32091
  - CVE-2022-32084
  - CVE-2022-38791

Changelog

For a complete list of changes made in MariaDB 10.5.17, with links to detailed information on each push, see the changelog.

For a full list of contributors to MariaDB 10.5.17, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.8 MariaDB 10.5.16 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.16 | Release Notes | Changelog | Overview of 10.5

Release date: 20 May 2022

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.16 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- innodb_disallow_writes removed (MDEV-25975)
- InnoDB gap locking fixes (MDEV-20605, MDEV-28422)
- InnoDB performance improvements (MDEV-27557, MDEV-28185)

Replication

- Server initialization time gtid_slave_pos purge related reason of crashing in binlog background thread is removed (MDEV-26473)
- Shutdown of the semisync master can't produce inconsistent state anymore (MDEV-11853)
- Binlogs disappear after rsync IST (MDEV-28583)
- master crash is eliminated in compressed semisync replication protocol with packet counting amendment (MDEV-25580)
- OPTIMIZE on a sequence does not cause counterfactual ER_BINLOG_UNSAFE_STATEMENT anymore (MDEV-24617)
- Automatically generated Gtid_log_list_event is made to recognize within replication event group as a formal member (MDEV-28550)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE using two or more unique key values at a time with MIXED format binlogging is corrected (MDEV-28310)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE stops issuing unnecessary "Unsafe statement" with MIXED binlog format (MDEV-21810)
- Incomplete replication event groups are detected to error out by the slave IO thread (MDEV-27697)
- mysqlbinlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed with the actual bytes (MDEV-14608)

Backup

- Incorrect binlogs after Galera SST using rsync and mariabackup (MDEV-27524)
- mariabackup does not detect multi-source replication slave (MDEV-21037)
- Useless warning "InnoDB: Allocated tablespace ID <id> for <tablename>, old maximum was 0" during backup stage (MDEV-27343)
- mariabackup prepare fails for incrementals if a new schema is created after full backup is taken (MDEV-28446)

Optimizer

- A SEGV in Item_field::used_tables/update_depend_map_for_order... (MDEV-26402)
- ANALYZE FORMAT=JSON fields are incorrect for UNION ALL queries (MDEV-27699)
- Subquery in an UPDATE query uses full scan instead of range (MDEV-22377)
- Assertion `item1->type() == Item::FIELD_ITEM ... (MDEV-19398)
- Server crashes in Expression_cache_tracker::fetch_current_stats (MDEV-28268)
- MariaDB server crash at Item_subselect::init_expr_cache_tracker (MDEV-26164, MDEV-26047)
- Crash with union of my_decimal type in ORDER BY clause (MDEV-25994)
- SIGSEGV in st_join_table::cleanup (MDEV-24560)
- Assertion `!eliminated' failed in Item_subselect::exec (MDEV-28437)

General

- Server error messages are now available in Chinese (MDEV-28227)
- For RHEL/CentOS 7, non x86_64 architectures are no longer supported upstream and so our support will also be dropped with this release
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Debian 9 "Stretch", Ubuntu 21.10 "Impish", and Fedora 34

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46669
  - CVE-2022-27376
  - CVE-2022-27377
  - CVE-2022-27378
  - CVE-2022-27379
  - CVE-2022-27380
  - CVE-2022-27381
  - CVE-2022-27382

- CVE-2022-27383
- CVE-2022-27384
- CVE-2022-27386
- CVE-2022-27387
- CVE-2022-27444
- CVE-2022-27445
- CVE-2022-27446
- CVE-2022-27447
- CVE-2022-27448
- CVE-2022-27449
- CVE-2022-27451
- CVE-2022-27452
- CVE-2022-27455
- CVE-2022-27456
- CVE-2022-27457
- CVE-2022-27458
- CVE-2022-32087
- CVE-2022-32086
- CVE-2022-32085
- CVE-2022-32083
- CVE-2022-32088

Changelog

7.0.7.2.9 MariaDB 10.5.15 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.15 | Release Notes | Changelog | Overview of 10.5

Release date: 12 Feb 2022

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.15 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

- This release fixes a blocking problem with the MariaDB 10.5.14 release when manually running mariadb-upgrade. (MDEV-27789)
- See MariaDB 10.5.14 for other changes since the previous release.

InnoDB

- Set innodb_change_buffering=none by default (MDEV-27734)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46665
  - CVE-2021-46664
  - CVE-2021-46661
  - CVE-2021-46668
  - CVE-2021-46663

Changelog

For a complete list of changes made in MariaDB 10.5.15, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.15, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.10 MariaDB 10.5.14 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.14 | Release Notes | Changelog | Overview of 10.5

Release date: 9 Feb 2022

This release is no longer available for download after a problem was noticed when manually running mariadb-upgrade. See MDEV-27789 for more details.

Please use a later release.

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.14 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- --skip-symbolic-links does not disallow `.isl` file creation (MDEV-26870)
- Indexed CHAR columns are broken with NO_PAD collations (MDEV-25440)
- insert-intention lock conflicts with waiting ORDINARY lock (MDEV-27025)
- Crash recovery improvements (MDEV-26784, MDEV-27022, MDEV-27183, MDEV-27610)

Galera

- Galera updated to 26.4.11
- Galera SST scripts should use ssl_capath (not ssl_ca) for CA directory (MDEV-27181)
- Alter Sequence do not replicate to another nodes with in Galera Cluster (MDEV-19353)
- Galera crash - Assertion. Possible parallel writeset problem (MDEV-26803)
- CREATE TABLE with FOREIGN KEY constraint fails to apply in parallel (MDEV-27276)
- Galera cluster node consider old server_id value even after modification of server_id `[wsrep_gtid_mode=ON]` (MDEV-26223)

Replication

- Seconds behind master corrected from artificial spikes at relay-log rotation (MDEV-16091)
- Statement rollback in binlog when transaction creates or drop temporary table is set right (MDEV-26833)
- CREATE-or-REPLACE SEQUENCE is made to binlog with the DDL flag to stabilize its parallel execution on slave (MDEV-27365)

Packaging & Misc

- prohibition running two upgrades in parallel (MDEV-27068, MDEV-27107, MDEV-27279)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Ubuntu 21.04 Hirsute, CentOS 8, and Fedora 33
- mariadb_repo_setup script updated to version 2022-02-08, with the following fixes and enhancements:
  - Default location of the script has been moved to: https://r.mariadb.com/downloads/mariadb_repo_setup (old location is deprecated, but still works)
  - The GPG keyring file, used with Debian and Ubuntu repositories, has moved to: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg and the checksum for the file can be found at: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg.sha256
  - Support for RHEL and SLES aarch64 repositories added
  - New function added to verify that the MariaDB Server version, if specified on the command line, follows the correct naming and that a corresponding repository actually exists.
  - Fixed repository pinning for Ubuntu and Debian repositories
  - MariaDB Server 10.7 is now the default server version

Docker Library

- Faster initialization by disabling binary logging during initialization (MDEV-27074)
- mysql_upgrade can be run if needed using the environment variable MARIADB_AUTO_UPGRADE=1 (MDEV-25670)
- A healthcheck script /usr/local/bin/healthcheck.sh is installed in the container with various checking options (MDEV-25434)
- mysql@localhost user is created with the environment variable MARIADB_MYSQL_LOCALHOST_USER=1 and additional grants (beyond USAGE) with MARIADB_MYSQL_LOCALHOST_GRANTS={global grant list} (MDEV-27732)
- skip innodb buffer pool loads/dumps on temporary startup/shutdown for faster startup/initialization, and accurate "healthcheck.sh --innodb_buffer_pool_loaded"
- change group ownership on datadir/socket dir (issue #401)
- log note about note on Securing system users, mysql_secure_installation not required (reddit suggestion)
- speed up Docker Library initialization of timezones (MDEV-27608, MDEV-23326)

Security

- Fixes for the following security vulnerabilities:

- CVE-2022-24052
- CVE-2022-24051
- CVE-2022-24050
- CVE-2022-24048
- CVE-2021-46659
- CVE-2022-0778
- CVE-2022-21595

7.0.7.2.11 MariaDB 10.5.13 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.13 | Release Notes | Changelog | Overview of 10.5

Release date: 8 Nov 2021

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.13 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

Galera

- Fix for `WSREP: invalid state ROLLED_BACK (FATAL)` (MDEV-25114)

InnoDB

- `ALTER TABLE…IMPORT TABLESPACE` fixes (MDEV-18543, MDEV-20931, MDEV-26131, MDEV-26621)
- `innodb_undo_log_truncate` fixes (MDEV-26445, MDEV-26450, MDEV-26672, MDEV-26864)
- Page I/O performance fixes (MDEV-25215, MDEV-26547, MDEV-26626, MDEV-26819)
- Replication timeouts with `XA PREPARE` (MDEV-26682)

Replication

- Memory hogging on slave by ROW event applier is eliminated (MDEV-26712)
- `mysql --binary-mode` now properly handles `\\0` in data (MDEV-25444)
- Fixes race condition between `SHOW BINARY LOGS` and `RESET MASTER` (MDEV-20215)
- Missed statement rollback in case transaction drops or create temporary table is corrected (MDEV-26833)

Audit Plugin

- The `QUERY_DDL` server_audit_events setting now logs `CREATE/DROP [PROCEDURE / FUNCTION / USER]` statements. See MariaDB Audit Plugin - Log Settings. (MDEV-23457)

Packaging & Misc

- Session tracking flag in OK_PACKET (MDEV-26868)
- Some views force server (and mysqldump) to generate invalid SQL for their definitions (MDEV-26299)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-35604
  - CVE-2021-46667
  - CVE-2021-46662
  - CVE-2022-27385
  - CVE-2022-27385
  - CVE-2022-31624

Changelog

For a complete list of changes made in MariaDB 10.5.13, with links to detailed information on each push, see the changelog.

Contributors

7.0.7.2.12 MariaDB 10.5.12 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.12 | Release Notes | Changelog | Overview of 10.5

Release date: 6 Aug 2021

Warning: This version can cause InnoDB file corruption on FreeBSD and on AIX. If you are using AIX, please, stick to an earlier release, or upgrade to a more recent release. If you are using FreeBSD, upgrade to the bugfix release (the version ends with _1) of the mariadb-server from the Ports Collection. See MDEV-26537.

MariaDB 10.5 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.12 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB no longer acquires advisory file locks by default (MDEV-24393)
- Encryption: Automatically disable key rotation checks for file_key_management plugin (MDEV-14180)
- Some fixes from MySQL 5.7.35 (MDEV-26205)
- Fixed scrubbing on AIX (MDEV-26110)
- Improved page flushing performance (MDEV-25954, MDEV-25948, MDEV-25801, MDEV-25113, MDEV-26004)

Optimizer

- A query that uses ORDER BY .. LIMIT clause and "Range checked for each record optimization" could produce incorrect results under some circumstances (MDEV-25858)
- Queries that have more than 32 equality conditions comparing columns of different tables ("tableX.colX=tableY.colY) could cause a stack overrun in the query optimizer (MDEV-17783, MDEV-23937)
- "Condition pushdown into derived table" optimization cannot be applied if the expression being pushed refers to a derived table column which is computed from expression that has a stored function call, @session variable reference, or other similar construct. The fix for MDEV-25969 makes it so that only the problematic part of the condition is not pushed. The rest of the condition is now pushed. (MDEV-25969)
- A query with window function on the left side of the subquery could cause a crash. (MDEV-25630)
- Fixed the issue fixed in MySQL Bug #76803: DML or locking SELECT statements that use outer joins could produce this warning in the error log: `[ERROR] InnoDB: Unlock row could not find a 3 mode lock on the record.` (MDEV-26106)

Packaging & Misc

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Ubuntu 20.10 Groovy
- Debian 11 Bullseye repositories added
- Galera updated to 26.4.9
- Linux on IBM Z (s390x) architecture added with releases on Ubuntu-20.04 Focal

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-2372
  - CVE-2021-2389
  - CVE-2021-46658

Changelog

For a complete list of changes made in MariaDB 10.5.12, with links to detailed information on each push, see the changelog.

be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.13 MariaDB 10.5.11 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.11 | Release Notes | Changelog | Overview of 10.5

Release date: 23 Jun 2021

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.11 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Items

This version of MariaDB is being released now to fix the following two regressions:

- Table alias from previous statement interferes later commands (MDEV-25672)
- Join using derived with aggregation returns incorrect results (MDEV-25714)

In addition to the above, this release also contains the following fixes:

InnoDB

- InnoDB spatial indexes miss large geometry fields after MDEV-25459 (MDEV-25758)
- Double free of transaction during truncate operation (MDEV-25663)
- Double free of table when inplace alter FTS add index fails (MDEV-25721)
- Potential hang in purge for virtual columns (MDEV-25664)
- Change buffer records are lost under heavy load (MDEV-25783)
- Not applying INSERT_REUSE_REDUNDANT (MDEV-25745)
- InnoDB recovery fails with `[ERROR] InnoDB: Not applying INSERT_REUSE_REDUNDANT due to corruption` (MDEV-25745)
- CHECK TABLE harvests InnoDB: Index 'abdcef' contains 10001 entries, should be 10000 (MDEV-25783)

Replication

- Do not replicate killed multi-table OPTIMIZE TABLE when the signal arrives before any table has been processed (MDEV-22530)
- Fix optimistic parallel applier to not deadlock on admin commands OPTIMIZE, REPAIR, and ANALYZE (MDEV-17515)
- Backport MDEV-20821 parallel slave server shutdown hang (MDEV-22370)
- Removed deprecated `--base64-output` to correct BINLOG clause in mysqlbinlog output (MDEV-25222)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46666
  - CVE-2021-46657

Changelog

For a complete list of changes made in MariaDB 10.5.11, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.11, see the MariaDB Foundation release announcement.

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.14 MariaDB 10.5.10 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.10 | Release Notes | Changelog | Overview of 10.5

Release date: 7 May 2021

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.10 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

- ST_DISTANCE_SPHERE for calculating the spherical distance between two geometries (point or multipoint) on a sphere (MDEV-13467)
- Crash with invalid multi-table update of view in 2nd execution of SP (MDEV-24823)
- Incorrect name resolution for subqueries in ON expressions (MDEV-25362)
- Complex query in Store procedure corrupts results (MDEV-25182)
- `DELETE HISTORY` may delete current data on system-versioned table (MDEV-25468)
- Crashes with nested table value constructors (MDEV-22786)
- Server crashes in `thd_clear_errors()` (MDEV-23542)
- The statement set `password=password('')` executed in PS mode fails in case it is run by a user with expired password (MDEV-25197)

mariabackup

- RENAME TABLE causes "Ignoring data file" messages (MDEV-25568)

InnoDB

- Deprecated the `*innodb` and `*none` options in innodb_checksum_algorithm (MDEV-25106)
- MVCC read from index on CHAR or VARCHAR wrongly omits rows (MDEV-25459)
- Race conditions in persistent statistics (MDEV-10682, MDEV-18802, MDEV-25051)

- Sequence created by one connection remains invisible to another (MDEV-24545)
- innodb_flush_method=O_DIRECT fails on compressed tables (MDEV-25121)
- RESET MASTER hangs (MDEV-24302)
- InnoDB crash recovery fixes (MDEV-25031, MDEV-25110)

Replication

- Replication Heartbeat event was uncapable to cary 4GB+ offsets (MDEV-16146)
- FLUSH LOGS race against Binlog checkpoint event creation (MDEV-24526)
- slave_compressed_protocol did not work correctly with semi-sync (MDEV-24773)
- DROP TABLE should not cause "Query caused different errors on master and slave" on slave when it failed on master (MDEV-25530)
- Killing server during RESET MASTER may lose MyRocks transaction (MDEV-25305)

Galera

- Galera updated to 26.4.8
- SET PASSWORD command fail with wsrep api (MDEV-25258)
- Long BF log wait turns on InnoDB Monitor output without telling, never turns it off (MDEV-25319)
- Assertion `` `state_ == s_exec' `` failed in `wsrep::client_state::start_transaction` (MDEV-22227)
- Frequently Crashing Mariadb Cluster 10.4.18 (MDEV-24980)
- Signal 11 on `TABLE_LIST::placeholder()` (MDEV-24878)
- `ALTER TABLE` not replicated with Galera in MariaDB 10.5.9 (MDEV-24956)
- "Flush SSL" command doesn't reload wsrep cert (MDEV-22668)
- Avoid unnecessary rollbacks with SR (MDEV-25553)

Packaging & Misc

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Ubuntu 16.04 Xenial and Fedora 32
- Ubuntu 21.04 Hirsute and Fedora 34 repositories added

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-2166
  - CVE-2021-2154
  - CVE-2022-21451

MongoDB protocol support files for the CONNECT engine are missing in this release.
If you want to use CONNECT engine with MongoDB, you need to download
Mongo2.jar or Mongo3.jar and put a path to this file into the `connect_class_path` in the `my.cnf`.

Changelog

For a complete list of changes made in MariaDB 10.5.10, with links to detailed information on each push, see the changelog.

7.0.7.2.15 MariaDB 10.5.9 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.9 | Release Notes | Changelog | Overview of 10.5

Release date: 22 Feb 2021

Last month long-time MariaDB VP of Engineering, Rasmus Johansson, passed due to complications from cancer. His loss has been felt keenly by the whole MariaDB team. Our thoughts are with his family during this difficult time and this release is dedicated to his memory.

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.9 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

InnoDB

- MDEV-24188 - Hang in `buf_page_create()` after reusing a previously freed page
- MDEV-24275 - InnoDB persistent stats analyze forces full scan forcing lock crash
- MDEV-24449 - Corruption of system tablespace or last recovered page
- MDEV-24109 - InnoDB hangs with innodb_flush_sync=OFF
- MDEV-24537 - innodb_max_dirty_pages_pct_lwm=0 lost its special meaning
- Fixed bugs in the handling of freed pages - MDEV-24569, MDEV-24695, MDEV-24765, MDEV-24864
- MDEV-12227 - Defer writes to the InnoDB temporary tablespace

Galera

- Galera updated to 26.4.7
- MDEV-23328 - Server hang due to Galera lock conflict resolution
- MDEV-23851 - BF-BF Conflict issue because of UK GAP locks
- MDEV-20717 - Plugin system variables and activation options can break mysqld --wsrep_recover
- MDEV-24469 - Assertion `active() == false` failed with "XA START.."
- MDEV-23647 - Garbd can't initiate SST anymore in 10.5
- MDEV-25179 - wsrep_provider and wsrep_notify_cmd system variables are now read-only

Replication

- MDEV-8134 - relay-log is corrected to rotate past 999999
- MDEV-23033 - fixed slave applier for row-based events with FK constraints on virtual columns
- MDEV-4633 - Relay_Log_Space of Show-Slave-Status is made thread-safe
- MDEV-10272 - add master host/port info to slave thread exit messages
- MDEV-23846 - improves mysqlbinlog error message issuing
- MDEV-24087 - replication of S3 ALTER PARTITION corrected
- MDEV-23610 - New privilege REPLICA MONITOR (also accessible as SLAVE MONITOR)

ColumnStore

- MariaDB ColumnStore updated to 5.5.1
- MariaDB ColumnStore deb and rpm packages now have a version of `10.5.9-5.5.1` so one can see both the server

version (10.5.9) and the plugin version (5.5.1) without needing to check the Available Versions table in the ColumnStore docs
- The MariaDB ColumnStore plugin is no longer provided for 32-bit x86 (i386) builds

Misc

- MariaDB is fixed to build on the Apple M1 CPU
- MariaDB is fixed to build on AIX
- MDEV-24122 - anomalies in mysql.user tables on previously 5.7 MySQL versions corrected
- MDEV-24093 - Detect during mysql_upgrade if `type_mysql_json.so` is needed and load it
- Binary tarballs now use WolfSSL v4.6.0 and pcre2-10.36
- MDEV-23630 - mysqldump --system option
- Fixes for the following security vulnerabilities:
  - CVE-2021-27928

Changelog

7.0.7.2.16 MariaDB 10.5.8 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.8 | Release Notes | Changelog | Overview of 10.5

Release date: 11 Nov 2020

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

- Out-of-cycle release to fix regressions in MariaDB 10.5.7
- Follow up to MDEV-19838 to alter protocol checks to support the following implementations (which add garbage to the end of some packets):
  - PHP PDO (all versions) (MDEV-24121)
  - mysqlnd (from PHP < 7.3) (MDEV-24121)
  - mysql-connector-python (all versions) (MDEV-24134)

    - and mysql-connector-java (all versions)
- Arbitrary InnoDB buffer pool and data file corruption (MDEV-24096)
- The query optimizer consumed a lot of memory when handling construct in form of `key_column [NOT] IN (large-list-of constants)` (MDEV-24117)

Changelog

For a complete list of changes made in MariaDB 10.5.8, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.8, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.17 MariaDB 10.5.7 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.7 | Release Notes | Changelog | Overview of 10.5

Release date: 3 Nov 2020

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

This release introduced an InnoDB data corruption bug (MDEV-24096). If any InnoDB tables contain indexed virtual columns or unique indexes on BLOB or TEXT columns, any InnoDB tables or tablespaces may become irreparably corrupted.

- Improved write performance (MDEV-23399, MDEV-23855, MDEV-24037)
- MDEV-18323 It is now possible to upgrade from MySQL 5.7 Tables containing JSON, by loading the MYSQL_JSON datatype plugin first. See Making MariaDB understand MySQL JSON.
- Update S3 engine to maturity Gamma
- mariadbd --temp-pool option deprecated and defaulted to zero (MDEV-22278)
- BLACKHOLE Storage Engine maximum index size increased from 1000 to 3500 bytes (MDEV-24017)
- Calculating (auto rounding) issue (MDEV-23702)
- Temporary tables can no longer overwrite existing files. Instead an error is returned should a conflict occur (MDEV-23569)
- Binlog checksum verification at recovery time (MDEV-23832)
- Verbose print-out of Geometry types by mysqlbinlog (MDEV-22330)

- SHOW BINLOG EVENTS from <pos> validates <pos> when binlog checksummed (MDEV-21839)
- Freeing memory of replicate_do_table (MDEV-23534)
- Corrected verbose mysqlbinlog output for multi-record Rows-log-event (MDEV-16372)
- SET GLOBAL replicate_do_db = DEFAULT no longer causes crash (MDEV-20744)
- User killed queries that were running an index condition pushdown in InnoDB will now return an error (MDEV-23938)
- Wrong direxec param data caused crash; Numerous fixes about Mac builds (by Dmitri Shulga) (MDEV-19838)
- server_audit plugin now logs proxy users (MDEV-19443)
- Crash on `SELECT` on a table with indexed virtual columns (MDEV-18366)
- InnoDB updated to 5.7.32 (MDEV-23989)
- Bug fixes related to adaptive hash index (MDEV-23452, MDEV-23370)
- Fixed a bug in the recovery of encrypted tables (MDEV-23456)
- Fixed a race condition in MVCC reads (MDEV-22924)
- ALTER TABLE fixes (MDEV-22277, MDEV-22939, MDEV-23199, MDEV-23356, MDEV-23499, MDEV-23672, MDEV-23685, MDEV-23722)
- Diskspace not reused for BLOB in data file (MDEV-23072)
- InnoDB: Failing assertion: `!space->referenced()` (MDEV-23651)
- `SIGSEGV` in `maria_create()` because of double free (MDEV-23222)
- `CREATE TEMPORARY TABLE .. LIKE` (system versioned table) returns error if unique index is defined in the table (MDEV-23968)
- Error upon querying the view, that selecting from versioned table with partitions (MDEV-23779)
- `CREATE .. SELECT` wrong result on join versioned table (MDEV-23799)
- `SIGSEGV` in `check_fields` on `UPDATE` (MDEV-22805)
- Parser fix (MDEV-23094)
- Add CRC-32 code to `mysys` , giving notable speedup in checksum calculation on x64 (MDEV-19935)
- Faster CRC-32C checksum calculations (MDEV-23495, MDEV-22749)
- Fixes to potential corruption bugs (MDEV-23973, MDEV-24054)
- Fixed delayed replication with S3 storage engine slave (MDEV-23691)
- Deadlock between `BACKUP STAGE BLOCK_COMMIT` and parallel replication (MDEV-23586)
- `CREATE` fails after `DROP` without `.frm` (MDEV-23549)

S3 Storage Engine

- Update S3 engine to maturity Gamma
- Add the s3_use_http and s3_port system variables

Galera

- Galera wsrep library updated to 26.4.6
- Fixed assertion failure on before_commit (MDEV-22681)
- Fixed assertion after ROLLBACK AND CHAIN (MDEV-22055)
- Fixed replication of DROP TRIGGER (MDEV-23638)
- IPv6 SST handling improved (MDEV-21770, MDEV-23576, MDEV-23580, MDEV-23581, MDEV-23574)
- Fixed SIGSEGV in lock_rec_unlock (MDEV-23101)
- Fixed replication of timezone if only 1 timezone is loaded (MDEV-22626)
- Fixed replication of CREATE OR REPLACE TRIGGER (MDEV-21578)
- Fixed SST FLUSH TABLES WITH READ LOCK timeout (MDEV-22543)

Notes

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for CentOS/RHEL 6 and Fedora 31
- Packages for Ubuntu 20.10 "Groovy Gorilla" added
- Packages for Debian 10 "buster" arm64 and ppc64el added
- Packages for Debian 9 "stretch" arm64 added

- Fixes for the following security vulnerabilities:
  - CVE-2020-14812
  - CVE-2020-14765

7.0.7.2.18 MariaDB 10.5.6 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.5.6 | Release Notes | Changelog | Overview of 10.5

Release date: 7 Oct 2020

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

- Fixes for the following security vulnerabilities:
  - CVE-2020-15180

Changelog

7.0.7.2.19 MariaDB 10.5.5 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.5

Release date: 10 Aug 2020

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

Deprecated variables

- innodb_thread_concurrency
- innodb_commit_concurrency
- innodb_replication_delay
- innodb_concurrency_tickets
- innodb_thread_sleep_delay
- innodb_adaptive_max_sleep_delay (MDEV-23379)

InnoDB

- Fixed corruption in delete buffering (MDEV-22497)
- Fixed a deadlock in FLUSH TABLES…FOR EXPORT (MDEV-22890)
- InnoDB data file extension is not crash-safe (MDEV-23190)
- Minor fixes related to encryption and FULLTEXT INDEX
- Dropping the adaptive hash index may cause DDL to lock up InnoDB (MDEV-22456)
- innodb_log_optimize_ddl=OFF is not crash safe (MDEV-21347)
- Mariadb service won't shutdown when it's running and the OS datetime updated backwards (MDEV-17481)
- Doublewrite recovery can corrupt data pages (MDEV-11799)
- Fixed race conditions related to buffer pool resizing
- ALTER TABLE fixes (MDEV-22637, MDEV-23244, MDEV-22988, MDEV-23295, MDEV-22771, MDEV-22811, MDEV-22899)
- Slow InnoDB shutdown on large instance (MDEV-22778)
- Fixes to performance regressions introduced in MariaDB 10.5.4 (MDEV-23017, MDEV-23369, MDEV-23410)
- Performance improvements (MDEV-22110, MDEV-22930, MDEV-23379, MDEV-22778)
- Correctly implemented the scrubbing of freed pages (MDEV-8139)
- Crash recovery fixes (MDEV-21347, MDEV-23190, MDEV-11799)

Replication

- Make the binlog dump thread to log into errorlog a requested GTID position (MDEV-20428)
- Fix stop of the optimistic parallel slave at requested START-SLAVE-UNTIL position (MDEV-15152)
- Properly handle `RESET MASTER TO` value, when the value exceeds the max allowed `2147483647` (MDEV-22451)
- Correct 'relay-log.info' updating by concurrent parallel workers (MDEV-22806)
- Eliminate deadlock involving parallel workers, `STOP SLAVE` and `FLUSH TABLES WITH READ LOCK` (MDEV-23089)
- Correct master-slave automatic reconnection by slave to always pass through all steps of the initial connect. Specifically, do not skip master notification about slave binlog checksum awareness (MDEV-14203)
- Refine mysqlbinlog output to print out `START TRANSACTION` at `Gtid_log_event` processing which satisfies clients that submit the output with `sql_mode=oracle` (MDEV-23108)
- Replication aborts with `ER_SLAVE_CONVERSION_FAILED` upon `CREATE ... SELECT` in ORACLE mode (MDEV-19632)

Optimizer

- Improve Protocol performance for numeric data by avoiding unnecessary character string conversions (MDEV-23162)
- ALTER TABLE ... ANALYZE PARTITION ... with EITS reads and locks all rows ... (MDEV-21472)
- Print ranges in the optimizer trace created for non-indexed columns when optimizer_use_condition_selectivity >2 Now the optimizer trace shows the ranges constructed while getting estimates from EITS (MDEV-22665)
- `LATERAL DERIVED` is not clearly visible in EXPLAIN FORMAT=JSON, make `LATERAL DERIVED` tables visible in `EXPLAIN FORMAT=JSON` output (MDEV-17568)
- Crash on WITH RECURSIVE large query (MDEV-22748)
- Crash with Prepared Statement with a '?' parameter inside a re-used CTE (MDEV-22779)

Other

- div_precision_increment is now taken into account for all intermediate calculations. Previously results could be unpredictable. Note that this means results will have a lower precision in some cases - see div_precision_increment (MDEV-19232)
- mariadb_schema data type qualifier allowing MariaDB native date types in an SQL_MODE that has conflicting data type translations.
- MariaDB could crash after changing the query_cache size (MDEV-5924)
- Errors and SIGSEGV on CREATE TABLE w/ various charsets (MDEV-22111)
- Crash in `CREATE TABLE AS SELECT` when the precision of returning type = 0 (MDEV-22502)
- XA: Reject DDL operations between PREPARE and COMMIT (MDEV-22420)
- Stop `mariabackup --prepare` on errors during innodb redo log applying (MDEV-22354)
- Server crashes in `mysql_alter_table` upon adding a non-null date column under `NO_ZERO_DATE` with `ALGORITHM=INPLACE` (MDEV-18042)
- Can't uninstall plugin if the library file doesn't exist (MDEV-21258)
- Mariabackup parameter cleanup (MDEV-18215, MDEV-21298, MDEV-21301, MDEV-22894)
- Rounding functions return wrong datatype (MDEV-23366, MDEV-23367, MDEV-23368, MDEV-23350, MDEV-23351, MDEV-23337, MDEV-23323)
- Create `mariadb.sys` user on each update even is the user is not needed (MDEV-23102)
- INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION required SUPER instead PROCESS privilege (MDEV-23003)
- Reinforce DDL operation rejection after XA PREPARE (MDEV-22420)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.5 for Ubuntu 19.10 Eoan and Fedora 30
- Fixes for the following security vulnerabilities:
  - CVE-2021-2022

Changelog

For a complete list of changes made in MariaDB 10.5.5, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.5, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.20 MariaDB 10.5.4 Release Notes

Download | Release Notes | Changelog | Overview of 10.5

Release date: 24 Jun 2020

MariaDB 10.5 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.4 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

This is the first Stable (GA) release in the MariaDB 10.5 series.

- This release of MariaDB Server includes the S3 storage engine. *Note, that plugins have independent maturity levels and S3 storage engine in 10.5.4 has **Alpha** maturity.*
- This release of MariaDB Server includes the MariaDB ColumnStore storage engine. *Note, that plugins have independent maturity levels and MariaDB ColumnStore in 10.5.4 has **Beta** maturity.*
- New Gamma version of the Spider Storage Engine, 3.3.15.
- DROP TABLE now reliably deletes table remnants inside a storage engine even if the .frm file is missing (MDEV-11412)
- Accelerated `crc32()` function for AMD64, ARMv8, POWER 8 (MDEV-22669)
- Lots of bug fixes, see the changelog.
- Galera wsrep library updated to 26.4.5

Variables

- Limit innodb_encryption_threads to 255 (MDEV-22258).
- Minimum value of max_sort_length raised to 8 (previously 4) so fixed size data types like DOUBLE and BIGINT are not truncated for lower values of max_sort_length (MDEV-22715).

InnoDB

- DROP TABLE improvements: MDEV-8069, MDEV-11412, MDEV-22456
- InnoDB Performance improvements: MDEV-15053, MDEV-22593, MDEV-22697, MDEV-22871, MDEV-22841

Changelog

For a complete list of changes made in MariaDB 10.5.4, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.4, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.21 MariaDB 10.5.3 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.5

Release date: 12 May 2020

MariaDB 10.5 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.3 is a ***Release Candidate*** (RC) release.

Do not use non-stable (non-GA) releases in production!

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

Syntax

- Application period tables: WITHOUT OVERLAPS (MDEV-16978)
- Introduce a file format constraint to ALTER TABLE. See innodb_instant_alter_column_allowed (MDEV-20590)

Large Pages

- Modernise Linux Large Page support (multiplesizes) (MDEV-18851)

Storage Engines

- Partitioned S3 tables are discoverable. This means that if you create a partitioned S3 table, both the partitioned table and its partitions can be directly used by another server that has access to the S3 storage. (MDEV-22088)

Performance

- Optimizer flag rowid_filter leads to long query (MDEV-21794)
- WSREP_ON is unnecessarily expensive to evaluate (MDEV-22203)
- Misc wsrep performance optimization (MDEV-7962)

Security

- Added system user for user view which allows to remove root (MDEV-19650)
- WolfSSL updated
- ALTER USER doesn't remove excess authentication plugins from mysql.global_priv (MDEV-21928)
- mysql_upgrade creating empty global_priv table (MDEV-21244)

Aria

- Updated aria_pack to support transactional tables and added the `--datadir`, `--ignore-control-file` and `--require-control-file` options. More details here

ALTER TABLE

- Error on online ADD PRIMARY KEY after instant DROP/reorder (MDEV-21658)
- Assertion failure in file data0type.cc (MDEV-20726)
- Server aborts upon attempt to create foreign key on spatial field (MDEV-21792)

- DROP COLUMN, DROP INDEX is wrongly claimed to be ALGORITHM=INSTANT (MDEV-22465)
- Introduce a file format constraint (MDEV-20590)
- FORCE all partition to rebuild if any one of the partition does rebuild (MDEV-21832)
- InnoDB aborts while adding instant column for discarded tablespace (MDEV-22446)
- Misc ALTER TABLE assertion failure (MDEV-22358)

Optimizer

- Optimizer, Wrong query results with `optimizer_switch="split_materialized=on"` (MDEV-21614)
- SHOW GRANTS does not quote role names properly (MDEV-20076)
- Paritioning INSERT chooses wrong partition for RANGE partitioning by DECIMAL column (MDEV-21195)

Mariabackup

- Mariabackup does not honor ignore_db_dirs from server config (MDEV-19347)
- Mariabackup `--ftwrl-wait-timeout` never times out on explicit lock (MDEV-20230)

Crash Recovery

- Loop of Read redo log up to LSN (MDEV-21826)
- `buf_page_get_gen()` should apply buffered page initialized redo log during recovery (MDEV-21572)
- Running out of file descriptors and eventual crash (MDEV-18027)
- Efficient InnoDB redo log record format (MDEV-12353)
- Punch holes when pages are freed (MDEV-15528)

Other

- Use MariaDB in error messages instead of MySQL (MDEV-17812)
- FULLTEXT INDEX, Assertion `!table->fts->in_queue' failed in `fts_optimize_remove_table` (MDEV-21550)
- Wrong estimate of affected BLOB columns in update of PRIMARY KEY (MDEV-22384)
- Duplicate key value is silently truncated to 64 characters in `print_keydup_error` (MDEV-20604)
- Session tracking returns incorrectly long tracking data (MDEV-22504)
- Add `pam_user_map.so` file to binary tarball package (MDEV-21913)
- Misc fixes for Mac build (MENT-606)
- mysql_upgrade is made aware of the upstream slave tables to issue warnings when that takes place (MDEV-10047)
- InnoDB ALTER TABLE fixes (MDEV-21564, MDEV-19092, MDEV-21549)
- InnoDB FULLTEXT INDEX fixes (MDEV-21563)
- Corruption for `SET GLOBAL innodb_` string variables (MDEV-22393)
- Test suite, Add JUnit support to MTR to generate XML test result (MDEV-22176)
- mysqldump parameter, `--ignore-table-data`, added (MDEV-22037)
- Refactored `MYSQL_BIN_LOG::xid_count_per_binlog` to satisfy UBSAN enabled build (MDEV-20923)
- Unregister of slave threads disconnected before COM_BINLOG_DUMP (Bug#29915479)
- Server can fail while replicating conditional comments (Bug#28388217)
- Added the `xml-report` option to mysql-test-run (MDEV-22176)
- Packages and repositories for Ubuntu 20.04 "focal" added

Changelog

announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.7.2.22 MariaDB 10.5.2 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.5

Release date: 26 Mar 2020

MariaDB 10.5 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.2 is a ***Beta*** release.

Do not use *beta* releases in production!

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

Syntax

- RELEASE_ALL_LOCKS (MDEV-10569)
- ALTER TABLE ... RENAME INDEX / KEY (MDEV-7318)
- ALTER TABLE ... RENAME COLUMN (MDEV-16290)
- Recursive CTE cycle detection using CYCLE clause (MDEV-20632)
- ALTER TABLE and RENAME TABLE now support `IF EXISTS`.

Privileges

- Split SUPER privilege to smaller privileges (MDEV-21743). New privileges were added so that more fine grained tuning of what each user can do can be applied:
  - BINLOG ADMIN
  - BINLOG REPLAY
  - CONNECTION ADMIN
  - FEDERATED ADMIN
  - READ_ONLY ADMIN
  - REPLICATION MASTER ADMIN
  - REPLICATION SLAVE ADMIN
  - SET USER
- The REPLICATION CLIENT privilege was renamed to BINLOG MONITOR. The old syntax is understood for compatibility (MDEV-21743).
- The SHOW MASTER STATUS statement was renamed to SHOW BINLOG STATUS (MDEV-21743). The old syntax is understood for compatibility.
- A number of statements changed the privileges that they require. The old privileges were historically inappropriately chosen in the upstream. 10.5.2 fixes this problem. Note, these changes are incompatible to previous versions. A number of GRANT commands might be needed after upgrade.
  - SHOW BINLOG EVENTS now requires the BINLOG MONITOR privilege (required REPLICATION SLAVE

prior to 10.5.2).
    - SHOW SLAVE HOSTS now requires the REPLICATION MASTER ADMIN privilege (required REPLICATION SLAVE prior to 10.5.2).
    - SHOW SLAVE STATUS now requires the REPLICATION SLAVE ADMIN or the SUPER privilege (required REPLICATION CLIENT or SUPER prior to 10.5.2).
    - SHOW RELAYLOG EVENTS now requires the REPLICATION SLAVE ADMIN privilege (required REPLICATION SLAVE prior to 10.5.2).
- In order to help the server understand which version a privilege record was written by, the mysql.global_priv.priv field contains a new JSON field, `version_id` (MDEV-21704)
- SHOW PRIVILEGES now correctly lists the `Delete history` privilege, rather than displaying it as `Delete versioning rows`. (MDEV-20382)

InnoDB

- An upgrade will only be possible after a clean shutdown. mariabackup --prepare will not work with backups taken before version 10.5.2.
- Efficient InnoDB redo log record format (MDEV-12353)
- Deprecate and ignore innodb_scrub_log and innodb_scrub_log_speed (MDEV-21870)
- Remove INFORMATION_SCHEMA.INNODB_TABLESPACES_SCRUBBING table and deprecate and ignore innodb-background-scrub-data-uncompressed, innodb-background-scrub-data-compressed, innodb-background-scrub-data-interval and innodb-background-scrub-data-check-interval (MDEV-15528)
- Deprecate and ignore innodb_log_files_in_group (MDEV-14425)
- Do not acquire InnoDB record locks when covering table locks exist (MDEV-14479)
- Issue a message on changing deprecated innodb_log_files_in_group (MDEV-21990)
- Optimize append only files for NVDIMM (MDEV-17084)
- Improve innodb redo log group commit performance (MDEV-21534)
- Punch holes when pages are freed (MDEV-15528)

Optimizer

- Allow packed sort keys in sort buffer (MDEV-21580)

Performance Schema

- Merge 5.7 P_S transaction instrumentation and tables (MDEV-16435)
- Merge 5.7 P_S memory instrumentation and tables (MDEV-16431)
- Merge 5.7 P_S mdl instrumentation and tables (MDEV-16432)
- Merge 5.7 P_S sxlocks instrumentation and tables (MDEV-16436)
- Merge 5.7 P_S user variables instrumentation and tables (MDEV-16439)
- Merge 5.7 P_S [show] status instrumentation and tables (MDEV-16438)
- Merge 5.7 P_S ps instrumentation and tables (MDEV-16433)
- Merge 5.7 P_S sp instrumentation and tables (MDEV-16434)

Replication

- `ENFORCE` option for slave_run_triggers_for_rbr (MDEV-21833)

ANALYZE FORMAT=JSON

- Add information about packed addon fields in ANALYZE FORMAT=JSON (MDEV-21838)

Binaries

- All binaries previously beginning with `mysql` now begin with `mariadb`, with symlinks for the corresponding `mysql` command. (MDEV-21303)

Galera

- Galera wsrep library updated to 26.4.4
- Galera Cluster Node During IST gets stuck going from "Synced" to "Joining:..." (MDEV-21002)

Other

- HeidiSQL updated to 11.0 (MDEV-22032)
- require_secure_transport system variable, for rejecting connections attempted using insecure transport (MDEV-13362)
- sql_if_exists session system variable, which adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES. (MDEV-19964)
- XA PREPARE transactions must survive client disconnection (MDEV-742)
- Binary tarball size has been reduced (MDEV-21943)

Changelog

For a complete list of changes made in MariaDB 10.5.2, with links to detailed information on each push, see the changelog.

7.0.7.2.23 MariaDB 10.5.1 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.5

Release date: 14 Feb 2020

MariaDB 10.5 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.1 is a ***Beta*** release.

Do not use *beta* releases in production!

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

InnoDB

- Remove dummy tablespace for the redo log (MDEV-18115)

- Optimize access to InnoDB page header fields (MDEV-21133)
- Remove multiple InnoDB buffer pool instances (MDEV-15058)
  - Deprecate and ignore innodb_buffer_pool_instances and innodb_page_cleaners
  - Columns that indicated the buffer pool instance from the Information Schema innodb_buffer_page, innodb_buffer_page_lru, innodb_buffer_pool_stats, innodb_cmpmem and innodb_cmpmem_reset tables now return a dummy value of `0` .
- Deprecate and ignore innodb_log_optimize_ddl (MDEV-19747)
- Prefer MDL to dict_sys.latch for innodb background tasks (MDEV-16678)
- Use fdatasync() for redo log where appropriate (MDEV-21382)
- Replace recv_sys.heap with list of buf_block_t (MDEV-21351)
- Several fixes to server hangs (MDEV-16264)

Optimizer

- Allow packed values of non-sorted fields in the sort buffer (MDEV-21263)

Replication and Galera

- slave_parallel_mode now defaults to `optimistic` (MDEV-18648).
- Make REPLICA a synonym for SLAVE in SQL statements (MDEV-20601)
- Galera GTID support (commit)
- Add new mode to wsrep_OSU_method in which Galera checks storage engine of the effected table (MDEV-20051)
- Galera: Replicate MariaDB GTID to other nodes in the cluster (MDEV-20720)

PCRE

- Migrate to PCRE2 (MDEV-14024)

Compatibility

- Show internal type for TIMESTAMP, DATETIME, and TIME columns (MDEV-19906)

Variables

- Numerous deprecated variables removed (MDEV-18650)
  - multi_range_count
  - thread_concurrency
  - timed_mutexes

7.0.7.2.24 MariaDB 10.5.0 Release Notes

The most recent release of MariaDB 10.5 is:
MariaDB 10.5.23 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.5

Release date: 3 Dec 2019

MariaDB 10.5 is the current development series of MariaDB. It is an evolution of MariaDB 10.4 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.5.0 is an ***Alpha*** release.

Do not use *alpha* releases in production!

For an overview of MariaDB 10.5 see the What is MariaDB 10.5? page.

Thanks, and enjoy MariaDB!

Notable Changes

This is the first alpha release in the MariaDB 10.5 series.

Notable changes of this release include:

INET 6 Data Type

- New INET6 data type for storing IPv6 addresses (MDEV-274).

Syntax

- INSERT ... RETURNING (MDEV-10014)
- REPLACE ... RETURNING (MDEV-10014)
- EXCEPT ALL and INTERSECT ALL (MDEV-18844)
- Database comments in CREATE DATABASE and ALTER DATABASE statements (MDEV-307)
- Setup default partitions for system versioning (MDEV-19903)
- Fix REFERENCES constraint in column definition (MDEV-20729)

JSON

- JSON_ARRAYAGG
- JSON_OBJECTAGG
- Add information about packed addon fields in ANALYZE FORMAT=JSON (MDEV-21838)

S3 Storage Engine

- S3 Storage Engine, a read-only storage engine that stores its data in Amazon S3 (MDEV-17841)

Thread Pool

- Information Schema tables (THREADPOOL_GROUPS, THREADPOOL_QUEUES and THREADPOOL_STATS) for internals of generic threadpool (MDEV-19313)

InnoDB

- innodb_adaptive_hash_index now defaults to `OFF` (MDEV-20487)
- innodb_checksum_algorithm now defaults to `full_crc32` (MDEV-19534)
- innodb_checksums has been removed (MDEV-19534)

- innodb_log_checksums has been deprecated (MDEV-19543)
- innodb_locks_unsafe_for_binlog has been removed (MDEV-19544)
- innodb_stats_sample_pages has been removed (MDEV-19551)
- innodb_undo_logs has been deprecated (MDEV-19570)
- innodb_rollback_segments has been removed (MDEV-19570)
- Set innodb_log_files_in_group=1 by default (MDEV-20907)
- Extend SHOW STATUS LIKE 'Innodb_%' (MDEV-18582)
- Clean up INFORMATION_SCHEMA.INNODB_ tables (MDEV-19940)
- Doublewrite buffer is unnecessarily used for newly (re)initialized pages (MDEV-19738)
- Defer change buffer merge until pages are requested (MDEV-19514)

InnoDB Refactoring

- Remove buf_page_t::newest_modification (MDEV-21132)
- Replace recv_sys_t::addr_hash with a std::map (MDEV-19586)
- Obsolete internal parser for FK in InnoDB (MDEV-20480)
- InnoDB thread pool for background tasks (MDEV-16264)

Binary Log

- Extended binlog metadata (MDEV-20477)

Query Optimizer

- ANALYZE for statements is improved, now it also shows the time spent checking the WHERE clause and doing other auxiliary operations (MDEV-20854)
- Inferred IS NOT NULL predicates can be used by the range optimizer (MDEV-15777)

Galera

- Galera 4 Inconsistency voting (MDEV-17048)

General

- The Information Schema SYSTEM_VARIABLES Table has a new column showing from which config file a variable derives its value (MDEV-12684)
- Switch Perl DBI scripts from DBD::mysql to DBD::MariaDB driver (MDEV-19755)
- The Aria max key length is now 2000 bytes, compared to 1000 bytes in MyISAM.

Do not use *alpha* releases in production!

Changelog

For a complete list of changes made in MariaDB 10.5.0, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.5.0, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8 MariaDB Server 10.4

Changes and Improvements in MariaDB 10.4
Current Version: 10.4.32 | Status: Stable (GA) | Release Date: 13 Nov 2023

Release Notes - MariaDB 10.4 Series
MariaDB 10.4 Series Release Notes

7.0.8.1 Changes and Improvements in MariaDB 10.4

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

MariaDB 10.4 is a previous major stable version. The first stable release of 10.4 was in June 2019, and it will be maintained until June 2024.

Contents

Implemented Features

Authentication

- See Authentication from MariaDB 10.4 for an overview of the changes.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB (MDEV-12484)
- User password expiry (MDEV-7597)
- Account Locking (MDEV-13095)
- The obsolete mysql.host table is no longer created (MDEV-15851)
- Much faster privilege checks for MariaDB setups with many user accounts or many database grants (MDEV-15649)
- mysql.user table is retired. User accounts and global privileges are now stored in the mysql.global_priv table (MDEV-17658)
- SET PASSWORD support for ed25519 and other authentication plugins (MDEV-12321)

InnoDB

- Added instant DROP COLUMN and changing of the order of columns (MDEV-15562)

- More Instant VARCHAR extension or ROW_FORMAT=DYNAMIC and ROW_FORMAT=COMPACT (MDEV-15563)
  - change CHAR(0) to any VARCHAR
  - change a CHAR that is longer than 255 bytes to VARCHAR or wider CHAR
  - change a VARCHAR that is shorter than 128 bytes into any longer VARCHAR
- Instant collation or charset changes for non-indexed columns (MDEV-15564)
- Reduced redo log volume for undo tablespace initialization (MDEV-17138)
- Removed crash-upgrade support for pre-10.2.19 TRUNCATE TABLE (MDEV-13564)
- Added key rotation for innodb_encrypt_log (MDEV-12041)
- Implement innodb_checksum_algorithm=full_crc32 (MDEV-12026)

Optimizer

- Implementation of the optimizer trace, one can enable the optimizer trace by enabling the system variable optimizer_trace (MDEV-6111)
- Engine Independent Table Statistics is now enabled by default; new default values are use_stat_tables=PREFERABLY_FOR_QUERIES and optimizer_use_condition_selectivity=4 (MDEV-15253)
  - Two new values for the variable use_stat_tables: `COMPLEMENTARY_FOR_QUERIES` and `PREFERABLY_FOR_QUERIES` (MDEV-17255)
  - Histograms are now collected by default (MDEV-18608).
  - analyze_sample_percentage variable added. The default value is 100 (`ANALYZE` will use the whole table), but one can also set analyze to only use a sample of table data to collect the statistics.
- Condition pushdown optimization now has bigger scope:
  - Conditions can be pushed into materialized IN-subqueries (MDEV-12387)
  - Conditions in `HAVING` clause can be pushed to WHERE. This behavior is controlled through optimizer switch flag `condition_pushdown_from_having` .
- The optimizer switch flag `optimize_join_buffer_size` now defaults to `on` (MDEV-17903)
- Rowid Filtering optimization added (MDEV-16188). It is controlled through optimizer switch flag `rowid_filter` .

Syntax

- Temporal tables extended with support for application-time periods (MDEV-16973 , MDEV-16974 , MDEV-16975 , MDEV-17082)
- Support of brackets (parentheses) for specifying precedence in UNION/EXCEPT/INTERSECT operations (MDEV-11953)
- New FLUSH SSL command to reload SSL certificates without server restart (MDEV-16266)
- New `CAST` target — `CAST(x AS INTERVAL DAY_SECOND(N))` (MDEV-17776)
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME (MDEV-16294)
- Unique indexes can be created on BLOB or TEXT fields (MDEV-371)

Variables

For a list of all new variables, see System Variables Added in MariaDB 10.4 and Status Variables Added in MariaDB 10.4.

- Added to the tcp_nodelay system variable (MDEV-16277)
- Removed the Innodb_pages0_read status variable (MDEV-15705).
- New sql-mode setting, `TIME_ROUND_FRACTIONAL` (MDEV-16991)
- New variable gtid_cleanup_batch_size for determining how many old rows must accumulate in the mysql.gtid_slave_pos table before a background job will be run to delete them.
- The default for eq_range_index_dive_limit is now `200` (previously `0`) (MDEV-18551)
- core_file on Windows now defaults to `ON` (MDEV-18439)

Replication

- Speed up rotation of binary logs, `SHOW BINARY LOGS` etc with optimizing binary log index file locking (MDEV-19116 , MDEV-19117).
- A new server command, SHUTDOWN WAIT FOR ALL SLAVES, and a new mysqladmin shutdown --wait-for-all-slaves option, are added to instruct the server to wait for the last binlog event to be sent to all connected slaves before shutting down. (MDEV-18450).

Backup

- BACKUP STAGE allows one to implement very efficient backups with minimal locking. MDEV-5336 .

Galera 4

In MariaDB 10.4.2 and later, Galera has been upgraded from Galera 3 to Galera 4.

Galera 4 Versions

The following table lists each version of the Galera 4 wsrep provider, and it lists which version of MariaDB each one was first released in. If you would like to install Galera 4 using yum, apt, or zypper, then the package is called `galera-4`.

Galera Version	Released in MariaDB Version
26.4.14	10.10.3, 10.9.5, 10.8.7, 10.7.8, 10.6.12, 10.5.19, 10.4.28
26.4.13	10.10.2, 10.9.4, 10.8.6, 10.7.7, 10.6.11, 10.5.18, 10.4.27
26.4.12	10.10.1, 10.9.2, 10.8.4, 10.7.5, 10.6.9, 10.5.17, 10.4.26
26.4.11	10.8.1, 10.7.2, 10.6.6, 10.5.14, 10.4.22
26.4.9	10.6.4, 10.5.12, 10.4.21
26.4.8	10.6.1, 10.5.10, 10.4.19
26.4.7	10.5.9, 10.4.18
26.4.6	10.5.7, 10.4.16
26.4.5	10.5.4, 10.4.14
26.4.4	10.5.1, 10.4.13
26.4.3	10.5.0, 10.4.9
26.4.2	10.4.4
26.4.1	10.4.3
26.4.0	10.4.2

New Features in Galera 4

The `mysql` database contains new tables related to Galera replication:

- `wsrep_cluster`
- `wsrep_cluster_members`
- `wsrep_streaming_log`

End users may read but not modify these tables.

The new streaming replication feature allows replicating transactions of unlimited size. With streaming replication, a cluster is replicating a transaction in small fragments during transaction execution. This transaction fragmenting is controlled by two new configuration variables:

- `wsrep_trx_fragment_unit (bytes, rows, statements)` defines the metrics for how to measure transaction size limit for fragmenting. Possible values are:
  - `bytes` : transaction's binlog events buffer size in bytes
  - `rows` : number of rows affected by the transaction
  - `statements` : number of SQL statements executed in the multi-statement transaction
- `wsrep_trx_fragment_size` defines the limit for fragmenting. When a transaction's size, in terms of the configured fragment unit, has grown over this limit, a new fragment will be replicated.

Transactions replicated through galera replication will now process the commit phase using MariaDB's group commit logic. This will affect transaction throughput, especially when binary logging is enabled in the cluster.

Limitations in Galera 4

Rolling Upgrades from Galera 3 to Galera 4

Rolling upgrades from MariaDB 10.3 (or earlier) to MariaDB 10.4 also require an upgrade from Galera 3 to Galera 4. Galera 4 has a lot of changes and improvements that were not present in Galera 3.

Prior to the General Availability (GA) releases of MariaDB 10.4 and Galera 4, earlier versions of MariaDB 10.4 and Galera 4 had bugs that could lead to problems if Galera 4 nodes were in a cluster with Galera 3 nodes during a rolling upgrade. In these versions, rolling upgrades were not supported. This meant that, in order to upgrade a cluster, the cluster had to be completely stopped, and the nodes could only be restarted after the entire cluster had been upgraded to MariaDB 10.4 and

Galera 4.

These bugs have been fixed in more recent versions, and rolling upgrades from Galera 3 to Galera 4 are supported. In order to perform a rolling upgrade, it is recommended to upgrade to MariaDB 10.4.6 or later and Galera 26.4.2 or later. However, as a general rule, users should try to ensure that they are upgrading to the latest versions of MariaDB 10.4 and Galera 4.

For more detailed information on how to upgrade, see Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster.

General

- Crash safe Aria-based system tables (MDEV-16421)
- Added Linux abstract socket support (MDEV-15655)
- Enabled C++11 (MDEV-16410)
- Performance improvements in Unicode collations (MDEV-17534, MDEV-17511, MDEV-17502, MDEV-17474)
- User data type plugins (MDEV-4912, in progress)
- Improvements with SQL standard INTERVAL support to help functions TIMESTAMP() and ADDTIME() return more predictable results.
  - Historically, MariaDB uses the TIME data type for both "time of the day" values and "duration" values. In the first meaning the natural value range is from '00:00:00' to '23:59:59.999999', in the second meaning the range is from '-838:59:59.999999' to '+838:59:59.999999'.
  - To remove this ambiguity and for the SQL standard conformance we plan to introduce a dedicated data type INTERVAL that will be able to store values in the range at least from '-87649415:59:59.999999' to '+87649415:59:59.999999', which will be enough to represent the time difference between TIMESTAMP'0001-01-01 00:00:00' and TIMESTAMP'9999-12-31 23:59:59.999999'.
  - As a first step we support this range of values for intermediate calculations when TIME-alike string and numeric values are used in INTERVAL (i.e. duration) context, e.g. as the second argument of SQL functions TIMESTAMP(ts,interval) and ADDTIME(ts,interval), so the following can now be calculated:

```
SELECT ADDTIME(TIMESTAMP'0001-01-01 00:00:00', '87649415:59:59.999999');
-> '9999-12-31 23:59:59.999999'

SELECT TIMESTAMP(DATE'0001-01-01', '87649415:59:59.999999')
-> '9999-12-31 23:59:59.999999'

SELECT ADDTIME(TIME'-838:59:59.999999', '1677:59:59.999998');
-> '838:59:59.999999'
```

- Support for window UDF functions via the new method x_remove (MDEV-15073)
- Json service for plugins (MDEV-5313)
- Change in behavior for FLUSH TABLES (MDEV-5336).
- The JSON_VALID function is automatically used as a CHECK constraint for the JSON data type alias in order to ensure that a valid json document is inserted (MDEV-13916)
- MariaDB Named Commands (MDEV-17591)
- MariaDB systemd multi-instance service have changed. See systemd page for details.

Security Vulnerabilities Fixed in MariaDB 10.4

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2023-5157: MariaDB 10.4.26
- CVE-2023-22084: MariaDB 10.4.32

7.0.8.2 Release Notes - MariaDB 10.4 Series

MariaDB 10.4.32 Release Notes

Status: Stable (GA) | Release Date: 13 Nov 2023

MariaDB 10.4.31 Release Notes

Status: Stable (GA) | Release Date: 14 Aug 2023

MariaDB 10.4.30 Release Notes

Status: Stable (GA) | Release Date: 7 Jun 2023

MariaDB 10.4.29 Release Notes

Status: Stable (GA) | Release Date: 10 May 2023

MariaDB 10.4.28 Release Notes

Status: Stable (GA) | Release Date: 6 Feb 2023

MariaDB 10.4.27 Release Notes

Status: Stable (GA) | Release Date: 7 Nov 2022

MariaDB 10.4.26 Release Notes

Status: Stable (GA) | Release Date: 15 Aug 2022

MariaDB 10.4.25 Release Notes

Status: Stable (GA) | Release Date: 20 May 2022

MariaDB 10.4.24 Release Notes

Status: Stable (GA) | Release Date: 12 Feb 2022

MariaDB 10.4.23 Release Notes

Status: Stable (GA) | Release Date: 9 Feb 2022

MariaDB 10.4.22 Release Notes

Status: Stable (GA) | Release Date: 8 Nov 2021

MariaDB 10.4.21 Release Notes

Status: Stable (GA) | Release Date: 6 Aug 2021

MariaDB 10.4.20 Release Notes

Status: Stable (GA) | Release Date: 23 Jun 2021

MariaDB 10.4.19 Release Notes

Status: Stable (GA) | Release Date: 7 May 2021

MariaDB 10.4.18 Release Notes

Status: Stable (GA) | Release Date: 22 Feb 2021

MariaDB 10.4.17 Release Notes

Status: Stable (GA) | Release Date: 11 Nov 2020

MariaDB 10.4.16 Release Notes

Status: Stable (GA) | Release Date: 3 Nov 2020

MariaDB 10.4.15 Release Notes

Status: Stable (GA) | Release Date: 7 Oct 2020

MariaDB 10.4.14 Release Notes

Status: Stable (GA) | Release Date: 10 Aug 2020

MariaDB 10.4.13 Release Notes
Status: Stable (GA) | Release Date: 12 May 2020

MariaDB 10.4.12 Release Notes
Status: Stable (GA) | Release Date: 28 Jan 2020

MariaDB 10.4.11 Release Notes
Status: Stable (GA) | Release Date: 11 Dec 2019

MariaDB 10.4.10 Release Notes
Status: Stable (GA) | Release Date: 8 Nov 2019

MariaDB 10.4.9 Release Notes
Status: Stable (GA) | Release Date: 5 Nov 2019

MariaDB 10.4.8 Release Notes
Status: Stable (GA) | Release Date: 11 Sep 2019

MariaDB 10.4.7 Release Notes
Status: Stable (GA) | Release Date: 31 Jul 2019

MariaDB 10.4.6 Release Notes
Status: Stable (GA) | Release Date: 18 Jun 2019

MariaDB 10.4.5 Release Notes
Status: Release Candidate (RC) | Release Date: 21 May 2019

MariaDB 10.4.4 Release Notes
Status: Release Candidate | Release Date: 7 Apr 2019

MariaDB 10.4.3 Release Notes
Status: Release Candidate | Release Date: 25 Feb 2019

MariaDB 10.4.2 Release Notes
Status: Beta | Release Date: 29 Jan 2019

MariaDB 10.4.1 Release Notes
Status: Beta | Release Date: 20 Dec 2018

MariaDB 10.4.0 Release Notes
Status: Alpha | Release Date: 9 Nov 2018

7.0.8.2.1 MariaDB 10.4.32 Release Notes

Download | Release Notes | Changelog | Overview of 10.4

Alternate download from mariadb.org

Release date: 13 Nov 2023

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.32 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- DROP INDEX followed by CREATE INDEX may corrupt data (MDEV-32132)
- ROW_FORMAT=COMPRESSED table: InnoDB: 2048 bytes should have been read. Only 0 bytes read. (MDEV-31875)
- Server aborts during alter operation when table doesn't have foreign index (MDEV-32527)
- row_merge_fts_doc_tokenize() handles FTS plugin parser inconsistently (MDEV-32578)
- InnoDB: tried to purge non-delete-marked record of an index on a virtual column prefix (MDEV-30024)
- lock_row_lock_current_waits counter in information_schema.innodb_metrics may become negative (MDEV-30658)
- SET GLOBAL innodb_max_purge_lag_wait=… hangs if innodb_read_only=ON (MDEV-31813)
- Auto-increment no longer works for explicit FTS_DOC_ID (MDEV-32017)
- Assertion `pos < table->n_def' failed in dict_table_get_nth_col (MDEV-32337)
- innochecksum man pages seem to be inconsistent with the binary (10.2.25) (MDEV-20583)
- innodb_compression_algorithm=0 (none) increments Innodb_num_pages_page_compression_error (MDEV-30825)
- wrong table name in innodb's "row too big" errors (MDEV-32128)
- Optimize is_file_on_ssd() to speedup opening tablespaces on Windows (MDEV-32228)

Optimizer

- Crash when HAVING in a correlated subquery references columns in the outer query (MDEV-29731)
- Server crashes at TABLE::add_tmp_key (MDEV-32320)
- Server crashes inside filesort at my_decimal::to_binary (MDEV-32324)
- Assertion `bitmap_is_set(&m_part_info->read_partitions, m_part_spec.start_part)' failed in ha_partition::handle_ordered_index_scan (MDEV-24283)
- Crash when searching for the best split of derived table (MDEV-32064)
- Test case from opt_tvc.test fails with statement memory protection (MDEV-32225)
- Significant slowdown for query with many outer joins (MDEV-32351)
- test_if_skip_sort_order() should catch the join types JT_EQ_REF, JT_CONST and JT_SYSTEM and skip sort order for these (MDEV-32475)

Replication

- rpl.rpl_parallel_temptable failure due to incorrect commit optimization of temptables (MDEV-10356)
- Lock wait timeout with INSERT-SELECT, autoinc, and statement-based replication (MDEV-31482)
- strings/ctype-ucs2.c:2336: my_vsnprintf_utf32: Assertion `(n % 4) == 0' failed in my_vsnprintf_utf32 on INSERT (MDEV-32249)
- Assertion fails in MDL_context::acquire_lock upon parallel replication of CREATE SEQUENCE (MDEV-31792)
- SHOW SLAVE STATUS Last_SQL_Errno Race Condition on Errored Slave Restart (MDEV-31177)
- seconds_behind_master is inaccurate for Delayed replication (MDEV-32265)
- detailize the semisync replication magic number error (MDEV-32365)
- Parallel replication deadlock victim preference code errorneously removed (MDEV-31655)

Galera

- Assertion `state() == s_executing || state() == s_prepared || state() == s_committing || state() == s_must_abort || state() == s_replaying' failed. (MDEV-24912)
- Assertion `state() == s_executing || state() == s_preparing || state() == s_prepared || state() == s_must_abort || state() == s_aborting || state() == s_cert_failed || state() == s_must_replay' failed (MDEV-31285)
- wsrep_sst_mariabackup not working on FreeBSD (MDEV-31467)
- Galera library 26.4.16 fails with every server version (MDEV-32024)
- Galera node remains paused after interleaving FTWRLs (MDEV-32282)
- Failed to insert streaming client (MDEV-32051)
- When set at runtime, wsrep_sst_method accepts any value (MDEV-31470)
- galera needs packaging script changes to successfully build (MDEV-32642)

Data Definition

- MariaDB crash on calling function (MDEV-23902)
- ASAN errors in grn_obj_unlink / ha_mroonga::clear_indexes upon index operations (MDEV-31970)

Scripts and Clients

- mariadb-binlog -T/--table (mysqlbinlog) option (MDEV-25369)
- mariadb-admin (mysqladmin) wrong error with simple_password_check (MDEV-22418)
- mariadb-install-db shows warning on missing directory $pamtooldir/auth_pam_tool_dir (MDEV-32142)
- main.mysql_client_test, main.mysql_client_test_comp failed on ASAN build with error: 5888, status: 23, errno: 2

(MDEV-19369)
- mariadb-install-db (mysql_install_db) doesn't properly grant proxy privileges to all default root user accounts (MDEV-21194)

Tests

- main.events_stress or events.events_stress fails with view-protocol (MDEV-31455)
- main.delete_use_source fails (hangs) with view-protocol (MDEV-31457)
- main.sum_distinct-big and main.merge-big fail with timeout with view-protocol (MDEV-31465)
- main.secure_file_priv_win fails with 2nd execution PS protocol (MDEV-32023)
- Windows : mtr output on is messed up with large MTR_PARALLEL (MDEV-32387)
- main.mysql_client_test_comp failed in buildbot, error on exec (MDEV-16641)

MariaBackup

- MariaBackup full backup failed with InnoDB: Failing assertion: success in storage/innobase/fil/fil0fil.cc line 657 (MDEV-18200)
- mbstream breaks page compression on XFS (MDEV-25734)

Character Sets, Data Types, Collations

- Prefix keys for CHAR work differently for MyISAM vs InnoDB (MDEV-30048)
- Inconsistent results of DISTINCT with NOPAD (MDEV-30050)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on INSERT (MDEV-28835)
- Compressed varchar values lost on joins when sorting on columns from joined table(s) (MDEV-31724)
- UBSAN shift exponent X is too large for 64-bit type 'long long int' in sql/field.cc (MDEV-32226)
- Wrong bit encoding using COALESCE (MDEV-32244)

Spider

- Spider UBSAN runtime error: applying non-zero offset x to null pointer in st_spider_param_string_parse::restore_delims (MDEV-31117)
- Segfault when setting spider_delete_all_rows to 0 and delete all rows of a spider table, ASAN heap-use-after-free in spider_db_delete_all_rows (MDEV-31996)
- ASAN errors in spider_fields::free_conn_holder or spider_create_group_by_handler (MDEV-28998)

General

- binlog_do_db option breaks importing sql dumps (MDEV-29989)
- Crashes in MDL_key::mdl_key_init with lower-case-table-names=2 (MDEV-32025)
- getting error 'Illegal parameter data types row and bigint for operation '+' ' when using ITERATE in a FOR..DO (MDEV-32275)
- Assertion `arena_for_set_stmt== 0' failed in LEX::set_arena_for_set_stmt upon SET STATEMENT (MDEV-17711)
- main.mysqlcheck fails on ARM with ASAN use-after-poison in my_mb_wc_filename (MDEV-26494)
- main.delayed fails with wrong error code or timeout when executed after main.deadlock_ftwrl (MDEV-27523)
- Assertion failed: !pfs->m_idle || (state == PSI_SOCKET_STATE_ACTIVE) (MDEV-28561)
- MyISAM wrong server status flags (MDEV-28820)
- Server crashes in check_sequence_fields upon CREATE TABLE .. SEQUENCE=1 AS SELECT .. (MDEV-29771)
- slow log Rows_examined out of range (MDEV-30820)
- " `rpm --setugids` " breaks PAM authentication (MDEV-30904)
- incorrect examined rows in case of stored function usage (MDEV-31742)
- Compilation failing on MacOS (unknown warning option -Wno-unused-but-set-variable) (MDEV-31890)
- Server crash upon inserting into Mroonga table with compressed column (MDEV-31966)
- hash unique corrupts index on virtual blobs (MDEV-32012)
- insert into an empty table fails with hash unique (MDEV-32015)
- Valgrind/MSAN warnings in dynamic_column_update_move_left (MDEV-32140)
- Memory leak showed in MDEV-6146 test suite (MDEV-32223)
- Test from subselect.test fails with statement memory protection (MDEV-32245)
- Memory leak when executing PS for query with IN subquery (MDEV-32369)
- Allow the setting of Auto_increment on FK referenced columns (MDEV-32018)
- mariadb-upgrade fails with sql_safe_updates = on (MDEV-29914)
- Assertion `!(thd->server_status & (1U | 8192U))' failed in MDL_context::release_transactional_locks (MDEV-32541)
- Information schema leaks table names and structure to unauthorized users (MDEV-32500)
- Missing CHACHA20-POLY1305 support in WolfSSL (MDEV-31653)
- incorrect error about cyclic reference about JSON type virtual column (MDEV-32586)

- Disable TLS v1.0 and 1.1 for MariaDB (MDEV-31369)
- Better indication of refusing to start because of ProtectHome (MDEV-25177)
- Database upgrade fails: slow_log table (MDEV-27757)
- myrocks_hotbackup.1 and test suite files installed when engine is disabled (MDEV-29993)
- client_ed25519.dll isn't inluded for HeidiSQL. (MDEV-31315)

Docker Official Images

- Invert single and double quotes for sql command definitions in healthcheck.sh due to failure under sql_mode=ANSI_QUOTES - contribution by Dominik Häckel
- healthcheck.sh --no-defaults behaviour was corrected - reported by Dominik Häckel
- Added /docker-entrypoint-init.d for tar{,compression} from mariadb-backup - instructions
- Refactor `docker_mariadb_init` in the entrypoint for extending the MariaDB image
- CIS failure due to world-writable directory /var/run/mysqld, added sticky bit - reported by @ollie1
- Add PROXY privileges for root@MARIADB_ROOT_HOST - reported by Matthieu Gusmini
- healthcheck.sh added --galera_online test, to match what the mariadb-operator does.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2023-22084

Changelog

For a complete list of changes made in MariaDB 10.4.32, with links to detailed information on each push, see the changelog.

Contributors

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.2 MariaDB 10.4.31 Release Notes

Download | Release Notes | Changelog | Overview of 10.4

Alternate download from mariadb.org

Release date: 14 Aug 2023

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.31 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

General

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 18.04 LTS "Bionic"
- mysqldump --force doesn't ignore error as it should (MDEV-31092)
- ROW variables do not get assigned from subselects (MDEV-31250)
- Crash after setting global session_track_system_variables to an invalid value (MDEV-25237)
- ODKU of non-versioning column inserts history row (MDEV-23100)
- UPDATE not working properly on transaction precise system versioned table (MDEV-25644)
- Assertion `const_item_cache == true' failed in Item_func::fix_fields (MDEV-31319)
- ANALYZE doesn't work with pushed derived tables (MDEV-29284)
- get_partition_set is never executed in ha_partition::multi_range_key_create_key due to bitwise & with 0 constant (MDEV-24712)
- Client can crash the server with a mysql_list_fields("view") call (MDEV-30159)
- I_S.parameters not immediatly changed updated after procedure change (MDEV-31064)

Character Sets, Data Types

- UBSAN: null pointer passed as argument 1, which is declared to never be null in my_strnncoll_binary on SELECT ... COUNT or GROUP_CONCAT (MDEV-28384)
- Possibly wrong result or Assertion `0' failed in Item_func_round::native_op (MDEV-23838)
- Assertion `(length % 4) == 0' failed in my_lengthsp_utf32 on SELECT (MDEV-29019)
- UBSAN: negation of -X cannot be represented in type 'long long int'; cast to an unsigned type to negate this value to itself in Item_func_mul::int_op and Item_func_round::int_op (MDEV-30932)
- Assorted assertion failures in json_find_path with certain collations (MDEV-23187)

InnoDB

- innochecksum dies with Floating point exception (MDEV-31641)
- Deadlock with 3 concurrent DELETEs by unique key (MDEV-10962)
- Assertion `!strcmp(index->table->name.m_name, "SYS_FOREIGN") || !strcmp(index->table->name.m_name, "SYS_FOREIGN_COLS")' failed in btr_node_ptr_max_size (MDEV-19216)
- MODIFY COLUMN can break FK constraints, and lead to unrestorable dumps (MDEV-31086)

Aria

- Various crashes upon INSERT/UPDATE after changing Aria settings (MDEV-28054)
- Various crashes/asserts/corruptions when Aria encryption is enabled/used, but the encryption plugin is not loaded (MDEV-26258)

Spider

- SIGSEGV in spider_db_open_item_field and SIGSEGV in spider_db_print_item_type, on SELECT (MDEV-29447)
- Spider variables that double as table params overriding mechanism is buggy (MDEV-31524)

Optimizer

- Assertion `last_key_entry >= end_pos' failed in virtual bool JOIN_CACHE_HASHED::put_record() (MDEV-31348)
- Problem with open ranges on prefix blobs keys (MDEV-31800)
- Equal on two RANK window functions create wrong result (MDEV-20010)
- Recursive CTE execution is interrupted without errors or warnings (MDEV-31214)
- MAX_SEL_ARG memory exhaustion is not visible in the optimizer trace (MDEV-30964)
- SHOW TABLES not working properly with lower_case_table_names=2 (MDEV-30765)
- Segfault on select query using index for group-by and filesort (MDEV-30143)

Replication

- Parallel Slave SQL Thread Can Update Seconds_Behind_Master with Active Workers (MDEV-30619)
- ALTER SEQUENCE ends up in optimistic parallel slave binlog out-of-order (MDEV-31503)
- STOP SLAVE takes very long time on a busy system (MDEV-13915)
- rpl.rpl_manual_change_index_file occasionally fails in BB with Result length mismatch (MDEV-30214)

Galera

- Node has been dropped from the cluster on Startup / Shutdown with async replica (MDEV-31413)
- MariaDB stuck on starting commit state (waiting on commit order critical section) (MDEV-29293)
- Assertion `state() == s_aborting || state() == s_must_replay` failed in int wsrep::transaction::after_rollback() (MDEV-30013)
- Assertion `!wsrep_has_changes(thd) || (thd->lex->sql_command == SQLCOM_CREATE_TABLE && !thd->is_current_stmt_binlog_format_row()) || thd->wsrep_cs().transaction().state() == wsrep::transaction::s_aborted` failed (MDEV-30388)
- Server crashes when wsrep_sst_donor and wsrep_cluster_address set to NULL (MDEV-28433)
- Create temporary sequence can cause inconsistency (MDEV-31335)
- Galera 4 unable to query cluster state if not primary component (MDEV-21479)

Changelog

7.0.8.2.3 MariaDB 10.4.30 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.30 | Release Notes | Changelog | Overview of 10.4

Release date: 7 Jun 2023

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.30 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Server crashes in st_join_table::choose_best_splitting (MDEV-31403)
- Crash with condition pushable into derived and containing outer reference (MDEV-31240)
- Revert "MDEV-30473: Do not allow GET_LOCK() / RELEASE_LOCK() in cluster"

Optimizer

- Crash with condition pushable into derived and containing outer reference (MDEV-31403 MDEV-31240)
- Crash with EXPLAIN EXTENDED for multi-table update of system table (MDEV-31224)

Changelog

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.4 MariaDB 10.4.29 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.29 | Release Notes | Changelog | Overview of 10.4

Release date: 10 May 2023

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.29 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- Crash on ROLLBACK in a ROW_FORMAT=COMPRESSED table (MDEV-30882)
- UNIQUE USING HASH accepts duplicate entries for tricky collations (MDEV-30034)
- rec_get_offsets() is not optimal (MDEV-30567)

Backup

- mariadb-backup doesn't utilise innodb-undo-log-directory (if specified as a relative path) during copy-back operation (MDEV-28187)
- mariabackup issues error messages during InnoDB tablespaces export on partial backup preparing (MDEV-29050)
- mariadb-backup does not copy Aria logs if aria_log_dir_path is used (MDEV-30968)

Replication

- Fixed a deadlock on parallel slave involving full image Write event on the sequence engine (MDEV-29621)

- Fixed an attempted out-of-order binlogging error on slave involving ALTER on the sequence engine (MDEV-31077)
- Corrected non-versioned master to versioned slave replication on no-unique attribute table (MDEV-30430)
- Mended encrypted binlog master to error out to gtid-mode slave when master could not decrypt a binlog file (MDEV-28798)
- Refined optimistic parallel slave to error-exit without any hang (MDEV-30780)

Optimizer

- Split Materialized optimization is improved to re-fill the materialized table only if necessary. The fewer number of table refills is taken into account when choosing query plan, too (MDEV-26301).
- Queries using `SELECT DISTINCT some_expression(aggregate_function())` could produce wrong query result. (MDEV-20057)
- EXPLAIN could erroneously report that Rowid Filter optimization is used for partitioned tables. Partitioned tables do not support it. (MDEV-30596)
- A bug in selectivity computations for SINGLE/DOUBLE_PREC_HB histograms could cause wrong estimates to be produced. This could cause the optimizer to pick sub-optimal query plans (MDEV-31067).

Docker Official Images

- Add replication setup to containers contributed by Md Sahil (MDEV-29762)

Security

- Fixes for the following security vulnerabilities :
  - CVE-2022-47015

Changelog

For a complete list of changes made in MariaDB 10.4.29, with links to detailed information on each push, see the changelog .

Contributors

For a full list of contributors to MariaDB 10.4.29, see the MariaDB Foundation release announcement .

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.5 MariaDB 10.4.28 Release Notes

Download | Release Notes | Changelog | Overview of 10.4

Release date: 6 Feb 2023

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.28 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

- As mentioned in the 10.4.27 release notes, our Yum/DNF/Zypper repositories for Red Hat Enterprise Linux, CentOS, openSUSE, and SUSE are changing **with this release** to being signed with a new GPG key with SHA2 digest algorithms instead of SHA1. See this blog post and the GPG page for more details.

InnoDB

- Full-text index corruption with system versioning (MDEV-25004)

Galera

- Fixes for cluster wide write conflict resolving (MDEV-29684)

Replication

- Parallel slave applying in binlog order is corrected for admin class of commands including ANALYZE (MDEV-30323)
- Seconds_Behind_Master is now shown now more precisely at the slave applier start, including in the delayed mode (MDEV-29639)
- `mysqlbinlog --verbose` is made to show the type of compressed columns (MDEV-25277)

JSON

- JSON_PRETTY added as an alias for JSON_DETAILED (MDEV-19160)

General

- Infinite sequence of recursive calls when processing embedded CTE (MDEV-30248)
- Crash with a query containing nested WINDOW clauses (MDEV-30052)
- Major performance regression with 10.6.11 (MDEV-29988)

Changelog

7.0.8.2.6 MariaDB 10.4.27 Release Notes

Download 10.4.27 | Release Notes | Changelog | Overview of 10.4

Release date: 7 Nov 2022

MariaDB 10.4 is a previous *stable* series of MariaDB, maintained until June 2024. It is an evolution of MariaDB 10.3 with

several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.27 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

SSL

- The server no longer tolerates incorrectly configured SSL (MDEV-29811). If you have enabled SSL in `my.cnf` but have not configured it properly (for example, a certificate file is missing), MariaDB used to silently disable SSL, leaving you under impression that everything was fine and connections were secure. Since this release, MariaDB will fail to start if SSL is enabled, but cannot be switched on.

Backup

- mariabackup --compress hangs (MDEV-29043)
- Assertion on info.page_size failed in xb_delta_open_matching_space (MDEV-18589)

InnoDB

- InnoDB unnecessarily extends data files (MDEV-13013)
- Adaptive hash index MDEV-27700, MDEV-29384
- MVCC and locking MDEV-29666, MDEV-27927
- Virtual columns MDEV-29299, MDEV-29753

Galera

- Galera updated to 26.4.13
- Galera server crashes after 10.3 > 10.4 upgrade (MDEV-29375)
- wsrep_incoming_addresses status variable prints 0 as port number if the port is not mentioned in wsrep_node_incoming_address system variable (MDEV-28868)

JSON

- JSON_VALUE() does not parse NULL properties properly (MDEV-27151)

Replication

- minor correction in unsafe warning message (MDEV-28827)
- False replication error-stop of REVOKE PRIVILEGES from a non-existing user on primary (MDEV-28530) in combination with a filtering replica is corrected
- SET DEFAULT ROLE replication is mended on a replica that filters system tables (MDEV-28294)

Repositories

- Beginning with the next release (Q1 2023), our Yum, DNF, and Zypper repositories for Red Hat, Fedora, and SUSE will be migrated to being signed with a new GPG key. The key we are migrating to is the same one we already use for our Debian and Ubuntu Repositories.
  - The short Key ID is: `0xC74CD1D8`
  - The long Key ID is: `0xF1656F24C74CD1D8`
  - The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
  - The key can be imported now in preparation for this change using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Docker Official Image

The following changes have been made to the `docker.io/library/mariadb` container image.

- The number of gpg packages packages has been removed, leaving enough to `apt-get update`, but `dirmngr` that would fetch keys has been removed. (inspired by issue #469)
- The environment variable `LANG=C.UTF-8` has been added for those that exec into containers and copy paste UTF8 characters (fixes issue #468).
- Adds OCI labels to image (fixes issue 436 and users need for version)
- MariaDB config: skip-host-cache and skip-name-resolve moved to `/etc/mysql/mariadb.conf.d/05-skipcache.cnf`

Security

- Fixes for the following security vulnerabilities: <</style

7.0.8.2.7 MariaDB 10.4.26 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.26 | Release Notes | Changelog | Overview of 10.4

Release date: 15 Aug 2022

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.26 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB corruption due to lack of file locking (MDEV-28495)
- FULLTEXT search with apostrophe, and mandatory words (MDEV-20797)
- ALTER TABLE IMPORT TABLESPACE corrupts an encrypted table (MDEV-28779)
- ALTER TABLE wrong-result fix (MDEV-26294)

Replication

- ER_SLAVE_INCIDENT error is specified now on slave to be seen with SHOW-SLAVE-STATUS (MDEV-21087)
- INCIDENT_EVENT is no longer binlogged when a being logged transaction can be safely rolledback (MDEV-21443)
- sequences related row-format events are made to correspond to binlog_row_image (MDEV-28487)

Galera

- Possible to write/update with read_only=ON and not a SUPER privilege (MDEV-28546)
- Node crashes with Transport endpoint is not connected mysqld got signal 6 (MDEV-25068)
- Galera4 not able to report proper wsrep_incoming_addresses (MDEV-20627)

Optimizer

- Server crash in JOIN_CACHE::free or in copy_fields (MDEV-23809)
  - Queries that use DISTINCT and an always-constant function like COLLATION(aggegate_func(...)) could cause a server crash. Note that COLLATION() is a special function - its value is constant even if its argument is not costant.
- Crash when using ANY predicand with redundant subquery in GROUP BY clause (MDEV-29139)
  - A query with a subuquery in this form could cause a crash:

```
... ANY (SELECT ... GROUP BY (SELECT redundant_subselect_here)) ...
```

- MariaDB Server SEGV on INSERT .. SELECT (MDEV-26427)
  - Certain queries in form "INSERT ... SELECT with_aggregate_or_window_func" could cause a crash.
- restore_prev_nj_state() doesn't update cur_sj_inner_tables correctly (MDEV-28749)
  - Subquery semi-join optimization could miss LooseScan or FirstMatch strategies for certain queries.
- Optimizer uses all partitions after upgrade to 10.3 (MDEV-28246)
  - For multi-table UPDATE or DELETE queries, the optimizer failed to apply Partition Pruning optimization for the table that is updated or deleted from.

CONNECT

- CONNECT Engine now supports INSERT IGNORE with Mysql Table type (MDEV-27766)

mysql Client

- New mysql client option, `-enable-cleartext-plugin` . Option does not do anything, and is for MySQL-compatibility purposes only.

General

- Crash in JSON_EXTRACT (MDEV-29188)
- ALTER TABLE ALGORITHM=NOCOPY does not work after upgrade (MDEV-28727)
- Server crash upon CREATE VIEW with unknown column in ON condition (MDEV-29088)
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Debian 10 "Buster" for ppc64el

Security

- Fixes for the following security vulnerabilities :
  - CVE-2023-5157
  - CVE-2022-32089
  - CVE-2022-32081
  - CVE-2018-25032
  - CVE-2022-32091
  - CVE-2022-32084
  - CVE-2022-38791

Changelog

7.0.8.2.8 MariaDB 10.4.25 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.25 | Release Notes | Changelog | Overview of 10.4

Release date: 20 May 2022

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.25 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- innodb_disallow_writes removed (MDEV-25975)
- InnoDB gap locking fixes (MDEV-20605, MDEV-28422)

Replication

- Server initialization time gtid_slave_pos purge related reason of crashing in binlog background thread is removed (MDEV-26473)
- Shutdown of the semisync master can't produce inconsistent state anymore (MDEV-11853)
- Binlogs disappear after rsync IST (MDEV-28583)
- master crash is eliminated in compressed semisync replication protocol with packet counting amendment (MDEV-25580)
- OPTIMIZE on a sequence does not cause counterfactual ER_BINLOG_UNSAFE_STATEMENT anymore (MDEV-24617)
- Automatically generated Gtid_log_list_event is made to recognize within replication event group as a formal member (MDEV-28550)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE using two or more unique key values at a time with MIXED format binlogging is corrected (MDEV-28310)
- Replication unsafe INSERT .. ON DUPLICATE KEY UPDATE stops issuing unnecessary "Unsafe statement" with MIXED binlog format (MDEV-21810)
- Incomplete replication event groups are detected to error out by the slave IO thread (MDEV-27697)
- mysqlbinlog --stop-never --raw now flushes the result file to disk after each processed event so the file can be listed

with the actual bytes (MDEV-14608)

Backup

- Incorrect binlogs after Galera SST using rsync and mariabackup (MDEV-27524)
- mariabackup does not detect multi-source replication slave (MDEV-21037)
- Useless warning "InnoDB: Allocated tablespace ID <id> for <tablename>, old maximum was 0" during backup stage (MDEV-27343)
- mariabackup prepare fails for incrementals if a new schema is created after full backup is taken (MDEV-28446)

Optimizer

- A SEGV in Item_field::used_tables/update_depend_map_for_order... (MDEV-26402)
- ANALYZE FORMAT=JSON fields are incorrect for UNION ALL queries (MDEV-27699)
- Subquery in an UPDATE query uses full scan instead of range (MDEV-22377)
- Assertion `item1->type() == Item::FIELD_ITEM ... (MDEV-19398)
- Server crashes in Expression_cache_tracker::fetch_current_stats (MDEV-28268)
- MariaDB server crash at Item_subselect::init_expr_cache_tracker (MDEV-26164, MDEV-26047)
- Crash with union of my_decimal type in ORDER BY clause (MDEV-25994)
- SIGSEGV in st_join_table::cleanup (MDEV-24560)
- Assertion `!eliminated' failed in Item_subselect::exec (MDEV-28437)

General

- Server error messages are now available in Chinese (MDEV-28227)
- For RHEL/CentOS 7, non x86_64 architectures are no longer supported upstream and so our support will also be dropped with this release
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Debian 9 "Stretch"

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46669
  - CVE-2022-21427
  - CVE-2022-27376
  - CVE-2022-27377
  - CVE-2022-27378
  - CVE-2022-27379
  - CVE-2022-27380
  - CVE-2022-27381
  - CVE-2022-27382
  - CVE-2022-27383
  - CVE-2022-27384
  - CVE-2022-27386
  - CVE-2022-27387
  - CVE-2022-27444
  - CVE-2022-27445
  - CVE-2022-27446
  - CVE-2022-27447
  - CVE-2022-27448
  - CVE-2022-27449
  - CVE-2022-27451
  - CVE-2022-27452
  - CVE-2022-27455
  - CVE-2022-27456
  - CVE-2022-27457
  - CVE-2022-27458
  - CVE-2022-32087
  - CVE-2022-32086
  - CVE-2022-32085
  - CVE-2022-32083
  - CVE-2022-32088

7.0.8.2.9 MariaDB 10.4.24 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.24 | Release Notes | Changelog | Overview of 10.4

Release date: 12 Feb 2022

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.24 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

- This release fixes a blocking problem with the MariaDB 10.4.23 release when manually running mariadb-upgrade. (MDEV-27789)
- See MariaDB 10.4.23 for other changes since the previous release.

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46665
  - CVE-2021-46664
  - CVE-2021-46661
  - CVE-2021-46668
  - CVE-2021-46663

Changelog

For a complete list of changes made in MariaDB 10.4.24, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.4.24, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). 7.0.8.2.10 MariaDB 10.4.23 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.23 | Release Notes | Changelog | Overview of 10.4

Release date: 9 Feb 2022

This release is no longer available for download after a problem was noticed when manually running mariadb-upgrade. See MDEV-27789 for more details.

Please use a later release.

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.23 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- --skip-symbolic-links does not disallow `.isl` file creation (MDEV-26870)
- Indexed CHAR columns are broken with NO_PAD collations (MDEV-25440)

Galera

- Galera updated to 26.4.11
- Galera SST scripts should use ssl_capath (not ssl_ca) for CA directory (MDEV-27181)
- Alter Sequence do not replicate to another nodes with in Galera Cluster (MDEV-19353)
- Galera crash - Assertion. Possible parallel writeset problem (MDEV-26803)
- CREATE TABLE with FOREIGN KEY constraint fails to apply in parallel (MDEV-27276)

Replication

- Seconds behind master corrected from artificial spikes at relay-log rotation (MDEV-16091)
- Statement rollback in binlog when transaction creates or drop temporary table is set right (MDEV-26833)
- CREATE-or-REPLACE SEQUENCE is made to binlog with the DDL flag to stabilize its parallel execution on slave (MDEV-27365)

Packaging & Misc

- prohibition running two upgrades in parallel (MDEV-27068, MDEV-27107, MDEV-27279)

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 21.04 Hirsute, CentOS 8, and Fedora 33
- mariadb_repo_setup script updated to version 2022-02-08, with the following fixes and enhancements:
  - Default location of the script has been moved to: https://r.mariadb.com/downloads/mariadb_repo_setup (old location is deprecated, but still works)
  - The GPG keyring file, used with Debian and Ubuntu repositories, has moved to: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg and the checksum for the file can be found at: https://supplychain.mariadb.com/mariadb-keyring-2019.gpg.sha256
  - Support for RHEL and SLES aarch64 repositories added
  - New function added to verify that the MariaDB Server version, if specified on the command line, follows the correct naming and that a corresponding repository actually exists.
  - Fixed repository pinning for Ubuntu and Debian repositories
  - MariaDB Server 10.7 is now the default server version

Docker Library

- Faster initialization by disabling binary logging during initialization (MDEV-27074)
- mysql_upgrade can be run if needed using the environment variable MARIADB_AUTO_UPGRADE=1 (MDEV-25670)
- A healthcheck script /usr/local/bin/healthcheck.sh is installed in the container with various checking options (MDEV-25434)
- mysql@localhost user is created with the environment variable MARIADB_MYSQL_LOCALHOST_USER=1 and additional grants (beyond USAGE) with MARIADB_MYSQL_LOCALHOST_GRANTS={global grant list} (MDEV-27732)
- skip innodb buffer pool loads/dumps on temporary startup/shutdown for faster startup/initialization, and accurate "healthcheck.sh --innodb_buffer_pool_loaded"
- change group ownership on datadir/socket dir (issue #401)
- log note about note on Securing system users, mysql_secure_installation not required (reddit suggestion)
- speed up Docker Library initialization of timezones (MDEV-27608, MDEV-23326)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2022-24052
  - CVE-2022-24051
  - CVE-2022-24050
  - CVE-2022-24048
  - CVE-2021-46659
  - CVE-2022-0778
  - CVE-2022-21595

Changelog

For a complete list of changes made in MariaDB 10.4.23, with links to detailed information on each push, see the changelog.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.11 MariaDB 10.4.22 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.22 | Release Notes | Changelog | Overview of 10.4

Release date: 8 Nov 2021

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.22 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

Galera

- Fix for `WSREP: invalid state ROLLED_BACK (FATAL)` (MDEV-25114)

InnoDB

- `ALTER TABLE…IMPORT TABLESPACE` fixes (MDEV-18543, MDEV-20931, MDEV-26131, MDEV-26621)
- `innodb_undo_log_truncate` fixes (MDEV-26450, MDEV-26672, MDEV-26864)

Replication

- Memory hogging on slave by ROW event applier is eliminated (MDEV-26712)
- `mysql --binary-mode` now properly handles `\\0` in data (MDEV-25444)
- Fixes race condition between `SHOW BINARY LOGS` and `RESET MASTER` (MDEV-20215)
- Missed statement rollback in case transaction drops or create temporary table is corrected (MDEV-26833)

Audit Plugin

- The `QUERY_DDL` server_audit_events setting now logs `CREATE/DROP [PROCEDURE / FUNCTION / USER]` statements. See MariaDB Audit Plugin - Log Settings. (MDEV-23457)

Packaging & Misc

- Session tracking flag in OK_PACKET (MDEV-26868)
- Some views force server (and mysqldump) to generate invalid SQL for their definitions (MDEV-26299)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-35604
  - CVE-2021-46667
  - CVE-2021-46662
  - CVE-2022-27385
  - CVE-2022-27385
  - CVE-2022-31624

Changelog

For a complete list of changes made in MariaDB 10.4.22, with links to detailed information on each push, see the changelog.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.12 MariaDB 10.4.21 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.21 | Release Notes | Changelog | Overview of 10.4

Release date: 6 Aug 2021

Warning: This version can cause InnoDB file corruption on FreeBSD and on AIX. If you are using AIX, please, stick to an earlier release, or upgrade to a more recent release. If you are using FreeBSD, upgrade to the bugfix release (the version ends with _1) of the mariadb-server from the Ports Collection. See MDEV-26537.

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.21 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

InnoDB

- InnoDB no longer acquires advisory file locks by default (MDEV-24393)
- Encryption: Automatically disable key rotation checks for file_key_management plugin (MDEV-14180)
- Some fixes from MySQL 5.7.35 (MDEV-26205)

Optimizer

- A query that uses ORDER BY .. LIMIT clause and "Range checked for each record optimization" could produce incorrect results under some circumstances (MDEV-25858)
- Queries that have more than 32 equality conditions comparing columns of different tables ("tableX.colX=tableY.colY) could cause a stack overrun in the query optimizer (MDEV-17783, MDEV-23937)
- "Condition pushdown into derived table" optimization cannot be applied if the expression being pushed refers to a derived table column which is computed from expression that has a stored function call, @session variable reference, or other similar construct. The fix for MDEV-25969 makes it so that only the problematic part of the condition is not pushed. The rest of the condition is now pushed. (MDEV-25969)
- A query with window function on the left side of the subquery could cause a crash. (MDEV-25630)

Packaging & Misc

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 20.10 Groovy
- Galera updated to 26.4.9

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-2372
  - CVE-2021-2389
  - CVE-2021-46658

MongoDB protocol support files for the CONNECT engine are missing in this release.
If you want to use CONNECT engine with MongoDB, you need to download
Mongo2.jar or Mongo3.jar and put a path to this file into the `connect_class_path` in the `my.cnf`.

Changelog

7.0.8.2.13 MariaDB 10.4.20 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.20 | Release Notes | Changelog | Overview of 10.4

Release date: 23 Jun 2021

MariaDB 10.4 is a previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.20 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Items

This version of MariaDB is being released now to fix the following two regressions:

- Table alias from previous statement interferes later commands (MDEV-25672)
- Join using derived with aggregation returns incorrect results (MDEV-25714)

In addition to the above, this release also contains the following fixes:

InnoDB

- InnoDB spatial indexes miss large geometry fields after MDEV-25459 (MDEV-25758)
- Double free of transaction during truncate operation (MDEV-25663)
- Double free of table when inplace alter FTS add index fails (MDEV-25721)
- Potential hang in purge for virtual columns (MDEV-25664)
- Change buffer entries for secondary indexes are lost on InnoDB restart (MDEV-25869)

Replication

- Do not replicate killed multi-table OPTIMIZE TABLE when the signal arrives before any table has been processed (MDEV-22530)
- Fix optistic parallel applier to not deadlock on admin commands OPTIMIZE, REPAIR, and ANALYZE (MDEV-17515)
- Backport MDEV-20821 parallel slave server shutdown hang (MDEV-22370)

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-46666
  - CVE-2021-46657

MongoDB protocol support files for the CONNECT engine are missing in this release.
If you want to use CONNECT engine with MongoDB, you need to download
Mongo2.jar or Mongo3.jar and put a path to this file into the `connect_class_path` in the `my.cnf`.

Changelog

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.14 MariaDB 10.4.19 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.19 | Release Notes | Changelog | Overview of 10.4

Release date: 7 May 2021

MariaDB 10.4 is the previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.19 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

- ST_DISTANCE_SPHERE for calculating the spherical distance between two geometries (point or multipoint) on a sphere (MDEV-13467)
- Crash with invalid multi-table update of view in 2nd execution of SP (MDEV-24823)
- Incorrect name resolution for subqueries in ON expressions (MDEV-25362)
- Complex query in Store procedure corrupts results (MDEV-25182)
- `DELETE HISTORY` may delete current data on system-versioned table (MDEV-25468)
- Crashes with nested table value constructors (MDEV-22786)
- Server crashes in `thd_clear_errors()` (MDEV-23542)
- The statement set `password=password('')` executed in PS mode fails in case it is run by a user with expired password (MDEV-25197)

mariabackup

- RENAME TABLE causes "Ignoring data file" messages (MDEV-25568)

InnoDB

- Deprecated the `*innodb` and `*none` options in innodb_checksum_algorithm (MDEV-25106)
- MVCC read from index on CHAR or VARCHAR wrongly omits rows (MDEV-25459)
- Race conditions in persistent statistics (MDEV-10682, MDEV-18802, MDEV-25051)
- Sequence created by one connection remains invisible to another (MDEV-24545)
- innodb_flush_method=O_DIRECT fails on compressed tables (MDEV-25121)

Replication

- Replication Heartbeat event was uncapable to cary 4GB+ offsets (MDEV-16146)
- FLUSH LOGS race against Binlog checkpoint event creation (MDEV-24526)
- slave_compressed_protocol did not work correctly with semi-sync (MDEV-24773)

Galera

- Galera updated to 26.4.8
- SET PASSWORD command fail with wsrep api (MDEV-25258)
- Long BF log wait turns on InnoDB Monitor output without telling, never turns it off (MDEV-25319)
- Assertion `` `state_ == s_exec' `` failed in `wsrep::client_state::start_transaction` (MDEV-22227)
- Frequently Crashing Mariadb Cluster 10.4.18 (MDEV-24980)
- Signal 11 on `TABLE_LIST::placeholder()` (MDEV-24878)
- `ALTER TABLE` not replicated with Galera in MariaDB 10.5.9 (MDEV-24956)
- "Flush SSL" command doesn't reload wsrep cert (MDEV-22668)
- Avoid unnecessary rollbacks with SR (MDEV-25553)

Packaging & Misc

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 16.04 Xenial

Security

- Fixes for the following security vulnerabilities:
  - CVE-2021-2166
  - CVE-2021-2154
  - CVE-2022-21451

MongoDB protocol support files for the CONNECT engine are missing in this release.
If you want to use CONNECT engine with MongoDB, you need to download
Mongo2.jar or Mongo3.jar and put a path to this file into the `connect_class_path` in the `my.cnf`.

Changelog

7.0.8.2.15 MariaDB 10.4.18 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.18 | Release Notes | Changelog | Overview of 10.4

Release date: 22 Feb 2021

Last month long-time MariaDB VP of Engineering, Rasmus Johansson, passed due to complications from cancer. His loss has been felt keenly by the whole MariaDB team. Our thoughts are with his family during this difficult time and this release is dedicated to his memory.

MariaDB 10.4 is the previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.18 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

InnoDB

- MDEV-24188 - Hang in buf_page_create() after reusing a previously freed page
- MDEV-24275 - InnoDB persistent stats analyze forces full scan forcing lock crash
- MDEV-24449 - Corruption of system tablespace or last recovered page

Galera

- Galera updated to 26.4.7
- MDEV-23328 - Server hang due to Galera lock conflict resolution
- MDEV-23851 - BF-BF Conflict issue because of UK GAP locks
- MDEV-20717 - Plugin system variables and activation options can break mysqld --wsrep_recover
- MDEV-24469 - Assertion `active() == false` failed with "XA START.."

- MDEV-23647 - Garbd can't initiate SST anymore in 10.5
- MDEV-25179 - wsrep_provider and wsrep_notify_cmd system variables are now read-only

Replication

- MDEV-8134 - relay-log is corrected to rotate past 999999
- MDEV-23033 - fixed slave applier for row-based events with FK constraints on virtual columns
- MDEV-4633 - Relay_Log_Space of Show-Slave-Status is made thread-safe
- MDEV-10272 - add master host/port info to slave thread exit messages
- MDEV-23846 - improves mysqlbinlog error message issuing

Misc

- MDEV-24122 - anomalies in mysql.user tables on previously 5.7 MySQL versions corrected
- Binary tarballs now use WolfSSL v4.6.0
- MDEV-23630 - mysqldump --system option
- Fixes for the following security vulnerabilities:
  - CVE-2021-27928

Changelog

For a complete list of changes made in MariaDB 10.4.18, with links to detailed information on each push, see the changelog.

Contributors

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.16 MariaDB 10.4.17 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.17 | Release Notes | Changelog | Overview of 10.4

Release date: 11 Nov 2020

MariaDB 10.4 is the previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.17 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

- Out-of-cycle release to fix regressions in MariaDB 10.4.16
- Follow up to MDEV-19838 to alter protocol checks to support the following implementations (which add garbage to the end of some packets):
  - PHP PDO (all versions) (MDEV-24121)
  - mysqlnd (from PHP < 7.3) (MDEV-24121)
  - mysql-connector-python (all versions) (MDEV-24134)
  - and mysql-connector-java (all versions)
- Arbitrary InnoDB buffer pool and data file corruption (MDEV-24096)
- The query optimizer consumed a lot of memory when handling construct in form of `key_column [NOT] IN (large-list-of constants)` (MDEV-24117)

Changelog

For a complete list of changes made in MariaDB 10.4.17, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.4.17, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.17 MariaDB 10.4.16 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.16 | Release Notes | Changelog | Overview of 10.4

Release date: 3 Nov 2020

MariaDB 10.4 is the previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.16 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

This release introduced an InnoDB data corruption bug (MDEV-24096). If any InnoDB tables contain indexed virtual columns or unique indexes on BLOB or TEXT columns, any InnoDB tables or tablespaces may become irrepairably corrupted.

- Set the default value of innodb_log_optimize_ddl to `OFF` by default (MDEV-23720)
- BLACKHOLE Storage Engine maximum index size increased from 1000 to 3500 bytes (MDEV-24017)
- Calculating (auto rounding) issue (MDEV-23702)
- Temporary tables can no longer overwrite existing files. Instead an error is returned should a conflict occur (MDEV-

23569)
- Binlog checksum verification at recovery time (MDEV-23832)
- Verbose print-out of Geometry types by mysqlbinlog (MDEV-22330)
- SHOW BINLOG EVENTS from <pos> validates <pos> when binlog checksummed (MDEV-21839)
- Freeing memory of replicate_do_table (MDEV-23534)
- Corrected verbose mysqlbinlog output for multi-record Rows-log-event (MDEV-16372)
- SET GLOBAL replicate_do_db = DEFAULT no longer causes crash (MDEV-20744)
- User killed queries that were running an index condition pushdown in InnoDB will now return an error (MDEV-23938)
- Wrong direxec param data caused crash; Numerous fixes about Mac builds (by Dmitri Shulga) (MDEV-19838)
- server_audit plugin now logs proxy users (MDEV-19443)
- Crash on `SELECT` on a table with indexed virtual columns (MDEV-18366)
- InnoDB updated to 5.7.32 (MDEV-23989)
- Bug fixes related to adaptive hash index (MDEV-23452, MDEV-23370)
- Fixed a bug in the recovery of encrypted tables (MDEV-23456)
- Fixed a race condition in MVCC reads (MDEV-22924)
- `ALTER TABLE` fixes (MDEV-22277, MDEV-22939, MDEV-23199, MDEV-23356, MDEV-23499, MDEV-23672, MDEV-23685, MDEV-23722)
- Diskspace not reused for BLOB in data file (MDEV-23072)
- InnoDB: Failing assertion: `!space->referenced()` (MDEV-23651)
- `SIGSEGV` in `maria_create()` because of double free (MDEV-23222)
- `CREATE TEMPORARY TABLE .. LIKE` (system versioned table) returns error if unique index is defined in the table (MDEV-23968)
- Error upon querying the view, that selecting from versioned table with partitions (MDEV-23779)
- `CREATE .. SELECT` wrong result on join versioned table (MDEV-23799)
- `SIGSEGV` in `check_fields` on `UPDATE` (MDEV-22805)
- Parser fix (MDEV-23094)
- Fixed crash in Innodb when rowid_filter query is killed (MDEV-22761)
- Fixed a crash with the NTH_VALUE function (MDEV-15180)
- Computing certain window functions on a server started with --encrypt-tmp_files=ON could cause a wrong query result or crash (MDEV-23867)
- A query with a certain form of WHERE clause over a table with multiple indexes could pick a less efficient range plan (MDEV-23811)
- Fixed a memory leak for correlated subqueries with ROLLUP (MDEV-17066)

Galera

- Galera wsrep library updated to 26.4.6
- Fixed assertion failure on before_commit (MDEV-22681)
- Fixed assertion after ROLLBACK AND CHAIN (MDEV-22055)
- IPv6 SST handling improved (MDEV-21770, MDEV-23576, MDEV-23580, MDEV-23581, MDEV-23574)
- Fixed SIGSEGV in lock_rec_unlock (MDEV-23101)
- Fixed replication of timezone if only 1 timezone is loaded (MDEV-22626)
- Fixed replication of CREATE OR REPLACE TRIGGER (MDEV-21578)
- Fixed SST FLUSH TABLES WITH READ LOCK timeout (MDEV-22543)

Notes

- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for CentOS/RHEL 6 and Fedora 31
- Packages for Ubuntu 20.10 "Groovy Gorilla" added
- Packages for Debian 10 "buster" arm64 and ppc64el added
- Packages for Debian 9 "stretch" arm64 added

- Fixes for the following security vulnerabilities:
  - CVE-2020-14812
  - CVE-2020-14765
  - CVE-2020-14776
  - CVE-2020-14789
  - CVE-2020-28912 (MDEV-24040)
  - CVE-2021-2194 (MDEV-18366)

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the

Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.18 MariaDB 10.4.15 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download 10.4.15 | Release Notes | Changelog | Overview of 10.4

Release date: 7 Oct 2020

MariaDB 10.4 is the previous *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.15 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

- Fixes for the following security vulnerabilities:
  - CVE-2020-15180

Changelog

7.0.8.2.19 MariaDB 10.4.14 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 10 Aug 2020

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.14 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Variables

- Limit innodb_encryption_threads to 255 (MDEV-22258).
- Minimum value of max_sort_length raised to 8 (previously 4) so fixed size data types like DOUBLE and BIGINT are not truncated for lower values of max_sort_length (MDEV-22715).

InnoDB

- Fixed corruption in delete buffering (MDEV-22497)
- Fixed a deadlock in FLUSH TABLES…FOR EXPORT (MDEV-22890)
- InnoDB data file extension is not crash-safe (MDEV-23190)
- Minor fixes related to encryption and FULLTEXT INDEX
- Dropping the adaptive hash index may cause DDL to lock up InnoDB (MDEV-22456)
- `innodb_log_optimize_ddl=OFF` is not crash safe (MDEV-21347)
- Mariadb service won't shutdown when it's running and the OS datetime updated backwards (MDEV-17481)
- Doublewrite recovery can corrupt data pages (MDEV-11799)
- Fixed race conditions related to buffer pool resizing
- ALTER TABLE fixes (MDEV-22637, MDEV-23244, MDEV-22988, MDEV-23295, MDEV-22771)
- Slow InnoDB shutdown on large instance (MDEV-22778)
- Performance improvements (MDEV-22778)
- Crash recovery fixes (MDEV-21347, MDEV-23190, MDEV-11799)

Replication

- Make the binlog dump thread to log into errorlog a requested GTID position (MDEV-20428)
- Fix stop of the optimistic parallel slave at requested START-SLAVE-UNTIL position (MDEV-15152)
- Properly handle `RESET MASTER TO` value, when the value exceeds the max allowed `2147483647` (MDEV-22451)
- Correct 'relay-log.info' updating by concurrent parallel workers (MDEV-22806)
- Eliminate deadlock involving parallel workers, `STOP SLAVE` and `FLUSH TABLES WITH READ LOCK` (MDEV-23089)
- Correct master-slave automatic reconnection by slave to always pass through all steps of the initial connect. Specifically, do not skip master notification about slave binlog checksum awareness (MDEV-14203)
- Refine mysqlbinlog output to print out `START TRANSACTION` at `Gtid_log_event` processing which satisfies clients that submit the output with `sql_mode=oracle` (MDEV-23108)
- Replication aborts with `ER_SLAVE_CONVERSION_FAILED` upon `CREATE ... SELECT` in ORACLE mode (MDEV-19632)

Optimizer

- ALTER TABLE ... ANALYZE PARTITION ... with EITS reads and locks all rows ... (MDEV-21472)
- Print ranges in the optimizer trace created for non-indexed columns when `optimizer_use_condition_selectivity >2` Now the optimizer trace shows the ranges constructed while getting estimates from EITS (MDEV-22665)
- `LATERAL DERIVED` is not clearly visible in `EXPLAIN FORMAT=JSON`, make `LATERAL DERIVED` tables visible in `EXPLAIN FORMAT=JSON` output (MDEV-17568)
- Crash on `WITH RECURSIVE` large query (MDEV-22748)
- Crash with Prepared Statement with a '?' parameter inside a re-used CTE (MDEV-22779)

Other

- div_precision_increment is now taken into account for all intermediate calculations. Previously results could be unpredictable. Note that this means results will have a lower precision in some cases - see div_precision_increment (MDEV-19232)
- mariadb_schema data type qualifier allowing MariaDB native date types in an SQL_MODE that has conflicting data type translations.
- MariaDB could crash after changing the query_cache size (MDEV-5924)
- Errors and SIGSEGV on CREATE TABLE w/ various charsets (MDEV-22111)
- Crash in `CREATE TABLE AS SELECT` when the precision of returning type = 0 (MDEV-22502)
- XA: Reject DDL operations between PREPARE and COMMIT (MDEV-22420)
- Stop `mariabackup --prepare` on errors during innodb redo log applying (MDEV-22354)
- Server crashes in `mysql_alter_table` upon adding a non-null date column under `NO_ZERO_DATE` with `ALGORITHM=INPLACE` (MDEV-18042)
- Can't uninstall plugin if the library file doesn't exist (MDEV-21258)
- Mariabackup parameter cleanup (MDEV-18215, MDEV-21298, MDEV-21301, MDEV-22894)
- Rounding functions return wrong datatype (MDEV-23366, MDEV-23367, MDEV-23368, MDEV-23350, MDEV-23351, MDEV-23337, MDEV-23323)
- Create `mariadb.sys` user on each update even is the user is not needed (MDEV-23102)
- Galera wsrep library updated to 26.4.5
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 19.10 Eoan and Fedora 30

- Fixes for the following security vulnerabilities:
  - CVE-2021-2022

Changelog

7.0.8.2.20 MariaDB 10.4.13 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 12 May 2020

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.13 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Events

- Fixed issue that, from MariaDB 10.3.19, disabled all events created by a server with a different `server_id`. Note that the fix does not re-enable affected events. (MDEV-21758)

Privileges

- SHOW PRIVILEGES now correctly lists the `Delete history` privilege, rather than displaying it as `Delete versioning rows`. (MDEV-20382)

Performance

- Optimizer flag rowid_filter leads to long query (MDEV-21794)
- WSREP_ON is unnecessarily expensive to evaluate (MDEV-22203)
- Misc wsrep performance optimization (MDEV-7962)

Security

- Added system user for user view which allows to remove root (MDEV-19650)
- WolfSSL updated
- ALTER USER doesn't remove excess authentication plugins from mysql.global_priv (MDEV-21928)
- mysql_upgrade creating empty global_priv table (MDEV-21244)

Aria

- Updated `aria_pack` to support transactional tables and added options: `--datadir`, `--ignore-control-file`, `--require-control-file`, more details here

ALTER TABLE

- Error on online ADD PRIMARY KEY after instant DROP/reorder (MDEV-21658)
- Assertion failure in file data0type.cc (MDEV-20726)
- Server aborts upon attempt to create foreign key on spatial field (MDEV-21792)
- DROP COLUMN, DROP INDEX is wrongly claimed to be ALGORITHM=INSTANT (MDEV-22465)
- Introduce a file format constraint to ALTER TABLE. See innodb_instant_alter_column_allowed (MDEV-20590)
- FORCE all partition to rebuild if any one of the partition does rebuild (MDEV-21832)
- InnoDB aborts while adding instant column for discarded tablespace (MDEV-22446)

FULLTEXT INDEX

- Assertion `` `!table->fts->in_queue' `` failed in `fts_optimize_remove_table` (MDEV-21550)
- FTS thread aborts during shutdown (MDEV-21563)

Optimizer

- Optimizer, Wrong query results with `optimizer_switch="split_materialized=on"` (MDEV-21614)
- SHOW GRANTS does not quote role names properly (MDEV-20076)
- Paritioning INSERT chooses wrong partition for RANGE partitioning by DECIMAL column (MDEV-21195)

Mariabackup

- Mariabackup does not honor ignore_db_dirs from server config (MDEV-19347)
- Mariabackup `--ftwrl-wait-timeout` never times out on explicit lock (MDEV-20230)

Crash Recovery

- Running out of file descriptors and eventual crash (MDEV-18027)

Galera

- Galera wsrep library updated to 26.4.4
- Galera Cluster Node During IST gets stuck going from "Synced" to "Joining:..." (MDEV-21002)

Other

- HeidiSQL updated to 11.0 (MDEV-22032)
- Wrong estimate of affected BLOB columns in update of PRIMARY KEY (MDEV-22384)
- Duplicate key value is silently truncated to 64 characters in `print_keydup_error` (MDEV-20604)
- Session tracking returns incorrectly long tracking data (MDEV-22504)
- Add `pam_user_map.so` file to binary tarball package (MDEV-21913)
- mysql_upgrade is made aware of the upstream slave tables to issue warnings when that takes place (MDEV-10047)
- Corruption for `SET GLOBAL innodb_` string variables (MDEV-22393)
- mysqldump parameter, `--ignore-table-data`, added (MDEV-22037)
- Server can fail while replicating conditional comments (Bug#28388217)
- Added the `xml-report` option to mysql-test-run (MDEV-22176)
- Packages and repositories for Ubuntu 20.04 "focal" added
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Debian 8 "Jessie"
- Fixes for the following security vulnerabilities:
  - CVE-2020-2752
  - CVE-2020-2812
  - CVE-2020-2814
  - CVE-2020-2760
  - CVE-2020-13249

Changelog

7.0.8.2.21 MariaDB 10.4.12 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Note that this version contains an issue that disabled all events created by a server with a different server_id. See MDEV-21758 for details.

Download | Release Notes | Changelog | Overview of 10.4

Release date: 28 Jan 2020

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features

not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.12 will be a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

General

- MDEV-21337: fix aligned_malloc()
- MDEV-21343: Threadpool/Unix- wait_begin() function does not wake/create threa ds, when it should
- wolfssl updated to v4.3.0-stable
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Ubuntu 19.04 Disco

Mariabackup

- MDEV-21255: Deadlock of parallel slave and mariabackup (with failed log copy thread)

InnoDB

- MDEV-20950: Reduce size of record offsets
- MDEV-19176: Reduce the memory usage during recovery
- MDEV-21429: TRUNCATE and OPTIMIZE are being refused due to "row size too large"
- MDEV-21500: Server hang when using simulated AIO
- MDEV-21509: Possible hang during purge of history, or rollback
- MDEV-21511: Wrong estimate of affected BLOB columns in update
- MDEV-21512: InnoDB may hang due to SPATIAL INDEX
- MDEV-21513: Avoid some crashes in ALTER TABLE...IMPORT TABLESPACE
- MDEV-18865: Assertion `t->first->versioned_by_id()' failed in innodb_prepare_commit_versioned
- MDEV-21260: InnoDB does not report error when trying open volumes on UNC paths on Windows

Aria

- MDEV-14183: aria_pack segfaults in compress_maria_file

Optimizer

- MDEV-21318: Wrong results with window functions and implicit grouping
- MDEV-16579: Wrong result of query using DISTINCT COUNT(*) OVER (*)
- MDEV-21383: Possible range plan is not used under certain conditions

Replication

- MDEV-18046: Crashes caused by random values to the offset option of SHOW BINLOG EVENT offset command
- MDEV-19376: Semisync Master could crash when it executed RESET MASTER and a replica reconnects using GTID protocol
- MDEV-20821: parallel slave server shutdown may hang when slave workers were online

Security

- Fixes for the following security vulnerabilities:
  - CVE-2020-2574
  - CVE-2020-7221

Changelog

For a complete list of changes made in MariaDB 10.4.12, with links to detailed information on each push, see the changelog.

7.0.8.2.22 MariaDB 10.4.11 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Note that this version contains an issue that disabled all events created by a server with a different server_id. See MDEV-21758 for details.

Download | Release Notes | Changelog | Overview of 10.4

Release date: 11 Dec 2019

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.11 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

General

- MDEV-13492: SEC_E_INVALID_TOKEN when server sends large message during SSL handshake

Mariabackup

- MDEV-18310: Aria engine: Undo phase failed from incremental backup

InnoDB

- MDEV-20949: Stop issuing '`row size`' error on DML
- MDEV-20832: Don't print "`row size too large`" warnings in error log if `innodb_strict_mode=OFF` and `log_warnings<=2`
- MDEV-21024: Remove redundant writes to the redo log
- MDEV-21069: Crash on `DROP TABLE` if the data file is corrupted
- some cleanup of AIO code, to better report errors
- MDEV-20611: MRR scan over partitioned InnoDB table produces "`Out of memory`" error
- MDEV-21088: Table cannot be loaded after instant `ADD/DROP COLUMN`
- MDEV-21045: heap-use-after-poison in `ADD PRIMARY KEY` after instant `ADD COLUMN`
- MDEV-21172: Memory leak after failed `ADD PRIMARY KEY`

- MDEV-21158: `trx_undo_seg_free()` is never redo-logged
- MDEV-20190: Instant operation fails when add column and collation change on non-indexed column

Optimizer

- MDEV-21044: Wrong result when using a smaller size for sort buffer
- MDEV-20611: MRR scan over partitioned InnoDB table produces "Out of memory" error
- MDEV-20407: mysqld got `signal 11 ; rowid_filter`

Replication

- MDEV-19376: `Repl_semi_sync_master::commit_trx` assertion failure
- MDEV-20707: Missing memory barrier in parallel replication error handler in `wait_for_prior_commit()`

Versioning

- MDEV-18929: 2nd execution of SP does not detect `ER_VERS_NOT_VERSIONED`
- MDEV-21011: Table corruption reported for versioned partitioned table after `DELETE`

Misc

- Packages for Fedora 31 have been added in this release
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for Fedora 29

Changelog

7.0.8.2.23 MariaDB 10.4.10 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Note that this version contains an issue that disabled all events created by a server with a different server_id. See MDEV-21758 for details.

Download | Release Notes | Changelog | Overview of 10.4

Release date: 8 Nov 2019

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.10 will be a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

- MDEV-20987: InnoDB fails to start when FTS table has FK relation
- See also the release notes for MariaDB 10.4.9 for additional items of note

Changelog

For a complete list of changes made in MariaDB 10.4.10, with links to detailed information on each push, see the changelog.

Contributors

7.0.8.2.24 MariaDB 10.4.9 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

After an upgrade MariaDB Server can crash if InnoDB tables exist with a `FULLTEXT INDEX` and a `FOREIGN KEY` constraint attached to them. We got reports that the crash already will be encountered on startup, but a crash is also possible at a later stage. See MDEV-20987 for more details.

Do not download or use this release.

Download | Release Notes | Changelog | Overview of 10.4

Release date: 5 Nov 2019

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.9 will be a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- MDEV-20864: Debug-only option innodb_change_buffer_dump for dumping the contents of the InnoDB change buffer to the server error log at startup.
- MariaBackup:
  - MDEV-18438: mbstream recreates xtrabackup_info on same directory as backup file
  - MDEV-20703: mariabackup creates binlog files in server binlog directory on --prepare --export step
- FULLTEXT INDEX:
  - MDEV-19647: Server hangs after dropping full text indexes and restart
  - MDEV-19529: InnoDB hang on `DROP FULLTEXT INDEX`
  - MDEV-19073: FTS row mismatch after crash recovery
  - MDEV-20621: FULLTEXT INDEX activity causes InnoDB hang
- MDEV-20927: Duplicate key with auto increment
- ALTER TABLE:
  - MDEV-20799: DROP Virtual Column crash
  - MDEV-20852: BtrBulk is unnecessarily holding `dict_index_t::lock`
- System-Versioned Tables:
  - MDEV-16210: FK constraints on versioned tables use historical rows, which may cause constraint violation
  - MDEV-20812: Unexpected `ER_ROW_IS_REFERENCED_2` or server crash in `row_ins_foreign_report_err` upon DELETE from versioned table with FK
- MDEV-20117: corruption after instant DROP/reorder COLUMN
- Galera wsrep library updated to 26.4.3
- Packages for Ubuntu 19.10 Eoan have been added in this release
- Fixes for the following security vulnerabilities:
  - CVE-2019-2974
  - CVE-2019-2938
  - CVE-2020-2780
  - CVE-2021-2144

Changelog

7.0.8.2.25 MariaDB 10.4.8 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 11 Sep 2019

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.8 will be a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- Connect updated to Connect 1.06.0010
- MDEV-20231: Update server HELP
- MDEV-20066: This bug could cause a table to become corrupt if a column was added instantly
- MDEV-15326: A race condition in InnoDB transaction commit that affects record locking was fixed
- MDEV-17187: Table doesn't exist in engine after ALTER of FOREIGN KEY
- MDEV-20301: InnoDB's MVCC has `O(N^2)` behaviors
- MDEV-18128: Simplify .ibd file creation
- MDEV-20060: Failing assertion: `srv_log_file_size <= 512ULL << 30` while preparing backup
- MDEV-20247: Replication hangs with "preparing" and never starts
- MDEV-17614: Remove unnecessary locking for `INSERT...ON DUPLICATE KEY UPDATE`
- MDEV-20311: row_ins_step accesses uninitialized memory
- MDEV-20479: Assertion failure in `dict_table_get_nth_col()` after `INSTANT DROP COLUMN`
- MDEV-20340: Encrypted temporary tables cannot be read with `innodb_checksum_algorithm=full_crc32`
- MDEV-19947: Repositories for RHEL 8 ppc64le added

Changelog

For a complete list of changes made in MariaDB 10.4.8, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.4.8, see the MariaDB Foundation release announcement.

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.26 MariaDB 10.4.7 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 31 Jul 2019

MariaDB 10.4 is the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.7 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- MDEV-19922: HeidiSQL updated to 10.2
- MDEV-19795: Merge upstream MyRocks.
- MDEV-17228: Encrypted temporary tables are not encrypted.
- MDEV-18328: Disks Plugin is now stable and requires the FILE privilege.
- MDEV-16508: Spider - sql_mode not maintained between spider node and data nodes.
- Merge relevant InnoDB changes from MySQL 5.7.27
- Adjust spin loops to the x86 PAUSE instruction latency (MDEV-19845)
- MDEV-20102: When the ctas from a big table is interrupted ,then you can't drop or recreate the table
- MDEV-19292: InnoDB's row size calculations were fixed, which might result in "Row size too large" errors when creating or altering tables with lots columns. This can occur even if previous MariaDB releases did not throw errors for the same tables. Some workarounds are listed at InnoDB Row Formats Overview: Upgrading Causes Row Size Too Large Errors.
- ALTER TABLE: MDEV-15641, MDEV-19630, MDEV-19916, MDEV-19974, MDEV-17301, MDEV-18266
- Indexed virtual columns: MDEV-16222, MDEV-17005, MDEV-19870
- FULLTEXT INDEX: MDEV-14154
- Encryption: MDEV-17228, MDEV-19914
- Galera + FOREIGN KEY: MDEV-19660
- Recovery & Mariabackup: MDEV-19978
- MDEV-20091: DROP TEMPORARY table is logged despite no CREATE was logged
- MDEV-19871: Add page id matching check in innochecksum tool
- MDEV-20179: Server hangs on shutdown during installation of Spider
- As per the MariaDB Deprecation Policy, this will be the last release of MariaDB 10.4 for OpenSUSE 42.3 and Ubuntu 18.10 "Cosmic"
- Fixes for the following security vulnerabilities:
  - CVE-2019-2805
  - CVE-2019-2740
  - CVE-2019-2739
  - CVE-2019-2737
  - CVE-2019-2758
  - CVE-2020-2922
  - CVE-2021-2007

Changelog

For a complete list of changes made in MariaDB 10.4.7, with links to detailed information on each push, see the changelog.

Contributors

7.0.8.2.27 MariaDB 10.4.6 Release Notes

Download | Release Notes | Changelog | Overview of 10.4

Release date: 18 Jun 2019

With this release, MariaDB 10.4 is now the current *stable* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.6 is a ***Stable (GA)*** release.

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- MariaDB Server is now statically linked with the bundled wolfSSL library in MSI and ZIP packages on Windows, as well as in .deb packages provided by Debian's and Ubuntu's default repositories (MDEV-18531).
  - See TLS and Cryptography Libraries Used by MariaDB for more details.
- MariaDB Named Commands (MDEV-17591)
- System-versioned tables: MDEV-19486
- Galera: MDEV-17458
- Virtual columns: MDEV-19027, MDEV-19602
- Recovery: MDEV-19541, MDEV-19587, MDEV-19435
- Encryption: MDEV-19509, MDEV-19695
- Other:
  - MDEV-19614 - SET GLOBAL innodb_ deadlock due to LOCK_global_system_variables
  - MDEV-19725 - Incorrect error handling in ALTER TABLE

Changelog

For a complete list of changes made in MariaDB 10.4.6, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.4.6, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.28 MariaDB 10.4.5 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 21 May 2019

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.5 is a ***Release Candidate (RC)*** release.

Do not use non-stable (non-GA) releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

General Server

- New mysqlimport option, `--ignore-foreign-keys` (MDEV-788).
- Setting sql_mode to `MSSQL` implements a limited subset of Microsoft SQL Server's language. See SQL_MODE=MSSQL (MDEV-19142).
- Add CAST(expr AS FLOAT) (MDEV-16872).
- List of slave transaction errors that will result in a retry rather than a halt (slave_transaction_retry_errors) have been increased by default, assisting Spider setups to be more robust (MDEV-16543).
- MDEV-15458 - Segfault in heap_scan() upon UPDATE after ADD SYSTEM VERSIONING
- MDEV-19235 - MariaDB Server compiled for 128 Indexes crashes at startup

JSON

- JSON_MERGE_PATCH and JSON_MERGE_PRESERVE (MDEV-13992)

InnoDB

- Merge InnoDB changes from MySQL 5.6.44 and 5.7.26
- Fixes of corruption or crashes: MDEV-19241, MDEV-13942, MDEV-19385, MDEV-16060, MDEV-18220, MDEV-17540
- InnoDB recovery fixes and speedup: MDEV-12699, MDEV-19356

Encryption

- MDEV-14398 - innodb_encrypt_tables will work even with innodb_encryption_rotate_key_age=0

System-Versioned Tables

- MDEV-15966 - System-versioned tables are now protected from TRUNCATE TABLE statements.

Information schema

- MDEV-19490 show tables fails when selecting the information_schema database

Statistics

- MDEV-19407 - Assertion `field->table->stats_is_read' failed in is_eits_usable
- New status variable, Aborted_connects_preauth, that records the number of connection attempts that were aborted prior to authentication (MDEV-19277).

Packaging

- As per the MariaDB Deprecation Policy, this is the last release of MariaDB 10.4 for Fedora 28
- Packages and a repository for Fedora 30 and Ubuntu 19.04 "disco" have been added with this release, visit the Repository Configuration Tool for instructions on adding the repository

Security

- Fixes for the following security vulnerabilities:
  - CVE-2019-2614

- CVE-2019-2627
- CVE-2019-2628

Changelog

For a complete list of changes made in MariaDB 10.4.5, with links to detailed information on each push, see the changelog.

Contributors

For a full list of contributors to MariaDB 10.4.5, see the MariaDB Foundation release announcement.

Be notified of new MariaDB Server releases automatically by subscribing to the MariaDB Foundation community announce 'at' lists.mariadb.org announcement list (this is a low traffic, announce-only list). MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.29 MariaDB 10.4.4 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now

Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 7 Apr 2019

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.4 is a ***Release Candidate*** release.

Do not use non-stable (non-GA) releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

- Enhancements:
  - MDEV-12026/MDEV-18644: innodb_checksum_algorithm=full_crc32 (more robust file format)
  - MDEV-13301: Optimize DROP INDEX, ADD INDEX into RENAME INDEX
  - MDEV-17380: innodb_flush_neighbors=ON should be ignored on SSD
- InnoDB data corruption fixes: MDEV-14126, MDEV-18981, MDEV-18879, MDEV-18972, MDEV-18272
- Performance fixes to purge, startup and shutdown: MDEV-18936, MDEV-18878, MDEV-18733
- Various fixes to ALTER TABLE
- Replication:
  - MDEV-18450: wait for all slaves shutdown
  - MDEV-19116, MDEV-19117: speed up rotation of binary logs, `SHOW BINARY LOGS` etc with optimizing binary log index file locking
- Includes Connector/C 3.1.0
- Repositories for CentOS 7, RHEL 7 & 8, Fedora 28 & 29, and SLES 12 & 15 now include a src.rpm file that you can

use to build MariaDB. Instructions for doing so are found on the Building MariaDB from a Source RPM page
- The Galera library in the repositories has been updated to version **26.4.2**
- As per the MariaDB Deprecation Policy, this is the last release of MariaDB 10.4 for Ubuntu 14.04 Trusty

Changelog

7.0.8.2.30 MariaDB 10.4.3 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 25 Feb 2019

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.3 is a ***Release Candidate*** release.

Do not use non-stable (non-GA) releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- MDEV-12484: The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB
- MDEV-11340: Allow multiple alternative authentication methods for the same user
- MDEV-7597: User password expiry
- MDEV-6111: Implementation of the optimizer trace, one can enable the optimizer trace by enabling the system variable optimizer_trace
- Temporal tables extended with support for application-time periods (MDEV-16973, MDEV-16974, MDEV-16975, MDEV-17082)
- MDEV-18551: The default for eq_range_index_dive_limit is now `200` (previously `0`)
- MDEV-17903: The optimizer switch flag `optimize_join_buffer_size` now defaults to `on`
- New optimizer switch flags `rowid_filter` and `condition_pushdown_from_having`
- MDEV-18439: core_file on Windows now defaults to `ON`
- MDEV-18608: Histograms are now collected by default.
- MDEV-13916: The JSON_VALID function is automatically used as a CHECK constraint for the JSON data type alias in order to ensure that a valid json document is inserted
- Spider updated to 3.3.14
- Unique indexes can be created on BLOB or TEXT fields (MDEV-371)
- MDEV-18564: wsrep_load_data_splitting is deprecated and now set to `OFF` by default
- analyze_sample_percentage system variable
- InnoDB ALTER TABLE fixes: MDEV-18222, MDEV-18256, MDEV-18016, MDEV-18295, MDEV-16849, MDEV-18219
- Mariabackup fixes: MDEV-18194, MDEV-18415, MDEV-18611

- New InnoDB features:
  - MDEV-12026: Implement innodb_checksum_algorithm=full_crc32
  - MDEV-15563: More Instant VARCHAR extension
  - MDEV-15564: Instant collation or charset changes for non-indexed columns
  - MDEV-16188: Use in-memory PK filters built from range index scans
- Debian has stopped supporting the ppc64el architecture for Debian 8 Jessie and so this is the last release of MariaDB 10.4 on Jessie for that architecture

Changelog

MariaDB plc customers will be notified for all new releases, security issues and critical bug fixes for all MariaDB plc products thanks to the Notification Services.

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.31 MariaDB 10.4.2 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 29 Jan 2019

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.2 is a ***Beta*** release.

Do not use *beta* releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

Notable changes of this release include:

- Galera 4 version 26.4.0 has been added in this release, see the **Galera 4 Notes** section for details
- Account Locking (MDEV-13095)
- a number of bugs related to MDEV-15562 Instant DROP COLUMN have been fixed
- New variable, max_password_errors for limiting the number of failed connection attempts by a user.
- MDEV-17475: Maximum value of table_definition_cache is now `2097152` .

Galera 4 Notes

Upgrading to Galera 4 version 26.4.0

Rolling upgrades from earlier 10.3 (or older) MariaDB releases are not supported in this release. For upgrading a 10.3-based cluster, any applications accessing the cluster should be stopped and the cluster shut down. Then for each cluster node the following procedure should be carried out:

- Install MariaDB 10.4.2 and Galera 4 version 26.4.0
- Start MariaDB server, but make sure it is not trying to connect to the cluster by configuring `wsrep_provider=none`
- While MariaDB server is running, run `mysql_upgrade` for the server
- Stop MariaDB server

After that, you can bootstrap the cluster. If there was ongoing application load on the cluster during the initial cluster shutdown phase, you should make sure to bootstrap the cluster with the node which was shutdown last.

We are working on rolling upgrade support for the final GA version of MariaDB 10.4. With a rolling upgrade, a live cluster can be upgraded node by node, and the cluster is able to process application load when having a hybrid setup of 10.3 and 10.4 nodes.

New Features in Galera 26.4.0

The 'mysql' schema contains new Galera replication related tables:

- `wsrep_cluster`
- `wsrep_cluster_members`
- `wsrep_streaming_log`

End users may read but not modify these tables.

The new streaming replication feature allows replicating transactions of unlimited size. With streaming replication, a cluster is replicating a transaction in small fragments during transaction execution. This transaction fragmenting is controlled by two new configuration variables:

- `wsrep_trx_fragment_unit (bytes, rows, statements)` defines the metrics for how to measure transaction size limit for fragmenting. Possible values are:
  - `bytes` : transaction's binlog events buffer size in bytes
  - `rows` : number of rows affected by the transaction
  - `statements` : number of SQL statements executed in the multi-statement transaction
- `wsrep_trx_fragment_size` defines the limit for fragmenting. When a transaction's size, in terms of the configured fragment unit, has grown over this limit, a new fragment will be replicated.

Transactions replicated through galera replication will now process the commit phase using MariaDB's group commit logic. This will affect transaction throughput, especially when binary logging is enabled in the cluster.

Limitations in Galera 26.4.0

- Upgrading from 10.3 version 25.3.25 to 10.4.2 version 26.4.0 must happen on a stopped cluster. Only after all nodes have been upgraded to MariaDB 10.4.2 and Galera 26.4.0 can the cluster be started up
- Splitting transactions of `LOAD DATA` execution will conflict with streaming replication, and should not be used if streaming replication is configured

Changelog

For a complete list of changes made in MariaDB 10.4.2, with links to detailed information on each push, see the changelog.

7.0.8.2.32 MariaDB 10.4.1 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 20 Dec 2018

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.1 is a ***Beta*** release.

Do not use *beta* releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

This will be the first beta release in the MariaDB 10.4 series.

Notable changes of this release include:

Syntax

- New FLUSH SSL command to reload SSL certificates without server restart (MDEV-16266)
- New `CAST` target — `CAST(x AS INTERVAL DAY_SECOND(N))` (MDEV-17776)

Variables

- New sql-mode setting, `TIME_ROUND_FRACTIONAL` (MDEV-16991)
- Two new values for the variable use_stat_tables: `COMPLEMENTARY_FOR_QUERIES` and `PREFERABLY_FOR_QUERIES` (MDEV-17255)
- Engine Independent Table Statistics is now enabled by default; new default values are use_stat_tables=PREFERABLY_FOR_QUERIES and optimizer_use_condition_selectivity=4 (MDEV-15253)
- New variable gtid_cleanup_batch_size for determining how many old rows must accumulate in the mysql.gtid_slave_pos table before a background job will be run to delete them.

Other Features

- Support for window UDF functions via the new method x_remove (MDEV-15073)
- Json service for plugins (MDEV-5313)
- Much faster privilege checks for MariaDB setups with many user accounts or many database grants (MDEV-15649)
- mysql.user table is retired. User accounts and global privileges are now stored in the mysql.global_priv table (MDEV-17658)
- Change in behavior for FLUSH TABLES (MDEV-5336).

Bug Fixes

Lots of miscellaneous fixes, including:

- Bug fixes for MDEV-15562 instant DROP COLUMN

Changelog

For a complete list of changes made in MariaDB 10.4.1, with links to detailed information on each push, see the changelog.

Contributors

MariaDB may already be included in your favorite OS distribution. More information can be found on the Distributions which Include MariaDB page.

7.0.8.2.33 MariaDB 10.4.0 Release Notes

The most recent release of MariaDB 10.4 is:
MariaDB 10.4.32 Stable (GA) Download Now
Alternate download from mariadb.org

Download | Release Notes | Changelog | Overview of 10.4

Release date: 9 Nov 2018

MariaDB 10.4 is the current *development* series of MariaDB. It is an evolution of MariaDB 10.3 with several entirely new features not found anywhere else and with backported and reimplemented features from MySQL.

MariaDB 10.4.0 is an ***Alpha*** release.

Do not use *alpha* releases in production!

For an overview of MariaDB 10.4 see the What is MariaDB 10.4? page.

Thanks, and enjoy MariaDB!

Notable Changes

This will be the first alpha release in the MariaDB 10.4 series.

Notable changes of this release include:

InnoDB

- Added instant DROP COLUMN and changing of the order of columns (MDEV-15562)
- Reduced redo log volume for undo tablespace initialization (MDEV-17138)
- Removed crash-upgrade support for pre-10.2.19 TRUNCATE TABLE (MDEV-13564)
- Added key rotation for innodb_encrypt_log (MDEV-12041)

Optimizer

- Push conditions into materialized IN subqueries (MDEV-12387)

Variables

- Added the tcp_nodelay system variable (MDEV-16277)
- Removed the global Innodb_pages0_read status variable (MDEV-15705).

General

- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME (MDEV-16294)
- The obsolete mysql.host table is no longer created (MDEV-15851)
- Support of brackets (parentheses) for specifying precedence in UNION/EXCEPT/INTERSECT operations (MDEV-11953)
- Crash safe Aria-based system tables (MDEV-16421)
- Added Linux abstract socket support (MDEV-15655)
- Enabled C++11 (MDEV-16410)
- SET PASSWORD support for ed25519 and other authentication plugins (MDEV-12321)
- Performance improvements in Unicode collations (MDEV-17534, MDEV-17511, MDEV-17502, MDEV-17474)
- User data type plugins (MDEV-4912, in progress)
- Improvements with SQL standard INTERVAL support to help functions TIMESTAMP() and ADDTIME() return more predictable results.
    - Historically, MariaDB uses the TIME data type for both "time of the day" values and "duration" values. In the first meaning the natural value range is from '00:00:00' to '23:59:59.999999', in the second meaning the range is from '-838:59:59.999999' to '+838:59:59.999999'.
    - To remove this ambiguity and for the SQL standard conformance we plan to introduce a dedicated data type INTERVAL that will be able to store values in the range at least from '-87649415:59:59.999999' to '+87649415:59:59.999999', which will be enough to represent the time difference between TIMESTAMP'0001-01-01 00:00:00' and TIMESTAMP'9999-12-31 23:59:59.999999'.
    - As a first step we support this range of values for intermediate calculations when TIME-alike string and numeric values are used in INTERVAL (i.e. duration) context, e.g. as the second argument of SQL functions TIMESTAMP(ts,interval) and ADDTIME(ts,interval), so the following can now be calculated:

```
SELECT ADDTIME(TIMESTAMP'0001-01-01 00:00:00', '87649415:59:59.999999');
-> '9999-12-31 23:59:59.999999'

SELECT TIMESTAMP(DATE'0001-01-01', '87649415:59:59.999999')
-> '9999-12-31 23:59:59.999999'

SELECT ADDTIME(TIME'-838:59:59.999999', '1677:59:59.999998');
-> '838:59:59.999999'
```

Changelog

7.0.8.3 Changes & Improvements in MariaDB 10.3

MariaDB 10.3 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.3 is:
MariaDB 10.3.39 Stable (GA) Download Now

Contents

MariaDB 10.3 is a previous major stable version. The first stable release was in May 2018, and it was maintained until May 2023.

For details on upgrading from MariaDB 10.2, see Upgrading from MariaDB 10.2 to 10.3.

MariaDB Server 10.3 is included in MariaDB TX 3.0. Watch the webinar recording to learn more about the new features included in this release.

The following lists the major new features in MariaDB 10.3:

Implemented Features

Syntax / General Features

- System-versioned tables (also known as AS OF) (MDEV-12894)
- Table Value Constructors (MDEV-12172) — GSoC 2017 project by Galina Shalygina
- Transform [NOT] IN predicate with long list of values INTO [NOT] IN subquery (MDEV-12176) — GSoC 2017 project by Galina Shalygina
- ROW TYPE OF now supports local SP variables (MDEV-14139)
- Aggregate stored functions (MDEV-7773) — GSoC 2016 project by Varun Gupta
- Support for LIMIT clause in GROUP_CONCAT() (MDEV-11297)
- PERCENTILE_CONT, PERCENTILE_DISC, and MEDIAN window functions (MDEV-12985)
- FOR ... END FOR statement (MDEV-14415)
- XA RECOVER FORMAT='SQL' (MDEV-14593)
- Oracle compatible SUBSTR() function (MDEV-14012) — contribution by Jérôme Brauge
- INVISIBLE columns (MDEV-10177) — GSoC 2016 project by Sachin Setiya

- Various scalability improvements (MDEV-14529, MDEV-14505)
- Sequences can now be used with DEFAULT.
- Semi-sync plugin merged into the server (MDEV-13073) — contribution by Alibaba
- CREATE SEQUENCE (MDEV-10139)
- SHOW CREATE SEQUENCE
- ALTER SEQUENCE
- DROP SEQUENCE
- NEXT VALUE FOR
- PREVIOUS VALUE FOR
- SETVAL()
- INTERSECT and EXCEPT. These are both now reserved words and can no longer be used as an identifier without being quoted (MDEV-10141)
- ROW data type for stored routine variables (MDEV-10914, MDEV-12007, MDEV-12291)
- TYPE OF and ROW TYPE OF anchored data types for stored routine variables (MDEV-12461)
- Cursors with parameters (MDEV-12457)
- DDL Fast Fail - WAIT/NOWAIT (MDEV-11379, MDEV-11388)
- CHR() function (MDEV-12685)
- DELETE statement can delete from the table that is used in a subquery in the `WHERE` clause (MDEV-12137)
- Stored routine parameters can use ROW TYPE OF (MDEV-13581)
- The server now supports the PROXY protocol - see also the new proxy_protocol_networks system variable (MDEV-11159)
- Instant ADD COLUMN (MDEV-11369) — *Tencent Game DBA Team, developed by vinchen.*
- UPDATE statements with the same source and target (MDEV-12874) — *from Jerome Brauge.*
- ORDER BY and LIMIT in multi-table update (MDEV-13911)
- DATE_FORMAT(date, format, locale) - 3 argument form of DATE_FORMAT (MDEV-11553)
- The MariaDB SQL/PL stored procedure dialect (enabled with sql_mode=ORACLE) now supports Oracle style packages. Support for the following statements has been added (MDEV-10591):
  - CREATE PACKAGE
  - CREATE PACKAGE BODY
  - DROP PACKAGE
  - DROP PACKAGE BODY
  - SHOW CREATE PACKAGE
  - SHOW CREATE PACKAGE BODY
- New sql_mode `SIMULTANEOUS_ASSIGNMENT` to make the SET part of the UPDATE statement evaluate all assignments simultaneously, not left-to-right.
- Correctness improvement - TRUNCATE honors transactional locks (MDEV-15061)
- Windows binaries now use high-precision timer when available (MDEV-15694). This makes much less probable for two queries to have the same `CURRENT_TIMESTAMP(6)` value, for example.
- Two new ALTER TABLE ... ALGORITHM options, INSTANT and NOCOPY, which allow operations that would require any data files to be modified, or that would require rebuilding the clustered index respectively, to be refused rather than potentially perform slowly (MDEV-13134)
- mysqldump `--ignore-database` option (MDEV-13336)

Compatibility

- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE() (MDEV-12172)
- When running with sql_mode=ORACLE, the server now understands a subset of Oracle's PL/SQL language instead of the traditional MariaDB syntax for stored routines. See MDEV-10142, MDEV-10764 and SQL_MODE=ORACLE From MariaDB 10.3 to know the current status.
- New sql_mode, EMPTY_STRING_IS_NULL.
- INTERSECT and EXCEPT are both now reserved words and can no longer be used as an identifier without being quoted (MDEV-10141)
- Functions that used to only return 64-bit now can return 32-bit results (MDEV-12619).

Compression

- Storage-engine Independent Column Compression (MDEV-11371) — *Tencent Game DBA Team, developed by willhan, also thanks to AliSQL.*
- On Linux, shrink the core dumps by omitting the InnoDB buffer pool (MDEV-10814)

Encryption

- Temporary files created by merge sort and row log are encrypted if innodb_encrypt_log is set to `1`, regardless of whether the table encrypted or not (MDEV-12634).

Optimizer/Performance

- Condition pushdown through `PARTITION BY` clause of window functions (MDEV-10855)
- New Lateral Derived optimization was introduced.
- Numerous performance improvements for high-concurrency load
- Numerous scalability and performance improvements to global data structures, including MDEV-14756, MDEV-15019, MDEV-14482, MDEV-15059, MDEV-15104
- Performance improvements to persistent data structures: MDEV-15090, MDEV-15132

Storage Engines

InnoDB

- innodb_fast_shutdown now has a new mode, `3`, which skips the rollback of connected transactions (MDEV-15832)

Spider

The Spider storage engine has been updated to 3.3.13. The partitioning storage engine has been updated to support all the new Spider features including:

- Direct join support. This allows Spider to do JOINS and GROUP BYs internally.
- Direct update and delete.
- Direct aggregates.
- slave_transaction_retry_errors and slave-transaction-retry-interval allow more control over handling delays or conflicts when applying binary logs.

Most of the features were done as part of MDEV-7698.

OQGRAPH

- OQGraph now supports the "leaves" algorithm (MDEV-11271) — contribution by Heinz Wiesinger

Partition Engine

- Numerous improvements for the partition engine (MDEV-7698) — contribution by Kentoku Shiba
  - Full text support.
  - Multi-range-read (Gives better performance when handling multiple ranges).
  - Support for condition pushdown.
  - HANDLER support
- Aggregate pushdown
- Bulk update/delete

Information Schema

- The Information Schema is optimized to use much less memory when selecting from INFORMATION_SCHEMA.TABLES or any other table with many VARCHAR or TEXT columns (MDEV-14275)
- The Information Schema Columns table now displays system versioning info in the EXTRA column - MDEV-15062

Logging

- Disable logging of certain statements to the general log or the slow query log with the log_disabled_statements and log_slow_disabled_statements system variables.
- A new option to log_slow_filter, `filsort_priority_queue`.

Replication

- Per-engine mysql.gtid_slave_pos tables (MDEV-12179) *— Implemented by Kristian Nielsen funded by Booking.com.*

Data Type API

10.3 continues refactoring for the data type API started in 10.2, which will make it possible to have user data type plugins. This work is still in progress (see MDEV-4912 for the current status and subtasks). Most of the task in this category do not change the server behavior. Some tasks do have a visible effect.

Idle Transactions

Connections with idle transactions can be automatically killed after a specified time period by means of the idle_transaction_timeout, idle_readonly_transaction_timeout and idle_write_transaction_timeout system variables.

System Variables

For a list of all new variables, see System Variables Added in MariaDB 10.3 and Status Variables Added in MariaDB 10.3.

- New system variable gtid_pos_auto_engines.
- New system variable secure_timestamp for restricting the direct setting of a session timestamp (MDEV-15923)
- session variables tracking is enabled by default (MDEV-11825)
- Remove deprecated variables innodb_file_format, innodb_file_format_check, innodb_file_format_max and innodb_large_prefix.
- version_source_revision - permits seeing which version of the source was used for the build (MDEV-12583).
- Added bind_address as a system variable (MDEV-12542).
- The max value of the max_prepared_stmt_count system variable has been increased from 1048576 to 4294967295
- The proxy_protocol_networks variable can now be modified without restarting the server (MDEV-15501)

Security Vulnerabilities Fixed in MariaDB 10.3

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2022-47015: MariaDB 10.3.39
- CVE-2022-38791: MariaDB 10.3.36
- CVE-2022-32091: MariaDB 10.3.36
- CVE-2022-32088: MariaDB 10.3.35
- CVE-2022-32087: MariaDB 10.3.35
- CVE-2022-32085: MariaDB 10.3.35
- CVE-2022-32084: MariaDB 10.3.36
- CVE-2022-32083: MariaDB 10.3.35
- CVE-2022-31624: MariaDB 10.3.32

7.0.9.1 Changes & Improvements in MariaDB 10.2

MariaDB 10.2 is no longer maintained. Please use a more recent release.

The most recent release of MariaDB 10.2 is:
MariaDB 10.2.44 Stable (GA) Download Now

Contents

MariaDB 10.2 is a previous major stable version. The first stable release was in May 2017.

For details on upgrading from MariaDB 10.1, see Upgrading from MariaDB 10.1 to 10.2.

The following lists the major new features in MariaDB 10.2:

Implemented Features

InnoDB as Default

- InnoDB is now the default storage engine. Until MariaDB 10.1, MariaDB used the XtraDB storage engine as default. XtraDB in 10.2 is not up to date with the latest features of InnoDB and cannot be used. As the InnoDB on disk format is identical to XtraDB's this will not cause any problems when upgrading to MariaDB 10.2. See Why does MariaDB 10.2 use InnoDB instead of XtraDB?

Syntax / General Features

- MyRocks storage engine added. (It has its own maturity level. In MariaDB 10.2.14, it is considered Gamma) (MDEV-9658)
- Window functions have been introduced.
- The SHOW CREATE USER statement was introduced
- New CREATE USER options for limiting resource usage and tls/ssl
- New ALTER USER statement
- Non-recursive Common Table Expressions
- Recursive Common Table Expressions (MDEV-9864)
- New WITH statement. `WITH` is a common table expression that allows you to refer to a subquery expression many times in a query (MDEV-8308 & MDEV-9864) — *Original code from Galina Shalygina*
- Support for CHECK CONSTRAINT (MDEV-7563)
- Support for DEFAULT with expressions (MDEV-10134)
- BLOB and TEXT fields can now have a DEFAULT value
- Lots of restrictions lifted for Virtual computed columns
- Number of supported decimals in DECIMAL has increased from `30` to `38` (MDEV-10138)
- Added catchall for list partitions (MDEV-8348)
- Oracle-style EXECUTE IMMEDIATE statement (MDEV-10585)
- PREPARE Statement/Dynamic SQL now understand most expressions (MDEV-10866, MDEV-10709).
- InnoDB tables now support spatial indexes
- ed25519 authentication plugin (MDEV-12160)
- Better InnoDB crash recovery progress reporting (MDEV-11027)
- Improvements to InnoDB startup/shutdown to make it more robust
- AWS Key Management plugin added for Windows, CentOS, RHEL, and Fedora packages
- Atomic writes support made more general. Shannon system SSD cards are now supported.

Incompatible Changes

- TokuDB has been split into a separate package, mariadb-plugin-tokudb.
- SQL_MODE has been changed; in particular, NOT NULL fields with no default will no longer fall back to a dummy value for inserts which do not specify a value for that field.
- Replication from legacy MySQL servers may require setting binlog_checksum to NONE.
- New reserved words: OVER, RECURSIVE, and ROWS.

Triggers

- Multiple triggers for the same event (MDEV-6112)
- The FOLLOWS/PRECEDES clauses have been added to the CREATE TRIGGER statement
- Multiple triggers are now counted in the Executed_triggers status variable (MDEV-10915)
- SHOW TRIGGERS and SHOW CREATE TRIGGER now include the date and time the trigger was created

Replication / Binary Log

- DML_only flashback can rollback instances/databases/tables to an old snapshot (MDEV-10570)
- New variable read_binlog_speed_limit permits restricting the speed at which the slave reads the binlog from the master (MDEV-11064) — *Original code from Tencent Game DBA Team, developed by chouryzhou.*
- Delayed replication is supported (MDEV-7145) — *Backported from MySQL 5.6 by Kristian Nielsen funded by Booking.com.*
- Compression of events in the binary log is supported (MDEV-11065) — *Original code from Tencent Game DBA Team, developed by vinchen.*
- Default binary log format changed to mixed (MDEV-7635)
- Default value of replicate_annotate_row_events changed to `ON` (MDEV-7635)
- Default value of slave_net_timeout reduced to 60 seconds (MDEV-7635)
- Default server_id changed from `0` to `1`

GeoJSON / JSON

- The JSON data type (an alias for LONGTEXT) was introduced.
- JSON functions added (MDEV-9143)
- Implement ST_AsGeoJSON and ST_GeomFromGeoJSON functions so the spatial features can be imported/exported using GeoJSON format (MDEV-11042)

Information Schema

- An information schema plugin to report all user variables, which creates the Information Schema USER_VARIABLES

Table (MDEV-7331)
- Changes to the Information Schema COLUMNS table. Literals are now quoted in the `COLUMN_DEFAULT` column to distinguish them from expressions (MDEV-13132), and two new columns added providing information about generated (virtual, or computed) columns (MDEV-9255).

EXPLAIN

- EXPLAIN FORMAT=JSON now shows `outer_ref_condition` field which contains the condition that the(?) SELECT checks on each re-execution (MDEV-9652)
- EXPLAIN FORMAT=JSON now shows `sort_key` field which shows the sort criteria used by `filesort` operation. (commit 2078392)
- EXPLAIN used to show incorrect information about how the optimizer resolved `ORDER BY` clause or `Distinct`. This was a long-standing problem with roots back in MySQL. Now, after MDEV-8646 and related fixes, the problem doesn't exist anymore. (For test cases, see MDEV-7982, MDEV-8857, MDEV-7885, MDEV-326)

Optimizations

- Connection setup was made faster by moving creation of THD to new thread (MDEV-6150)
- Pushdown conditions into non-mergeable views/derived tables (MDEV-9197, condition-pushdown-into-derived-table-optimization) — *Original code from Galina Shalygina*
- ANALYZE TABLE has been re-implemented so as not to lock the entire table when collecting engine independent statistics (MDEV-7901)
- Internal CRC32 routines use the optimized implementation on Power8 — MDEV-9872
- Table cache can automatically partition itself as needed to reduce the contention (MDEV-10296)

Compatibility

- 88 new NO PAD collations added. In `NO PAD` collations, end spaces are significant in comparisons (MDEV-9711) — *Original code from Daniil Medvedev*
- MariaDB now works when started with a MySQL 5.7.6+ data directory (MDEV-11170)

CONNECT

- Zipped File Tables for the CONNECT storage engine (MDEV-11295)
- The CONNECT engine now supports the JDBC Table type (MDEV-9765)

System Variables

For a list of all new system variables, see System Variables Added in MariaDB 10.2. Variable changes include:

- New variable to disable deadlock detection innodb_deadlock_detect
- aria_recover has been renamed to aria_recover_options (MDEV-8542)
- Default values of the aria_recover and myisam_recover_options system variables changed to `BACKUP,QUICK`
- The server version can now be faked to work around dated applications that require a particular version string (MDEV-7780)
- slave_parallel_workers is now an alias for slave_parallel_threads
- New status variables com_alter_user, com_multi and com_show_create_user
- New variable for setting a directory for storing temporary non-tablespace InnoDB files, innodb_tmpdir
- New variable read_binlog_speed_limit permits restricting the speed at which the slave reads the binlog from the master (MDEV-11064)
- innodb_log_files_in_group can now be set to `1` (MDEV-12061)
- The thread pool now gives higher priority to connections that have an active transaction. This can be controlled with the new thread_pool_prio_kickup_timer and thread_pool_priority system variables. (MDEV-10297)
- Default value of group_concat_max_len changed to 1M (MDEV-7635)
- Default value of sql_mode changed to STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITU (MDEV-7635) (MariaDB 10.2.4 and later)
- Default value of innodb_compression_algorithm changed to `zlib` - this does not mean pages are now compressed by default, see compression (MDEV-11838)
- Default value of innodb_log_compressed_pages changed to `ON` from MariaDB 10.1.2 to MariaDB 10.1.25 (MDEV-7635 and MDEV-13247)
- Default value of innodb_use_atomic_writes and innodb_use_trim changed to `ON`
- The unused innodb_api_* variables have been removed (MDEV-12050)
- tmp_disk_table_size was added to allow one to limit the size of temporary disk tables stored in tmpdir. At the same time tmp_memory_table_size was added an alias for tmp_table_size. At some point we plan to deprecate

`tmp_table_size`. (MariaDB 10.2.7 and later).

Status Variables

For a list of all new status variables, see Status Variables Added in MariaDB 10.2.

Scripts

- Continuous binary log backup has been added to mysqlbinlog (MDEV-8713)
- mysql_zap and mysqlbug have been removed (MDEV-7376, MDEV-8654)

Other Changes

- Added support for OpenSSL 1.1 and LibreSSL (MDEV-10332)
- Persistent AUTO_INCREMENT for InnoDB (MDEV-6076)
- Support COM_RESET_CONNECTION (MDEV-10340)
- "fast mutexes" have been removed. These aren't faster than normal mutexes, and have been disabled by default for years (MDEV-8111)
- Old GPL client library is gone; now MariaDB Server comes with the LGPL Connector/C client library (MDEV-9055)
- MariaDB is no longer compiled with jemalloc
- TokuDB is now a separate package, not part of the server RPM (because TokuDB still needs jemalloc).
- Upgrading to a new major release no longer requires setting innodb_fast_shutdown to `0`. Omitting it can make the upgrade process a lot faster. (MDEV-12289)

Security Vulnerabilities Fixed in MariaDB 10.2

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

7.0.10.1 Changes & Improvements in MariaDB 10.1

MariaDB 10.1 is no longer supported. Please use a more recent release.

The most recent release of MariaDB 10.1 is:
MariaDB 10.1.48 Stable (GA) Download Now

Contents

MariaDB 10.1 is a previous stable version of MariaDB. The first stable release was in October 2014.

For details on upgrading from MariaDB 10.0, see Upgrading from MariaDB 10.0 to 10.1.

The following lists the major new features in MariaDB 10.1:

Implemented Features

Galera

- Galera, a true multi-master solution, is a standard part of MariaDB 10.1.
- Two new Information Schema tables for examining wsrep information, WSREP_MEMBERSHIP and WSREP_STATUS (MDEV-7053)

Encryption

- Table, Tablespace and log Encryption.

Page Compression

- InnoDB/XtraDB Page Compression
- Page compression for FusionIO.

Replication

- Optimistic mode of in-order parallel replication (MDEV-6676)
- domain_id based replication filters - see CHANGE MASTER TO (MDEV-6593)
- Enhanced semisync replication; Wait for at least one slave to acknowledge transaction before committing (MDEV-162).
- Triggers can now be run on the slave for row-based events.
- Dump Thread Enhancements from Google. Makes multiple slave setups faster by allowing concurrent reading of binary log. (MDEV-7257)
- Commits in certain instances in parallel replication complete immediately, avoiding losing throughput when many

transactions need conflicting locks. See binlog_commit_wait_count.
- RESET_MASTER is extended with `TO #` which allows one to specify the number of the first binary log. (MDEV-8469)
- Due to the implementation of SQL standards-compliant behavior when dealing with Primary Keys with Nullable Columns, in certain edge cases, there may be replication issues when replicating from a MariaDB 10.0 master to a MariaDB 10.1 slave using statement-based replication. See MDEV-12248 .

Roles

- SET DEFAULT ROLE (MDEV-5210).
- New columns for the INFORMATION_SCHEMA.APPLICABLE_ROLES table.

Optimization

- ORDER BY optimization is improved by several fixes for real-world cases.
- Don't create frm files for temporary tables (MDEV-4260).
- MAX_STATEMENT_TIME can be used to automatically abort long running queries. (MDEV-4427).
- UNION ALL works without usage of a temporary table (MDEV-334). The feature was backported from MySQL 5.7
- Scalability fixes (MDEV-7004). Up to 60% higher throughput in sysbench benchmarks on Power8.
- Make simple queries faster as we call malloc() fewer times.
- Automatic discovery of performance schema tables (simpler mysql_install_db code). (MDEV-4262), Performance Schema tables no longer use `.frm` files.
- Other Webscale patches (MDEV-6039)
- MDEV-7728 xid cache scalability was significantly improved (by using lock-free hash)

GIS

- Support for Spatial Reference systems for the GIS data (MDEV-60), new `REF_SYSTEM_ID` column attribute can be used to specify Spatial Reference System ID for columns of spatial data types:
- More functions from the OGC standard added (MDEV-4045):
  - ST_Boundary
  - ST_ConvexHull
  - ST_IsRing
  - ST_PointOnSurface
  - ST_Relate
- INFORMATION_SCHEMA.GEOMETRY_COLUMNS table.
- INFORMATION_SCHEMA.SPATIAL_REF_SYS table.

Syntax

- Consistent support for `IF EXISTS` , `IF NOT EXISTS` , and `OR REPLACE` clauses:
  - CREATE DATABASE (MDEV-7280)
  - CREATE FUNCTION UDF (MDEV-7283)
  - CREATE ROLE (MDEV-7288)
  - CREATE SERVER (MDEV-7285)
  - CREATE USER (MDEV-7288)
  - CREATE VIEW (MDEV-7283)
  - DROP ROLE (MDEV-7288)
  - DROP USER (MDEV-7288)
  - CREATE EVENT and DROP EVENT (MDEV-7281)
  - CREATE INDEX and DROP INDEX (MDEV-7284)
  - CREATE TRIGGER and DROP TRIGGER (MDEV-7286)
- Information Schema plugins can now support SHOW and FLUSH statements . New statements include:
  - SHOW QUERY_RESPONSE_TIME
  - FLUSH QUERY_RESPONSE_TIME
  - SHOW LOCALES
- New columns for the INFORMATION_SCHEMA.APPLICABLE_ROLES and INFORMATION_SCHEMA.VIEWS tables.
- ANALYZE statement provides output that looks like EXPLAIN output, but also includes data from the query execution (how many rows were actually read, etc).
- EXPLAIN FORMAT=JSON is a re-implementation of similar feature in MySQL 5.6
- ANALYZE FORMAT=JSON produces detailed information about the statement execution
- GET_LOCK() now supports microseconds in the timeout, no longer rounding fractions to the nearest integer (MDEV-4018)
- Compound statements can be used outside of stored programs.

- The number of rows affected by a slow UPDATE or DELETE is now recorded in the slow query log - see also mysql.slow_log Table. (MDEV-4412)
- SQL standards-compliant behavior when dealing with Primary Keys with Nullable Columns. Note that this could cause replication issues in certain edge cases when replicating from a MariaDB 10.0 master to a MariaDB 10.1 slave. using statement-based replication. See MDEV-12248.
- Explicit or implicit casts from MAX(string) to INT, DOUBLE or DECIMAL now produce warnings (MDEV-8852).

XtraDB / InnoDB

- Allow up to 64K pages in InnoDB (old limit was 16K) (MDEV-6075).
- The Facebook/Kakao defragmentation patch (see Defragmenting InnoDB Tablespaces) which uses OPTIMIZE TABLE to defragment InnoDB tablespaces).

Collations

- Added the `utf8_thai_520_w2`, `utf8mb4_thai_520_w2`, `ucs2_thai_520_w2`, `utf16_thai_520_w2` and `utf32_thai_520_w2` collations.

Variables

For a list of all new variables, see System Variables Added in MariaDB 10.1 and Status Variables Added in MariaDB 10.1. Some of these, and other variable-related changes, include:

- INFORMATION_SCHEMA.SYSTEM_VARIABLES gives information, like description and value origin, for system variables (MDEV-6138).
- MDEV-6858 New server variable enforce_storage_engine
- New status variables to show the number of grants on different objects (see Status Variables Added in MariaDB 10.1)
- Default size of query_alloc_block_size changed from `8192` to `16384` and query_prealloc_size from `8192` to `24576` to avoid the need for simple queries with one join to call `my_malloc`.
- Added variable default-tmp-storage-engine (From MySQL 5.6) (MDEV-6107).
- SET STATEMENT - set variables for the duration of the query (MDEV-5231). This is a backport of Per-query Variable Statement feature of Percona Server 5.6 (which, in turn, is based in MySQL GSoC 2009 project by Joseph Lukas), with many bugs fixed.
- --mysql56-temporal-format option to use the MySQL-5.6 low level formats to store TIME, DATETIME and TIMESTAMP types. (MDEV-5528)
- Backport innodb_default_row_format (MDEV-14904)
- `mysqld --help --verbose` now shows valid variables for ENUM variables. (MDEV-6137)
- MDEV-6981 New status variables to track MASTER_GTID_WAIT time.
- MDEV-7198 New status variable Slave_skipped_errors.
- `--silent-startup` mysqld option. If specified, mysqld does not print Notes to the error log during startup.

Plugins

- Password validation plugin API (MDEV-6431).
- simple_password_check password validation plugin. It can enforce a minimum password length and guarantee that a password contains at least a specified number of uppercase and lowercase letters, digits, and punctuation characters.
- cracklib_password_check password validation plugin. It only allows passwords that are strong enough to pass CrackLib test. This is the same test that `pam_cracklib.so` does, installed by default on many Linux distributions.
- ed25519 authentication plugin for traditional password-based authentication. A new, secure alternative to the old `mysql_native_password` plugin.

Security

- Enhance security using special compilation options - MariaDB is now compiled with security hardening options by default. It is an additional protection layer that makes new, yet unknown, security vulnerabilities more difficult to exploit. (MDEV-5730)

Security Vulnerabilities Fixed in MariaDB 10.1

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2021-2144: MariaDB 10.1.42

7.0.11 MariaDB Server 10.0

Changes & Improvements in MariaDB 10.0

Current Version: 10.0.38 | Status: Stable (GA) | Release Date: 31 Jan 2019

Release Notes - MariaDB 10.0 Series

MariaDB 10.0 Series Release Notes

Changelogs - MariaDB 10.0 Series

MariaDB 10.0 changelogs.

7.0.11.1 Changes & Improvements in MariaDB 10.0

MariaDB 10.0 is no longer maintained. Please use a more recent release.

The most recent release in the MariaDB 10.0 series is:

MariaDB 10.0.38 Download Now

MariaDB 10.0 is a previous stable series of MariaDB. It is built on the MariaDB 5.5 series with backported features from MySQL 5.6 and entirely new features not found anywhere else. The first stable release was in March 2014, and the final release was in January 2019.

For details on upgrading from MariaDB 5.5, see Upgrading from MariaDB 5.5 to MariaDB 10.0.

Blog posts with details of the reasoning behind calling this version MariaDB 10:

- http://blog.mariadb.org/mariadb-10-0-and-mysql-5-6/
- http://blog.mariadb.org/what-comes-in-between-mariadb-now-and-mysql-5-6/
- http://blog.mariadb.org/explanation-on-mariadb-10-0/

Contents

Implemented Features

Features that are in a release.

New Features

- For a list of all new variables, see System Variables Added in MariaDB 10.0

- Parallel Replication
- Global Transaction ID (MDEV-26)
- Multi source replication (MDEV-253) — *Original code from Taobao, developed by Peng Lixun*.
- Slave started with `--binlog-format=STATEMENT` can replicate from master with any type of `--binlog-format` Starting from MariaDB 10.0.22.

- Cassandra storage engine (MDEV-4695)
- CONNECT storage engine (MDEV-4146)
- Better table discovery. Sequence storage engine. Assisted discovery in FederatedX (MDEV-3808)
- Spider storage engine (MDEV-4438)
- TokuDB storage engine (MDEV-4507)
- Mroonga full-text search storage engine

- QUERY_RESPONSE_TIME plugin

- Engine independent table statistics (MDEV-3806)
- Subquery optimizations: EXISTS-to-IN optimization, (MDEV-38 - NOT EXISTS to IN), MDEV-537, MDEV-3862
- Histogram-based statistics for non-indexed columns (MDEV-4145)

- SHOW EXPLAIN command (MDEV-165)
- EXPLAIN in the slow query log (MDEV-407)
- Per thread memory usage (MDEV-4011). — *Original code from Taobao, developed by Peng Lixun*.
  - information_schema.processlist has two new columns: `MEMORY_USAGE` and `EXAMINED_ROWS`.
  - SHOW STATUS has a new variable: Memory_used.
- SHOW PLUGINS SONAME 'XXX' (MDEV-3807)
- SHUTDOWN statement (MDEV-4660)
- Killing a query by query id, not thread id (MDEV-4911)

- Faster UNIQUE key generation with ALTER TABLE (MDEV-539)
- Implement async commit checkpoint in InnoDB and XtraDB (MDEV-532)
- Support for atomic writes on FusionIO DirectFS (MDEV-4338)

- DELETE ... RETURNING (MDEV-3814)
- IF (NOT) EXISTS clauses for ALTER TABLE (MDEV-318)
- CREATE OR REPLACE TABLE (MDEV-5491)
  - slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Dynamic columns now support names (MDEV-377, summary of changes)
- multiple use locks (GET_LOCK) in one connection (MDEV-3917)
- Better error messages (all error numbers now include descriptive text explaining what the number means)
- table attributes with sysvar as a default value (MDEV-4022)

- regular expression enhancements
  - new regular expression library with modern features (PCRE)
  - new functions REGEXP_REPLACE, REGEXP_INSTR, REGEXP_SUBSTR.
- Roles (MDEV-4397)
- metadata_lock_info information schema. Shows you which meta data locks are active.
- Adjustable hash size for MyISAM and Aria. This can greatly improve shutdown time (from hours to minutes) if you are using a lot of MyISAM/Aria tables with delayed keys.
- FLUSH TABLES ... FOR EXPORT
- The Extended Keys optimization is enabled by default
- MariaDB audit plugin
- filesort-with-small-limit-optimization is now visible through the slow query log and a new status variable, sort_priority_queue_sorts
- Error log flood protection

New Features Re-implemented From a Similar MySQL Feature

- CURRENT_TIMESTAMP as DEFAULT for DATETIME columns (MDEV-452)
- EXPLAIN for INSERT/UPDATE/DELETE (MDEV-3798, MWL#51)

New Features Backported from MySQL 5.6

- New InnoDB *— from MySQL 5.6.14 in MariaDB 10.0.8 onwards*
- New Performance schema *— from MySQL 5.6.10 in MariaDB 10.0.4 onwards*
- New Information Schema tables, updates and defaults.
- Optimized read only transaction (for InnoDB). This includes support for TRANSACTION READ ONLY.
- Filesort optimization for queries using the `ORDER BY ... LIMIT` optimization - A useful optimization for showing only a few rows of a bigger result set. (MDEV-4026)
- backport --plugin-load-add (MDEV-3860)
- Online ALTER TABLE (MDEV-3933) (ALGORITHM=INPLACE, etc)
- InnoDB persistent statistics.
- privileges on temporary tables
- character set related extenstions
- GET DIAGNOSTICS
- EXCHANGE PARTITION
- Partition selection
- Temporal literals (such as `TIME'12:34:56'`)
- WEIGHT_STRING() function
- Collation customization improvements (see Supported Characters Sets and Collations)
- TO_BASE64() and FROM_BASE64() functions

Incompatible Changes

- New reserved word: RETURNING. This can no longer be used as an identifier without being quoted.

Security Vulnerabilities Fixed in MariaDB 10.0

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

There are 2 related questions.

7.0.12.1 Changes & Improvements in MariaDB 5.5

MariaDB 5.5 is no longer supported. Please use a more recent release.

The most recent release in the MariaDB 5.5 series is:
MariaDB 5.5.68 Download Now

Contents

MariaDB 5.5 is MariaDB 5.3 + MySQL 5.5, with added features. The first stable release was in April 2012, and the final release in May 2020.

For upgrading to MariaDB 10.0, the more recent stable release, see Upgrading from MariaDB 5.5 to MariaDB 10.0.

Feature Comparison Matrix

We have created an Optimizer Feature Comparison Matrix showing the new optimizer features in MariaDB 5.5 and 5.3 compared to MySQL 5.5 and 5.6.

See also a detailed breakdown of System variable differences between MariaDB 5.5 and MySQL 5.5.

New Features

- Significantly more efficient thread pool, comparable in functionality to the closed source feature in MySQL Enterprise.
- Non-blocking client API Library (MWL#192)
- @@skip_replication option (MWL#234)
- SphinxSE updated to version 2.0.4.
- Extended Keys support for XtraDB and InnoDB
- New INSTALL SONAME statement (MWL#77)
- New LIMIT ROWS EXAMINED optimization (MDEV-28)
- `mysql_real_connect()` Changes
  - In MySQL, and in MariaDB versions before 5.5.21, `mysql_real_connect()` removes from the MYSQL object any options set with `mysql_option()` when it fails. Beginning with MariaDB 5.5.21, options are preserved by a failing `mysql_real_connect();` use `mysql_close()`, as normal, to clear them.
  - This only has effect if the MYSQL object is reused after a `mysql_real_connect()` failure (which is unusual). No real-life incompatibilities are expected from this change (it is unlikely that an application would rely on options being automatically removed between connection attempts).
- The variables `replicate_do_*`, `replicate_ignore_*`, and `replicate_wild_*` have been made dynamic, so they can be changed without requiring a server restart. See Dynamic Replication Variables for more information.
- New status variables for checking if features are used. These are very useful in user feedback to tell developers how much a feature is used:
  - Feature_dynamic_columns
  - Feature_fulltext
  - Feature_gis
  - Feature_locale
  - Feature_subquery
  - Feature_timezone
  - Feature_trigger
  - Feature_xml
- New status variables to see what's going on:
  - Opened_views
  - Executed_triggers

    - Executed_events
- New plugin to log SQL level errors. SQL_ERROR_LOG
- New variable OLD_MODE to set compatibility behavior with older MySQL or MariaDB versions.

Information Schema

There are a number of new INFORMATION SCHEMA tables:

- INNODB_SYS_COLUMNS
- INNODB_SYS_FIELDS
- INNODB_SYS_FOREIGN
- INNODB_SYS_FOREIGN_COLS
- PARAMETERS
- TABLESPACES

Minor Extensions

- Updates to performance schema tables are not stored in the binary log and thus not replicated to slaves. This is to ensure that monitoring of the master will not cause a slower performance on all slaves. This also fixes a crash on the slaves.

New features are added to MariaDB 10.0.

Deprecated / Disabled Features

- PBXT is no longer in the binary builds/distributions. It's however still in the source distributions and in the source tree. The reason is that PBXT is no longer actively maintained, has a few bugs that are not fixed and is not in widespread use.

Switching Between InnoDB and XtraDB

MariaDB 5.5 comes with both XtraDB (compiled in) and InnoDB (as a plugin). By default MariaDB 5.5 uses XtraDB. If you want to switch to use InnoDB you can do:

```
mysqld --ignore-builtin-innodb --plugin-load=innodb=ha_innodb.so \
--plugin_dir=/usr/local/mysql/lib/mysql/plugin
```

(plugin_dir should point to where ha_innodb.so is installed)

The above options can of course also be added to your my.cnf file:

```
[mysqld]
ignore-builtin-innodb
plugin-load=innodb=ha_innodb.so
plugin_dir=/usr/local/mysql/lib/mysql/plugin
```

If you want you can also compile MariaDB with InnoDB as default.

Security Vulnerabilities Fixed in MariaDB 5.5

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

Contents

The focus for MariaDB 5.3 is to radically improve performance for subqueries, as well as for joins and single-table queries over large data sets.

MariaDB 5.3 is based on MariaDB 5.2 and thus on MariaDB 5.1 and MySQL 5.1. It is no longer being supported.

Some of the code was backported from MySQL 6.0 (a MySQL version that was never released as GA by Oracle), some was re-engineered and enriched by new features, and some code was written from scratch.

Any new feature or combination of features can be switched on/off dynamically via the optimizer_switch system variable.

The first stable (GA) release of MariaDB 5.3 was MariaDB 5.3.5, which was released on 29 Feb 2012.

You can download the latest binaries of MariaDB 5.3 here, or get the latest source code from launchpad.

Feature Comparison Matrix

We have created an Optimizer Feature Comparison Matrix showing the new optimizer features in MariaDB 5.5 and 5.3 compared to MySQL 5.5 and 5.6.

Query optimizer

Subquery optimizations

Subqueries are finally usable in practice. It is no longer necessary to rewrite subqueries manually into joins or into separate queries. MariaDB 5.3 aims to provide reasonably efficient handling for all kinds of subqueries. All problems with `EXPLAIN` taking a long time have also been resolved.

- Semi-join subquery optimizations
  These transform subqueries into 'semi-joins', entities similar to inner joins, and then use join optimizer to pick the best semi-join execution strategy. Overall the process is similar to how joins are processed in MySQL,MariaDB and other database systems.
  - Table pullout optimization
  - FirstMatch execution strategy
  - Semi-join Materialization execution strategy
  - LooseScan execution strategy
  - DuplicateWeedout execution strategy
- Non-semi-join optimizations
  If a subquery is not a semi-join, MariaDB 5.3 will make a cost-based choice between these two strategies:

    - Materialization for non-correlated subqueries, with efficient NULL-aware execution
    - IN-to-EXISTS transformation (the only optimization inherited from MariaDB 5.2 and MySQL 5.1/5.5)

- Subquery Cache
  The subquery cache makes sure that subqueries are re-executed as few times as possible, improving performance of already optimized subqueries.
- Subqueries are never executed during `EXPLAIN`, thus resulting in almost instant `EXPLAIN`.
- DISTINCT and GROUP BY without HAVING are optimized away from subqueries.

The Subquery Optimizations Map shows new subqueries optimizations graphically.

Optimizations for derived tables and views

- No early materialization of derived tables (e.g. subqueries in a `FROM` clause) and materialized views (`EXPLAIN` is always instantaneous)
- Thanks to Derived Table Merge optimization, mergeable derived tables are now processed like mergeable VIEWs.
- Derived Table with Keys optimization gives the optimizer an option to create indexes over materialized derived tables
- Fields of merge-able views and derived tables are involved now in all optimizations employing equalities

Disk access optimization

- Index Condition Pushdown
- Multi-Range-Read optimization (MRR)
    - Key-ordered retrieval

Join optimizations

- Block-based Join Algorithms
- Block Nested Loop algorithm can be used for outer joins
- Block Hash Join (classic algorithm) is implemented and can be used for any equi-joins
- Block Index Join (Batch Key Access Join) is supported and can exploit the benefits of ordered retrievals for primary and secondary keys provided by the new implementation of MRR
- All block based algorithms for joins can use the benefits of new incremental join buffers
- All block based algorithms fully support outer joins including nested outer joins
- All block based algorithms can use the benefits of the first match optimization for semi-joins and the non-exist optimization for outer joins
- All block based algorithms for joins can exploit the benefits of index condition push-down.
- The total memory space used by the query for join buffers can be limited now, and block based algorithms can allocate join buffers up to their needs (not exceeding the set limits).
- Condition over outer tables extracted from ON expressions of outer joins are evaluated before inner tables are accessed (supported for both regular index join and block index join)
- Early checks for nulls for the fields from any null-rejecting conditions are performed

Index Merge improvements

- Correct optimization of index_merge vs range access: Fair choice between range and index_merge optimizations
- index_merge/sort_intersection strategy

Optimizer control

- @@optimizer_switch variable can be used to turn on/off all new optimizations.

NoSQL-style interfaces

- HandlerSocket plugin included.
- Faster HANDLER commands; HANDLER READ now also work with prepared statements.
- Dynamic Columns support.

Replication and binary logging

- Group commit for the binary log — MariaDB 5.3 implements group commit which works when using XtraDB with the binary log enabled. (In previous MariaDB releases, and all MySQL releases at the time of writing, group commit works in InnoDB/XtraDB when the binary log is disabled, but stops working when the binary log is enabled).

- Annotation of row-based replication events with the original SQL statement — When using row-based replication, the binary log does not contain SQL statements, only discrete single-row insert/update/delete *events*. This can make it harder to read mysqlbinlog output and understand where in an application a given event may have originated, complicating analysis and debugging.This feature adds an option to include the original SQL statement as a comment in the binary log (and shown in mysqlbinlog output) for row-based replication events.
- Checksums for binlog events. This is a backport of the same feature in MySQL 5.6. It was implemented in MWL#180.
- Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT — In MariaDB 5.3, `START TRANSACTION WITH CONSISTENT SNAPSHOT` now also works with the binary log. This means it is possible to obtain the binlog position corresponding to a transactional snapshot of the database without blocking any other queries. This is used by the command "`mysqldump --single-transaction --master-data`" to do a fully non-blocking backup which can be used to provision a new slave. "`START TRANSACTION WITH CONSISTENT SNAPSHOT`" now also works consistently between transactions involving more than one storage engine (currently XTraDB and PBXT support this).
- Row-based replication for tables with no primary key — This feature can improve the performance of row-based replication on tables that do not have a primary key (or other unique key), but which do have another index that can help locate rows to update or delete. With this feature, index cardinality information from `ANALYZE TABLE` is considered when selecting the index to use (before this feature is implemented, the first index was selected unconditionally).
- `mysqlbinlog` will now omit redundant `use` statements around `BEGIN`, `SAVEPOINT`, `COMMIT`, and `ROLLBACK` events when reading MySQL 5.0 binlogs.

Datatypes

- Microsecond support for NOW() and timestamp, time, and datetime columns.
- CAST() now supports AS DECIMAL[(M,D)] and AS INT.
- CAST() and all other datetime/time functions now supports microsecond fully.

Windows performance improvements

- Backported Windows performance patches from MySQL 5.5.
- Asynchronous IO in XtraDB is redesigned and is now faster, due to the use of IO completion ports.
- Additional durability option for XtraDB : `innodb_flush_method` can now be `O_DSYNC`, like on Unixes. The effect of using this option is that the log file is opened with `FILE_FLAG_WRITETHROUGH`, and `FlushFileBuffers()` is not done. This may improve speed in write-heavy scenarios.
- A new Windows MSI installer.
- Includes a GUI-tool, HeidiSQL.

Miscellaneous

- GIS precise operations
- New status variables: `Rows_tmp_read`, `Handler_tmp_write`, and `Handler_tmp_update` which count what happens with internal temporary tables. `Rows_read`, `Handler_write` and `Handler_update` no longer count operations on internal temporary tables.
- New status variable `Handler_read_rnd_deleted`, which is number of deleted rows found and skipped while scanning a table. Before this was part of `Handler_read_rnd_next`.
- New variable 'in_transaction' that is 1 if you are in a transaction, 0 otherwise.
- Progress reports for `ALTER TABLE` and `LOAD DATA INFILE`. In addition Aria tables gives progress reports for `REPAIR TABLE` and `CHECK TABLE`. The progress can be seen in `SHOW PROCESSLIST`, `INFORMATION_SCHEMA.PROCESSLIST` and is sent to MariaDB clients that calls `mysql_real_connect()` with the new `CLIENT_PROGRESS` flag. `mysql` command line client supports the new progress indications.
- PBXT consistent commit ordering — This feature implements the new commit ordering storage engine API in PBXT. With this feature, it is possible to use "`START TRANSACTION WITH CONSISTENT SNAPSHOT`" and get consistency among transactions which involve both XtraDB and InnoDB. (Without this feature, there is no such consistency guarantee. For example, even after running "`START TRANSACTION WITH CONSISTENT SNAPSHOT`" it was still possible for the InnoDB/XtraDB part of some transaction *T* to be visible and the PBXT part of the same transaction *T* to not be visible.)
- MariaDB unique error numbers now start from `1900` to not clash with MySQL error numbers.
- `/*M!##### */` new executed comment syntax that can be used when you want use new MariaDB syntax but still want your program to be compatible with MySQL.
- A MariaDB optimized version of mytop is included in the MariaDB distribution.
- Enhanced KILL syntax:

```
KILL [HARD | SOFT] [CONNECTION | QUERY] [thread_id | USER user_name]
```

- `max_user_connections` (both the global variable and the `GRANT` option) can be set to `-1` to stop users from connecting to the server. The global `max_user_connections` variable does not affect users with the `SUPER` privilege.
- The IGNORE directive does not ignore all errors (like fatal errors), only things that are safe to ignore.

You can access the MariaDB 5.3 tree from launchpad.

Security Vulnerabilities Fixed in MariaDB 5.3

Contents

MariaDB 5.2 contains features that didn't have time to go into MariaDB 5.1. For all practical purposes it's a drop in replacement for MariaDB 5.1 (and thus MySQL 5.1).

MariaDB 5.2 is based on MariaDB 5.1 and thus MySQL 5.1.

The new features in 5.2 are quite isolated and as most have been in use by members in the MySQL community for a long time. Current versions of MariaDB 5.2 are stable and can be downloaded from http://downloads.askmonty.org.

New storage engines

- OQGRAPH
  - Allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions)
- SphinxSE: Text search within MariaDB.
  - A built-in Sphinx client which allows MariaDB to talk to searchd, run search queries, and obtain search results.

New features

- Virtual columns
  - Columns that are an expression and are calculated on retrieval.
- Extended User Statistics
  - Client, User, Index and Table statistics.
- Segmented MyISAM key cache
  - The key cache's global mutex is split into several mutex which gives a notable speed improvement under multi user load. We have registered up to 250% more performance thanks to this.
- Pluggable Authentication
  - Authentication is done via an extensible plugin, which makes it easy to add any kind of authentication to MariaDB.
- Storage-engine-specific CREATE TABLE
  - Allows one to specify additional attributes per field, index or table to the storage engine.
- Enhancements to INFORMATION SCHEMA.PLUGINS table
  - We expose more information about the plugins, like maturity levels.
- Group commit for the Aria engine.
  - Speeds up multi user inserts.

Other things

We have also done several smaller speed improvements, bug fixes and code cleanups.

Security Vulnerabilities Fixed in MariaDB 5.2

Contents

In short, MariaDB 5.1 is a binary drop in replacement of MySQL 5.1, but with performance like MySQL 5.5 (thanks to XtraDB), fewer bugs, and more features. Thanks to the extended and improved `mysql_upgrade` program it's also easier to upgrade from MySQL 5.0 to MariaDB 5.1 than to MySQL 5.1.

MariaDB 5.1 is based on MySQL 5.1. We do a merge once a month with MySQL5.1 to ensure all MySQL bug fixes get into MariaDB.

See also:

- MariaDB versus MySQL - Compatibility

New storage engines:

- Aria: A crash-safe storage engine based on MyISAM.
- XtraDB: Drop-in replacement for InnoDB based on the InnoDB plugin.
- PBXT: A transactional storage engine with a lot of nice features.
- FederatedX: Drop-in replacement for Federated.

Speed improvements

- CHECKSUM TABLE is faster.
- We have eliminated/improved some not needed character set conversions. Overall speed improvements is 1-5 % (according to sql-bench) but can be higher for big result sets with all characters between 0x00-0x7f.
- Our use of the Aria storage engine enables faster complex queries (queries which normally use disk-based temporary tables). The Aria storage engine is used for internal temporary tables, which should give you a speedup when doing complex selects. Aria is usually faster for temporary tables when compared to MyISAM because Aria caches row data in memory and normally doesn't have to write the temporary rows to disk.
- There are some improvements to DBUG code to make its execution faster when debug is compiled in but not used.

Extensions & new features

- Table Elimination (New optimization) (MWL#17)
- Pool of Threads (Allows you to have 200,000+ connections to MariadB)
- MariaDB can handle up to 32 key segments per key (up from 16)
- Added `--abort-source-on-error` to the mysql client.
- Microsecond Precision in Processlist
- mysqltest extensions

Easier to upgrade

We have made it easy to upgrade from MySQL 5.0 to MariaDB 5.1

- InnoDB and Archive tables are now upgraded properly.
- More options to mysql_upgrade and mysqlcheck to find out what's going on.
- Cleaned up wrong warnings from mysqlcheck.

(Upgrading from MySQL 5.1 to MariaDB 5.1 is a trivial 1 min exercise as MariaDB is a binary drop in replacement of MySQL. Just remove MySQL and install MariaDB and things will ***just work***)

Better Testing

- More tests in the test suite.
- All tests runs now clean without having to restart test. (Oracle re-runs tests 3 times and assumes things are ok if one tests works)

- Test builds with different configure options to get better feature testing.
- Remove invalid tests. (e.g. Don't test feature **"X"** if that feature is not in the build you are testing.)

Fewer warnings and bugs

- A build is not regarded ok if there are any errors or compiler warnings.
- We have fixed a lot of bugs in the MySQL code which we have found while merging the MySQL code into MariaDB and by running the extended test suite.

Security Vulnerabilities Fixed in MariaDB 5.1

> For a complete list of security vulnerabilities (CVEs) fixed across all versions of MariaDB, see the Security Vulnerabilities Fixed in MariaDB page.

- CVE-2013-1548: MariaDB 5.1.66
- CVE-2013-1531: MariaDB 5.1.67
- CVE-2013-0389: MariaDB 5.1.67
- CVE-2013-0385: MariaDB 5.1.67
- CVE-2013-0384: MariaDB 5.1.67
- CVE-2013-0383: MariaDB 5.1.67
- CVE-2013-0375: MariaDB 5.1.67
- CVE-2012-5612: MariaDB 5.1.67
- CVE-2012-5611: MariaDB 5.1.67, MariaDB 5.1.66
- CVE-2012-5060: MariaDB 5.1.66
- CVE-2012-4414: MariaDB 5.1.66 [2]
- CVE-2012-3197: MariaDB 5.1.66
- CVE-2012-3180: MariaDB 5.1.66
- CVE-2012-3177: MariaDB 5.1.66
- CVE-2012-3173: MariaDB 5.1.66
- CVE-2012-3167: MariaDB 5.1.66
- CVE-2012-3166: MariaDB 5.1.66
- CVE-2012-3163: MariaDB 5.1.66
- CVE-2012-3160: MariaDB 5.1.66
- CVE-2012-3158: MariaDB 5.1.66
- CVE-2012-3150: MariaDB 5.1.66
- CVE-2012-1734: MariaDB 5.1.66
- CVE-2012-1705: MariaDB 5.1.67
- CVE-2012-1703: MariaDB 5.1.62
- CVE-2012-1702: MariaDB 5.1.67
- CVE-2012-1690: MariaDB 5.1.62
- CVE-2012-1689: MariaDB 5.1.66
- CVE-2012-1688: MariaDB 5.1.62
- CVE-2012-0574: MariaDB 5.1.67
- CVE-2012-0572: MariaDB 5.1.67
- CVE-2012-0540: MariaDB 5.1.66
- CVE-2009-4484: MariaDB 5.1.42

The following CVEs are also fixed in MariaDB 5.1 but the fix is not tied to a specific version number:

- CVE-2012-0113
- CVE-2011-2262
- CVE-2012-0116
- CVE-2012-0118
- CVE-2012-0087
- CVE-2012-0101
- CVE-2012-0102
- CVE-2012-0115
- CVE-2012-0119
- CVE-2012-0120
- CVE-2012-0484
- CVE-2012-0485
- CVE-2012-0490
- CVE-2012-0112
- CVE-2012-0114
- CVE-2012-0492
- CVE-2012-0075

8 The Community

MariaDB is a project developed by the open source community. The MariaDB Foundation is the main steward for the project. However, anyone can participate in the development.

The following links provides information to help you participate in making MariaDB a success

News & Information

News, web logs and other published information related to MariaDB.

Bug Tracking

How to Report Bugs and Make Feature Requests.

Contributing & Participating

Getting Help With MariaDB

Extracting Entries from the Binary Log

Using mariadb-binlog to extract entries from the binary log for debugging.

There are 18 related questions.

8.1.1 MariaDB Community Bug Reporting

Contents

For reporting documentation bugs specifically, see Reporting Documentation Bugs.

MariaDB's bug and feature tracker is found at https://jira.mariadb.org.

This page contains general guidelines for the community for reporting bugs in MariaDB products. If you want to discuss a problem or a new feature with other MariaDB developers, you can find the email lists and forums here.

Known Bugs

First, check that the bug isn't already filed in the MariaDB bugs database.

For the MariaDB bugs database, use JIRA search to check if a report you are going to submit already exists. You are not expected to be a JIRA search guru, but please at least make some effort.

- Choose `Issues => Search for issues` ;
- If the form opens for you with a long blank line at top, press `Basic` on the right to switch to a simpler mode;
- In the `Project` field, choose the related project, (`MDEV` for generic MariaDB server and clients);
- In the `Contains text` text field, enter the most significant key words from your future report;
- Press `Enter` or the magnifying glass icon to search.

If you see bug reports which are already closed, pay attention to the 'Fix version/s' field -- it is possible that they were fixed in the *upcoming* release. If they are said to be fixed in the release that you are currently using or earlier, you can ignore them and file a new one (although please mention in your bug report that you found them, it might be useful).

If you find an open bug report, please vote/add a comment that the bug also affects you along with any additional information you have that may help us to find and fix the bug.

If the bug is not in the MariaDB bugs database yet, then it's time to file a bug report. If you're filing a bug report about a bug that's already in the MySQL bugs database, please indicate so at the start of the report. Filing bug reports from MySQL in the MariaDB bugs database makes sense, because:

- It shows the MariaDB team that there is interest in having this bug fixed in MariaDB.
- It allows work to start on fixing the bug in MariaDB - assigning versions, assigning MariaDB developers to the bug, etc.

Reporting a Bug

Bugs and feature requests are reported to the MariaDB bugs database.

JIRA Privacy

Please note that our JIRA entries are public, and JIRA is very good at keeping a record of everything that has been done. What this means is that if you ever include confidential information in the description there will be a log containing it, even after you've deleted it. The only way to get rid of it will be removing the JIRA entry completely.

Attachments in JIRA are also public.

Access to a comment can be restricted to a certain group (e.g. Developers only), but the existing groups are rather wide, so you should not rely on it either.

If you have private information -- SQL fragments, logs, database dumps, etc. -- that you are willing to share with MariaDB team, but not with the entire world, put it into a file, compress if necessary, upload to the mariadb-ftp-server, and just mention it in the JIRA description. This way only the MariaDB team will have access to it.

Reporting Security Vulnerabilities

As explained above, all JIRA issues are public. If you believe you have found a security vulnerability, send an email to security@mariadb.org, please, do not use JIRA for that. We will enter it in JIRA ourselves, following the responsible disclosure practices.

Contents of a Good Bug Report

Below is the information we need to be able to fix bugs. The more information we get and the easier we can repeat the bug, the faster it will be fixed.

A good bug report consists of:

a. The environment (Operating system, hardware and MariaDB version) where the bug happened.
b. Any related errors or warnings from the server error log file. Normally it is `hostname.err` file in your database directory, but it can be different depending on the distribution and version; if you cannot find it, run `SELECT @@log_error` on the running server. If either the variable or the file it points at is empty, the error log most likely goes to your system log. If this is systemd you can get the last 50 lines of the MariaDB log with `journalctl -n 50 -u mariadb.service`. If possible, attach the full unabridged error log at least from the last server restart and till the end of the log.,
c. If the problem is related to MariaDB updates, or otherwise changing the version of the server, recovery from a previous crash, and such, then include the previous versions used, and the error log from previous server sessions.
d. The content of your my.cnf file or alternatively the output from `mariadbd --print-defaults` or `SHOW VARIABLES`.
e. Any background information you can provide (stack trace, tables, table definitions (`show-create-table SHOW CREATE TABLE {tablename}`), data dumps, query logs).
f. If the bug is about server producing wrong query results: the actual result (what you are getting), the expected result (what you think should be produced instead), and, unless it is obvious, the reason why you think the current result is wrong.
g. If the bug about a performance problem, e.g. a certain query is slower on one version than on another, output of `EXPLAIN EXTENDED <query>` on both servers. If its a `SELECT` query use analyze-format-json ANALYZE FORMAT=JSON.
h. A test case or some other way to repeat the bug. This should preferably be in plain SQL or in mysqltest format. See **mysqltest/README** for information about this.
i. If it's impossible to do a test case, then providing us with a backtrace information would be of great help.

JIRA Fields

The section below describes which JIRA fields need to be populated while filing reports, and what should be put there. Apart from what's mentioned below, you don't have to fill or change any fields while creating a new bug report.

Project

If you are filing a report for MariaDB server, client programs, or MariaDB Galera cluster, the target project is `MDEV`. Connectors and MaxScale have separate projects with corresponding names. If you choose a wrong project, bug processing can be delayed, but there is no reason to panic -- we'll correct it. If you inform us about the mistake, we'll change it faster.

Some project names include:

- CONC - MariaDB Connector/C
- CONJ - MariaDB Connector/J
- CONJS - MariaDB Connector/node.js
- CONPY - MariaDB Connector/Python
- MCOL - ColumnStore
- MDBF - MariaDB Foundation Development (anything related to the mariadb.org domain)
- MDEV - MariaDB server, client programs, or MariaDB Galera Cluster
- MXS - MaxScale
- ODBC - MariaDB Connector/ODBC

Type

Feature requests are not the same as bug reports. Specify a `Task` type for feature requests in Jira, and a `Bug` type for bug reports. Like with the project field, choosing a wrong type will put the request to the wrong queue and can delay its processing, but eventually it will be noticed and amended.

See also plans for next release for things that we are considering to have in the next MariaDB release.

Summary

Please make sure the summary line is informative and distinctive. It should always be easy to recognize your report among other similar ones, otherwise a reasonable question arises -- why are they not duplicates?

Examples:

- good summary: *Server crash with insert statement containing DEFAULT into view*
- not a good summary: *mariadbd crash*

Generally, we try not to change the original summary without a good reason to do it, so that you can always recognize your own reports easily.

Priority

We do not have separate Severity/Priority fields in JIRA, so this Priority field serves a double purpose. For original reports, it indicates the importance of the problem from the reporter's point of view. The default is 'Major'; there are two lower and two higher values. Please set the value accurately. While we do take it into account during initial processing, increasing the value above reasonable won't do any good, the only effect will be the waste of time while somebody will be trying to understand why a trivial problem got such a high priority. After that, the value will be changed, and the report will be processed in its due time anyway.

Affected Versions

Put everything you know about which versions are affected. There are both major versions (10.6, 10.5 etc.) and minor versions (10.5.9, 10.4.12, etc.) available for choosing. Please always specify there the exact version(s) (X.Y.Z) which you are working with, and where you experience the problem.

Additionally, If you know the exact version where the problem appeared, please put it as well. If the problem has been present, as far as you know, in all previous releases, you can also put there the major version, e.g. 10.0. Alternatively, you can mention all of it in the description or comments.

Please also note in the description or comments which versions you know as *not* affected. This information will help to shorten further processing.

Environment

Put here environment-related information that might be important for reproducing or analyzing the problem: operating system, hardware, related 3rd-party applications, compilers, etc.

Description

The most important part of the description are steps to reproduce the problem. See more details about bug report contents above in the section Contents of a good bug report.

If in the process of reproducing, you executed some SQL, don't describe it in words such as "I created a table with text columns and date columns and populated it with some rows" -- instead, whenever possible, put the exact SQL queries that you ran. The same goes for problems that you encountered: instead of saying "it did not work, the query failed, I got an error", always paste the exact output that you received.

Use {noformat}...{noformat} and {code}...{code} blocks for code and console output in the description.

Attachments

If you have SQL code, a database dump, a log etc. of a reasonable size, attach them to the report (archive them first if necessary). If they are too big, you can upload them to ftp.askmonty.org/private. It is always a good idea to attach your cnf file(s), unless it is absolutely clear from the nature of the report that configuration is irrelevant.

Links

If you found or filed a bug report either in MariaDB or MySQL or Percona bug base which you think is related to yours, you

can put them in the `Links` section; same for any external links to 3rd-party resources which you find important to mention. Alternatively, you can just mention them in the description or comments.

Tags

You don't have to set any tags, but if you want to use any for your convenience, feel free to do so. However, please don't put too generic values -- for example, the tag `mariadb` is meaningless, because everything there is `mariadb` . Don't be surprised if some tags are removed later during report processing.

Bugs that also Affect MySQL or Percona

Our normal practice is to report a bug upstream if it's applicable to their version. While we can do it on your behalf, it is always better if you do it yourself -- it will be easier for you to track it further.

If the bug affects MySQL, it should also be reported at MySQL bugs database. If the bug affects Percona server and not MySQL, it should go to Percona Launchpad.

Collecting Additional Information for a Bug Report

Getting a Stack Trace with Details

See the article How to produce a stack trace from a core file.

Extracting a Portion of a Binary Log

See the article here.

Getting Help with your Servers

If you require personalized assistance, want to ensure that the bug is fixed with high priority, or want someone to login to your server to find out what's wrong, you can always purchase a Support contract from MariaDB plc or use their consulting services.

8.1.2 Reporting Documentation Bugs

Contents

Documentation bugs and feature requests should be reported at https://jira.mariadb.org.

This page contains general guidelines for the community for reporting documentation bugs.

Known Bugs

First, check that the bug isn't already filed in the MariaDB bugs database.

For the MariaDB bugs database, use JIRA search to check if a report you are going to submit already exists. You are not expected to be a JIRA search guru, but please at least make some effort.

- Choose `Issues => Search for issues` ;
- If the form opens for you with a long blank line at top, press `Basic` on the right to switch to a simpler mode;
- In the `Project` field, choose the related project, (`MDEV` for generic MariaDB server and clients);

- In the `Contains text` text field, enter the most significant key words from your future report;
- Press `Enter` or the magnifying glass icon to search.

If you see bug reports which are already closed, but you still see the error, please confirm that the issue still exists in the Knowledge Base.

If you find an open bug report, please vote/add a comment that the bug also affects you along with any additional information you have that may help us to find and fix the bug.

If the bug is not in the MariaDB bugs database yet, then it's time to file a bug report.

Reporting a Bug

Bugs and feature requests are reported to the MariaDB bugs database.

JIRA Privacy

Please note that our JIRA entries are public, and JIRA is very good at keeping a record of everything that has been done. What this means is that if you ever include confidential information in the description there will be a log containing it, even after you've deleted it. The only way to get rid of it will be removing the JIRA entry completely.

Attachments in JIRA are also public.

Access to a comment can be restricted to a certain group (e.g. Developers only), but the existing groups are rather wide, so you should not rely on it either.

JIRA Fields

The section below describes which JIRA fields need to be populated while filing reports, and what should be put there. Apart from what's mentioned below, you don't have to fill or change any fields while creating a new bug report.

Project

If you are filing a report for documentation about MariaDB server, client programs, or MariaDB Galera Cluster, the target project is `MDEV`. Connectors and MaxScale have separate projects with corresponding names. If you choose a wrong project, bug processing can be delayed, but there is no reason to panic -- we'll correct it. If you inform us about the mistake, we'll change it faster.

Some project names include:

- CONC - MariaDB Connector/C
- CONJ - MariaDB Connector/J
- CONJS - MariaDB Connector/node.js
- CONPY - MariaDB Connector/Python
- MCOL - ColumnStore
- MDBF - MariaDB Foundation Development (anything related to the mariadb.org domain)
- MDEV - MariaDB server, client programs, or MariaDB Galera Cluster
- MXS - MaxScale
- ODBC - MariaDB Connector/ODBC

Type

Feature requests are not the same as bug reports. Specify a `Task` type for feature requests in Jira, and a `Bug` type for bug reports. Like with the project field, choosing a wrong type will put the request to the wrong queue and can delay its processing, but eventually it will be noticed and amended.

Summary

Please make sure the summary line is informative and distinctive. It should always be easy to recognize your report among other similar ones, otherwise a reasonable question arises -- why are they not duplicates?

Examples:

- good summary: *SELECT max_statement_time clause example gives incorrect results*
- not a good summary: *code example doesn't work*

Generally, we try not to change the original summary without a good reason to do it, so that you can always recognize your own reports easily.

Priority

We do not have separate Severity/Priority fields in JIRA, so this Priority field serves a double purpose. For original reports, it indicates the importance of the problem from the reporter's point of view. The default is 'Major'; there are two lower and two higher values. Please set the value accurately. While we do take it into account during initial processing, increasing the value above reasonable won't do any good, the only effect will be the waste of time while somebody will be trying to understand why a trivial problem got such a high priority. After that, the value will be changed, and the report will be processed in its due time anyway.

Component/s

Documentation bugs should have "Documentation" added as a component in order to be correctly assigned.

Affected Version/s

Since the documentation is not version-dependent, you can put N/A in this field.

Environment

Usually this can be left empty, but if applicable, put any environment-related information that might be important for reproducing or analyzing the problem.

Description

The most important part of the description are the steps to reproduce the problem. Link to the page on the Knowledge Base with the error/s. Where applicable, provide a sample structure and results clearly demonstrating the problem.

Use {noformat}...{noformat} and {code}...{code} blocks for code and console output in the description.

Links

If the documentation error relates to an existing bug/feature request in JIRA (for example an undocumented new feature), you should link it here. Alternatively, you can just mention them in the description or comments.

Tags

You don't have to set any tags, but if you want to use any for your convenience, feel free to do so. However, please don't put too generic values -- for example, the tag `mariadb` is meaningless, because everything there is `mariadb` . Don't be surprised if some tags are removed later during report processing.

8.1.3 MariaDB Community Bug Processing

Contents

This page describes how community bug reports are processed among our products and explains what you need to notice while tracking bugs.

Commitments

MariaDB does not have any SLA or guaranteed reaction times on bugs in Jira. While we are taking bugs reported by the community very seriously, and aim to provide response and to handle issues as fast as possible, MariaDB does not have a dedicated bug verification team, this activity is performed on the best-effort basis.

To make sure your bug report will be confirmed and moved forward faster, please follow **the guidelines** about creating bug reports.

Bug Verification Routine

As of today, initial bug processing routine in MariaDB is not strictly formalized. This section describes the de-facto status rather than any policy.

The process is different for bug reports (*Bug* type in JIRA) vs feature requests (*Task* type). The process described below is related to bug reports.

Incoming Queue

All new bug reports go to the waiting list, to be reproduced and confirmed by a member of the team. The bug stays in the queue until one or more of the conditions below are met:

- Bug report is assigned to a developer;
- Bug report gets status 'Confirmed';
- Bug report gets the label 'upstream';
- Bug report is closed (on whatever reason).

With other things equal, bug reports in the queue are initially handled in the FIFO manner; however, there are various factors that make things not equal.

Bug Processing Order

First thing that is taken into account is **Priority**. It does not mean that everything needs to be filed as Critical; on the contrary, it means that Priority should be chosen wisely. Although a report with higher Priority will be looked at sooner, as soon as it becomes clear that the Priority is set to a higher value than the problem deserves, it will be amended and put back to the queue. However, if the high priority is justified, we will try to process the report as fast as possible.

Another important factor is **the quality of the report** itself.

- If the report is written well and **has all information**, including a reproducible test case, it can be verified and moved forward quickly.
- If the report is written clearly enough, but does not have enough information, it will get fast enough first response where we will request the missing details; but the further exchange can take a lot of time until we get everything we need to work on the issue.
- Finally, reports which are written in a tangled and incomprehensible manner get the slowest response time, because even if eventually it turns out that they do have all required information, it is difficult and time-consuming to extract and process, so they can be put aside for some time.

First Response

Complete processing of a reported bug can be complicated and time-consuming, especially the reproducing part. We do not want our users to wait for long not knowing if their bug report has even been noticed, we try to provide first response quicker than that.

First response to the bug, which we are trying to provide as quickly as possible, is one of these:

- If we can reproduce the problem based on the information that was provided in the initial description, the report gets the status Confirmed.
- If it is obvious from the initial description that the bug report is a **duplicate** of an existing one, or the problem has already been fixed in later releases or in the upcoming release, or the described behavior is not a bug, or, in very rare cases, it is admitted to be a bug, but it is not going to be fixed, the report gets closed with the corresponding Resolution value and a comment with the explanation.
- If the bug report at least appears to describe a real bug, but we do not have enough information to proceed, we will request the information from the reporter, and the report will go to the **Need feedback** list.
- If on some reason it is clear from the bug report that it will be very difficult to reproduce based on the information from the user, but there is a reason to believe that the problem can be analyzed by code inspection, the bug report can be assigned to a developer who is an expert in the corresponding area for the analysis.

We realize that "as quickly as possible" is a relative term. The dream scenario is that all reports are responded to in a matter of hours; however, more realistically, it can take a few days, and in some cases, when the team is overly busy with a big upcoming release or some other extraordinary events, it can even be weeks.

Need Feedback

When a report does not have all the information to reproduce the problem right away (which is quite often the case), we will ask the reporter to provide the missing information. Usually it takes more than one iteration to get everything right, so it is important that you respond to the questions as precisely as you can. Please make sure that you answered **all** questions (or, if you cannot answer some of them, please say so, otherwise we will have to ask again, and more time will be wasted on it).

There is no status "Need Feedback" in our JIRA; instead, we are using the label `need_feedback`. As long as the report has this label, it remains on the "Waiting for feedback" list. The label is set and removed manually by whoever asks for the feedback and receives it; so it can happen that the reporter has provided the response, but it remained unnoticed and the bug keeps waiting. It will be our fault, but human errors happen; it would help a lot if the reporter removed the label along with providing the feedback.

E-mail Notifications

This question arises fairly often, so it deserves mentioning.

As already said before, the `need_feedback` label is set and *removed* manually. JIRA e-mail updates about it can be confusing when you look at them quickly. For example, when someone *removes* the label, the email looks like this:

```
Elena Stepanova updated MDEV-9791:
----------------------------------
    Labels:   (was: need_feedback)
```

What it says that the `Labels` field has become empty, while before it had been `need_feedback`. People often misread it and ask "What else do you need from me? I've answered your questions". This update means that at the moment we don't need anything, your report is back to the incoming queue, and your feedback will be analyzed as soon as possible. Then, we will possibly ask more questions and set the label again, and the notification will look like this:

```
Elena Stepanova updated MDEV-9801:
----------------------------------
    Labels: need_feedback  (was: )
```

Successful Outcome

If the feedback exchange was fruitful and we received enough information to proceed, the bug report will go through the normal **verification steps**.

Incomplete Reports

Reports do not stay open on the "Need Feedback" list forever. After a month of waiting, if we do not get a response from the reporter, and still cannot proceed without it, we close the report as **Incomplete** with the corresponding comment. This state is not irreversible: you can still add comments and provide the information even when the report is closed as Incomplete, and it will be re-opened.

Worst Case Scenario

Sometimes it happens that after iterations of feedback requests we run out of ideas what else to ask from the reporter, and still could not verify the bug, or that the reporter is willing to collaborate with us, but cannot provide the necessary information on objective reasons (usually when the problem happens on a production instance). In some cases we might close the report as "Cannot reproduce", which we consider our loss; but more often we want to keep it open, in hope that more information arrives, maybe from a different source, and together with this report they will help us get to the bottom of the problem; if it happens so, the report gets assigned to somebody without being confirmed, just so it remains at least on somebody's radar, and it will stay open for a long time. It does not mean it is forgotten, it means that for the time being we hit the wall. You are very welcome to comment on such reports, whenever you think you might have something to add, because this is exactly what we are waiting for.

Bug Verification

Normally the bug report has to go through the following steps before it is moved forward to fixing:

- the described problem needs to be reproduced;
- it needs to be checked against all active post-Beta versions of MariaDB where it is theoretically applicable (as of the moment of writing this article, it is 5.5, 10.0, 10.1);
- in case it is a relatively recent regression, the guilty change needs to be found;
- the component or functional area should be determined, so that the bug gets assigned to the right person.

After that the bug is ready for fixing.

Bug Fixing Routine

Sometimes it seems hard to understand from the outside how MariaDB development team chooses which bugs to fix in a particular release, or why some bugs are fixed faster than others, or why critical bugs stay untouched for a long time.

Sprint Model for Bug Fixing

MariaDB currently uses 1- or 2-week sprint model for server development and bugfixing. It needs a separate article to describe it in more detail, but for bugfixing, in a nutshell it means the following.

- one or two weeks before a scheduled release the team creates a new sprint and evaluates existing bugs which affect this release;
- the selected bugs are added to the new sprint;
- during the active sprint, the developer is supposed to work on the tasks which are part of the sprint, unless a true emergency arises.

There are two important consequences of this model which sometimes cause a confusion:

1) If the current sprint is for one version, e.g. 10.0, and you file a bug for another version, e.g. 10.1, then, even if the bug is really critical, it won't be jumped on right away: it makes no sense, because the 10.1 is not going to be released next week anyway, while 10.0 will be. When the 10.0 sprint finishes, and 10.1 sprint starts, your bug will be picked up for that sprint and fixed then.

2) If the current sprint for 10.1 is already in progress, newly created 10.1 reports normally won't be included into it, unless they are considered so extremely important that the developer is allowed to ignore the sprint plan.

Bugs Chosen for a Sprint

When a new sprint is created, bugs which affect the scheduled release are evaluated.

- from all such bugs assigned to a developer, each developer chooses bugs he is able to work on during the given time interval;
- bug priority plays the most significant role in this process, but this is not the only factor.
    - `Blocker` bugs must be either fixed or degraded before the release goes out;

- `Critical` bugs should be chosen above other bugs, except for `Blocker` s;
- among `Major` bugs,
  - bugs with patches, either external, or upstream, or internal, are usually prioritized above ordinary bug reports;
  - external reports (community reports) are ranked higher than bugs reported by the development team;
  - bugs which can realistically be fixed in the given time interval are chosen more frequently than those that are likelly to take several cycles;
  - bugs which affect the reporter in a worse matter get more attention than those that have viable workarounds;
- `Minor` bugs are usually fixed when there are no more urgent tasks.

Tracking Progress

If a bug report has passed through verification stage, either being confirmed, or pushed forward to the development-level analysis as is, there can be various updates on it. It is important to understand what they mean.

JIRA Fields to Watch

All JIRA fields are public, but some of them are mainly used for internal development process, while others are more user-facing. **This article** describes which fields should be populated during the initial report submission. There is a different set of fields important for tracking purposes.

Resolution vs. Status

It might come as counter-intuitive, but in the existing JIRA structure, the `Status` field does not mean much for the user, it is mainly used for development and management purposes. On the contrary, the `Resoluton` field is entirely user-facing: it does not participate in planning or development. It remains the same 'Unresolved' for the whole life of the report, and is only changed when the bug gets closed, demonstrating the reason why it was closed.

Resolution

- `Unresolved` - the bug report remains open, the work has not been finished.
- `Fixed` - the bug has been fixed, see **Fix version/s** and possibly comments to the report for more information. This is almost always a terminal state, we do not re-open fixed bugs even if they later re-appear; please create a new one instead. The only case when it can be re-opened is when the 'Fix version/s' have not been released yet.
- `Duplicate` - the bug report is identical to an already existing open (or recently fixed) report, which will be quoted in the comments and/or links. It is usually a terminal state, unless it is proven later that the report was not a duplicate after all.
- `Not a bug` - the described behavior is not a bug, there will be a comment explaining why. It is usually a terminal state, unless you object and show why it is a bug. If the report is in fact a feature request, then rather than closing it as 'Not a bug', we will switch the type to 'Task'.
- `Incomplete` - we had requested feedback from the user and waited for 1 month, but did not receive it. It is a pseudo-terminal state, the report can be re-opened any time when the requested information is provided.
- `Cannot reproduce` - rather rarely used "resolution", which means we could not find the way to confirm the problem described by the reporter, and ran out of ideas what other information to request from the reporter in order to reproduce it.
- `Won't fix` - another rarely used "resolution", which means that the bug is admitted, but we have no intention to fix it. Usually it happens when the bug only affects old versions, and is not important enough to fix in the old versions; or, when it is related to systems or architectures we don't officially support.

Status

- `Open`, `Confirmed` - this distinction is used in our internal queues, but from the user's perspective the difference is slim: setting the bug report to 'Confirmed' does mean that we are satisfied with the information provided in the report, but the user will also know about it from our comments and other updates. Otherwise, bugs in both statuses can be considered for fixing.
- `In Progress`, `Stalled` - different intermediate states of bugs which help developers to filter their lists and management to gather a picture of the current activity. For the user, there is no important difference -- despite the negative semantics, 'Stalled' does not mean that something is wrong with the bug report, only that the developer is not working on it actively at the moment.
- `In review` - means, literally, that a peer review has been requested.
- `Closed` - means that the bug report is closed, on whatever reason. The real reason is in the 'Resolution' field.

Fix Versions

This is an important field for progress tracking. After the bug is confirmed or otherwise acknowledged, this field is populated with a set of major versions where we intend to fix it. E.g. if the field is set to `10.0 10.1`, it means that at the moment we consider it for fixing in some future 10.0 release (not necessarily the next one), and the bugfix will be merged into the next 10.1 release after that; but we do not consider it for fixing in 5.5, even if it is affected to.

To some extent, you can influence the initial plans: if you see that the fix is not targeted for versions where you think it should be, you can comment on the report, and if you provide convincing arguments and make your case, it can be reconsidered.

The value of the field is not a promise to fix the bug in the mentioned releases. It can be changed both ways: during further analysis, the developer can find out that it can be safely fixed in an earlier release, or, on the contrary, that it cannot be safely fixed in the GA release, and the fix can only go to the next versions which are currently under development.

After the bug is fixed, the value of the field is changed to the exact versions, e.g. `10.0.25 10.1.14`. It means that the patch has been pushed into the 10.0 branch, and will be released with 10.0.25 release; it also means that the patch *will be* merged to 10.1 tree and released with 10.1.14 release, but it does not mean that it is already in the 10.1 branch.

Priority

As the other article says, the **Priority** field serves two purposes. During the initial bug creation, it indicates the importance of the bug report from the user's perspective (in other bug tracking systems it is called 'Severity' or alike). After the bug has been confirmed, the same field is used for development purposes, to prioritize bug fixing (real 'Priority'). While we take into account the reporter's view on the matter, we can change the initial priority both ways, depending on the information we revealed during the problem analysis, versions affected, etc.

The value of the field normally means the following:

- `Blocker` - we currently think that the bug must be fixed before the next release(s) set in the 'Fix version/s' field;
- `Critical` - the bug should be picked up for fixing earlier than any other bugs apart from blockers;
- `Major` - the bug will be present in the main queue for fixing in the upcoming 'Fix version/s', although only a part of such bugs will be fixed in every release;
- `Minor`, `Trivial` - the bugs will be picked up when the assignee does not have more pressing issues for the upcoming release.

Please note that the Priority field only demonstrates our intentions at the moment, it does not guarantee that things will happen according to these intentions.

Labels

Labels are mostly used for more convenient filtering and don't carry much importance otherwise. However, there are a few that affect the processing of a bug report:

- `need_feedback` - its role during the initial bug processing was already described **above**. However, after a bug is confirmed and queued for fixing, it should not appear anymore; and even if it's left by mistake, it won't affect the progress.
- `upstream` - the label means that the bug also exists in the upstream version of the corresponding component - normally, in MySQL server or a client program, but can also be in Percona's XtraDB or TokuDB. Normally there should also be a link to the upstream bug report. Setting this label means that we might want to take for a while and see whether the bug is fixed in the upstream version before we fix it in MariaDB directly. It was usual for 5.5, less usual for 10.x where bugfixes, apart from InnoDB, are not merged automatically. The label is still set, but it is more for informational purposes than to affect the priority.
- `upstream-fixed` - the label means that the bug used to exist in the upstream version, but not anymore. It means that there is nothing more to wait; moreover, it might be worth picking up the bug soon and at least evaluating the upstream bugfix.

Bug Reports with Patches

MariaDB encourages contributors to provide bug fixes; so, bug reports which come with the fixes in general have a quicker turnaround. The bug fix can come in a form of Git pull request, or, in simple cases, as a diff pasted in or attached to the bug report itself.

Principles for External Bug Reports

There are some basic rules for bugs, particularly for setting the **Resolution** value, which we want to stick to and which might be different from procedures you came across in other projects. It mainly concerns *external* bugs (those that come from the community), for internal ones we can cut corners more freely.

This all is easier to understand if one remembers that the **Resolution** or its analogues in other bug-tracking systems is a *user-facing* field, as already mentioned above, and that it relates more to the report, than to the bug itself.

Duplicate

An older bug report cannot be a duplicate of a newer one, it is nonsensical. The only possible exception is when an older bug has no useful information whatsoever *and* the reporter does not provide any helpful feedback, while a newer report was not closed as a duplicate right away and got some useful updates. The common example of such exception is when the first report is just an optimized stack trace, no query, no data, nothing to work with, while the second report has a test case. But if the first reporter at least makes an effort to collaborate, the report deserves to be treated with respect.

Bug reports which have essentially different descriptions and/or test cases should not be duplicates. The common example is this: a developer creates a bug saying something like "this and that pieces of code are wrong, it should be so and so"; and then a user files a bug saying "this SQL produces a wrong result on this data set". Even if they are about *the same error in the code* at the end, they are not duplicate *bug reports*.

Obviously, a report can never be a duplicate of anything private (luckily it does not concern MariaDB server so far, as the bug reports are public).

In general, a bug report is a duplicate of another one if, and only if, the new reporter could find the existing report just by a reasonable **JIRA search**.

Cannot Reproduce

A bug report should not be closed as "cannot reproduce" if it was once verified/confirmed, but disappeared in later versions. It's unfair to the reporter, and also dangerous to the product. We should know why a bug stopped being reproducible -- either we find when and how it was fixed (and close the report as "Fixed in version X by a patch for Y"), or we discover that it wasn't in fact fixed, but just masked. The simplest example is a change of execution plan in optimizer: server would crash on a particular query, then due to a change in optimizer it started using a different plan for the same query, so it wouldn't go through the crashing path anymore. The crash is still there, though.

In general, the "cannot reproduce" resolution is a last resort. Usually if we can't reproduce something, it means that either the reporter did not provide required information (and then the resolution should be "Incomplete"), or we don't know what to request from the reporter, and then we should keep thinking, rather than close it. Of course, it happens that the bug is genuinely not reproducible, but it shouldn't be decided lightly.

8.1.4 MariaDB Security Bug Fixing Policy

See MariaDB Security Policy.

8.1.5 Building MariaDB Server for Debugging

Contents

Instructions on how to build a mysqld that contains all the information we need to fix the problem: (A more detailed explanation can be found here.)

Note: this text has been extracted into a separate article from Reporting bugs, see its full history there.

- Add the --core-file option to your /.my.cnf or /etc/my.cnf file under the [mysqld] tag.
- Get the latest MariaDB code from GitHub.
- Compile MariaDB with the **-g** compiler flag (Unix).
- Optionally: with more checking Compile MariaDB for debugging - will cause slowdown.
- Shut down your old mysqld server.
- Install the new compiled `mysqld` binary. Note that if you are compiling same version of MariaDB that you have already installed it's enough to just copy this one binary!
- Restart mysqld.

Compiling with **-g** should not cause any notable slowdown of the server.

You can of course also do **make install**, but the above way allows you to go back to your old binary if needed.

If you get any errors about a wrong number of error messages, you can fix that by copying the corresponding language file from **sql/share** over your old ones (this should be reasonably safe to do).

```
cp sql/share/english/* mariadb-install-dir/share/mysql/english
```

What to Do When You Get a Crash After Installing a Debug Binary

Now when you get a crash do the following:

- Create a README file that describes the problem. You can use the mysqlbug script to generate a template for this.
- Create a tar file containing the core, the mysqld binary and README. If possible, also add any database files that could help us repeat the problem!

```
sh> tar cvfz /tmp/mariadb-bug-'short-description'.tgz mariadb-data-dir/core* mariadb-
install-dir/libexec/mysqld README
```

- Send it to our secure ftp server:

```
sh> ftp -a ftp.askmonty.org
ftp> cd private
ftp> binary
ftp> put /tmp/mariadb-bug-'short-description'.tgz
ftp> quit
```

- To be able to follow the progress, create a bug report in JIRA about this. This should be easy to do based on the information you have in your README file.

8.1.6 Extracting Entries from the Binary Log

This article is relevant if the problem is on a replication slave.

Note: this text has been extracted into a separate article from Reporting bugs, see its full history there.

Sometimes a binary log event causes an error of some sort. A whole binary log file is sometimes impractical due to size or sensitivity reasons.

Step 1: Copy the binary log locally

This is just in case you don't quite extract the right information first. If the binlog expired off and you haven't got the right information, your bug report may not easily be reproducible.

```
sudo cp /var/lib/mysql/mysql-bin.000687 ~/
sudo chown $USER: ~/mysql-bin.000687
```

Step 2: Create an extract header

Binary logs have a header portion. Without the header mariadb-binlog won't be able to read it. The header also contains valuable session information

We look at the binary log to see how big the header and session information is:

```
mariadb-binlog --base64-output=decode-rows --verbose mysql-bin.000687 | more
/*!50530 SET @@SESSION.PSEUDO_SLAVE_MODE=1*/;
/*!40019 SET @@session.max_insert_delayed_threads=0*/;

SET @@session.collation_database=DEFAULT/*!*/;
BEGIN
/*!*/;
# at 328
```

We see that the session information ends at 328 because of the last line, so we extract to that point.

```
dd if=mysql-bin.000687 of=mysql-bin.000687-extract-offset-129619 bs=1 count=328
```

We need to find out at what offset the entry at 129619 ends and it might be useful to extract some previous entries as well.

```
mariadb-binlog --base64-output=decode-rows --verbose mysql-bin.000687 | grep  '^# at ' |  grep -C
# at 127602
# at 127690
# at 128201
# at 128290
# at 128378
# at 128829
# at 128918
# at 129006
# at 129459
# at 129548
# at 129619
# at 129647
# at 130070
# at 130097
# at 130168
# at 130196
# at 130738
# at 130942
# at 130969
# at 131040
# at 131244
```

Take a look at those entries with:

```
mariadb-binlog --base64-output=decode-rows --verbose --start-position 129006  --stop-position 130
```

Now let's assume we want to start at our original 129619 and finish before 130168

```
dd if=mysql-bin.000687 bs=1 skip=129619 count=$(( 130168 - 129619 ))  >> mysql-bin.000687-extract
```

Check the extract:

```
mariadb-binlog mysql-bin.000687-extract-offset-129619
```

Upload this to the private uploads or attach to the public bug report if nothing sensitive there.

8.2 Contributing & Participating

There are many ways to contribute to MariaDB.

Getting Help With MariaDB

Review of resources available when you need help.

Reporting Documentation Bugs

Reporting a bug or feature request in the MariaDB documentation.

MariaDB Community Bug Reporting

Guidelines for reporting bugs in MariaDB software.

Contributing to the MariaDB Project

How to contribute to the MariaDB project: code, documentation, feedback, etc.

Contributing Code

Guidelines and procedures for contributing code to MariaDB.

Project Suggestions

List of MariaDB Projects in which you might Assist.

Log of MariaDB Contributions

List of contributions and contributors to MariaDB and how to log them.

Donate to the Foundation

Donating to the MariaDB Foundation.

Sponsoring the MariaDB Project

Ways to sponsor the MariaDB project (e.g. with labor or funds).

Web Hosting Providers Offering MariaDB

List of known web hosting providers that offer MariaDB to their clients.

Using Git with MariaDB

How to use git to troubleshoot the source code or contribute code to MariaDB.

Google Summers of Code

Information on Google Summer of Code for each year since 2013.

Google Season of Docs

Information on each Google Season of Docs.

8.2.1 Getting Help With MariaDB

If you can't find help in the MariaDB documentation, you can also subscribe to the mailing lists or Zulip to communicate with MariaDB users and developers.

There's an active help community on DBA StackExchange.

If you have a question about a feature that is not properly documented or something that is not working as expected, go to the corresponding Knowledge Base page and ask your question there.

You can report and check on bugs which are unique to MariaDB in JIRA.

In some cases the documentation for MySQL can be used. Note that the MySQL documentation will not mention new features added in MariaDB, or other changes since introduced in MariaDB. See MariaDB versus MySQL and in greater detail under the MariaDB category.

MariaDB plc offers commercial support.

8.2.2 Contributing to the MariaDB Project

Contents

The success of MariaDB depends on the participation of the community. MariaDB would not be as good as it is today without the participation of the entire MariaDB community.

Getting Started

There are several ways to contribute besides Contributing Code, and not all of them require strong C/C++ skills. Areas for non-developers include:

- Reporting Bugs
  - To report a bug you'll need to sign up for an account by clicking on the Create an account link below the login fields
- Suggesting Features
- Answering questions in the Knowledge Base
- Helping other people answering problems or even fixing their bugs on IRC in the **#maria** channel on Libera.Chat or on MariaDB's Zulip instance at https://mariadb.zulipchat.com.
- Testing and Benchmarking
  - Bug tests can be uploaded to the 'private' directory of our FTP server.
- Creating documentation and KB articles for MariaDB, or translating existing documentation.
- Advocating MariaDB in your area.
- Participate in open source events and talk about MariaDB.
- Running a BuildBot on a platform which is not currently represented.
- Donate time or money to the MariaDB project.
- Ask your company to sponsor a feature.

- MariaDB Foundation page on getting involved

> **Contributing to the Knowledge Base** is a great way to help improve MariaDB.

MariaDB Email Lists

A great way to get started in MariaDB is to participate in e-mail discussions via our mailing lists (whichever list best matches your interests):

- developers
- discuss
- docs

Sensitive security issues can be sent directly to the persons responsible for MariaDB security: security [AT] mariadb (dot) org.

You can find additional email address, email archives and ways to connect with MariaDB people here.

All MariaDB contributors are expected to follow the Ubuntu Code Of Conduct.

Getting Started for Developers

- Contributing Code

See also the pages for new developers on the MariaDB Foundation website:

- Getting Started For Developers
- Get the Code, Build It, Test It
- Writing Good Test Cases for MariaDB Server
- Submitting a Pull Request

8.2.3 Contributing Code

Contents

This page contains general guidelines and procedures for contributing code. If you have any questions we invite you to ask on the maria-developers mailing list, on our Zulip instance at https://mariadb.zulipchat.com, or on the #maria IRC channel on https://libera.chat/. Other email lists and places to find MariaDB can be found here.

General information about contributing to MariaDB (for developers and non-developers) is found on the Contributing to the MariaDB Project page.

Finding Development Projects to Work on

There are many open development projects for MariaDB which you can contribute to (in addition to any ideas you may have yourself).

- We are using JIRA to manage the MariaDB project. Go to https://jira.mariadb.org and click on "Projects" to get to the MariaDB project. Browse around the unresolved and unassigned issues to see if there is something that interests you. Some issues have sponsors and you can be paid for doing them!
- A list of beginner friendly tasks is also available.
- Check the development plans for the next MariaDB version.
- Join maria-developers and ask for suggestions of tasks you could do. Please include your programming experience and your knowledge of the MariaDB source and how much you know about using MySQL/MariaDB with the email so

that we know which tasks we can suggest to you.

- If this is your first project, check out the Suggested Development page. It lists projects that will make a good start.
- Join MariaDB's Zulip instance at https://mariadb.zulipchat.com and ask for suggestions.
- Join #/maria on https://libera.chat/ IRC and ask for suggestions.

If you have your own ideas, please submit them to JIRA so other MariaDB developers can comment on them and suggest how to implement them. You can of course also use the maria-developers list for this.

What to Expect From a MariaDB Server Developer

This section is mainly directed to developers with commit rights to the MariaDB git repository. However, we hope it's also useful for anyone wanting to contribute code to MariaDB to know what a reviewer will expect from them.

This is not about coding style or if one should prefer C instead of C++. That would be a separate topic that should be created sooner or later.

The Basics

When coding, try to create code that 'never has to be changed again'. Try to make the code as performant as possible. In general it is acceptable to spend 50% more time to make the code 15% faster than what you originally intended. Take that into account when you plan your time estimates! That said, don't try to add classes or functionality that is not yet used.

The code should be easy to read and follow the coding standards of the project. Patches that are smaller and simpler are often better than complex solutions. Don't make the server depend on new external libraries without first checking with Sergei or Monty!

Add code comments for anything that is not obvious. When possible, use assertions within the code to document expectations of arguments etc. In general, if the code requires complex comments, think if there is a better way to structure the logic. Simpler is often better and with fewer bugs.

What to Have in a Commit Comment

- Jira issue number and summary ex: MDEV-23839 innodb_fast_shutdown=0 hang on change buffer merge
- An empty line
- A short description of the problem
- A description of the solution
- Any extra information needed to understand the patch
- The commit message should be self contained and the reviewer shouldn't preferably have to look at the Jira at all to understand the commit. This doesn't mean that the commit message should include all background and different design options considered, as the Jira should contain.
- Name of all reviewers and authors should be clear from the commit message. The preferred way would be (one line per person)
  - Reviewed-by: email
  - Co-authored-by: email
  - See https://docs.github.com/en/free-pro-team@latest/github/committing-changes-to-your-project/creating-a-commit-with-multiple-authors for details
- The default is that all code should be reviewed. Only in really extraordinary cases, like merge (where the original code was already reviewed) then it can be self-reviewed, which should clear from the commit. In this case the code should of course be tested extra carefully both locally and in buildbot before pushing.

Testing

- All code should have a test case that shows that the new code works or, in case of a bug fix, that the problem is fixed! It should fail with an unpatched server and work with the new version. In the extreme case that a test case is practically impossible to do, there needs to be documentation (in the commit message, optionally also in Jira) how the code was tested.
- The test case should have a reference to the Jira issue, if such one exists.
- Patches related to performance should be tested either by the developer (for simple commits) or by performance testers. The result should be put in Jira with a summary in the commit.
- Complex patches and should be tested by QA in a bb- branch before pushing. The Jira entry should include information that this has been done and what kind of test has been run.
- For anything not trivial, one should run either Valgrind or ASAN/MSAN on the new code. (Buildbot will do this for you if you can't get valgrind or ASAN to work). At least the test case added should be tested by either. If the developer cannot do that for some reason, he should check the buildbot builders that do this and ensure that at least his test case doesn't give any warnings about using not initialized memory or other failures.
- For complex code the developer should preferably use gcov or some similar tool to ensure that at least not all not-

error branches are executed. “mtr --gcov” or “dgcov.pl” can help you with this.

Getting Your Code into the Main MariaDB Tree

All code in MariaDB comes from one of the following sources:

- MySQL
- Code developed by people employed by the MariaDB Foundation.
- Code developed by people employed by MariaDB Corporation.
- Code shared with the MariaDB Foundation under the MCA.
- Code with a known origin that is under a permissive license (BSD or public domain).

If you want the code to be part of the main MariaDB tree, you also have to give the MariaDB Foundation a shared copyright to your code. This is needed so that the foundation can offer the code to other projects (like MySQL).

You do this by either:

1. Signing the MariaDB Contributor Agreement (MCA) and then scanning and sending it to the foundation.
2. Sending an email to maria-developers where you say that your patch and all fixes to it are provided to the MariaDB Foundation under the MCA.
3. Licensing your code using the BSD license.

We need shared copyright for the following reasons:

1. to defend the copyright or GPL if someone breaks it (this is the same reason why the Free Software Foundation also requires copyright assignment for its code)
2. to be able to donate code to MySQL (for example to fix security bugs or new features)
3. to allow people who have a non-free license to the MySQL code to also use MariaDB (the MCA/BSD allows us to give those companies the rights to all changes between MySQL and MariaDB so they can use MariaDB instead of MySQL)

More information about the MCA can be found on the MCA FAQ page.

Before Pushing Code to a Stable Branch

- Ensure that you have compiled everything for your new code, in a debug server (configured with cmake -DCMAKE_BUILD_TYPE=Debug) including embedded and all plugins that may be affected by your code change..
- Run the mysql-test-run (mtr) test suite locally with your debug server.
- For anything complex the full test suite should be run.
- For something absolutely trivial, at least the main suite must be run.
- Always push first to a bb- branch to test the code. When the bb- branch is green in buildbot you can push to the main branch. Take care of checking that Windows builds compiles (take extra care of checking this as this often fails) and that valgrind and msan builds doesn’t show any problems with your new test cases.
- If you have to do a rebase before pushing, you have to start from the beginning again.
- When porting code from third parties (such as MySQL), make sure to attribute copyright to the right owner, in the header of each modified file.
- For example: Copyright © 2000, 2018, Oracle and/or its affiliates. Copyright © 2009, 2020, MariaDB
- The only exception is that if the changes are trivial and the rebase was trivial and the local mysql-test-run worked, then you can push directly to the main branch. Only do this if you are 99% sure there are no issues! * Please don't make us regret that we have made this one exception! When we have protected git branches, then the above rule will be enforced automatically as the protection will take care of this.

Working on a New Project

- First create a Jira entry that explains the problems and the different solutions that can be used to solve the problem. If there is a new syntax include examples of queries and results.
- After getting an agreement of the to-be-used solution, update the Jira entry with the detailed architecture of the suggested solution.
- When the architecture is reviewed, the assigned developer can start coding.
- When the code is ready, the Jira entry should be updated with the reviewer.
- The reviewer checks the code and either approves it to be pushed or gives comments to the developers that should be fixed. In the later case the developer updates the code and gives it back to the reviewer. This continues until the code is approved.
- If the design changes during the project, the design in Jira needs to be updated.

Working on a Bug Fix

- Ensure that the Jira issue is up to date.
- For complex bugs that require redesign, follow the process in "Working on a new project"

- For simpler bugs, one can skip the listing of different solutions and architecture. However one should still document the reason for the bug and how it's fixed or to-be-fixed, in a JIRA comment.

Making Things Easier for Reviewers

- Ensure that code compiles, all MTR test works before asking for a review
- Try to split a bigger project into smaller, self-contained change sets.
- Automatic things, like renames of classes, variables, functions etc is better to be done in a separate commit.

When Reviewing Code

Remember that the stability and security of any project hangs a lot on the reviewers. If there is something wrong with an accepted patch, it's usually the reviewer who is to be blamed for it, as the reviewer was the one who allowed it to go in!

- Ensure that the code is licensed under New BSD or another approved license for MariaDB (basically any open source license not conflicting with GPL) or that the contributor has signed the MCA.
- GPL is only allowed for code from MySQL (as MariaDB is already depending on MySQL code).
- Ensure that commits are not too large. If the code is very large, give suggestions how to split it into smaller pieces. Merge commits, when rebasing is possible, are not allowed, to keep history linear.
- Check that the commits message describes the commit properly. For code that improves performance, ensure that Jira and the commit message contains information about the improvements.
- Check that there are no unexplained changes in old tests.
- Check the quality of the code (no obvious bugs, right algorithms used)
- Check if any code can be simplified or optimized. Using already existing functions, are loops optimal, are mutexes used correctly etc.
- Check that there is an appropriate test case for the code. See ‘testing’ for what is required!
- Ensuring the code follows the coding standard for MariaDB. This document should be created shortly, but in the meantime ask an old MySQL/MariaDB developer if you are unsure.
- Ensuring that the code follows the architecture agreed for in Jira (if it's in Jira).
- Code should be easy to understand (good code comments, good function and variable names etc).
- Ensure you understand every single line of code that is reviewed. If not, ask the developer to add more comments to get things clear or ask help from another reviewer.
- No performance degradations for all common cases.
- Any code that touches any sensitive area (files, communication, login, encryption or security) needs to have another reviewer that is an expert in this area.

8.2.4 Donate to the Foundation

To donate, please visit the MariaDB Foundation donations page.

8.2.5 Sponsoring the MariaDB Project

Sponsorships are crucial for ongoing and future development of the MariaDB project! There are a number of easy ways you for you to help the project:

- Fund the development of a specific feature. You can find a list of suggested features to sponsor here or in JIRA. Feel free to sign in and add more projects to either place!
- Contribute with developer time. If your organization has talented developers familiar with MariaDB or MySQL codebase they can become part of the MariaDB team and contribute to the development of the MariaDB project.
- Hire a developer that you dedicate to work on the MariaDB project.
- A pure donation with no strings attached

To get going with the sponsorship please visit the MariaDB Foundation sponsorships page.

8.2.6 Using Git with MariaDB

Tricks and tips on how to use Git, the source control system MariaDB uses.

MariaDB Source Code

How to get the source code for MariaDB from GitHub.

Using Git

Working with the git repository for the source code of MariaDB on GitHub.

2.1.2.8.2 MariaDB Source Code

8.2.6.2 Using Git

Contents

Just Getting the Source

If you just want to get the latest source and you don't require the ability to push changes to the MariaDB repository, you can use the following command to check out the latest 10.5 branch:

```
git clone -b 10.5 https://github.com/MariaDB/server.git
```

Setup up git for MariaDB

- Set your name with git

```
git config --global user.name "Ivan Ivanov"
git config --global user.email "ivan@mariadb.com"
```

- Go to https://github.com/settings/ssh and add your public SSH key (GitHub Help).
- Clone the repository

```
git clone git@github.com:MariaDB/server.git
cd server
git checkout 10.5
```

- Config repository pull and alias for fast forward:

```
git config pull.ff only
git config --global alias.ff "merge --ff-only"
```

Commit comments

In git commit messages are normally formatted as

```
subject

body
more body
...
```

That is, the first line is considered a *subject*, much like email subject. Many git commands and pages on github only show the commit subject, not the complete comment. After the subject goes an empty line, then the detailed description of the comment. Please, structure your commit comments this way, don't forget the empty line.

Branches

This is an important concept, and git branches do not have equivalents in bzr.

In Bazaar, we all used to have one shared repository, within which there were many branches. This seems to be impossible with git?

In Git, each repository has only one branch that is currently checked out.

```
git branch
```

List Existing Branches

To see which branches exists locally and remotely:

```
git branch --all
```

To Move to Work on a Specific Branch

```
git checkout branch-name
```

Note that if the output from `git branch --all` is `remotes/origin/XXX` you should just use `XXX` as branch name.

Making a Local Copy of a Branch (Like bzr clone)

```
branch clone old_directory new_directory
cd new_directory
git remote set-url origin git@github.com:MariaDB/server.git
git pull
```

Remove Last Commit From a Branch

```
git reset --hard HEAD^
```

Fetch a Branch Someone Has Done a Rebase on

If you get the following error on pull:

```
shell>  git pull
X11 forwarding request failed on channel 0
fatal: Not possible to fast-forward, aborting.
```

Instead of removing your copy and then clone, you can do:

```
git reset --hard origin/##branch-name##
```

Other Things About Branches

- Note: branches whose names start with `bb-` are automatically put into the buildbot.

Equivalents For Some bzr Commands

CAVEAT UTILITOR. Check the manual before running!

- `bzr status` is `git status`
- `bzr diff` is `git diff`
- `bzr log` is `git log`
- `bzr revert` is `git reset --hard`
- `bzr revert filename` is `git checkout filename`
- `bzr parent` is `git remote -v` (but there are more detailed commands)
- `bzr parent to-default-mariadb-repo` git remote set-url origin git@github.com:MariaDB/server.git
- `bzr push` is `git push REMOTENAME BRANCHNAME` . REMOTENAME is typically "origin", for example: `git push origin HEAD:10.3-new-feature` . The HEAD: stands for "from current branch".
- `bzr clean-tree --ignored` is `git clean -Xdf` (note the capital X!)
- `bzr root` is `git rev-parse --show-toplevel`
- `bzr missing --mine-only` is `git cherry -v origin` (kind-of).

GUIs

- `bzr gcommit` is `git citool`
- `bzr viz` is `gitk`
- `bzr gannotate` is `git gui blame`

Commit Emails

In the MariaDB project, it is a good idea (and a long tradition since MySQL Ab) to have all your commits sent to a commits@mariadb.org mailing list. It allows others to follow the progress, comment, etc.

A script and instructions on how to setup commit triggers in Git are here: http://bazaar.launchpad.net/~maria-captains/mariadb-tools/trunk/files/head:/git_template/ . Jira task for commit trigger was MDEV-6278.

Attributing Code to Someone Else

If you add code on behalf of someone else, please attribute the code to the original author:

- Run `git citool` and move changed files to staged.
- Don't `commit` , abort instead
- run `git commit --author="Original author name <email_address>"`

The above is needed as `git citool` can't handle the `--author` option.

Applying a Pull Request

At the end of the pull request page there is a button "Merge pull request" and next to it a link "command line instructions". Click the link, you'll see something like

Step 1: From your project repository, check out a new branch and test the changes.

```
git checkout -b mariadb-server-joeuser-cool-feature 10.3
git pull https://github.com/joeuser/mariadb-server cool-feature
```

Step 2: Merge the changes and update on GitHub.

```
git checkout 10.3
git merge --no-ff mariadb-server-joeuser-cool-feature
git push origin 10.3
```

Note where to pull from — **https://github.com/joeuser/mariadb-server cool-feature**.

Now, checkout the branch you want to merge it to, say, bb-10.3-stage, and do the following

```
git fetch https://github.com/joeuser/mariadb-server cool-feature
git checkout FETCH_HEAD
git rebase @{-1}
```

Now's the time to compile the code, test it, fix, if necessary. Then

```
git checkout @{-1}
git ff @{-1}
```

If you want to do small changes to the pull request, do it in a separate commit, after `git rebase @{-1}` above. If you want to do *big* changes to the pull request, perhaps you shouldn't merge it in the first place, but ask the contributor to fix it?

Examples

Diff For Last Commit

```
git show
```

Applying New Code From Main Tree to a Branch

You are working on a branch (`NEW_FEATURE`) and would like to have into that branch all changes from the main branch (`10.1`).

```
git checkout 10.1
git pull
git checkout NEW_FEATURE
git rebase 10.1
```

Applying a Bugfix in the Main Branch

You've just fixed and committed a bug in the main 10.1 branch and want to merge it with the latest 10.1. Often a rebase is better in this case. Assuming your current checked out branch is 10.1:

```
git fetch origin
git rebase origin/10.1
```

This will work even if you have done multiple commits in your local 10.1 tree.

Dealing With Conflicts When One Tries to Push

What to do when you have fixed a bug in the main tree but notices that someone has changed the tree since you pulled last time. This approach ensures that your patch is done in one block and not spread out over several change sets.

```
git clone 10.1
cd 10.1
< fix a bug here>
git citool
git push
# ^ and the above fails, because someone has pushed to 10.1 in between
git branch tmp
# ^ copy our work to branch named 'tmp'
get checkout 10.1
git reset --hard HEAD^
# ^ remove our work from '10.1' local branch'
git pull
# ^ get changes from remote
git checkout tmp
git rebase 10.1
# ^ switch to 'tmp' and try to rebase 'tmp' branch on top of 10.1 branch.
#   here you will be asked to merge if necessary
git checkout 10.1
git pull --ff . tmp
# ^ switch back to the '10.1' branch, and pull from 'tmp' branch.
git branch -D tmp
#^ this removes the tmp. branch
git push
```

Finding in Which MariaDB Version a Commit Exists

```
sh> git tag --contain e65f667bb60244610512efd7491fc77eccceb9db
mariadb-10.0.30
mariadb-10.1.22
mariadb-10.1.23
mariadb-10.2.5
mariadb-10.3.0
mariadb-galera-10.0.30
```

8.2.6.3 Configuring Git to Send Commit Notices

Commit emails for MariaDB are sent to `commits@mariab.org`. You can find the archive here.

To allow others to see what you are working on in your MariaDB tree, you should:

1. subscribe to the email list
2. configure git to send your commits to `commits@mariab.org`.

Download the post-commit git trigger script. Configure as

```
git config --global hooks.postcommitrecipients "commits@mariadb.org"
git config --global hooks.postcommitbranches "*"
```

Also you might want to check the README for the post-commit trigger.

The post-commit git trigger uses *sendmail* for sending emails. Some platforms don't have *sendmail* and then you'll need to modify to make use of something that is supported.

Also, the post-commit trigger is just one approach. You can also use git-email on at least Debian and Fedora to send commit emails to the MariaDB commits email list.

8.3 Legal Matters

GNU General Public License, Version 2

Full text of the GNU General Public License, Version 2

Legal Notices for the Knowledge Base

List of licenses and trademarks associated with the content in the MariaDB Knowledge Base.

8.3.1 GNU General Public License, Version 2

```
      GNU GENERAL PUBLIC LICENSE
         Version 2, June 1991

 Copyright (C) 1989, 1991 Free Software Foundation, Inc.,
 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

       Preamble

  The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
License is intended to guarantee your freedom to share and change free
software--to make sure the software is free for all its users.  This
General Public License applies to most of the Free Software
Foundation's software and to any other program whose authors commit to
using it.  (Some other Free Software Foundation software is covered by
the GNU Lesser General Public License instead.)  You can apply it to
your programs, too.

  When we speak of free software, we are referring to freedom, not
price.  Our General Public Licenses are designed to make sure that you
have the freedom to distribute copies of free software (and charge for
this service if you wish), that you receive source code or can get it
if you want it, that you can change the software or use pieces of it
```

in new free programs; and that you know you can do these things.

  To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

  For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

  We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

  Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

  Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

  The precise terms and conditions for copying, distribution and modification follow.

      GNU GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

  1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

  2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

    a) You must cause the modified files to carry prominent notices
    stating that you changed the files and the date of any change.

    b) You must cause any work that you distribute or publish, that in
    whole or in part contains or is derived from the Program or any
    part thereof, to be licensed as a whole at no charge to all third

part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is

void, and will automatically terminate your rights under this License.
However, parties who have received copies, or rights, from you under
this License will not have their licenses terminated so long as such
parties remain in full compliance.

  5. You are not required to accept this License, since you have not
signed it. However, nothing else grants you permission to modify or
distribute the Program or its derivative works. These actions are
prohibited by law if you do not accept this License. Therefore, by
modifying or distributing the Program (or any work based on the
Program), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Program or works based on it.

  6. Each time you redistribute the Program (or any work based on the
Program), the recipient automatically receives a license from the
original licensor to copy, distribute or modify the Program subject to
these terms and conditions. You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties to
this License.

  7. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License. If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Program at all. For example, if a patent
license would not permit royalty-free redistribution of the Program by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under
any particular circumstance, the balance of the section is intended to
apply and the section as a whole is intended to apply in other
circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system, which is
implemented by public license practices. Many people have made
generous contributions to the wide range of software distributed
through that system in reliance on consistent application of that
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
be a consequence of the rest of this License.

  8. If the distribution and/or use of the Program is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Program under this License
may add an explicit geographical distribution limitation excluding
those countries, so that distribution is permitted only in or among
countries not thus excluded. In such case, this License incorporates
the limitation as if written in the body of this License.

  9. The Free Software Foundation may publish revised and/or new versions
of the General Public License from time to time. Such new versions will
be similar in spirit to the present version, but may differ in detail to
address new problems or concerns.

Each version is given a distinguishing version number. If the Program
specifies a version number of this License which applies to it and "any
later version", you have the option of following the terms and conditions
either of that version or of any later version published by the Free
Software Foundation. If the Program does not specify a version number of
this License, you may choose any version ever published by the Free Software
Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

```
<one line to give the program's name and a brief idea of what it does.>
Copyright (C) <year>  <name of author>

This program is free software; you can redistribute it and/or modify
it under the terms of the GNU General Public License as published by
the Free Software Foundation; either version 2 of the License, or
(at your option) any later version.

This program is distributed in the hope that it will be useful,
but WITHOUT ANY WARRANTY; without even the implied warranty of
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the
GNU General Public License for more details.

You should have received a copy of the GNU General Public License along
with this program; if not, write to the Free Software Foundation, Inc.,
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.
```

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be mouse-clicks or menu items--whatever suits your program.

```
You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the program, if
necessary.  Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the program
  `Gnomovision' (which makes passes at compilers) written by James Hacker.

  <signature of Ty Coon>, 1 April 1989
  Ty Coon, President of Vice

This General Public License does not permit incorporating your program into
proprietary programs.  If your program is a subroutine library, you may
consider it more useful to permit linking proprietary applications with the
library.  If this is what you want to do, use the GNU Lesser General
Public License instead of this License.
```

8.3.2 Legal Notices for the Knowledge Base
